Library of Congress Cataloging-in-Publication Data

Names: Information Resources Management Association, editor.
Title: Pharmaceutical sciences : breakthroughs in research and practice / Information Resources Management Association, editor.
Other titles: Pharmaceutical sciences (Information Resources Management Association)
Description: Hershey PA : Medical Information Science Reference, [2017]
Identifiers: LCCN 2016046061| ISBN 9781522517627 (hardcover) | ISBN 9781522517634 (ebook)
Subjects: | MESH: Drug Industry--trends
Classification: LCC HD9665.5 | NLM QV 736.1 | DDC 338.4/76151--dc23 LC record available at https://lccn.loc.gov/2016046061

British Cataloguing in Publication Data
A Cataloguing in Publication record for this book is available from the British Library.

All work contributed to this book is new, previously-unpublished material. The views expressed in this book are those of the authors, but not necessarily of the publisher.

For electronic access to this publication, please contact: eresources@igi-global.com.

List of Contributors

Abdolmaleki, Azizeh / *Islamic Azad University of Touyserkan, Iran*.....770
Achary, P. Ganga Raju / *Institute of Technical Education and Research (ITER), Siksha 'O'Anusandhan University, India*.....1573
Afantitis, Antreas / *NovaMechanics Ltd., Cyprus*.....1314
Agarwal, Rahul / *Shiv Nadar University, India*.....683
Ahmad, Tokeer / *Jamia Millia Islamia, India*.....1492
Amit, Yadav / *National Center for Cell Science (NCCS) – Pune, India*.....1258
Anderluh, Marko / *University of Ljubljana, Slovenia*.....820
Andricopulo, Adriano D. / *Instituto de Física de São Carlos, Universidade de São Paulo, São Carlos, Brazil*.....956
Apostolakis, Ioannis / *National School of Public Health, Greece*.....31
Bacelo, Daniel / *Universidad de Belgrano, Argentina*.....929
Barakat, Khaled H. / *University of Alberta, Canada*.....1092,1144
Basak, Piyali / *Jadavpur University, India*.....711
Basu, Anamika / *Gurudas College, India*.....711
Basu, S. K. / *University of Lethbridge, Canada*.....1175
Bayir, Ece / *Ege University, Turkey*.....1212
Becker, Julie / *University of the Sciences, USA*.....1457
Benfenati, Emilio / *IRCCS-Istituto di Ricerche Farmacologiche Mario Negri, Italy*.....929
Berler, Alexander / *National School of Public Health, Greece & epSOS, Greece*.....31
Bhatnagar, Sonika / *Netaji Subhas Institute of Technology, India*.....877
Bhattacharya, Simanti / *University of Kalyani, India*.....795
Bilgi, Eyup / *Ege University, Turkey*.....1212
Bonner, James C. / *North Carolina State University, USA*.....1476
Borišek, Jure / *National Institute of Chemistry, Slovenia*.....820
Bouloudenine, Manel / *Mohamed Chérif Messaâdia University, Algeria & Badji Mokhtar University, Algeria*.....1394
Bououdina, Mohamed / *University of Bahrain, Bahrain*.....1394
Brand, Jordan / *San Francisco VA Medical Center, USA & University of California – San Francisco, USA*.....486
Carotti, Angelo / *Università degli Studi di Bari "Aldo Moro", Italy*.....929
Castro, Eduardo A. / *Instituto de Investigaciones Fisicoquímicas Teóricas y Aplicadas INIFTA (UNLP, CCT La Plata-CONICET), Argentina*.....929
Chakravarty, Rupak / *Panjab University, India*.....99
Chattaraj, Pratim K. / *Indian Institute of Technology Kharagpur, India*.....1517

Table of Contents

Preface xvi

Volume I

Section 1
Clinical Trials, Education, and Information Access

Chapter 1
Overview of Clinical Trial and Pharmacovigilance Process and Areas of Application of Computer System 1
Sowmyanarayan Srinivasan, Accenture Services Pvt Ltd, India

Chapter 2
Pharmacogenomics Genome Wise Association Clinical Studies 14
Udayaraja G. K., IGB, Saudi Arabia

Chapter 3
Normalizing Cross-Border Healthcare in Europe via New E-Prescription Paradigms 31
Alexander Berler, National School of Public Health, Greece & epSOS, Greece
Ioannis Apostolakis, National School of Public Health, Greece

Chapter 4
Web 2.0 Tools in Biomedical and Pharmaceutical Education: Updated Review and Commentary 73
Ângelo Jesus, Instituto Politécnico do Porto, Portugal
Maria João Gomes, Universidade do Minho, Portugal

Chapter 5
Open Access Initiatives in Medical Biology: A Study of Institutional Repositories in India 99
Rupak Chakravarty, Panjab University, India

Section 2
Drug Delivery and Patient Care

Chapter 6
Application of Nanoparticles as a Drug Delivery System 128
Vijay Kumar Singh, Bundelkhand University, India
Raj K. Keservani, Rajiv Gandhi Proudyogiki Vishawavidyalaya, India

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 7
Non-Ionic Surfactant Vesicles (Niosomes) as New Drug Delivery Systems 154
Abbas Pardakhty, Kerman University of Medical Sciences, Iran

Chapter 8
Cancer Drug Delivery: Pharmacogenetics, Biomarkers, and Targeted Therapies..... 185
Jai N. Patel, Levine Cancer Institute, USA
Jeryl Villadolid, Levine Cancer Institute, USA

Chapter 9
CNS Targeted Nanoparticle Drug Delivery: CNS Drug Delivery..... 229
Dimple Sethi Chopra, Punjabi University, India

Chapter 10
Engineered Gellan Polysaccharides in the Design of Controlled Drug Delivery Systems..... 246
Sabyasachi Maiti, Gupta College of Technological Sciences, India

Chapter 11
Improving Pharmaceutical Care through the Use of Intelligent Pharmacoinformatics..... 274
Tagelsir Mohamed Gasmelseid, International University of Africa, Sudan

Chapter 12
Personalized Medicine in the Era of Genomics..... 297
Navneet Kaur Soni, Delhi Technological University, India
Nitin Thukral, Delhi Technological University, India
Yasha Hasija, Delhi Technological University, India

Chapter 13
Role of Resveratrol (RES) in Regenerative Medicine 328
James A. Stokes III, Alabama State University, USA
Manoj K. Mishra, Alabama State University, USA

Chapter 14
Strategies for Expanding Access and Improving the Quality of Pharmaceutical Services 340
Marcus Vinícius Dias-Souza, Federal University of Minas Gerais, Brazil

Chapter 15
An Overview of Therapeutic Applications..... 366
Sandeep Waghulde, University of Mumbai, India
Pravin Naik, University of Mumbai, India

Chapter 16
Bioinformatics and Its Therapeutic Applications 391
Sarvesh Kumar Gupta, IIIT Allahabad, India
Kamal Kumar Chaudhary, IIIT Allahabad, India
Nidhi Mishra, IIIT Allahabad, India

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 17
A Perspective on the Phytopharmaceuticals Responsible for the Therapeutic Applications 425
Rajesh K. Joshi, Regional Medical Research Centre (Indian Council of Medical Research), India

Chapter 18
Resealed Erythrocytes as Drug Carriers and Its Therapeutic Applications 459
Prabhakar Singh, University of Allahabad, India
Sudhakar Singh, Kolkata Medical College, India
Rajesh Kumar Kesharwani, NIMS University, India

Chapter 19
Sedation and Analgesia 486
Jordan Brand, San Francisco VA Medical Center, USA & University of California – San Francisco, USA

Section 3
Functional Foods

Chapter 20
Phytonutrients of Nutraceutical Importance: Exploring Antimicrobial, Antiproliferative, and Antioxidant Activities 521
Marcus Vinícius Dias-Souza, Federal University of Minas Gerais, Brazil
Renan Martins dos Santos, Federal University of Minas Gerais, Brazil

Chapter 21
Prediction of Structural and Functional Aspects of Protein: In-Silico Approach 551
Arun G. Ingale, North Maharashtra University, India

Chapter 22
Flavonoids: Prospective Strategy for the Management of Diabetes and Its Associated Complications 569
Vineet Mehta, Jaypee University of Information Technology, India
Udayabanu Malairaman, Jaypee University of Information Technology, India

Chapter 23
Food Allergy and Food Poisoning: Toxicology on Culinary Sciences 613
Jose Iñaki Alava Marquinez, Basque Culinary Center, Mondragon University, Spain
Miguel Angel Lopez, Basque Culinary Center, Mondragon University, Spain

Chapter 24
Food and Cardiac Health: Protective Effects of Food on Cardiovascular System 640
Aditi Jain, Jaypee Institute of Information Technology, India
Vibha Rani, Jaypee Institute of Information Technology, India

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Section 4
Molecular Modeling and Drug Design

Chapter 25
Molecular-Docking-Based Drug Design and Discovery: Rational Drug Design for the Subtype Selective GPCR Ligands 656
Soo-Kyung Kim, California Institute of Technology, USA
William A. Goddard III, California Institute of Technology, USA

Chapter 26
Role of Molecular Docking in Computer-Aided Drug Design and Development 683
Rahul Agarwal, Shiv Nadar University, India
Ashutosh Singh, Shiv Nadar University, India
Subhabrata Sen, Shiv Nadar University, India

Chapter 27
Molecular-Docking-Based Anti-Allergic Drug Design 711
Anamika Basu, Gurudas College, India
Piyali Basak, Jadavpur University, India
Anasua Sarkar, Jadavpur University, India

Chapter 28
Molecular Docking Technique to Understand Enzyme-Ligand Interactions 727
Kailas Dashrath Sonawane, Shivaji University, India
Maruti Jayram Dhanavade, Shivaji University, India

Chapter 29
Molecular Modelling, Dynamics, and Docking of Membrane Proteins: Still a Challenge 747
Nanda Kumar Yellapu, Vector Control Research Centre, India

Volume II

Chapter 30
Molecular Docking Challenges and Limitations 770
Jahan B. Ghasemi, University of Tehran, Iran
Azizeh Abdolmaleki, Islamic Azad University of Touyserkan, Iran
Fereshteh Shiri, University of Zabol, Iran

Chapter 31
Different Types of Molecular Docking Based on Variations of Interacting Molecules: Variations of Molecular Docking 795
Amit Das, University of Kalyani, India
Simanti Bhattacharya, University of Kalyani, India

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 32
The Comparison of Docking Search Algorithms and Scoring Functions: An Overview and Case Studies 820
Marjana Novič, National Institute of Chemistry, Slovenia
Tjaša Tibaut, National Institute of Chemistry, Slovenia
Marko Anderluh, University of Ljubljana, Slovenia
Jure Borišek, National Institute of Chemistry, Slovenia
Tihomir Tomašič, University of Ljubljana, Slovenia

Chapter 33
Application of Docking Methodologies in QSAR-Based Studies 850
Omar Deeb, Al-Quds University, Palestine
Heidy Martínez-Pachecho, Universidad del Papaloapan, Mexico
Guillermo Ramírez-Galicia, Universidad del Papaloapan, Mexico
Ramón Garduño-Juárez, Universidad Nacional Autónoma de México, Mexico

Chapter 34
Protein Structure Prediction Using Homology Modeling: Methods and Tools 877
Akanksha Gupta, Netaji Subhas Institute of Technology, India
Pallavi Mohanty, Netaji Subhas Institute of Technology, India
Sonika Bhatnagar, Netaji Subhas Institute of Technology, India

Chapter 35
QSAR Studies on Bacterial Efflux Pump Inhibitors 898
Khac-Minh Thai, University of Medicine and Pharmacy at HCMC, Vietnam
Trong-Nhat Do, University of Medicine and Pharmacy at HCMC, Vietnam
Thuy-Viet-Phuong Nguyen, University of Medicine and Pharmacy at HCMC, Vietnam
Duc-Khanh-Tho. Nguyen, University of Medicine and Pharmacy at HCMC, Vietnam
Thanh-Dao Tran, University of Medicine and Pharmacy at HCMC, Vietnam

Chapter 36
QSPR/QSAR Analyses by Means of the CORAL Software: Results, Challenges, Perspectives 929
Andrey A. Toropov, IRCCS-Istituto di Ricerche Farmacologiche Mario Negri, Italy
Alla P. Toropova, IRCCS-Istituto di Ricerche Farmacologiche Mario Negri, Italy
Emilio Benfenati, IRCCS-Istituto di Ricerche Farmacologiche Mario Negri, Italy
Orazio Nicolotti, Università degli Studi di Bari "Aldo Moro", Italy
Angelo Carotti, Università degli Studi di Bari "Aldo Moro", Italy
Karel Nesmerak, Charles University in Prague, Czech Republic
Aleksandar M. Veselinović, University of Niš, Serbia
Jovana B. Veselinović, University of Niš, Serbia
Pablo R. Duchowicz, Instituto de Investigaciones Fisicoquímicas Teóricas y Aplicadas INIFTA (UNLP, CCT La Plata-CONICET), Argentina
Daniel Bacelo, Universidad de Belgrano, Argentina
Eduardo A. Castro, Instituto de Investigaciones Fisicoquímicas Teóricas y Aplicadas INIFTA (UNLP, CCT La Plata-CONICET), Argentina
Bakhtiyor F. Rasulev, Jackson State University, USA
Danuta Leszczynska, Jackson State University, USA
Jerzy Leszczynski, Jackson State University, USA

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 37
2D and 3D QSAR Studies on a Series of Antichagasic Fenarimol Derivatives 956
Anacleto S. de Souza, Instituto de Física de São Carlos, Universidade de São Paulo, São Carlos, Brazil
Leonardo G. Ferreira, Instituto de Física de São Carlos, Universidade de São Paulo, São Carlos, Brazil
Adriano D. Andricopulo, Instituto de Física de São Carlos, Universidade de São Paulo, São Carlos, Brazil

Chapter 38
The "ETA" Indices in QSAR/QSPR/QSTR Research 978
Kunal Roy, Jadavpur University, India
Rudra Narayan Das, Jadavpur University, India

Chapter 39
Importance of Applicability Domain of QSAR Models 1012
Kunal Roy, Jadavpur University, India
Supratik Kar, Jadavpur University, India

Chapter 40
Molecular Dynamics Simulations for Biological Systems 1044
Prerna Priya, Bose Institute – Kolkata, India
Minu Kesheri, Banaras Hindu University, India
Rajeshwar P. Sinha, Banaras Hindu University, India
Swarna Kanchan, Birla Institute of Technology and Science (BITS), India

Chapter 41
Protein Ligand Interaction Fingerprints 1072
Ali HajiEbrahimi, Shiraz University of Medical Sciences, Iran
Hamidreza Ghafouri, Shiraz University of Medical Sciences, Iran
Mohsen Ranjbar, Shiraz University of Medical Sciences, Iran
Amirhossein Sakhteman, Shiraz University of Medical Sciences, Iran

Chapter 42
Protein-Protein Docking: Are We There Yet? 1092
Horia Jalily Hasani, University of Alberta, Canada
Khaled H. Barakat, University of Alberta, Canada

Chapter 43
Protein-Protein Interactions (PPIs) as an Alternative to Targeting the ATP Binding Site of Kinase: In Silico Approach to Identify PPI Inhibitors 1115
Sailu Sarvagalla, Pondicherry University, India
Mohane Selvaraj Coumar, Pondicherry University, India

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 44
Rational Drug Design Rational Drug Design: One Target, Many Paths to It 1144
Khaled H. Barakat, University of Alberta, Canada & Fayoum University, Egypt
Michael Houghton, University of Alberta, Canada
D. Lorne Tyrrel, University of Alberta, Canada
Jack A. Tuszynski, University of Alberta, Canada

Chapter 45
Smart, Innovative and Intelligent Technologies Used in Drug Designing 1175
S. Deshpande, Data Consulting, New Delhi, India
S. K. Basu, University of Lethbridge, Canada
X. Li, Industrial Crop Research Institute, Yunan Academy of Agricultural Sciences, China
X. Chen, Institute of Food Crops, Yunan Academy of Agricultural Sciences, China

Section 5
Nanostructures and Technology

Chapter 46
Hybrid Plasmonic Nanostructures: Environmental Impact and Applications 1193
Ahmed Nabile Emam, National Research Centre, Egypt
Ahmed Sadek Mansour, Cairo University, Egypt
Emad Girgis, National Research Centre, Egypt
Mona Bakr Mohamed, Cairo University, Egypt

Chapter 47
Implementation of Nanoparticles in Cancer Therapy 1212
Ece Bayir, Ege University, Turkey
Eyup Bilgi, Ege University, Turkey
Aylin Sendemir Urkmez, Ege University, Turkey

Chapter 48
Nanomedicine: Therapeutic Applications and Limitations 1258
Roy Gaurab, National Center for Cell Science (NCCS) – Pune, India
Shetti Dattatrya, National Center for Cell Science (NCCS) – Pune, India
Yadav Amit, National Center for Cell Science (NCCS) – Pune, India
Kundu Gopal C, National Center for Cell Science (NCCS) – Pune, India

Chapter 49
Nanosuspensions in Nanobiomedicine 1286
Muthukrishnan Lakshmipathy, Sathyabama University, India
Anima Nanda, Sathyabama University, India

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 50
Quantitative Nanostructure-Activity Relationship Models for the Risk Assessment of NanoMaterials 1314
Eleni Vrontaki, NovaMechanics Ltd., Cyprus & University of Athens, Greece
Thomas Mavromoustakos, University of Athens, Greece
Georgia Melagraki, NovaMechanics Ltd., Cyprus
Antreas Afantitis, NovaMechanics Ltd., Cyprus

Chapter 51
QSAR-Based Studies of Nanomaterials in the Environment 1339
Valeria V. Kleandrova, University of Porto, Portugal
Feng Luan, Yantai University, China & University of Porto, Portugal
Alejandro Speck-Planche, University of Porto, Portugal
M. Natália D. S. Cordeiro, University of Porto, Portugal

Chapter 52
Stratagems of Nanotechnology Augmenting the Bioavailability and Therapeutic Efficacy of Traditional Medicine to Formulate Smart Herbal Drugs Combating 1367
Anita Margret, Bishop Heber College, India

Section 6
Toxicology

Chapter 53
Toxic Effects of Engineered Nanoparticles on Living Cells 1394
Manel Bouloudenine, Mohamed Chérif Messaâdia University, Algeria & Badji Mokhtar University, Algeria
Mohamed Bououdina, University of Bahrain, Bahrain

Chapter 54
Cyanobacterial Toxins in Water Sources and Their Impacts on Human Health 1428
Zakaria Mohamed, Sohag University, Egypt

Chapter 55
Pharmaceuticals and Personal Care Products as Emerging Water Contaminants 1457

Preface

The constantly changing landscape surrounding modern pharmaceutical science makes it challenging for experts and practitioners to stay informed of the field's most up-to-date research. That is why IGI Global is pleased to offer this two-volume comprehensive reference collection that will empower students, researchers, and academicians with a strong understanding of these critical issues by providing both broad and detailed perspectives on cutting-edge theories and developments. This compilation is designed to act as a single reference source on conceptual, methodological, and technical aspects, as well as to provide insight into emerging trends and future opportunities within the discipline.

Pharmaceutical Sciences: Breakthroughs in Research and Practice is organized into six sections that provide comprehensive coverage of important topics. The sections are:

1. Clinical Trials, Education, and Information Access
2. Drug Delivery and Patient Care
3. Functional Foods
4. Molecular Modeling and Drug Design
5. Nanostructures and Technology
6. Toxicology

The following paragraphs provide a summary of what to expect from this invaluable reference source:

Section 1, "Clinical Trials, Education, and Information Access," opens this extensive reference source by highlighting the pivotal nature of clinical studies and educational initiatives in contemporary medical practice. Through perspectives on software innovations, health policies, and information management, this section demonstrates the importance of research and education in the pharmaceutical industry. The presented research facilitates a better understanding of the continuous developments in learning tools and clinical studies for medical professionals.

Section 2, "Drug Delivery and Patient Care," includes chapters on emerging tools, innovations, and approaches for improved drug delivery techniques. Including discussions on nanoparticles, medical informatics, and personalized medicine, this section presents research on the impact of therapeutic innovations in patient wellness and care. This inclusive information assists in advancing current practices in various therapeutic applications.

Section 3, "Functional Foods," presents extensive coverage on utilizing foods for enhanced nutrition, health, and disease reduction. By identifying components such as protein structure, phytonutrients, and

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

health effects, this section highlights the effects of food intake on overall health. These inclusive perspectives contribute to the available knowledge on health promotion through nutraceuticals.

Section 4, "Molecular Modeling and Drug Design," discusses coverage and research perspectives on innovative approaches to drug design and development techniques. Through analyses on molecular docking, computer-aided methodologies, and QSAR studies, this section contains pivotal information on the shifting landscape of modeling and design techniques for pharmaceuticals. The presented research facilitates a comprehensive understanding of various methodologies for drug design and molecular modeling.

Section 5, "Nanostructures and Technology," includes scholarly perspectives on the use of nanomaterials in the medical industry. Highlighting trends in therapeutic techniques, nanomedicine, and nanotechnology, this section presents critical information on the implementation of nanostructures for improved medical care and practice. These innovative perspectives highlight the growing presence of nanomedicine in the pharmaceutical industry.

Section 6, "Toxicology," concludes this reference book with the presentation of research on the dangers and impacts of toxins and poisonous substances on human health. Through perspectives on engineered particles, water contaminants, and nanoparticles, this section illustrates the vital importance of understanding potential toxicity and its dangerous effects. This section provides a comprehensive examination of toxicology in medical contexts.

Although the primary organization of the contents in this work is based on its six sections, offering a progression of coverage of the important concepts, methodologies, technologies, applications, social issues, and emerging trends, the reader can also identify specific contents by utilizing the extensive indexing system listed at the end.

As a comprehensive collection of research on the latest findings related to *Pharmaceutical Sciences: Breakthroughs in Research and Practice,* this publication provides researchers, practitioners, and all audiences with a complete understanding of the development of applications and concepts surrounding these critical issues.

Chapter 1
Overview of Clinical Trial and Pharmacovigilance Process and Areas of Application of Computer System

Sowmyanarayan Srinivasan
Accenture Services Pvt Ltd, India

ABSTRACT

The overall process of getting a drug to the market is a long one and takes 10-15 years and costing close to a billion dollar. The success rate as the compound travels from the initial discovery phase to clinical and then through to the market is about 1 in 10,000. The two key phases which together contribute the most to the cost and timeline are clinical development and pharmacovigilance. These two phases together also account for the maximum number of failures. In this chapter, we will look in detail at these two phases with a focus on the business process and process areas which have application of computer systems. The chapter will focus on looking at the various phases of clinical development and their endpoints. Clinical development is the process of testing a drug for safety and efficacy in human subjects. Clinical trial is conducted in 3 phases with the 4th phase which is ongoing post approval which forms an important part of the pharmacovigilance process. These phases will be elaborated in detail.

INTRODUCTION AND BACKGROUND

The overall process of getting a drug to the market is a long one and takes 10-15 years and costing close to a billion dollar. The success rate as the compound travels from the initial discovery phase to clinical and then through to the market is about 1 in 10,000. The two key phases which together contribute the most to the cost and timeline are clinical development and pharmacovigilance. These two phases together also account for the maximum number of failures. In this chapter, we will look in detail at these two phases with a focus on the business process and process areas which have application of computer systems.

Figure 1 illustrates the value chain of bringing a drug to the market starting from understanding of disease to commercialization of the drug for the disease. (R&D Pipeline Management, University of Wisconsin, n.d)

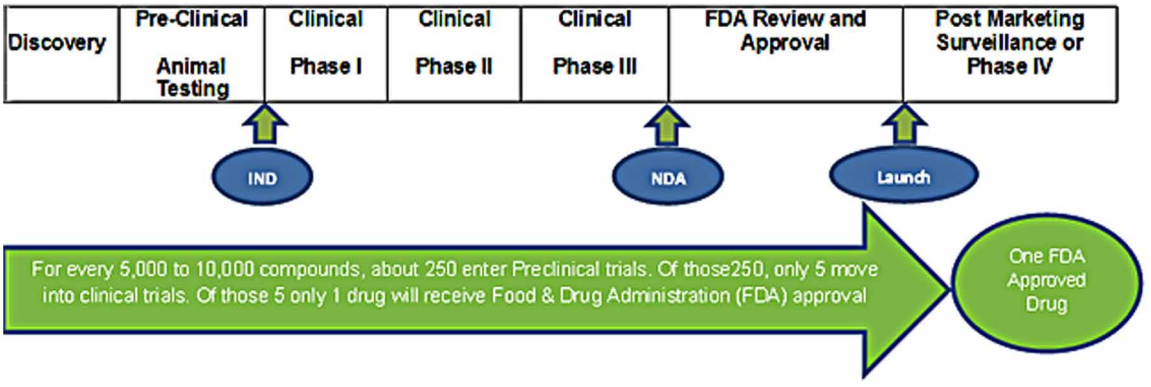
The entire process of drug discovery and development starts *in silico* (in the computer), moves to *in vitro* (in the laboratories) and then finally *in vivo* (inside living beings like animals and humans). This is keeping with the spirit of ensuring safety to all living beings. As the molecule progresses to becoming a drug it graduates from computer to laboratory to living beings.

The initial phase of drug discovery is focused on understanding the disease better and potential drug targets that are relevant for the disease which is largely driven by biology. This part primarily focuses on:

- Understanding the mechanism of diseases;
- Identifying potential targets for therapeutic intervention;
- Evaluating potential drug candidates.

Once the disease is better understood and potential targets identified, the next phase focuses on various aspects of the molecule that can become potential drugs and is largely driven by chemistry. This part addresses the following needs:

- Inventing or identifying safe & effective chemical entities that will become potential drug candidates.
- These drug candidates will act as leads to act on the target disease



These two initial phases of biology and chemistry are largely *in silico* and *in vitro*.

One of the key qualifying parameter for a molecule to become a drug is its medicinal properties. This science is called medicinal chemistry and this characterizes the molecule before it is used in any living being.

Medicinal chemistry is a scientific discipline involved with designing, synthesizing and developing pharmaceutical drugs.

Medicinal chemistry involves the identification, synthesis and development of new chemical entities suitable for therapeutic use. It also includes the study of existing drugs, their biological properties, and

Figure 1.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

their quantitative structure-activity relationships (QSAR). One of the key set of parameters that defines the molecule is referred to as ADMET (Absorption, Distribution, Metabolism, Excretion, and Toxicity).

- **Absorption:** Refers to movement of drug into the body from the site of administration. Before a compound can exert a pharmacological effect in tissues, it has to be taken in to the bloodstream — usually via mucous surfaces like the digestive tract (intestinal absorption). Uptake into the target organs or cells needs to be ensured, too.
- **Distribution:** Refers to movement of drug from intravascular to extravascular compartment. The compound needs to be carried to its effector site, most often via the bloodstream. From there, the compound may distribute into tissues and organs, usually to differing extents.
- **Metabolism:** Refers to chemical transformation of drug. Compounds begin to be broken down as soon as they enter the body. The majority of small-molecule drug metabolism is carried out in the liver by redox enzymes, termed cytochrome P450 enzymes.
- **Excretion:** Refers to removal of drug from the body. Compounds and their metabolites need to be removed from the body via excretion, usually through the kidneys (urine) or in the feces. Unless excretion is complete, accumulation of foreign substances can adversely affect normal metabolism.
- **Toxicity:** Adverse effects occurring as a result of repeated daily dosing of a drug compound, or exposure to the drug compound, for part of an organism's lifespan. With experimental animals, the period of exposure may range from a few days to 6 months. (Clinical Pharmacology I, MCCQE Review Notes, 2002)

ADMET is an extremely important set of parameter since about 50% of the drug candidates fail due to unacceptable side effects and toxicities (ADMET). Some of these failures occur much later in the value chain resulting in additional spend that is avoidable. So it is critical that a compound needs to have a favorable ADMET profile for it to become a drug

Due to this very important nature of ADMET life sciences companies have started monitoring drugs for ADMET across the value chain. ADMET is measured all the way from *in silico* to *in vitro* to *in vivo*. The tests and the end points measured may vary. *in silico* ADMET is also popularly called Predictive ADMET (Gombar VK[1], Silver IS, Zhao Z., 2003).

Once the medicinal property and safety of the drug is established the molecule becomes a potential drug and is taken up for testing in animals and this phase is called preclinical.

A preclinical study is done to test promising compounds in animals. Companies conduct extensive toxicological tests and animal studies to determine whether the drug is likely to be safe and effective in humans.

If data from the above preclinical study prove the drug's safety and effectiveness, the pharmaceutical research organization submits all the results and files an Investigational New Drug Application (IND) in Food and Drug Administration (FDA) for US and other relevant regulatory authorities for other countries to test drug candidates in humans.

Primary Objectives of Preclinical Studies

- Support for human pharmacology
- Prediction of human pharmacokinetics

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Support for human toxicology
- Support in screening new dosage forms and formulations

Once a drug is determined to have a therapeutic use and safety has been tested in animals the drug becomes a candidate for development. Since drug development is so expensive, compound are carefully considered based on their market potential, availability of other treatments, and difficulty of bringing the drug to market. This phase is called clinical trials and is conducted over four phases as described below.

Clinical Phase 1 Trials

- In phase I, researchers test an experimental drug or treatment in a small group of people (20-80) for the first time to evaluate its safety, determine a safe dosage range, and identify side effects.
- Phase 1 studies are designed to determine:
  - Metabolic and pharmacologic actions of the drug in humans,
  - Side effects associated with increasing doses,
  - Early evidence on effectiveness.
- Phase 1 studies evaluate:
  - Drug metabolism,
  - Structure-activity relationships,
  - Mechanism of action in humans.

Clinical Phase 2 Trials

- In phase II trials, the experimental study drug or treatment is given to a larger group of people (100-300) to see if it is effective and to further evaluate its safety.
- Helps to determine the common short-term side effects and risks associated with the drug and to determine optimal dosing (dose and regimen). This is done by subjecting the volunteers/patients through various strengths of dose and arriving at the optimal dose.
- The trials done are typically well controlled and closely monitored.

Clinical Phase 3 Trials

- In phase III trials, the experimental study drug or treatment is given to large groups of people (1,000-3,000) to confirm its effectiveness, monitor side effects, compare it to commonly used treatments, and collect information that will allow the experimental drug or treatment to be used safely.
- Intended to gather the additional information about effectiveness and safety that is needed to evaluate the overall benefit-risk relationship of the drug.
- Helps in establishing that the current drug works better than other drugs currently available.
- Provide an adequate basis for extrapolating the results to the general population and transmitting that information in the physician labeling.

The three phases of clinical trials are followed by submissions and approvals. There are designated organizations in various countries that review and approve drugs in various countries.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

An NDA is filed following the successful testing on humans. A New Drug Application is the submission of documentation of safety and efficacy of the new drug to seek approval for marketing. It is also known as a "Marketing Application". The FDA in US reviews the NDA and approves the product for manufacturing and launch.

Table 1 summarizes the typical activities and success ratio across the 3 phases of the clinical trials

In the last several years with drugs showing toxic side effects post approval, a new phase called Phase 4 studies or Post marketing surveillance has been introduced. Post-marketing surveillance ensures that drugs once launched commercially, the safety of a drug is monitored closely. Both regulatory authorities and life sciences companies share responsibility for post-marketing surveillance. Here are some additional details on this phase.

- Post-marketing surveillance (also known as Phase IV trial) is the practice of monitoring the safety of a pharmaceutical drug or device after it has been launched in the market and forms an important part in retrospective or observational studies. Post-marketing surveillance is a part of Pharmacovigilance, an area that we will cover in subsequent sections. All Post-marketing surveillance studies are phase IV trials; however, the converse is not true.
- Since clinical trials are conducted in a comparatively controlled environment on fewer patient subjects, there is quite a chance to miss out studying the impact of the drug on medical conditions that might prevail in general populations, other than the participating subjects; hence, post-marketing surveillance can further refine, or confirm or deny, the safety of a drug after it is used in the general population by large numbers of people who have a wide variety of medical conditions in a neutralized environment.
- Post-marketing surveillance is a mandate imposed by the FDA for drug safety. Various approaches are used to monitor the safety of licensed drugs such as spontaneous reporting databases, prescription event monitoring, electronic health records, patient registries and record linkage between health databases. These data are reviewed to highlight potential safety concerns in a process known as data mining.
- In certain instances, a licensed drug's labeling might need to get updated, its indication may need to be limited to particular patient groups, or in rare cases, the drug might need to be withdrawn from the market completely.

The entire process of drug discovery and development and the associated phases can be summarized in Table 2. (Michigan Institute for Clinical and Health Research, n.d; Cern Foundation, n.d; ClinicalTrials.gov, n.d)

Table 1.

	Number of subjects (approx.)	**Duration (approx.)**	**Purpose**	**Percentage drugs successfully tested**
Phase I	20 to 80	Up to several months	Primarily safety dose (based on tolerance)	70%
Phase II	100 to 300	Up to 2 years	Effective dosage, short term safety/ side effects	33%
Phase III	1000 to 3,000	Up to 4 years	Efficacy and comparison to commonly used treatments, long term safety	25 – 30%

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2.

Process	Typical Activities
New Entity	1. Molecular modification 2. Organic synthesis 3. Medicinal chemistry
Pre-Clinical Studies	1. Pharmacokinetics 2. Pharmacology/Toxicology 3. ADMET 4. Pre-Formulation/Formulation 5. Manufacturing control
IND	1. Submission 2. FDA review and approval
Clinical Trials	1. Phase 1 2. Phase 2 3. Phase 3 4. Formulation 5. Manufacturing controls
NDA	1. Submission 2. Review, Inspection and Approval
Post Marketing Surveillance	1. Product defect reporting 2. Adverse event reporting

Regulations Involved in Drug Development

The process of clinical trials and pharmacovigilance is highly regulated and governed by FDA in the US, EMEA in Europe and MHRA in the UK and other such authorities in different countries.

Here are some reasons why regulations and regulatory authorities are critical for success.

- Ensuring Good practices during the Laboratory research phase, Clinical phase and the Manufacturing phase.
- Ensuring that the consumer (patients, clinical research subjects) are informed and their consent is obtained.
- Ensuring that the identity of patients / clinical research subjects are protected.
- Ensuring Security and Authenticity of e-data submitted to the FDA (21 CFR Part 11).
- Ensuring that all the Life Sciences processes and applications perform their functions "as intended" (Computer Systems Validation).
- Ensuring Safety, Efficacy and Quality of the end-product.

Relevance of Computer Systems in Clinical Trials

Clinical trials are structured and conducted in a very scientific manner to ensure hypothesis generation and validation using statistical techniques. The clinical trials generate data over a period of time which needs to be stored, processed and submitted in pre-defined formats and these are the areas where computer systems are playing a big enabling role to make the overall process efficient and reliable.

Most common experimental designs implemented in clinical trials across phases are randomized controlled trails (RCT) but there is a new emerging area called adaptive design that is being used fre-

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

quently nowadays. Adaptive design is to make the design flexible to account for findings from previous stage of clinical trials. Adaptive design will be explained later in this chapter. The key aspects of RCT are as follows.

- **Randomization:** Subjects are assigned to intervention vs. Control treatment in random process to overcome confounding factors and any imbalance in the assignment.
- **Blinding:** None of the participants or researchers knows about the specific treatment details. This is done to reduce bias and unwarranted special care to any patients as that may manipulate the results
- **Stratification:** Patients are stratified to create balance among the stratifying variables such as gender, age and so on. This is done to achieve balance with respect to stratifying variables and also gain knowledge about sub groups in the patient population.

The various activities within the clinical trials process can be outlined as in Table 3. Each trial has one of more studies as part of the trial process. Each study involves enrolment of sites typically hospitals or clinics and a principal investigator in the site who in turn recruits patients along with his supporting staff within each of these identified sites.

Each of these activities involves set of start and end points that are inter related and come together to ensure a successful trial.

There are several computer systems that support the activities outlined above. Some examples of such systems are as defined below.

- **Electronic Data Capture Systems (EDC):** These systems help capture all the patient information in a structured format so that they can be easily extracted and analyzed at various points during the conduct of the studies. This is set up for every study.
- **Clinical Trial Management Systems (CTMS):** These systems help capture trial related information like sites, investigators and other non-patient related information which are important to the conduct of the trials.
- **Clinical Supplies Management Systems (CSMS):** These systems capture information related to supply of materials used in the conduct of the trials.
- **Clinical Data Repository (CDR):** These systems help bring together information from multiple studies/trials and make them available for analysis to arrive at insights and conclusions that are then used to file for approval with the regulatory authorities.

Table 3.

Study design and planning	Site initiation	Patient enrollment and recruitment	Study conduct	Analysis, reporting and study close out
1. Study planning 2. Protocol development 3. Investigator selection	1. Site selection 2.. Site initiation 3. Contract management	1. Patient screening 2. Patient recruitment 3. Informed consent 4. Patient enrollment for specific studies	1. Subject registration and randomization 2. Data entry in case report forms (CRFs) 3. Data validation and cleansing 4. Query generation and resolution	1. Data analysis, reports for submission 2. Database lock 3. Data retention and archiving

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Usually these systems do not operate in isolation. The systems are integrated and data flows across them thereby enabling easy understanding of the status of trials and insights on the progress of the trial and the ability to meet the expected end point.

Relevance of Computer Systems in Pharmacovigilance

Pharmacovigilance is the science of collecting, monitoring, researching, assessing and evaluating information from life sciences companies, healthcare providers and patients on the adverse effect of medications, biological products, etc. with a view to:

- Identifying new information about hazards associated with medicines
- Preventing harm to patients

Why Do We Need Pharmacovigilance

- Unexpected adverse reactions.
- Drug-Drug interactions.
- Long term efficacy.
- Quantify and recognise risk factors.
- Adverse drug Reactions (ADRs).
- Limitations of pre-marketing data:
    - Pre-Clinical data: insufficient predictive value.
    - Clinical Trial data provide provisional evidence of safety but: Too small (patient number limited), limited duration, do not represent the real world.

The Pharmacovigilance process can be outlined as in the Table 4. The process starts from the receipt of an adverse event (AE) and moves from the intermediate processing steps to determine the nature of the event eventually leading to a time bound submission to the health authorities. (Uppsala, n.d)

The above processes are supported by a set of computer systems that enable proactive monitoring and reporting. Some such systems are explained below.

- **Adverse Events Reporting Systems (AERS):** These systems help capture adverse events and have workflows that enable processing and eventual submission to health authorities
- **Safety Datawarehouse:** These systems bring adverse events information from various different sources and store it in a single location to enable reporting. Various health authorities have different requirements and frequencies for reporting safety adverse events.

One of the key benefits of a safety warehouse is also the ability to run signal detection. Signal detection is a pro-active approach to identifying potential adverse events and correlations.

- **Signal Detection:** Signal detection aims at finding causality between intervention(s) to adverse event(s) that have not been earlier found or refuted. These findings which can be beneficial or

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 4.

Process	Activities
Adverse event case receipt	1. Receive AE case 2. Document receipt 3. Index, file source documents
Adverse event case triage	1. Identify duplicate adverse event cases 2. Assign priority 3. Enter other case data into adverse event reporting system (AERS) 4. Perform preliminary quality assessment of data entered
Event assessment	1. Prepare company narrative for review 2. Assess case from medical perspective 3. Perform final review of case for report ability
Processing follow up information	1. Identify additional information required to analyze and report the case 2. Follow up to obtain additional information 3. Update additional information in AERS
Risk/Benefit Analysis	1. Perform risk/benefit analysis based on AERS data and data available with regulatory agencies 2. Prepare analysis reports
Regulatory submission	1. Prepare safety report 2. Facilitate final review by regulatory affairs 3. Submit report to regulatory agency 4. Track submission date of report and follow up, if any

harmful require\deserve immediate attention from the concerned groups. The findings deviate from what is expected from the drug or medical entity. Signal detection is traditionally done by examining the medical evaluation of case reports. But a more comprehensive and practical way of analyzing is through data mining. Data mining allows for a systematic evaluation of the adverse events. Generally a score is assigned based on statistical computation and the higher magnitude of the score reflects stronger association between the adverse event and the drug. Ultimately these scores act as a guideline for providing safety alerts. Based on previous knowledge and understanding of the current data, a threshold is chosen for these scores. Scores exceeding this threshold requires attention. The thresholds for detecting safety signals are a trade-off between sensitivity and specificity. Too stringent threshold results in missing significant signals and thereby effecting sensitivity and too relaxed threshold results in too many false positives impacting the specificity. (Uppsala, n.d)

FUTURE RESEARCH DIRECTIONS

Innovations in Clinical Development

Clinical development is also evolving with technology as new techniques like simulation, predictive modeling, and process automation mature and is available to be used in the design of better trials. The concept of personalized medicine and diagnostics is the new focus as safety events make it evident that one drug does not suit all patients.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Adaptive Trial Design

An adaptive clinical trial is a clinical trial that evaluates patients' reactions to a drug beginning early in a clinical trial and modifies the trial in accordance with those findings. The adaptation process continues throughout the trial. Modifications may include dosage, sample size, drug undergoing trial, patient selection criteria and "cocktail" mix. In some cases, trials have become an ongoing process that regularly adds and drops therapies and patient groups as more information is gained. The aim is to more quickly identify drugs that have a therapeutic effect and to zero in on patient populations for whom the drug is appropriate. A key modification is to adjust dosing levels. Traditionally, non-adverse patient reactions are not considered until a trial is completed.

The FDA issued draft guidance on adaptive trial design in 2010. In 2012, the President's Council of Advisors on Science and Technology (PCAST) recommended that FDA "run pilot projects to explore adaptive approval mechanisms to generate evidence across the lifecycle of a drug from the premarket through the post market phase." While not specifically related to clinical trials, the Council also recommended that FDA "make full use of accelerated approval for all drugs meeting the statutory standard of addressing an unmet need for a serious or life threatening disease, and demonstrating an impact on a clinical endpoint other than survival or irreversible morbidity, or on a surrogate endpoint, likely to predict clinical benefit."

Adaptive trials have resulted in accelerated trials and are supportive of personalized medicine and sub population strategies explained in the next section below. (FDA, n.d)

Translation Medicine and Personalized Medicine

Translational Medicines: Translating Laboratory Discoveries to New Therapies

Translational research is typically a three step process where studies performed in a lab are translated into treatments and/or therapies that are effectively integrated into medical practice.

The first step of translational research is investigating a topic such as the cause of a medical condition or a specific treatment. Researchers then look for new ways to approach some of medical science's most confounding issues.

Discoveries made in the laboratory are used to prompt clinical trials where research findings are given a practical application. During this phase, study volunteers and participants are exposed to the findings from the lab and data about participants' responses, feelings and reactions is recorded. If a positive outcome is achieved, the third step is to put the finding into practice. Doctors implement the researcher's findings, supported by the results from the clinical trials, and patients receive a new form of treatment or therapy.

This three step circular process is often described as taking a "bench to bedside" approach where researchers take what they learned at the research bench and apply it to patients at their bedside.

The process being circular starts at different points and applies the techniques to find effective drugs. (Clinical and Translational Science Institute, University of California Los Angeles n.d)

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Personalized Medicine

Personalized medicine refers to tailoring the drugs based on the genetic profile of the patients. The focus is on how patients with different genetic variations respond to the therapeutic treatment and thereby design the drugs accordingly. The advent of genomics technologies like next generation sequencing technologies eases and facilitates personalized medicine. Most of the clinical trials fail at later stages of trials such as Phase III. The main reason is the inappropriate selection of targets. This can remedy pharmacogenomics which is a major tool for personalized medicine. This ensures whether variations in molecular makeup of patients attributes to inefficacy and it can be proved that the intervention can be beneficial to patient populations as determined by the pharmacogenomics.

Centers conducting clinical trials should use real world clinical data obtained from medical institutions, hospitals and academic centers and use them as basis in clinical trial design as most of the clinical trials are controlled designs gathering information from real world data does help. Genomes or exomes of subjects participating in clinical trials needs to be sequenced and subjected to therapeutic intervention to undermine risk benefits of drugs based on genetic profiles. Personalized medicine also helps determine optimal does for the patients. (FDA, n.d)

Simulations and Human Disease Models

Computer simulation of clinical trials has evolved over the past two decades from a simple instructive approach to complete simulation models yielding pharmacologically sound, realistic trial outcomes. The need to make drug development more efficient and informative and the awareness that many industries make extensive use of simulation in product development have advanced considerably the use of simulation of clinical trials in pharmaceutical product development over the past decade.

The availability of data through various open industry initiatives and the reducing research productivity is driving significant adoption of simulation models and making it an integral part of the drug development process.

The other aspect of simulations is complete disease models. These are human models built with the understanding of biology and replicate the behavior of the disease in the computer human model built using experimental and derived data. These models provide researchers with a tool to both understand the mechanisms driving untreated disease progression and to predict physiological responses to therapeutic interventions, including variability across different patient phenotypes. (FDA, n.d)

Innovations in Pharmacovigilance

Pharmacovigilance is moving from a reactive reporting focus to a proactive model where monitoring of safety events start very early and multiple channels including social media are being effectively leveraged to track and report such incidents.

Increasing Use of Social Media to Capture Safety Data

The healthcare industry uses digital media for a number of purposes, including raising disease and treatment awareness, safety issues of drugs, clinical trial enrolment, recruitment and patient support.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

With people engaging on health issues more and more online, it is essential that companies track this information and derive important insights out of it to have a better vigilance on patient safety

CONCLUSION

Viewpoint: Future of Drug Development

Drug development is a very old process and over the period as the complexity of diseases has increased, most of the known diseases have been addressed, is facing increasing challenges around innovation and more importantly productivity.

There are several late stage failures of drugs and this attrition is causing an increase in the cost of every successful drug that comes to the market. Clearly there is a need to re-look at the approaches being used in drug development and very rapidly bring in changes that allow for more focused way to improve the techniques used and increase innovation.

As explained in the new innovations in this chapter, there are several new techniques and technologies that have emerged over the last decade which raise hopes of a dramatic change in the way drug development is done. Also the move from one drug fits all to a more focused targeted approach also enables bringing new therapies to the market faster.

One other key trend that will continue to evolve is the use of computer systems across the drug discovery and development processes to increase chances of success as the drug moves through the value chain. This is now supported by increasing availability of data which is a key for success of any computer based approach.

In summary computer systems are becoming increasingly important for drug development and their use will increase steadily. We will study more details in the subsequent chapters more details on their usage and applications.

KEY TERMS AND DEFINITIONS

Clinical Study: A research study using human subjects to evaluate the effect of interventions or exposures on biomedical or health-related outcomes. Two types of clinical studies are interventional studies (or clinical trials) and observational studies.

IND: Investigational New Drug.

NDA: New Drug Application.

Pharmacovigilance (PV): The science and activities relating to the detection, assessment, understanding and prevention of adverse effects or any other drug-related problem.

This work was previously published in Software Innovations in Clinical Drug Development and Safety edited by Partha Chakraborty and Amit Nagal, pages 1-13, copyright year 2016 by Medical Information Science Reference (an imprint of IGI Global).

Chapter 2
Pharmacogenomics Genome Wise Association Clinical Studies

Udayaraja G. K.
IGB, Saudi Arabia

ABSTRACT

Pharmacogenomics deals with drug responses in individual based on genetic variation in genome. Based on genetic variations, drugs may produce more or less therapeutic effect, and same way in side effects also. Physicians can use information about your genetic makeup to choose those drugs and drug doses to get better therapy. Optimizing drug therapy and rational dose adjustment with respect to genetic makeup will maximize drug efficacy and minimal adverse effects. This broken traditional 'trial and error' method of 'one drug fits all', and 'one dose fits all' which contributing to 25–50% of drug toxicity or treatment failures. This will contribute to improve the ways in which existing drugs are used, genomic research will lead to drug development to produce new drugs that are highly effective without serious side effects. This approach to bring personalized medicine more practice and drug combinations are optimized for each individual' genetic makeup.

INTRODUCTION

Human genetic profiling can be done by microarray expression, human SNP arrays and whole genome variants determination by using next generation sequencing technology. Whole genome wide screening approach enables better understanding about genetic profile, and provides possibility to check efficacy design for any animal experimental design. These technologies are made available to simultaneously monitor many cellular transcripts in parallel allows that result in more complete analysis of complex disease states and prediction of therapeutic response. Applications ranging from expression profiling to SNP genotyping, microarray gene expression in oncology are revolutionized with more clinical support to ensure better analysis of role of genetics in drug response.

Allelic variation in individual genotype also provides phenotypic relation, like intermediate, ultra-rapid, non-response categories of CYPgenes metabolizer etc. Several genetic events influence a same phenotypic trait, therefore, establishing genotype-to-phenotype relationships can be far from consensual with many enzymatic patterns. Many genes involved in pharmacokinetics process have been described as being highly polymorphic. Genes likes DPD, UGT1A1, TPMT, CDA involved in the pharmacokinetics of 5-FU/capecitabine, irinotecan, 6-mercaptopurine and gemcitabine/cytarabine, respectively. Patients affected by these genetic polymorphisms will experience severe/lethal toxicities upon drug intake, and that pre-therapeutic screening does help to reduce the risk of treatment-related toxicities through adaptive dosing strategies (Evans & Relling, 1999).

Drug adverse effects vary from patient to patient as well as disease to disease. Drug response characteristics are very complex and depends on profound gene-drug interactions. For drugs that have a narrow therapeutic index caused by inactivation of certain polymorphic drug-metabolizing enzyme and expected to have an increased risk of adverse drug reactions. Some drugs require a metabolic activation by polymorphic drug- metabolizing enzyme (for example, codeine) low therapeutic efficacy or treatment failure. For many drugs that have a broad therapeutic window caused by genetic variants which leads to impaired drug metabolism.

Pharmacogenomics researchers have already identified many genes whose variations affect drug responses. They also know where to look for the numerous others they are bound to discover in the future. Pharmacogenomics tests are used to identify the patients are most likely to respond to certain cancer drugs, tests provide tools for physicians to better manage medication selection and side effect amelioration. Pharmacogenomics is also known as companion diagnostics, meaning tests being bundled with drugs. Examples include KRAS test with cetuximab and EGFR test with gefitinib. Beside efficacy, germline pharmacogenetics can help to identify patients likely to undergo severe toxicities when given cytotoxics showing impaired detoxification in relation with genetic polymorphism like canonical 5-FU.

All drugs cannot be personalized, clinical significance in tailored medicine for prodrugs, drugs with a narrow therapeutic index and drugs that target a key molecule or a critical pathway. Drug safety is the first arena in which patients can benefit from pharmacogenetics and pharmacogenomics. Tumor responses to the inhibitors of oncogenic tyrosine kinases are associated with the presence of activating mutations within the genes encoding the target kinases, targeted cancer therapy is thus a promising individualized drug therapy. The U.S. Food and Drug Administration (FDA) recommends genetic testing for certain chemotherapy drugs like mercaptopurine (Purinethol) to patients with acute lymphoblastic leukemia. Some people have a genetic variant that interferes with their ability to process the drug. This processing problem can cause severe side effects and increase risk of infection, unless the standard dose is adjusted according to the patient's genetic makeup.

Using microarray, cellular transcripts expression in disease states and after treatment to identify drug response at molecular level. Microarray is either silicon chip or glass slide contain series of immobilized complementary DNA molecules or oligonucleotide probes. Targeted DNA labelled with a fluorescent, transcripts abundance based on amount of hybridized labelled dye on each microarray. Each gene represented by a probe set with 11-12 pairs of oligos composed of 25 nucleotides. This approach would make it possible to consider the measured intensities as a proxy for actual mRNA concentration. The scanner produce DAT file is the intensity for each pixel on the array and CEL file, which is the summary of probe intensity for every probe on the array. An expression file, which is the Affymetrix Suite compilation of the probes into gene expression values. An intensity of each probes are corrected

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

for background noise normalize combined into probeset expression values. Normalization will remove systematic measurement errors, both within and between arrays. These can be seen in the scatterplot matrices as deviations from linearity between arrays. This should improve our power to detect differential expression. Transcriptional profiling has use to identify class of tumors, response to therapy etc. Many studies used in cases like acute leukemias, diffuse large B-cell lymphomas, and breast tumors (Evans & Johnson, 2001; McLeod & Evans, 2001; Phillips,Veenstra,Oren,Lee & Sadee, 2001).

BACKGROUND

DNA variation in human genome occurs at every 100 to 300 bases leads to amino acid change in protein coding and noncoding part of the genome. Some of these variations may not produce any effect in cell but few can cause pathogenic effect and can also change influence in drug response etc. Most of the population showing monogenic (single-gene) or mendelian inherited pharmacological traits are caused by genetic polymorphisms. Phenotype differences caused by homozygosity of an SNP with 1% has a frequency in the population of one in 10000. Plasma concentration versus time curve (AUC) or the mean steady-state concentration of the drug is a very specific marker of drug elimination. Low concentration leads to rapid elimination and a high plasma concentration will slow down elimination. If the elimination of drug depends on one enzyme, then the drug level is a very specific in vivo marker of the enzyme in question.

Pharmacogenetics of drug metabolizing enzymes and particular the cytochrome P450 (CYP) enzymes has been in focus for almost 30 years. Remainder of this chapter deals with in vivo methodologies and strategies in CYP pharmacogenetics. Drug metabolism takes place in liver which transforms drug into active molecule called as biotransformation, metabolism typically inactivates drugs, some drug metabolites are pharmacologically active sometimes even more so than the parent compound. Metabolism processing by oxidation, reduction, hydrolysis, hydration, conjugation, condensation, or isomerization; whatever the process, the goal is to make the drug easier to excrete. The enzymes involved in metabolism are present in many tissues but generally are more concentrated in the liver. Drug metabolism rates vary among patients. The intensity and duration of pharmacological action of most lipophilic drugs are determined by the rate they are metabolized to inactive products. Cytochrome P450 monooxygenase system is the most important pathway in this regard. This depends on phenotype & genotype of the patients. However, in cases where an enzyme is responsible for metabolizing a pro-drug into a drug, enzyme induction can speed up this conversion and increase drug levels, potentially causing toxicity. Some patients metabolize a drug so rapidly that therapeutically effective blood and tissue concentrations are not reached; in others, metabolism may be so slow that usual doses have toxic effects. Individual drug metabolism rates are influenced by genetic factors, coexisting disorders, and drug interactions. For many drugs, metabolism occurs in 2 phases. Phase I reactions involve formation of a new or modified functional group or cleavage, these reactions are non-synthetic. Phase II reactions involve conjugation with an endogenous substance reactions are synthetic. Metabolites formed in synthetic reactions are more polar and thus more readily excreted by the kidneys and the liver than those formed in non-synthetic reactions. The most important enzyme system of phase I metabolism is cytochrome P-450 (CYP450), a microsomal superfamily of isoenzymes that catalyzes the oxidation of many drugs. The electrons are supplied by NADPH–CYP450 reductase, a flavoprotein that transfers electrons from NADPH to CYP450. CYP450 enzymes can be

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

induced or inhibited by many drugs and substances resulting in drug interactions in which one drug enhances the toxicity or reduces the therapeutic effect of another drug (Evans & Relling, 1999; Collins, 2010, pp. 2–3).

Genetic variation accounts for some of the variability in the effect of drugs with N-acetyltransferases, individual variation creates a group of people who acetylate slowly and those who acetylate quickly, split roughly 50:50 in the population of Canada. This variation may have dramatic consequences, as the slow acetylators are more prone to dose-dependent toxicity. Cytochrome P450 monooxygenase system enzymes can also vary across individuals, with deficiencies occurring in 1 – 30% of people, depending on their ethnic background. Some drugs metabolized by single CYP but not same for all drugs, if the drug has a low therapeutic index and if clinical dose titration is not feasible. For CYP2D6 the possible candidates include tricyclic antidepressants, some antipsychotics, and some antiarrhythmics and for CYP2C9 the possible candidates could be warfarin and phenytoin. However pheno or genotyping for CYP enzymes has never achieved widespread use in clinical practice because, as explained above, the response is not determined alone by a single enzyme or gene.

Individual differences in drug metabolism and therapeutic response based on genetic makeup, cytochrome P450 (CYP) genes, which encode enzymes that influence the metabolism of the most drugs. Various metabolic phenotypes like normal, intermediate, ultra-rapid, and poor is based upon the allelic variation within the individual genotype. However, several genetic events can influence a same phenotypic trait, and establishing genotype-to-phenotype relationships can thus be far from consensual with many enzymatic patterns. Number of evidence suggests that patients affected by these genetic polymorphisms will experience severe/lethal toxicities upon drug intake, and that pre-therapeutic screening does help to reduce the risk of treatment-related toxicities through adaptive dosing strategies. Depending on the type of CYP variation present, the patient's metabolizer phenotype and the type of drug, therapeutic drug response is often suboptimal. Poor metabolizers are unable to metabolize certain drugs efficiently, resulting in a potentially toxic build-up of an active drug or the lack of conversion of a prodrug into an active metabolite. In contrast, in ultra-rapid metabolizers, an active drug is inactivated quickly, leading to a sub therapeutic response, while a prodrug is quickly metabolized, leading to rapid onset of therapeutic effect. Sometimes drugs inhibit metabolizing enzyme like quinidine inhibit CYP2D6 which leads to poor metabolizer (Belle & Singh, 2008; Ermak, 2013, pp. 2).

The CYP2C19 enzyme contributes to the metabolism of a large number of clinically relevant drugs and drug classes such as antidepressants, proton pump inhibitors (PPIs), and the antiplatelet prodrug clopidogrel. Like other CYP450 genes, inherited genetic variation in CYP2C19 and its variable hepatic expression contributes to interindividual phenotypic variability in CYP2C19-substrate metabolism. The CYP2C19 "poor metabolism" phenotype was initially discovered by studies on impaired mephenytoin metabolism and the major molecular defect responsible for the trait is the CYP2C19*2 (c.681G>A; rs4244285) loss-of-function allele. CYP2C19 genotype has since been shown to affect the metabolism of several drugs and clinical CYP2C19 genetic testing is currently available. CYP2C19 is predominantly expressed in the liver and, to a lesser extent, in the small intestine. Constitutive expression of CYP2C19 is largely mediated by hepatic nuclear factors 4 alpha (HNF4alpha, HNF4A) and 3 gamma, and transcriptional activation is mediated by the drug responsive nuclear receptors CAR, PXR, and GRalpha, suggesting regulation by endogenous hormones and by drugs such as rifampicin. In vitro expression studies have recently shown that the GATA-4 transcription factor also upregulates CYP2C19 transcriptional activity by binding to two predicted GATA-specific promoter elements. Reduced CYP2C19 activity among women using steroid oral contraceptives results from transcriptional down-regulation of CYP2C19 expression

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

through binding of ligand-activated estrogen receptor alpha to a specific ERE consensus half-site in the CYP2C19 promoter. Certain selective serotonin reuptake inhibitors have an inhibitory effect on CYP2C19, which may cause drug-drug interactions with co-administered CYP2C19-metabolized drugs. For example, early studies suggested that omeprazole diminished the pharmacodynamic antiplatelet effects of clopidogrel and increased corresponding cardiovascular risks. However, it is currently not clear if identified changes in ex vivo platelet aggregation due to concomitant omeprazole and clopidogrel administration translates into clinically meaningful outcome differences. Although a number of genotyping technologies can be used to interrogate variant CYP2C19 alleles in Clinical Laboratory Improvement Amendments (CLIA)-approved laboratories, two genotyping platforms have been approved by the U.S. Food and Drug Administration (FDA) (Mohd Zaki Salleh, 2013).

CYP2C9 is a phase I drug-metabolizing cytochrome P450 (CYP450) enzyme isoform that plays a major role in the oxidation of both xenobiotic and endogenous compounds. Also identified CYP2C9 as one of several CYP2C genes clustered in four gene group CYP2C8-CYP2C9-CYP2C19-CYP2C18 size of 500kb region on chromosome 10q24. Single nucleotide polymorphism (SNP) identified between the CYP2C8 and CYP2C9 genes, primarily expressed in the liver, and the expression level is reported to be the second highest among CYP isoforms. Only the CYP enzyme CYP3A4 is quantitatively more highly expressed in human liver. It has been estimated that CYP2C9 is responsible for the metabolic clearance of up to 15%-20% of all drugs undergoing Phase I metabolism. CYP2C9 is induced by rifampicin which has been shown consistently to increase the clearance of drugs eliminated by CYP2C9. The clearance of losartan, phenytoin, tolbutamide and S-warfarin is approximately doubled in healthy volunteers or patients treated with rifampicin. CYP2C9 is inhibited by amiodarone, fluconazole, and sulphaphenazole among other drugs. Dangerous drug-drug interaction can arise when an inhibitor such as one of these is added to a therapeutic regime that include drugs with a low therapeutic index, such as S-warfarin, tolbutamine, and phenytoin. For example, there are numerous studies documenting potentiation of the anticoagulant effect of warfarin in patients coadministered with amiodarone. CYP2C9 is the enzyme responsible for the metabolism of the S-isomer of warfarin that is principally responsible for the anticoagulant effect of the drug. The crystal structure of both human CYP2C9 in complex with warfarin and unliganded CYP2C9 showed unanticipated interactions between CYP2C9 and warfarin, revealing a new binding pocket, suggesting that CYP2C9 may simultaneously accommodate multiple ligands during its biologic function. Structural analysis suggested that CYP2C9 may undergo an allosteric change when binding warfarin. The gene coding for the CYP2C9 enzyme is highly polymorphic, including functional variants of major pharmacogenetic importance. Changes in metabolic activity caused by genetic variants in CYP2C9 play a major role in pathogenesis due to ADRs. Patients with low enzyme activity are at risk of ADR, especially for CYP2C9 substrates with a narrow therapeutic window, such as S-warfarin, phenytoin, glipizide, and tolbutamide. A large body of literature investigates two common non-synonymous variants within CYP2C9, leading to poor metabolism phenotypes. Individuals with these variants are at risk of prolonged bleeding time and increased incidence of severe bleeding in warfarin therapy, higher possibility of low blood sugar levels during glipizide and tolbutamide therapy, and more frequent symptoms of overdose in phenytoin therapy (Mohd Zaki Salleh, 2013, pp. 1371; Desta, 2002, pp. 913-58).

The cytochrome P450 2D6 (CYP2D6) is an enzyme of great historical importance for pharmacogenetics and is now thought to be involved in the metabolism of up to 25% of the drugs that are in common use in the clinic. Several years before the gene was cloned, researchers observed that Caucasian subjects responded in a bimodal pattern to certain drugs such as debrisoquine and sparteine, with most patients exhibiting “normal” pharmacokinetics, whereas others seemed to have great difficulty in metabolizing

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

debrisoquine or sparteine. Debrisoquine and sparteine became examples of so-called probe drugs, and were used to phenotype patients. This finding led researchers to conclude that there were common polymorphisms in an as yet unidentified metabolic gene that contributed to the variable pharmacokinetics of these drugs. The protein responsible for the altered metabolism was later purified from human liver microsomes. The gene encoding this protein was initially localized to chromosome 22 and cDNA was cloned from human liver cDNA libraries using an antibody against the rat ortholog. The deduced human protein revealed 73% sequence similarity with the rat protein and by use of human-rodent somatic cell hybrids the gene was localized to human chromosome 22, confirming the earlier study. This gene came to be called CYP2D6, and is part of the cytochrome P450 gene family a group of enzymes that is responsible for Phase I metabolism and elimination of numerous endogenous substrates and a diverse array of drugs. Among the drug-metabolizing CYPs, CYP2D6 is the only non-inducible enzyme, which results in a large contribution of genetic variation to the interindividual variation in enzyme activity. CYP2D6 is highly polymorphic, with over 90 known allelic variants (Tranah, 2005).

CYP2D6 became an object of intense research following its identification as the gene responsible for the altered activity observed with debrisoquine and other drugs. It soon became apparent that there were many different polymorphisms in all parts of the world that impacted CYP2D6 activity. There were alleles that led to a complete loss of CYP2D6 activity, which were common in the initially studied Caucasian populations; however, studies in populations of other ethnic origins revealed reduced function and even hyperfunctional CYP2D6 alleles. A system of assigned patients into four categories based on their ability to metabolize CYP2D6 substrates began to emerge. They are, listed in order of highest functioning to lowest: ultrarapid metabolizers (UM), extensive metabolizers (EM), intermediate metabolizers (IM), and poor metabolizers (PM). An individual's highest functioning CYP2D6 allele predicts his/her phenotypic activity. EMs possess at least one fully functional CYP2D6 allele, and are thought of as phenotypically normal. IMs and PMs are not able to metabolize CYP2D6 substrates as well as their EM counterparts, and may be at increased risk for adverse effects resulting from higher plasma levels of the parent drug, or lack of efficacy resulting from an inability to form an active metabolite. UMs, or ultrarapid metabolizers, possess multiple functional copies of a single CYP2D6 gene. The CYP2D6 copy number has been found to be from 2-13. Each functional copy of CYP2D6 that is present increases the rate of metabolism of CYP2D6 substrates significantly. CYP2D6 allele distributions exhibit significant interethnic differences.

Personalized medicine is to achieve maximum therapeutic efficacy with minimum the risk of drug toxicity for an individuals. Inter-individual genetic profile significant to diseases susceptibility, and response to drugs. After the completion of the Human Genome Project, an explosion of genetic susceptibility to complex diseases and genetic variability will cause differences in drug responses between the individuals. Genomics has become an integral part of modern drug development, and a large number of pharmaceutical companies are using this information to identify novel drug targets, identify patient subpopulations that are likely to benefit from the therapy under development, or for other screening purposes (Collins, 2010, pp. 2–3; Crawley, 2007, pp. 821-822).

Genetic Basis of Variable Drug Response

Drug response involves various phenotypic factors, gene drug interactions is clinically important to dose determining factor. Based on the response, it will be inefficacy, efficacy, resistance, and toxicity. The

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

drug-metabolizing enzymes, three clinically important isoforms cytochrome P450 (CYP)2D6, CYP2C9, and CYP2C19 responsible for major drug metabolism which possess a large number of functionally significant genetic polymorphisms. Drugs those produce a broad therapeutic window possible for carrying genetic variant or variants may exhibit impaired drug metabolism and disposition,but these may be of limited clinical relevance (Takahashi & Echizen,2003).

MAIN FOCUS OF THE CHAPTER

Affymetrix

The GeneChip arrays are chemically attractive between DNA nucleotides adenine (A), guanine (G), thymine (T) and cytosine (C). In this C bond with G and T bond with A. DNA strand matches a complementary strand of RNA, the two strands are complementary and will stick to each other. Also a single base that doesn't match its partner able to make one single strand from sticking to another single strand. Hybridization is use for base pairing attraction to identify each SNP genotype. Human Genome Project made DNA sequence around any SNP can genotype with sequencing methods. The surface of the Affymetrix arrays look like square checkerboard. The 10K array, which is a piece of glass about the size of a thumbnail, has over 400,000 squares. These squares are called features. The features on Affymetrix arrays are incredibly small about 8 microns across. Probe is a unique DNA strand which fit in this square. One square would hold the ATTCATG probe we built, and another square would hold the ATTTATG probe. But, while each square holds one type of probe, there isn't just one probe in each square, but millions of identical copies of the same. These probes one layer at a time, using the same type of manufacturing technology that is used to build computer semiconductors. Multiple probes are synthesized in parallel.

A probe designed to genotype a SNP for extracted the DNA from our sample, DNA can be taken from any biological sample such as blood or saliva. The DNA ready to be genotyped can analyze the SNPs from the DNA you extracted, need to make millions of copies of each piece of DNA containing a SNP. Copying the sequence containing the SNP allows the DNA to be more easily detected on the array and the SNP to be more easily genotyped. The copied of all the SNPs that will be analyzed on the microarray, chemical process to fragment the DNA chains up into millions of short pieces. Then chemical called biotin are attached to each strand and this will act as a molecular glue for fluorescent molecules that will later be washed over the array. Passing the laser on the array will get fluorescent on molecule where the sample RNA has stuck to the DNA probes on the array.

The prepared DNA sample is washed over the array for 14 to 16 hours. The number of molecules involved in this wash are staggering. There are millions of copies of each DNA probe in every square on the chip, and there are also millions upon millions of pieces of tagged DNA from the sample and match will be made. If the sequence of bases in the sample DNA matches that of a DNA probe, then there will be a perfect match and the sample will stick to the probe. The hybridized RNA is tagged with molecular glue (biotin), it's as if each hybridized square on the array has been coated with sticky glue. The glow in the dark molecules (red ball) stick to the biotin glue, the fluorescent molecules are shaken away and the stain only sticks to those places on the array where DNA has bound. After all of this, researchers shine a laser light on the array, causing the stain to fluoresce (Apidianakis, et al., 2005; Boerma, et al., 2002).

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

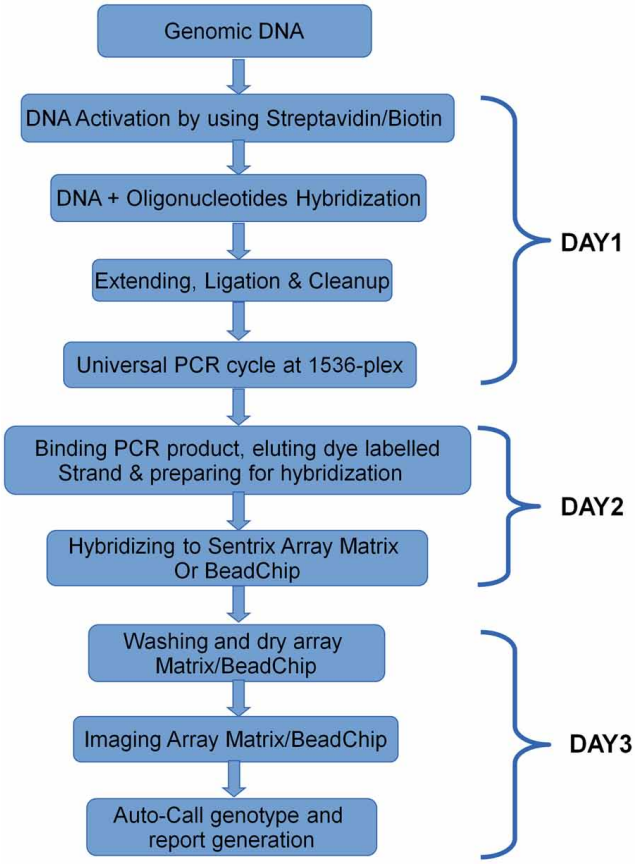
Illumina

BeadArray technology is the use of 3μM beads contains a large number of a specific oligonucleotide and a 23 bases that randomly assemble in either a fibre optic bundle substrate or a silica slide substrate. This available on two types, 96-sample array matrix format based on fibre optic bundle and the BeadChip format based on the silica slide. The randomly assembled beads are then decoded through a series of sequential hybridization processes. Illumina SNP genotyping includes the GoldenGate, iSelect, Infinium II and Infinium HD assays. The GoldenGate assay is based on allele specific extension and ligation used to interrogate 384 - 1536 SNPs simultaneously with multiplex also. The Infinium II assay, coupled with BeadChips, allows large scale interrogation of variations in the human genome at unlimited levels of loci multiplexing. Whole genome BeadChips covering SNP content ranging from 240,000 to 1 million and iSelect Infinium for custom Genotyping Panels.

Golden Gate

The activated DNA used for binding parametric particles by robust proces, depending upon the multiplex level, this equates to only 160pg of DNA per SNP genotype call. Assay oligonucleotides, hybridization buffer, and paramagnetic particles are then combined with the activated DNA in the hybridization. Three oligonucleotides are use to sequence for each SNP locus. Two oligos are specific to each allele of the SNP site, called the Allele-Specific Oligos(ASOs). A third oligo that hybridizes several bases downstream from the SNP site is the Locus-Specific Oligo (LSO). All three oligonucleotide sequences contain regions of genomic complementarity and universal PCR primer sites;the LSO also contains a unique address sequence that targets a particular bead type. Up to 1,536 SNPs may be interrogated simultaneously in this manner using GoldenGate technology. During the primer hybridization process, the assay oligonucleotides hybridize to the genomic DNA sample bound to paramagnetic particles, then washing performed to reduce noise by removing excess and mis-hybridised oligonucleotides. These joined, fulllength products provide a template for PCR using universal PCR primers P1, P2, and P3.

Universal PCR primers P1 and P2 are Cy3 and Cy5 labeled. After downstream-processing the single-stranded, dye-labeled DNAs are hybridized to their complement bead type through their unique address sequences. Hybridization of the GoldenGate Assay products onto the Array Matrix or BeadChip allows for the separation of the assay products in solution, onto a solid surface for individual SNP genotype readout. After hybridization, the BeadArray Reader is used to analyze fluorescence signal on the Sentrix Array Matrix or BeadChip, which is in turn analyzed using software for automated genotype clustering and calling (Mohd Zaki Salleh, 2013). Overall workflow shown in figure1.



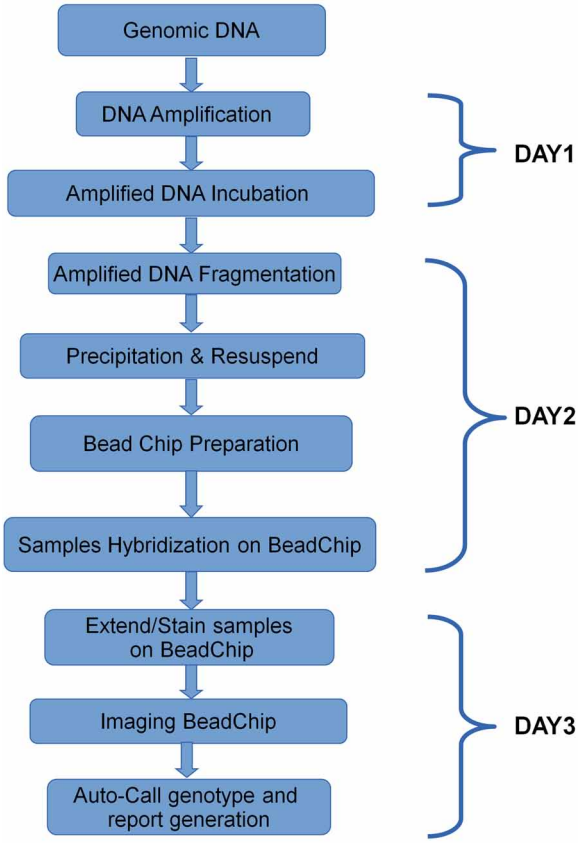
Infinium II Assay Workflow

Genotyping Assay is designed to interrogate a large number of SNPs at unlimited levels of loci multiplexing. Using a single bead type and dual color channel approach, the Infinium II Assay scales genotyping from 10,000 to hundreds of thousands of SNPs per sample. Illumina's optional Laboratory Information Management System (LIMS) and automation ensure positive sample tracking while reducing time required and labor costs.

This amplification has no appreciable allelic partiality. Additionally, a relatively low DNA sample requirement of 750 ng is sufficient to assay over 500,000 SNP loci. The amplified product is then

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Illumina GoldenGate Workflow



fragmented by a controlled enzymatic process that does not require gel electrophoresis. After alcohol precipitation and resuspension of the DNA, the BeadChip is prepared for hybridization in the capillary flow-through chamber; samples are applied to BeadChips and incubated overnight. The amplified and fragmented DNA samples anneal to locus-specific 50-mers during the hybridization step. One bead type corresponds to each allele per SNP locus. After hybridization, allelic specificity is conferred by enzymatic base extension. Products are subsequently fluorescently stained. The intensities of the beads' fluorescence are detected by the Illumina. BeadArray Reader, and are in turn analyzed using Illumina's software for automated genotype calling. With Illumina's optional Laboratory Information Management System (LIMS) to ensure positive sample tracking, the Infinium II Assay is a robust protocol with a straight forward workflow that can be automated or processed manually (Armstrong, et al., 2002; Mohd Zaki Salleh, 2013). Overall workflow shown in figure2.

Data Processing and Software Tools

Genotyping of specific gene or whole genome by using either Affymetrix or Illumina can be perform to get personal genetic profile of the patient. Individualizing therapy can be provide either through diagnosis of risk factors or markers which present in the patient. Overall process should be genotyping, markers

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Illumina Infinium Workflow

identification and pathogenicity or clinical impacts to predict drug response. Each genotyping platform providing their own genotype call software like genotype console from Affymetrix, Genome Studio from Illumina etc. Apart from those software, some commercial software supporting multiple platforms for data analysis. CLC genomics workbench, Partek genomics suite, DNA STAR, GeneSpring GX from Agilent etc. PharmGKB is pharmacogenetics knowledge base of genomic, phenotype and clinical information curated from pharmacogenetic studies. This data base can use to browse, query, download, submit, edit and process the pharmacogenetic information for registered members and subset is publicly available. Retrieving markers with associated clinical information will provide diagnostic level annotation to use personal medication [23,24].

ISSUES AND SUGGESTED RECOMMENDATIONS

This arrays are high intensive labour requirement for synthesizing, purifying, and storing DNA solutions before microarray fabrication is more expensive. Also during genotyping experiments in the laboratory, sequence homologies between clones representing different closely related members of the same gene family may result in a failure to specifically detect individual genes and instead may hybridize to spot designed gene to happen cross hybridization. In situ oligonucleotide array formats are expensive spe-

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

cialized equipments to carry out the hybridization, staining of label, washing, and quantitation process. Ready made in situ oligonucleotide array format are still expensive, although there has been reductions in cost as the market of microarrays has expanded. Short-sequences used on the array confer high specificity, they may have decreased sensitivity/binding compared with glass cDNA microarrays. Such low sensitivity however is compensated for by using multiple probes. Array designs are not flexible, there are occasions when the production of the array, hybridization and detection equipment are restricted to centralized manufacturer facilities, thus limiting the researcher's flexibility. Similarly, the cost and time needed to manufacture the in situ oligonucleotide array format makes it uneconomical for an average laboratory to synthesize its own chips. Multiplexing can reduce per individual cost, integrating data analysis up to secondary level may reduce complexity of the analysis, drug specific markers arrays or disease specific markers may useful to focus more [20,21].

For example anticoagulant drug Warfarin is one of the most commonly using via oral treatment for a range of thrombotic conditions, including deep vein thrombosis, pulmonary embolus and atrial fibrillation. The aim of treatment with Warfarin is to prevent arterial and venous thromboembolism by thinning the blood to a safe and effective level. Ideally patients recieving Warfarin treatment should have stable INR's within a specified and disease specific range: for example, in order to prevent recurrent myocardial infarction patients should have INR's of between 2.5 to 3.5. Despite the longstanding and widespread use of Warfarin, both loading and maintainance dose, for any particular patient, displays wide variability. While the majority of such variation is thought to be due to lifestyle and environmental factors, Warfarin action and metabolism also has a pharmacogenetic component. CYP P450 genes are important in drug response. However, in this case, it is variation in the CYP2C9 gene that is important as well Single Nucleotide Polymorphism variation in the VKORC1 gene. As in the case of thiopurine metabolism, mutations of the CYP2C9 gene can create phenotypes that are extremely sensitive to Warfarin and, hence, are at an increased risk of ADR. Thus, in a similar way to thiopurine treatment, Warfarin pharmacogenetics can be used to improve safety in drug prescription. However, in this case, another gene is also implicated in drug metabolism at the other end of the spectrum: here SNP variation in the VKORC1 gene appears to mediate the efficacy of Warfarin treatment. As noted above Warfarin has a narrow theraputic index. That CYP2C9 variants mediate the safety of Warfarin treatment, and VKORC1 independently mediate its efficacy, are not the only complications for clinicians in making both, inital, and long-term, prescribing decisions. The effect of Warfarin is heavily infulenced by a number of lifestyle and environmental factors, phenotypic factors like age, weight, alcohol consumption, drug reigeme compliance, and diet. These account for around 80% of variation in Warfarin patient INR and, given the serious consequences of both over and under anticoagulation, require that this drug therapy is accompanied by intensive and costly pharmacovigilance regimes [33, 34, 35].

FUTURE DISCUSSION AND CONCLUSION

Based on the Pharmacogenomics research on CYP enzymes states the role of genetic factors for variation in drug response can predict. Genetic profile will help to determine some extent of drug response but a single gene or by a group of genes not enough to get predict fully. With full human genome it is possible for the treatment to the individual patient on the basis of the patient genetic profile. Genotyping as an aid to select the right dose of the right drug in the individual patient would be of theoretical use if the response is mainly determined by a single gene or a limited group of genes, and if all of the

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

environmental and constitutional influences have a more limited influence, and besides are known in detail and can be measured in the individual patient. Coming years in the CYP field studying pharmacogenetics or genomics will lead to new important insights and discoveries that will ultimately lead to the development of new and better drugs and to the rational use of drugs that are already on the market. At present, after not reached in patients & physician may be lack of pharmacogenomics knowledge and gap between sequencing & data analysis. In future, integrating knowledge data base with software tools will provide on-spot clinical significance of markers after genotype call.

KEY TERMS AND DEFINITIONS

Acetylators: An organism capable for metabolic acetylation.

Acute Lymphoblastic Leukemia: Also called acute lymphoblastic leukemia, is a cancer that starts from white blood cells called lymphocytes in the bone marrow (the soft inner part of the bones, where new blood cells are made).

Allele: (short for allelomorph) A variant of a gene were the DNA sequence differs between two or more variants.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Allelic Variation: The presence or number of different allele forms at a particular locus (locus or loci = place) on a chromosome (allelic variation is sometimes used more loosely to describe the overall diversity present).

Antiarrhythmics: Drugs that are used to treat abnormal heart rhythms resulting from irregular electrical activity of the heart.

Antidepressant: A substance that is used in the treatment of mood disorders, as characterized by various manic or depressive affects.

Antipsychotics: A class of medicines used to treat psychosis and other mental and emotional conditions.

Cellular Transcription: The process in a cell by which genetic material is copied from a strand of DNA to a complementary strand of RNA (called messenger RNA).

Chemotherapy: A category of cancer treatment that uses chemical substances, especially one or more anti-cancer drugs.

Complementary DNA: (c-DNA) DNA synthesized from a messenger RNA (mRNA) template in a reaction catalysed by the enzymes reverse transcriptase.

Conjugation: A process by which one bacterium transfers genetic material to another through direct contact.

Cytotoxics: The quality of being toxic to cells.

Detoxification: The physiological or medicinal removal of toxic substances from a living organism, including, but not limited to, the human body and additionally can refer to the period of withdrawal during which an organism returns to homeostasis after long-term use of an addictive substance.

Electrophoresis: Separations technique that is based on the mobility of ions in an electric field.

Endogenous: Those that originate from within an organism, tissue, or cell.

Genetic Makeup: The genes that determine what you look like and what physical characteristics you have.

Genetic Polymorphism: The occurrence in the same population of two or more alleles at one locus, each with appreciable frequency, where the minimum frequency is typically taken as 1%.

Genetic Profiling: Science of identifying individual genetic characteristics by way of DNA analysis.

Genetic Variation: Variation in alleles of genes, occurs both within and among populations.

Genome: The complete set of genes or genetic material present in a cell or organism.

Genome Variants: Variations of genomes between members of species, or between groups of species thriving in different parts of the world as a result of genetic mutation.

Genotype: Genetic makeup of a cell, an organism, or an individual usually with reference to a specific characteristic under consideration.

Genotyping: Process of determining the genetic constitution – the genotype – of an individual by examining their DNA sequence.

Germline: The cellular lineage of a sexually reproducing organism from which eggs and sperm are derived; also - the genetic material contained in this cellular lineage which can be passed to the next generation.

Homozygosity: A cell is said to be homozygous for a particular gene when identical alleles of the gene are present on both homologous chromosomes. The cell or organism in question is called a homozygote.

In Situ: In the normal location. An in situ tumor is one that is confined to its site of origin and has not invaded neighboring tissue or gone elsewhere in the body.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

International Normalized Ratio (INR): A state of achieving anticoagulation for prothromboin time.

Lipophilic Drugs: Drugs that are able to dissolve much more easily in lipid (a class of oily organic compounds) than in water.

Metabolites: The products of enzyme-catalyzed reactions that occur naturally within cells.

Microarray Expression: Provides a comprehensive portrait of the transcriptional world enabling us to view the organism as a 'system' that is more than the sum of its parts.

Monogenic: Involving or controlled by a single gene.

Next Generation Sequencing: Method for sequencing genomes at high speed, at low cost and with great accuracy.

Oligonucleotide: Short, single-stranded DNA or RNA molecules that have a wide range of applications in genetic testing, research, and forensics.

Oncogenic: Causing development of a tumour or tumours.

PCR: Polymerase chain reaction, or PCR, is a laboratory technique used to make multiple copies of a segment of DNA. PCR is very precise and can be used to amplify, or copy, a specific DNA target from a mixture of DNA molecules.

Pharmacodynamics: The study of what a drug does to the body, whereas pharmacokinetics is the study of what the body does to a drug.

Pharmacogenetics: The branch of pharmacology concerned with the effect of genetic factors on reactions to drugs.

Pharmacokinetics: The branch of pharmacology concerned with the movement of drugs within the body.

Phenotype: The set of observable characteristics of an individual resulting from the interaction of its genotype with the environment.

Phenotypic Trait: An obvious and observable trait; it is the expression of genes in an observable way. An example of a phenotypic trait is hair color, there are underlying genes that control the hair color, which make up the genotype, but the actual hair color, the part we see, is the phenotype.

Polymorphisms: The presence of genetic variation within a population, upon which natural selection can operate.

Probe: A fragment of DNA or RNA of variable length (usually 100-1000 bases long) which is used in DNA or RNA samples to detect the presence of nucleotide sequences (the DNA target) that are complementary to the sequence in the probe.

Scatterplot Matrices: A great way to roughly determine if you have a linear correlation between multiple variables. This is particularly helpful in pinpointing specific variables that might have similar correlations to your genomic or proteomic data.

SNP: A Single Nucleotide Polymorphism (SNP, pronounced snip; plural snips) is a DNA sequence variation occurring commonly within a population (e.g. 1%) in which a single nucleotide — A, T, C or G — in the genome (or other shared sequence) differs between members of a biological species or paired chromosomes.

SNP Arrays: A type of DNA microarray which is used to detect polymorphisms within a population.

Therapeutic Index: A comparison of the amount of a therapeutic agent that causes the therapeutic effect to the amount that causes death (in animal studies) or toxicity (in human studies).

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Thrombosis: Local coagulation or clotting of the blood in a part of the circulatory system.

Thromboembolism: Obstruction of blood vessel by a blood clot that has become dislodged from another site in the circulation.

Tumors: A swelling of a part of the body, generally without inflammation, caused by an abnormal growth of tissue, whether benign or malignant.

Chapter 3
Normalizing Cross-Border Healthcare in Europe via New E-Prescription Paradigms

Alexander Berler
National School of Public Health, Greece & epSOS, Greece

Ioannis Apostolakis
National School of Public Health, Greece

ABSTRACT

The 21st century started with some significant efforts globally in the e-health sector. This was mainly pushed as a generic strategy from many nations and international organizations in order to cope with issues such as ageing population, demographic shift, social security limitations, and financial instability. A second reason was the introduction of new technologies such as cloud computing, Web interoperability standards, mobile health, and social media that are steadily changing the way healthcare has been seen in the last decades. In addition to that, globalization, commuting, immigration, and increased mobility raised the issue of cross-border healthcare and the right to access normalized healthcare services anywhere, anytime. In that context, the authors analyze the technological offerings and result of the epSOS (European Patient Smart Open Services) framework and how it has affected strategic decisions in electronic prescription in Greece, thus creating a new useful e-health national application. They prove that by rethinking healthcare, reusing established standards such as HL7 CDA (Health Level Seven Clinical Document Architecture) and IHE (Integrating the Healthcare Enterprise) profiles, it is possible to propose a new innovative system that is in fact based upon new technological propositions such as REST (Representational State Transfer) architecture and cloud computing.

INTRODUCTION

The healthcare delivery landscape will change significantly in the future to master changes of society, such as constant population ageing and demographic rise (Mirkin, 2001). Those changes have already started and demand that e-health plays a significant role within a reformed healthcare system (European

DOI: 10.4018/978-1-5225-1762-7.ch003

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Commission, 2012). It is commonly agreed that e-health is a benefit for the patients, the healthcare practitioners, the healthcare provider organizations and the nations as a whole.

Eysenbach states that:

E-health is an emerging field in the intersection of medical informatics, public health and business, referring to health services and information delivered or enhanced through the Internet and related technologies. In a broader sense, the term characterizes not only a technical development, but also a state-of-mind, a way of thinking, an attitude, and a commitment for networked, global thinking, to improve health care locally, regionally, and worldwide by using information and communication technology. (Eysenbach, 2001)

The future of healthcare is to be patient-centric and with a focus on health promotion and health maintenance. Patient centred healthcare implies that patients and their relatives have a more active role in the design and enforcement of new healthcare treatments. So, patient should be the centre of care and all related information and decisions should incorporate each patient's individual options for better treatment. Patients and practitioners should operate in partnership so that medical decisions respect patient's need, beliefs and preferences. Practitioners should focus on making sure that patients have substantial information and support so that they can make appropriate decisions and participate in their own care (Institute of Medicine, 2001). New e-health services with the use of ICT (Information and Communication Technologies) such as Internet, cloud computing, social media are reshaping day by day the healthcare delivery systems (Apostolakis et al, 2012; Gwee, 2011; Cambria et al, 2010).

Appropriate and viable use of interoperable e-Health solutions has already demonstrated its ability to propose a strategy for reshaping the system towards a patient centred system. In other words, e-health seems to have the ability to enable and establish patient centred healthcare systems, where information systems interoperate and exchange patient information seamlessly on behalf of patient's welfare and social rights. However, the more complex and the more fragmented the healthcare provision and the insurance systems are the more complex and fragmented will the e-Health services be. Both positive as negative lessons learned from the past should influence future decisions (Calliope, 2010b).

On the demand side, citizens and patients want to be empowered and are increasingly well informed with the use of social media. Life expectancy steadily rises (Leon, 2011) and so is the prevalence of chronic conditions that are more often diagnosed at early stages. At the moment, the vast majority of national healthcare budgets concerns chronic disease management (Kaiser, 2012). Medical treatments, diagnostics tools and procedures, as well as the extensive use of new technologies in equipment and pharmaceutical industry increase the cost of healthcare. The use of new ICT technologies can and should automate and optimize healthcare delivery and related costs to the extent possible. Patient societies and other stakeholders demand and expect that no geographical borders exist in healthcare delivery, that seamless and adequate continuum of care prevails. Today's citizens are far more mobile for leisure or work than before, and this is well studied and documented (Rosenmöller et al, 2006; Glinos, 2012). Early epidemiological surveillance via warning and alert systems (WHO, 2005), as well as research and continuous professional training will require enhanced secondary use of aggregated health data of individuals to support the effectiveness, efficiency and sustainability of the health systems.

On the supply side, the demographic shift and population ageing has puts increased pressure on healthcare delivery systems (Mirkin, 2001, Bloom, 2011). In addition, the increase of patients' numbers creates a shortage of skilled healthcare labour resources and medical expertise. As a consequence

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

healthcare systems and process should be re-invented to deal with those pressures. In addition, the increased complexity of healthcare delivery and the need for increasingly shared information demand new working procedures and workflows.

The World Health Organization (WHO) has issued an important report in 2002 (WHO, 2002), that focused on that year, on the amount of disease, disability and death in the world that is attributed to a specific selection of the most significant risks to human health. The same document also calculates how much of this burden could be avoided in the upcoming decades, if the same risk factors are reduced from now and onwards. One way to reduce risk is to establish monitoring facilities (AHRQ, 2003; NHMRC, 2010). They would then control, benchmark and assess risk factors at a national and a global level. In that sense, Health cannot be restricted within national borders. In the way the planet, with the significant intervention of technology, has moved towards globalized structures, people, goods and services are constantly moving between regions and nations. As health is concerned, it is obvious that cross border healthcare has become an inevitable matter to deal with in all its instances: legal, social, technical, medical. Extensive information exist in the reference section of this chapter (WHO 2002b; WHO 2008b; Salgado, 2010, Samb et al, 2009). Globalization is putting the social cohesion of many countries under stress, and health systems, as key constituents of contemporary societies, are not performing as well as they should (WHO, 2008).

European Union has foreseen the aforementioned needs and open issues and has created policy papers and directives to respond to them (European Commission, 2004 & 2012), especially noting the need for standardization and cross border healthcare regulations in an attempt to provide adequate care for all citizens independently of their location within a unified Europe. As a consequence, the Large Scale Pilot Project on cross border e-Health interoperability, epSOS (European Patient Smart Open Services), and the thematic network of CALLIOPE (CALL for InterOPErability) until 2011 and now the e-Health Governance Initiative are the new drivers for creating, initially, new working paradigms in e-Prescription and Patient Summary use cases across Europe (eHGI, 2012).

EpSOS has created a series of new technical and functional requirements that enable the safe routing of medical information across regional and national healthcare systems, based on the efficient reuse of existing standards and integration profiles. After more than three years of hard work to develop feasible cross-border e-Health services, the efforts of the epSOS project team have now culminated in the large scale pilot entering into operational mode on the 13th of April 2012. In this piloting phase, the developed solutions are tested in a real-life environment during a one-year period (epSOS, 2008).

The technical and functional requirements already have a significant acceptance within EU member states (20 of which participate in epSOS) and not only (Norway, Switzerland and Turkey have Joined epSOS). In that sense, a significant, common ground has been introduced, assessed, disseminated and openly accepted concerning interoperability issues, codification and nomenclature reuse, transcoding, security, data privacy and many more.

EpSOS has introduced concepts such as the National Contact Point (NCP) which is, in fact, an enterprise information bus that securely, seamlessly transport medical information across healthcare systems of any type and complexity. This enables a democratic regulation of health IT market allowing common testing procedures (by reusing profiles and test tools provided by IHE), common interoperability frameworks (by accepting common HL7 CDA r2 type documents for the electronic prescription) and certification procedures (by deploying national certification and accreditation bodies and reusing IHE, EuroRec Institute or HL7 EHR-FS (Electronic Healthcare Record Functional System) standards and methods).

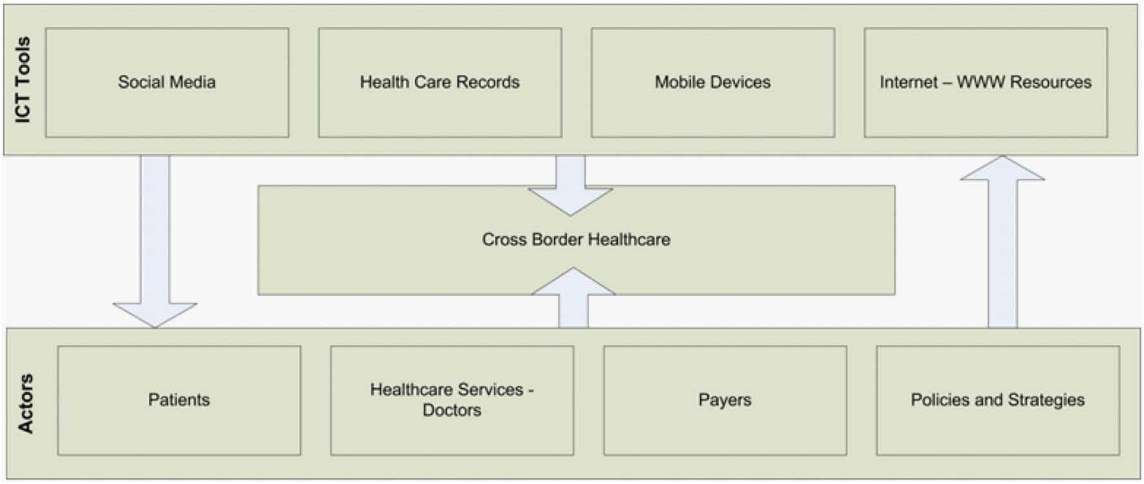
EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

In this chapter we propose to demonstrate the flexibility and reuse of the epSOS framework at a national and regional level by depicting the Greek e-Prescription case. It will explain how new and innovative e-services were introduced, in order to shape the new paradigm shift in e-Health in the 21st Century. From a methodological point of view, the chapter will follow a top down approach starting from presenting in the Background section; the high level European strategic decisions and mandates will then proceed to a thorough presentation and analysis of the epSOS case and analyze the current situation regarding e-Prescription. The next paragraphs present a detailed analysis of specific adoption of the EU approach at a country level with emphasis on the New Greek e-Prescription case, which introduces a new business paradigm in e-Prescription. In the "future research direction" section, we will propose the relative areas where future research is dominant in relation with the topics of this chapter. Finally, the author with deploy a synthesis of the chapter and state their opinions and beliefs in the conclusion section.

BACKGROUND

The Need for Cross Border Healthcare

WHO in its 2010 report (WHO, 2010) states the need for finding financial tools to achieve universal health coverage for patients and citizens. The literature on universal health coverage mostly focuses on five main themes such as accessibility to healthcare resources, population coverage capacity, point of care geography, rights to healthcare access and population protection from social and economic consequences of the lack of health. In that sense WHO is seeking ways to find ways to make universal health coverage financially sustainable especially in more underserved countries (Stuckler et al, 2010)



People are increasingly impatient with the inability of health systems to deliver services that meet stated demands and new needs. So many European patients, for example, seek healthcare services on the global scale, either because their country is, unfortunately, unable to serve them, or because they seek high expertise and skills at the point of delivery. In the latter case, information and communication technologies (ICT) have proven again to be a driver for fast information dissemination via the Internet and social media (Biermann et al, 2006; DeVries, 2012; Chou et al, 2009; Eysenbach 2002; Eysenbach, 2008).

As a consequence, Europe for many years know has focused on the subject and tried to find ways to include the need for cross border healthcare and adequate quality of healthcare delivery for all European citizens. Cross-border health care has simply become a more prominent phenomenon in the European Union (E.U.). When in need of medical treatment, patients supported by social media, for example, act as informed consumers who claim the right to choose their own provider beyond their national borders. Cross-border health care is also not restricted to patients. Medical doctors and nurses go abroad for training, to provide services temporarily or to establish them in another Member State. Increasingly, individual doctors and hospitals in different Member States cooperate with each other (Wismar et al, 2011). The above mentioned relations between actors and tools for cross border healthcare are depicted in Figure 1.

In order to deal with the cross border issue Europe has envisaged three alternatives to reduce legal burden. The first alternative focuses on the law of each country. So, when an action or service is performed in a different country that the country of establishment, then the applicable law is the one of the country of establishment. This is a basic principle taken focusing of the free movement of services and goods. The second alternative is the introduction of specific ruling in the framework of coordination

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Cross border healthcare actors and new tools

of social systems, which resulted in the establishment of the council regulation No 1408/71 of 14 June 1971 that focused in building a common European labor market. The third alternative was the most complex and time consuming that ended recently with the adoption of the new "Directive 2011/24/EU of the European parliament and the council of 9 March 2011on the application of patients' rights in cross-border healthcare" (OJEU, 2011). In fact, this was an open discussion and need noted more than a decade ago (Busse & Wismar, 2002).

European Strategy for E-Health

The European Union provides a common framework, policies, and service across all Member States. In many areas, there are common policies, but healthcare remains a national prerogative. There are substantial variations between the respective national healthcare systems, although, many similar issues exist – i.e. ageing population, chronic diseases prevalence, financial pressures. However, the capital right for mobility, both for patients and healthcare workers, has intensified the need for sharing of health records across national boundaries and the use of standards, processes and technologies to support them. In this ambiguous environment, most Member State Governments assume that they have full responsibility and control over their own health services, on the basis of Article 152 of the Amsterdam Treaty, but in fact, it is apparent that the Single European Market (SEM) has a substantial impact on health services (Busse & Wismar, 2002). The SEM relies on a set of principles such as free movement of goods and services and freedom of establishment. Those influence health services since patient often move for business, leisure of better care selection, thus demanding to receive equal care with Europe based upon SEM principles (Wismar et al, 2011).

The "Bolkestein Directive on services in the internal market", introduced in December 2006 (OJEU, 2006), kept the delivery of healthcare out of scope. A number of official rulings of the European Court of Justice (ECJ), regarding the application of the internal market principles to health, clearly state, that internal market regulation have an influence on the delivery of health services. Consequently, a legal document was called for, to settle the ECJ's open issues, concerning patients' rights to get reimbursement

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

for healthcare services done in another Member State. This resulted in the directive 2011/24/EU as a response to the raised concerns, in the context of cross-border healthcare, with a focus on e-Prescription.

This Directive states that patients are allowed to receive healthcare in another Member State and get reimbursement up to the costs accepted in the country of origin, as if this treatment had been provided inland. For reasons of general interest, a country may restrain the application of cross-border healthcare rules on reimbursement. In order to monitor incoming flows of patients and to ensure efficient access to healthcare, the country of delivery of care is allowed to adopt measures concerning access to treatment where this is justified. This means that the Directive targets European citizens and protect their rights to equal care within E.U. borders, but it is not effective for other foreigners where other official documents and bilateral agreements are legally binding healthcare processes. Finally, Member States need to establish national contact points in order to provide patients with information concerning their rights and practical aspects of getting cross border healthcare.

In parallel, the EU has also matured in terms of introducing ICT in the healthcare sector in order to deal with issues such as those aforementioned. In the past decades a series of important studies, reports and communications, issued by the European Commission, urge Member States to take immediate action in that domain. Willing not to make extensive description of EU strategic goals and decisions, it is nevertheless important to state at least the most important steps that lead us to today's situation and future promising prospects. Those are duly noted and analyzed in CALLIOPE project documentation (Calliope, 2010a, 2010b) with the focus on e-Health.

The vision for health is for a smart, citizen-centered health system paradigm in which each citizen's needs are at the centre of redesigned health and social care services, but there are a number of challenges to address. Some of those issues have been technically addressed at a regional level (Berler, 2009). Europe's Member States are continually attempting to respond to demand for quality, safety and access. They are also fighting for healthcare systems sustainability in an unfriendly environment led by of demographic changes, ageing population reactions, increasing incidence of chronic diseases, rising demand for personalized healthcare and financial pressures.

The 2010 OECD (Organisation for Economic Co-operation and Development) report (OECD, 2010) provides clear evidence of the benefits that can result from ICT implementation into four domains: increasing quality of care and efficiency, reducing operating costs of clinical services, reducing administrative costs and enabling new care modalities. European Union's current initiatives focus on implementing the Europe 2020 strategy (European Commission, 2010a), while keeping up on the recommendation made in the Communication of the European Commission in 2004 (European Commission, 2004). This chapter is also proposing an analytical listing of further reading in this subject.

In short, "Europe 2020" proposes three priorities: Smart growth, Sustainable growth and Inclusive growth. The Digital Agenda (European Commission, 2010b), as part of the Europe 2020 strategy, places e-Health in a cross-sectoral framework with the following action points:

- **Key Action 13:** Undertake pilot actions to provide Europeans with secure online access to their personal health data by 2015 and to achieve by 2020 extensive deployment of telemedicine and telecare services.
- **Key Action 14:** Define a minimum common data set for interoperability of healthcare records to be accessed or exchanged electronically by 2025.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Major reports and studies (Stroetmann et al, 2011; Valeri, 2010; Warden, 2012) conclude that there is a significant healthcare improvement potential using e-Health as a catalyst. Examples of quantified potentials include (Gartner, 2009):

- 5 million outpatient prescription errors per year could be avoided through e-Prescriptions.
- 100,000 inpatient adverse drug events per year could be avoided through Clinical Decision Support and Computerized Physician Order Entry Systems. This would free up 700,000 bed-days per year, corresponding to a value of almost €300 million.
- 9 million bed-days per year could be released, through the use of Electronic Patient Records, thus increasing output or decreasing waiting times, corresponding to a value of approximately €3,7 billion.

Project epSOS

In order to support health policies at a European Level, standardization effort in healthcare, e-health, to promote and to establish the enforcement of the new EU Directive on cross border healthcare, the European Commission, via the Information and Communication Technologies Policy Support Program (ICT PSP) as part of the Competitiveness and Innovation Framework Program, is co-funding the Large Scale Pilot (LSP) "European Patient Smart Open Service" or epSOS in short.

EpSOS mandate is to design, build and evaluate a service oriented infrastructure that demonstrates cross-border interoperability between electronic health record systems in Europe (epSOS, 2008). EpSOS is a large scale pilot involving more than 105 healthcare provider point of care (Hospitals / General Practitioner / Medical Specialist offices) and 168 Pharmacies all spread across 23 countries in Europe. The whole extend and description of the pilot settings can be reached electronically via epSOS central access point at www.epsos.eu. The project features are shortly described in Table 1.

EpSOS goal is to offer seamless healthcare to European citizens and a technical and functional framework for cross border healthcare. Key goals are to enhance the quality and safety of healthcare services for people travelling or commuting to another country. Moreover in Europe, it concentrates on developing a practical e-Health framework and ICT infrastructure that enables secure access to patient health information among different European healthcare systems. EpSOS aspiration is to makes a significant contribution to patient safety by reducing the frequency of medical errors when providing quick access to patient summary documentation. In emergency situations, this documentation may provide

Table 1. epSOS in figures

Time period	1st July 2008 - 31st December 2013
Duration	66 months (5 1/2 years)
Volume	€ 36,5 Million: co-funded by the European Commission Competitiveness and Innovation Programme (CIP) within the ICT Policy Support Programme
Number of Beneficiaries	47 Beneficiaries (national ministries of health, national/regional competence centers, a consortium of industry and the Project Management Team):
Number of countries	23 different European countries: 20 EU member states and 3 non-EU member states.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

the medical personnel with important life-saving information and minimize the repetition of diagnostic procedures that are both costly and unnecessary (Abba, 2009; Forni, 2010).

The project also tests for more than one full year the technical, legal and organizational concepts developed during the project. EpSOS today tests cross-border services in the following areas concerning patient summary and cross-border use of e-prescriptions. In a later phase (epSOS has been extended until end of 2013) the project envisions the following new scenarios: Integration of the 112 emergency services at each nation, Integration of the European Health Insurance Card (EHIC), patient access to their own data, the latter being the most important for all as noted in the new e-health action plan released by the European Commission in December 2012 (European Commission 2012).

epSOS intention is to prove that cross-border healthcare services are possible within Europe. Patients will have the opportunity when seeking healthcare in participating epSOS pilot countries to have access to epSOS cross border healthcare services in many different scenarios whether as tourists, business travelers, commuters or exchange students. All epSOS material is freely available to reuse and distribute via its Web portal.

Rethinking E-Health and Reusing What's Worth

Eysenbach described the term e-health as emerging in 2001. This is not the case anymore. As described in previous paragraphs, designing e-health services is not new, almost two decades have passed at a global level with extensive business planning, business process reorganization activities, brainstorming, piloting, standardization activities, and many more (Eder, 2000; Harmoni, 2002; Shortliffe et al, 2001; Stegwee, 2001; Black, 2011). We are now on the process of rethinking e-health's definition, focusing more on issue such as patient centered healthcare (Finkelstein, 2012), patient empowerment (Wald, 2011) and social media in healthcare (Neuhauser, 2003; Gwee, 2011; DeVries, 2012).

During this process, a lot of effort was dedicated to consensus building and stakeholder's managements. In fact, this is the right thing to do since in healthcare everyone is a stakeholder (Yasnoff, 2004). One of the most crucial issues that all involved technocrats learned is that what is essential is the user satisfaction, where a user is practically anybody. In that sense, building successful application is not about using the best technology nor the more innovative one, it is about understanding what is needed to be done (Iakovidis 1998; Iakovidis, 2000).

So, what is actually needed to make the e-health story a success? After many years of globally successful and unsuccessful projects, the most noteworthy thing relies in the three pillars of quality in healthcare as described by Avedis Donabedian many years ago (Donabedian, 1980, 1982, 1985, 1993, 2003): a healthcare organization is a system formed by the interaction of structures, processes, and outcomes. Structures establish processes that create healthcare outcomes. Those have a back effect on structures which then need to change or adjust new processes to meet the new required outcomes. Healthcare outcomes should be more influential than financial outcomes in any healthcare system. As such, intangible assets are more valuable than tangible assets. (Cleverley, 2007; Berler 2005; Berler, 2008). Redirecting the Donabedian approach to the case of creating sustainable e-health systems since outcomes are mostly located in the Medical domain, we need to focus on the processes (thus functional specifications) and structures (thus standards and semantics).

It becomes then quite clear that what is needed is to focus on semantics and interoperability. In fact, the epSOS project did exactly that. This multi-million international co-investment spent most of its

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

financial and human resources on decrypting those two sides of the Donabedian triangle by building cross border consensus, by focusing on semantic interoperability and by sticking to existing and viable international healthcare standards.

Using ICT for Health Policy and Management

Nations face similar challenges of meeting the increased need for care that are caused by the rapid aging of populations and the respective increase in patients with chronic and expensive diseases. In publicly financed health systems such as the ones existing in Europe (each one with its variations), these challenges are transformed into demand for care and a strain on shrinking healthcare budgets (OECD, 2011). The historical origins of national healthcare systems across the EU often vary. This is reflected in all aspects of a healthcare system: the structure, the manpower and its skills, the financing models. Nevertheless, all systems converge towards common future visions concerning healthcare delivery models and reforms needed to manage common epidemiological and financial pressures. ICT technologies can help in addressing key health policy and management issues (Calliope, 2010b) such as:

- **Patient Centered Care and Personalized Care:** The individual—patient, citizen—is a fundamental part of the care group who cooperates with healthcare practitioners to reach safe health related decisions. A healthcare system must respect cultural traditions, personal preferences and values, family situations, and lifestyles. The empowered individual is thus an active participant in the regional, national, and possibly international health system network, a trend that is highly supported by social media and their related applications. Healthcare in the near future will be a personalized care totally independent and focused to each one of us, driven by our own biological markers. DNA analysis will make possible new feature of personalized care such as health promotion, disease prediction, prevention, and individualized therapy
- **Continuity of Care Integration:** Patient-centered care demands that providers, departments, and healthcare settings are coordinated and operate efficiently. Care integration provides an effective means to reducing waste and to balancing health needs against demands for care. It aims to realize a new model of cross-sectoral, person-centered service delivery that will break down boundaries between different organizations' missions and resources. Semantics and Interoperability are the cornerstones of care integration. Languages and processes must be ported to each stakeholder individually. The seamless care environment should be one where the ratio of effectiveness to cost reaches its highest value while avoiding duplicating information.
- **Information Management:** As stated earlier the seamless interchange of information is key to the success of any electronic service in the healthcare sector. Information management means to know what the needed information are, at what time, and whom to address it to. In fact, it is all about semantic interoperability.
- **Rethinking Health Policy:** Generally, much of the health of populations is dependent on social and environmental factors. Thus, healthcare systems have a remarkable opportunity to control costs by extending influence outside their borders, supporting WHO policies for international health regulations with the support of new technologies for early epidemiology warning and crisis management.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

- **Open Collaboration of Stakeholders:** Consensus building and strategic partnerships for healthcare restructuring can manage healthcare complex processes, foresee different type of risks and establish common values. Open and transparent collaboration between major stakeholders is of tremendous importance to set up a viable mechanism that will handle the needed changes.
- **Incentives:** creating effective and operable e-health processes must be rewarded at all levels. As a consequence, regulatory bodies at a national and international level need to establish adequate incentives.
- **Legal Aspects:** Legislation should be a facilitator by legally supporting innovation and its change dynamics by means of full protection and legal certainly, rather than inserting constant burden and insecurity as it is often, unfortunately, the case. This can be achieved in synergy with other enablers including standardization bodies, clinical governance and through fostering security and quality cultures under an integrated framework of trust that is enforced and protected by law.

E-Services for the Healthcare Sector: It's an Interoperability Issue

Taking into account all the above issues, a successful electronic service, e-Prescription, for example, should focus on solving, or at least propose a series of tools of dealing with semantic sustainability and interoperability. In fact, semantic sustainability is an interoperability issue; it is one of the pillars of an interoperability framework that historically had three distinct dimensions: organizational, semantic, and technical. The European Interoperability Framework—EIF (ISA 2011)—extends this by adding political and legal dimension, resulting in Political – Legal – Organizational – Semantic –Technical (see Table 2).

All the dimensions of the proposed EIF model interact with each other. Each dimension though is extremely valuable to achieve an end to end interoperability. Especially in healthcare the Political and Legal dimension are of extreme importance due to the domain's complexity (eHGI, 2012). The other three dimensions are somehow known and dealt with many years ago, unfortunately, in a separate manner and from different stakeholders. In 2009, the United States' branch of the Institute of Electrical and Electronic Engineers (IEEE) revised its initial definition of interoperability for the healthcare sector stated in 1990 as being too vague:

In healthcare, the ability "to use the information that has been exchanged" means not only that healthcare systems must be able to communicate with one another, but also that they must employ shared

Table 2. European interoperability framework dimensions

Political Context	Legal Interoperability	Organisational Interoperability	Semantic Interoperability	Technical Interoperability
Political mandates and statements	Legal foundations	Business process alignment	Ability to share information	Apply Open International Standards
Policies	Data privacy	Organisational interconnectivity	Reuse of coded data and International Standards and Nomenclatures	Ability of Systems to exchange information
Business needs - Social Needs	Access to information	Interaction between two or more distinct organisations	Use commonly agreed data sets	Collaborative data processing and transaction synchronizations

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

terminology and definitions. This latter emphasis places a much greater burden upon system designers and electronic engineers to make the information truly usable in the distributed clinical setting of our healthcare environment" (IEEE-USA, 2009, p 1).

Historically, technical interoperability in the healthcare started in the mid 80s via a group of visionaries under the umbrella of what is today known as Health Level Seven – HL7 (Datta, 2010). Semantic interoperability and the creation of commonly understood data set started way behind the era of computing since the need for medical practitioners to interact existed before with the use of nomenclature and codifications such as the International Classification for Diseases – ICD, Systematized Nomenclature of Medicine – SNOMED, and many others (Stroetmann, 2009). Organizational Interoperability is also often seen as process interoperability, where the correct organization and management of processes and workflows between distinct and independent organization is the key issue (Gibbons, 2007). In healthcare, for example, the creation and maintenance of a master patient index is such an issue, the exchange of medical information as part of a nationwide healthcare record is another. It is clear that coded data and data exchange in not enough to achieve interoperability, processes need to be there to integrate and orchestrate the information (Ducrou 2009).

The European Commission introduced the concepts of Political Context and Legal interoperability in order to reach a consensus and manage business and legal complexity amongst the European nations. The classical three-dimension model for interoperability did not result in to practical success since legal constraints and the associated policies tampered the good technical and scientific results.

This "five dimension model" for interoperability is now the key for the successful completion of large scale implementation projects in the healthcare sector. It is the basis for an Interoperability Framework (Berler, 2004; Mykkänen, 2006; Grilo, 2010) that is necessary to achieve consistent and interoperable healthcare scenarios, such as needed for cross border healthcare. As a consequence, project epSOS embraced this approach and created its own interoperability Framework. This document analyses all the steps taken in each of the five aforementioned interoperability dimensions (epSOS, 2010).

Europe (and epSOS) decided to opt for the reuse of existing standards in the fields, the collaboration with existing standard organization bodies and interaction with industry vendors and communities to enhance sustainability of the final result. Project epSOS collaborated with official standardization bodies such as International Standards Organization (ISO), International Electro-technical Commission (IEC) and International Telecommunication Union (ITU). It also collaborated with the United Nations Centre for Trade Facilitation and Electronic Business (UN/CEFACT), the European Telecommunications Standards Institute (ETSI), Health Level Seven (HL7), the European Committee for standardization (CEN) and the International Health Terminology Standards Development (IHTSD). The established interoperability framework also included standards and processes from the Organization for the Advancement of Structured Information Standards (OASIS), and the World Wide Web Consortium (W3C). This framework has also references to the Internet Engineering Task Force (IETF), the European Computer Manufacturers Association (ECMA), the Object Management Group (OMG), the Web Services Interoperability Organization (WS-I) and Integrating the Healthcare Enterprise (IHE).

From all the above HL7 and IHE do have a leading role. HL7 is the Standards Development Organizations that has created the CDA (Clinical Document Architecture) Release 2.0 used to create and semantically exchange documents in the form of XML (eXtensible Markup Language) documents while IHE is the Profile Enforcement Organization that have created the needed analytical technical frameworks and integration profiles. Those XML Medical documents must be valid according to CDA.xds

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

schema. A CDA document has in two sections a "header" and a "body". The aim of this chapter is not to expand on technical analysis of both standards that can be located in their respective Web portals (www.hl7.org and www.ihe.net) and further readings of this chapter. It is necessary though to understand that epSOS specifications substantially reuse concepts and processes from those two principal international independent organizations.

Of course, other standards need to be used to create the adequate interoperability framework with all its pillars. SAML 2.0 (Security Assertion Markup Language), for example is an adequate choice for encoding security tokens (OASIS, 2005b). Legal interoperability usually is about handling data privacy and confidentiality issues, thus creating a need for a strong security and legal framework. XACML (eXtensible Access Control Markup Language) deals with identity management issues and handles complex rules and policies related to patient consent mechanisms needed to give or revoke access to personal and sensitive medical information (OASIS, 2005a). Other standards such as WS-security and WS-Trust from the World Wide Web Consortium (W3C) complete a full security framework related to Web Services technologies. Since the goal of Web service technology is to provide an interoperable platform that facilitates distributed computing based on the messaging paradigm, a standardized messaging platform is an essential requirement. The foundation for the standards is the SOAP (Simple Object Access Protocol) Messaging Framework which defines an XML based message format and rules for message processing. IPSec (Internet Protocol Security) and SSL (Secure Sockets Layer) provide additional security by networking protocols in order to secure the communication channel based on encryption and public key infrastructure technologies.

Semantic interoperability is of foremost importance. Data elements should be coded, for example, with UCUM (Unified Code for Units of Measures) and HL7 code system. Adequate terminology must be used to control, transcode and translate the vocabulary. The most dominant terminology standards are EDQM (Standard Terms of European Directorate of Quality in Medicine), LOINC (Logical Observation Identifiers names and codes), ATC (Anatomical Therapeutic Chemical classification system), ICD (International Statistical Classification of Diseases and Related Health Problems) and SNOMED CT (Systematized Nomenclature of Medicine-Clinical Terms).

E-Prescription

E- Prescribing is the use of computing devices to create, modify, review, and/or transmit medication prescriptions from a healthcare provider to a pharmacy (Center for Health Transformation 2008). The Institute of Medicine published a report on medication errors, revealing startling statistics on the dangers patients face in the healthcare system in the US, where 1.5 million medication errors happened every year, up to 98,000 Americans are killed every year by preventable medical errors, and more than 7,000 Americans are killed every year from preventable medication errors (Kohn, 2000).

In general, an electronic Prescription Service (e-Prescription) consists of electronic prescribing and electronic dispensing. e Prescribing is defined as the electronic prescribing of medicine with the use of software by a legally authorized health professional and the electronic transmission of said prescription data to a pharmacy where the medicine can then be dispensed (Hider, 2002; Hale, 2007). E-Dispensing is defined as the electronic retrieval of a prescription and the dispensing of medicine to the patient as indicated in the corresponding e-Prescription. Once the medicine has been dispensed, the dispenser is to report the dispensation information using the e-Prescription software (epSOS, 2008).

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

E- Prescribing has been the subject of extensive discussions, white papers, policy papers, strategic plan and e-Health Roadmap (Center for Health Transformation, 2008; Teich, 2004). By itself, it should be a simple process: the use of ICT to make a medicine prescription at a healthcare provider organization and dispense this prescription at a pharmacy. In reality it is a complex service that encompasses many stakeholders, involve fully or partially a lot of people with conflicting interests, thus making process story boarding a puzzle in multiple dimensions. This complexity can be explored in the literature where many nations, profiling and standardization bodies has released extensive functional and technical documentation. To the Authors' knowledge, the most complete sets of specification can be reached, most of them as open data (creative commons rules or similar), via the Web. Table 3 is a non-exhaustive list of similar specifications.

In the United States, e-Prescription started as pilots and standardization activities in 1995 and became an increasing necessity due to the Medicare modernization act established in 2003 (Hale, 2007). As stated in the national progress report on e-prescribing and interoperable Healthcare for 2011, (Surecripts, 2011), the number of e-prescription issued increased from 54 Million in 2008 up to 789 Million in 2011 which an incremental increase of 15 times in four years time. In the same period, the active prescribers have risen from 74.000 to 390.000 users. Certified software systems were 43 in 2008 and are 157 in 2011. By the end of 2011, 58 percent of office based physicians in the United States had adopted electronic prescribing. This figure was 10 percent in 2008.

Nowadays, only some European countries have managed to create an operational National e-Prescription service for the primary care sector. Nevertheless, most of the EU Member States mention e-Prescription in their e-Health strategy and implementation plan since 2006 (European Commission 2007), a number which reached 22 in 2010 (Stroetmann et al, 2011). Denmark, England, Estonia, Iceland, Scotland, Croatia, Greece, Belgium, and Sweden are nations that have implemented or are in the process of implementing

nationwide e-Prescription systems. The Netherlands have established and are using e-Prescription in some regions, with different maturity levels, depending on the GP or hospital environment. In Spain, the region of Andalucía has implemented a fully functional regional e-Prescription service. However, this services in not applicable for the other Spanish regions, which are engaged in different regional strategies. Norway, the Czech Republic, Austria, Finland, Italy, France, Portugal and Poland are currently piloting different solution at a regional or national level.

In Estonia, the digital prescription (e-prescribing) was launched in 2010. This countrywide project lasted 5 years and its aim was to make e-prescribing of drugs possible in every doctors' office and filling in digital prescriptions in every pharmacy of Estonia. In May 2011, just 15 months after the launch, 84% of prescriptions are issued digitally. More than 95% of pharmacies are ready to process e-prescriptions. According to a survey "Citizens' satisfaction with health and healthcare" 91%, of users of digital prescription are satisfied with the service (EIPA, 2011).

In Denmark (Purves 2002) reported ten years ago that Medcom has effectively rolled out e-Prescription in Denmark with on average 63% of all prescriptions items transferred electronically in 2002—this varies across Counties. It has taken 8 years to get to this point, where 3500 GP's in about 2000 general practice with 14 different IT-systems—85% of the GP's are able to send electronic prescriptions and 332 pharmacies with 4 different IT-systems—100% are able to receive electronic prescriptions. Today 85% of Danish prescriptions are electronically transferred (MEDCOM, 2012).

After Denmark, Sweden is the most e-health oriented nation in Europe. In December 2007, 68% of all new prescriptions were transferred electronically in Sweden (Åstrand, 2009). In another study, most respondent physicians believed they were able to provide the patients better service by e-Prescribing (92%), and regarded e-Prescriptions to be time saving (91%) and to be safer (83%), compared to handwritten prescriptions (Hellström, 2009). Finally, a nationwide survey showed that a vast majority of Swedish patients had positive attitudes towards e-prescriptions and electronic storing of prescriptions (Hammar, 2011).

Iceland has a national e-Prescription system, is based on one technical solution and it has the approval of the Data Protection Ombudsman. Medical Practitioners enter the prescription through a portal which is part of the national Healthnet framework. All healthcare facilities are connected to a single administrative entity and make use of special data sets (Doupi, 2010). In England, the program "connecting for Health" responsible for computerizing the National Healthcare System (NHS), started designing the Electronic Prescribing System (EPS) in the 1990s. The EPS project has been divided into two "releases": In Release One (R1) (which has now been completed), a mechanism was developed whereby General Practitioners (GP) systems can download drug data automatically from the core network, but the system still uses a paper prescription infrastructure. In Release Two (R2), the main feature is the switch to an electronic encrypted signature instead of the traditional paper signature. The only physical item remaining will be a numeric or barcode token, which the patient can present to the pharmacist when picking up his or her prescription. Currently R2 is in the deployment phase with only 1.5 Millions of prescriptions have been dispensed via this system (Van Dijk, 2011).

In the Netherlands, the first computer at a Dutch GP office was installed in 1978. By 1990, 23 percent of GPs were using a computer. Today, 97 percent of GPs use a computer-based GP Information System (Van Dijk, 2011). The electronic prescribing procedure through e-Prescription between GPs and pharmacists has been regional routine in the Netherlands for many years now via the regional OZIS network, a regionally accessible electronic medication record communication protocol layer responsible for medication data exchange. Up till now, no national standard has been defined yet. The take up for

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

the regional transmission of e-Prescription lies between 20 and 50%, whereas a distinction has to be made between general GPs and specialists: GPs have an estimated take up of 50% and specialists below 10% (Flim, 2010).

There are multiple reports and documents on how different nations are coping with the introduction of e-Prescription systems and related electronic services. The authors provide a short list of further readings where extensive information can be extracted. The Greek case and its innovative approach are described in more details in the next sections of this chapter.

DESIGNING A NATIONAL E-HEALTH INFRASTRUCTURE THAT IS CROSS BORDER HEALTHCARE READY: A PARADIGM SHIFT AND A SUCCESS STORY

Creating Sustainability with ICT in Healthcare

EpSOS has introduced concepts such as the National Contact Point (NCP) which is, in fact, an enterprise information bus that securely, seamlessly transport medical information across healthcare systems of any type and complexity. This enables a democratic regulation of the health IT market allowing common testing procedures (by reusing profiles and test tools provided by IHE), common interoperability frameworks (by accepting common HL7 CDA r2 type documents for the electronic prescription) and certification procedures (by deploying national certification and accreditation bodies and reusing IHE, Eurorec or HL7 EHR-FS standards and methods).

Semantic interoperability is one of the keys towards sustainable and interoperable information systems. EpSOS invested a lot on securing the semantic interoperability layer, due to its dramatic importance and enhanced by the cultural and linguistic puzzle that comprises the European Union. As a consequence, across epSOS participating nations, there are different languages, different standards and different coding schemes, and so the challenge was how to address this. The solution was to produce two master files: the Master Value Sets Catalogue (MVC), which applies across all members and the epSOS Master Translation / Transcoding Catalogue (MTC). The content of the MVC is in English; the terms are based on criteria defined by the use-cases identified by the Participating Nations. Each nation has then translated the terms into their language and transcoded into them in their national coding system, thus creating the epSOS Master Translation / Transcoding Catalogue (MTC). The value sets in the MVC have been selected from many Standards Development Organizations (SDOs) as noted earlier in this chapter. The MVC and MTC are supported by the epSOS Central Reference Terminology Server; each nation has its own Local Terminology Repository as a copy of its MTC. If an update is made to the epSOS Central Reference Terminology Server, the Local Terminology Repositories are notified and updated.

At a European Level, the European Commission is preparing itself for the large scale deployment of e-Health services under the Connecting Europe Facility (CEF) which will run in the timeframe between 2014 and 2020. The need for ensuring cross-border connectivity through optimizing functional, semantic and technical interoperability is necessary, including enabling cross-organizational & cross-border information flows to support further clinical needs such as chronic disease management. This leads to the second fundamental need for sustainability: create the Market. Thus, in addition to semantic interoperability, which requires institutions and procedures from the buyer side, the provider side need to adhere, support and enhance the needed technical viable solutions that encompass all technical and functional specifications needed additionally for cross border healthcare. In order to support that the European Com-

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

mission via its EIF program is supporting the establishment of open source reference implementations to boost the economic market and reduce investment risks for the Market. EpSOS also focused a lot on this instance, by initially creating a reference implementation of the needed components that all together create the aforementioned NCP. This reference implementation is to be strategically created and ported into open source software built, supported by participating nations, as well as the industry team of the project, OpenNCP as it is named, should be ready by the end of the project in 2013. All material is and will be made publicly available on the EU open source repository at the Join-up (www.joinup.eu) portal.

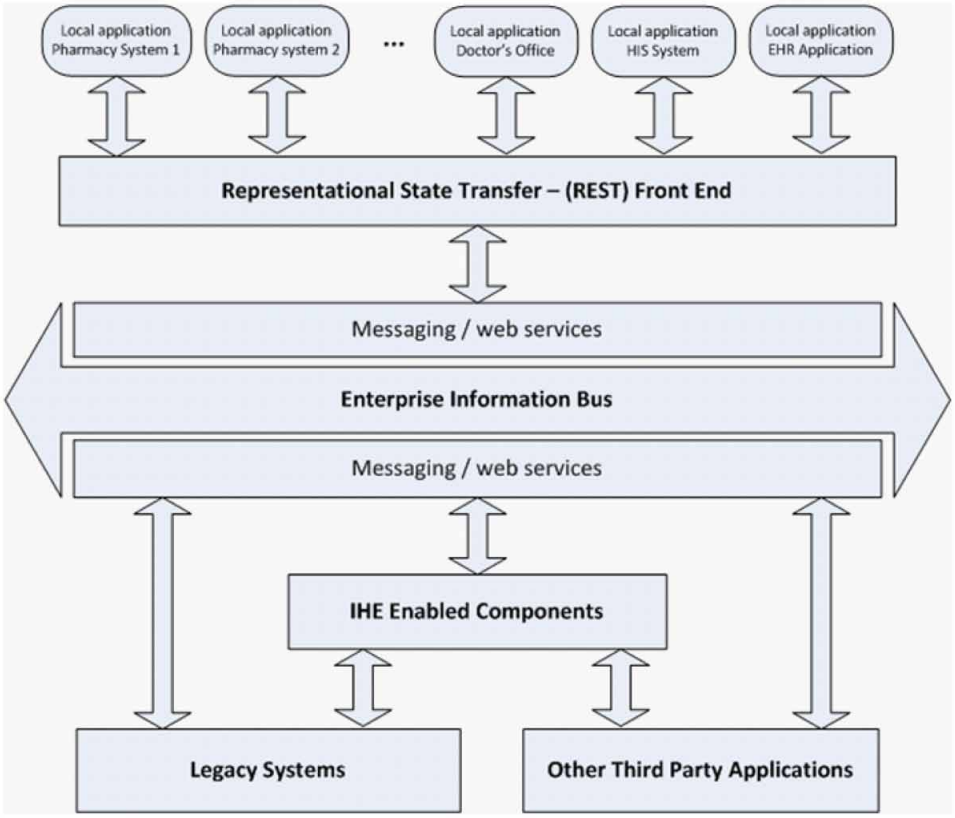
Use of epSOS Specifications: The Case of Greece

Project epSOS selected W3C SOAP as a top level messaging protocol considering the project's tight time frame for implementation and piloting, the strong demand for well known security measures and the existing experiences in industry (epSOS, 2010). An alternative is to use the REST (Representational State Transfer) architectural style, which relies on HTTP (Hypertext Transfer Protocol) commands and URIs (Uniform Resource Identifier). IHE and HL7 experts, task forces and working groups commonly agree on those technological approaches, and define healthcare actors as Web services and actions as REST commands.

Finally, coming to the Greek case, Greece is participating in epSOS from the beginning of the project with significant participation at all levels. Recent development in Greece and the introduction of a new central e-Prescription system that operated for the first time in October 2010 changed the importance of the epSOS project at a National level. The Greek pilot in epSOS focuses only in a simple scenario of dispensing EU citizen existing prescription in a number of pharmacies in Greece. At the design phase of the project, Greece had no existing e-Health infrastructure in place. This lead to a paradigm shift: while all countries organised themselves in order to connect existing systems with the proposed NCP structure of epSOS, Greece decided to do the opposite and expand its initial small pilot system so that it can be immediately "epSOS ready", thus being able to handle both national and cross border prescriptions. This has been depicted in the official tender documents of the National e-Prescription system initially released in August 2011 and heavily supported by the European Commission (IDIKA, 2011). The aforementioned issues are the reasons that are positioning the Greek case as a different approach in e-prescription implementation at a global scale.

In parallel the initial pilot system, which is a Web-based system, grew substantially covering basic prescription scenarios, solving initial user interface issues, creating and training the user community. In August 2012, the system is able to handle more than 590.000 prescription transactions per day (IDIKA 2012a). The pilot Web system is able to cover classic prescription transactions but was unable to provide the rich environment needed by the end users both at the pharmacies (dispensing the prescriptions) and at the physicians (creators of the prescriptions), creating an ongoing debate on the quality and capabilities of the system as a whole. It is at that point that it was decided to invest in the epSOS specification and mostly in its interoperability framework. This resulted in the creation of an Enterprise Service Bus, a simplified approach of the epSOS NCP than proposed to exchange all prescription (and future documents) in the CDA R2 format proposed by epSOS (IDIKA, 2012b).

The proposed overall architecture relies on the REST architectural style on the end user application layer for two main reasons: the existing system is based on Web technologies to which the REST archi-



EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

tecture is faster to implement and secondly the existing system did not support CDA type documents nor had the ability to create such high level WS to implement a full WS SOAP approach. This architecture is depicted in Figure 2.

This architecture implies the creation of a RESTful API that is called by the third party end user applications. Information is transported via WS/Messaging services and an enterprise service bus to ensure and monitor document delivery to the main eP system. The use of additional IHE compliant tools enables the system to be compliant with epSOS scenarios and specifications while enabling the possibility of more enhanced cross border or cross enterprise scenarios between multiple data repositories

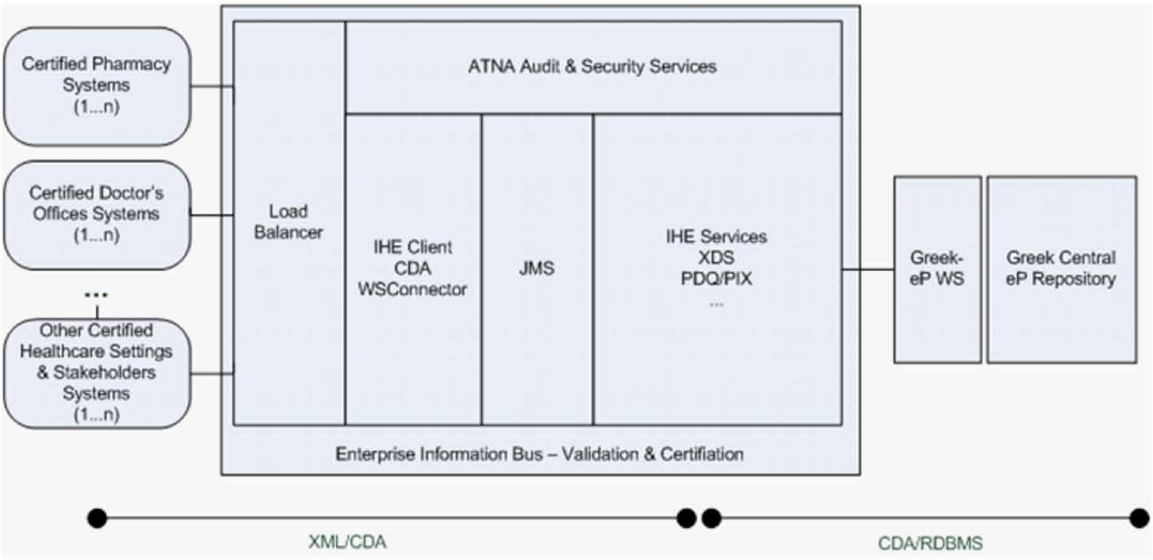


Figure 3 describes the Enterprise Information Bus (EIB) application layer from a functional point of view. In that sense, the Greek eP System has created a series of WS to handle information exchange. Those are connected to the IHE service components that transform and validate the information in HL7 CDA format. All messages are queued via a Java Messaging Service (JMS) and sent to the appropriate recipient ensuring safe delivery (will keep message history until safe delivery). The IHE client is the RESTful structure that via a set of commands makes the information available to the end users applications passing through a Load balancing mechanism to ensure timely delivery and workload distribution (a series of virtual machines). On top, the ATNA (Audit Trail and Node Authentication) Audit and security service logs and monitor the whole process ensuring data security and privacy according to the respective IHE ATNA integration profile. All messages are encrypted, and users are strongly authenticated

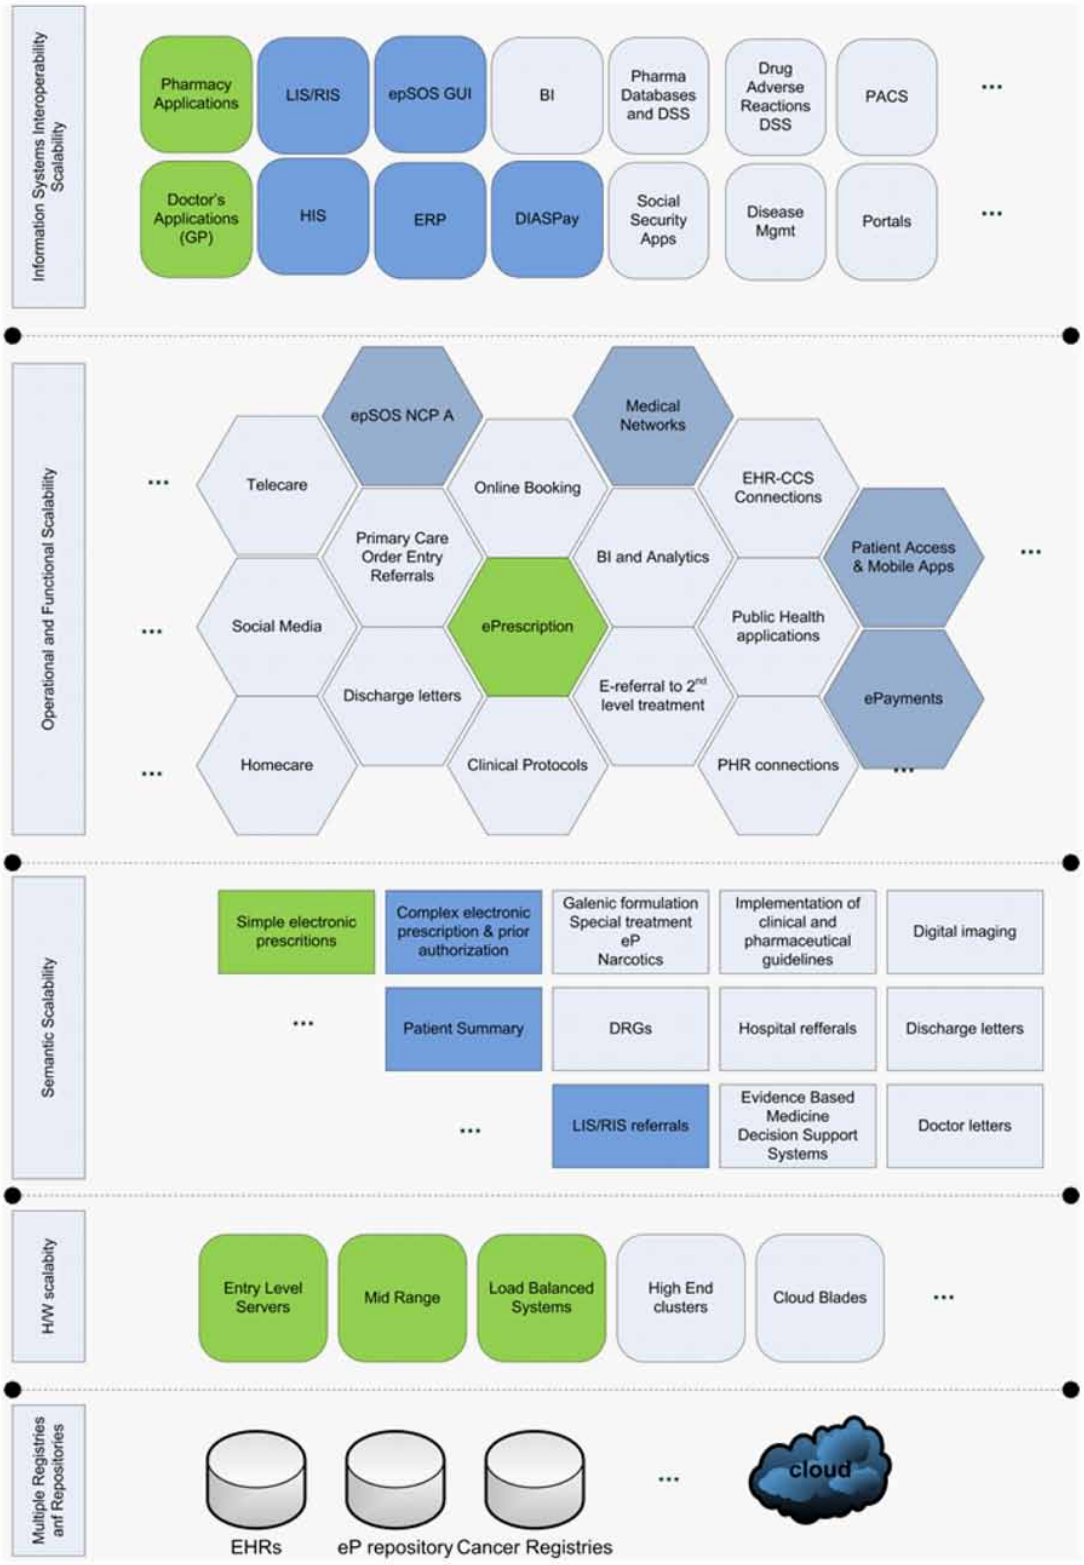
Figure 2. REST type architecture of the Greek eP system

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Enterprise information bus logical architecture

(use of API KEY and hashtags conformant to RFC 2104 specifications). The whole system is epSOS compatible since it can handle SAML messaging and Public Key Infrastructure (PKI) tokens.



The propose architecture has a series of significant benefits and advantages, namely:

- The system is epSOS Ready and will allow the Greek Government to implement its obligations under the EU Directive 2011/24/EC on time before the deadline of October the 25th, 2013.
- The system is HL7 compliant allowing for efficient functional scalability and interoperability.
- The system can implement both cross border healthcare scenarios and national prescription scenarios.
- The system is technologically up to date with the current technological trends.
- The system is service oriented and compatible with both REST and WS/SOAP technology.
- The system is "cloudable" and thus can operate in various business scenarios in the future both as a governmental cloud or a private cloud or both.
- The system has a strong and internationally approved interoperability framework.
- The system is based on current profiling approached and profile standards (namely IHE) enabling a democratic involvement of the market and reducing the "vendor lock in effect."
- The system allows third party software to be certified to specific use cased and scenarios enhancing market competition and quality of services.

As shown in Figure 4 the system is high scalable at many levels. It can support the integration with multiple repositories (IHE Cross-Enterprise Document Sharing-XDS compliant structures), it is scalable on a physical architecture point of view enabling complex, and up to date virtualization techniques, and it is scalable at the semantic interoperability level, at the service provision level and the information systems interoperability.

Solutions and Recommendations

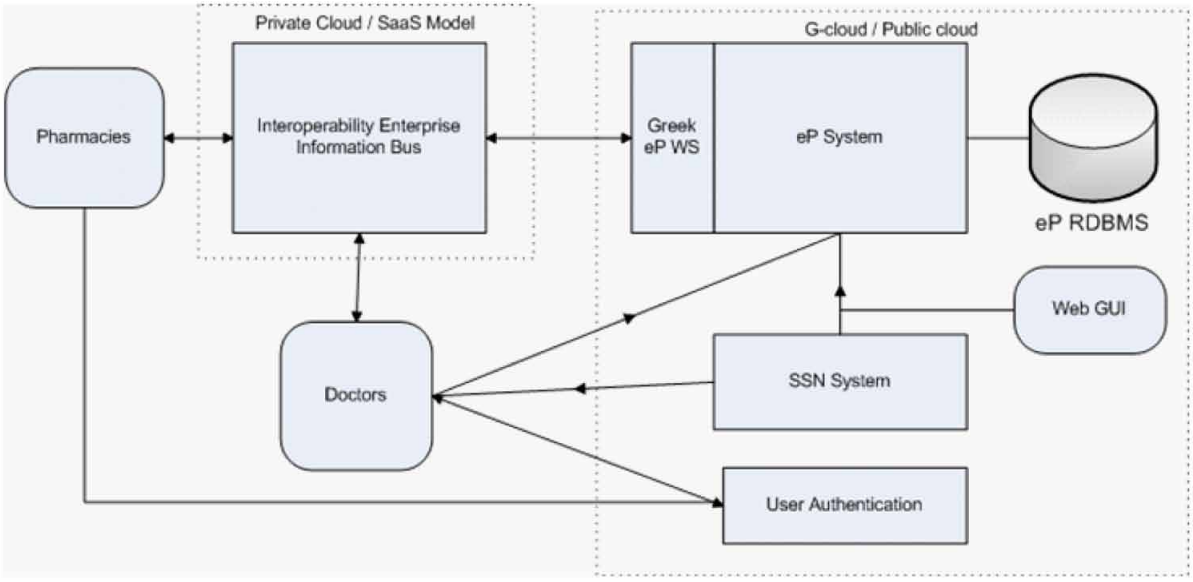
The case of Greece is in our opinion a good focal point were European strategies, cross border healthcare needs, e-prescription implementation and e-health standards all collide to create a new strategy that could be the mirror of Europe's future. Greece was for many years a lager in e-health issues and is probably still is in some features. This case proves that by focusing on European policy, major steps can be made in a quite reasonable time frame. Of course, Greece has the need and the opportunity to rely on Europe to restructure its entire government and national strategy, willing to come closer to Europe mindset. As a conclusion, one could say that in the e-prescription case the reuse of European standards and methods can conclude to success and a European best practice. Europe has vastly invested in e-health. Those investments seem to have quite good acceptance overseas and reach out to decision makers in the United States, since the cross border scenarios used with epSOS for Europe present little discrepancy to be effectively implemented at a global scale. The recent Memorandum of Understanding that has been signed between Europe and the US clearly marks that success story (MoU, 2010).

Coming back to the proposed solution in Greece, one of the main benefits of the proposed architecture is its flexibility to operate in different business modalities. In Figures 5, 6, 7, and 8 we shortly present four different mode of operation.

Figure 5 describes the logic of a central EIB facility strongly bound to the existing eP system. This proposition has the fastest implementation time since the EIB is located in the same physical structure of the current eP system. By the use of virtualisation methods, one can efficiently use physical devices in the best possible manner. In this case since the eP system is operated as Governmental cloud setup, the EIB facility can only operate as a G-cloud structure. Otherwise, the whole system has to be given as managed service or business service provision in order to work in another business mode. In this case, providing control of sensible data out of a public setting may under some circumstances created data protection related risks.

Figure 5. Central EIB facility

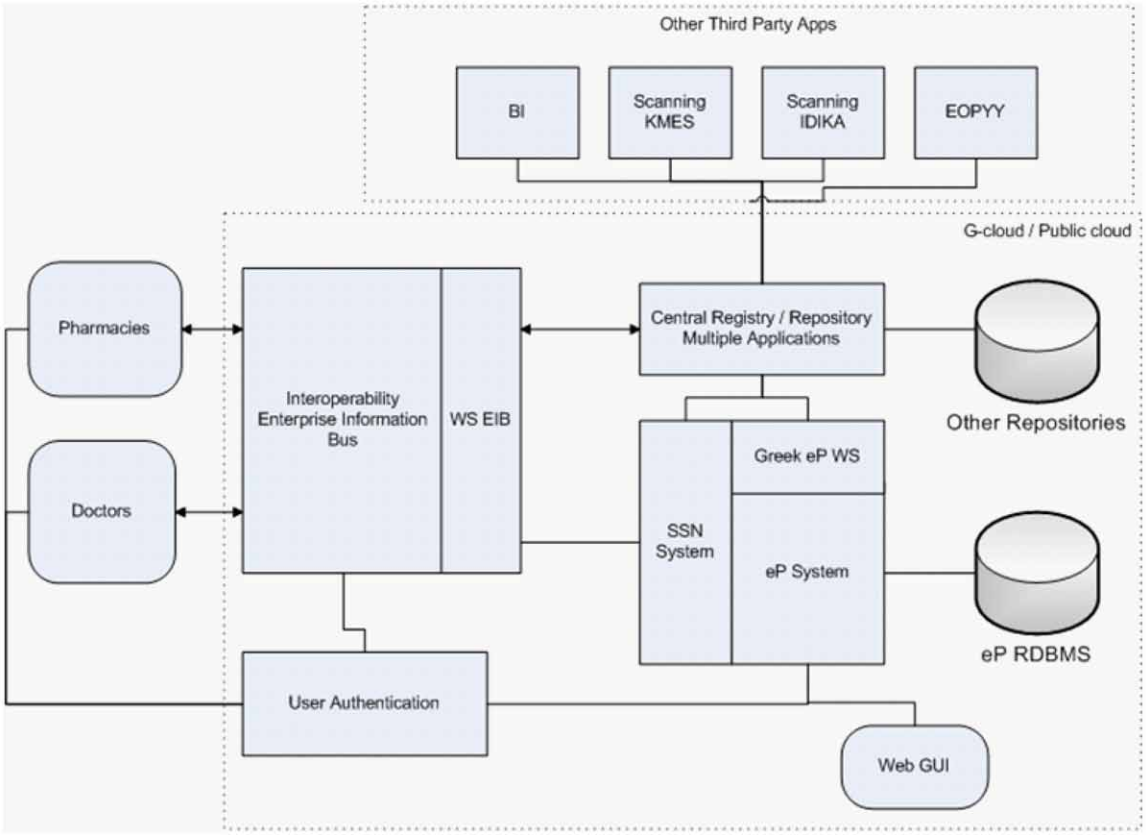
EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use



In Figure 6 we propose to operate the EIB service as a separate service that can be located in another physical location, other that the location of the eP system. This scenarios increases flexibility and enable to operate the EIB in a private cloud model in a Software as a Service mode enabling new and more viable financial models for sustainability.

Figure 7 correspond to an EIB that has the capacity of handling multiple repositories enabling in that sense the possibility to have more complex business scenarios. Such a setting can serve with the same infrastructure more than one e-health scenarios and multiple healthcare stakeholders. For example the same EIB could handle discharge letters and e-referral documents and link the primary and secondary healthcare facilities. The system can both operate in a G-cloud or a private cloud setting, and thus does not create any business barriers. In fact, both operation modes could be combined in a hybrid cloud approach where the EIB could run in a SaaS mode in a private cloud while the eP system and/or any other system can be in the G-cloud.

Finally, Figure 8 points out a variation of the system where we can have multiple, federated EIB structures connected to the central eP system (or other systems and repositories) by enhancing the reuse of IHE enabled components that are XDS compliant (multiple repositories). This scenario is extremely flexible allowing, for example, the EIB structure to be managed by relevant stakeholder group and collectively connect their software system uniformly to central government systems. This would allow for faster implementation of regional settings and architecture versus a more rigid and inflexible central system. This scenario has of course to be compliant with national strategies concerning healthcare data handling. It has though the advantages that there is no single point of failure and in case of unexpected events the system can partially operated serving specific geographical locations or specific stakeholders groups (i.e. pharmacy associations, etc).

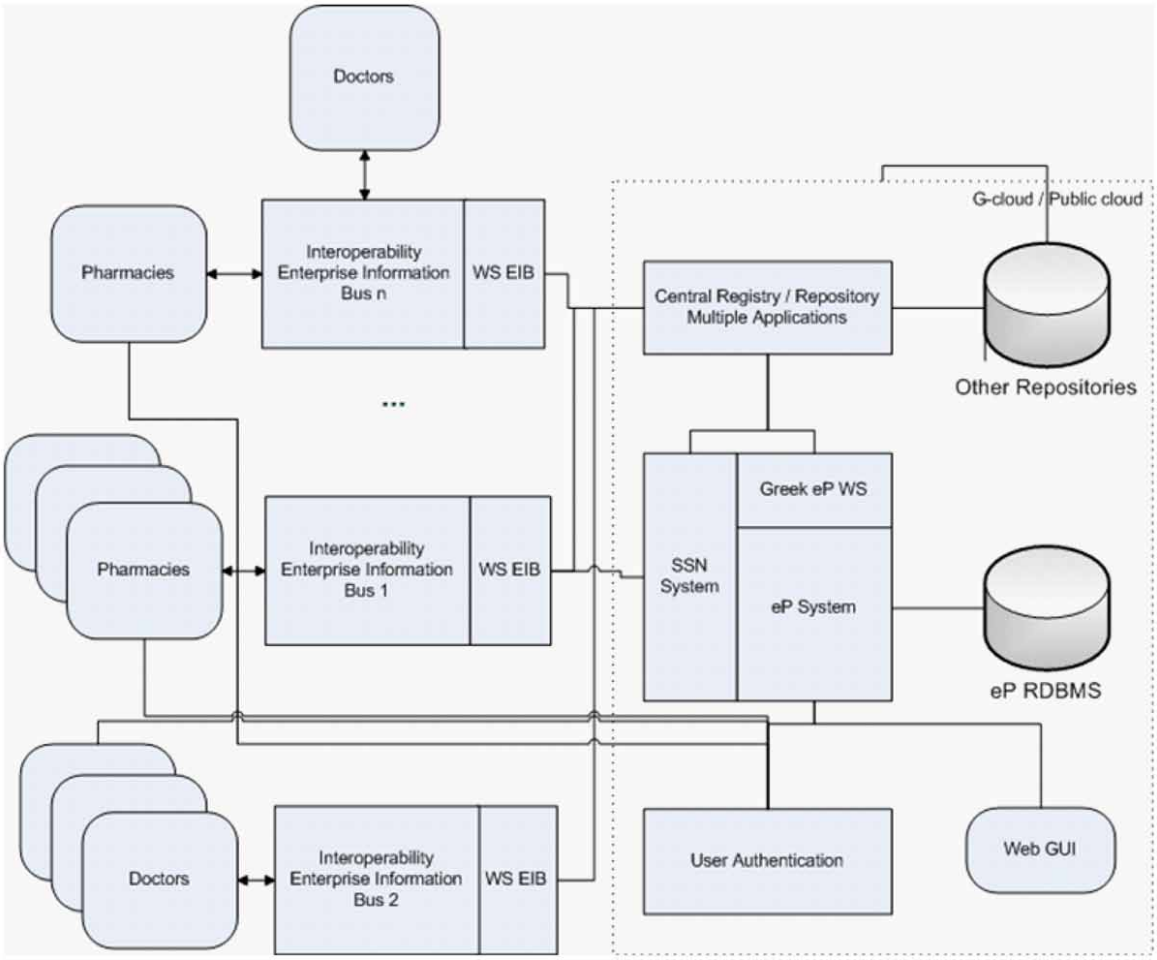


The State Authority that manages the e-Prescription (IDIKA) system decided to implement the architecture of the independent EIB mostly because of its increasing role in Greece as a de facto e-health

Figure 6. Software as a service EIB facility

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 7. Independent EIB facility



competence authority and the need to incorporate and reuse IEB components as much as possible for the seamless integration of other information systems in place. Other systems that need to be integrated for example are existing legacy systems such as the prescription antifraud and control system (KMES) located at the National organization for the provision of healthcare services (EOPYY in Greek). Up to the date of finalization of this chapter, the EIB structure is handling transaction for the community pharmacies, whose stakeholder's organization (pan-Hellenic society of pharmacies) heavily supported the integration of the existing pharmacy information systems with the e-Prescription system. All 12 software providers have been able to interoperate via the EIB and certify their respective products. IDIKA has setup a thorough roadmap to complete the integration process of all interested stakeholders and existing public information systems that need to transparently interoperate with the e-Prescription system. A significant next step of the system is to allow physicians to electronically prescribe not only medicines but also send referrals and order entries for examinations and treatments.

In order for the above to happen, some fundamental issues need to be strongly kept in mind and continuously dealt with. It is essential to always keep in mind that e-Health can only grow and expand if all stakeholders are informed and participate in decision making process via a well established consensus building mechanism. Such a mechanism can be installed with the assistance of organizations that have built their success and results based upon consensus. HL7 and its affiliates as well as IHE are organization capable of supporting central e-Health competence centre in deploying such mechanisms.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 8. Federated EIB facility

A second point of importance is certification. There is no serious and robust interoperability framework without rules and code of ethics. This is a point that was immediately foreseen by the European Commission which has established the necessary structures in all interoperability related project. In epSOS, this role has been dedicated to IHE. IHE Europe is a member of the consortium and is providing testing and certification services to the Commission. As a consequence, epSOS has periodically undergone the so called "projectathons" that are exact replicas of the connectathon process that certifies adherence of software products to IHE integration profiles. We believe that is in the best interest of the Greek government to incorporate such practices as soon as possible. The exact process of IHE is well described on its international Web portal.

A third point is installing an open mechanism for data privacy and security. All European countries have to adhere to particularly strong framework that protects personal data for misuse or abuse. The fundamental rights and the principles recognized in particular by the European Convention of Human Rights and Fundamental Freedoms (1950) have to be respected and duly protected. The fundamental right of privacy is of key importance (Art 8). Also, rights to healthcare have been recognised in the Charter of Fundamental Rights of the EU in 2000. The right to healthcare during a temporary stay in another

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

member state (MS) was foreseen in Regulation 1408/71, for all persons insured under the legislation of a MS. The common EU framework on data protection is provided by "Directive 95/46/EC of the European Parliament and of the Council of 24 October 1995 on the protection of individuals with regard to the processing of personal data and on the free movement of such data". It is the most prestigious European legally binding document governing protection of personal data. The EU Article 29 Working Party (hereinafter "the WP29") has played a key role promoting harmonization of data protection in order to achieve a high level of data protection in the EU, fostering compliance with the data protection standards set up by Directive 95/46/EC and providing guidance and advice to the different actors in the data protection arena (WP29, 2004). Its Working document on the processing of personal data relating to health in electronic health records (WP 131) provides guidance on a uniform interpretation of the Directive 95/46/EC. Although documents of WP29 are not legally binding this document is one of those which must be taken into consideration. We recommend that the Greek e-Prescription system adhere to the strong policies for data privacy of epSOS (epSOS, 2009).

A fourth point of recommendation is to always keep in mind the patient itself. The European Directive on data protection and its Greek exact translation (Law 2472/1997) clearly states that all personal and sensitive data belong to the patient, and as a consequence he has a right to know on how his personal information is processed. He has the right to revoke access to his data (totally or partially) and can grant access to specific third parties. For this to happen, a series of processes and regulations must be in place. In addition, this is a must as cross border healthcare is concerned since in the country of treatment the rules that are valid are the rules and policies of the country of establishment. EpSOS has established extremely strict rules for handling patient consent and is now moving to the next step which is to grant direct patient access. We recommend that the Greek e-Prescription systems incorporate those rules. From a technical point of view XACML, is an open protocol that enable to handle direct rules based upon central e-Identity structure, thus personalising access rights to information.

FUTURE RESEARCH DIRECTIONS

Cross border healthcare is an issue that has been foreseen from a public health point of view from the World Health Organization at least since 2002 in order to reduce health risks and cross border dissemination of diseases. Information technology is now being seen a key driver to this. EpSOS is as such by itself a living proof of the importance of normalizing healthcare processes across nations. Another fact is the newly installed collaboration at a high level on this issue between the United States and the European Union. In fact, a Memorandum of Understanding (MoU, 2010) has been signed in mid December 2010. This MoU opens the agenda for joint working groups in creating commonly accepted policies in the region of health IT. Thus, this is an area of research that surpasses the health IT domain and promotes research in areas such as health economics, interoperability, health policy and many more. In that sense, cross border healthcare is not a European term but a global one. The same concepts that apply to Europe certainly apply to the borders between states and provinces in the United States, Canada and elsewhere. The recent MoU between the US and the European Commission clearly mark the interest of the American policy makers to import from Europe all the best practices that are possible.

Another important area of research is the direct implication of the end user. At a global level, it is already proven that new technologies such as mobile health and social media are already altering the patient – physician equation (Apostolakis et al, 2012). Social media in healthcare have introduced the

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

term Social Health. Gwee (2011) describes the 6 Ps' of social health which reflect the leading role of social media in health as being personalization, participatory (online patient communities and e-Patients), preventative medicine, Peer-to-Peer patients, portability and passion. As a consequence, in a world of constant changes where social media and mobile applications are changing the way we know the delivery of healthcare services, it obvious to say that those two areas by themselves or combined are valid area of research. E-Health services are already hugely improved and will be even more affected in the near future. Patients are already demanding to have direct access to their information that is being handled via national or international e-health settings. For example epSOS has foreseen this need adding a patient access feature to the epSOS services (epSOS, 2010). On the same path in the United States, the Blue Button Project is expanding, giving the opportunity to the end user to control and manage the access to his medical information created during the various episodes of care (Chopra, 2010).

When expanding the end user involvement one cannot omit the Patient oriented outcomes domain which is our third relevant discussion and future research direction. It seems that information technology do have some impact on healthcare outcomes by reducing medical errors and empowering the patient (Mitchell, 2010). Clinical outcome measures examine discrete, patient-focused endpoints such as readmission, length of stay, morbidity and mortality. Those are easily monitored by information systems (ACEP, 2010). An alternative approach is to start from the patient's needs and select a goal oriented approach to monitor healthcare outcomes for each individual alone (Reuben, 2012). Going a few steps further patient oriented outcomes are often monitored easily by patients via the support of patient advocates and patient societies. Both are handling extremely well the new social media and tools on behalf of the patients. Thanks to social media, patient advocacy is moving from focusing on lobbying government officials towards working more with individuals online to create local change in communities (Brandt, 2011).

A fourth relevant area of discussion a continuous improvement that will not leave the healthcare sector unaffected is cloud computing. We already described an architecture that enables both cross border healthcare and allow establishing different cloud computing scenarios. One thing is certain, in an era of global financial instability where healthcare costs are redesigned and restructured cloud computing and its different business model will play a key role. This has been clearly depicted in a recent study for the Greek market (Danchev, 2011). Cloud computing is becoming a trend of the IT landscape. Each year, millions of users add up and remotely use data centers and Web-based applications in order to exchange various types of information.

Finally, the domain of interoperability itself is a driver for further research. For example, HL7 International has done, within 2012, two extremely significant announcements that will change once again the shape of interoperability. Initially, it has officially announced its decision to make much of its intellectual property (IP), including standards, freely available under licensing terms. This landmark decision represents HL7's commitment to the betterment of healthcare worldwide by ensuring that all stakeholders have equal access to its healthcare information technology standards. The new policy is expected to take effect in the first quarter of 2013 (HL7, 2012a). The second turning point is the release of Fast Healthcare Interoperability Resources (FHIR) Initiative (http://HL7.org/fhir). FHIR is a new HL7 draft standard for data exchange in healthcare that is based on current industry principles, including the cloud, Web 2.0 and RESTful principles. It defines a set of "resources" representing granular clinical concepts that can be managed in isolation, or aggregated into complex documents (HL7, 2012b). This flexibility offers coherent solutions for a range of interoperability problems. As described in this chapter, the proposed architecture is a RESTful implementation, and as such, is already in line with upcoming future developments.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

In parallel, IHE has focused a lot in the integration process of devices and mobile devices. It has created a new technical framework called IHE Patient Care Device and has also implemented a new integration profile for Mobile Health Devices (MHD) that also reuses RESTful approaches. This is a booming area of research and innovation not so much in the technical background but mostly in creating, new innovative, healthcare scenarios that implicate the use of connected medical devices and mobile applications. It is thus not surprising that high tech evangelist envision a world of 50 billion interconnected devices by 2020 in a machine to machine (M2M) mode (Ericsson, 2011).

CONCLUSION: DISCUSSION

In this chapter we made an attempt to analyze as thoroughly as possible the need of cross border healthcare and how the European Union, which indeed needs to solve existing issues in that domain, is proposing to deal this theme. As stated earlier, people are increasingly impatient with the inability of health services to deliver services that meet stated demands and new needs. So many patients seek healthcare services on the global scale, either because their country is, unfortunately, unable to serve them, or because they seek high expertise and skills at the point of delivery. As a consequence, Europe for many years know has focused on the subject and tried to find ways to include the need for cross border healthcare and adequate quality of healthcare delivery for all European citizens. Cross-border health care has simply become a more prominent phenomenon in the European Union (E.U.). Those issues have been taken into account in the directive 2011/24/EU with a focus on the need for e-health. As a consequence, the European Commission has established an e-health network (article 14 of the Directive).

Part of the solution relies on creating ICT facilities that will enable to interchange medical information between nations is a seamless and secure fashion. The epSOS project is operating since 2008 as a facilitator and a test bed to gradually get to the needed result. All participating nations gave their best of themselves in this endeavor and have manager to reach consensus in many issues. As it is stressed many times in this chapter, e-Health success does not rely solely on technological excellence but mostly on the way consensus and common decision are made. Until now the results are promising since for the initially designated scenarios of cross border healthcare an extensive set of technical and functional specification focusing on e-prescription and patient summary, were openly and publicly released.

This effort is closely monitored both by the EU Commission which expects to reach to a solution that will make the implementation of the new Directive on cross border healthcare a reality, and by the nation themselves. Each nation seems to act differently to the new prospect. In general, smaller countries such as Greece, Slovakia, and Portugal for example tend to seek a way to transfer this knowledge back home and do the best possible action with the local stakeholders to adhere and implement the new technologies. Other countries, the more mature ones in the e-health domain, such as Sweden, Denmark, Finland, Norway do their best to connect their existing infrastructure to the new need pointed out at a European level. All the other rely in between and act in various flavors according to stakeholders needs and taking into account that ongoing strategic plan are in the process of deployment.

It is important to distinguish the policy layer from the technological layer when trying to introduce new paradigms in a domain so complex as healthcare. The policy layer is needed in order to set the goals and agree on actions and plans. The technological layer has its complexities but the recent developments

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

in healthcare interoperability have made the solutions to look more feasible. HL7 is a global leader in this domain and will grant free access to its standards starting from 2013. IHE is another key driver in this domain, having cleared out successfully an important series of barriers by proposing and continuously improving its technical frameworks and integration profiles.

The case of Greece, has proven until now that efficient reuse of best practices and adherence to new technological solutions of the 21st century, namely interoperability standard reuse, cloud computing business models, and semantic clarity via CDA document, can make the deployment of user friendly new e-services in the healthcare sector. The Greek e-Prescription case has incorporated epSOS specifications and other innovative technological features. The final success remains to be seen, analyzed and assessed in the forthcoming years. Until now though one cannot deny the huge success it already has since a nonexistent application in October 2010 is now able to handle almost 600.000 transactions per day. Of course many steps have still to be made and many battles to be won.

From the technical point of view, CDA specifications seem to work fine and cope with the complexity of the healthcare sector. The proposed introduction of RESTful technologies has proven to operate correctly. The recent trend toward this technology both by HL7 with the FHIR Initiative and IHE with its new integration profiles prove the validity and technical excellence of the proposed solution. In fact a recent connectathon in Baltimore, US was conducted by 16 large IT companies under the supervision of HL7 International proved that FHIR will very soon be the new version of the HL7 family of standards. From our side we feel lucky to have had the opportunity to monitor closely those new developments and participate in their application and test beds in the European Health IT world. A lot has still to be done and all hope for a soon adoption of e-Health technologies so that we deal more efficiently with global issues such as cross border healthcare, ageing population, healthcare systems restructuring, financial difficulties and many more.

KEY TERMS AND DEFINITIONS

CDA: The HL7 Clinical Document Architecture (CDA) is an XML-based markup standard intended to specify the encoding, structure and semantics of clinical documents for exchange. CDA is part of the HL7 version 3 standard. Akin to other parts of the HL7 version 3 standard it was developed using the HL7 Development Framework (HDF) and it is based on the HL7 Reference Information Model (RIM) and the HL7 Version 3 Data Types. CDA documents are persistent in nature. The CDA specifies that the content of the document consists of a mandatory textual part (which ensures human interpretation of the document contents) and optional structured parts (for software processing). The structured part relies on coding systems (such as from SNOMED and LOINC) to represent concepts. CDA Release 2 has been adopted as an ISO standard, ISO/HL7 27932:2009.

Cloud Computing: Is the use of computing resources (hardware and software) that are delivered as a service over a network (typically the Internet). The name comes from the use of a cloud-shaped symbol as an abstraction for the complex infrastructure it contains in system diagrams. Cloud computing entrusts remote services with a user's data, software and computation.

Cross-Border Healthcare: Means healthcare provided or prescribed in a Member State other than the Member State of affiliation.

eHealth Interoperability: Is a characteristic of an ICT enabled system or service in the healthcare domain that allows its user to exchange, understand and act on citizens/patients and other health-related information and knowledge in a commonly interpreted way. In other words, it is a means of crossing linguistic, cultural, professional, jurisdictional and geographical border in eHealth.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Electronic Prescribing or E-Prescribing (e-Rx): Is the computer-based electronic generation, transmission and filling of a medical prescription, taking the place of paper and faxed prescriptions. E-prescribing allows a physician, nurse practitioner, or physician assistant to electronically transmit a new prescription or renewal authorization to a community or mail-order pharmacy. It outlines the ability to send error-free, accurate, and understandable prescriptions electronically from the healthcare provider to the pharmacy. E-prescribing is meant to reduce the risks associated with traditional prescription script writing. It is also one of the major reasons for the push for electronic medical records. By sharing medical prescription information, e-prescribing seeks to connect the patients team of healthcare providers to facilitate knowledgeable decision making.

E-Services: Are all electronic services together comprise integrated ICT supported health services to citizens. Examples of such services are electronic identification, authentication and authorisation services, telemonitoring, access to electronic health records, ePrescribing, e-dispensation, and e-reimbursement.

Health Level Seven (HL7): Is a non-profit organization involved in the development of international healthcare informatics interoperability standards."HL7" also refers to some of the specific standards created by the organization (e.g., HL7 v2.x, v3.0, HL7 RIM). HL7 and its members provide a framework (and related standards) for the exchange, integration, sharing, and retrieval of electronic health information. The 2.x versions of the standards, which support clinical practice and the management, delivery, and evaluation of health services, are the most commonly used in the world.

Healthcare: Means health services provided by health professionals to patients to assess, maintain or restore their state of health, including the prescription, dispensation and provision of medicinal products and medical devices.

Integrating the Healthcare Enterprise (IHE): Is an initiative by healthcare professionals and industry to improve the way computer systems in healthcare share information. IHE promotes the coordinated use of established standards such as DICOM and HL7 to address specific clinical need in support of optimal patient care. Systems developed in accordance with IHE communicate with one another better, are easier to implement, and enable care providers to use information more effectively.

Prescription: Means a prescription for a medicinal product or for a medical device issued by a member of a regulated health profession within the meaning of Article 3(1)(a) of Directive 2005/36/EC who is legally entitled to do so in the Member State in which the prescription is issued.

Representational State Transfer (REST): Is a style of software architecture for distributed systems such as the World Wide Web. REST has emerged as a predominant Web service design model. The term representational state transfer was introduced and defined in 2000 by Roy Fielding in his doctoral dissertation. Fielding is one of the principal authors of the Hypertext Transfer Protocol (HTTP) specification versions 1.0 and 1.1. Conforming to the REST constraints is generally referred to as being "RESTful."

This work was previously published in Research Perspectives on the Role of Informatics in Health Policy and Management edited by Christo El Morr, pages 168-208, copyright year 2014 by Medical Information Science Reference (an imprint of IGI Global).

Chapter 4
Web 2.0 Tools in Biomedical and Pharmaceutical Education: Updated Review and Commentary

Ângelo Jesus
Instituto Politécnico do Porto, Portugal

Maria João Gomes
Universidade do Minho, Portugal

ABSTRACT

Web 2.0 technologies are being rapidly integrated in higher education, which dramatically influences the ways learners approach and use information. Knowledge transfer has evolved into a two-way process. Users no longer simply consume and download information from the web; they create and interact with it. Several theoretical works were developed in order to discuss the possibilities of integration of Web 2.0 tools in Pharmacy, Medicine, Allied Health, Nursing and many other Biomedical Areas. Other works have started gathering qualitative and quantitative evidence of the importance of Web 2.0 tools in the learning process. By performing this integrative review, this paper will provide an overview of what is being done in biomedical and pharmaceutical education, and elaborate some of the potential opportunities and challenges that these applications present. With this updated review we hope to give our contribution to consolidate research in this promising area.

INTRODUCTION

Internet social applications, normally referred as Web 2.0 tools, are making their way in the new teaching paradigms of higher education. Since their early development, primarily for entertainment and social communication within the general population, applications such as blogs, social video sites, and virtual worlds (Barsky, 2006) are being adopted by higher education institutions in a vast range of scientific areas (Boulos, Maramba, & Wheeler, 2006). It has been argued that Web 2.0 technologies have the potential to change the education of healthcare professionals, from a didactic one way process to a collaborative and participative process, empowering the student to be an equal participant in the learning

process(Ward, Moule, & Lockyer, 2009). Web 2.0 applications appear to offer exciting new ways to teach, however, research into the use and evaluation of Web 2.0 tools in Biomedical and Pharmaceutical Education is still in its infancy, and the current pedagogic evidence about these tools is still lacking (Boulos et al., 2006)(Cain & Fox, 2009). In specific areas such has Pharmacy and Allied Health education, the examples are not wide, but the increasing use of teaching methodologies such as case based learning (Jesus, Cruz, & Gomes, 2011), might contribute to the implementation and dissemination of these tools. Wikis, blogs, podcasts and other tools have already been mentioned in some papers regarding higher education (Poonawalla & Wagner, 2006) (Kamel Boulos & Wheeler, 2007). These Web 2.0 technologies are in fact emerging as platforms to enable or encourage students to collaboratively create and share their own insights into current and emerging themes within their education. The number of tools and users are increasing and finding a place in healthcare management, education and practice (Ward et al., 2009). While it seems Web 2.0 might offer the potential for online learning to support pedagogy, in higher education there is little understanding of how and where it is being used to support biomedical education (Ward et al, 2009). This study is aimed to explore what specific Web 2.0 tools are being used, with what purposes and in what contexts.

In this updated review we will also focus on the most recent evidence about the use o Web 2.0 tools in pharmaceutical education, and share our own experiences on this topic.

METHODOLOGY

The study design is descriptive (MacMillan & Shumaker, 1997) and adopted the format of an integrative review (Cooper, 1984) since the objective was to make a synthesis of results (secondary analysis) from previous studies (primary analysis), in order to respond to new questions, new hypotheses and to verify or establish new relationships (Fortin, 2009). It is well documented that research reviews are considered research of research, and therefore should meet the same standards as primary research in methodological accuracy (Cooper, 1998). Cooper (1998) has delineated the process of conducting a research review as encompassing a problem formulation stage, a literature search stage, a data evaluation stage, a data analysis stage, and a presentation stage.

Problem Formulation Stage

This study primarily aims to characterize the use of Web 2.0 tools in biomedical and pharmaceutical education between the years of 2004 to 2014, and gather data to assess the potential educational values and hurdles to overcome. To constitute the categories of analysis we kept in mind the specificity of the object. Accordingly, the following variables were considered:

1. Year of publication,
2. Type of web 2.0 tool,
3. Biomedical area,
4. Type of publication,
5. Type of article and, finally,
6. Type of empirical study.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

For the variable "biomedical area" we started with 5 main categories – Medicine and Dental Medicine; Nursing; Pharmacy and Pharmacology, Allied Health and Other Topics. For the variable "type of publication" we considered three categories – journal article, proceedings and other. For the variable "type of article," we adapted the proposals of Coutinho (2008) and Poirier et al (2009), and considered four main categories – theoretical/ reflection, empirical, instructional design and assessment studies (IDEAS)[1], and study protocol descriptions. Finally, in the variable "type of empirical study" we started with an initial range of six categories adapted from the proposal of Gomes & Coutinho (2008): quasi - experimental, survey, case study, mixed study, action research and qualitative study. During the data analysis we didn't found any paper that falls in the categories "case studies" and "action research". Brief research design descriptions of retrieved studies are summarized in Table 1. Classification and definition are based in the proposals of O'Brien (2001), Poirier et al., (2009) and Coutinho (2011).

Literature Search Stage

Well-defined literature search strategies are critical for enhancing the accuracy of any type of review because incomplete and biased searches result in an inadequate database and the potential for inaccurate results (Cooper, 1998). Ideally, all of the relevant literature on the problem or topic of interest is included in the review; yet obtaining this literature can be challenging and costly (Jadad, Moher, & Klassen, 1998). Our literature search consisted mainly on electronic search of published articles and congress proceedings, in international educational databases and university repositories. Published journal articles and conference proceedings, between 2004 and 2014, relating to the use of Web 2.0 tool in Biomedical and Pharmaceutical Higher Education were searched in the databases ERIC; EBSCO Academic Search

Table 1. Brief research design descriptions of retrieved studies

Type of Article		Brief Description
Empirical Study	Quasi-experimental	It is similar to an experimental design, where strict control and randomization of treatment conditions are not possible.Usually the groups of subjects are already created by some previous criteria whic are independent from the aims of the research study.This is typical in educational settings
	Survey	Structured questions given to participants, by means of interviews or questionnaires.
	Qualitative Study	Family of methods involving an interpretive, naturalistic approach of the subject.
	Mixed Study	Applies principles of Qualitative and Quantitative research
	Case Study	A form of qualitative research, the case study looks intensely at an individual or small group, drawing conclusions only about that participant or group and only in that specific context.
	Action Research	Action research involves utilizing a systematic cyclical method of planning, taking action, observing, evaluating (including self-evaluation) and critical reflection prior to planning the next cycle.
Theoretical/Reflection		Include expert opinions, reflections and theoretical aspects on the topic.
Instructional Design and Assessment Studies (IDEAS)		Includes articles that describe new courses, parts of courses, integration of selected competencies across the curriculum, assessment of instructional outcomes,the use of technologies and new delivery methods
Study Protocol		Described, proposed or ongoing research, providing a detailed account of the hypothesis, rationale, and methodology of the study

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Complete, MEDLINE, PubMed, JSTOR, CINAHL, Science Citation Index Expanded, Social Sciences Citation Index and Conference Proceedings Citation Index. Keywords, utilized in the search, consisted in: "blog", podcast", "virtual worlds", "Wiki", "Docs"," Web 2.0", " Health Education"," Biomedical Education", "Medicine Education", "Nurse Education" and "Pharmacy Education" in several combinations. The titles, abstracts, and keywords of each of these articles were reviewed by two members of the research team, to assess their relevance to the research at hand. The references of the selected articles were also surveyed for appropriate articles. Computerized databases are efficient and effective; however, limitations associated with inconsistent search terminology and indexing problems may yield only about 50% of eligible studies (Whittemore & Knafl, 2005). Thus, and following the recommendations of Conn, Valentine, Cooper, & Rantz (2003), other approaches to searching the literature were included, such as, journal hand searching and searching research registries. A total of 55 articles were selected for further analysis.

Data Evaluation

The final sample for this integrative review included empirical studies, theoretical reports instructional design and assessment studies, and study protocols. Empirical reports included a wide variety of methods. Due to the diverse representation of primary sources, reports were coded according to two criteria relevant to this review: methodological or theoretical accuracy and data relevance on a 2-point scale (high or low). Since there are limited studies on this topic, an in order not to compromise the review, no report was excluded, based on this data evaluation rating system; however, the score was included as a variable in the data analysis stage. High relevance was only attributed to empirical studies.

Data Analysis

Data analysis required that the data from primary sources was ordered, coded, categorized, and summarized into a unified and integrated conclusion about the research problem (Cooper, 1998). Data analysis comprised of data coding from primary sources to simplify, abstract, focus, and organize data into a manageable framework (Whittemore & Knafl, 2005). Relevant data of each subgroup classification was extracted from all primary data sources and compiled into a matrix. The matrix was created according to the assumptions and categories mentioned earlier. This approach provides succinct organization of the literature, which facilitates the ability to systematically compare primary sources on specific issues, variables, or sample characteristics.

Presentation

Conclusions are reported in table form. Explicit details from primary sources and evidence to support conclusions will be provided to demonstrate a logical chain of evidence, allowing the reader of the review to ascertain that the conclusions do not exceed the evidence (Oxman, 1994).

PROSPECTS

By performing this integrative review, this chapter will provide an overview of what is being done in biomedical and pharmaceutical education, and elaborate on some of the potential opportunities and challenges that these applications present. We hope to give our contribution to consolidate research in this promising area.

RESULTS PRESENTATION AND DISCUSSION:

Year of Publication

The documents retrieved were published over a time period between the end of 2004 and the third quarter of 2014 (see Table 2). The year which shows the highest number of publications, was 2009 with 13 documents, followed by the years 2010 and 2011 with ten to eleven records.

Web 2.0 Tools

One of the main aspects to consider in the literature search, and data evaluation, was the Web 2.0 tool utilized in the studies (Table 3). Taking into account the diversity of tools available, and the possible combinations, our option was not to previously set categories, but to categorize, according to the data evaluation. During the data analysis process we accounted for 9 categories: "Web 2.0"; "Podcast/Vodcast"; "Wikis"; "Blogs"; "Second Life"; "Twitter®"; "Wikis + Blog", "Wikis + Blog + Podcast" and finally "Google Apps® and Similar". The "Web 2.0" category was considered due to the number of theoretical and empirical works being published, regarding the general application of Web 2.0 tools in biomedical sciences, or the application of more than three specific tools in the same context.

Biomedical Area

Medicine is the largest biomedical area represented in this study. This result may be explained by the large literature being published by medical professionals, the large number of medical faculties, and also because other biomedical areas, like Allied Health and Pharmacy, represent a younger existence when compared with traditional Medical Education. During the development of the study we coded two new variables – "Allied Health and Nursing"; "Allied Health and Medicine"- which are related to experiments conducted with both kind of professionals (Table 4). In this updated review we focused in newer studies regarding pharmaceutical education.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 3. Number of articles according with each Web 2.0 tool

Web Tool	Total Number of Articles	Type of Articles			
		Empirical	Theoretical/ Reflection	Instructional Design / Assessment Studies	Study Protocol
Web 2.0	11	2	7	2	0
Podcast /Vodcast	11	8	1	2	0
Wikis	10	5	1	3	1
Blogs	6	4	0	2	0
Virtual Worlds	5	1	2	2	0

Biomedical Area	Total Studies Retrivied
Medicine and Dental Medicine	21
Pharmacy and Pharmacology	15
Nursing	11
Allied Health	3
Allied Health and Medicine	1
Allied Health and Nursing	1
Other Topics	3
Total number of Articles	55

Type of Publication

Regarding the variable type of publication, journal articles are the most common source and medium of dissemination of work being done in Biomedical Education with Web 2.0 tools, consisting on a total of 40. This may be due to two major factors. Firstly, conference proceedings, by themselves, do not constitute a characteristic and homogeneous group of scientific work that can be easily accessed through the web, mainly because only a few organizations with long-standing organization history of scientific conferences have indexing. Additionally, situations where proceedings are published (full text) in supplements of related Journals, we choose to categorize them as Journal Articles.

Type of Article and Type of Empirical Studies

As previously stated, four main categories were considered, for the variable type of article: theoretical/ reflection; empirical study; instructional design and assessment study, and study protocol (Table 5). The empirical studies relating to the topic in question, were categorized accordingly with the followed methodology. The following table summarizes the results. Surveys are the most common type of empirical study.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 5. Number of articles according with type of article and type of empirical study

RESULTS BY WEB 2.0 TOOL USED

Web 2.0

Web 2.0 technologies are being rapidly integrated in higher education, which dramatically influences the ways learners approach and use information. Knowledge transfer has become a two-way process. Users no longer simply consume and download information from the web; they create and interact with it (Rosh et al., 2009). Several theoretical works were developed in order to discuss the possibilities of integration of Web 2.0 tools in Pharmacy (Cain & Fox, 2009), Medicine (Chu et al., 2010), Allied Health (O'Sullivan & McGlynn, 2010) and many other Biomedical Areas. Other works have started gathering evidence of the importance of Web 2.0 tools for students and even show some quantitative and qualitative results. Initial works like the one from Sandars et al., (2008) propose a very straightforward approach. With a survey type study, they aimed to determine the nature and extent of the use of social software by first year medical students. From a sample of 212 students, they discovered that over 90% used instant messaging and 70% social networking sites. There was no significant difference between males and females. Blogs were read by about a fifth of the students and 8% wrote their own blogs. A fifth of males stated that they were users of media sharing and contributed to wikis. Social bookmarking was rarely used by either sex. On a more complex approach George & Dellasega (2011) used and evaluated the integration of new social media tools into the curricula of two graduate-level medical humanities electives offered to 4th year students at Penn State College of Medicine. Five social media tools were selected - Twitter®, YouTube®, Flickr®, Blogger® and Skype® - to promote student learning. At the conclusion of each course, students provided quantitative and qualitative course evaluation. Results demonstrate that students gave high favorability ratings to both courses, and expressed that the integration of social media into coursework augmented learning and collaboration. Others identified challenges such has demands on time, concerns about privacy and lack of familiarization with technology. These reports represent an integrated approach to the use of Web 2.0 technologies in Biomedical Higher Education. Reports relating to the use of specific tools are presented below.

Podcast and Vodcast

Much that is written about podcasting refers to its ability to enhance convenience, flexibility and accessibility to learning (Nathan & Chan, 2007). It appears that when one examines the purpose behind the use of podcasting, it falls into three broad categories: enhancing the flexibility of learning, increasing

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

accessibility to learning (particularly in relation to enabling mobile access) and enhancing the student's learning experience (particularly in on campus courses through the use of more blended learning experiences) (McGarr, 2009). We found 10 articles relating to the use of podcast/vodcast in biomedical education. Six of them were surveys. Meade et al. (2009) tried to provide an evaluation of the usefulness of pharmacology podcasts as a supplementary learning tool for Non Medical Prescribing Students. The focus of this evaluation was on student use of the podcasts, perceptions of the usefulness and any potential impact on students' pharmacological knowledge. The podcasts were made available to students through WebCT® and the authors tracked two successive cohorts of nurse prescribing students (n = 69). Survey data, investigated reasons for podcast use and perceived usefulness of podcasts as a learning tool. Their results showed that not only 91% of students accessed at least one podcast but also that 93% of students used the podcasts to revisit a lecture. Only 22% used the podcasts because they had missed a pharmacology session. Most students (81%) generally listened to the entire podcast rather than specific sections and most (73%) used them while referring to their lecture handouts. More than 90% of students found the podcasts helpful as a learning tool, as a revision aid and in promoting their understanding of the subject. Of the 69 students, 64 completed the pharmacology exam. In order to examine any impact of podcasts on student knowledge, their exam results were compared with those of two historical cohorts who did not have access to podcasts (n = 70). Evaluation of range of marks obtained, mode mark and mean mark suggested improved knowledge in students with access to podcasts compared to historical cohorts of students who did not have access to pharmacology podcasts(Meade et al., 2009). Also in the UK, but with medical students, Shantikumar (2009) aimed to investigate medical students' perceptions of a series of enhanced podcasts for revision of contents. Thirteen audiovisual podcasts covering general surgery were developed, consisting of a PowerPoint slideshow with a voiceover narrative. A questionnaire was distributed to 211 final year medical students, two months after the podcast became available. Results showed that students who used the resource felt that the enhanced podcasts were straightforward to access, were a useful learning supplement, and felt that similar resources for the remainder of the undergraduate medical syllabus would be useful for revision purposes (Shantikumar, 2009). Similar results were described by Pilarski et al (2008) in first year medical students. According to their results, the availability of lecture recordings aided medical students in their studies and reduced stress and anxiety. Student response to the recordings was positive, and no negative outcomes were noted by students or faculty (Pilarski et al., 2008).

Analogous methods were used in Nursing Education (Forbes & Hickey, 2008), (Stiffler et al., 2011). In both cases, the authors provided an overview of the potential uses and techniques for implementing podcasting in nursing education, and described students perceptions and attitudes. The results are in consonance with the above-mentioned studies. Although these are promising results we must not be drawn to generalize their conclusions. First of all, the survey type study does not provide all relevant information about context on the application of podcasts. Secondly, student performance in these cases, except Meade et al (2009), is not categorized or even measured in a consistent way. However, student's perceptions and responses to these implementations are crucial for their success, but more detailed, in-depth studies are required in order to truly account for an impact in biomedical and pharmaceutical education. This will imply bigger samples and longer studies.

We only came across with one qualitative study exploring the use of podcast in biomedical education. Meade et al. (2011) conducted semi-structured interviews with seven non-medical prescribing students. Their results determined that students used podcasts for revisiting lectures, preparing for exams, to clarify or revise specific topics and, to a lesser extent, to catch up on a missed lecture. Barriers to

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

podcast use were identified, mainly around technological issues. Lack of experience and lack of access to suitable technology to access podcasts proved a barrier for some students. Students found that using podcasts allowed them to have greater control over their learning and to gauge their learning needs, as well as helping them build their understanding of a complex topic (Meade et al., 2011). The qualitative methods provide a depth of understanding of issues that is not possible through the use of statistically based, quantitative investigations. The qualitative approach can be a useful tool since it centralizes and places primary value on how students understand experience and operate with web 2.0 tools. The results of qualitative studies can be of interest to educators and policy makers when design a strategy for the implementation of such tools in their specific academic context.

Initially we did not consider a category for vodcasts, however, in the array of literature, one study referring to vodcast in medical education was found (Schreiber et al., 2010) and one in Pharmacy (Pierce & Fox, 2012). In the first study the authors compared information recall and student experience and preference after live lectures and video podcasts in undergraduate medical education. A crossover trial was performed with a total of 100 students. The first group attended a live lecture on arthritis and then a video podcast on vasculitis, while the second group attended a live lecture on vasculitis and then a video podcast on arthritis. The study hypothesis was that knowledge after vodcast would not be significantly different from knowledge after live lectures. The primary outcome was the score on the multiple-choice questionnaire after each intervention. This study found that students showed similar information recall after video podcasts and live lectures, but preferred live lectures. Students appreciated the convenience and control over vodcasts, but found them, generally, less engaging. Design strengths in this study included testing the students only after the interventions, to avoid influencing the educational intervention with the test itself and keeping the two interventions as similar as possible using the same speaker, the same PowerPoint® slides, and the same verbal information. Authors, point out however, that selection bias might have been present, since participation was out of hours and voluntary and also a significant dropout rate occurred.

Pierce and Fox (2012), promoted vodcast of lectures prior to the scheduled class and then discussed interactive cases of patients with end-stage renal disease in class. Students' performance on the final examination significantly improved compared to performance of students the previous year who completed the same module in a traditional classroom setting. Althought these results are very promissing, we must consider taht this experiment was based in a "Flipped Classroom" model, which may also contribute to the performance improvement.

These studies open possibilities for future interventions, and although conclusions were not always favorable to the Web 2.0 tool (Stewart et al., 2013), several factors were identified as confounding factors. We suggest that any pursue in this type of designs take in consideration the duration of the intervention, the possible selection bias and of course a better isolation of threats to the internal validity. The incorporation of podcasts in biomedical and pharmaceutical education, namely in support of a mobile form of learning, may have potential, but the reason given to justify its use should be student led, and not technology led. Educators need to be cautious of the claims made in relation to new and emerging technologies, particularly in the assumptions made by proponents of the technologies (McGarr, 2009). The development of future policies in institutions should be cognisant of the limitations of the technology in supporting a more mobile form of learning. If used to provide access to records of previous lectures, or to provide summaries and syntheses of course material, careful consideration should be given to how the students should use the material. If seen as the primary source of material and learning by

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

the students, this type of technology may not contribute to the students' learning experience. So it is important to ensure that students possess the study skills needed to use the support material effectively.

Blogs

Blogs may serve as a potential teaching tool, as well as an important channel for Biomedical Education. Previous research has shown that blogging, integrated into curriculum, may increase student's motivation, critical thinking, class interaction, and student's course satisfaction (Beldarrain, 2006; Olofsson, Lindberg, & Hauge, 2011). Blogging may even propel students to take social and political actions outside of the virtual environment (Oomen-Early & Burke, 2007). Concerning the use of blogs alone, in biomedical and pharmaceutical education, a total of 6 articles were retrieved. Regarding instructional design and assessment, two examples were found, in Pharmacy (Bouldin et al., 2006) and Medicine (Chretien et al., 2008), respectively. Bouldin et al., (2006) applied blogs to a reflective journaling exercise in a communication course during the second-professional year at the University of Mississippi School of Pharmacy, in order to encourage students to reflect on course concepts and apply them to environments outside the classroom, and to assess their communication performance. Seventy-eight students enrolled in the study. Two blog entries per week were required for full credit. Blogs were evaluated at three points during the entire term, and at the end of the course, students evaluated the assignment using a survey. Results showed that the assignment contributed to student learning and increased awareness level for approximately 40% of the class, however, there were some limitations. Because of the proximity to the end of the semester, student responses may have been influenced by the total curricular workload; moreover this evaluation was only taken at one point in time.

Chretien et al.(2008) performed a similar study with 91 medical students during a basic medicine clerkship rotation at an academic institution over a one-year period. Students were asked to contribute with reflective postings to the class blog during their rotation (each rotation was four weeks long). They were able to read each other's postings and leave feedback in a comment section. An instructor provided feedback on entries, aimed to stimulate further reflection. Students could choose anonymous names if desired. One hundred and seventy seven posts were written, and only a minority was not reflective. The instructor's feedback stimulated additional reflection and one-third of students left feedback comments. Both studies show that it is possible to foster reflective thinking by the use of blogs in such different biomedical areas as Pharmacy and Medicine and even provide opportunities to support student professional development. It is notable that the number of students in each study is quite considerable, a quality not often seen in these types of studies. However, the number of tutors /instructor wasn't proportional, and this caused an incomplete and not as frequent feedback. Additionally, both studies were conducted in only one institution, which may limit generalization. Nevertheless, as instructional design and assessment studies, these studies show and describe thoroughly the process by which any educator can implement and assess the opportunities promoted by blogs in their classrooms, or even during clinical practice.

Regarding the survey type study, Goldman et al (2008) evaluated whether "seminar blogs" enhanced learning in a graduate-level introductory public health school class. An online survey was conducted and the main questions were about blog use, perceived impact on learning, and interactions with classmates. The survey also asked about the "ease of blogging" compared with speaking in class, the development of group dynamics, potential usefulness of blogging in student's work, and advantages and disadvantages of seminar blogs. Results generally favor the study objective, however several limitations are addressed. First of all, the study was conducted in a post-graduate setting, where subject's age and maturity may (or

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

may not) contribute for the study objectives. As referred by the authors, the short time frame (8 weeks) may have been too brief to fully determine the developing of group dynamics or social presence. And finally we should keep in mind that this a descriptive study based on student self-report of effects on learning and participation and only with a comparison group would we be able to assess the impact of the blogs on specific measurable educational outcomes.

Oomen-Early and Burke (2007) also conducted a survey to explore faculty and students' perceptions of blogging as an effective teaching and learning tool within the online health education classroom. The researchers measured if blogging increased students' interaction, engagement, and feelings of connectedness with peers. Results are favorable to the study objective, but again we are dealing with a small sample of students. This study, shows however a great deal of care in developing a survey (validated by expert and tested in a group of students), and points out several limitations and challenges regarding the use of online free blog hosting services. Using a much more robust study design Fischer et al. (2011), conducted a comparative study of student reflective writings, produced using either a blog format or a traditional essay to assess differences in content, depth of reflection and student preference. Students were quasi-experimentally assigned to one of the two groups, and although no significant difference was determined in themes addressed, or levels of reflection, the authors showed that it's possible, and quite achievable to promote the use of blogs in biomedical teaching. The study suggests that the use of blogs, in no way diminishes the ability for reflective writing. Moreover the fact that blogs support features such as, image, sound and video, can in fact enhance the participation and may even encourage those who feel greater reluctance in participate in these reflective activities. Nevertheless one should not draw hasty conclusions, since more studies in different knowledge areas, with a greater number of students and over a longer period than are necessary.

We also came across with a qualitative study, conducted by Melissa Tan et al. (2010) who aimed to determine the impact of blogging on the clinical reasoning of physiotherapy students. With a sample of 83 students, the authors divided them randomly in 8 groups. Each group had a tutor/moderator (faculty member), and all students were required to contribute to and participate in reflective practice discussions within their blog group for the duration of their clinical program with at least one post and comments on two of their group members' original posts per week. Data was retrieved and analyzed using NVivo®. About 475 blog posts were analyzed. Results demonstrated that the students applied a range of clinical reasoning skills categorized as collaborative; diagnostic; ethical; interactive; and procedural reasoning. Of these, 90% were procedural, ethical and interactive reasoning. The authors concluded, even though the students were dispersed across facilities and changed locations every four-five weeks, that blogging provided these physiotherapy students with opportunities to explore clinical reasoning dilemmas, in a safe space. The blog enabled the students to maintain connections with their peers and supported them in their fieldwork practice. This apparently promoted the development of metacognition at both an individual and collective level. This research indicates a promising result, that blogging can be used to promote learner self-discovery and to assist self-regulated learning in biomedical science. Evidence suggests that blogs help to create connections between students with diverse opinions and interests. This encourages critical thinking and teaches the value of respect towards other students' points of view. Discussions in blogs may also promote higher levels of thinking, because people can think before answering back. They can be used for individual students, or for groups, fostering collaborative learning. Some limitations were however addressed by the authors, of the studies reviewed, but they were attained as ways to improve the experience, and none of them could theoretically diminish the main conclusions.

Wikis

Wikis are increasingly being used as means of sharing and communicating medical knowledge. The Medpedia Project, is a good example of an up-to-date, unbiased medical information repository, maintained by health experts from all around the world, and of free access (Park, Crocker, Nussey, Springate, & Hutchings, 2010). The use of wikis is quite common in other educational levels (K-12). But their potential is already being discovered by faculty members. Wikis (as tools for group authoring and collaboration) have substantial applications. Often group members collaborate on a document by emailing to each member of the group a file that each person edits on their computer, and some attempt is then made to coordinate the edits so that everyone's work is equally represented; using a wiki pulls the group members together and enables them to build and edit the document on a single, wiki page (Parker & Chao, 2007). Students can even use a wiki to develop research projects, with the wiki serving as ongoing documentation of their work, build a collaborative annotated bibliography or develop map concepts. Wikis can also be useful for brainstorming, and editing a given topic, to produce a linked network of resources. Teachers can also use wikis as a knowledge base, enabling them to share reflections and thoughts regarding teaching practices, documentation or presentation tool in place of conventional software.

The use of wikis alone, is one of the most documented, with a total of 10 articles retrieved, ranging from theoretical works (Younger, 2010), to instructional design and assessments' (Miller et al., 2009; Ros-Rodriguez et al., 2011; Boutin & Therriault, 2011), surveys (Mirk et al., 2010; Miller et al., 2012) study protocols (Archambault et al., 2010) and mixed studies (Varga-Atkins et al., 2010). There are even studies associating Wikis to Blogs (Billings, 2009; Sandars et al., 2008) and Podcast (Mathieu, 2007; Boulos et al., 2006) however, all of them are theoretical works, in several biomedical areas. Even teachers are discussing the use of wikis to promote and update study materials for their students (Rodríguez, Carrillo, & Alvarez, 2010). Focusing on instructional design and assessments', Miller et al. (2009) described their use of wikis in Advanced Pharmacy Practice, with an overall student answers with more 90% of respondents either strongly agreeing or agreeing that wikis helped reinforce concepts and ideas and that they enjoyed working with wikis. Within the same study type, Ros-Rodriguez et al. (2011) recently published their experience in the development of a Virtual Classroom of Pharmacology. Using wiki utilities the students had to transform an initial pdf outline to a wiki format. The students had to create or edit one wiki for each lesson outline and to include hyperlinks for the main concepts to additional material located in the "Virtual Classroom of Pharmacology" and had also to create a glossary with those terms. The student involvement in the task led them to relate, integrate and assimilate the knowledge about those particular aspects of pharmacology. Besides, the authors conclude that the generation of these materials reinforced the learning and promoted work as a team. Also in instructional design and assessments, Boutin & Therriault (2011) presented a pedagogical experience in an Occupational Therapy program that used a wiki to enable the learner to become a" knowledge producer and actor of hi/her learning"(Boutin & Therriault, 2011). The authors targeted three courses, each with different objectives intended for the wiki. Following application of the wiki, the degree of satisfaction of students and professors and the impact thereof on the acquisition of skills was evaluated through an online survey. The published results, from both student and faculty, seem to indicate that using a wiki as a learning tool contributes to the acquisition of knowledge and the development of skills in this new competency-based program of occupational therapy.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

On a different approach, Llambí et al. (2011) developed a quasi-experimental model in which they designed and implemented a blended-learning course on tobacco cessation. Three hundred thirty-five health professionals participated in the course. Of these, 145 attended the on-site workshop, 216 participated in the online activities, and 109 completed both phases. When comparing pre and post test scores, the authors found a statistically significant difference among those who completed both phases compared with those who only did the online phase ($p = .003$ and $p = .009$, respectively), demonstrating that wikis, could be a useful tool in promoting continuing education activities for health professionals. We must however mention that tests were completed by a minority of the participants, since fewer than half performed the pretest and fewer than a third completed both and allowed paired analysis. The fact that tests were not compulsory became a weakness of this study. Using a mixed approach, Varga-Atkins et al. (2010) tried to discover whether the use of wikis could enhance medical students' development of professionalism. Using both survey and interviews, 32 students were questioned. The authors described that the wikis helped students finding, compiling, evaluating and sharing resources related to their learning objectives on professionalism. Secondly, it was demonstrated by the study that the online wiki spaces could have a role in enhancing students' development of "professionalism in a wider sense". Although, using quite a small sample and limited time span, this is a pioneer study, which can be a launch base for more broad research in several subjects of biomedical education. More outcomes are expected as Archambault et al. (2010) develops also a mixed study on the use of wikis. The authors published the study protocol for the mixed study, that aims to develop and test the metrological qualities of a questionnaire for the assessment of healthcare professionals' intentions and the determinants of those intentions to use wiki-based reminders that promote best practices in trauma care. This promising work may contribute even further for the use of wikis in biomedical and health education.

The only survey type study regarding wikis in biomedical education at this point is the research conducted by Woulfe et al. (2009). The authors applied a "wiki approach" to Master of Pharmacy students at The University of Sydney. Normally these students were required to submit a series of group-generated PBL cases. However faculty members often reported a fragmented approach and a lacking in "patient-focus". After a successful pilot study in 2007, the authors introduced a wiki format, with a view to encourage a whole patient approach to the task. A total of 38 students were divided into 6 tutorial groups in each semester, producing one PBL case summary per group per week for a total of 10 weeks. In the first semester, students were required to submit their case summaries on paper. In the second Semester, they were required to write their case summaries in a wiki. The results are not favorable to the study objective. The technical difficulties reported by students appear to have greatly affected the quality of their case summaries, as well as influenced their perceptions of the wiki. This increases the awareness of educators for the necessity for training in the use of the wikis, before instructional changes.

We also introduced a "wiki iniciative" in our own pharmacotherapy course (Jesus, Gomes, & Cruz, 2012, 2013), mainly as an e-portfolio for the students, in Wikispaces. The choice of platform was based on the capabilities provided by the same level of editing (integrating text, images, links, videos, audio, documents, presentations and other features embed), the issue of privacy and access and log edits, and you can follow in detail the contributions of each group member. Students should produce a new page for each case would be presented with only one case per week. In total 20 were developed e-portfolios with different characteristics. A systematic analysis of the contributions made by the students allowed the observation of commitment and motivation from them and formed the basis of a quantitative evaluation.

Microblogging

Microblogging is the practice of posting small pieces of digital content on the Internet (EDUCAUSE, 2009). Microblogging has become popular among groups of friends and even professional colleagues who frequently update content and follow each other's posts, creating a sense of online community (EDUCAUSE, 2009). Although literature about this Web 2.0 tool is still in its infancy, we uncovered two theoretical studies in nursing education(Skiba, 2008; Bristol, 2010), and four studies relating the use of Twitter® in Pharmacy Education (Fox & Varadarajan, 2011; Bussières et al., 2012; Camiel et al., 2014b, 2014a). The first study describes implementation and effectiveness assessment of Twitter® use, in encouraging interaction between faculty members, guests, and students in a pharmacy course taught simultaneously on 2 campuses. Students were required to tweet a minimum of 10 times over several class sessions. The course instructor and guest professionals also participated but no limit of tweets was established for them. One hundred forty-three students were enrolled in the course: 119 in one campus and 24 at the satellite campus. Course requirements were the same across campuses. The Twitter® activity, was worth 2% of the grade. Students were also given an opportunity to earn 5 bonus points by completing an online, anonymous evaluation of the Twitter® activity. The results presented by Fox and Varadarajan (2011), indicate that more than eighteen hundred tweets were made by students, guests and the instructor. Students tweeted most frequently with each other and found value in reading each other's tweets. From the 131 students that completed the optional evaluation survey 71% percent indicated that Twitter® was distracting, 69% believed it prevented note taking, and more than 80% indicated that it facilitated class participation and allowed an opportunity to voice opinions. These results led the researchers to conclude that the use of Twitter® in pharmacy courses (or any other biomedical course) balanced the potentially positive aspects of the technology, such as increased interaction among students, with potentially negative aspects, such as the interruptive nature of Twitter® use and the large volume of tweets generated by assignment. Far from extolling the benefits of Twitter®, this study shows clearly and objectively the results obtained, even if they do not translate into a steadfast discovery the potential of microblogging. The study design, the number of professionals involved and the methodological description shows a high robustness, which can definitely be a starting point for other researches or experiments in the biomedical classroom.

In 2012, Bussières and colleagues (2012), examined the use of Twitter® in a first-year pharmacy law course, as a backchannel (an electronic discussion that occurs simultaneously in real time during a lecture or conference where students may post questions, comments, or respond to other posts). The authors compared the frequency of questions either through Twitter® or hand-raising. Of 200 students, only 8 asked questions using Twitter® vs 30 questions with hand-raising. Despite the authors' feelings that the use of Twitter® was a failure, students reported that backchannel allowed those students to express themselves who otherwise might not have. The idea of using Twitter® as a backchannel was also pursued by Camiel and colleagues (2014a). In their paper, the authors describe the use of Twitter® in a "large required, lecture-based, team-taught nonprescription drugs/self-care products course". The students were remineded students at the beginning of each lecture that backchannel was being used. The feed was continuasly monitored, and after class, responses to unanswered questions were posted on the course learning-management system discussion board. The author promoted a survey at the end of the year, where 266 students completed an anonymous voluntary survey, where thirty-nine percent (and 40% neutral) felt that being anonymous to their classmates was important to them. In their written

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

comments, a number of students commented positively about not needing to raise their hand to ask a question in front of the entire class.

In more recent article, the authors (Camiel et al., 2014b) explore the use of Twitter® for the building of a personal learning network. Although the initial results showed a high percentage of students (36%) that were not confortable using Twitter, and even considering that the use of a personal learning network was a new concept, the final results were very promising, with more than 50% students planning to continue using Twitter® as a social network.

One must consider that as diverse as microblogging may be, it has some shortcomings. Although microblogging promotes writing and editing as fun activities, and therefore may be used in informal learning (Ebner, Lienhardt, Rohs, & Meyer, 2010) there is the possibility that students get distracted and carried away during ongoing lessons due to microblogging with their mobile phones. Not only is this addiction harmful to their education but it is also disrespectful to the teachers or lectures. Further, educators insist that due to microblogs being limited to adopting 140 characters for message updates, it could potentially lead to bad grammar usage by students (Grosseck & Holotesku, 2008).

Google Apps and Similars

The use of Google Apps or other similar applications isn't particularly widespread. Only one study (Phadtare et al., 2009), using GoogleDocs® was retrieved. With a heterogeneous sample of 48 participants (from a medical, nursing and physiotherapy background from US and Brazil) randomly assigned to two groups, the authors proposed to compare on-line vs. traditional classroom-based methods for teaching scientific writing. In the on-line group, participants used virtual communication, GoogleDocs® and standard writing templates, and in the standard group participants received standard instruction without the aid of virtual communication and writing templates. Outcome variables consisted of manuscript quality and self-reported participant satisfaction. The quality of each manuscript was evaluated according to well-defined parameters using a scale. The obtained results suggest that the on-line scientific writing group performed significantly better than the standard writing guidance group in terms of writing quality. They also reported greater overall satisfaction and a greater number of participant-mentor communication events. The authors agree that the use of GoogleDocs® enhanced participants' familiarity with this method of collaboration, as well as improved the mentors' efficiency. Although being a study with several statistical procedures and high strength study design, Phadtare et al. (2009) also address the problems associated with using imperfect measurement scales, which can be prone to subjective bias. The authors also reflected on the lack of tools to objectively evaluate manuscript quality and participants' self-assessment, which makes it difficult to interpret the results of this type of study. Several other factors are also pointed out, as possible influences, including participants' previous experience with on-line courses, their grades, computer competency, and interaction with the system in question, as well as the instructor skills and the presence or absence of supervision.

Virtual Worlds

Virtual worlds, such as Second Life®, are described as online computer-based simulations where the user is given the impression of being in another place/location through replications of real life objects(Honey et al., 2009). Second Life® enables learners to manipulate information and synchronously interact with other people, via a digital representation, also known as an avatar (Rogers, 2009). Virtual worlds, like

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Second Life®, have the ability to create an artificial social structure where problem-based scenarios can be created and developed, allowing students to actively (co) construct mental models of technical and interpersonal skills (Dickey, 2005). While some literature discusses the uses of Second Life® in positive terms (Boulos et al., 2007; Kirriemuir, 2008, Hansen et al., 2009) citing its ability to support interaction and collaborative learning there is little research about actual projects. Our research retrieved one instructional design and assessment study, one qualitative study and one survey type study. Rogers, (2009) proposed to discover how virtual world simulations can assist nursing students developing characteristics and skills essential to future roles as healthcare professionals. In order to accomplish his goal, the author compiled a series of investigative interviews that researched the attitudes and experiences of a sample of sixteen nursing students enrolled in a Bachelor of Nursing Program, who were previously exposed to six simulated clinical scenarios created in Second Life®. Students were placed into groups based only on their year level and exposed to the simulation in separate locations to replicate the intended purpose of the simulation (Rogers, 2009). The students agreed that the simulation in Second Life® assisted them in the development of technical and non-technical skills and in most cases the students found the technology quite easy to use. Also, the online simulation enabled the students to collaborate and solve the scenarios as a team (even though they were isolated in the real world), allowing students to actively co-construct technical and interpersonal skills (Rogers, 2009).

Also in nursing education Honey et al. (2009) conducted a pilot study based around a simulation of a woman having a postpartum hemorrhage. The focus of the scenario was on recognizing abnormal presentation in a postpartum assessment, nursing interventions for hemorrhage, and communication among health care professionals. Although the project led to significant publication on technical issues and simulation development in Second Life, results about student's participation and assessment are scarce and insufficient for a detailed analysis. With a more structured approach, but with a different objective Wiecha et al (2010), proposed, designed and delivered a pilot postgraduate medical education program in Second Life. They enrolled and trained 14 primary care physicians in an hour-long, highly interactive event in the virtual world on the topic of type 2 diabetes. Participants completed surveys to measure change in confidence and performance on test cases to assess learning. The post survey also assessed participants' attitudes toward the virtual learning environment. On a seven-point Likert scale, participants' mean reported confidence increased from pre to post online event with respect to insulin selection, initiation and dose adjustment on test cases, the percent of participants providing a correct insulin initiation plan increased from 60% pre to 90% post. All participants agreed that this experience in Second Life® was an effective method of medical education, that the virtual world approach was superior to other methods of online education. Although these last conclusions are in fact favorable, most of the results retrieved show that insufficient evidence is still available about the potential of Virtual Worlds in Biomedical education.

There are also potential problems with using a virtual world as an educational tool. It's not intuitive, it contains many types of environments, some of which are inappropriate for educational and professional uses. Non-student avatars may appear in student locations, and some of those avatars can manipulate and even act aggressively toward others. Nevertheless, where problems arise, the teacher must see ways to overcome them. The careful planning of activities, and an on-demand technical support, are undoubtedly two features to keep in mind while developing an online educational experience in virtual worlds. Further research is also necessary to investigate the attitudes of students towards technology-supported learning and to identify and further explain links between the students' personal online practices and

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

their experiences in Virtual Worlds. Moreover it is advisable to demonstrate real, quantifiable outcomes (with large number of students) of these types of interventions in order to objectively assess their impact on student learning.

FUTURE RESEARCH DIRECTIONS

Despite the great deal of opportunities for the implementation of Web 2.0 applications within higher education, there are several challenges that are not permitting a widespread use. These include finding faculty members who are willing to accept change and adopt new pedagogical approaches. Increasing faculty members' acceptance of these new tools may require efforts at improving the perceived usefulness and benefits of the applications (Cain & Fox, 2009). Institutions have great deal of power on these challenges, and the role of leadership and management is crucial in promoting short-term workshops/seminars to increase informatics literacy and promote pedagogical innovations/adaptations. Another aspect to consider, especially in survey studies is standardization. Standardization provides survey research with some of its great strengths, because standardization makes it possible to seriously consider surveys as measurement tools (Beatty, 2001). Studying students is always difficult and always involves subjectivity, but the potential for measurement gives survey research great scientific credibility. It also allows for efficiency in handling data, provides for clear quality control criteria, and minimizes random error introduced by the interviewer (Beatty, 2001). Validating these instruments can take long periods of time but it will benefit outcomes and the validity of the conclusions.

All the conclusions and results presented in this chapter are about professionals who are trained in several types of methodologies and study designs. They must know how to perform and assess studies like clinical trials and other experimental studies that have strong design strength. Similarly, studies performed in order to assess the impact of Web 2.0 tools in biomedical and pharmaceutical education need to follow the same principle. We are aware that we cannot be so straightforward in Educational Sciences, but there are options and ways to better control and predict threats to the study conclusions, giving more strength to our results. IDEAS studies and surveys have their role in creating evidence, but quasi-experimental studies and qualitative studies can provide a stronger, wider and more reliable research. The privacy issue has also arisen during the use of Web 2.0 tools, with focus in wikis and blogs. The issue can be easily controlled, if blogs are password protected, or accessed by invitation only, and if wikis are developed inside LMS Systems, like Moodle, and accessible only to members. This will also avoid vandalism and promote student participation (Boulos et al., 2006). Nevertheless an active tutor role is required in order to readily access, edit or comment on new materials posted by students. Last but not least, the technical difficulties felt by students in some of the studies referred are an alert that, although we live in a society of information, maybe we need a little more care in educating our students about these technologies in order to truly benefit from them.

Indeed, Web 2.0 tools and applications have a powerful place in instruction and in the classroom, but caution is warranted regarding the strategies used. Instead of beginning instructional planning with these tools in mind, the learning objectives and instructional strategies should guide the adoption process. An awareness of the different tools, gives faculty members additional mechanisms from which to choose, but selecting an appropriate instructional strategy is even more important.

KEY TERMS AND DEFINITIONS

Blog: A kind of journal published on the World Wide Web consisting of posts typically displayed in reverse chronological order so the most recent post appears first. Blogs are usually the work of a single individual, occasionally of a small group, and often are themed on a single subject.

Microblogging: Microblogging is the practice of posting small pieces of digital content on the Internet.

Podcast: A type of digital media consisting of an episodic series of audio files subscribed to and downloaded through web syndication or streamed online to a computer or mobile device.

Virtual Worlds: Described as online computer-based simulations where the user is given the impression of being in another place/location through replications of real life objects.

Vodcast: A type of digital media consisting of an episodic series of video files subscribed to and downloaded through web syndication or streamed online to a computer or mobile device.

Web 2.0: Web 2.0 is a loosely defined intersection of web application features that facilitate participatory information sharing, interoperability, and user-centered design.

Wiki: A website whose users can add, modify, or delete its content via a web browser using a simplified markup language or a rich-text editor. Most are created collaboratively.

ENDNOTE

[1] Coutinho (2008) proposes four categories: theoretical/ reflection, empirical, reports of educational experiences and study protocols. Poirier et al. (2009) presents a more structured approach to reports of educational experiences – called Instructional Design and Assessment Studies (IDEAS).

This work was previously published in Advancing Pharmaceutical Processes and Tools for Improved Health Outcomes edited by Tagelsir Mohamed Gasmelseid, pages 52-78, copyright year 2016 by Medical Information Science Reference (an imprint of IGI Global).

Chapter 5
Open Access Initiatives in Medical Biology: A Study of Institutional Repositories in India

Rupak Chakravarty
Panjab University, India

ABSTRACT

Open Access (OA) is reshaping the world by redefining the scholarly communication methods with focus on building a knowledge society. It has the power to democratize the knowledge by removing hurdles from free access to scholarly works while encouraging knowledge sharing. Institutional Repositories (IRs) play a vital role in the OA movement by facilitating the Green Route to Open Access. In India, some elite educational and research institutes such as the Indian Statistical Institute, some CSIR Laboratories, IITs, and IIMs have taken significant initiatives in building IRs. In addition to theses, a few Universities have also taken the initiative and now have their own IRs as their proudest possession. However, many Indian Irs, once functional are in bad shape and a few have been closed. This paper deals with IR initiatives in the discipline of Medicine and Biology including. The paper discusses their scope, collection strength, growth rate and their current status.

1. INTRODUCTION

The journey of man from a nomadic society to knowledge society is very interesting and perhaps never ending. Free flow of information has played a pivotal role in this journey. But the journey is still incomplete as there exits a thirst – thirst for knowledge and is still unquenched. To facilitate a free flow of information, especially scholarly information is very crucial. At the same time it is a challenge as financial aspects are also involved in this. Scholarly communication has the potential to make this world a better place to live in as it is based upon the philosophy of equal access to knowledge. Open Access is augmenting and enriching the scholarly communication cycle and making the world a global village.

Scholarly communication can be understood as the system through which research and other scholarly works are created, evaluated, disseminated to the scholarly community, and preserved for future use. It is the cyclical process It is a cyclical process in which content is generated, reviewed, disseminated, acquired, preserved, discovered, accessed, and assimilated for the advancement of scholarship. The assimilation can potentially lead to generation of new content and thus start a new iteration of the process (or life cycle).

2. OPEN ACCESS AND THE TWINS

Open access (OA) means unrestricted online access to peer-reviewed scholarly research. Open access is primarily intended for scholarly journal articles, but is also provided for a growing number of theses, book chapters, and scholarly monographs. Open access comes in two degrees: gratis OA, which is free online access, and libre OA, which is free online access plus some additional usage rights.

The Budapest statement defined open access as - "There are many degrees and kinds of wider and easier access to this literature. By 'open access' to this literature, we mean its free availability on the public internet, permitting any users to read, download, copy, distribute, print, search, or link to the full texts of these articles, crawl them for indexing, pass them as data to software, or use them for any other lawful purpose, without financial, legal, or technical barriers other than those inseparable from gaining access to the internet itself. The only constraint on reproduction and distribution, and the only role for copyright in this domain, should be to give authors control over the integrity of their work and the right to be properly acknowledged and cited."

The Bethesda and Berlin statements add that for a work to be open access, users must be able to "copy, use, distribute, transmit and display the work publicly and to make and distribute derivative works, in any digital medium for any responsible purpose, subject to proper attribution of authorship."

The two ways authors can provide OA are Green and Golden Routes/Roads. In green OA, authors self-archive their journal articles in an OA repository (IR). In the Golden OA approach, the author decides to submit the research papers in a selected repository, making it freely available over the world wide web. In Gold Open Access, the end users i.e. The readers are not supposed to pay any subscription cost, but the author has to pay the Article Processing Charges (APCs). The third approach, which is also becoming an accepted model is Hybrid OA which is most commonly associated with Gold Open Access. In this OA model is a mix of subscription charges and publication fees. In this model, some articles are available only to subscribers, while others are made available at no charge to anyone searching the web. Authors pay an additional fee for the open access option. They may do this because open access is a requirement of their research funding agency. Or they may do it so that non-subscribers can access their article for free. In this model, only the articles for which the authors have covered APCs are available for free.

According to Bo-Christer "in just over two years [2009-2012] the number of journals from major publishers offering hybrid Open Access has more than doubled, from approximately 2,000 to over 4,400. Since the overall numbers of journals from these publishers has remained on the same level, the hybrid share has risen from 25% to around 50% of all eligible journals."

3. PHARMACOLOGY

Pharmacology is the branch of medicine and biology concerned with the study of drug action, (Vallance P & Smart TG, January 2006) where a drug can be broadly defined as any man-made, natural, or endogenous (within the body) molecule which exerts a biochemical and/or physiological effect on the cell, tissue, organ, or organism. More specifically, it is the study of the interactions that occur between a living organism and chemicals that affect normal or abnormal biochemical function. If substances have medicinal properties, they are considered pharmaceuticals. IUPAC defines pharmacology as Science of drugs, including their origin, composition, pharmacokinetics, pharmacodynamics, therapeutic use, and toxicology.

4. RESEARCH PROBLEM

New technologies, specifically ICT, and innovative models are enhancing the shared model of scholarly information. The shared literature may include research papers, primary data and other evidence, creative activity and other products of research and scholarship including across institutions and audiences. However, on account of the exponential price rise in journal subscription, libraries, especially in underdeveloped and developing countries were finding it difficult to serve their readers adequately and qualitatively. They are still finding their budget either shrinking or stagnant. The problem is further aggravated as the funders and taxpayers do not have access to the research they pay for. Producing a research paper may require time and money. Scholars are devoid of scholarly content and open access to scholarly literature is the only solution to this problem. Also, there is need of conducting research in the discipline of Medicine and Biology repositories in India.

5. LITERATURE REVIEW

Halliday (2001) in his paper titled "Scholarly Communication, Scholarly Publication and the Status of Emerging Formats," explored the role of scholarly communication and provided a working definition of scholarly publication consisting of a list of criteria, which may be used to analyse the degree to which emerging formats can be categorized as scholarly publications. The paper also helped to identify the means by which they may be supplemented so that their status may be promoted to that of the 'scholarly publication.'

Ghosh (2006) in his paper "Open Access and Institutional Repositories: A Developing Country Perspective – A Case Study of India," discussed the concept of scholarly communication as a method wherein the author facilitates the availability and distribution of scholarly communication freely, as a means and effort to solve the problem of inaccessibility, primarily due to financial constraints, particularly in the developing countries. He mentioned that in India there has been a gradual realization of the usefulness of open access among various institutions. Various Open Access Initiatives have been undertaken and are operational. Many are in the developmental stage. Some Initiatives have also been taken in the area of metadata harvesting services, particularly publicly funded ones. He claimed that the future of open access in India is dependent upon a proper policy and developing a proper framework: in the implementation of open access, LIS Professionals should play a proactive role in the growth of collections in Institutional Repositories. The paper provides an overview about the present state of Open Access Initiatives by various institutions of the country.

Koganuramath (2006) discussed the future plans towards implementation of Institutional Repositories in JNU Central Library and also described some of the available Institutional Repository (IR) software. He stressed that IR is the one and only way to make the whole world know the esteem of a university. Being a premier university in teaching and research programmes, IR aims to manage networked information services, research work for benefits of faculty, students, and research scholars.

Chakravarty (2006) in the paper titled "Institutional Repositories: A Perspective for the Universities," discussed the current situation of scholarly communication. According to him, the world is witnessing a sea change in the area of scholarly communication. Perhaps the control over scholarly communication has started a gradual shift from commercial publishers to academic organizations and many authors initiatives in the area of Open Access. OA is perhaps opening up the major barriers that higher education institutes and libraries face, especially when it comes to escalating journal prices and shrinking budgets. Institutional Repositories are one of the two most powerful tools to empower and strengthen the open access movement. Universities and other academic institutions of the developed countries are already reaping the rich benefits of IRs. He emphasizes that the technology is free, the software is available free of cost, and the universities are also having the necessary infrastructure for implementing institutional repositories at their premises. The only required link that is missing is the awareness and willingness. He argues that it is high time that Indian universities make a decision and a strong commitment to develop institutional repositories and convince the faculty members and research scholars to deposit papers in digital archives. He also considered that IR may also contain learning objects in digital formats, thus facilitating IT-enabled pedagogy in Indian Universities.

Rao (2007) in the paper "Institutional Repository: A Key Role for Libraries," mentioned that institutional repository is a digital archive, owned and maintained at institutional level. It is a tool for collecting, storing, and disseminating information to advance scholarly communication. This paper also mentioned essential elements of institutional repositories. He also discussed the challenges for creating

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

institutional repositories at a national level. The key role of the libraries in successfully implementing the institutional repositories is discussed.

Vishala (2007) in the article "Building Institutional Repository: Role of the Library" emphasized in an intellectual life and output of an institution. Institutional repositories are being recognized as an essential infrastructure for scholarship in the digital world. The paper seeks to provide an overview of institutional repositories and their benefits to the institutions and also describes the role of library in building institutional repositories.

Singh (2007) in this article titled "Open Source Software: A Comparative Study of Greenstone and DSpace," provided the information that software is available free of cost with source code for anyone to use. Open source software reduces the cost of creating digitization. Among open source software, Greenstone and DSpace are becoming more popular in India. This paper deals with comparisons of these two popular open source softwares. This paper helps the professionals who are planning to create and help the professionals who are planning to create an institutional repository.

Potel (2007) in his paper titled "Institutional Digital Repositories/e-Archives: INFLIBNET Initiatives in India," the author describes the technological advances, storing knowledge in less-expensive ways to create institutional preservations. INFLIBNET (Information and Library Network centre) decided to opt for DSpace for institutional repository and archive its publications, conference proceedings, and lecture notes. Tghe paer narrated the practical experiences and provides an overview of INFLIBNET's Institutional Repository and Digital Archive-India developed for the Indian academic and research community to archive their intellectual work.

Gyatri (2007) in her paper titled "Sharing Digital Resources with an Institutional Repository," emphasised on the need for storing, reusing, and sharing these digital information resources for knowledge sharing and conservation of time and effort. She discussed the concept of IR as "collection of digital objects" is where digital content assets are stored, searched, and retrieved for later use. Institutional repositories are being developed by academic institutions for the purpose of knowledge sharing, reuse, and preservation. This paper discusses the DSpace open source digital repository software, implemented at ICFAI Business School, Ahmadabad, and highlighted the need for information sharing.

Khan (2008) in his paper titled "An Assessment on Present Situation of Institutional Digital Repositories in India: A Study," highlighted the present status of Institutional Repository (IR) in India by its collection type, subject coverage, and total number of digital repository collection available to the academic community as open sources. For this purpose, the directory of Open Access Repositories (Open DOAR) and the Registry of Open Access Repositories (ROAR) have been consulted. This paper focuses to develop humanities and social sciences, institutional repositories in India. Results have been shown by collection type and subject coverage.

Nazim (2008) in his paper titled "Open Access Journals and Institutional Repositories: Practical Need and Present Trends in India," described trends in open access publishing in India. Data was collected from directors of Open Access Journals and Institutional Repositories. The URL of each Institutional Repository and Open Access Journal was visited to collect relevant data and included information from earlier studies. Case study method was used to know the trends of open access publishing in India. The data is analysed based on certain parameters, such as number of Institutional Repositories and Open Access Journals, number of documents, software used, types of documents, etc. Among the top 25 Open Access publishing countries, India ranks 12th for the overall number of journals, but drops to 18th for journals with online content. However, its positioning in the list of open access journals is fifth. At

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

present, India ranks 12th in the list of countries with registered interoperable archives in the Registry of Open Access Repositories (ROAR).

Kamila (2009) in her paper titled "Institutional Repository Project in India," discussed the concept of the Institutional Repository, its relevance, merits, software requirements, and current trends in India, with special reference to the initiatives at Burdwan University, Burdwan.

Antelman (2010) in his article titled "Do Open-Access Article Have a Greater Research Impact?," Focussed at four disciplines at varying stages of adoption of open access—philosophy, political science, electrical and electronic engineering, and mathematics—to see whether they have a greater impact as measured by citations in the ISI web of science database when their authors make them freely available on the Internet. The finding revealed that, across all four disciplines, freely available articles do have a greater research impact. Shedding light on this category of open-access reveals that scholars in diverse disciplines are adopting open-access practices and being rewarded for it.

Dev (2010) in his article titled "Institutional Repository," urged to create a way for organizations to provide users with a method for self-service preservation and dissemination of digital users with a method for self-service preservation and dissemination of digital information. He found that, many organizations have reported difficulty convincing users to voluntarily deposit material into their repositories. The paper discussed the experience of The University of Rochester and carried out studies of its faculty and students to determine the reasons for their lack of interest in using the repository. Driven by these user needs, the University of Rochester created institutional repository which offers tools for authoring, collaboration, portfolios, and analytics—providing value throughout the authoring and academic lifestyles.

Bhat (2010) in his paper titled "Open Access Repositories in Computer Science and Information Technology: An Evaluation," the author explained evaluation of nine Open Access Repositories in the field of computer science IT. The repositories were identified from the open DOAR, Directory of Open Access Repositories (http://www.opendoar.org/), the findings revealed that most of the repositions are maintained by 1-2 faculty members on a part-time basis. Most of the repositories follow policies for selection of content and submission of documents have provision for withdrawal of content by the authors and voluntary faculty deposit policies. Backups are taken for short-term preservation of the content, but still no strategies for long-term preservation of the content. He observed that authors are responsible for ensuring copyright compliance of their articles. Most repositories have feedback from users. A few repositories provide access statistics. The paper provided recommendations for the establishment and management of open access repositories.

Nazim, M., and Mukherjee, B. (2011). The article discusses the status of institutional repositories (IRs) in Asia, with information on the effect of information communication technologies (ICT) on academic publishing. Topics include the efforts to launch an Open Access (OA) model that utilizes the Internet to broaden access to information resources and publications, the definition of IRs as a platform through which the research output of a specific university or research organization is available, and the growth and distribution of IRs throughout Asian countries based upon the survey results.

Jain, P. (2011). The paper reviewed the recent literature about institutional repositories (IRs) including the benefits and possible obstacles of setting up an IR. It discussed librarians' and authors' participative roles and open access. The findings reveal that in spite of all the obstacles to successful implementation, including associated negative perceptions, IRs have been increasingly recognised as a vital tool for scholarly communication and an important source of institutional visibility and a viable source of institutional knowledge management. The paper aimed at institutions with low-use repositories and at institutions considering initial development of an IR. The paper outlines the implications for IR practice

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

for different groups, namely authors, librarians and academic administrative staff. It could, therefore, be used to persuade and influence different sets of stakeholders at institutions with under-populated or embryonic IRs, about the value of open access, the importance of depositing material and the potential functionality afforded by IR packages.

Krishnamurthy, M. M., and Kemparaju, T. D. (2011). The purpose aimed to study the IRs in use in Indian universities and research institutes. Repositories in various institutions in India were accessed and described in a standardised way. The 20 repositories studied covered collections of diverse types. Most of these collections have unique content. Originality/value - The goal of this study is to study the IR software and data based on the content type, metadata and characteristics. The paper also describes the collections and some important observations from this study.

Sawant, S. (2012). The study aimed to investigate various issues concerning the management of institutional repositories (IRs) developed in India. The survey method was used with the help of a web questionnaire. The questionnaire was e-mailed to the entire population i.e., all IRs identified in India. It was observed that 79 per cent of the institutions had used the DSpace IR software package. The respondents considered end-user interface to be the top-ranking IR-system feature. It was found that all IRs supported text (HTML, Postscript, PDF, Spreadsheet etc.) file formats. Half of the respondents marked bitstream copying as a long-term preservation strategy. Almost all institutional repositories were OAI-PMH compliant.. The study identified the existence of 16 functional IRs, some of which were not registered in any of the directories such as ROAR or Open DOAR.

Roy, B., Mukhopadhyay, P., and Biswas, S. (2012). The article presents the results of an analytical study investigating institutional digital repositories (IDRs) in India. An overview of the goals of IDRs and their association with the open access movement has been discussed. It was observed that the IRs are developing at a reasonably rapid pace in India and that they have the potential to be a very useful resource is commented on. Detailed information on the structure, policies, and capabilities of the 60 Indian IDRs studies is also offered and commented on.

Nagra, K. A. (2012). The author observed that IRs are increasingly becoming an essential component of academic institutions. An institutional repository showcase scholarly and research output to the wider community, and significantly helps in institutional advancement and outreach. It has the benefit of sharing and marketing research with others. It also provides an opportunity to raise the profile and brand awareness of an institution, faculty and students to the global community. Building an effective and successful institutional repository for an academic institution requires careful planning and enthusiasm from the institution's community. This article describes the detailed steps based on the review of the literature and the author's experience in creating institutional repositories. The libraries need to make critical decisions and choices before designing or redesigning institutional repositories. Among them are the funding, staffing, technology, metadata, content and operations to build, manage and run the institutional repositories successfully.

(Johnson, 2002; Nagahban, 2010). A study of nine libraries in the National Capital Region of India was conducted to: identify the benefits of IRs, learn the satisfaction level of users with respect to IR facilities, identify the incentives for publication in IRs, and identify the appropriate policies to be adopted by institutions for implementing IRs. The results of the responses from the 496 respondents indicate that: 1) Most Faculty members and Research scholars in this study indicated that they do not publish their research in IRs. 2) Opinions about the benefits of IRs are user-specific. For instance, a substantially larger percentage of those Faculty members and Research scholars in the study who do use IRs are Most satisfied with potential benefits of IR while a relatively higher percentage of Students fall in the Satisfied

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

category. 3) The benefits of IRs ranked higher, although this varied by the different user groups was wider readership. Students ranked this and "quality aspect" – the opportunity to improve the quality of one's work through the provision of feedback from other researchers. 4) A serious concern about publishing in IRs is the potential for plagiarism and overall lower control over one's work. A second concern is the potential loss of content in IRs, which are often not archived as well as scholarly journals are. The findings suggest that institutions need to give due attention to policies related to two aspects of publication, especially those related to quality and copyright issues and to the academic value of research output. Other policy-related topics include a citation in another publication with due acknowledgement, inclusion in indexing systems for retrieval, interoperability with other IRs, and Permanent storage.

Haridasan, S., and Rani, K. (2012). The article offers information on the research conducted to evaluate the Institutional Repositories (IRs) initiatives in Indian universities. It mentions that the Electronic Thesis or Dissertation (ETDs) is the most commonly deposited material in IRs. It revealed that Dspace is the commonly used software and English is the most prominent language used by all IRs and the popularity about IRs can be increased through postings in list serves, web search engines and metadata harvesting services.

Fralinger, L., and Bull, J. (2013). The authors attempted to identify factors that might affect the international usage of US IRs as part of assessment efforts to determine an IR's return-on-investment. A survey was disseminated to IR administrators asking for demographic information, international usage counts for website hits and downloads, and any internationalization efforts connected to the IR in order to determine any influencing factors on an IR's international usage. While many IRs reported various rates of international usage, the largest group of respondents did not report an international usage rate for both page hits and downloads, despite overwhelmingly expressing an importance of international traffic to their IR and parent institution. Research limitations/implications – It is not clear if this non-reporting of international usage could be due to ignorance, apathy, or lack of technological support on the part of the IR administrators. Practical implications – Determining international usage as a part of an IR assessment might be problematic or even impossible for many US IRs. Originality/value – This study suggests that many IR administrators either do not know, do not care, and/or cannot record international usage data for their respective IRs, which could hinder determining an international return-on-investment for the IR.

Inefuku, H. W. (2013). In the interest of providing access to and preserving scholarship produced by faculty, students and staff, many universities have developed and implemented institutional repositories. Repositories are often organized into communities that correspond to campus units, including departments, research centres and institutes, and administrative offices. Universities, however, frequently undergo academic restructuring, which can make repository organization out of sync with university organization. This article addresses the impact of academic restructuring on repositories and looks to practices from archival arrangement and description to create repository organizational structures and community descriptions flexible enough to reflect the university organization, despite changes arising from academic restructuring.

Ruiz-Conde, E., and Calderón-Martínez, A. (2014). Are institutional repositories mere warehouses for digital documents or are they in fact establishing themselves as a rigorous option for the spread of scientific knowledge? This study analyses the competitive environment of the Top100 university repositories, defined as leaders in terms of market participation and penetration. The study also analyses the basic functionalities of preservation and diffusion of academic production through factors related to the prestige of the repositories and of the institutions that operate them. The results show that repositories with a larger digital academic supply are associated with the production of demonstrated scientific rigour.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Nwadiuto Igwe, K. (2014). The paper is a blueprint designed for the development of the country, with emphasis on making it one of the top developed economies by the year 2020. The study showed that knowledge/information (its generation, acquisition, utilization and possible application) was not accorded the due attention as a tool for the vision's success. Added to the above statement is the fact that the research findings and intellectual output of higher education institutions (HEIs) and research-based institutes in the country mostly in the form of grey literature (i.e. Unpublished technical/research reports, manuals, theses and dissertations, monographs, etc.) gather dust in their institutions of origin, with little or no visibility, thereby affecting accessibility, utilization and application. This paper advocated for a national policy for the development and management of open access repositories in institutions, where the research findings and intellectual outputs of these institutions will be domiciled, which will be easily accessible online for utilization and possible application in various sectors of the economy for the realization of vision 20: 2020.

6. INSTITUTIONAL REPOSITORY (IR): AN INTRODUCTION

Clifford Lynch defines IR as " a university-based Institutional Repository is a set of services that a university offers to its members of its community for the management and dissemination of digital materials created by the institution and its community members. It is most essentially an organizational commitment to the stewardship of these digital materials, including long-term preservation where appropriate, as well as organization and access or distribution." Foster and Gibbons describe IR as "an electronic system that captures, preserves, and provides access to the digital work products of a community." Wikipedia defines IR as "an online locus for collecting and preserving in digital form the intellectual output of an institution, particularly a research institution. For a university, this would include materials such as research journals, articles before (pre-prints) and after (post-prints) undergoing peer review and digital versions of theses and dissertations, but it might also include other course notes, or learning objects."

6.1 Types of Material

Types of resource material include blue print, pre-print, post-print, working paper, thesis/dissertation, technical report, conference papers, progress reports, research articles, A-V chips, teaching material, diversity of contents and language used in full texts undergoing peer review and digital versions of course notes. The contents can be classified, restricted, or unrestricted/open.

6.2 Characteristics of Institutional Repositories

- Promote self-archiving.
- Are institutionally defined rather than subject based.
- Have wider distribution.
- Increases dissemination, collect content in a single location.
- Are supported by Scholarly Communication.

The following characteristics of Institutional Repository (IRs) are outlined by Crow (2002) Shearer (2003) and Ware (2004):

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

- **Digital:** IR collect mainly digital information. This is different to the mandate of the university archives which is to collect all types of content related to the university
- **Institutionally Defined:** Unlike the traditional discipline-specific and digital libraries, institutional repositories capture the research of the entire population of the institution
- Institutional repositories collect scholarly material exclusively. In this context, scholarship includes (preprints, post prints, technical reports, etc.)
- **Cumulative and Perpetual:** This refers to the long-term nature of data preservation and accessibility through IR
- **Open Access:** A key defining feature of IR is the free and open access to their content
- **Interoperability:** This refers to the fact that IRs can be used by both data providers (who expose data in various forms) and service providers (who process and add value to the data)
- **Self-Archiving:** Most IRs requires the author or someone associated with the author to deposit the content directly.

6.3 Need and Advantage

Institutional Repositories facilitate innovation, wider access, visibility to research output, preserve institutional heritage, reduce publication delay, faster communication, increase citation, strength research, easy access to grey literature, persistent URL, research work archive. While the most popular open source and hosted applications share the advantages that institutional repositories bring to institutions, such as the increased visibility and impact of research output, interoperability and availability of technical support, institutional repository advocates tend to favour open source solutions for the reason that they are by their nature more compatible with the ideology of the freedom and independence of the internet from commercial interests. On the other hand, some institutions opt for outsourced commercial solutions.

In her briefing paper on open access repositories, advocate Alma Swan lists (Swan, Alma. "Open Access institutional repositories: A Briefing Paper". *Open Scholarship*. Retrieved 24 September 2013.) The following as the benefits that repositories bring to institutions:

- Opening up outputs of the institution to a worldwide audience;
- Maximizing the visibility and impact of these outputs as a result;
- Showcasing the institution to interested constituencies – prospective staff, prospective students and other stakeholders;
- Collecting and curating digital output;
- Managing and measuring research and teaching activities;
- Providing a workspace for work-in-progress, and for collaborative or large-scale projects;
- Enabling and encouraging interdisciplinary approaches to research;
- Facilitating the development and sharing of digital teaching materials and aids, and
- Supporting student endeavours, providing access to theses and dissertations and a location for the development of e-portfolios.

The Institutional Repository will:

- Help to develop National Research Repository infrastructure by setting up, populating, and linking individual repositories.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Stimulate development of services that draw on research information made available through the repository infrastructure.
- Provide a window that gives open access to improve the sponsoring institution visibility and status.
- Support the Open Access model of publication.

Institutional Repositories are an online locus for collecting, preserving, disseminating in digital form. Institutional Repositories are intellectual research output of an institution. It manages and disseminates its research material created by community members. Librarian plays a role of a leader in planning and building these repositories. They act as experts in the collection, preserve for document and providing digital information.

7. RESEARCH METHODOLOGY

The present study uses *Open*DOAR for generating a list of IRs in the field of Medicine and Biology. *Open*DOAR is a project to provide a comprehensive and authoritative list of repositories categorised by several criteria like country, software, subject, etc. It has two subject categories related to the scope of the present study. One is Biology and Biochemistry and the other is Health and Medicine. Indian IRs under these two subject categories were explored for further study. Eight IRs was listed under each subject category respectively, with minor overlapping. The total number of relevant IRs after combining the results of the two lists and removing the overlapping comes out to be 12. For the purpose of data analysis last five year data were collected from individual repositories.

Table 1. List of Indian IRs in medical biology

SN	Repository Name	No. of Records	Software	Status
1	CMFRI Digital Repository	9661	EPrints	Operational
2	Digital Knowledge Repository of Central Drug Research Institute (CDRI)	796	DSpace	Operational
3	ePrints@NII	10	EPrints	Broken
4	EPrints@NIRT	830	EPrints	Operational
5	Eprints@SBT MKU	89	EPrints	Broken (data till October 2011)
6	Indian Institute of Petroleum (IIP) Institutional Repository	454	DSpace	Broken
7	Institutional Repository@CSIO	311	EPrints	Operational
8	IR@NPL	996	EPrints	Operational
9	Eprints @MDRF	676	Eprints	Operational
10	Open Access Repository: Indian Academy of Sciences	91745	Eprints	Operational
11	KNOOR: Knowledge Repository Open Network	911	DSpace	Operational
12	OpenMED@NIC	2904	Eprints	Operational
Total		**108502**		

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

8. DATA ANALYSIS

Out of these twelve repositories, 3 were found to be broken, i.e. non-functional. The Open Access Repository of Indian Academy of Sciences (publications of Fellows) has maximum number of records – 91745. Table 2 also reveals that the total research output under OA by these IRs in Medicine and Biology including Pharmacology is 108502.

Indian IRs has a share of 5.84% of the total IRs in Biology and Biochemistry whereas its contribution is 3.2% in the discipline of Health and Medicine. Table 2 also reveals that Indian IRs in Medicine and Biology at global level is 4.12%.

Figure 2 reveals that 15% Indian IRs are dedicated to Medicine and Biology and 85% are dedicated to other disciplines.

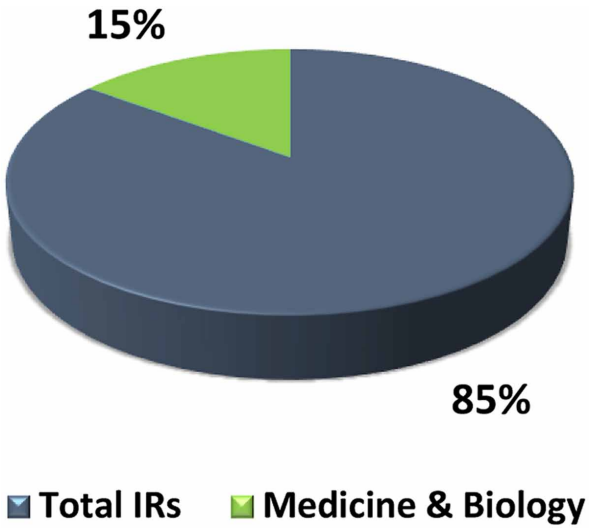

Figure 3 depicts that The Open Access Repository of Indian Academy of Sciences has the highest share of scholarly outputs in Medicine and Biology. While the CMFRI Digital Repository has 9661 records followed by OpenMED@NIC which has only 2904 records, although it specifically deals in Medical Sciences.

DSpace is an open-source digital asset management system originally created by developers from MIT and HP Labs in 2002. EPrints is a free and open-source software package originally developed by researchers at the University of Southampton School of Electronics and Computer Science in 2000 (making it the oldest of the platforms in this report). It was designed specifically for archiving research

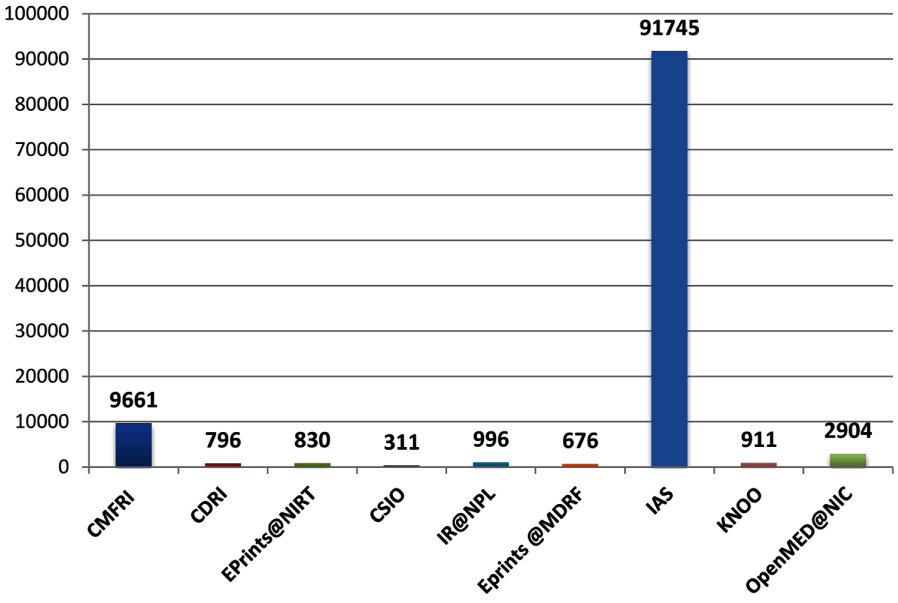
Table 2. Share of Indian IRs in medicine and biology at global level

SN	Discipline	World	India
1	Biology and Biochemistry	137	8 (5.84%)
2	Health and Medicine	251	8 (3.2%)
	Total	388	16 (4.12%)

Figure 2. Medicine and biology IRs of India

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Share of scholarly literature by Indian IRs



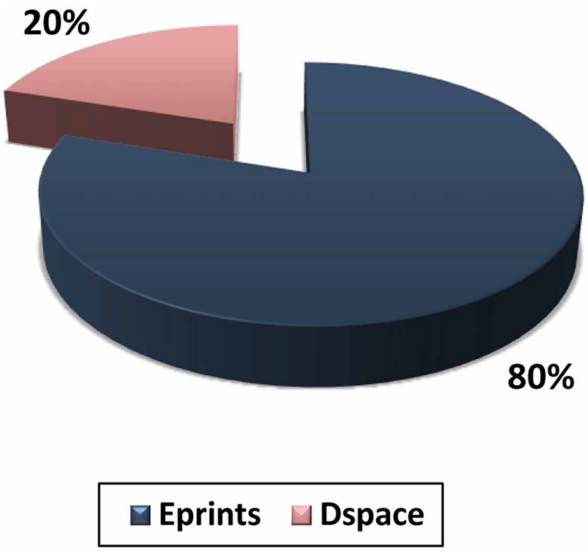


Figure 4. IR software preference

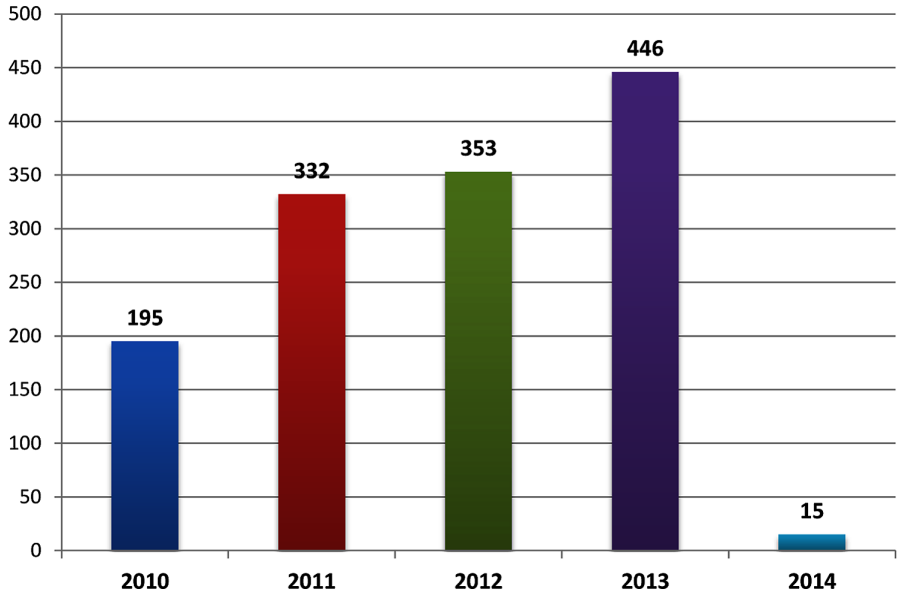
papers, theses and teaching materials, though it can accept any content. The other popular IR software includes Fedora, Figure 4 reveals that 80% of the Indian IRs on selected discipline are running on Eprints software whereas only 20% of the IRs are based on Dspace.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

9. INDIAN IR IN MEDICINE AND BIOLOGY

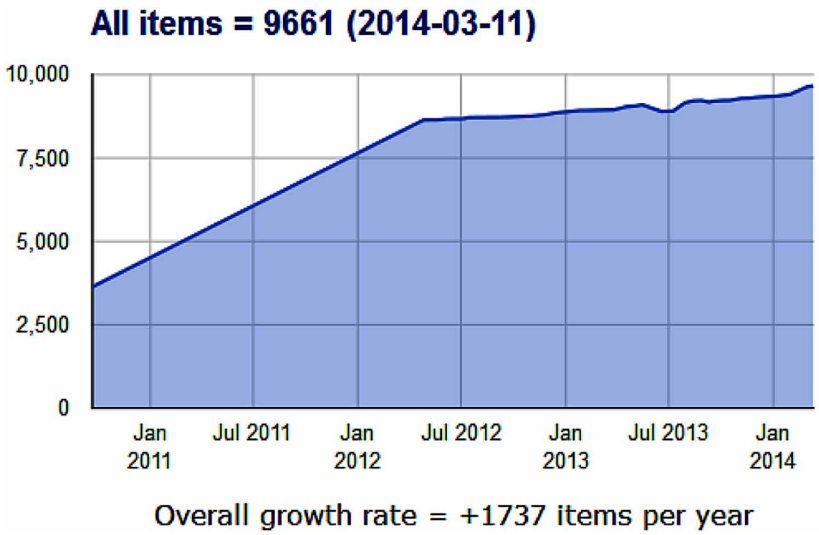
9.1 Eprints@CMFRI



Eprints@CMFRI is the Open Access Institutional Repository of Central Marine Fisheries Research Institute. The research outputs of CMFRI include: journal papers, conference papers, reports, theses, patents etc. - are uploaded/self-archived by CMFRI scientists who do research on fisheries and related areas. Interested users can freely download and use documents as most of them are directly accessible and full-text downloadable. 'Request Copy' forms can be used for documents to which direct full-text download is restricted due to publisher embargo.

Figures 5 and 6 reveal that there is a significant rise in the number of scholarly content from 2011 which continued up to 2012. After July 2012 it has maintained a constant growth rate with the minor upward trend. The figure also reveals that the overall growth rate is over 1737 items per year.

9.2 Digital Knowledge Repository of Central Drug Research Institute (DKR@CDRI)

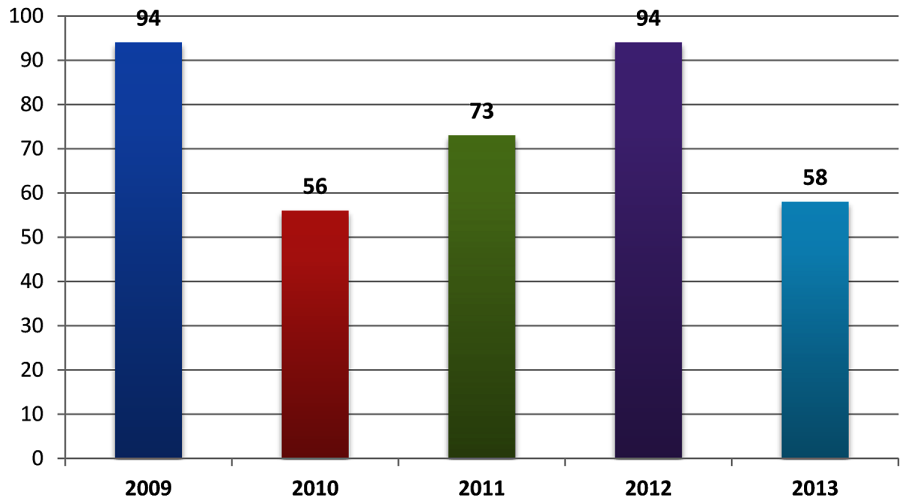


CDRI is considered to be a pioneer multidisciplinary research organization in the field of biomedical research where all the infrastructure and expertise are available to develop a drug right from its concept to market. The very latest techniques and methodologies are employed for developing drugs, diagnostics and vaccines to combat diseases prevalent among mankind in general and Indian population in particular. For administrative and scientific purposes the Institute's manpower has been grouped into 17 R&D divisions and few divisions providing technical and scientific support. In order to carry out work in cohesion and in a focused environment, the research works have been grouped into following six major

Figure 5. Growth rate of CMFRI IR

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 6. Growth statistics of CMFRI IR 2011 onwards



research areas. DKR@CDRI strives to collect, preserve and disseminate different institutional publications (journal articles, conference proceeding articles, technical reports, thesis, dissertations, etc.). Users can search, browse and access publications of CDRI from this collection.

Figure 7 indicates that the highest number of e-prints were archived in the year 2009 and 2012 (94 each). However, there is a downfall in the number of records in the year 2013 as only 58 records were added during this year.

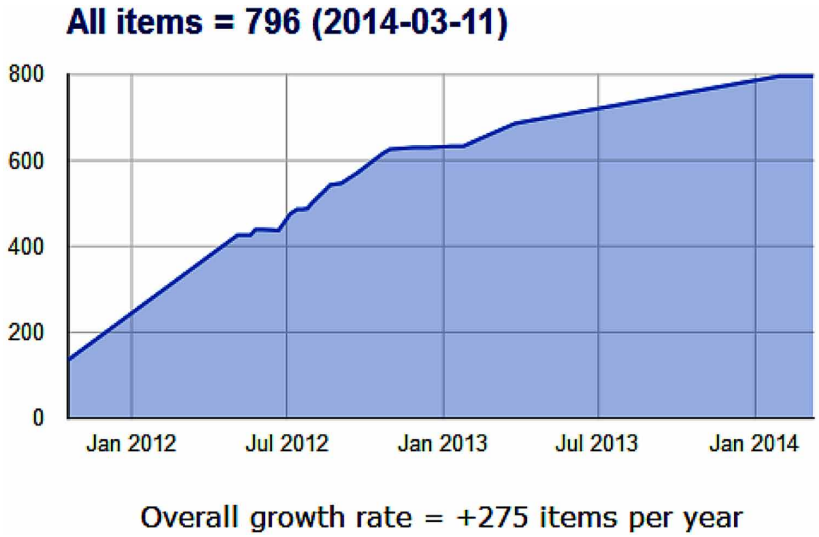


Figure 8 reveals that there is a rise in self-archiving from 2012 and is mentioned upto January 2014. This is a positive sign as more scholarly work is now available under open access. The figure also reveals that the overall growth rate is over 275 items per year.

Figure 7. Growth rate of DKR@CDRI

Figure 8. Growth statistics of DKR@CDRI 2012 onwards

9.3 EPrints@NIRT

The National INstitute for Research in Tuberculosis (Formerly Tuberculosis Research Centre (TRC)), a permanent institute, under the Indian Council of Medical Research (ICMR), is an internationally recognized institution for Tuberculosis (TB) research. It is a Supranational Reference Laboratory and a WHO Collaborating Centre for TB Research and Training. Recently, an International Centre for Excellence in Research (ICER) in collaboration with NIH was established at the Centre. The centre evolved supervised intermittent chemotherapy, especially in urban areas and large cities subsequently. Later, treatment for approximately 6 months with powerful drugs has been shown to be equally effective and these regimens were evaluated under field conditions.

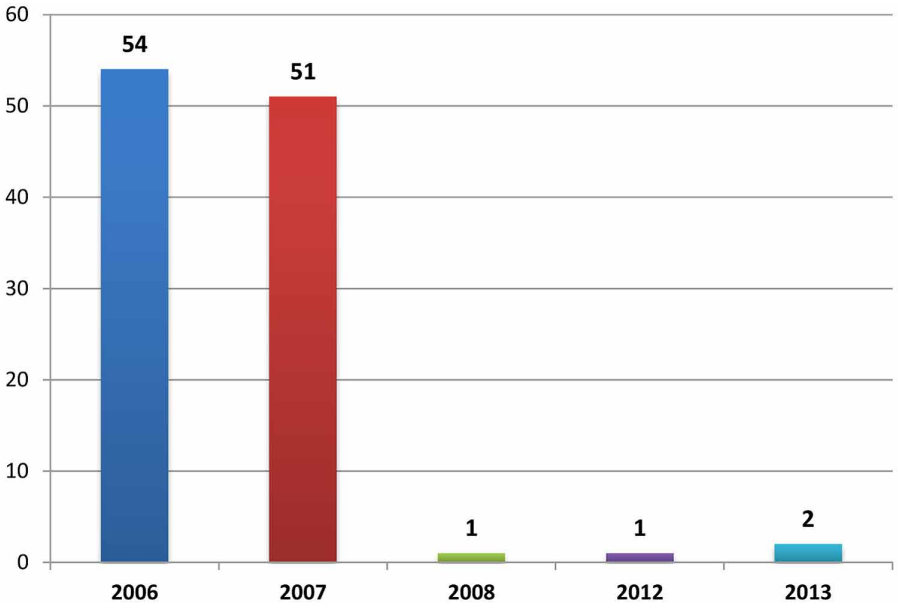
This is the Institutional Repository of the National Institute for Research in Tuberculosis (NIRTIR) Chennai, India. A scholarly archiving facility for NIRT scientific community, where the institute's intellectual output is preserved, searched and shared. The archive runs on EPrints, an open source software package. We expect the service to facilitate long-term preservation of our research output and provide easy access to these publications, as well as improve their impact. Further, by making our research findings freely available, we hope to contribute to the expanding knowledge base in the global fight against tuberculosis.

The data collected from EPrints@NIRT presents a very sad picture as we can see that after the year 2007 there is a steep fall in the deposit rate (Figure 9). To get the idea of post 2012, the IR growth chart from OpenDOAR was consulted which is reproduced in Figure 10.

Figure 10 reveals that the self-archiving momentum picked up from August 2013 and continued aupto December 2013 after which it become steady.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 9. Growth rate of EPrints@NIRT



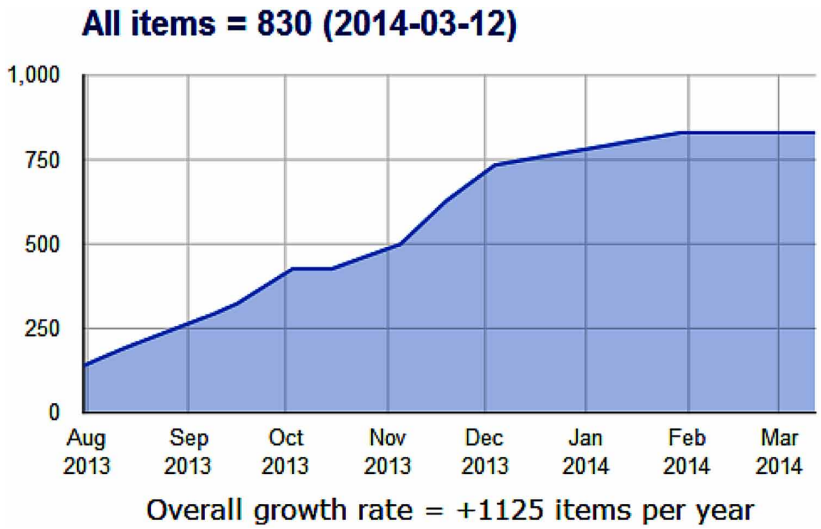


Figure 10. Growth statistics of EPrints@NIRT 2013 onwards

9.4 EPrints@CSIO

Central Scientific Instruments Organisation (CSIO), a constituent unit of Council of Scientific & Industrial Research (CSIR), is a premier national laboratory dedicated to research, design and development of scientific and industrial instruments. It is a multi-disciplinary and multi-dimensional apex industrial research & development organisation in the country to stimulate growth of Instrument Industry in India covers wide range and applications.

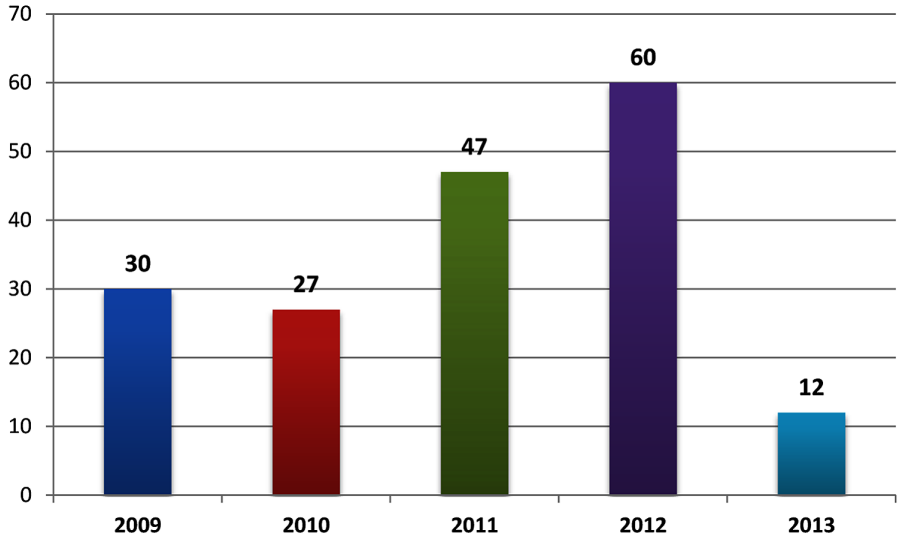
EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

CSIO's Institutional Repository is the digital archive of the research output of our scientists. This knowledge base covers journal articles, conference papers, technical reports, presentation/lectures, pre-prints, Thesis, images etc. One can browse the documents by author, division, subject, date and document type. Both simple and advanced search facilities have been provided. CSIO scientists are welcome to submit their publications on their own by registering.

Figure 11 reveals that the highest deposit ware made in the year 2012 whereas only 27 submissions were made in 2010. In the year 2013, the IR has observed lower self-archiving rate. For post 2012 self-archiving rate the OpenDOAR date is presented below.

Figure 12 reveals that the archiving rate is almost constant from September 2013 to March 2014 and the overall growth rate is above 45 per year.

Figure 11. Growth rate of EPrints@CSIO



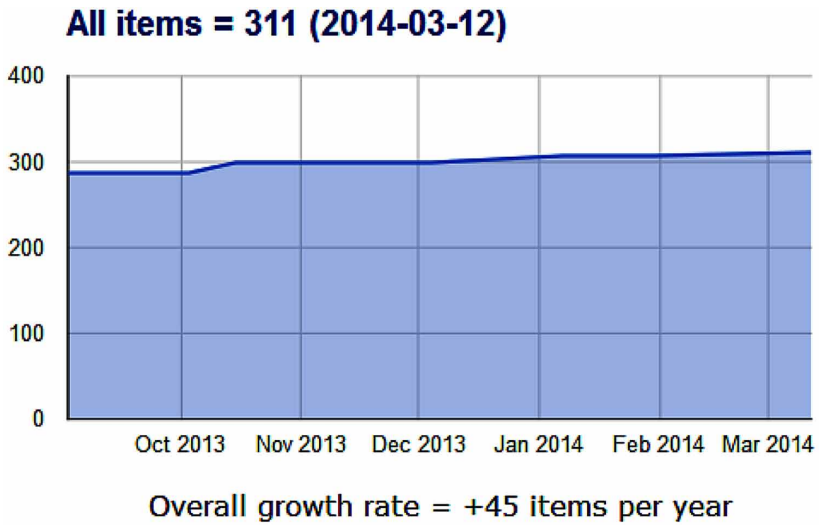


Figure 12. Growth statistics of EPrints@CSIO 2013 onwards

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

9.5 Eprints@SBT MKU

This is official website of School of Biotechnology (SBT), Madurai Kamraj University (MKU). This repository provides access to the research output of the institute. Users may set up Atom or RSS feeds to be alerted to new content. The software used is EPrints, the subjects covered are biology and biochemistry, content covered are articles and language used is English. As the repository is now in broken stage data is available till 2011 only. Figure 13 shows the growth rate of collection in SBT MKU EPrint@ NML from 2006 to 2011.

9.6 IR@NPL (National Physical Laboratory)

IR@NPL has been established/maintained by the National Physical Laboratory (NPL), New Delhi, India. It is an online digital archive of research outputs of Scientists/ Researchers of the NPL. The purpose of IR@NPL is to capture, preserve and provide free worldwide access to the intellectual outputs of the NPL in the form of journal articles, research papers, conference papers, technical reports, preprints, technical bulletin, annual reports, golden jubilee document, sameeksha etc. IR@NPL can be accessed globally, but submission of documents to this repository is reserved only for the NPL community. Deposits in this repository can be browsed by author, subject, year and document type, also have simple and advance search facility.

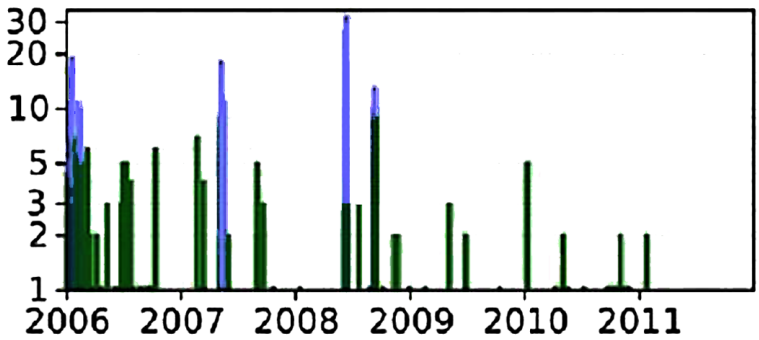

Figure 14 reveals that the highest archiving was done in the year 2010 (343) followed by the year 2009 (312), 2011 (165) and 162 in the year 2008. Lowest submission was observed in the year 2012.

Figure 15 reveals that there has been a constant submission rate after August 2013 and is maintained till March 2014. According to the above graph, the overall growth rate is more than 74 items per year.

9.7 Eprints @MDRF

The prevalence of Diabetes Mellitus is growing in epidemic proportions all over the world, particularly in India. It is now known that India has the highest number of diabetic subjects, in the world even higher than China and USA. India has the highest prevalence rates of diabetes i.e. about 20% of the total diabetic population in the world. In 1996, Dr. V. Mohan and Dr. M. Rema felt the need for an exclusive

Figure 13. Growth rate of EPrints@SBT MKU

Diabetes Research Foundation to do original research work with the excellent infrastructural facilities. This resulted in the setting up of the Madras Diabetes Research Foundation (MDRF)

MDRF scientists do research on Diabetes and related fields and publish the outputs in professional journals and conferences. With a view to eliminating barriers to access our local research outputs, this open access repository has been set up. Here MDRF scientists archive post-prints of the research papers soon after it is accepted by journal publishers. In some cases published version is archived with “Request

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Copy" facility. Users can send "article request" through this facility. Dr. MGR Medical University and University of Madras have recognized MDRF as a research centre for the PhD program. Eprints@MDRF holds all the theses guided by MDRF scientists

Figure 16 displays the deposit rate of pre and post prints in the MDRF repository during the year 2010 to 2014. The figure reveals that the submission rate has neither witnessed a steep rise or downfall in the submission rate. However, only three submissions were being made at the time of writing the paper (March 2014).

Figure 17 depicts the growth rate of research publications after October 2013. The overall growth rate is above 90 items per year.

Figure 16. Growth rate of Eprints @MDRF

9.8 Open Access Repository: Indian Academy of Sciences (IAS)

The Indian Academy of Sciences was founded and registered as a society in 1934 with the aim to promote the progress and uphold the cause of science, both in pure and applied branches. We strive to meet our objectives through original research and dissemination of scientific knowledge to the community via our meetings, discussions, seminars, symposia and publications. The academy as on date has around 1,500+ Fellows, out of which, past members account for 600-700. It is estimated that the total number of articles published so far by all fellows in various national and international publications could be around 100,000.

Publications of the IAS fellows repository collects, preserves and disseminates in digital format the research output created by the fellows of the Indian Academy of Sciences. It enables the Academy community to deposit their preprints, postprints and other scholarly publications, and organizes these publications for easy retrieval. While Publications of the IAS fellows can be accessed by anybody, submission of documents to this repository is limited to the fellows of the Academy only. Publications of the IAS fellows repository are running on EPrints open archive software, a freely distributable archive system available from eprints.org. Publications of the IAS fellows complies with the Open Archives Initiative (OAI) framework allowing publications to be easily indexed by web search engines and other indexing services.

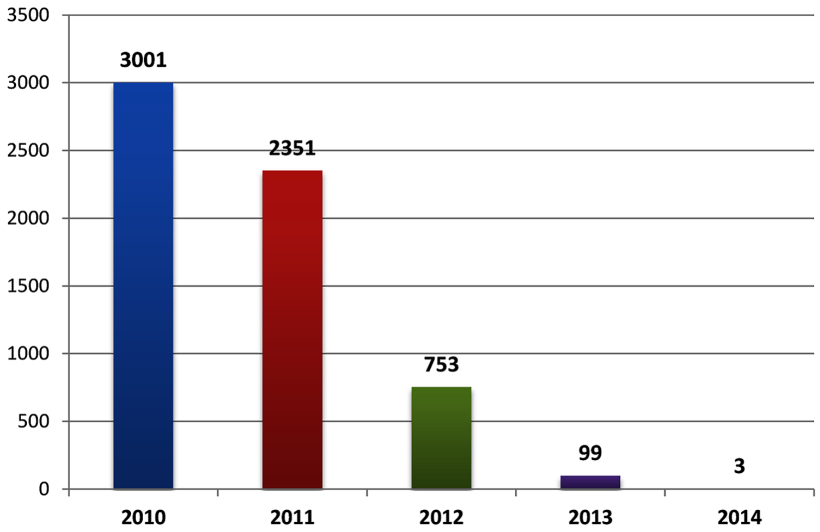

Figure 18 depicts that there is a sharp decline in the growth of IR in terms of archived papers. Number of records submitted in the year 2010 were 3001 which decreased to 2351 in the year 2011 and this trend continued in 2012 (753 records) and 2013 (99 records).

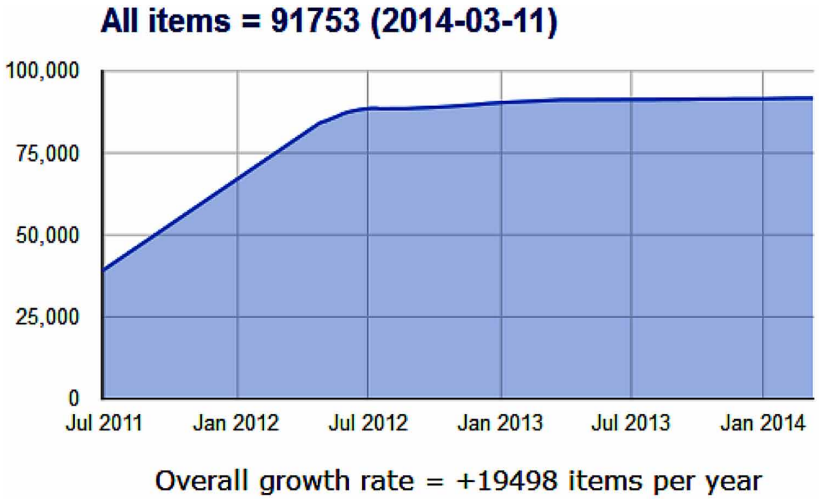
Figure 19 reveals that the overall growth rate of the IR is about 19500 items per year.

9.9 KNoor: Knowledge Repository Open Network



Knoor - Knowledge Repository Open Network is a joint Initiative of Premier Institutes of Jammu and Kashmir (J&K)". This repository is funded by University Grants Commission (UGC), the apex body of

Figure 18. Growth rate of IAS repository

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 19. Growth statistics of Indian Academy of Sciences repository

the Indian Higher Education system under the UGC-Major Project "E-repository for J&K". It provides access to the research output from research institutes of the J&K (viz. S.K Institute of Medical Sciences, S.K University of Agricultural Science & Technology and University of Kashmir). The interface is available in English. Many items are available as abstracts only. Users may set up RSS feeds to be alerted to new content. It provides an interface for the Faculty members and researchers, for creating their own collections in the IR. It also maintains multilingual Phd Theses. Authors are supposed to mail their contributions for uploading in the Repository (peer reviewed papers only OR pre-prints) for their free, open access and high visibility. Authors are also required to check whether concerned publisher permits self-archiving at SHERPA/RoMEO's publisher copyright policies. The service is designed, maintained and regulated by the Department of Library and Information Science (University of Kashmir) with infrastructure support from Directorate of IT&SS, University of Kashmir.

Figure 20 reveals that the growth in the number of IT records has been consistent from 2011 onwards. It decreased from 82 (2009) to 30 (2010) but after that it gained momentum and there has been a constant growth in archiving by the researchers and scientists.

Figure 21 reveals that the self-archiving rate has increased from 2012 to 2014 and the overall growth rate is over 170 items per year.

9.10 OpenMED@NIC

OpenMED is an Open Access Archive in the area of Medical and Allied Sciences, including biomedical, Medical Informatics, Dental, Nursing and Pharmaceutical Sciences. It is international in scope and includes both published (post-prints) and unpublished (pre-prints) peer-reviewed documents having relevance to research in these disciplines. It is hosted by Bibliographic Informatics Division, National Informatics Centre (India) using the GNU EPrints Archive Software. The major objective of OpenMED is to provide a free facility for authors to self-archive their publications for making them available under open access and improve their impact. It encourages authors to make their work visible, searchable and usable by potential users. The metadata (core descriptive information about the documents) is expected to

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 20. Growth rate of KNoor

be aggregated by various service providers and search engines compliant with OAI-PMH (Open Archives Initiative Protocol for Metadata Harvesting). It would help providing the authors the maximum exposure as well as easy and free access to the users. Submitted documents are placed into the submission buffer and becomes part of the OpenMED@NIC archive on their acceptance.

Figure 22 reveals that there is continuing decline in paper archiving as it was 188 in the year 2008 which came down to 38 in the year 2012.

Figure 23 reveals that the overall growth rate for OpenMED repository is 218 items per year.

10. CONCLUSION

An Institutional repository is gradually becoming the life and blood of a research organization as it provides the appropriate platform to showcase the research productivity. At the same time it also serves the humanity by facilitating open access to quality literature. It protects and preserves the intellectual capital of its research scientists.

Number of IRs in the field of medicine and biology specially covering Pharmacology as a subject is very low. Although there are many premier institutions undertaking R&D work in this domain but not all of them are having dedicated Irs. Moreover, the existing IRs lack in collection, excluding a few of them.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

In such a scenario, the authors/scientists should be motivated for motivated for self- archiving. If self-archiving does not attract their attention, the approach of mediated-archiving should be facilitated. Other factors which need to be taken care of include quality, adequate budget for establishing new IRs as well as maintaining existing IRs, proper marketing and promotion of IRs, HR training for metadata creation and metadata harvesting, etc. More IRs in universities should be created, as it will enhance research and growth of the Nation's Research output. IRs should be designed to support and achieve the needs and goals of the institution, as it is the tangible way for the institution to communicate with the rest of the world.

Open Access is very important in the discipline of Pharmacology as humans, howsoever developed and advanced can't win immortality and will continue to suffer from diseases. There is an urgent requirement of free scholarly communication in this field so as to provide state-of-the-art solutions for well being of the society. It should be free from all barriers and should explore optimum benefits of Open Access either by following the golden route (OA Journals) or the green route (self-archiving in IRs).

Chapter 6
Application of Nanoparticles as a Drug Delivery System

Vijay Kumar Singh
Bundelkhand University, India

Raj K. Keservani
Rajiv Gandhi Proudyogiki Vishawavidyalaya, India

ABSTRACT

Small colloidal particles having their diameter in the range of 50 to 500nm are defined as Nanoparticles. These are usually prepared either by using biodegradable or non-biodegradable polymers and are usually classified in two broad categories: (1) Nanocapsules: a type of reservoir system in which an oil or aqueous core is surrounded by a polymeric membrane. (2) Nanospheres: a type of matrix system. Preparation of nanoparticle as a drug delivery system is one of the most widely accepted approach since the prepration of nanoparticle were easy and convenient to scale up. Their high stability and conveniently easy to freeze-dried their preparations provide some additional advantages to choose Nanoparticles as a good drug delivery system. Inspite of them Nanoparticles were were able to achieve with success tissue targeting of many drugs (antibiotics, cytostatics, peptides and proteins, nucleic acids, etc.).

1. INTRODUCTION

In microcapsules drug is encapsulated as small particles or as a drug solution in a polymer fi lm or coat, whereas microspheres are solid polymeric spheres which entrap drug. Equivalent structures with particle diameters ranging from 50 to 500 nm are referred to as nanocapsules and nanoparticles. Nanoparticles (NPs) of different size and physicochemical properties have been introduced to many fields of life and biomedical sciences over the last decade (Oberdörster et al., 2005). It is worth noting that nanoparticles can be made from a fully variety of bulk materials and that they can explicate their actions depending on both the chemical composition and on the size and/or shape of the particles (Brunner et al., 2006). The literature on the ecotoxicity of nanoparticles and nanomaterials as well as the chemistry of both manufactured and natural NSPs is summarized in recent reports (Handy et al. 2008, Yu-Nam & Lead

DOI: 10.4018/978-1-5225-1762-7.ch006

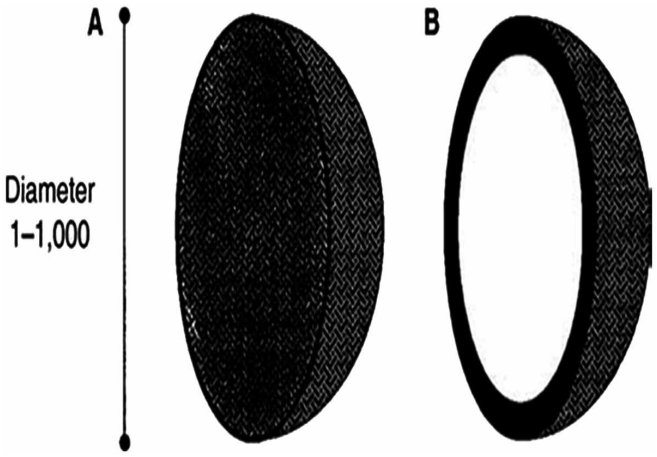
2008). Medical therapies have become more tailored to specific diseases and patients in recent years. Most pharmaceutical agents have primary targets within cells and tissues; ideally, these agents may be preferentially delivered to these sites of action within the cell. Selective subcellular delivery is likely to have greater therapeutic benefits. Cytosolic delivery, for instance, is desirable for drugs that undergo extensive exportation from the cell via efflux transporters such as multi-drug resistance proteins and P-glycoproteins (Faraji & Wipf, 2009).

2. PREPARATION OF NANOPARTICLES

Polymer nanoparticles including nanospheres and nanocapsules (Figure 1) can be prepared according to numerous methods that have been developed over the last 30 years. The development of these methods occurred in several steps. Historically, the first nanoparticles proposed as carriers for therapeutic applications were made of gelatin and cross-linked albumin (Scheffel et al., 1972; Marty et al., 1978). Then, to avoid the use of proteins that may stimulate the immune system and to limit the toxicity of the cross-linking agents, nanoparticles made from synthetic polymers were developed. At first, the nanoparticles were made by emulsion polymerization of acrylamide and by dispersion polymerization of methylmethacrylate (Birrenbach, Speiser 1976; Kreuter, 1976). These nanoparticles were proposed as adjuvants for vaccines. However, since they were made of non-biodegradable polymers, these nanoparticles were rapidly substituted by particles made of biodegradable synthetic polymers. Couvreur et al., proposed to make nanoparticles by polymerization of monomers from the family of alkylcyanoacrylates already used in vivo as surgical glue. They succeeded in making nanoparticles by polymerization of the monomers in oil-in-water type emulsions prepared with an acidified aqueous phase (Couvreur et al., 1979).



During the same period of time, Gurny et al., proposed a method based on the use of another biodegradable polymer consisting of poly(lactic acid) used as surgical sutures in humans (Gurny et al., 1981). In this method, nanoparticles were formed directly from the polymer. Based on these initial investigations, several groups improved and modified the original processes mainly by reducing the amount of surfactant and organic solvents. At that time, the methods developed were only able to produce nanospheres (Figure 1) (Legrand et. al. 1999). A breakthrough in the development of nanoparticles occurred in 1986 with the development of methods allowing the preparation of nanocapsules corresponding to particles displaying a core-shell structure with a liquid core surrounded by a polymer shell. From 1986, there was also an acceleration in the development of new methodologies for the preparation of all types of nanoparticles.

The nanoprecipitation technique was proposed (Fessi et al., 1986) as well as the first method of interfacial polymerization in inverse microemulsion (Gasco & Trotta, 1986). In the following years, the methods based on salting-out, (Alle´man, 1992) emulsion–diffusion, (Quintanar & Guerrero, 1998) and double emulsion (Zambaux, 1998) were described. Finally, during the last decade, new approaches were considered to develop nanoparticles made from polysaccharides based on the gelation properties of these natural macromolecules (Vauthier & Couvreur, 2000a). These nanoparticles were developed for peptides and nucleic acid delivery. Another goal was the development of surface modified nanoparticles to produce long circulating particles able to avoid the capture by the macrophages of the mononuclear phagocyte system after intravenous administration (Gref, 1997).

All the methods can be classified into two groups depending on whether the nanoparticles are formed at the same time than the polymer itself requiring a polymerization reaction or are directly obtained

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Schematic representation of a nanosphere (A) and of a nanocapsule (B). In nanospheres, the whole particle consists of a continuous polymer network. Nanocapsules present a core-shell structure with a liquid core surrounded by a polymer shell.

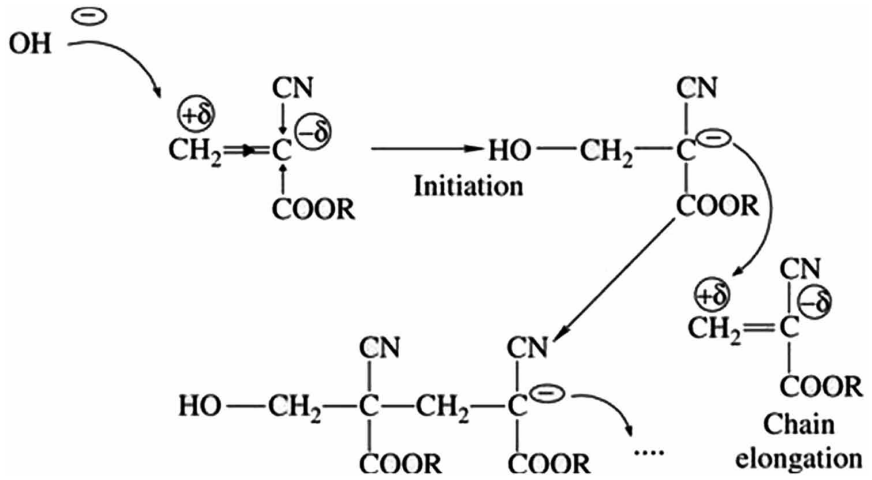
from a polymer. There are numerous valuable reviews on the subject (Quintanar & Guerrero, 1998b). The general principles of the methods leading to nanoparticle preparation are described and details of the most representative over are given.

Preparation of Nanoparticles by Polymerization

Nanospheres (Kucuk & Edirisinghe 2014) are mostly prepared by emulsion polymerization whereas nanocapsules are obtained by interfacial polymerization performed in emulsion or in microemulsion. In emulsion polymerization, the monomer itself, if liquid, is dispersed under agitation in a continuous phase in which it is non-miscible.

The polymerization is usually initiated by the reaction of the initiators with the monomer molecules that are dissolved in the continuous phase of the emulsion.

The polymerization continues by further addition of monomer molecules that diffuse toward the growing polymer chain through the continuous phase. The growing polymer chain remains soluble until it reaches a certain molecular weight for which it becomes insoluble. Therefore, phase separation occurs leading to the nucleation of the polymer particles and the formation of the tyndall scattering effect. Further growth of the nucleated particles occurs according to a mechanism that depends on the stability conditions of the whole system. This includes capture of new growing polymer chains, fusion or collision between nucleated particles (Lowell, 1997). Throughout the polymerization, the monomer input in the continuous phase of the emulsion takes place by diffusion from the monomer droplets, which play the role of monomer reservoirs.



When the reaction is completed, the particles formed contains a large number of polymer chains (Lowell, 1997). Emulsion polymerization can be performed in emulsifier free systems and in both oil-in-water and waterin-oil emulsions. The poly(alkylcyanoacrylate) nanospheres, widely used as drug carriers, are prepared by emulsion polymerization according to a method initially introduced by Couvreur et al. The monomers (isobutylcyanoacrylate, isohexylcyanoacrylate, n-butylcyanoacrylate) are dispersed in

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

a continuous acidified aqueous phase under magnetic agitation. The anionic polymerization of the alkylcyanoacrylate is rapidly and spontaneously initiated by the remaining OH_ ions of the acidified water and is completed within 3–4 h depending on the monomer type (Figure 2). The preparation is performed at low pH (pH _ 2.5) to slow down the anionic polymerization of the alkylcyanoacrylate, therefore allowing the polymer to arrange as colloidal particles. Dextran 70 or Pluronic_ F68 are usually dissolved in the aqueous phase to ensure the stability of the polymer particles. The size of the nanospheres can be controlled by the amount of Pluronic_ F68 from a diameter of 40–250nm for concentrations ranging from 3 to 0%, respectively. (Seijo, et. al. 1990) Numerous drugs have been associated with these nanospheres including doxorubicin, an anticancer agent, a peptide growth hormone, and several antibiotics. Antisense oligonucleotides were adsorbed on the nanosphere surface via the formation of an ion-pair with a cationic surfactant, cethyltrimethylammonium bromide. Finally, it should be mentioned that some drugs can lose their biological activity during the preparation of poly(alkylcyanoacrylate) nanospheres. Generally, these molecules contain chemical functions that are able to initiate the polymerization of alkylcyanoacrylates and be covalently attached to the polymer constituting the nanospheres. The mode of such an interaction has been elucidated for two molecules including phenylbutazone (an anti-inflammatory drug) and vidarabine (an antiviral molecule). In contrast, the side reactions can be used to achieve the covalent linkage of defined compounds to give specific properties to the nanospheres. This has been used with poly(ethylene glycol) that initiated the polymerization of isobutylcyanoacrylate to give poly(ethylene glycol)-coated nanospheres, therefore presenting a more hydrophilic surface than those prepared according to the original method (Seijo, 1990). Methylidene malonates are other monomers that give biodegradable polymers and polymerize according to a similar mechanism than alkylcyanoacrylates. These monomers were also used to make nanospheres by emulsion polymerization for drug delivery (De Keyser, 1991).

Nanocapsules can be prepared by interfacial polymerization of alkylcyanoacrylates. The main advantage of using these monomers is their very fast polymerization rate when they come into contact with water. Oil containing nanocapsules were prepared by the rapid dispersion of an ethanol phase including ethanol, the oil, the monomer, and the molecule to be encapsulated in an aqueous solution of surfactant. When the ethanol diffuses in the aqueous phase, tiny individual oil droplets form, and because of the

Figure 2. Anionic polymerization of alkylcyanoacrylate initiated by the OH^- from the dissociation of the water molecule

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

contact with water at the oil/water interface, the polymerization of the alkylcyanoacrylate takes place on the droplet surface (Gallardo, 1993). This method is mainly adapted for the encapsulation of oily soluble substances. However, surprisingly, highly water-soluble molecules such as insulin could be entrapped in these nanocapsules with high encapsulation yields (up to 97%) (Aboubakar., 1999).

Water containing nanocapsules were prepared by interfacial polymerization of the alkylcyanoacrylate in water-in-oil microemulsions. In these systems, water swollen micelles of surfactants of small and uniform sizes are dispersed in an organic phase. To prepare nanocapsules, the monomer is added to the oily phase of the already prepared microemulsion.

The anionic polymerization of the alkylcyanoacrylate is initiated at the surface of the water swollen micelles and the polymer formed locally to make the shells of the nanocapsules. In the method first introduced by Gasco and Trotta, the microemulsions were prepared with hexane as the organic phase and Aerosol-OT as the surfactant. Both of these constituents are not compatible for the development of an acceptable drug carrier system. Thus, the method was recently adapted to microemulsions formulated with more biocompatible compounds, but still quite high concentrations of surfactant (up to 14 wt%) are required for their preparation (Watnasirichaikul, 2000). The nanocapsules obtained by this method are dispersed in an organic medium and can mainly be used for oral administration. Indeed, for intravenous administrations, it is necessary to transfer the nanocapsules into an aqueous continuous phase. Such a transfer still remained a problem until recently, since the total elimination of the organic phase and the redispersion of the nanocapsules, in water is a difficult task to achieve avoiding the aggregation of the nanocapsules. Recently, Lambert et al. proposed to perform this operation by ultracentrifugation of the nanocapsule dispersion over a layer of pure water. Using this simple approach, the nanocapsules transferred from the organic phase to the aqueous phase without any aggregation problem during the centrifugation. In addition, this technique allows the elimination of the excess surfactant, which remains in the organic phase. This nanoencapsulation method has special interest for the encapsulation of water soluble molecules such as peptides and nucleic acids including antisense oligonucleotides (Lambert et al., 1998).

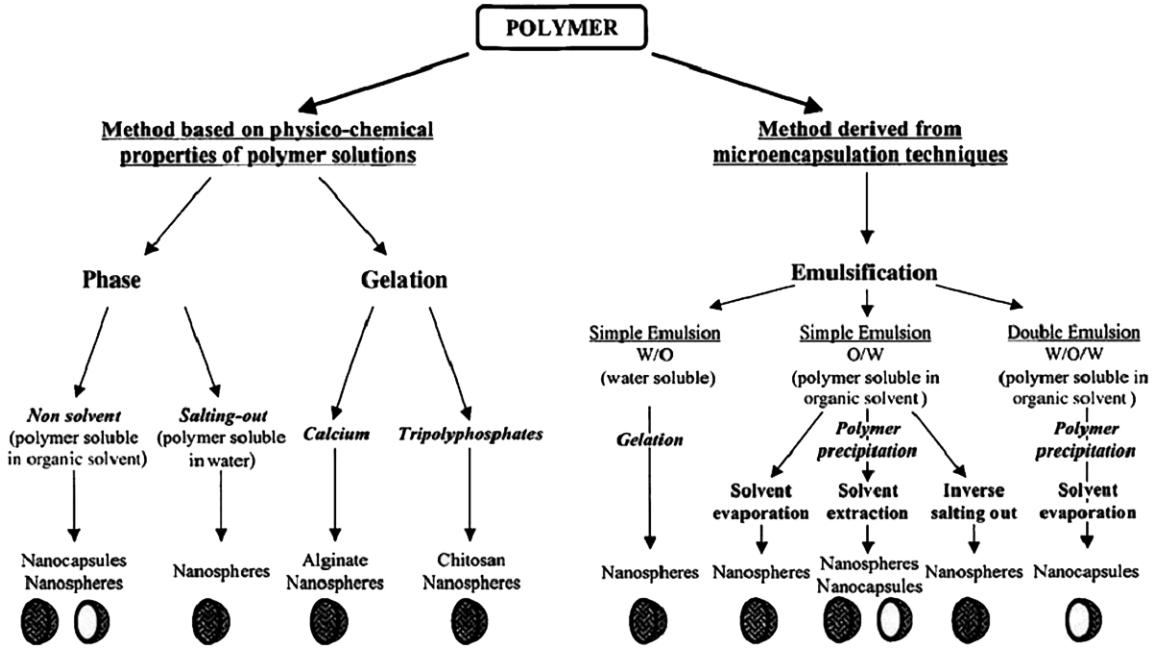
Preparation of Nanoparticles Using a Polymer

In this group of methods, the nanoparticles are obtained from a polymer, which was prepared according to a totally independent method. This approach presents the major advantage that the polymers entering the composition of the nanoparticles are well characterized and their intrinsic physicochemical characteristics will not depend on the conditions encountered during the preparation of the nanoparticles as it can be the case with the previously described methods. Most methods starting from polymers have taken advantages of the physicochemical properties of the polymer used in terms of its solubility or its faculty to form a gel under certain conditions. Basically, two approaches are followed. One is based on the spontaneous formation of colloidal particles of the polymer that are then stabilized in a second step of the procedure. The second approach is based on the adaptation of methods initially developed to make microparticles. In this case, the goal is to reduce the size of the particles formed with these methods. A third approach leading to the formation of very specific particles named SupraMolecular BioVectors by their authors (De Miguel, 1995) is described separately. The different ways to produce nanoparticles from a polymer is summarized in Figure 3.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Methods Based on the Spontaneous Formation of the Nanoparticles

Spontaneous formation of nanoparticles can be achieved by taking advantage of the solubility and gelling properties of a dissolved polymer. Usually, the step allowing polymer colloidal particles to form is reversible, and it is necessary to complete the procedure by a second step required to stabilize the particles.



Based on the solubility properties of a polymer, the general principle is to prepare a solution of the polymer and to induce a phase separation by the addition of a non-solvent of the polymer or by a salting-out effect. The occurrence of the phase separation can be followed by turbidimetric measurements or investigated using ternary phase diagrams (Stainmesse, 1990). Phase separations leading to polymer colloid particles are usually obtained with diluted solutions of polymers. In a ternary phase diagram, it corresponds to a small domain.

Using higher polymer concentrations in the solvent, the colloidal particles formed at the limit of the phase separation as followed by turbidimetric measurements in the case of proteins. To facilitate the formation of colloidal dispersion of polymer particles, it is better to induce the phase separation in totally miscible solvent–non-solvent systems. At that stage, the particles form spontaneously and quasi-instantaneously.

Once the proper conditions to obtain the polymer colloidal nanoparticles are identified, the particles must be stabilized. This is usually achieved either by the elimination of the polymer solvent by evaporation or by chemical cross-linking of the polymer as it is the case with proteins (Weber, 2000).

This method, also known as the nanoprecipitation method, can be applied to numerous synthetic polymers. In general, the polymer is dissolved in acetone and the polymer solution is added into water. The acetone is then evaporated to complete the formation of the particles. Surface active agents are usually added to water to ensure the stability of the polymer particles. This easy technique of nanoparticle

Figure 3. Summary of the different methods to prepare nanospheres and nanocapsules from a polymer

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

preparation was scaled up for large batch production. It leads to the formation of nanospheres. Nanocapsules can easily be prepared by the same method just by adding a small amount of an organic oil in the polymer solution. When the polymer solution is poured into the water phase, the oil is dispersed as tiny droplets in the solvent–non-solvent mixture and the polymer precipitates on the oil droplet surface. This method leads to the preparation of oil-containing nanocapsules and can be valuably used for the encapsulation of liposoluble drugs. Techniques based on the use of proteins are much more adapted to the encapsulation of hydrosoluble compounds and were recently developed to produce gelatin nanospheres as carrier systems for gene delivery.

Based on the gelation properties displayed by certain polymers, nanoparticles are formed spontaneously by controlling the gelation process. This approach has been developed with alginate and chitosan that form highly water-swollen gels. The gelling agents for these two natural polysaccharides are respectively calcium and tripolyphosphate. Nanoparticles are formed in a certain domain of concentrations of the polysaccharide and of the gelling agent. With the alginate, it has been shown that nanoparticles can be prepared when the respective concentrations of alginate and calcium are comprised in the domain of the pregel stage of the alginate gelling process (alginate 0.6 wt%, calcium chloride 0.9 mM). At this composition, tiny particles of gels form resulting from inter and intramolecular aggregations of alginate molecules caused by the interaction with calcium. These aggregates are stabilized by the formation of a polyelectrolyte complex with polylysine. Alginate and chitosan nanoparticles are interested for nucleic acid and protein delivery as recently reviewed by (Vauthier & Couvreur, 2000).

Methods Derived from Microencapsulation Techniques

Methods derived from microencapsulation techniques require the formation of an emulsion as a first step of the procedure. To produce nanometer-scale-sized particles, the size of the emulsion droplets must be small enough. This can be achieved by the use of special equipments such as high pressure homogenizers and microfluidizers. The energy input produced by these apparatus is important and is mainly due to high turbulence and cavitation forces. It allows an efficient dispersion of the polymer solution in the continuous phase. Once the desired emulsion is prepared, the formation of the nanoparticles can be induced according to two routes including the gelation of the polymer and the precipitation of the polymer either by solvent displacement or by solvent evaporation. Gelation can be induced by increasing the pH, adding calcium, or decreasing the temperature of emulsions containing respectively, chitosan, alginate, and agarose. In the solvent displacement technique, the emulsion is formed with a solvent of the polymer, which is partially soluble in water and with an aqueous phase saturated with the solvent. Once the emulsion is formed with ethylacetate as an example, it is diluted by the further addition of water to displace the solvent from the dispersed phase inducing the polymer precipitation. This principle was also developed on the base of an inverse salting out method. In this procedure, a solution of polymer in acetone is dispersed in an aqueous phase containing a high concentration of salt to keep the acetone nonmiscible with water. Just by diluting the emulsion with a large amount of pure water, the acetone is then extracted from the dispersed phase inducing the polymer precipitation. The total elimination of the acetone can be achieved by evaporation. Finally, precipitation of the polymer solubilized in the dispersed phase can also be induced by the removal of the solvent by evaporation. In this method named emulsification solvent evaporation, the polymer solvent diffuses through the aqueous continuous phase and evaporates at the air/water interface. The emulsion should remain under agitation during the time required for the total evaporation of the solvent. These methods produce nanospheres.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

To make nanocapsules, small amounts of oil can be added in the dispersed phase of the emulsion that will form the nanocapsules by solvent displacement. Nanocapsules can also be prepared with the solvent evaporation technique from a double water-in-oil-in-water emulsion. The removal of the organic solvent of the intermediate phase of this double emulsion by evaporation causes the polymer to precipitate at the surface of the inner aqueous phase. Whereas nanocapsules made by the solvent displacement method is more adapted for the encapsulation of lipophilic compounds, this last method allows the encapsulation of hydrosoluble compounds.

Preparation of SupraMolecular BioVector

SupraMolecular BioVector consists of polysaccharide nanospheres surrounded by a bilayer of phospholipids (De Miguel, 1995). At the origin, these systems were developed to mimic the low density lipoproteins that are natural colloidal structures encountered in the blood circulation and designed for the transport of cholesterol and cholesterol esters in vivo. SupraMolecular Bio-Vector are prepared in several steps including the functionnalization and chemical cross-linking of a polysaccharide (starch or dextran), the purification and the drying of the modified polysaccharide followed by the fragmentation of the resulted powder under high pressure to produce small polysaccharide nanoparticles. Finally, a lipid bilayer is adsorbed on the surface of the nanoparticles. The chemical modification of the polysaccharide forming the core of the Supra Molecular BioVector lead to various possibilities in terms of the type of molecules that can be associated with such a carrier system. Indeed, the polysaccharide core can be either negatively or positively charged or even neutral opening large application potential.

Preparation of Surface Modified Nanoparticles

Once intravenously administered, the body distribution of the nanoparticles is controlled by their surface properties. Indeed, despite their small size, nanoparticles display an enormous specific surface area that makes the interaction with the surrounding medium very important especially for their fate in vivo. Thus, the preparation of surface modified nanoparticles received much attention during the last decade to produce nanoparticles that are able to circulate for a long period of time in the blood stream at first and, more recently, to achieve an effective targeting of the device or to improve their bioadhesivity to mucosae. Nanoparticles that are able to circulate for a long time in the blood stream should not be recognized by macrophages of the mononuclear phagocyte system. To achieve this goal, at least one of the two major known mechanisms involved in the recognition of foreign particles by macrophages should be avoided. These two mechanisms include the particle opsonisation and the complement activation, which consists in protein adsorption and subsequent recognition by macrophages. A barrier to protein adsorption could be achieved by creating an efficient barrier of steric hindrance, therefore, by coating or adsorbing hydrophilic polymers to nanoparticle surface.

Nanospheres coated with poly(ethylene glycol) were first obtained by the simple adsorption of triblock copolymers of poly(ethylene glycol)–poly(propyleneglycol)–poly(ethylene glycol) on the surface of already prepared nanospheres. To improve the stability of the poly(ethylene glycol) coating, nanospheres were prepared by nanoprecipitation or by emulsification solvent evaporation using copolymers of poly(lactic acid)–co-poly (ethylene glycol) or of poly(alkylcyanoacrylate)–co-poly(ethylene glycol). Finally, poly (ethylene glycol) can initiate the polymerization of alkylcyanoacrylate to produce poly(ethylene glycol)-coated poly-(alkylcyanoacrylate) nanoparticles by emulsion polymerization. To

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

make nanoparticles able to escape complement activation, Passirani et al., proposed to coat nanospheres with heparin. This compound, which is a polysaccharide, is a physiological inhibitor of complement activation in vivo. Heparin-coated poly(methylmethacrylate) nanoparticles were prepared by emulsion polymerization. In the method, the radical polymerization of methylmethacrylate was initiated by heparin according to an original method involving cerium ions and allowing heparin to covalently attach to poly(methylmethacrylate) (Passirani, 1998; Passirani,1999).

The next step now is the development of targeted nanoparticles toward a specific cell type. This has recently been investigated by Stella et al., who prepared poly(alkylcyanoacrylate) nanoparticles showing residues of folic acid on their surface. These nanoparticles will be used to target cancer cells overexpressing a membrane receptor for the folic acid. The targeting moiety, consisting on the folic acid, was grafted on the surface of poly(aminopoly(ethylene glycol) cyanoco-hexadecylcyanoacrylate) nanoparticles that were obtained by nanoprecipitation (Stella et al., 2000). In another way, chitosan was used as a coating agent for nanoparticles to improve their bioadhesive properties after oral and nasal administration. Indeed, chitosan is known to have bioadhesive properties as well as an interesting absorption enhancing capacity.

3. CHARACTERIZATION OF NANOPARTICULATE DRUG CARRIERS

Nanoparticles can be characterized by all the different physico chemical techniques that apply for polymer colloids. Concerning the development procedure of nanoparticles as drug carriers, the main physico chemical parameters that are investigated are the shape, the size, the surface properties, the density, and the concentration of the particles. The size as well as the size distribution are important parameters to be determined to achieve safe intravenous administration. Surface properties are also important to consider as nanoparticles display considerable specific surface area responsible for the interactions with the surrounding medium. Finally, the density and the concentration are required to deduce the specific surface area of the particles together with the size.

Nanoparticles can be visualized using different microscopy techniques. Transmission electron microscopy is usually applied to nanoparticles after negative staining with phosphotungstate acid or with uranyl acetate after it has been checked that the staining agents do not modify the particles. Recent progress in transmission electron microscopy now allows direct observations of the nanoparticles without the use of any staining agent that may cause artefacts in some cases. In particular, direct observations of the nanoparticles after a sample of the nanoparticle dispersion has been freezing at very low temperature can be carried out by cryotransmission electron microscopy. Scanning electron microscopy is performed on samples coated with a thin layer of gold metal to produce the contrast. These techniques as well as those based on atomic force microscopy give useful images of the nanoparticles showing their shape. Measurements of the size and of the size distribution require determination of the diameters number of individual nanoparticles that may be assisted by the use of valuable image analysis softwares. The internal structure of the nanoparticles can be observed by freeze fracture and cryotransmission electron microscopy.

Generally, mean size and size distribution of nanoparticles are evaluated by quasi-elastic light scattering also named photocorrelation spectroscopy. This method is based on the evaluation of the translation diffusion coefficient, D, characterizing the Brownian motion of the nanoparticles. The nanoparticle hydrodynamic diameter, pH is then deduced from this parameter from the Stokes Einstein law. Other techniques can be used to determine the size and the size distribution of the nanoparticles. The field

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

flow fractionation method is based on the separation of particles according to their size in a thin glass channel in which the flow carrying on the nanoparticles is submitted to an external perpendicular force produced either by a crossed flow or a sedimentation. This technique, which can be applied for particles in a wide range of size (10 nm to several hundred *m*m), will gain more attention in the future for size determination and also for nanoparticle surface analysis. Size and size distribution of nanoparticles can also be determined by size exclusion chromatography performed on appropriate gels. This approach, requiring less equipment than the previous methods, presents the main limitation that only particles having a diameter lower than 120nm can be characterized by this method. As mentioned earlier, surface characteristics of the nanoparticles are of primary importance for the interaction of the nanoparticles with the surrounding medium. The main nanoparticle surface characteristics that are considered are the charge, the hydrophilicity, the chemical composition and the capacity to absorb proteins and to induce complement activation.

The charge of the nanoparticle surface is usually evaluated by the measurement of their zeta potential, which gives information about the overall surface charge of the particles and how it is affected by changes in the environment. Zeta potential is affected by the surface composition of the nanoparticles, the presence or the absence of adsorbed compounds, and the composition of the dispersing phase, mainly the ionic strength and the pH. The hydrophilicity of the nanoparticle surface can be evaluated by hydrophobic interaction chromatography. This technique, based on affinity chromatography, allows a very rapid discrimination between hydrophilic and hydrophobic nanoparticles. The nanoparticles are passed through a column containing a hydrophobic interaction chromatography gel. The nanoparticles that are retained by the gel and only eluted after the addition of a surfactant are considered as hydrophobic, whereas the nanoparticles that do not interact with the gel and that are directly eluted from the column are considered as hydrophilic. Apart from the hydrophobic interaction chromatography, the field flow fractionation techniques recently appeared to present interesting potential for the characterization of nanoparticles with different surface characteristics.

X-ray photoelectron spectroscopy (ESCA) can be use to determine the chemical composition of the nanoparticle surface. This technique is a very useful tool for the development of surface modified nanoparticles providing a direct evidence of the presence of the components that are believed to be on the nanoparticle surface.

The capacity of the nanoparticles to adsorb proteins and to activate the complement in vivo after intravenous administration will influence the fate of the carrier and its body distribution. To approach this aspect, in vitro tests have been developed to investigate the profile of the type of serum proteins that adsorbed onto the nanoparticle surface after incubation in serum and to evaluate the capacity of the nanoparticles to induce complement activation. The analysis of the protein adsorbed onto the nanoparticle surface can be performed by 2D-polyacrylamide gel electrophoresis. This technique allows the identification of the proteins that adsorbed onto the nanoparticle surface. To evaluate modifications of the composition of the adsorbed protein with time, a faster method based on capillary electrophoresis can also be used. Finally, the activation of the complement produced by nanoparticles can be evaluated either by a global technique or by a specific method measuring the specific activation of the component C3. In the global technique, nanoparticles are incubated with serum and, after the incubation, the remaining non-activated complement in the serum is evaluated using a red blood cell lysis test. The concentration of nanoparticle in the dispersion can be deduced from gravimetric determination or by turbidimetric measurements based on the application of the Mie's law. Density of the nanoparticles is evaluated either by pycnometry or by isopycnic centrifugation (Quintanar-Guerrero, 1999).

4. PHARMACEUTICAL APPLICATIONS OF NANOPARTICLES

Nanoparticles were first developed in the mid-seventies by Birrenbach & Speiser. Later on, their application for the design of drug delivery systems was made available by the use of biodegradable polymers that were considered to be highly suitable for human applications. At that time, the research on colloidal carriers was mainly focusing on liposomes, but no one was able to produce stable lipid vesicles suitable for clinical applications. In some cases, nanoparticles have been shown to be more active than liposomes due to their better stability. This is the reason why in the last decades many drugs (e.g., antibiotics, antiviral and antiparasitic drugs, cytostatics, protein and peptides) were associated to nanoparticles (Birrenbach & Speiser, 1976).

Intravenous Administration

Fate of Nanoparticles and Their Content after Intravenous Administration

the main interest of nanoparticles is their ability to achieve tissue targeting and enhance the intracellular penetration of drugs. After intravenous administration, nanoparticules are taken up by the liver, spleen and to a lower extent the bone marrow. Within these tissues, nanoparticles are mainly taken up by cells of the mononuclear phagocyte system (MPS). The uptake occurs through an endocytosis process after which the particles end up in the lysosomal compartment where they are degraded producing low molecular weight soluble compounds that are eliminated from the body by renal excretion. As a result of the MPS site specific targeting, avoidance of some organs was made possible, thus reducing the side effects and toxicity of some active compounds. Due to their strong lysosomal localization, one could imagine that nanoparticles are not suitable to target to the cytoplasm. To avoid their trapping within the lysosomal compartment, several compounds able to destabilize the lysosomal membrane were added to the nanoparticulate systems (e.g., cationic surfactant) allowing some drugs to be delivered to the cytoplasm. Recently, to avoid MPS uptake, several groups have developed a strategy consisting of the linkage to the nanoparticles of poly(ethylene glycol) derivatives. (Peracchia, 1999) This linkage results in a lower uptake of nanoparticles by the MPS and in a longer circulation time. As a consequence, these so-called stealth_ nanoparticles would be able to extravasate across endothelium that becomes permeable due to the presence of solid tumors.

Application to the Treatment of Intracellular Infections

Intracellular infections were found to be a field of interest for drug delivery by means of nanospheres. Indeed, infected cells may constitute a ''reservoir'' for micro organisms, which are protected from antibiotics inside lysosomes. The resistance of intracellular infections to chemotherapy is often related to the low uptake of commonly used antibiotics or to their reduced activity at the acidic pH of lysosomes. To overcome these effects, the use of ampicillin, a β lactam antibiotic, bound to nanospheres was proposed as endocytozable formulation.(66) The effectiveness of polyisohexylcyanoacrylate (PIHCA) nanospheres was tested in the treatment of two experimental intracellular infections.

Firstly, ampicillin-loaded nanospheres were tested in the treatment of experimental Listeria monocytogenes infection in congenitally athymic nude mice, a model involving a chronic infection of both liver and spleen macrophages. After adsorption of ampicillin onto nanospheres, the therapeutic activity of

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

ampicillin was found to increase dramatically over that of the free drug. Bacterial counts in the liver were at least 20-fold reduced after linkage of ampicillin to PIHCA nanospheres. In addition, nanoparticulate ampicillin was capable of ensuring liver sterilization after two injections of 0.8 mg of nanospheres bound drug, whereas no such sterilization was ever observed with any of other regimens tested. Reappearance of living bacteria in the liver after the end of the treatment was probably due to a secondary infection derived from other organs such as the spleen, which was not completely sterilized by the treatment. Secondly, nanosphere-bound ampicillin was tested in the treatment of experimental salmonellosis in C57/BL6 mice, a model involving an acute fatal infection. All mice treated with a single injection of nanoparticle-bound ampicillin survived, whereas all control mice and all those treated with unloaded nanospheres died within 10 days post infection. With free ampicillin, an effective-curative effect required three doses of 32mg each. Lower doses (3 _ 0.8mg and 3 _ 16 mg) delayed but did not reduce mortality. Thus, the therapeutic index of ampicillin, calculated on the basis of mice mortality, was increased by 120-fold when the drug was bound to nanospheres.

In order to clarify the mechanism by which nanospheres improved the antimicrobial efficacy of ampicillin, Forestier et al., have compared in vitro the efficacy of ampicillin bound to poly(isobutylcyanoacrylate) (PIBCA) nanospheres with that of free ampicillin in terms of survival of L. monocytogenes in mouse peritoneal macrophages. After 30 h of incubation, nanospheres-bound ampicillin decreased the number of viable bacteria by 99% as compared to the controls whereas with free ampicillin, the number of bacteria was slightly lower than in the controls (Forestier et al., 1992). Nanoparticle-ampicillin thus appeared to bemuchmore effective than free ampicillin for inhibiting intracellular growth of L. monocytogenes. With in vitro Salmonella typhimurium infected macrophages, the situation was a little bit more complicated since the bactericidal effect of ampicillin-bound PIHCA nanospheres was poor although the intracellular capture of ampicillin was dramatically increased and its efflux in the extracellular medium reduced. In another study, confocal microscopy and transmission electron microscopy were used to establish the intracellular traffic of ampicillin bound-PIHCA nanospheres and its relation with the bacteria within the subcellular compartments. The data obtained clearly demonstrated the active uptake by phagocytosis of ampicillin-bound PIHCA nanospheres by murine macrophages and their localization in the same vacuoles as the infecting bacteria, but in a restrictive way. Thus, it was difficult to understand the limited bactericidal effect of ampicillin-bound nanospheres. The most probable explanation is to be found in the resistance mechanism of S. typhimurium involving the inhibition of the phagosome–lysosome fusion, which lets some bacteria in phagosomes free of nanospheres. If this proposed hypothesis (inhibition of phagosome–lysosome fusion) is correct, the dramatic efficiency observed in vivo should rather be due to the specific targeting of the infected tissues (rich in reticuloendothelial cells), than to an efficient intracellular targeting as it could be supposed.

In order to eliminate both dividing and non-dividing bacteria, a fluoroquinolone antibiotic, ciprofloxacin, has been associated with PIBCA and PIHCA nanospheres. In an animal model of persisting Salmonella infection, although an effect on the early phase of the infection was observed, neither free nor nanospherebound ciprofloxacin was able to eradicate truly persisting bacteria. Since they accumulate in the MPS, nanospheres hold promise as drug carriers for the treatment of visceral leishmaniosis. Thus, it has been shown that PIHCA nanospheres can be used as a carrier of primaquine whose activity was increased 21-fold against intracellular Leishmania donovani when associated with nanospheres. A part of the activity was attributed to the fact that phagocytosis of nanospheres led to the induction of a respira-

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

tory burst, which was more pronounced in infected than in non-infected macrophages. Dehydroemetine is also one of the drug candidates for this treatment but has some side effects involving the heart, which were reduced after linkage with nanospheres.

Application to the Treatment of Cancer

When given intravenously, anticancer drugs are distributed throughout the body as a function of the physicochemical properties of the molecule. A pharmacologically active concentration is reached in the tumor tissue at the expense of massive contamination of the rest of the body. For cytostatic compounds, this poor specificity raises a toxicological problem, which presents a serious obstacle to effective therapy. The use of colloidal drug carriers could represent a more rational approach to specific cancer therapy. In addition, the possibility of overcoming multidrug resistance might be achieved by using cytostatics-loaded nanospheres. The antitumor efficacy of doxorubicin-loaded nanospheres was first tested using the lymphoid leukemia L-1210 as a tumor model. In this study, one intravenous injection of doxorubicin-loaded PIBCA nanospheres was found to be more effective against L1210 leukemia than when the drug was administered in its free form following the same dosing schedule. Although the increased life span (ILS %) of mice injected with doxorubicin-loaded PIBCA nanospheres was twice as high as the ILS % for free doxorubicin, there were no long-term survivors.

The effectiveness of doxorubicin-loaded PIHCA nanospheres against L1210 leukemia was even more pronounced than that of doxorubicin loaded onto PIBCA nanospheres. The drug toxicity was markedly decreased when it was bound to this sort of nanospheres, so that impressive results were obtained with this formulation at doses for which the therapeutic efficiency of free doxorubicin was completely masked by the overpowering toxicity of the drug. Furthermore, preliminary experiments suggested that one i.v. bolus injection of doxorubicin-loaded nanospheres was more active, in L1210-bearing mice, than perfusion of the free drug for 24 h.

The superiority of doxorubicin targeted with the aid of poly(alkylcyanoacrylate) nanospheres was later confirmed in a murine hepatic metastases model (M5076 reticulosarcoma). Irrespective of the dose and the administration schedule, the reduction in the number of metastases was much greater with doxorubicin-loaded nanospheres than with free doxorubicin, particularly if treatment was given only when the metastases were well established. The improved efficacy of the targeted drug, as clearly confirmed by histological examinations, shows that both the number and the size of the tumor nodules were lower when doxorubicin was administered in its nanoparticulate form. Furthermore, liver biopsies of animals treated with the nanosphere-targeted drug showed a lower cancer cell density inside tumor tissue. Necrosis was often less widespread with the nanosphere-associated drug than in the control group and the group treated with free doxorubicin.

Studies performed on total homogenates of livers from both healthy and metastases-bearing mice showed extensive capture of nanoparticulate doxorubicin by the liver; no difference in hepatic concentrations was noted between healthy and tumor-bearing animals. In order to elucidate the mechanism behind the enhanced efficiency of doxorubicin-loaded nanospheres, doxorubicin measurements were made in both metastatic nodules and neighboring healthy hepatic tissue. This provided quantitative information concerning the drug distribution within these tissues. During the first 6 h after administration, the exposure of the liver to doxorubicin was 18 times greater for nanosphere-associated doxorubicin. However, no special affinity for the tumor tissue was detected and the nanospheres were seen by electron microscopy to be located within Kupffer cells (macrophages). However, at later time-points, the

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

amount of drug in the tumor tissue increased in nanosphere-treated animals to 2.5 times the level found in animals given free doxorubicin. Since uptake of nanospheres by neoplastic tissue is unlikely, this increase in the doxorubicin concentration in tumor tissue probably resulted from doxorubicin released from healthy tissue, in particular Kupffer cells. Hepatic tissue could play the role of drug reservoir from which prolonged diffusion of the free drug (from nanospheres entrapped in Ku¨ pffer cell lysosomes) toward the neighboring malignant cells occurs.

This hypothesis raises the question of the long-term effect of an 18-fold increase of doxorubicin concentration in the liver. Although toxicological data have shown that doxorubicin-loaded nanospheres were not significantly or unexpectedly toxic to the liver in terms of survival rate at high doses, body weight loss, and histological appearance, this possibility should be borne in mind, especially since a temporary depletion in the number of Kupffer cells, and hence the ability to clear bacteria, was observed in rats treated with doxorubicin-loaded liposomes. A systematic study using unloaded poly(alkylcyanoacrylate) nanoparticles confirmed a reversible decline in the phagocytic capacity of the liver after repeated dosing, as well as a slightinflammatory response. Nanoparticle-associated doxorubicin also accumulated in bone marrow, leading to a myelosuppressive effect. However, this tropism of carriers might be useful to deliver myelostimulating compounds such as granulocyte colony stimulating factor to reverse the suppressive effects of intense chemotherapy. Nanospheres are also captured by splenic macrophages. In this study, the spleen architecture was shown to play a role in the localization of the nanospheres: in mice, uptake was mainly observed in metallophilic macrophages of the marginal zone whereas in rats, which have sinusoidal spleens similar to that of humans, particles were found in the red pulp macrophages.

On the other hand, alteration of the drug distribution profile by linkage to nanospheres can, in some cases, considerably reduce the toxicity of a drug because of reduced accumulation in organs where the most acute toxic effects are exerted. This concept was indeed illustrated with doxorubicin, which displays severe acute and chronic cardiomyopathy. After intravenous administration to mice, plasma levels of doxorubicin were higher when the drug was adsorbed onto nanospheres and at the same time the cardiac concentration of the drug was dramatically reduced. In accordance with the observed distribution profile, doxorubicin associated with nanospheres was found to be less toxic than free doxorubicin. The ability of tumor cells to develop simultaneous resistance to multiple lipophilic compounds represents a major problem in cancer chemotherapy. Cellular resistance to anthracyclines has been attributed to an active drug efflux from resistant cells linked to the presence of transmembrane P-glycoprotein, which was not detectable in the parental drug-sensitive cellline. Drugs, such as doxorubicin, appear to enter the cell by passive diffusion through the lipid bilayer. Upon entering the cell, these drugs bind to P-glycoprotein, which forms transmembrane channels and uses energy from ATP hydrolysis to pump these compounds out of the cell. To solve this problem, many authors have proposed the use of competitive P-glycoprotein inhibitors, such as the calcium channel blocker verapamil, which are able to bind to P-glycoprotein and to overcome pleiotropic resistance. However, since the adverse effects of verapamil are serious, its clinical use to overcome multidrug resistance is limited.

During the past few years, many studies have been devoted to evaluating the antitumor potential of carrier-drug complexes (Brasseur, et. al., 1980). The effect of nanospheres loaded with doxorubicin, resistance to which is known to be related to the presence of P-glycoprotein, was evaluated. The cytotoxicity of free-doxorubicin, doxorubicin- loaded PIHCA nanospheres (NP-Doxorubicin) (mean diameter 300 nm), and nanospheres without drug (NP), against sensitive (MCF7) and multidrug resistant (Doxorubicin R MCF7) human breast cancer cell lines was compared. MCF7 cells were more sensitive to free-doxorubicin than Doxorubicin R MCF7 cells with a 150-fold difference in the IC50. No significant

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

difference was observed in the survival rate of MCF7 treated with free-Doxorubicin or NPdoxorubicin. In contrast, for doxorubicin R MCF7, the IC50 for doxorubicin was 130-fold lower when NPdoxorubicin were used instead of free-doxorubicin. These results indicated that nanospheres provided an effective carrier for introducing a cytotoxic dose of doxorubicin into the pleiotropic resistant human cancer cell line Doxorubicin R MCF7.

Complementary experiments, conducted with other sensitive and resistant cell lines, have confirmed this efficacy of nanospheres. Doxorubicin resistance was circumvented in the majority of the cell lines tested, and some encouraging results were obtained in vivo in a P388 model growing as ascites. Further studies were undertaken to elucidate the mechanism of action of polyalkylcyanoacrylate nanospheres. The incubation time and number of particles per cell were important factors and, when PIBCA nanospheres were used, doxorubicin accumulation within P388/ADR resistant leukemic cells was increased compared with free drug, although no endocytosis of nanospheres occurred. On the other hand, when the less rapidly degradable PIHCA nanospheres were used, reversion was observed in the absence of increased intracellular drug. The degradation products of poly (alkylcyanoacrylate) nanospheres (mainly poly(cyanoacrylic acid)) were also able to increase both accumulation and cytotoxicity of doxorubicin, although they were soluble in the culture medium. Hence, the reversion of resistance seems to be due both to the adsorption of nanospheres on the cell surface and to theformation of a doxorubicin-poly(cyanoacrylic acid) ion pair, which facilitates the transport of the drug across the cell membrane.

In the light of the results obtained with doxorubicinloaded nanospheres in the liver metastases model described earlier, (Chiannilkulchai, 1989) the role of macrophages as a reservoir for doxorubicin was tested in a two-compartment coculture system in vitro with both resistant and sensitive P388 cells. Even after prior uptake by macrophages, doxorubicin-loaded PIBCA nanospheres were able to overcome resistance. However, this reversion was only partial. It was decided to take advantage of the particulate drug carrier offers to associate an anticancer drug and a compound capable of inhibiting the P-glycoprotein. This approach was tested with doxorubicin and cyclosporin A bound to the same nanospheres and was found to be extremely effective in

reversing P388 resistance (Soma, 1999). The association of cyclosporine A with nanospheres would ensure that it reaches the same sites as the anticancer drug at the same time and would also reduce its toxic side effects.

As early as 1986, researcher observed that other colloidal carriers, like nanocapsules, administered by the IV route in rabbits, were taken up rapidly by organs of the mononuclear phagocyte system (Khouri et al., 1986). One application that takes advantage of this uptake concerns nanocapsules of (muramyl tripeptide cholesterol) (MTP-Chol). This immunostimulating agent is able to activate macrophages and induce toxicity toward tumor cells, and would therefore be a useful agent to treat metastatic cancer. The mechanisms by which activated macrophages arrest tumor proliferation include production of nitric oxide and TNF-*a*. It was showed in in vitro models of rat alveolar macrophages and RAW 264.7 mouse monocyte macrophage line that nanocapsules based on poly(D,L-lactide) containing MTP-Chol are more efficient activators than the free drug. This action could be due to an intracellular delivery of the immunomodulator encapsulated in nanocapsules after phagocytosis and to an intermediate transfer of the drug to serum proteins (Seyler, 1999). This system has also demonstrated its efficiency in vivo; in fact (Barratt et al. 1994), reported that antimetastatic effects of nanocapsules contained MTP-Chol in a model of liver metastases. Some antimetastatic activity was also seen after oral administration.

Nanospheres for Oligonucleotide Delivery

Oligodeoxynucleotides are potentially powerful new drugs because of their selectivity for particular gene products in both sense and antisense strategies. However, using antisense oligonucleotides in therapeutics is a challenge to pharmaceutical technology because of their susceptibility to enzymatic degradation and their poor penetration across biological membranes. Nanoparticulate preparations might be an interesting alternative because of better stability in the presence of biological fluids. In the case of nanospheres made of synthetic polymers (poly(alkylcyanoacrylate), poly (lactic acid)), since oligonucleotides have no affinity for the polymeric matrix, association with nanoparticles has been achieved by ion pairing with a cationic surfactant, cetyltimethylammonium bromide (CTAB) adsorbed onto the nanoparticle surface (Fattal, 1998). Oligonucleotides bound to poly(alkylcyanoacrylate) nanospheres in this way were protected from nucleases in vitro and their intracellular uptake was increased (Chavany, 1994). In addition, nanospheres were able to concentrate intact oligonucleotides in the liver and in the spleen (Nakada, et. al. 1996). Antisense oligonucleotides formulated in this way were able to specifically inhibit mutated Ha-ras-mediated cell proliferation and tumorigenicity in nude mice (Schwab, 1994).

This approach has recently been applied to the association of a phosphodiester antisense oligonucleotide directed against the 30 non-translated region of the PKC*a* gene with nanospheres prepared from PIBCA. These nanospheres were able to inhibit PKC*a* neoexpression in cultured Hep G6 cells. Nanospheres containing oligonucleotides have also been formulated from a naturally occurring polysaccharide, alginate, which forms a gel in the presence of calcium ions. In this case, the oligonucleotides penetrate into the gel matrix by reptation, thus providing a high loading yield and good protection against nuclease (Aynie, 1999).

Subcutaneous/Intramuscular Administration

Subcutaneous administration of nanoparticles was achieved mainly for the delivery of peptides and vaccines. It allows slow release of the entrapped drugs therefore reducing the number of administrations, increasing blood half-life of the active drug, and finally, in some cases, reducing side effects.

PIBCA nanospheres were injected subcutaneously to rats. Autoradiographic pictures obtained after using radiolabelled polymer have shown a progressive staining reduction in the muscular tissue suggesting that nanospheres were slowly biodegraded. In the same study, nanospheres were found to release a peptide (GRF) in a sustained manner. Comparison of the

AUC of free GRF and GRF-loaded nanospheres showed that in addition to the slow release process nanospheres were able to improve the bioavailability of the peptide. This improvement could be attributed to the fact that free administered GRF is very quickly metabolized at the injection site, whereas it is partly protected from massive enzymatic degradation when it is administered associated with nanospheres (Gautier, 1992).

A few examples of the use of nanospheres as adjuvant for antigens/allergens delivery were described in the literature. The main advantage of this approach is to design single shot vaccine. In this case the drug carrier has to remain at the site of administration and deliver either continuously or pulsatively the antigen. The use of slowly degradable polymers (PLA, PMMA) is suitable for this application, since peptide or protein release is more adequate. Poly(methyl methacrylate) were first investigated as adjuvants for injectable vaccines. These nanospheres were claimed to be biodegradable after subcutaneous or intramuscular injection and shown to exhibit very powerful adjuvant properties for a number of antigens.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

However, the adjuvant properties were shown to be better when the antigen was incorporated during the polymerization process than when adsorbed onto nanospheres (Mahmoudi et al., 2010). When comparing the effect of PMMA with other polymers (polystyrene and 2-hydroxyethyl methacrylate/methyl methacrylate copolymer, HEMA: MMA), it was also demonstrated that a decrease in particle size and an increase in the hydrophobicity of nanospheres increased the antibody response after immunization against influenza whole and split virus, bovine serum albumin, and HIV2 split virus (Kreuter, 1978).

Oral Route

There are numerous reports showing that uptake and translocation of nanoparticles and microparticles take place after oral administration to animals (Jani, 1989). Different mechanisms have been proposed to explain the translocation of particulate material across the intestine: i) uptake via Peyer's patches or isolated lymphoid follicles; ii) intracellular uptake; and iii) intracellular/paracellular passage. The uptake of poly(alkylcyanoacrylate) nanocapsules by Peyer's patches has been shown by Damge´ et al., (Damge et al., 1988) When administered in the lumen of an isolated ileal segment of the rat, polylalkylcyanoacrylate nanocapsules were found preferentially over Peyer's patches through which they passed massively and rapidly.Nanocapsules were clearly visible in M-cells and in intercellular spaces around the lymph cells. Intracellular uptake of nanospheres has been proposed by Kreuter, Muller and Munz (Kreuter, 1989; Muller & Munz, 2000) based on electron-microscopic autoradiographic investigations showing radioactivity into epithelial and goblet cells after oral administration of poly(hexylcyanoacrylate) (PHCA) nanospheres labeled with 14C. The translocation of particles by a paracellular pathway has been evidenced in a study done by Aprahamian et al., using PIBCA nanocapsules. Nanocapsules were filled with an iodinized oil (lipiodol) in order to render them detectable using a scanning electron microscope equipped with an energy-dispersive X-ray spectrometer (Aprahamian et al., 1987). When they were administered in an isolated segment of a dog jejunum, they appeared as vesicles associated with intraluminal mucus. Subsequently, they were observed in intravillus capillaries in close contact with red cells or adsorbed to the inner wall of endothelial cells. Among these three mechanisms and according to many studies involving nanoparticles made of other biodegradable and nondegradable polymers, translocation via the uptake in Peyer's patches seems to be the major pathway for a rapid and substantial passage after oral administration of nanoparticles. Although it might exist in certain situations, the passage of particles between the absorptive cells is rather less likely if the barrier of tight junctions has not been disrupted. Although there are abundant reports from various independent workers showing evidence of absorption of particulate systems by the gastrointestinal tract, the oral absorption of nanoparticles remains a controversial issue. However, even if a more clear estimation of the quantity of absorbed particles is needed as well as a better understanding of the factors affecting particles uptake, it must be concluded that translocation of small sized particles like poly(alkylcyanoacrylate) nanoparticles is possible. The question remains if the extent of particle translocation is compatible with a strategy of drug administration with therapeutic perspectives. This will be discussed below.

Oral Delivery of Peptides and Proteins and Vaccines

Poly(isobutylcyanoacrylate) nanocapsules were shown 10 years ago to be able to encapsulate insulin and to increase its activity as assessed by a reduction of glycemia. Several aspects of this phenomenon are surprising: encapsulation of a hydrophilic drug in the oily core of nanocapsules; reduction of glycemia

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

was only obtained with diabetic animals; hypoglycaemia appeared two days after a single administration and was maintained for up to 20 days depending on the insulin doses, although the amplitude of the pharmacological effect (minimum level of blood glucose) did not depend on the insulin dose. Damge´ et al. (Damge et al., 1990) and Lowe and Temple (Lowe and Temple, 1994) suggested that nanocapsules could protect insulin from proteolytic degradation in intestinal fluids, based on the protection of encapsulated insulin, observed in the presence of different enzymes in vitro. Later studies showed that insulin did not react with the alkylcyanoacrylate monomer during the formation of nanocapsules and was located within the oily core rather than adsorbed on their surface.

The capacity of insulin nanocapsules to reduce glycemia could be explained by their translocation through the intestinal barrier, as suggested by Damge´ et al., (Damge et al. 1997) for example by paracellular pathway or via M cells in Peyer's patches (Michel, 1991). Recently, the use of Texas Red_-labeled insulin allowed this translocation to be visualized more readily (Aboubakar, 2000). One hour after oral administration, nanocapsules reached the ileum. The presence of fluorescent areas within the mucosa and even in the lamina propria suggested that insulin-loaded nanocapsules could cross the intestinal epithelium. Although this passage is certainly an important factor, it does not explain the duration of the hypoglycemia. This prolonged action could be due to the retention of a part of the colloidal system in the gastrointestinal tract. Interestingly, a prolonged hypoglycemic effect was also observed with insulin entrapped in poly(alkylcyanoacrylate) nanospheres when these were dispersed in an oily phase containing surfactant. This suggests that some components of nanocapsules could act as promoters of absorption. Recently, Damge´ et al. showed that the incorporation of octreotide, a somatostatin analogue, in poly(alkylcyanoacrylate) nanocapsules also improved and prolonged the therapeutic effect of this peptide, after administration by the oral route (Damge et al., 1997).

Even if the main limitation to oral administration of poly(alkylcyanoacrylate) nanoparticles is that their passage through the intestinal barrier is probably restricted and sometimes erratic, they represent an interesting tool for oral delivery of antigens. Indeed, M-cells appear to be the main site for the uptake of poly(alkylcyanoacrylate) nanoparticles after oral administration (Damge et al., 1997).and, furthermore, it is generally accepted that limited doses of antigen are sufficient for a mucous immunization. In fact, oral delivery of antigens may be considered as the most convenient means of producing an IgA antibody response. However, it is importantly limited by enzymatic degradation of antigens in the GI tract and, additionally by their poor absorption (Yildirimera et al., 2011). Thus, it has been postulated that the use of micro- or nanoparticles for the oral delivery of antigens should be efficient if those systems are able to achieve the protection of the antigenic molecule. Poly(alkylcyanoacrylate) nanoparticles have been shown to enhance the secretory immune response after their oral administration in association with ovalbumin (O'Hagan, 1989). This result was not fully reproduced in the case of poly(acrylamide) nanoparticles loaded with the same antigen. It was postulated that in the case of poly(acrylamide) nanospheres, much of the antigen was located at the surface of the polymer and could have been degraded during its passage through the gut. The relatively high surface concentration of ovalbumin adsorbed onto poly(butylcyanoacrylate) nanospheres may have reduced the ability of the proteolytic enzymes in the gut to gain access to and to degrade the antigen, resulting in a greater antigen availability.

Ocular Delivery

The anatomical structure and the protective physiological process of the eye exert a strong defense against ocular drug delivery. This is the reason why conventional ocular dosage forms exhibit extremely low

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

bioavailability. Limited absorption of the drug through the lipophilic corneal barrier is mainly because of short precorneal residence time due to the tear turn-over, rapid nasolacrimal drainage of instilled drug from the tear fluid, and non-productive absorption through the conjonctiva. Only a small proportion (1–3%) of the applied drug penetrates the cornea and reaches intraocular tissues. For these reasons, it is necessary to develop efficient and more acceptable ocular therapeutic systems.

Different strategies can be carried out to improve the precorneal residence time and/or penetration ability of the active ingredient. Among them, one approach consists of using colloidal drug delivery systems such as nanoparticles. Initial studies carried out with nanocapsules, as ocular drug carriers, attempted to increase the penetration of lipophilic drugs into the eye by prolonging the precorneal residence time, as observed with other colloidal systems, liposomes and nanospheres. These studies, which concerned antiglaucomatous agents, such as betaxolol, carteolol, and metipranolol encapsulated in nanocapsules, only showed a reduction of the non-corneal absorption (systemic circulation) leading to reduced side-effects as compared with the free drug (Losa, 1993). These systemic side-effects are due to a poor ocular retention of drugs that are directly absorbed into the systemic circulation by conjunctival and nasal blood vessels. In two cases (carteolol and betaxolol), encapsulation in nanocapsules produced an improved pharmacological effect (reduction of intraocular pressure) than produced by free drug and nanospheres (although the penetration of nanocapsules was not tested) and reduced cardiovascular systemic side-effects. Metipranolol showed the same activity alone and associated with nanocapsules but, as in the case of carteolol and betaxolol, its side-effects were reduced. When betaxolol was used, the nature of the polymer making up the nanocapsule wall was found to be important, and poly (*e*-caprolactone) was more efficient than PIBCA or poly(lactic-co-glycolic acid) (Marchal-Heussler, 1993).

Calvo et al., explored the mechanisms of interaction of nanocapsules with ocular tissues to better understand the pharmacological responses obtained with antiglaucomatous agents. By confocal microscopy, they showed that poly(*e*-caprolactone) nanocapsules could specifically penetrate the corneal epithelium by an endocytic process without causing any damage to the cells, in contrast with PIBCA nanoparticles, the uptake of which was associated with cellular lysis (Calvo et al., 2001). These results explained the improved therapeutic effect and the reduction of systemic side-effects as a result of drug loss through the conjunctiva provided by poly(*e*-caprolactone) nanocapsules by increasing corneal epithelium penetration of lipophilic drugs. Calvo et al., also excluded the influence of the oily inner structure in the activity of the nanocapsules, in the light of the absence of differences in penetration between nanospheres and nanocapsules (Park et al. 2015; Afrooz et al., 2015), in contrast with Marchal-Heussler et al., who observed a better therapeutic effect with nanocapsules than with nanospheres (Marchal-Heussler et al. 1992). Moreover, Calvo et al. demonstrated with indomethacin-loaded nanocapsules that the colloidal nature of the carrier was the main factor influencing its ocular bioavailability. The same authors were also interested in the influence of the nature and the charge of the surface of nanocapsules on their physical stability and on their ocular bioavailability. They found that coating the negatively charged surface of poly(*e*-caprolactone) nanocapsules with cationic polymers could prevent their degradation caused by the adsorption of lysozyme, a positively charged enzyme found in tear fluid (Calvo et al. 1997). Moreover, they noticed that a cationic polymer, chitosan, adsorbed on the surface of nanocapsules was able to provide the best corneal drug penetration without any local intolerance as compared to another positively charged polymer. This was achieved by a combination of effects: Penetration of particles into the corneal epithelial cells, mucoadhesion of positively charged particles onto negatively charged membranes, and a specific effect on the tight junctions (Calvo et al. 1997).

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

This effect of improvement of ocular absorption was also reported by Calvo et al. 1996 with the immunosuppressive peptide cyclosporin A. The corneal level of the drug was increased fivefold as compared with an oily solution of the drug owing to a highly loaded nanocapsule preparation, also containing poly (*e*-caprolactone). The efficacy of this topical formulation has also been observed on a penetrating keratoplasty rejection model in the rat (Holzwarth et al., 2014) and also proposed an alternative preparation of cyclosporin nanocapsules based on poly(alkylcyanoacrylate) dispersed in poly(acrylic acid) gel able to drastically reduce toxicity of poly(alkylcyanocrylates) on the cornea and to promote absorption of the drug (Harper et al., 2015).

Chapter 7
Non-Ionic Surfactant Vesicles (Niosomes) as New Drug Delivery Systems

Abbas Pardakhty
Kerman University of Medical Sciences, Iran

ABSTRACT

Lipid vesicular systems composed of hydrated amphihiles with or without bilayer inducing agents such as cholesterol. On the basis of used amphiphilic molecule different nomenclature are used as liposomes, ufasomes and niosomes. Nonionic surfactants with mono-, di- or trialkyl chains form niosomes which are lipid vesicles with more chemical stability in comparison with phospholipids of liposomes. Both hydrophobic and hydrophilic chemicals can be encapsulated in niosomes as a new drug delivery system. This drug carrier system could have administered via injection, oral, pulmonary, vaginal, rectal, ophthalmic, nasal or transdermal routes with penetration enhancing potential. This chapter presents a detailed explain about niosome forming components, methods of preparation and routes of administration. Many examples for drug delivery potential of niosomes are also available in this review. Vaccine adjuvant and genetic substances vector capabilities are not given here.

INTRODUCTION

There are versatile lists of amphiphilic compounds for production of lipid vesicles which on the basis of used amphiphiles or structural compounds, different nomenclature has been used such as liposomes (Kaminskas et al. 2012), niosomes (Moazeni et al. 2010; Akbari et al. 2013), ufasomes (Patel et al. 2011), ethosomes (Liu et al. 2012), eliposomes (Lattin et al. 2012) and so on. In lipid vesicular systems, polar headgroups of amphiphilic molecules are oriented into aqueous compartments and their lipophilic parts form bilayer membranes. Niosomes are bilayer vesicles composed mainly of hydrated non-ionic surfactants in addition to, in many cases, cholesterol (CHOL) or its derivatives (Pardakhty and Moazeni 2013). Cosmetic industry was the place for the first account of niosome production (Handjani-Vila et Al. 1979) after which a large number of niosome applications in drug, vaccine and gene delivery have been

explored. While most niosomes are in the nano or sub-micron (colloidal) size range, not many authors used the "nanoniosome" or "nanovesicle" titles in their published articles due to introduction the new nanotechnology related phrases during the few recent years. Niosomes are capable to encapsulate both hydrophilic and lipophilic substances which the first ones usually are entrapped in vesicular aqueous core or adsorbed on the bilayer surfaces, and lyophobic molecules are encapsulated by their partitioning into the lipophilic domain of the bilayers. Incorporation of charged molecules into non-ionic surfactant vesicles forms charged or hybrid niosomes (Sennato et al. 2008). Vesicles can be also prepared from the mixed cationic and anionic surfactant systems such as cetyltrimethylammonium bromide and sodium lauryl sulfate (CTAB-SLS) (Aiello et al. 2010). These types of vesicles are presented as "cat-anionic" or "catanionic" vesicles. Catanionic vesicles can also be formed from electrostatic interaction between an ionized drug, such as diclofenac (Zhao et al. 2013) or alprenolol (Dew et al. 2012) and a positively/negatively charged surfactant.

Non-ionic surfactants have more chemical stability against oxidation and are less thermo-labile in comparison to phospholipids, the main constituent of liposomes (Fang et al. 2001; Tarekegn et al. 2010) thus less significant care in handling and storage are needed. Furthermore, greater versatility and lower cost make this type of vesicles more attractive in drug, gene and vaccine delivery (Florence 1993). From the pharmaceutical manufacturing stand of view the superiority of niosomes is simple methods required for industrialized and large–scale production of them without the use of pharmaceutically unacceptable solvents (Sahin 2007). In this chapter the most important aspects of niosomes and drug delivery potentials will be reviewed. Application of niosomes as gene or vaccine delivery tools will not discussed in this chapter.

Amphiphiles (Surfactants)

Following the application of some forms of energy such as mechanical or heating, the formation of niosomes is a self-assembly process due to high interfacial tension between aqueous medium and the lipophilic alkyl chain(s) resulted in the association of non-ionic surfactant monomers into vesicles (Uchegbu and Vyas 1998). Concurrently, the hydrophilic headgroups of amphiphilic molecules make water mediated interactions counter the previous formed force, finally result in bilayer formation. The

Muzzalupo et al. 2008.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

energy required to form vesicles with amphiphile molecules has three contributors related to the surface energy, the mechanical energy due to overpressure and the chemical potential excess (Manconi et al. 2005).

Formation of niosomes needs at the first step to an amphiphilic molecule, but in many cases the presence a wedge shaped molecule such as CHOL is essential to turn the micellar structure of surfactant aggregates to bilayer arrangement (Pozzi et al. 2009). The lipophilic moiety of amphiphile molecule may be contain one (Varshosaz et al. 2003), two (Okahata et al. 1981)or three (Yoshioka et al. 1994; Jain and Vyas 1995; Jain et al. 2005)alkyl or perfluoroalkyl(Zarif et al. 1994)groups or in some cases a single steroidal group(Echegoyen et al. 1988).

Amino acid-based surfactants (Guedj et al. 1994; Polidori et al. 1994), glycolipids (Polidori et al. 1997) and crown ether compounds (Echegoyen, Hernandez et al. 1988; Darwish and Uchegbu 1997; Muzzalupo et al. 2007; Paolino et al. 2007)were used to form niosomes in aqueous hydration media. More recently gemini surfactants, composed of two amphiphilic molecules connected to each other by a spacer, were also used to form niosomes (Muzzalupo et al. 2008; Paolino et al. 2008) (Figure 1).

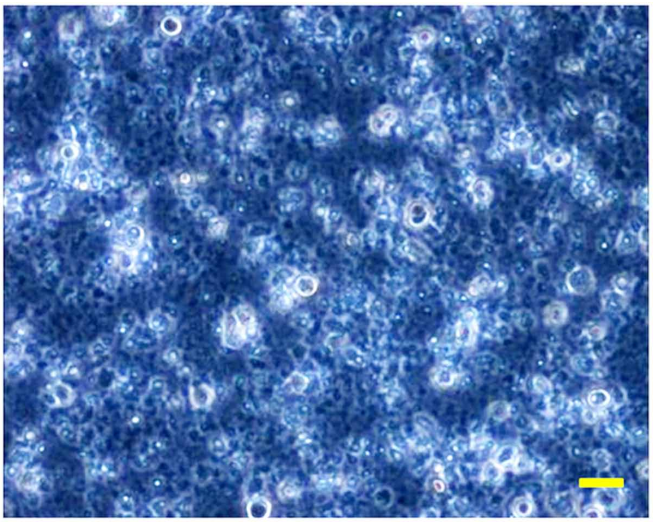
The flexibility of compounds capable for vesicle forming is due to different and various polar head groups attached to saturated or unsaturated alkyl chain(s) composed of 12 to 18 carbon atoms (C_{12}-C_{18}). However, here the main non-ionic surfactant classes used for niosome production will be presented which are alkyl ethers, alkyl esters, alkyl amides andsome other amphipathic compounds such as fatty acids.

Alkyl Ethers

Surfactant I (polyglyceryl-3 cethyl ether) has one n-alkyl chain and was the first amphihpile used for niosomes preparation (Handjani-Vila, Ribier et al. 1979). This amphiphile has been used for preparation of niosomes encapsulating adriamycin (Rogerson et al. 1987) and diclofenac sodium (Türker et al. 2005). Özer et al. (Özer et al. 2013) showed diclofenac sodium niosomes formulated by Surfactant I/ CHOL could bear different γ-radiation doses.

Hofland et al. (1992); Hofland et al. (1993); Hofland et al. *1994) reported the formation of a series of vesicles composed of n-alkyl polyoxyethylene ether surfactants(C*n*EO*m*) mainly designed for topical delivery of therapeutic compounds. Van Hal et al. (van Hal et al. 1996)used C*n*EO*m*, in which the number of oxyethylene units (*m*) ranged from 3 to 7 and the number of carbon atoms (*n*) ranged from 12 to 18, in order to obtain a systematic variation in length of alkyl chain and headgroup. They showed without CHOL in C_nEO_3 surfactants the vesicle formation was probable by sonication method but increasing the polyoxyethylene units to C_nEO_7 put an end to vesicle formation. Bouwstra et al (Bouwstra et al. 1997) also reported the vesicle forming ability of $C_{14}EO_5$ and $C_{16}EO_5$ in the absence of CHOL. Pardakhty et al. (2007) prepared vesicles composed of $C_{16}EO_2$ (Brij® 52), $C_{18}EO_2$ (Brij 72), $C_{18}EO_{10}$ (Brij 76), $C_{9=9}EO_2$ (Brij 92) and $C_{9=9}EO_{10}$ (Brij 97) without any added CHOL by film hydration method. In contrast with their results, Suwakul et al. (Suwakul et al. 2006)reported the lack of niosome formation with the mentioned surfactants in the absence of CHOL. This is maybe caused by different used methods for preparation of vesicles and unlike encapsulated drug's nature; Suwakul's group utilized direct sonication of molten lipids, in addition to use of propylthiouracil, a lyophobic drug which interact with bilayer formation ability of the applied surfactants and even made the bilayer less accommodating for CHOL molecules (Suwakul, Ongpipattanakul et al. 2006).While we used film hydarttion method with a water soluble molecule, insulin(Pardakhty, Varshosaz et al. 2007).

Various lipophilic drugs such as cycloslporin-A(Niemiec et al. 1995; Waranuch et al. 1998), erythromycin (Jayaraman et al. 1996), estradiol (Hofland, van der Geest et al. 1994), finasteride (Tabbakhian



EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

et al. 2005; Tabbakhian et al. 2006) minoxidil (Balakrishnan et al. 2009), tretinoin (Manconi et al. 2002; Manconi et al. 2003; Manconi et al. 2006), triamcinolone acetonide (Sankar et al. 2013), and some water soluble ones like α-interferon (Niemiec, Ramachandran et al. 1995), cimetidine (Lieb et al. 1994), and recombinant human granulocyte-macrophage colony stimulating factor (rhGM-CSF) (Memisoğlu et al. 1997),were encapsulated in C_nEO_m containing vesicles. All the mentioned vesicular formulations were formulated for topical delivery to stratum corneum, follicular (pilosebaceous units) and the other parts of the dermis. Hofland, van der Geest et al. (1994) studied permeation of estradiol from C_nEO_m niosomes. They showed that direct contact between niosomes and skin was imperative to exert the highest effect on drug transport. This effect even reported when pretreatment of the skin withnon-occlusive C_nEO_m niosomes enhanced the iontophoretic transport of R-apomorphine through human abdominal skin (Li et al. 2001). Hydroxychloroquine niosomes composed of Brij 98/CHOL were also formulated for topical management of oral lichen planus (Bendas et al. 2013).

Alkyl Esters

Among the alkyl esters, the most important and frequently used surfactants are sugar esters. These surfactants contain a sugar group as the polar headgroup of the amphiphilic molecule. The sugar moieties can be sucrose, glucose, sorbitan, methyl glucose, mallitol, or other sugars. The hydroxyl moieties of the sugars are partially esterified with alkyl chains. Kiwada et al. (KIWADA et al. 1985; Kiwada et al. 1985)used alkyl glycosides for preparation of vesicles and Schenk et al. (Schenk et al. 1989)worked on vesicles of sucrose ester surfactants. Sucrose cocoate, a mixture of fatty acid sucrose esters, was used for vesicle formation and encapsulation of sulfadiazine or diclofenac, both for topical delivery in nanoniosome forms (Tavano et al. 2010). Manconi et al. (Manconi et al. 2006)also reported the formation of niosomes composed of decylpolyglucoside with or without CHOL entrapping methylene blue as a hydrophilic model compound.

Figure 2. Dark field microscopy photomicograph of Leishmania major recombinant gp63 (r-GP63) multilamellar vesicles (MLVs) containing Span 60/cholesterol (70:30 molar ratio); magnification 40×40, bar = 5 μm

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Sorbitanmono esters (Span®) can be known as the basic and the most widely applied surfactants used for niosome preparations (Figure 2). Many articles could be found in literature about using sorbitan ester niosomes for entrapping different compounds with various physicochemical and therapeutic properties such as acetazolamide (Guinedi et al. 2005; Aggarwal et al. 2007), acyclovir(Attia et al. 2007), insulin (Khaksa et al. 2000; Ning et al. 2005), methotrexate (Chandraprakash et al. 1990; Chandraprakash et al. 1992), doxorubicin (Uchegbu et al. 1995; Uchegbu et al. 1996); vincristine (Parthasarathi et al. 1994), hydroxycamptothecin (Shi et al. 2006; Hong et al. 2009), vasoactive intestinal peptide (Dufes et al. 2004) and salicylic acid (Junyaprasert et al. 2008).

Generally, by increasing the hydrocarbon chain length from C_{12} to C_{18} and also more rigidity in bilayers by saturation of hydrophobic chain (stearate vs. oleate) in sorbitan esters vesicles, the encapsulation of water soluble molecules such as insulin (Varshosaz, Pardakhty et al. 2003), colchicine (Hao et al. 2002), salicylic acid and p-hydroxyl benzoic acid (Hao and Li 2010) or poorly soluble compounds such as flurbiprofen (Mokhtar et al. 2008)will be increased. Sorbitan esters can form vesicles in the presence or absence of molecules which operate co-operatively to form bilayer membranes; for instance, Span 60 with C_{18} mono-alkyl chain has been used for vesicle formation alone (Varshosaz et al. 2003), with CHOL (Suwakul, Ongpipattanakul et al. 2006) or CHOL/cholesteryl poly-24-oxyethylene ether (Solulan C24) (Uchegbu, Double et al. 1995). Kato et al. prepared temperature-sensitive fusogenic niosomes composed of Span 80 alone, or with CHOL (Kato et al. 2008).

Shi, Fang et al. (2006) used different poly (methoxypolyethyleneglycol cyanoacrylate-co-n-hexadecyl cyanoacrylate) (PEG-PHDCA) acted as surface modification materials, Span 60 and CHOLto encapsulate hydroxycamptothecin in "stealth nanoniosomes". The tumor inhibition rate of PEG5000-PHDCA niosomes (92.5 nm) at a dose of 2 mg/kg was five times that of drug injection at 4 mg/kg. Used PEG was likely to fold on the surface of the niosomes due to its compressibility, which is favorable for niosomes to prevent aggregation and improve its ability to evade macrophages uptake (Shi, Fang et al. 2006). Hong et al. (Hong, Zhu et al. 2009) modified the stealth nanoniosomes by coupling periodate-oxidated transferrin to terminal amino group of PEG to produce the active targeting vesicles with average diameters of 116 nm. Compared with injected free drug/non-stealth and stealth niosomes, transferrin holding PEG-PHDCA niosomes demonstrated the strongest cytotoxicity to three carcinomatous cell lines (KB, K562 and S180cells), the greatest intracellular uptake especially in nuclei, the highest tumor concentration and largest are under the intratumoral hydroxycamptothecin concentration curve, as well as the most powerful anti-tumoractivity with the inhibition rate of 71% against S180 tumor in mice.

Yoshioka, Sternberg et al. (1994) studied the vesicle forming ability of sorbitan monoesters and a sorbitan triester (Span 85). Sorbitan tri-stearate (Span 85) was also utilized for rifampicin niosome preparation (Jain and Vyas 1995). Increasing the amount of CHOL led to decrease in the entrapment efficiency of rifampicin due to rigidity increase of niosomal bilayers following CHOL content increment (Baillie et al. 1985).

Even though the polyoxyethylene sorbitan esters (Tween®) are more soluble and have higher hydrophilic lipophilic balance (HLB) values in comparison to sorbitan esters, this class of surfactants have been used for vesicle preparation in combination with sufficient amount of CHOL (Carafa et al. 1998; Di Marzio et al. 2011; Di Marzio et al. 2012). Carafa et al. (2006) reported the formation of pH sensitive nanoniosomes made from polxoxyethylene sorbitan mono-laurate (Tween 20), CHOL and its derivative, cholesteryl hemisuccinate, as pH-sensitive molecule. More recently a novel class of compounds based on Tween 20 surfactant bearing different pH-sensitive head groups (i.e., glycine, N-methyl-glycine, N,N-dimethyl-glycine) were used successfully for delivery of Na calcein, a carboxylic fluorescent dye,

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

to human hepatoblastoma (HepG2) cell line (Masotti et al. 2010). Di Marzio et al. (Di Marzio, Marianecci et al. 2011) studies suggest that the Tween 21/CHOL nanovesicle is also a pH-sensitive system. The pH-sensitivity and more bilayer fluidity of Tween 21 vesicles could be related to the lower content of counter ions and associated waters of hydration near the head groups, bearing only 4 PEG units, in comparison with Tween 20, bearing 20 PEG units.

Nano size niosomes composed of polyoxyethylene sorbitan monostearate (Tween 61) and CHOL were used for encapsulation of azelaic acid and its derivatives (Panyosak et al. 2009), diclofenac diethylammonium (Manosroi et al. 2008), glucose (Manosroi et al. 2008), and rice bran extract (Manosroi et al. 2012). Manosroi et al. (2010) reported the entrapment enhancement of three peptides including bacitracin, insulin and bovine serum albuminin neutral, anionic and cationic Tween 61 niosomes.

Utilizing of combination of sorbitan esters and their polyethoxylated derivatives has led to stable and efficient vesicles encapsulating of ciprofloxacin (Moazeni, Gilani et al. 2010)with low cytotoxicity against alveolar human carcinoma cell line (A549) suggesting a good aerosol drug delivery system. Combinations of different Spans and Tweens with CHOL were also successfully utilized to encapsulate ciprofloxacin in nanoniosomes for enhance intracellular delivery of this flouroquinolone (Akbari, Abedi et al. 2013; Akbari et al. 2015); the high physical stability of the prepared niosomes shown as little size change during the storage may be was due to the steric stabilization of vesicles following the incorporation of polyoxyethylene bearing surfactants, Tweens, in the formulations. Desai and Finlay (Desai and Finlay 2002) demonstrated the potential of encapsulating all-trans-retinoic acid in niosomes composed of Span 20 or Span 60 with Tween 80 and delivering it as an inhaled aerosol by nebulization. Such a combination, even though without CHOL and in the presence of Span 80/Tween 80/PEG 6000/water has been experimented for vesicle forming ability by transformation of lamellar liquid crystal structure to vesicular ones enable for encapsulation both hydrophilic (ribavirin) and hydrophobic (ibuprofen) substances (Liu and Guo 2007). Devaraj et al. (2002) prepared different niosomal formulations in which a combination of polysorbates (Tweens), polyglyceryl-3-diisostearate and different fatty alcohols used for vesicle formation and encapsulation of anti-inflammatory drug, ketorolac. Combination of Span 20 or Tween 20/ polyglycero-6-oleate was also used for stable nano size niosomes enable to encapsulate three model peptide or proteins (Cortesi et al. 2007). Span and Tween niosomes were also used for encapsulation of poorly water soluble antifungal drug, itraconazole (Alomrani et al. 2015). Rat abdominal skin permeation studies showed Span niosomes had enhancement penetration of itraconazole compared to its solution; however, it was less in magnitude than that of Tweens.

Alkyl Amides

Zarif, Gulik-Krzywicki et al. (1994) studied the supramolecular assemblies or vesicles produced by applying alkyl galactosides and glucosides incorporating amino acid spacers. They also reported the formation of perfluoralkyl glycolipid-based vesicles (Zarif 2002). Uchegbu (Uchegbu 1998)reported the formation of nanoniosomes composed of palmitoyl muramic acid/CHOL/Solulan C24 which were loaded with doxorubicin by the use of ammonium sulfate gradients. The biodistribution of prepared 200 nm vesicles in male Balb/c mice after i.v. administration were found to avoid liver uptake but not splenic uptake when compared to drug loaded Span 60 niosomes. N-palmitoylglucosamine (NPG) niosomes were also prepared by sonication of NPG/ Span 60/CHOL/ Solulan C24 which had a z-average mean diameter of 164 nm (Dufes et al. 2000).

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Other Amphiphilic Compounds

Many other compounds with surfactant-like behavior have been used for vesicle formation; for example, long chain fatty acids such as oleic acid can be used for vesicle formation which usually named as unsaturated fatty acid vesicles or 'ufasomes' (Gebicki and Hicks 1973). Intranasal lyophilized gels containing ufasomes were prepared from oleic acid to circumvent the low and erratic absorption of orally administrated cinnarizin (Salama and Aburahma 2015).

Covalently bound alkyl amino acids with efficient amphiphilic properties have been used for vesicle formation (Neumann et al. 1987).

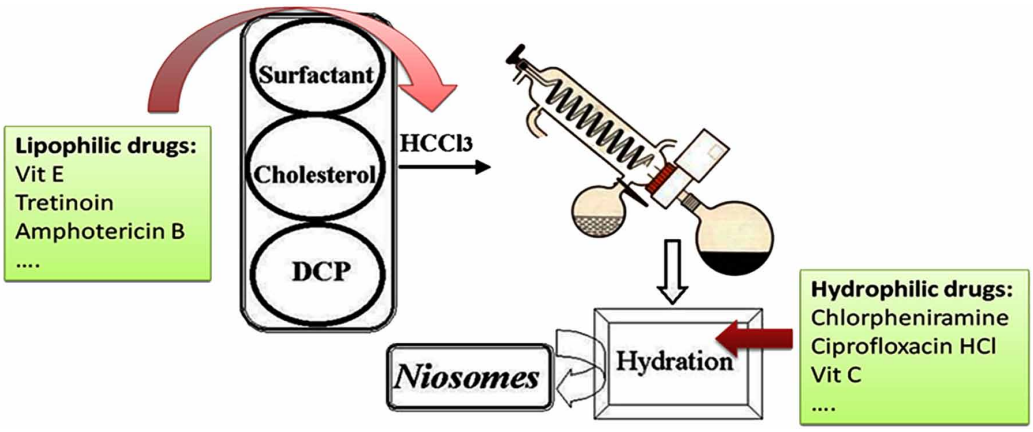
Gopinath et al. (2004) utilized one ascorbic acid derivative, ascorbyl palmitate, for vesicle formation and *in vitro* transdermal delivery of azidothymidine by these vesicles which named as 'aspasomes'. Conacher et al. (2001) has also developed drug delivery vehicles called 'bilosomes', which are vesicles prepared from bile salts such as deoxycholate for oral immunization with peptide and protein antigens.

BILAYER INDUCING AGENTS

Cholesterol

The most common additive found in niosomal systems is cholesterol (CHOL) which is known to abolish the gel to liquid phase transition of liposomal and niosomal systems, resulting in less leakiness of the vesicles and improved niosomes stability (Junyaprasert, Teeranachaideekul et al. 2008). Surface pressure measurements on monolayers of nonionic surfactant/CHOL mixtures demonstrated a condensing effect of CHOL as evidenced by the decrease in the effective area per molecule as the CHOL content of the monolayer increased. This effect might have attributed to the accommodation of CHOL in the molecular cavities formed by surfactant monomers assembled into vesicles and is responsible for the observed decreased permeability of CHOL-containing membranes compared to CHOL free membranes (Devaraj et al. 2002). CHOL is used to complete the hydrophobic moiety of high HLB single alkyl chain non-ionic surfactants for vesicle formation (Masotti, Vicennati et al. 2010). In general, it has been found that a molar ratio of 1:1 between CHOL and non-ionic surfactants is an optimal ratio for the formulation of physically stable niosomal vesicles (Nasseri 2005). Some reports denote the formation of monohydrate or anhydrous CHOL crystals among the surfactant/CHOL bilayers (Caracciolo et al. 2008). The minimum amount of CHOL required to form vesicles without evoking surfactant aggregates or other irregular structures depended on the type of surfactant and it's HLB (van Hal, Bouwstra et al. 1996; Uchegbu and Vyas 1998).

Other Bilayer Inducing Agents



Non-ionic surfactant vesicles have been formed with different lipid compositions without CHOL. In Table 1, a complete list of these compounds was presented. The resultant vesicles showed different physicochemical behaviors; for example, polyhedral niosomes were formed from systems containing $C_{16}G_2$ (hexadecyl diglycerol ether) and Solulan C24 alone, while cholesterol-containing systems formed spherical vesicles (Arunothayanun et al. 2000).

Table 1. Different compounds utilized for niosome preparation in the absence of cholesterol

Bilayer Additives	Used Surfactant	Encapsulated Compound	Reference(s)
Soybean phosphatidylcholine	Span 80	------	(Kato, Walde et al. 2008)
PEG 400	Span 80	Ribavirin or ibuprofen	(Hua and Liu 2007)
PEG 6000	Tween 80/Span 80	Hemoglobin	(Liu et al. 2007)
PEG 6000	Tween 80/Span 80	Ribavirin or ibuprofen	(Liu and Guo 2007)
Poly-24-oxyethylene cholesteryl	Hexadecyl diglycerol	5(6)-carboxyfluorescein	(Arunothayanun, Bernard et al. 2000)
ether (Solulan C24)	ether (C16G2)		
Fatty alcohols	Tween 20, 40, 60, 80	Ketorolac tromethamine	(Devaraj, Parakh et al. 2002)
(C12, C14, C16, C18, and C16+18)			
Absolute ethanol	Span 20, 40, 60, 80	Flurbiprofen (proniosome)	(Mokhtar, Sammour et al. 2008)

Figure 3. Thin film hydration (hand shaking) for preparation of MLV niosomes

Methods of Niosome Preparation

Generally, there are two classes of niosome or liposome preparation methods; the first set includes dissolving the whole lipids in organic solvent(s) for molecular level mixing of the bilayer constituents, then removing the organic solvent and hydration of formed lipid thin films or surfaces by an aqueous medium. The second series of vesicle formulation comprises the direct mixing of lipids and hydration medium, usually in high elevated temperature, which have omitting the hazardous effect of trace residuals of organic solvents on entrapped substance or biologically applied environments.

Detailed preparation methods which use organic solvents are presented here:

1. **Thin Film Hydration (Hand Shaking):** In this method all lipids are dissolved in an organic solvent, typically chloroform. The solvent is evaporated under reduced pressure and the hydration phase containing water soluble components is added at a temperature higher than phase transition temperature of used surfactants (Figure 3). This is the most common method of niosome preparation and for instance was reported for encapsulating of nimesulidea (Shahiwala and Misra 2002).

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

2. **Reverse-Phase Evaporation:** Vesicle forming ingredients are dissolved in chloroform/diethyl ether and water in oil emulsion is formed by sonication of two phase's mixture. The organic solvent(s) is evaporated in a rotary evaporator and the resultant viscous niosomal suspension is diluted by adding aqueous phase. This technique was reported for preparation of acetazolamide niosomes (Guinedi, Mortada et al. 2005).
3. **Ether Injection:** Lipids are dissolved in diethyl ether and slowly injected into the preheated aqueous phase (about 60°C) by a needle. Under this condition, the organic solvent is evaporated and niosomal suspension is formed as used for entrapment of some newly synthesized beta-blockers (Piplani, Kumar et al. 2015).
4. **Dehydration Rehydration Method:** The prepared vesicles are freeze dried (lyophilized) and then rehydrated by appropriate aqueous dehydration rehydration (DRV) medium (Tafreshi and Mirdamadi 2015). We used this method for encapsulation of N, N-diethyl-meta-toluamide, as an insect repellant, in niosomes (Amanatfard et al. 2015).
5. **Solvent Evaporation from Double Emulsion Droplets:** By using a microfluidic flow focusing device to form the double emulsion (monodisperse water–oil–water emulsion droplets) following by organic solvents evaporation from the oil shells, giant vesicles are created (Foster et al. 2010).
6. Comprehensive lipid vesicle preparation techniques without need to use an organic solvent are described below:
7. **Heating and Sonication of Lipids:** A mixture of vesicle forming lipids is melted in a glass test tube. The pre-warmed aqueous phase containing the drug is then added to the molten lipid. The mixture is immediately sonicated at elevated temperature in an ultrasonic bath followed by vortexing. This method was used for encapsulation of propylthiouracil (Suwakul, Ongpipattanakul et al. 2006).
8. **Homogenization of Lipids:** Initially, a combination of lipids and absolute ethanol is heated in tightly sealed glass vials in water bath (55–60°C). To each of the formed transparent solutions, the specified amount of drug containing hot distilled water (55–60°C) is added while warming in the water bath till a clear or translucent proniosomal solution is obtained. By addition an appropriate buffer, niosomes are formed and processed with a high-pressure homogenizer. Niosomes of tenofovir, an anti-HIV drug, were formulated by this technique (Zidan et al. 2011).
9. **Lamellar Liquid Crystal (LLC) Transformation:** This method is based on the microstructure and transformation of surfactant/polymer mixtures such as Tween 80, poly(ethylene glycol) (PEG) 6000, Span 80 and water which are vortex mixed to prepare the LLC at specific mass ratio (Liu and Guo 2007). PEG aqueous solution is then added to the LLC and the samples are mixed by sonicating to prepare niosomes.
10. **Heating (Mozafari) Method:** This method involves the hydration of the lipid vesicle components in an aqueous medium followed by the heating of these components, in the presence of glycerol (3% v/v), up to *c.*120°C (Pardakhty and Moazeni 2013).
11. **Application of Super Critical CO_2 ($scCO_2$):** Lipids and aqueous phase containing drug are added into the view cell and the temperature is raised to 50°C. CO_2 gas is introduced into the view cell and pressure and temperature in the view cell are maintained at 200 bar and 50±1°C, respectively. The pressure was released after 30 min and the niosomal dispersion is obtained (Manosroi, Chutoprapat et al. 2008). Rapid expansion of supercritical solution (RESS)-based process coupled with a gas ejector again uses $scCO_2$ in elevated temperature to change the dissolved surfactant into multilamellar or unilamellar niosomes (Wagner and Rizvi 2015).

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

12. **Inert Gas Bubble:** Introduction of inert gas (N_2) bubbles into a coarse dispersion of non-hydrated lipids produces stable lipid vesicular dispersions with a mean particle size in the range between 0.2 and 0.5 μm (Talsma et al. 1994).
13. **Microfluidic Hydrodynamic Focusing:** Surfactant mixture dissolved in a water miscible solvent such as isopropyl alcohol and aqueous phase are vigorously mixed in microchannels under high hydrodynamic pressure (Lo et al. 2010). The resultant nanoscaled niosomes had narrower size distributions in comparison with traditional methods.
14. **Electroformation of Vesicles:** This procedure is based on swelling of membrane-forming lipid deposit on an electrode assisted by applied alternating electric fields to generate vesicles in aqueous solutions of the amphiphilic molecules (Okumura and Iwata 2011). The resulting giant vesicles of 30–50 μm, some as large as 100 μm, were formed with the standard setup.

Niosomes as New Drug Delivery Systems

Niosomes are currently used as versatile drug delivery systems with many pharmaceutical applications. Various routes for niosome administration are available which in this section some examples for therapeutic medicines incorporated in such vesicular systems are listed. In transdermal route of drug administration, many vesicles have been derived from proniosomal formulations which were more stable and appropriate dosage forms for topical application.

Nasal Route

Nasal mucosa offers advantages to deliver drugs to brain via olfactory route thus provides rapid onset of drug action and hence faster therapeutic effect (Ravouru et al. 2013; Illum 2015). Niosomes of sumatriptan succinate were prepared and evaluated for nasal absorption using an ex vivo animal model, showing 78.1% of the drug absorption (Gayathri Devi and Udupa 2000). Folic acid, a water soluble vitamin, showing difficulty in crossing blood-brain barrier (BBB), was successfully encapsulated in niosomes and administered through nasal cavity of rats (Ravouru, Kondreddy et al. 2013).

Ophthalmic Route

There are some problems of conventional ocular therapy, such as short residence time, loss of drug through nasolacrimal drainage, impermeability of corneal epithelium and frequent instillation (Guinedi, Mortada et al. 2005). To overcome these limitations, colloidal drug delivery systems, such as niosomes, have been evaluated.

Aggarwal et al. (Aggarwal et al. 2004)prepared acetazolamide-loaded Span 60/ CHOL niosomes and evaluated their intraocular pressure (IOP) lowering potential in adult male rabbits. Results of the study indicated that it was possible to develop a safe (as indicated by corneal toxicity studies) and physiologically active topical niosomal formulation of acetazolamide relative in efficiency to the newer local carbonic anhydrase inhibitor, dorzolamide. Selected acetazolamide niosomal formulations composed of Span 60/ CHOL were tested for their intraocular pressure lowering activity on normotensive albino rabbits and the results were compared with that of plain niosomes and acetazolamide solution (1%) prepared using polyethylene glycol 400 (7%, v/v) and propylene glycol (53%, v/v) (Guinedi, Mortada et

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

al. 2005). Multilamellar acetazolamide niosomes formulated with Span 60/CHOL in a 7:4 molar ratio were found to be the most effective and showed prolonged decrease in IOP.

Niosomes prepared by reverse phase evaporation (REV) method loaded with acetazolamide were coated with 0.05% Carbopol934P in order to increase the retention time of the drug in the eye of New Zealand albino rabbits (Aggarwal, Pal et al. 2007). Microdialysis method for determination of drug levels in aqueous humor showed a significant broadening of peak time and concentration extent for the bioadhesive coated niosomal formulation. Similar results were reported for brimonidine tartrate, an α2-adrenergic agonist indicated in open angle glaucoma, when entrapped in Span 60/CHOL niosomes (Prabhu et al. 2010).

The potential ocular irritancy and/or damaging effects of niosomal formulations containing gentamicin sulfate were evaluated by observing them for any redness, inflammation, or increased tear production, upon application to the eyes of albino rabbits (Abdelbary and El-gendy 2008); no sign of irritation for all tested niosomal formulations.

Conjunctival and corneal tolerability assessment of ocular naltrexone niosomes on the hen's egg test-chorioallantoic membrane (HET-CAM) and bovine corneal opacity and permeability (BCOP) models showed good ocular tolerability and minimal ocular tissue irritation (Abdelkader et al. 2010; Abdelkader et al. 2011; Abdelkader et al. 2012).

Atenolol (Abu Hashim et al. 2014), cyclopentolate (Perini et al. 1996), ganciclovir (Mutha et al. 2013), ofloxacin (Gupta et al. 2010), pilocarpine (Sheena et al. 1997), prednisolone (Gaafar et al. 2014), some newly synthesized beta blockers (Piplani, Kumar et al. 2015), tacrolimus (Li et al. 2014) andtimolol (Kaur et al. 2010) were also successfully entrapped in niosomes and evaluated for ophthalmic drug delivery.

Oral Route

The delivery of peptide and protein therapeutic agents to the systemic circulation through oral administration is hindered by numerous barriers, including proteolytic enzymes, sharp pH gradients and low epithelial permeability (Lee and Yamamoto 1989). Niosomes could be used to overcome these barriers and improve protein absorption following oral delivery. Yoshida et al. (Yoshida et al. 1992) investigated oral delivery of 9-desglycinamide-8-arginine vasopressin entrapped in niosomes in an *in vitro* intestinal loop model and reported that stability of peptide increased significantly. Animals treated with oral niosome-encapsulated insulin (100 IU/Kg) showed decreased levels of blood glucose and elevated serum insulin, which in the case of Brij 92 vesicles, hypoglycemic effect was significant ($P < 0.05$) (Pardakhty et al. 2011). More recently, Span 60/CHOL/N-trimethyl chitosan (TMC) niosomal nanostructure has been used to enhance insulin permeability through Caco-2 cell monolayer 4-fold, compared with insulin alone (Moghassemi et al. 2015).

Niosomes also could be used for improvement of botanical extract oral absorption and distribution; the in vivo distribution study of *Ginkgo biloba* extract nano-vesicles composed of Tween 80/Span 80/CHOL showed that the flavonoid glycoside content in heart, lung, kidney, brain, and blood of rats treated with niosomal carrier system was greater than those treated with the oral *Ginkgo biloba* extract tablet (Jin et al. 2013).

Di Marzio et al. (Di Marzio et al. 2013)prepared polysorbate 20 nano-niosomes for oral delivery of unstable or poorly soluble compounds by film hydration associated with sonication in order to reduce the size down to sub-micron range. These vesicles were stable in different pH and in simulated gastrointestinal media with high mucoadhesion properties.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Niosomes could be used to enhance the aqueous solubility of poorly soluble compounds, thus improving their oral bioavailability. *In vivo* study on rats revealed five-time increment in bioavailability of ganciclovir after oral administration of Span60/CHOL (3:2 molar ratio) as compared with tablet (Akhter et al. 2012). Sezgin-Bayindir et al. (2015) formulated candesartan cilexetil-loaded niosomes and mixed niosomes with promising water solubility and bile solution stability promotion of entrapped compound. Developed niosomal griseofulvin improved the oral bioavailability and maintained therapeutic level of drug for a longer period of time as compared to free griseofulvin in albino rats (Jadon et al. 2009). Acyclovir (Attia, El-Gizawy et al. 2007), carvedilol (Arzani et al. 2015), celecoxib (Nasr 2010), gliclazide (Tamizharasi et al. 2009), paclitaxel (Bayindir and Yuksel 2010), piroxicam (Abdallah et al. 2011) and tenofovir disoproxil fumarate (Kamboj et al. 2014)are some drugs which their oral bioavailabilities were enhanced after encapsulation in niosomal formulations. Cationic niosomes were also used for improving oral bioavailability and lung targeting efficiency afteroral or intravenous administration of azithromycin in rats, respectively (Non-Lecithoid 2014).

Parenteral Route

Many researchers used parenteral route of administration such as intramuscular injection of luteinizing hormone releasing hormone (LHRH) vesicles (Arunothayanun et al. 1999) and subcutaneous injection of norfloxacin niosomes (Abdelaziz et al. 2015) for evaluation of prepared drug delivery systems. However, anticancer therapy and brain targeting are two main goals which could be used for effective niosomal drug delivery and here would be focused on.

Anticancer chemotherapy by using vesicular systems have many benefits such as reduced organ toxicity (O'brien et al. 2004), enhanced antineoplastic efficacy (ElBayoumi and Torchilin 2009), prolonged circulation of vesicular carriers (Cosco et al. 2009)and less mortality in patients (Hamilton et al. 2002). Gude et al. (2002) prepared cisplatin-loaded niosomes and investigated them for antineoplastic activity in experimental metastatic model of B16F10 melanoma. Theophylline and its combination effect with free cisplatin and niosomal cisplatin were also carried out in the same model. Treatment with niosomal cisplatin (1 mg/kg) and combination of the same with theophylline (15 mg/kg) showed significant reduction in the number of lung nodules as compared to untreated control as well as with free cisplatin (1 mg/kg).

Carboplatin was incorporated into niosomes and the therapeutic efficacy of prepared vesicles against S-180 lung neoplasm model was evaluated (Lu et al. 2003). Antitumor effect was increased and differed significantly ($p<.05$) compared with the original drug of the same dose. Cisplatin-loaded niosomes (CP-NMs) were prepared under optimized conditions with Span 40 and cholesterol and their anticancer efficacy was tested in rabbits bearing VX2 sarcoma (Yang et al. 2013). The rabbits locally injected with the CP-NMs gave significantly superior results of inhibition of tumor growth, much lower mortality and improved results of body weight change and inhibition of tumor metastasis to inguinal lymph nodes and liver compared to those treated in the same way with the drug solution.

The blood–brain barrier (BBB) is the most important barrier impeding drug transport into the brain via the blood circulation (Chen and Liu 2012). Many attempts have been done to overcome this barrier for effective drug delivery into brain such as administration of lipid vesicles; both conventional niosomes or niosomal surface decorated with a targeting agent, such as N-palmitoylglucosamine (NPG), permit an enhanced drug delivery to brain parenchyma (Paolino et al. 2011). Niosomal formulation functionalized with NPG loaded with doxorubicin was intravenously injected in rats for reducing drug accumulation in heart and increasing brain concentration of drug (Bragagni et al. 2012). I.v. injection of vasoactive

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

intestinal peptide (VIP)-loaded glucose-bearing niosomes to mice confirmed the presence of intact VIP in brain after administration of VIP-loaded niosomes, but not after administration of VIP solution (Dufes, Gaillard et al. 2004).

A niosomal formulation, functionalized with NPG, was also developed as potential brain targeted delivery system for an endogenous neuropeptide, dynorphin-B (Bragagni et al. 2014); i.v. administration of dynorphin-B optimized niosomal formulation to mice (100 mg/kg) showed a pronounced antinociceptive effect, significantly higher ($P< 0.05$) than that given by i.v. administration of the simple solution of the peptide.

Recently, Span-Tween 60/CHOL niosomes of ascorbic acid and α-tocopherol were i.v. administered in male rats with cerebral ischemia-reperfusion induced by middle cerebral artery occlusion for 30 min (Varshosaz, Taymouri et al. 2014); i*n vivo* results showed that the used niosomes had more neuroprotective effects against cerebral ischemic injuries than free ascorbic acid.

Pulmonary Route

Pulmonary administration of drug-loaded vesicles may represent an interesting approach for both the targeting of drugs to lungs and the improvement of the passage of drugs through the mucus barrier and hence of their intracellular uptake (Carafa, Di Marzio et al. 2006). One of most targeted lung diseases for colloidal drug delivery is tuberculosis, due to emersion of Mycobacterium multi-, single- and extensive-drug resistance infections in humans (Garg et al. 2015). Jain and Vyas (Jain and Vyas 1995) injected micron-sized rifampicin-loaded niosomes through the caudal vein into albino rats. More than 60% of the drug was localized in the lungs after 3 h. Rifampicin niosomes attained substantially higher drug concentrations in thoracic lymph nodes when administered through the intraperitoneal (i.p.) route suggesting compartmentalization of the drug took place in the lymphous tissue when administered through this route of administration (Jain et al. 2006).

However, for pulmonary route of administration, promising results were obtained after biological evaluation of selected pyrazinamide niosomal formulations on guinea pigs infected with *Mycobacterium tuberculosis* (El-Ridy et al. 2011). Encapsulation of ethambutol hydrochloride in niosomal formulations for the treatment of tuberculosis also showed higher efficacy and safety compared with the free drug (El-Ridy et al. 2015). The organ distribution pattern of rifampicin (Mullaicharam and Murthy 2004) and gentamicin sulfate (Mullaicharam and Murthy 2006)from niosomes was also studied in albino rats; after intratracheal administration of niosomal-entrapped drugs, a 145-time and 27-time increase in drug accumulation capacity of rifampicin and gentamicin niosomes to free drug solution in lungs was observed, respectively. Mehta and Jindal (Mehta and Jindal 2013) used Tyloxapol, a biocompatible surfactant, for preparation of nano-sized niosomes with high encapsulation efficiencies of antituberculosis drugs (rifampicin, isoniazid and pyrazinamide).

Topical Route

The ability of a particle to diffuse through the *stratum corneum* (for particles of the same charge) depends mainly on its size and viscoelastic properties (Babu et al. 2009). Niosomal bilayers could fuse in *stratum corneum*, the main barrier impeding drug transport through human skin (Hofland, van der Geest et al. 1994), resulting to penetration enhancing effect of lipid vesicular systems both for water soluble or insoluble compounds. Alvi et al. (Alvi et al. 2011)reported that vesiculization of 5-FU not

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

only improved the topical delivery, but also enhanced the cytotoxic effect of 5-FU in actinic keratosis and non-melanoma skin carcinoma. There are many clinical applications of topical niosomes and proniosomes for treatment of acne, cutaneous inflammation, cutaneous leishmaniasis, hair loss and alopecia, local anesthesia, psoriasis, skin and nail fungal infections, vitiligo and whitening effect (Rahimpour and Hamishehkar 2012; Hamishehkar et al. 2013; Rahimpour et al. 2015). Proniosomes are liquid crystalline-compact niosomal hybrid that can be hydrated to form niosomal dispersion instantly before use (Rahimpour, Kouhsoltani et al. 2015).

Asadi et al. (Asadi et al. 2012) prepared and evaluated topical anti-leishmanial effect of paromomycin niosomes in balb/C mice model with promising results. Non-steroidal anti-inflammatory drugs such as acelofenac (Nasr et al. 2008; Solanki et al. 2010; Srinivas et al. 2010), diclofenac(Raja et al. 1994; Manosroi et al. 2008; Özer, Turker et al. 2013), flurbiprofen (Reddy and Udupa 1993; Mokhtar, Sammour et al. 2008),indomethacin (Noori 2012), ketorolac (Alsarra et al. 2005), meloxicam (El-Menshawe and Hussein 2013) andpiroxicam (Solanki et al. 2007; Chandra and Sharma 2008; AHMED et al. 2013)have been formulated as niosomal or proniosomal formulation for enhancement of drug transport through skin after transdermal route of administration.

Minoxidil is a lipophilic drugs approved by FDA for topical use in androgenic alopecia. For increasing skin latency and penetration, many reports are available for niosomal encapsulation and application of minoxidil (Mura et al. 2007; Balakrishnan, Shanmugam et al. 2009; Mura et al. 2009; Mura et al. 2011; Mali et al. 2013). Recently, by a randomized and controlled double-blind clinical trial, we endorsed the superiority and better efficacy of minoxidil niosomes in comparison to conventional formulation (Shamsi Meymandi et al. 2014). Manosroi et al. reported in vivo hair growth promotion activity of gel containing niosomes loaded with the *Oryza sativa* bran fraction (Manosroi et al. 2012). The *in vitro* permeation, skin retention and hair follicular transport of finasteride were reported by Tabbakhian et al. (Tabbakhian, Daneshamouz et al. 2005; Tabbakhian, Tavakoli et al. 2006).

A combination of iontophoresis and vesicular entrapment have been used for transdermal transport enhancement of, finasteride (Prasanthi and K Lakshmi 2013), isosorbide dinitrate (Jain et al. 2011) and triamcinolone acetonide (Sankar, Babu et al. 2013).

Vaginal Route

Ning et al. (Ning, Guo et al. 2005) prepared insulin-loaded Span 40 and 60 niosomes and investigated the hypoglycemic effects and insulin concentrations after vaginal administration of vesicles to rats in comparison to subcutaneous administration of insulin solution. The same research group developed alternative formulations (liposomes/niosomes) for the vaginal administration of clotrimazole to provide sustained and controlled release of appropriate drug for local vaginal therapy, were evaluated as delivery vehicles (Ning et al. 2005). The prepared liposomes/niosomes were incorporated into 2% carbopol gel, and the systems were evaluated for drug stability in phosphate-buffered saline (pH 7.4) and simulated vaginal fluid at 37 ± 1°C.

Zidan and Habib prepared tenofovir niosomal gel to overcome the low permeability of this antiretroviral drug through mucosal membranes. Vesicular size, shape and surface charge, drug entrapment efficiency, *in vitro* release, and skin permeation were used to assess the gels. In addition, their biological performance on *Lactobacillus crispatus* viability and mucoadhesion to porcine vaginal tissue was also assessed with promising results.

CONCLUSION

Niosomes are widely used by research scientists for improving drug pharmacokinetic, targeting, and penetration through biological membranes. Intracellular delivery of therapeutic compounds, enhancing the stability and solubility of vast range of chemical compounds and reducing the toxic effect of some active therapeutic agents are also utilized by niosomal drug delivery. This lipid vesicular system are also widely used in cosmetic industry and can be used for vaccine and gene delivery.

Chapter 8
Cancer Drug Delivery: Pharmacogenetics, Biomarkers, and Targeted Therapies

Jai N. Patel
Levine Cancer Institute, USA

Jeryl Villadolid
Levine Cancer Institute, USA

ABSTRACT

Advancements in cancer drug delivery have led to the development of personalized oncology care through molecularly-driven targeted therapies. Understanding molecular and cellular mechanisms which drive tumor progression and resistance is critical in managing new treatment strategies which have shifted from empiric to biomarker-directed therapy selection. Biomarker-directed therapies have improved clinical outcomes in multiple malignancies as monotherapy and in combination with other treatment modalities, however the changing scope of treatment options presents new opportunities and challenges for research. Furthermore, pharmacogenetics may provide a rationale method of personalizing anticancer drug dosing and supportive care management for oncology patients. This chapter reviews biomarker classifications and pharmacogenetics in anticancer therapy and supportive care. Examples of biomarker-directed therapies and clinical assays, in addition to future directions of molecular profiling in oncology therapy management are discussed.

INTRODUCTION

Novel methods of individualizing cancer drug delivery and selection are critical to improve patient outcomes given the large heterogeneity in drug response that exists across the cancer patient population. Until recently, the majority of genomic cancer research has been in discovery and validation; however, as our knowledge of tumor molecular profiling improves, the implementation of genomic cancer medicine in the clinic becomes increasingly tangible, paralleled with the development of dozens of targeted cancer therapies (Tran et al., 2012). Our current understanding of cancer at the molecular level has resulted in a

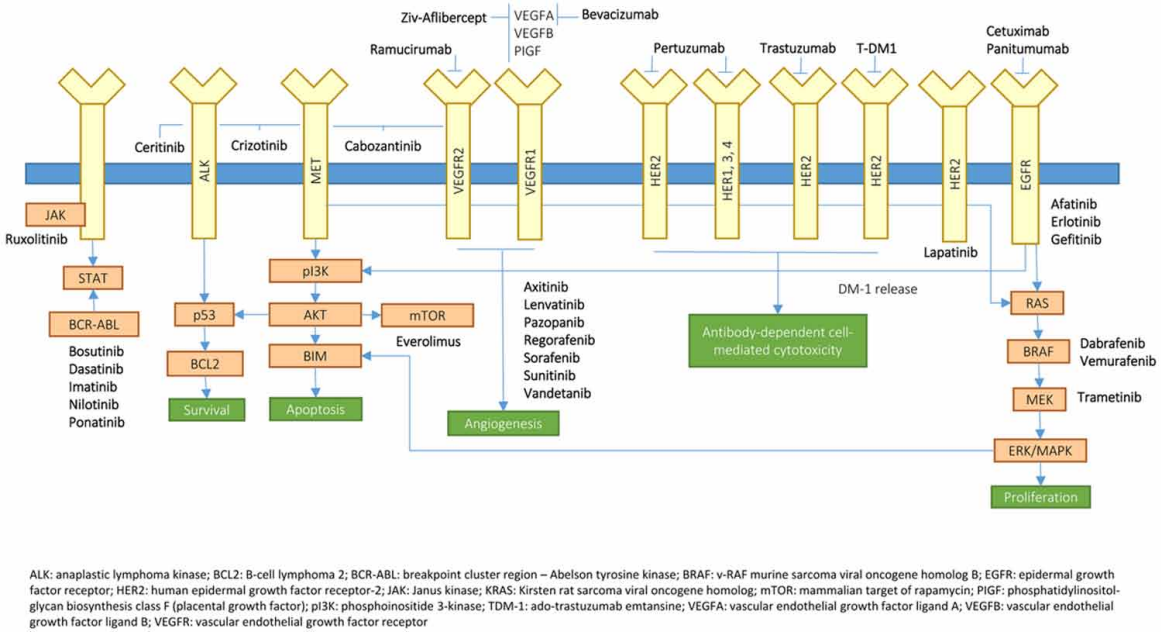
shift from characterizing tumors solely based on their anatomical location and histology to consideration of their molecular profile, opening an array of possibilities for a targeted approach to cancer therapy (Macconaill, Van Hummelen, Meyerson, & Hahn, 2011).

Pharmacogenetic biomarkers found within the tumor and the host offer valuable information for personalizing anticancer drug delivery. As the number of clinical assays available to test for pharmacogenetic biomarkers increases, it is imperative for clinicians to understand the therapeutic implications of mutations occurring within these molecular pathways to aid in drug selection and delivery. This chapter aims to summarize clinically relevant pharmacogenetic biomarkers, which may be used to personalize cancer therapy selection and dosing, in addition to a review of pharmacogenetics in supportive care management related to the treatment of cancer-related symptoms. Tables 1 and 2 summarize clinically relevant somatic and germ-line pharmacogenetic biomarkers and drug targets, and their respective clinical assays available in practice.

BACKGROUND: BIOMARKERS OVERVIEW



DNA analysis for pharmacogenetic purposes can be performed with either somatic or germ-line DNA. The major difference between somatic and germ-line DNA is the origin of the mutated cell (Patel, Mandock, & McLeod, 2014). While germ-line DNA is found in germ cells (sperm or egg) and therefore inherited and transmitted to the offspring, somatic DNA is found within the tumor after conception and subsequently not passed on to offspring, i.e. acquired after birth. Germ-line DNA is readily obtained by blood samples, and variations, if present, will occur homogenously throughout any randomly drawn blood sample within the same individual. Somatic DNA must be obtained by tumor biopsy and is therefore subject to sample selection. Common practice is to obtain one biopsy from the primary tumor for molecular analysis, as it was assumed that tumors were homogenous and the section sampled accurately represented the complete tumor composition. However, there is evidence to suggest that intra-tumor heterogeneity exists within cancer, where molecular analysis of one biopsy site may differ from another biopsy site (Gerlinger et al., 2012). Additionally, somatic mutations may change or evolve during cancer progression, resulting in a significant challenge in applying routine cancer pharmacogenetics to the clinic. While germ-line DNA is particularly useful for determining the pharmacokinetic behavior of a drug by understanding variations in drug metabolizing enzymes and/or transporters, somatic DNA is particularly useful in determining the pharmacodynamic effect of a drug and ultimately tumor response (Deenen, Cats, Beijnen, & Schellens, 2011).

Cancer biomarkers can be broadly categorized into two classifications: prognostic and predictive. A prognostic biomarker is mainly associated with disease outcome in the absence of treatment (i.e. Oncotype Dx, Mammaprint), while a predictive biomarker is valuable in assessing drug response (i.e. *ALK* [anaplastic lymphoma kinase], *BCR-ABL*, *EGFR* [epidermal growth factor receptor] (Mandrekar & Sargent, 2009; Patel, 2014).

Alternatively, some biomarkers may be classified as both prognostic and predictive (i.e. human epidermal growth factor receptor-2 [*HER2*], KRAS [Kirsten rat sarcoma viral oncogene homolog], and *BRAF* [v-RAF murine sarcoma viral oncogene homolog B]). Figure 1 highlights several strategic growth pathways, which cancer cells can activate through somatic mutations, and their respective targeted therapies. Pharmacodynamic biomarkers, a subset of predictive biomarkers, are useful in measuring the treatment effects of a drug on the tumor or on the host and can be used to guide dose selection; examples

Figure 1. Summary of somatic biomarkers and targeted therapies

ALK: anaplastic lymphoma kinase; BCL2: B-cell lymphoma 2; BCR-ABL: breakpoint cluster region – Abelson tyrosine kinase; BRAF: v-RAF murine sarcoma viral oncogene homolog B; EGFR: epidermal growth factor receptor; HER2: human epidermal growth factor receptor-2; JAK: Janus kinase; KRAS: Kirsten rat sarcoma viral oncogene homolog; mTOR: mammalian target of rapamycin; PIGF: phosphatidylinositol-glycan biosynthesis class F (placental growth factor); pI3K: phosphoinositide 3-kinase; TDM-1: ado-trastuzumab emtansine; VEGFA: vascular endothelial growth factor ligand A; VEGFB: vascular endothelial growth factor ligand B; VEGFR: vascular endothelial growth factor receptor

include dihydropyrimidine dehydrogenase (*DPYD*), thiopurine-S-methyltransferase (*TPMT*) and uridine diphosphate glucuronosyl transferase 1A1 (*UGT1A1*) amongst others (Patel, 2014; Sawyers, 2008).

[This figure depicts examples of key signaling pathways and downstream effects of somatic biomarker molecular targets. One example pathway is the inhibition of vascular endothelial growth factor (VEGF) which can disrupt tumor angiogenesis through multiple mechanisms. Bevacizumab inhibits VEGF ligand A, ziv-aflibercept acts as a decoy receptor for VEGF ligands A and B and placental growth factor (PIGF), and ramucirumab inhibits the interaction between VEGF receptor 2 and its ligands. Although small molecule tyrosine kinase inhibitors such as axitinib, lenvatinib, pazopanib, regorafenib, sorafenib, sunitinib, and vandetanib all target VEGF, these agents also have additional targets that differentiate indications and potential adverse effects. Other signaling pathways include inhibition of anaplastic lymphoma kinase (ALK), HER2, and EGFR which can lead to changes in tumor survival, apoptosis, antibody-dependent cell-mediated cytotoxicity, and proliferation.]

SOMATIC PHARMACOGENETIC BIOMARKERS

ALK

Anaplastic lymphoma kinase (ALK) is a member of the insulin receptor tyrosine kinase family (RTK), first found to be associated with the (2;5)(p23;q35) chromosome translocation in Ki-1 lymphoma or anaplastic large cell lymphoma. The fusion of the echinoderm microtubule-associated protein like-4 (*EML4*) gene with the *ALK* gene was identified in 2007 from an inversion in chromosome 2 that juxta-

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

poses the 5' end of the *EML4* gene with the 3' end of the *ALK* gene. This protein allows activations of the RAS-MEK-ERK, Janus kinase 3 (JAK3)-STAT3, and PI3K-AKT pathways (Iragavarapu et al., 2015).

The *ALK* translocation is detected using fluorescence in situ hybridization (FISH) as the gold standard assay in the United States. Other assays include, immunohistochemistry (IHC) and reverse transcription polymerase reaction of cDNA (RT-PCR). The overall incidence of *ALK* translocations reported in the NSCLC population ranges from 2 to 7% and occurs independently of *EGFR* or *KRAS* mutations. Similar to *EGFR* mutations, *ALK* rearrangements in NSCLC are associated with clinical and histopathologic features. Patients with *ALK* gene rearrangements are relatively younger, male, and never or light smokers (<10 pack years) (Iragavarapu et al., 2015).

Crizotinib is a small molecular tyrosine kinase inhibitor (TKI) that competitively binds to and inhibits *ALK* and is approved by the Food and Drug Administration (FDA) for the treatment of locally advanced or metastatic *ALK*–positive NSCLC. In a phase III trial with treatment-naïve patients, crizotinib showed a statistically significant improvement in progression-free survival (PFS) (10.9 vs. 7 months), response rate (74 vs. 45%), and quality of life compared to standard chemotherapy with pemetrexed plus either cisplatin or carboplatin (Solomon et al., 2014). In a phase III trial with patients previously treated with one prior platinum-based chemotherapy regimen, crizotinib improved PFS (7.7 vs. 3 months, $p<0.05$) and objective response rate (ORR) (65% vs. 20%; $p <0.05$) compared to single-agent pemetrexed or docetaxel (Shaw et al., 2013). Crizotinib is generally continued until there is evidence of disease progression or unacceptable toxicity. The most common toxicities include visual disturbances, nausea, diarrhea, edema, and fatigue.

Although the majority of patients with *ALK*-positive NSCLC derive substantial benefit from crizotinib, the majority of patients will develop resistance to crizotinib during the first year. Mechanisms of resistance to crizotinib may be due to the development of new, secondary *ALK* mutations, amplification of the *ALK* fusion gene, or activation of alternating pathways that bypass the *ALK* pathway. Secondary *ALK* mutations include *L1196M*, which results from the substitution of leucine by methionine at position 1196 of the *ALK* kinase domain and alters the ATP-binding site of *ALK*, and *C1156Y*, which results in the substitution of a cysteine by tyrosine at position 1156. *KIT* gene amplification has been identified as a potential bypass-signaling pathway (Iragavarapu et al., 2015).

More recently, ceritinib, a second generation *ALK*-inhibitor that is approximately 20 times more potent than crizotinib received accelerated FDA approval for the treatment of patients with metastatic *ALK*-positive NSCLC who are resistant or unable to tolerate crizotinib. The efficacy of ceritinib was established in a multicenter, single-arm, open-label clinical trial where patients with metastatic *ALK*-positive NSCLC who progressed while receiving or were intolerant to crizotinib had an improvement in ORR of 58% and 56% in crizotinib naïve and resistant cases, respectively (Shaw et al., 2014). Both agents have similar adverse effects and are metabolized by the cytochrome P450 enzyme system.

As evident by crizotinib and ceritinib, the drug development paradigm for highly targeted therapies is changing, allowing earlier, accelerated approval of exceedingly effective therapies, years before phase III randomized studies are completed. Alectinib is a second generation *ALK* inhibitor that was approved in Japan for the treatment of patients with recurrent or relapsed *ALK*-positive NSCLC, and is now FDA approved following Breakthrough Therapy Designation by the United States for patients who progressed on crizotinib. Clinical trials of new *ALK* inhibitors that can potentially overcome resistance mechanisms in addition to combination targeted therapy with EGFR, TRK, FAK, and ROS1 are ongoing (Iragavarapu et al., 2015; Seto et al., 2013).

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

BCR-ABL

The *BCR-ABL* chromosomal abnormality is formed by a translocation between chromosomes 9 and 22, resulting in a fusion between the breakpoint cluster region (*BCR*) and the *c-ABL* oncogene (the Philadelphia chromosome, t(9;22) (q34.1;q11.21)) (Heisterkamp, Stam, Groffen, de Klein, & Grosveld, 1985). The chimeric *BCR-ABL* tyrosine kinase (TK) is constitutively active, triggering signal transduction pathways associated with cell survival. The translocation occurs in >95% of chronic myeloid leukemia (CML) cases, 25% of adult acute lymphocytic leukemia (ALL) cases, and 3% of pediatric ALL cases (de Klein et al., 1982; Fielding, 2011). The discovery of the TKIs, imatinib, nilotinib, dasatinib and most recently, bosutinib and ponatinib, have resulted in mean cytogenetic response rates > 90% (Jabbour et al., 2011). Although these TKIs have slightly different mechanisms, they primarily exert their activity by binding to the *ABL* domain of the TK and preventing the binding of ATP, thereby preventing phosphorylation and subsequent activation of various downstream substrates. Imatinib, nilotinib, and ponatinib all bind to the inactive conformation of the *ABL* kinase, preventing the conformational switch to the active form. Dasatinib inhibits both the active and inactive conformations and bosutinib inhibits both *SRC* and *ABL*. Nilotinib has a higher affinity for the *ABL* kinase domain than imatinib, resulting in greater potency and selectivity (Bixby & Talpaz, 2009). Both nilotinib and dasatinib are >100-fold more potent than imatinib in vitro.

Roughly 10% of patients will initially present with resistance to TKIs, and close to 20% will develop resistance within five years (Mauro, 2006). Primary resistance is observed when a patient fails to achieve a desired response to treatment (up to 25% of patients in the chronic phase of CML) and secondary resistance occurs when patients with an initial response ultimately relapse (up to 80, 50, and 15% at around two years for patients in blast crisis, accelerated phase or chronic phase of CML, respectively). The principal mechanisms of resistance to TKIs are point mutations in the kinase domain of the *BCR-ABL* protein, resulting in the inability of the TKI to bind to the *BCR-ABL* protein. The T315I mutation of the *ABL* gene represents the highest magnitude of resistance, as current TKIs require threonine at position 315 in order to bind to their targets (Gorre et al., 2001).

A newer compound, ponatinib (a pan-*BCR-ABL* inhibitor), is the only TKI shown to be effective in overcoming resistance mediated by the T315I mutation. Although ponatinib received accelerated approval by the FDA for the treatment of CML in adults with resistance or intolerance to prior tyrosine kinase inhibitor therapy, its indication has been narrowed due to the risk for life-threatening vascular complications, thrombosis, and hepatotoxicity (Bixby & Talpaz, 2009; T. Zhou et al., 2011).

BRAF

BRAF mutations have been identified in a wide range of cancers including 40 to 60% of malignant melanomas, 45% of papillary thyroid cancer, 10% of colorectal cancers, and 3-5% of lung cancers and gynecologic cancers. Mutations result in a substitution of glutamic acid at amino acid 600 (*V600E*) in 80 to 90% of cases or a substitution of lysine for valine (*V600K*) in 10 to 20% of cases, causing downstream signaling through the mitogen-activated protein kinase (MAPK) pathway (Chapman et al., 2011). Inhibition of the MAPK pathway in patients whose tumors contain a *BRAF V600* mutation using either a *BRAF* inhibitor and/or a *MEK* inhibitor is a targeted therapeutic approach to the treatment of advanced

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

melanoma. As such, all patients with advanced melanoma should have their tumors assayed for the presence of a *BRAF* mutation. *BRAF* mutations are more frequent in patients with early age at tumor onset, truncal primary, and lack of chronic skin damage. Patients with a *BRAF V600* mutation and bulky disease, visceral metastases, elevated serum LDH, or a poor performance status are more likely to have rapidly progressive disease and a shorter overall survival (Chapman et al., 2011).

BRAF inhibitors have been shown to have a shorter time to response for the treatment of advanced melanoma compared to immunotherapy such as ipilimumab, however, the duration of response is short and almost all patients eventually have disease progression. There are currently two *BRAF* inhibitors that are FDA approved for the treatment of advanced melanoma, vemurafenib and dabrafenib. In a phase III trial comparing vemurafenib to dacarbazine in previously untreated, *BRAF* V600E mutation-positive patients, vemurafenib improved overall survival (OS) compared to dacarbazine (13.6 vs. 9.7 months, HR 0.70, 95% CI 0.57-0.87) (McArthur et al., 2014). Dabrafenib increased median PFS compared to dacarbazine (median 5.1 vs. 2.7 months, HR 0.33, 95% CI 0.20-0.54, $p<0.0001$) (Hauschild et al., 2012). Similar to vemurafenib, the most frequent grade 2 or greater toxicities were dermatologic. Dabrafenib must be taken on an empty stomach and has active metabolites, less squamous cell carcinoma, rash, photosensitivity, and increased pyrexia, hyperglycemia, and hypophosphatemia compared to vemurafenib (Trinh, Davis, Anderson, & Kim, 2014).

Resistance quickly develops in roughly 20-25% of *BRAF* mutant, metastatic melanoma patients treated with vemurafenib, with a mean time to diagnosis of first lesion at approximately 10 weeks. A number of mechanisms have been elucidated, including the paradoxical activation of the MAPK pathway through *RAS* mutations, elevation of pERK, and additional acquired mutations (*NRASQ61, MEK1*) (Su et al., 2012).

A potent inhibitor of *MEK1* and *MEK2*, trametinib, has been studied as monotherapy and in combination with dabrafenib to overcome resistance due to downstream effects in the MAPK pathway. Blocking a paradoxical activation of the MAPK pathway with *MEK* inhibition may also reduce the incidence of skin toxicity. The combination of dabrafenib and trametinib resulted in prolonged PFS (median 11.0 vs. 8.8 months, HR 0.67, 95% CI 0.53-0.84), higher ORR (69 vs. 53%) and prolonged OS (median 25.1 vs. 18.7 months, HR 0.71, 95% CI 0.55-0.92) compared with dabrafenib alone. The combination is also associated with less toxicity, but increased pyrexia and chills (Flaherty et al., 2012). OS was significantly increased in the combination when compared against vemurafenib in previously untreated patients with *BRAF V600* mutation-positive melanoma (one-year survival rate 72 vs. 65%, HR for death 0.69, 95% CI 0.53-0.89) (Robert, Karaszewska, et al., 2015).

Patients with *BRAF*-mutated colorectal tumors tend to have significantly shorter PFS and OS compared to wild-type patients, and also have the potential to impair the effects of EGFR-inhibitor therapy in *KRAS* wild-type patients (Di Nicolantonio et al., 2008). The benefit observed with vemurafenib in melanoma patients was not evident in colorectal cancer (CRC) patients harboring the *BRAF* mutation, indicating the significant influence of tumor origin and microenvironment on treatment response. Early phase studies suggest EGFR inhibition in addition to vemurafenib may overcome the resistance mechanisms demonstrated in CRC (Prahallad et al., 2012). The data for BRAF inhibition in lung cancer is scarce, although case reports have demonstrated clinical activity with vemurafenib (Peters, Michielin, & Zimmermann, 2013). Interim results of a phase II study of dabrafenib in *BRAF* V600E-positive NSCLC patients who failed at least one line of chemotherapy showed early antitumor activity with an ORR of 54% (Planchard et al., 2013).

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

C-KIT

The CD117 antigen is almost universally expressed by gastrointestinal tumors (GISTs) and is part of the KIT transmembrane receptor tyrosine kinase (RTK) that is the product of the KIT proto-oncogene, *c-KIT* (Rubin, Fletcher, & Fletcher, 2000). The *c-KIT* proto-oncogene encodes a receptor TK, which binds to stem cell factor ligand, allowing for the development of melanocytes, erythrocytes, germ cells, and mast cells, ultimately resulting in dimerization, autophosporylation, and signal transduction (Yasuda et al., 2007). More than 80% of GISTs express a mutation in the *c-KIT* gene that leads to oncogenic signaling in the cell; 75% of the *c-KIT* mutations affect exon 11, while other mutations affect exon 9, 13, or 17. However, uncontrolled *c-KIT* activation may be present in the absence of *c-KIT* mutations, which occurs in 4 to 5% of cases. *C-KIT*-negative GISTs may be attributed to transcriptional silencing mechanisms or different activating mutations (e.g. platelet-derived growth factor receptor alpha [*PDGFRA*]) (Emile et al., 2004). Adult patients with confirmed GIST that are *c-KIT* or *PDGFRA* mutation-negative usually have tumors localized the stomach, whereas GISTs expressing *c-KIT* mutations are often larger in size and more frequently invade adjacent tissues (Heinrich et al., 2003).

Imatinib inhibits several targets including *BCR-ABL, c-KIT,* EPHA2, PDGFR, and *SRC*. By binding to the ATP-binding pocket required for phosphorylation and activation of *c-KIT* and PDGFR, imatinib has induced dramatic clinical benefit for the treatment of GIST (Balachandran et al., 2011). The partial response rate for GISTs harboring exon 11 *c-KIT* mutations is approximately 80-85% when administering imatinib, whereas patients with tumors containing an exon 9 *c-KIT* mutation, or no detectable mutation, have partial response rates closer to 45-50% (Heinrich et al., 2003). Studies show a rapid response as early as 24 hours after the first dose of imatinib. Long-term follow-up studies show an estimated 10-year survival rate of 22% (Demetri et al., 2014).

Although imatinib is highly effective in GIST, patients may acquire resistance through secondary mutations in *c-KIT* with an average median time to progression of about 2 to 3 years. Use of more potent or multi-targeted inhibitors that target other receptors like PDGFR such as sunitinib can help overcome resistance (Demetri et al., 2006; Reichardt et al., 2012). Regorafenib was most recently approved in 2013 for patients who are no longer responsive to imatinib and sunitinib (Demetri et al., 2013).

EGFR

Epidermal growth factor receptor (EGFR, also called dHER1 or erbB-1) tyrosine kinases are cell surface receptors that dimerize to activate and control intracellular signaling via the PI3K-AKT and RAS-MEK-ERK pathways (Yarden & Shilo, 2007). *EGFR* mutations are present in about 15% of NSCLC adenocarcinoma in the United States and occur more frequently in Asians and non-smoking females (Shepherd et al., 2005; Thatcher et al., 2005). Deletions in exon 19 and a missense mutation at exon 21, resulting in an arginine to leucine substitution (*L858R*), account for 90% of all *EGFR* mutations and are associated with a higher response rate to EGFR TKIs (gefitinib, erlotinib, afatinib) compared to traditional chemotherapy (Lynch et al., 2004).

Currently, screening for *EGFR* mutations is used to select stage IV NSCLC patients who may receive erlotinib in the first-line setting. In 2013, the FDA approved a companion diagnostic test for erlotinib and authorized expanded approval for first-line use in patients with metastatic NSCLC that test positive for the *EGFR* activating mutation. Data from 13 phase III trials comparing EGFR TKIs and platinum-based chemotherapy show prolonged PFS in patients with *EGFR*-positive advanced NSCLC, however,

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

no significant increase in OS was noted (Lee et al., 2013). Erlotinib improved PFS (13.1 vs. 4.6 months, HR 0.16; 95% CI 0.10-0.26) and ORR (83 vs. 36%) compared with standard gemcitabine plus carboplatin in patients receiving initial therapy for advanced NSCLC with *EGFR* mutations (C. Zhou et al., 2011). Compared to platinum-based doublet therapy, erlotinib also increased PFS (median 9.7 vs. 5.2 months, HR 0.37, 95% CI 0.25-0.54) with no significant difference in OS (Rosell et al., 2012).

Afatinib was FDA approved in 2013 for first-line therapy of metastatic NSCLC in *EGFR* mutation-positive patients. It covalently binds to the kinase domains of EGFR (ErbB1), HER2 (ErbB2), and HER4 (ErbB4) and irreversibly inhibits tyrosine kinase autophosphorylation, resulting in downregulation of ErbB signaling. This irreversible binding allows for enhanced activity in resistant tumors that have progressed after initial *EGFR* inhibitor therapy (Miller et al., 2012). Data from two phase III trials did not show a statistically significant increase in OS when comparing afatinib to chemotherapy for NSCLC (median 25.8 vs. 24.5 months, HR 0.91, 95% CI 0.75-1.11). Mutation analysis showed a significant benefit in OS and PFS in patients with exon 19 deletion and a significant benefit in PFS but not OS for patients with *L858R* mutations (Yang et al., 2015).

Patients initially responding to EGFR TKIs can subsequently develop disease progression due to acquired resistance. Two primary mechanisms of resistance to EGFR inhibitors include a secondary point mutation in *EGFR* (*T790M*) that blocks the capacity for erlotinib to inhibit the receptor, and the amplification of *MET*, which activates similar downstream signaling pathways. *MET* amplification is thought to account for resistance in 5 to 20% of patients who progressed after treatment with erlotinib or gefitinib (Bean et al., 2007). Multiple agents have also been developed for patients that have acquired a resistance mutation with *T790M* and have limited benefit from EGFR tyrosine kinase inhibition, including AZD9291 (61% response rate in *T790M* mutation-positive patients) and rociletinib (59% response rate in *T790M* mutation-positive patients) (Sequist et al., 2015; Yang et al., 2015). Combination therapy may be beneficial in patients whose tumors contain an *EGFR* driver mutation (Herbst et al., 2011).

HER2

HER2 is a transmembrane glycoprotein EGFR that belongs to a family of four receptors EGFR/HER1, HER2, HER3, HER4) responsible for cell growth, survival and differentiation through signal transduction activation of the PI3K/Akt and RAS/RAF/MEK/MAPK pathways (Arteaga et al., 2012).

HER2 status represents both a prognostic and predictive biomarker. Amplification of HER2 occurs in about 20% of patients with early stage breast cancer. Prior to the introduction of HER2-directed therapies, HER2 overexpression was associated with high recurrence rates and increased mortality. A high level of HER2 overexpression by either 3+ immunohistochemical staining (IHC) for the HER2 protein or evidence of *HER2* gene amplification by fluorescence in situ hybridization (FISH >2.0), is a strong predictive factor for sensitivity to HER2-targeted agents (Arteaga et al., 2012).

Trastuzumab binds to the extracellular domain of the HER2 receptor and is thought to work by several potential mechanisms including antibody-dependent-cell-mediated cytotoxicity (ADCC), inhibition of cleavage of the extracellular domain of the receptor, inhibition of ligand-dependent dimerization, and inhibition of downstream signaling pathways (Arteaga et al., 2012). Trastuzumab is recommended in the adjuvant setting as monotherapy after completion of chemotherapy, in combination with paclitaxel or docetaxel or given concurrently with carboplatin and docetaxel. A meta-analysis including eight randomized clinical trials showed that the combination of trastuzumab with adjuvant chemotherapy produced a significant benefit in disease-free survival (DFS) (HR 0.60, 95% CI 0.50-0.71), OS (0.66,

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

95% CI 0.57-0.77), locoregional recurrence (OR = 0.53), and distant recurrence (OR = 0.62), as compared to chemotherapy alone (Moja et al., 2012). Trastuzumab in the neoadjuvant setting also improves pathological complete response rates and event-free survival in patients with locally advanced or early stage breast cancer. In addition, it is approved in metastatic *HER2*-positive disease in combination with paclitaxel, docetaxel or as monotherapy.

Mechanisms of resistance to trastuzumab include loss of or increased HER2 expression, increased ligand (TGF-α) expression, steric hindrance of the antibody interaction, inhibition of binding by extracellular domain fragments cleaved from the HER2 receptor, and alternate signaling pathways. Incomplete HER family blockade could allow another HER receptor to compensate when one receptor is blocked. *PIK3CA* and *PTEN* expression may affect the sensitivity of tumor cells to trastuzumab and lapatinib. Variability of human breast cancer cell lines with regard to growth factor receptors, co-amplification of other genes, and acquired drug resistance phenotypes may be limitations to correlating resistance and HER2 overexpression (Arteaga et al., 2012).

Lapatinib is a small molecule TKI that reversibly inhibits intracellular HER2 and EGFR (HER1) by suppressing tyrosine autophosphorylation and downstream pathways. Studies have demonstrated that lapatinib may have additive or synergistic activity if combined with trastuzumab with better central nervous system penetration. Use of lapatinib has led to significant improvements in time to progression in metastatic HER2 positive breast cancer in combination with capecitabine compared to capecitabine alone (HR=0.49; P<0.001) (Geyer et al., 2006). Resistance to lapatinib may include survival pathways leading to upregulation of transcription factors leading to increased estrogen receptor signaling and an estrogen receptor-independent mechanism of acquired autoresistance (Arteaga et al., 2012).

Pertuzumab is a monoclonal antibody that binds the extracellular dimerization domain of HER2 and prevents it from binding to itself or other members of the EGFR family. It is administered in combination with trastuzumab for more complete HER2 inhibition. The combination of trastuzumab, pertuzumab, and a taxane showed an improvement in median PFS compared with placebo (19 vs. 12 months; HR 0.62, 95% CI 0.51-0.75), improvement in overall response rate (80 vs. 69%), and median OS (56.5 vs. 40.8 months, HR 0.68, 95% CI 0.56-0.84) (Baselga et al., 2012).

Most recently, ado-trastuzumab emtansine (TDM-1), an antibody-drug conjugate composed of trastuzumab, a thioether link, and an extremely potent antimicrotubule agent, DM1, was approved for the treatment of metastatic breast cancer. Compared with trastuzumab plus docetaxel, ado-trastuzumab emtansine showed a longer median PFS (14 vs. 9 months, HR 0.58, 95% CI 0.36-0.97) and higher ORR of 64 vs. 58% (Hurvitz et al., 2013).

KRAS

KRAS belongs to a group of small GTP-binding proteins, known as the RAS superfamily or RAS-like GTPases. More than 150 *RAS*-like genes have been identified in mammalian genomes. Activating mutations in the *KRAS* gene impair the ability of the KRAS protein to switch between active and inactive states, leading to cell transformation and increased resistance to chemotherapy and biological therapies targeting EGFR. *KRAS* gene point mutations have been detected in pancreatic carcinomas (>80%), colon carcinomas (40–50%), and lung carcinomas (30–50%), but are also present in biliary tract malignancies, myeloid leukemias, endometrial, cervical, bladder, liver, and breast cancers. The Qiagen Therascreen *KRAS* RCQ PCR kit is FDA-approved to detect seven different mutations of the *KRAS* gene within exon 2, however testing for all *RAS* mutations may be preferred (Jancik, Drabek, Radzioch, & Hajduch, 2010).

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

The National Comprehensive Cancer Network (NCCN) recommends testing for *KRAS* and *NRAS* exons 2, 3, and 4 in patients being considered for an anti-EGFR agent.

The *KRAS* genes associated with colon cancer appear most often in codons 12 (28%) and 13 (8%) of exon 1 and less frequently in codon 61. Mutations in codon 12 are more frequent in primary metastatic carcinoma, suggesting a more aggressive phenotype. A mutation in codon 13 has been shown to be associated with reduced survival rates. Expression of *KRAS*, mainly on exon 2 (codons 12 and 13) has been associated with upregulated carcinoembryonic antigen (CEA) expression, disturbance of epithelial cell polarization, and increased adhesiveness of colon cancer cells (Jancik, Drabek, Radzioch, & Hajduch, 2010). *KRAS* mutation status is the most important predictor of resistance to EGFR-inhibitors used in colon cancer, cetuximab or panitumumab; both the median PFS of cetuximab-treated patients and OS found to be superior in a *KRAS* wild-type group than in a *KRAS* mutant group (31 vs. 10 weeks, and 16 vs. 7 months, respectively) (Lievre et al., 2008).

Cetuximab is approved for use in combination with FOLFIRI (fluorouracil, leucovorin, irinotecan) for first-line treatment of patients with *KRAS* wild-type CRC. Patients with wild-type *KRAS* treated with cetuximab had a median OS of 23.5 vs. 20 months and PFS of 9.9 vs. 8 months compared to those patients who did not receive cetuximab (Van Cutsem et al., 2009). Cetuximab is also approved for squamous head and neck cancer.

In 2006, a humanized monoclonal anti-EGFR1 IgG2 antibody, panitumumab, was approved for the treatment of patients with metastatic CRC who progressed after chemotherapy. Patients with metastatic CRC who were previously untreated and had *KRAS* mutations had a predicted response to panitumumab when added to FOLFOX (fluorouracil, leucovorin, oxaliplatin) compared to FOLFOX alone. The mutations were associated with inferior PFS and OS (Douillard et al., 2013). In a phase III trial, panitumumab monotherapy was compared to best supportive care and *KRAS* mutations were detected using polymerase chain reaction on DNA from tumor. PFS of patients with wild-type compared to mutant *KRAS* gene tumors was 12 vs. 7 weeks, showing that panitumumab monotherapy efficacy in metastatic CRC is confined to patients with wild-type *KRAS* tumors and *KRAS* status should be considered in patients who may be candidates for therapy. (Amado et al., 2008). Mutations in the *KRAS* gene in codons 12 and 13 were detected in 21% of NSCLC. *RAS* gene (exon 1: codons 12, 13, or 61) with or without increases in *EGFR* copy numbers did not derive benefit from erlotinib in NSCLC and had about a 96% chance of disease progression (Massarelli et al., 2007).

PD-1

Programmed death 1 protein (PD-1) is an immune checkpoint receptor that is expressed by activated T cells and binds to its ligands, PD-L1 and PD-L2, to provide a negative signal for T cell activation and proliferation. Anti-PD-1 monoclonal antibodies such as nivolumab and pembrolizumab disrupt the interaction between PD-1 and its ligands to provide an immune antitumor response. In contrast to CTLA-4-mediated inhibition, which is a central event, PD-1-mediated inhibition can occur peripherally in the tumors, providing a potential mechanism for adaptive immune resistance. Checkpoint inhibitor pathways have a mechanism of action that is not limited to one tumor or tissue type. Tumor expression of PD-L1 in early trials appears to predict a higher response rate, longer PFS and OS compared to tumors that do not express PD-L1; however, sensitivity of assays and appropriate cutoff values for expression are heavily debated (Pardoll, 2012).

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Pembrolizumab was studied in patients with advanced melanoma in three dose cohorts and showed an overall ORR of 33%, one-year OS of 66%, and median PFS 4.4 months (Duad, Ribas, Robert, & al., 2015). Pembrolizumab regimens (10 mg/kg every 2 or 3 weeks) also significantly prolonged PFS when compared to ipilimumab (47.3% and 46.6% for pembrolizumab, respectively, and 26.5% for ipilimumab) with an OS HR of 0.63-0.69 at one year (Robert, Schachter, et al., 2015).

Nivolumab received accelerated FDA-approval in December 2014 based on tumor response and durability of response in patients with previously treated metastatic melanoma. In a phase III trial comparing nivolumab to investigators choice chemotherapy (dacarbazine or carboplatin and paclitaxel) in patients with unresectable or metastatic melanoma who progressed on ipilimumab and a *BRAF*-inhibitor (if *BRAF* mutation-positive), nivolumab improved ORR compared with chemotherapy (32% vs. 10%, 95% CI 3.5-23.1) with a longer duration of response (median not reached vs. 3.5 months with chemotherapy) (Weber et al., 2015). In previously untreated patients with wild-type *BRAF* mutations, OS was significantly increased in patients treated with nivolumab compared to dacarbazine (one-year OS rate 73% vs. 42%, HR 0.42, 99.8% CI 0.25-0.73) (Robert, Long, et al., 2015). The combination of nivolumab and ipilimumab in patients with wild-type *BRAF* mutations showed an improved ORR of 61% vs. 11% ($P<0.001$) compared to ipilimumab monotherapy, however a higher rate of grade 3 to 4 drug-related adverse effects occurred with combination therapy (54% vs. 24%) compared to monotherapy (Postow et al., 2015).

Based on current published clinical trials, both pembrolizumab and nivolumab seem to be more effective than ipilimumab in patients regardless of *BRAF* mutation status, with a more tolerable safety profile, and a possible biomarker for response (anti-PD-L1), however additional studies are ongoing to determine their place in therapy.

The FDA indication for nivolumab was expanded to include the treatment of metastatic, squamous NSCLC in March 2015 based on a single-arm trial in patients who progressed after receiving platinum-doublet therapy with an ORR of 14.5% (95% CI 8.7-22.2) (Rizvi et al., 2015). There have also been positive preliminary results in the second-line non-squamous NSCLC setting after failure of platinum-based doublet chemotherapy and TKI with a 27% risk reduction in death with nivolumab compared to docetaxel (Spigel et al., 2015). PD-1 inhibition continues to be a target of interest for new cancer drug development for both hematologic and oncologic tumor types, in addition to identifying novel combinations of chemotherapy and/or targeted therapy with immunotherapy.

VEGF

Vascular endothelial growth factor (VEGF) promotes angiogenesis through endothelial cell proliferation and migration. The biological effects of VEGF are mediated by two receptor tyrosine kinases, VEGFR-1 and VEGFR-2 (Ferrara, Gerber, & LeCouter, 2003). Genetic variability in the promoter regions of VEGF affects the activity and expression of the VEGF protein, which may impact the benefit of targeted VEGF inhibitor therapy (Schneider, Radovich, & Miller, 2009). No biomarkers have been validated to date to identify patients who are more likely to benefit from VEGF inhibitor therapy, however many agents have been recently approved in multiple malignancies (Gerger, LaBonte, & Lenz, 2011).

The VEGF family contains VEGF-A, VEGF-B, VEGF-C, VEGF-D, VEGF-E, and placental growth factor (PLGF). VEGF-A was the first pharmacologically targeted VEGF family member and acts selectively on vascular endothelial cells. VEGF-A expression is regulated by hypoxia, whereby the promotion of new blood vessel formation occurs to respond to reduced tissue oxygenation. The pro-angiogenic

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

role of VEGF is inhibited by anti-VEGF and anti-VEGF-receptor antibodies, soluble VEGF "decoy" receptors, and small molecule TKIs (Ferrara, Gerber, & LeCouter, 2003).

Bevacizumab is a humanized monoclonal antibody directed against VEGF that targets VEGF-A. A pooled analysis of trials comparing chemotherapy with and without bevacizumab in the first-line setting of metastatic CRC showed a 19% reduction in risk of death (HR 0.81, 95% CI 0.70-0.93), however OS improvement was modest (median 19.8 vs. 17.6 months) (Hurwitz et al., 2013). Bevacizumab is FDA approved for the treatment of metastatic CRC, both as first-line in combination with fluorouracil-based chemotherapy and as second-line after progression on a first-line bevacizumab-containing regimen (Bennouna et al., 2013). Bevacizumab is also FDA approved in cervical cancer, glioblastoma, NSCLC, ovarian, and renal cell cancer.

Soluble "decoy" receptors consisting of native VEGFR sequences can bind to VEGF and prevent its interaction with VEGFRs on tumor or endothelial cells. Aflibercept is a recombinant fusion protein that contains the VEGF-binding domains of VEGFR1 and VEGFR2 fused to the Fc domain of human IgG1 and acts as a decoy receptor for VEGF, inactivating receptor binding to VEGF-A and VEGF-B (Holash et al., 2002). Aflibercept has a higher affinity for VEGF-A than bevacizumab and is approved for use in combination with FOLFIRI for the treatment of metastatic CRC that is resistant to or has progressed on an oxaliplatin-containing regimen. Patients who progressed during or within six months of receiving oxaliplatin-containing chemotherapy with or without bevacizumab had longer OS and PFS if treated with FOLFIRI plus aflibercept compared to FOLFIRI plus placebo (13.5 vs. 12.1 months and 6.9 vs. 4.7 months, respectively), regardless of bevacizumab exposure (Van Cutsem et al., 2012).

More recently, an antibody that targets the cell surface receptor for VEGF (VEGFR) has been approved to block VEGF signaling. Ramucirumab is a recombinant IgG1 monoclonal antibody that prevents the interaction of VEGF receptor 2 (VEGFR2) and its ligands. Two trials have shown survival benefit for treatment of second-line advanced or metastastic gastric or gastroesophageal junction adenocarcinoma for ramucirumab as monotherapy or in combination with paclitaxel. In one trial, patients with previously treated advanced or metastatic gastric or gastroesophageal junction adenocarcinoma and treated with either ramucirumab had an improved median PFS (2.1 vs 1.3 months) and OS (5.2 vs. 3.8 months, HR 0.78, 95% CI 0.60-0.998) compared to placebo (Fuchs et al., 2014). In another trial, weekly paclitaxel plus ramucirumab in patients who had disease progression after first-line platinum fluropyrimidine-based combination therapy for metastatic gastric or gastroesophageal junction adenocarcinoma had an OS benefit of 9.6 vs. 7.4 months (HR 0.807, 95% CI 0.768-0.962), PFS (4.4 vs. 2.9 months), and ORR (28 vs. 16%) compared to placebo (Wilke et al., 2014). Based on these results, the FDA approved ramucirumab both as a single agent and in combination with paclitaxel for advanced or metastatic gastric of gastroesophageal junction adenocarcinoma in the second-line setting. This indication was also expanded to include treatment of second-line NSCLC (median OS 10.5 vs. 9.1 months in patients treated with docetaxel plus ramucirumab compared to docetaxel plus placebo after progression on platinum doublet therapy for NSCLC) and second-line treatment of metastatic colorectal cancer (median OS 13.3 vs. 11.7 months and PFS 5.7 vs 4.5 months in patients receiving FOLFIRI plus ramucirumab compared to FOLFIRI plus placebo) (Garon et al., 2014; Tabernero et al., 2015).

Oral, small molecule VEGF inhibitors are available, but may have targets in addition to VEGF. The broader specificity is due to the structural similarity of the catalytic ATP-binding site region. This broad activity may enhance the action of VEGF inhibitors by allowing inhibition of multiple signaling pathways, however there could be additional toxicity based on other targets. These agents typically have shorter half-lives compared to monoclonal antibodies. Some examples of multi-targeted VEGF

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

inhibitors and their targets include: axitinib (VEGFR1-3), lenvatinib (VEGFR, RET, FGFR), pazopanib (VEGFR1-3, PDGFR, FGFR1 and 3, c-KIT), sorafenib (VEGFR2, FLT3, PDGFR, FGFR-1), sunitinib (c-KIT, VEGFR1-3, PDGFR-α, PDGFR-β, FLT3, CSF-1R, RET), regorafenib (VEGFR1-3, RET, c-KIT, PDGFR, FGFR), and vandetanib (VEGFR, RET, EGFR). These agents have approvals for the treatment of multiple malignancies such as renal cell carcinoma and thyroid carcinoma (Zhang, Tan, Ding, Xin, & Jiang, 2012; Zhong & Bowen, 2011).

Although VEGF inhibitors have been shown to prolong survival in multiple malignancies, the benefit often does not last longer than a few months, potentially due to tumor resistance or adaptation. Tumor production of alternative angiogenic factors, such as fibroblast growth factor (FGF) and human growth factor (HGF), may contribute to resistance to VEGF inhibition (Ebos, Lee, & Kerbel, 2009).

GERM-LINE PHARMACOGENETIC BIOMARKERS

CYP2D6 and Tamoxifen

Tamoxifen is a selective estrogen receptor modulator and is widely used to treat hormone receptor positive breast cancer. Tamoxifen is a prodrug that requires bioactivation to the more active metabolite, endoxifen, via the hepatic enzyme cytochrome P450 2D6 (CYP2D6). The gene coding for this enzyme, *CYP2D6*, is highly polymorphic, where the**1* allele is the wild-type allele resulting in normal enzyme activity (i.e. extensive metabolizers [EM]), while **3*, **4*, and **5* result in null enzyme activity (i.e. poor metabolizers [PM]), and the **9*, **10*, and **17* alleles result in reduced enzyme activity (i.e. intermediate metabolizers [IM]). Patients with multiple copies of the functional allele are considered ultrarapid metabolizers (UM). The most common variant allele, **4*, is present in roughly 18% of Caucasians, moderately present in African Americans (7-9%), and rarely present in Asians (<1%) (Jin et al., 2005). The intermediate **10* allele is present in 40% of patients of Japanese origin, while the **17* allele is present in about 25% of patients of African origin (Bradford, 2002; Jin et al., 2005).

A retrospective cohort study of over 1300 patients demonstrated higher recurrence rates for PMs and IMs compared to EMs (29% and 20.9% vs. 14.9%, respectively) (Schroth et al., 2009). Subsequently, a prospective, genotype-guided study demonstrated a significant increase in endoxifen exposure in PMs/IMs as the dose was increased from 20 mg to 40 mg daily. While a significant difference in endoxifen levels was observed between EMs and IMs at the standard dose, this difference was diminished after doubling the dose in IMs, whereas concentrations in PMs were still significantly lower compared to IMs/EMs even at the 40 mg dose (Irvin et al., 2011). The influence of endoxifen exposure on response was not addressed in this study, limiting the clinical translation of these findings on breast cancer recurrence. However, studies have demonstrated that patients with the lowest endoxifen concentrations have the highest risk of relapse, suggesting that a therapeutic threshold may be needed for optimal benefit (Madlensky et al., 2011; Saladores et al., 2014). This data further implies that PMs and IMs may be unable to achieve this therapeutic threshold at standard tamoxifen doses.

Controversy exists on the clinical utility of *CYP2D6* testing as two of the largest studies investigating the *CYP2D6*-tamoxifen relationship and breast cancer recurrence demonstrated no association between genotype and recurrence rates (Rae et al., 2012; Regan et al., 2012); however, flaws in the genomic study design, such as use of tumor DNA as opposed to germ-line DNA, have been noted by pharmacogenetic experts (Nakamura et al., 2012). Subsequently, Rae et al. identified concordance rates >95% between

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

CYP2D6 genotypes obtained from tumor-derived and germ-line DNA from 122 breast cancer patients (Rae et al., 2013). Alternatively, Goetz et al. genotyped nearly 1200 breast tumor samples and demonstrated loss of heterozygosity (LOH) in over a third of samples, while also documenting that non-malignant tissue did not exhibit LOH (Goetz et al., 2015). Investigators also reported that while there was approximately 20% discordance between tumor and buccal cell genotypes, there was 100% concordance between non-malignant and buccal cell genotypes (Goetz et al., 2015), suggesting that breast tumor tissue should not be used to genotype for *CYP2D6* and may result in false genotypes. Lastly, the development of oral endoxifen may bypass the pharmacogenetic issues presented (Ahmad, Ali, Ahmad, Sheikh, & Ahmad, 2010). Advocates of *CYP2D6* genetic testing indicate that until prospective, adjuvant trial data is available, the current evidence is sufficient to accept the *CYP2D6*-tamoxifen pharmacogenetic relationship in postmenopausal women (Brauch et al., 2013); however, the appropriate dose adjustment and ultimate impact on breast cancer recurrence appear to be unclear.

DPYD and 5-Fluorouracil

Dihydropyrimidine dehydrogenase (DPD), the rate-limiting enzyme involved in the metabolism of 5-fluorouracil (5-FU) to 5,6-dihydrofluorouracil, has been shown to exhibit polymorphic potential (Toffoli & Cecchin, 2007). Given that 80% of 5-FU is metabolized by DPD, a loss of enzyme activity has the potential to extend the half-life of 5-FU by up to 100-fold, enhancing the prolonged cytotoxic effect of the agent, including side effects such as severe neutropenia and diarrhea. However, the frequency of null enzyme activity is very low at <1%, while about 5-7% have intermediate enzyme activity (Saif, Ezzeldin, Vance, Sellers, & Diasio, 2007). More than 30 variants of *DPYD*, the gene coding for DPD, have been identified and result in functional changes in enzyme activity (Van Kuilenburg, Meinsma, Zoetekouw, & Van Gennip, 2002). The polymorphic variant most commonly associated with DPD deficiency is a splice-site mutation, *IV14+1G>A* (also referred to as *DPYD*2A*), located on the exon 14-flanking region and causing skipping of 165 base pairs (Toffoli & Cecchin, 2007).

In a multicenter trial, approximately 700 patients with various cancers and treated with 5-FU were genotyped for *DPYD*. Investigators observed a positive predictive value of 0.46 for overall toxicity in patients carrying the *DPYD*2A* variant; however, of interest was a gene/sex-interaction resulting in an OR for overall toxicity of 41.8 ($P<0.0001$) for male patients but only 1.33 ($P>0.05$) for female patients (Schwab et al., 2008). A smaller study demonstrated that 60% of 60 patients who had experienced severe 5-FU-related toxicity had decreased DPD enzyme activity, independently of genotype (Van Kuilenburg, Meinsma, Zoetekouw, & Van Gennip, 2002). In a prospective genotype-guided clinical trial, investigators administered an initial 5-FU dose reduction of $\geq$ 50% with subsequent dose titration based on clinical tolerance in CRC patients carrying the *DPYD*2A* allele. Safety was compared with 45 historical *DPYD*2A* controls having administered 5-FU at the full dose. Of 1,700 patients screened, only 17 were heterozygous for the variant allele. Results demonstrated that the risk of grade $\geq$ 3 toxicity was reduced from 68% in historical controls to 15% and drug-induced death was reduced from 10 to 0% in patients receiving genotype-guided dosing. Furthermore, 5-FU exposure in *DPYD*2A* carriers at reduced doses was comparable to fully dosed non-carriers, supporting the role of genotype-guided therapy to decrease drug toxicity (M.J. Deenen et al., 2011). Most recently, a systematic review of candidate genes associated with capecitabine (the oral prodrug of 5-FU) toxicity in 927 CRC patients demonstrated that global toxicity was associated with the *DPYD* alleles *2846T>A* and **2A* (combined OR, 5.51; $P = 0.0013$) (Rosmarin et al., 2014).

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Based on the available literature, it is evident that patients with *DPYD* variants (or DPD deficiency) are at an increased risk of 5-FU induced toxicity; however, measuring catalytic DPD activity in peripheral blood mononuclear cells is challenging. Standardized cut-offs for deficient DPD activity are not readily available and different laboratories may use different thresholds for activity (Yen & McLeod, 2007). Furthermore, there are implications on cost and resources as the minor allele frequency is very low resulting in a high number of patients needed to screen to prove a beneficial impact on reducing toxicity. Additionally, experimental protocols for genotyping are often laborious, intensive and limit the number of patients who can be tested (Yen & McLeod, 2007), ultimately limiting the utility of genetic testing in clinical practice. Nonetheless, the Clinical Pharmacogenetics Implementation Consortium (CPIC) guidelines provide recommendations for dosing based on DPD enzyme activity: patients with normal enzyme activity require no dose adjustment; patients with decreased enzyme activity require at least a 50% dose reduction, followed by titration of dose based on toxicity or exposure, and patients with complete enzyme deficiency should receive an alternative drug (Caudle et al., 2013).

TPMT and 6-Mercaptopurine

Thiopurine-S-methyltransferase (TPMT) is a cytosolic enzyme ubiquitously expressed in the human body and catalyzes the S-methylation of thiopurines, including 6-mercaptopurine (6-MP), into inactive compounds. 6-MP is one of the backbone agents used to treat ALL in both children and adults. It inhibits the formation of purine ribonucleotides, ultimately leading to cell death (McLeod, Lin, Scott, Pui, & Evans, 1994). Severe hematological toxicity, including myelosuppression, is the most common adverse effect associated with 6-MP (McLeod, Krynetski, Relling, & Evans, 2000). The *TPMT* locus is subject to genetic polymorphisms with roughly 6-11% of the population being heterozygous and 0.2%-0.6% being homozygous for the variant allele. *TPMT *2* and **3* alleles account for approximately 95% of the defective TPMT activity (Stanulla et al., 2005). The risk of myelosuppression is significantly elevated in patients who harbor *TPMT* genetic variants, given elevated circulating thioguanine nucleotide levels (Stanulla et al., 2005).

A study of 180 children with ALL treated with a 6-MP-based regimen demonstrated that wild-type, heterozygous, and homozygous-deficient patients were able to tolerate the full dose of 6-MP for 84%, 65%, and 7%, of the total weeks of therapy, respectively. Additionally, a statistically significant inverse relationship between thioguanine nucleotide concentrations and *TPMT* was observed, with an average concentration (pmol/8 $\times$ 10^8 erythrocytes) of 417, 963, and 3,565 in *TPMT* homozygous wild type, heterozygous, and homozygous deficient patients, respectively (Relling et al., 1999). In a prospective study, investigators determined that the OR for patients with at least one variant allele and receiving a 30-70% dose reduction based on genotype was 1.30 (equivalent to the risk seen in wild type patients receiving full dose 6-MP), whereas the OR of toxicity for patients with at least one variant allele and receiving standard 6-MP dosages (no dose adjustment for genotype) was 4.0 (Stocco et al., 2009). In a comprehensive phenotype-genotype study of 1214 healthy volunteers, investigators identified a clearly defined trimodal distribution of TPMT activity with 0.6% deficient, 9.9% intermediate and 89.5% normal to high. Four novel variants were identified resulting in 17 individuals with intermediate TPMT activity discordant to genotype. Taking these variants into account, the overall concordance rate between genotype and phenotype was 98.4% (Schaeffeler et al., 2004).

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Given the available data, *TPMT* genetic testing is routinely utilized to identify ALL patients with defective enzyme activity (Relling et al., 2011). CPIC guidelines recommend an initial 10-fold dose reduction of 6-MP in patients with two inactive alleles and reduced doses (30-70% of the full dose) in heterozygous patients (Relling et al., 2013).

TYMS and 5-Fluorouracil

Thymidylate synthase (TS), a critical enzyme involved in DNA synthesis, serves as the primary target of 5-FU. *TYMS*, the gene coding for TS, contains 28-base pair tandem repeat units found in the 5' untranslated region (UTR), acting as an enhancer to the *TYMS* promoter (Toffoli & Cecchin, 2007). As 5-FU is involved with the inhibition of TS, low *TYMS* expression induced by *TYMS 2R* (two repeats) or the 6-base pair (bp) deletion in the *TYMS* 3'-UTR would subsequently increase the cytotoxic effects of 5-FU, whereas high expression induced by *TYMS 3R* (three repeats) or 6-bp insertion in the 3'-UTR would decrease the efficacy of 5-FU [73].Approximately 25% of European patients are homozygous for *TYMS 3R/3R*, 20% are homozygous for *2R/2R*, and 55% are heterozygous for *2R/3R*.

In a study of 65 patients with rectal cancer treated with 5-FU-based preoperative chemoradiotherapy, patients harboring the *TYMS 3R/3R* genotype achieved a 22% down-staging rate, whereas *2R/2R* patients achieved a 60% down-staging rate (Villafranca et al., 2001). In a genotype-guided clinical trial of 135 patients with rectal cancer, investigators administered 5-FU chemoradiation plus irinotecan to patients with the *TYMS 3R/3R* or *3R/4R* genotypes, i.e. the poor-risk group (27.4%), and administered standard 5-FU chemoradiation alone to those with *2R/2R, 2R/3R*, and *2R/4R*, i.e. the good-risk group (72.6%). Down-staging and complete tumor response rates were 64.4% and 20% for good risk and 64.5% and 42% for poor-risk patients, respectively, suggesting that the addition of irinotecan may help overcome 5-FU resistance. However, the addition of irinotecan in good risk patients was not addressed (Tan et al., 2011). Lastly, in a large analysis of 927 colorectal cancer patients treated with capecitabine or another 5-FU-based regimen, investigators identified that global toxicity (grades 0/1/2 vs. grades 3/4/5) was associated with the common polymorphisms *TYMS 2R/3R* and *3'UTR 6bp ins-del* (combined OR, 1.31; $P = 9.4 \times 10^{-6}$) (Rosmarin et al., 2014). A large number of studies support the association between *TYMS* and 5-FU response/toxicity (Patel, Fuchs, Owzar, Chen, & McLeod, 2013); however, a paucity of prospective, interventional clinical trials exists, owing to the current lack of clinical utility. Despite availability of clinical assays, large prospective, interventional trials are warranted to confirm *TYMS* as a predictive biomarker for 5-FU therapy.

UGT1A1 and Irinotecan

Uridine diphosphate glucuronosyltransferase 1A1 (UGT1A1) conjugates SN-38, the active component of irinotecan, a topoisomerase I inhibitor, to a glucuronide inactive metabolite, SN-38G. More than 60 polymorphisms in *UGT1A1* have been identified, most of which result in TA (thymine-adenine) repeats in the promoter region of the gene. The wild type allele is referred to as *UGT1A1*1*, while the most common and studied variant, *UGT1A1*28*, results in up to a 70% reduction in enzyme activity (other less frequent variants include **6*, **60*, and **93*). The frequency of the **28* allele is 39% in patients of European, 16% of Asian, and 43% of African origins. Roughly 10–20% of Caucasians and African Americans are homozygous for **28*, while less than 5% of Asians are homozygous for **28* (Perera, Innocenti, & Ratain, 2008). A meta-analysis demonstrated a significant increase in grade 3/4 neutropenia for **28/*28*

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

patients at medium (150-250 mg/m^2) and high doses (>250 mg/m^2) (OR=3.22, P=0.008 and OR=27.8, P=0.005, respectively) (Hoskins, Goldberg, Qu, Ibrahim, & McLeod, 2007). The current U.S. FDA approved package insert includes the *UGT1A1 *28/*28* genotype as a risk factor for severe neutropenia.

Given the genetic basis for irinotecan intolerance, investigators performed a prospective, genotype-guided phase I study in metastatic colorectal cancer patients receiving FOLFIRI. Patients were stratified by *UGT1A1* genotype and received dose escalations to the maximum tolerated dose (MTD). Results demonstrated that the MTDs of irinotecan were 370 and 310 mg/m^2 in **1/*1* and **1/*28*, respectively, suggesting higher tolerable doses in wild-type and heterozygous patients compared to the standard 180 mg/m^2 dose currently administered to all patients as part of the routine FOLFIRI regimen (Toffoli et al., 2010). A subsequent and similar genotype-guided dose escalation study determined the MTD to be 390, 340, and 150 mg/m^2 in **1/*1, *1/*28,* and **28/*28*, respectively (Marcuello et al., 2011). Although not powered to detect differences in clinical outcome, the first study identified a significantly higher response rate in patients treated at doses ≥ MTD vs. those treated at doses < MTD (65% vs. 25%; P<0.05) (Toffoli et al., 2010). Similarly, the second study demonstrated significantly higher response rates in patients treated at ≥ 260 mg/m^2 (median dose) compared to those receiving < 260 mg/m^2 (67% vs. 24%; P<0.05), in addition to a significant difference in time to disease progression (16 vs. 7 months, respectively; P<0.05) (Marcuello et al., 2011). A similar trial of patients receiving irinotecan monotherapy demonstrated fixed MTDs of 850 mg, 700 mg, and 400 mg in **1/*1*, **1/*28* and **28/*28* patients. Interestingly, at the MTD for each genotype, dosing by genotype resulted in similar SN-38 areas under the curve (AUCs; $r^2 = 0.0003$; P=0.97), while the irinotecan AUC was correlated with the actual dose ($r^2 = 0.39$; P<0.001) (Innocenti et al., 2014).

While it is evident that *UGT1A1 *28/*28* patients are at an increased risk of toxicity and dose reduction to ≤150 mg/m^2 in these patients is appropriate, the optimal irinotecan dose in **1/*1* and **1/*28* patients is unknown and is currently under investigation in a phase II genotype-guided study of irinotecan dosing in metastatic CRC patients receiving FOLFIRI plus bevacizumab (Clinicaltrials.gov: NCT02138617).

SUPPORTIVE CARE PHARMACOGENETIC BIOMARKERS

Antidepressants

Antidepressant drugs are widely prescribed to cancer patients to treat depression and anxiety disorders, however, only one-third of these patients exhibit a beneficial therapeutic response (Rush et al., 2006). Potential reasons for lack of drug response include clinical heterogeneity, diagnostic uncertainty, environmental and social factors, and genetic factors.

The heterogenous response to antidepressant drugs, particularly tricyclic antidepressants (TCAs) and selective serotonin reuptake inhibitors (SSRIs), may be in part due to differences in cytochrome P450 activity, by which the majority of antidepressants are metabolized by. The main enzymes involved in antidepressant drug metabolism are CYP2D6, CYP2C9, CYP2C19, CYP3A4 and CYP1A2, with CYP2D6 involved in the metabolism of approximately half of the commonly prescribed psychotropic drugs (Staddon, Arranz, Mancama, Mata, & Kerwin, 2002). Studies with nortriptyline showed that *CYP2D6* poor metabolizers (PMs) reached therapeutic plasma levels with initial starting doses, whereas escalated doses would result in a higher risk of toxicity. Alternatively, patients with functional (extensive metabolizers [EMs]) or ultra-rapid metabolizer (UM) phenotypes required higher doses to reach thera-

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

peutic plasma levels (Bertilsson, Dahl, Dalen, & Al-Shurbaji, 2002). Another study also identified an association between *CYP2D6* genotype and plasma level concentrations of venlafaxine, however, did not find any such association for desvenlafaxine. When subjects received venlafaxine 75 mg, the area under the concentration-time curve (AUC) and maximum concentration (Cmax) of O-desmethylvenlafaxine (the primary active metabolite) were 445% and 434% higher, respectively, in *CYP2D6* EMs compared with PMs ($P \leq 0.001$) (Nichols, Focht, Jiang, Preskorn, & Kane, 2011).

Variations in the *CYP2C19* gene have also been shown to be associated with antidepressant response, including citalopram, imipramine and clomipramine. Additionally, tertiary amines (e.g. amitriptyline) are mainly metabolized by CYP2C19 to desmethyl metabolites (e.g., nortriptyline). Therefore, variations in CYP2C19 metabolism may modulate antidepressant activity and side effects through the pharmacological actions of the tertiary amines. Serotonin reuptake inhibition has been shown to be more pronounced in *CYP2C19* PMs due to the decreased conversion to nortriptyline (Hicks et al., 2013). In addition, *CYP2C19* alleles have been shown to affect escitalopram metabolism (Jin et al., 2010; Noehr-Jensen et al., 2009) including a positive association in the European consortium project Genome-Based Therapeutic Drugs for Depression (GENDEP) (Huezo-Diaz et al., 2012). Investigators identified that those homozygous for the *CYP2C19*17* allele (UM phenotype) had a significantly lower mean escitalopram concentrations (approximately 2-fold, $P = 0.0001$) and a higher mean metabolic ratio ($P = 0.0003$) than EMs, while those homozygous for alleles conferring the PM phenotype had a higher mean escitalopram concentration than EMs (1.55-fold, $P = 0.008$). Furthermore, the side-effect profile of amitriptyline appears to be dependent on a combination of alleles coding for *CYP2D6* and *CYP2C19* (Huezo-Diaz et al., 2012).

A larger analysis combined samples from four studies and found an association between *CYP2D6* alleles and treatment response to venlafaxine (Lobello et al., 2010). Specifically, investigators identified that, compared with PMs, EMs had significantly greater mean changes from baseline on 4 of 5 depression rating scales (all 4 comparisons, $P \leq .020$) and a greater percentage experiencing response or remission ($P \leq .015$) (Lobello et al., 2010). However, other studies have found no such association for either *CYP2D6* or *CYP2C19* alleles (Grasmader et al., 2004; Serretti et al., 2009). Particularly, an analysis in the large STAR*D sample set did not find an association with either *CYP2D6* or *CYP2C19* and response to citalopram (Fava et al., 2003). As a result, the clinical translation and use of these genes in practice has been limited and larger prospective studies are needed to fully elucidate these effects. Nonetheless, CPIC guidelines provide dosing recommendations for amitriptyline, desipramine, doxepin, imipramine, nortriptyline and trimipramine (see https://www.pharmgkb.org/page/cpic). Other genetic determinants of response to antidepressant therapies include variations in p-glycoprotein, monoamine metabolic enzymes, 5-HT genes, dopamine genes, and norepinephrine genes; however, these have not been validated and further research is needed to elucidate the role of these genes in response to therapy (Narasimhan & Lohoff, 2012).

Antiemetics

Chemotherapy-induced nausea and vomiting (CINV) is one of the most debilitating adverse drug effects experienced by patients treated with cytotoxic chemotherapy (Blower, 2002; Rojas & Slusher, 2012). Ineffective CINV control occurs in $\geq 25\%$ of all cancer patients despite antiemetic administration (Feyer & Jordan, 2011). Three classes of medications are considered standard to treat CINV: 5-hydroxytryptamine (5HT; serotonin) type 3 (5HT3) receptor antagonists (5HT3-RAs), neurokinin 1 receptor antagonists, and corticosteroids (Basch et al., 2011; Roila et al., 2010). Variability in emetic control with 5HT3-RAs

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

has resulted in the examination of the genetic variance in 5HT3 receptor subunits, genetic differences in cytochrome P450 metabolism of the various 5HT3-RAs, and polymorphisms associated with drug transporters (Blower, 2002; Fasching et al., 2008; Tremblay et al., 2003; Yaakob, Malone, Exintaris, & Irving, 2011).

The five subunits that make up the 5HT3 receptor pentamer have been identified as 5HT3A, 5HT3B, 5HT3C, 5HT3D, and 5HT3E (Bruss et al., 2000; Krzywkowski, Jensen, Connolly, & Brauner-Osborne, 2007; Yaakob, Malone, Exintaris, & Irving, 2011). The subunits and the genes coding for them have become the target of studies of genetic variation to explain suboptimal control with 5HT3-RAs (de Wit, Aapro, & Blower, 2005; Gandara et al., 1998; Machu, 2011; Ward, Kotasek, & McKinnon, 2008; Yaakob, Malone, Exintaris, & Irving, 2011). A study demonstrated that patients who were homozygous for the polymorphism, -100_-120delAAG promoter region deletion in the start codon of 5HT3B, had a much higher frequency of vomiting than other patients (Tremblay et al., 2003). Multivariate analysis further identified that poor CINV control associated with the deletion was not due to the level of chemotherapeutic emetic risk or co-administered medications (Tremblay et al., 2003). Another study assessed 5HT3C receptor gene polymorphisms and CINV incidence post ondansetron and dexamethasone administration in 110 breast cancer patients treated with anthracyclines. Results identified a SNP in the gene *K163N*, which was associated with increased incidence of poorly controlled CINV in 50% of *CC* homozygous patients (P=0.009) as compared with 22% of *AA* or *AC* patients (Fasching et al., 2008). The clinical implications of the genetic variability within the individual subunits of the 5HT3 receptor remain to be seen. Using genetic variations in 5HT3 receptors to predict efficacy from 5HT3-RAs is limited owing to the need for validation across larger and more diverse populations. The 3C, 3D, and 3E subunits have failed to produce any statistically significant variations that could impact clinical decision making.

CYP2D6 is notable as a major metabolic pathway for several of the 5HT3-RAs. The 5HT3-RAs ondansetron, palonosetron, tropisetron, and dolasetron rely on CYP2D6 metabolism in differing degrees, whereas granisetron does not rely on CYP2D6 metabolism. Therefore, the identification of a patient's *CYP2D6* phenotype may help guide clinician choices in antiemetic therapy. The weakest control of CINV with 5HT3-RAs is seen in the UM population who rapidly metabolize these medications resulting in loss of efficacy (de Wit, Aapro, & Blower, 2005; Ingelman-Sundberg, 2004; Tzvetkov et al., 2012). A study reported that UM patients had a significantly higher mean number of vomiting episodes compared to IMs, PMs, and EMs receiving cyclophosphamide, cisplatin, or carboplatin (2.3 ± 2.5 vs 0.2 ± 1.0 ($P<0.001$) episodes of vomiting, respectively). In addition, UM patients have experienced severe nausea despite use of ondansetron or tropisetron (Kaiser et al., 2002). Other antiemetic options remain for suspected UM patients with poor CINV control. Granisetron is the only 5HT3-RA that does not involve CYP2D6 in its metabolism; thus, conferring a reasonable option in a suspected UM patient (Bloomer et al., 1994), in addition to other antiemetics such as dexamethasone, lorazepam, prochlorperazine, etc.

Lastly, the ATP-binding cassette subfamily B member 1 (ABCB1) transporter (also known as p-glycoprotein, a multi-drug-resistant protein) functions as an efflux pump for a variety of substances, including ondansetron (Babaoglu et al., 2005; Ishikawa, Hirano, Onishi, Sakurai, & Tarui, 2004). Given that ABCB1 is thought to be an active component of the blood brain barrier, the potential of genetic variations to influence antiemetic activity is of importance. The *ABCB1 3435C>T* variant has been correlated with significantly reduced expression of ABCB1, resulting in increasing concentrations of medications that require ABCB1 for drug efflux (Babaoglu et al., 2005; Ishikawa, Hirano, Onishi, Sakurai, & Tarui, 2004). A study demonstrated that 93%, 48% and 56% of patients who were treated with granisetron and were homozygous for the *TT*, *CT* and *CC* genotypes, for the *3435C>T* variant ex-

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

perienced a significantly higher rate of CINV control (P<0.05), respectively. The presence of the *3435 C>T* variant did not significantly improve CINV control in the ondansetron group, and had no effect in the tropisetron group (Babaoglu et al., 2005). Lastly, a study of 215 children with acute myeloid leukemia (AML) treated with high-dose cytarabine and pre- and post-chemotherapy ondansetron identified a significant association between *ABCB1* polymorphisms and antiemetic efficacy in the acute phase, but not in the delayed phase (He et al., 2014). Specifically, the *CG* haplotype (*C3435T* and *G2677T*) was associated with a higher risk of grade 3/4 nausea and vomiting (P=0.003 and P= 0.026, respectively). After adjustment for patient-specific clinical factors in a multivariate analysis, the *CG* haplotype was identified as a predictive marker of grade 3/4 CINV (P = 0.003 and P = 0.039, respectively). In addition, a significant association between the *3435CC* genotype and grade 3/4 vomiting in AML patients was observed (P = 0.016) (He et al., 2014).

Although polymorphisms exist that may explain variability in 5HT3-RA efficacy, the only current clinically actionable gene may be *CYP2D6*, given the test is readily available in practice and may be used to guide 5HT3-RA regimen choices. Further prospective studies are needed to replicate remaining polymorphisms, such as those in the 5HT3 receptor and drug transporters (i.e. ABCB1).

Opioids

CYP2D6 is the primary metabolic enzyme responsible for the activation of weaker opioids (codeine, tramadol, oxycodone and hydrocodone) into stronger opioids (morphine, o-desmethyltramadol, oxymorphone and hydromorphone, respectively). As mentioned previously, the **3*, **4*, and **5* alleles account for approximately 95% of the poor metabolizer (PM) phenotype, while multiple copies of a functional allele result in the ultra-rapid metabolizer (UM) phenotype (most often occurring with **1* or **2* duplications) (Bernard, Neville, Nguyen, & Flockhart, 2006).

Codeine and tramadol rely almost exclusively on CYP2D6 for activation to their active metabolites, morphine and O-desmethyltramadol, respectively. The clinical analgesic effect of codeine is mainly attributed to its conversion to morphine, which has a 200 times higher affinity and 50 times higher intrinsic activity at the mu-opioid receptor than codeine itself (Mignat, Wille, & Ziegler, 1995). Case reports of codeine fatalities in *CYP2D6* UMs (Ciszkowski, Madadi, Phillips, Lauwers, & Koren, 2009; Gasche et al., 2004; Koren, Cairns, Chitayat, Gaedigk, & Leeder, 2006; Madadi et al., 2011; Madadi et al., 2010; Madadi & Koren, 2008) resulted in a black box warning being issued in 2013, stating that codeine use in certain children with the UM phenotype may result in life-threatening adverse events or death. As a result, several U.S. institutions require preemptive *CYP2D6* genotyping prior to codeine administration. Similarly, a case report of tramadol-induced respiratory depression was reported in a UM patient who also had renal impairment (Stamer, Stuber, Muders, & Musshoff, 2008). Alternatively, it has been demonstrated that the analgesic activity of tramadol in PM patients is significantly reduced (Musshoff, Madea, Stuber, & Stamer, 2006; Stamer et al., 2003; Stamer et al., 2007; Stamer, Stuber, Muders, & Musshoff, 2008). In a prospective study of nearly 300 patients recovering from abdominal surgery, the percentage of non-responders was significantly higher in the PM group (46.7%) compared with the EM group (21.6%; p=0.005) (Stamer et al., 2003).

Oxycodone and hydrocodone are metabolized by CYP2D6 to more potent metabolites, oxymorphone and hydromorphone, respectively, and by CYP3A4 to inactive metabolites, noroxycodone and norhydrocodone (Stauble et al., 2014). In one study, *CYP2D6* PMs required significantly larger cumulative oxycodone doses for equianalgesic effect compared to EMs (25 mg vs. 16 mg; P=0.005) (Stamer et al.,

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

2013). Similarly, a study showed that PMs achieved 8-fold lower hydromorphone concentrations vs. UMs, which significantly correlated with pain relief (Stauble et al., 2014). Another study demonstrated that *CYP2D6* UMs experienced 40% higher pain tolerance thresholds compared to EMs, while PMs had a 20-30-fold lower pain tolerance compared to EM/IMs (Samer et al., 2010). Furthermore, drug-gene and drug-drug interactions may overlap, resulting in additive effects on drug disposition and ultimately therapeutic response and/or toxicity.

Catechol-O-methyltransferase (COMT) is responsible for the inactivation of catecholamines (dopamine, adrenaline and norepinephrine), which are involved in pain modulation. As a result, genetic variability in *COMT* can contribute to pain sensitivity. It has been shown that a common variant allele (*1947G>A*) (allele frequency 48%) results in a three- to four-fold reduction in COMT enzyme activity (Lotta et al., 1995). A study of 207 Caucasian cancer patients demonstrated that patients with the *GG* genotype required significantly more morphine (155 mg/24 hours) compared to *AG* (117 mg/24 hours) and *AA* genotypes (95 mg/ 24 hours) ($P<0.05$) (Rakvag et al., 2005).

Lastly, the mu-opioid receptor, the primary site of action of opioids, is encoded by the gene opioid receptor-like 1 (*OPRM1*). The *OPRM1 118A>G* polymorphism (allele frequency 8-17%) results in less effective opioid analgesia. One study demonstrated that cancer patients with the *GG* genotype required higher morphine doses for pain relief compared to *AA* patients (Klepstad et al., 2004). Another study showed that patients undergoing total knee arthroplasty with the *GG* genotype consumed approximately 60% more morphine than patients who were heterozygous or homozygous wild-type (Chou et al., 2006).

CPIC guidelines (Crews et al., 2014) provide pharmacogenetic-based dosing recommendations for codeine, while the Dutch Pharmacogenetics Working Group (DPWG) (Samer, Lorenzini, Rollason, Daali, & Desmeules, 2013) provides guidelines for codeine, oxycodone and tramadol (amongst other classes of drugs metabolized by CYP2D6, such as antidepressants). Understanding genetic variations in *CYP2D6*, *COMT* and *OPRM1* may allow for better analgesia selection and dosing.

Voriconazole

Voriconazole is a triazole antifungal agent commonly used to treat and prevent invasive fungal infections (IFIs) in patients undergoing allogeneic hematopoietic stem cell transplant (HSCT) and other hematological conditions. The half-life of voriconazole is estimated to be approximately 6 to 9 hours; however, this may be highly variable due to the drug's non-linear saturable pharmacokinetics, which results in high inter-patient variability in exposure. Voriconazole steady state concentrations are estimated to reach at 5-7 days, with an optimal therapeutic concentration of 1.0-5.5 mg/L. Overall, only 50% of patients achieve the pre-defined therapeutic range by 5-7 days (Hicheri, Cook, & Cordonnier, 2012; Troke, Hockey, & Hope, 2011), while as many as 50% of patients treated with prophylactic doses of 200 mg twice daily have sub-therapeutic levels (<1.0 mg/L) (Trifilio et al., 2007).

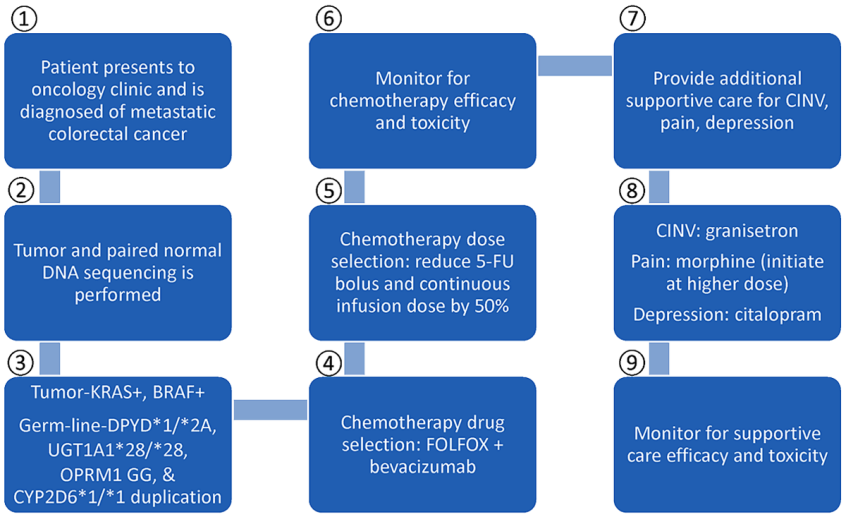
Therapeutic drug monitoring (TDM) of voriconazole is useful due to unpredictable pharmacokinetics, the drug's narrow therapeutic index, and serum concentrations that are associated with both efficacy and toxicity (Troke, Hockey, & Hope, 2011). Furthermore, drug interactions and genetic polymorphisms in *CYP2C19,* the gene coding for the drug metabolizing enzyme of voriconazole which inactivates the parent compound, have an effect on serum concentrations (Mikus, Scholz, & Weiss, 2011). Sub-therapeutic voriconazole trough concentrations (<1.0 mg/L) have been associated with therapeutic failure (Hamada, Seto, Yago, & Kuroyama, 2012). In a prospective treatment trial, patients randomized to receive TDM-guided dosing had a significantly greater percentage of complete or partial response

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

compared to the non-TDM group (81% vs. 57%, respectively; P=0.04) (Park et al., 2012). However, another study demonstrated a significant association between IFI-related mortality and initial trough concentrations ≤0.35 mg/L at day 5 (OR 11.0; P=0.004), even when TDM was subsequently utilized to target a therapeutic concentration, suggesting TDM alone may have limitations such as low initial trough concentrations and better methods of preemptive dose individualization are warranted (Miyakis, van Hal, Ray, & Marriott, 2010).

The greatest risk of voriconazole failure due to inadequate drug concentrations is in *CYP2C19 *1/*17* and **17/*17* UMs who rapidly inactivate voriconazole (Hamada, Seto, Yago, & Kuroyama, 2012; Hassan et al., 2011; Hicks et al., 2014; Owusu Obeng, Egelund, Alsultan, Peloquin, & Johnson, 2014; Pieper et al., 2012; Wang et al., 2014). *CYP2C19 *1/*1* (extensive metabolizer; EM) patients are expected to metabolize voriconazole normally, whereas patients homozygous for **2* and/or **3* are considered PMs and may achieve higher voriconazole concentrations (although the correlation between high concentrations and toxicity is inconsistent, and toxicity is often reversible). The frequency of UMs, EMs, IMs and PMs in the European population is approximately 31%, 42%, 19% and 3%, respectively (Owusu Obeng, Egelund, Alsultan, Peloquin, & Johnson, 2014). A study demonstrated that nearly 20% of 747 routine TDM samples had voriconazole concentrations ≤0.2 mg/L, and 80% of subjects with these sub-therapeutic concentrations harbored at least one *CYP2C19*17* allele (Hassan et al., 2011). Therefore, the greatest concern for voriconazole is sub-therapeutic concentrations in UM patients. A population pharmacokinetic model was used to simulate various dosage regimens in order to optimize therapeutic dosing according to *CYP2C19* status and found that voriconazole dosed 200 mg by mouth twice daily in PM patients was comparable to 300 mg by mouth twice daily in non-PM patients (Wang et al., 2014). Although there is a paucity of data on the direct influence of *CYP2C19* genotype-guided voriconazole dosing on clinical outcomes, substantial evidence exists to support the relationship between both genotype-exposure and exposure-response (Owusu Obeng, Egelund, Alsultan, Peloquin, & Johnson, 2014). Studies examining the clinical utility of prospective, *CYP2C19*-guided voriconazole dosing are currently underway.

FUTURE RESEARCH DIRECTIONS



More than 100 drugs approved by the U.S. FDA include pharmacogenetic biomarkers in the drug label, the majority of which are related to cancer therapies. With declining costs and faster turnaround times for next generation sequencing, enormous amounts of molecular data will be generated for each patient. The results from thousands of patients being profiled from around the world will provide critical information on drug-gene associations and clinical outcomes. Future research on clinical implementation of these molecular results will be pivotal in translating molecular profiling from bench to bedside. However, for pharmacogenetic tests to be adopted in clinical practice, it must provide reliable, actionable and predictive information that the clinician would not have otherwise known. Figure 2 summarizes an example of personalized cancer medicine and how a clinician can translate pharmacogenetic test results into actionable prescribing decisions.

[This diagram summarizes how pharmacogenomic information, including both somatic and germline, can be used to personalize anticancer and supportive care pharmacotherapy.

1. The patient presents to clinic, a biopsy is obtained, and the pathologist reviews the results with the multidisciplinary team.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Example of personalized cancer medicine: translating pharmacogenomic results into actionable prescribing decisions

DPYD-dihydropyrimidine dehydrogenase; UGT1A1-uridinediphosphate glucuronosyl transferase 1A1; OPRM1-mu-opioid receptor gene; CYP2D6-cytochrome P450 2D6; 5-FU-5-fluorouracil; FOLFOX- 5-FU, oxaliplatin, leucovorin; CINV-chemotherapy-induced nausea and vomiting;

2. The patient has confirmed metastatic CRC and both tumor and paired normal DNA are sent for DNA sequencing.
3. Next generation sequencing identifies a KRAS and BRAF mutation in the tumor, in addition to a DPYD, UGT1A1, OPRM1 and CYP2D6 mutation in the germ-line DNA.
4. Because the patients' tumor has a KRAS mutation, EGFR inhibitor therapy is ruled out, and because the patient has a UGT1A1 mutation, they would be at an increased risk for irinotecan-induced toxicity, therefore, FOLFIRI is ruled out. The recommendation is to initiate first-line therapy with FOLFOX plus bevacizumab.
5. Because the patient has a DPYD mutation, the 5-FU bolus and continuous infusion dose are reduced by 50% to avoid excessive toxicity.
6. The patient is closely monitored for drug efficacy and toxicity.]
7. The patient experiences CINV, pain and depression, therefore, supportive care is needed.
8. Given the CYP2D6 duplication, the optimal choice of a serotonin receptor antagonist would be granisetron for CINV, morphine (or another opioid not metabolized by CYP2D6) for pain (consider higher dose due to OPRM1 GG genotype, which confers increased pain sensitivity), and citalopram (or another antidepressant not metabolized by CYP2D6).
9. Finally, monitor closely for supportive care efficacy and toxicity.

Reliance on prospective, randomized controlled clinical trials (RCTs) as the sole method of justifying implementation may not be realistic. While RCTs are generally considered the gold standard, the delay in conducting and interpreting results may potentially deprive patients of life-saving or extending therapies. Initiatives such as the American Society of Oncology's (ASCO) CancerLinq (http://cancerlinq.org/), NCI Match (http://www.cancer.gov/about-cancer/treatment/clinical-trials/nci-supported/nci-match),

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

ASCO's TAPUR study (http://www.asco.org/practice-research/targeted-agent-and-profiling-utilization-registry-study) and other biomarker-driven basket trials will provide critical information to better assign targeted therapies to molecular aberrations and ultimately allow evaluation of clinical outcomes for eventual translation into clinical practice. Furthermore, germ-line DNA from patients enrolled into cancer clinical trials and the drug development process should be exploited to retrospectively discover and validate germ-line pharmacogenetic associations, with subsequent pilot studies to investigate the clinical implementation of promising variants.

CONCLUSION

A concerted effort should be made by researchers and clinicians to implement pharmacogenetic and biomarker-driven therapies in clinical practice. The examples outlined in this chapter provide evidence for the use of both somatic and germ-line DNA to personalize anticancer therapy and supportive care management. As more driver mutations are being discovered and the pharmaceutical industry continues to develop more and more targeted therapies, clinicians must be aware of the molecular mechanisms which perpetuate tumor growth, and an understanding of how molecularly targeted therapies can be effective in slowing or stopping cancer progression. National and institutional treatment pathways should make a focused effort to incorporate molecular profiling and biomarker driven therapies where appropriate, which will allow for the promise of personalized drug delivery in the oncology patient population.

Chapter 9
CNS Targeted Nanoparticle Drug Delivery:
CNS Drug Delivery

Dimple Sethi Chopra
Punjabi University, India

ABSTRACT

The idea of formulating brain permeable nanoparticles stems from the need to treat various neurological disorders like Parkinson's disease, Alzheimer's disease, schizophrenia, depression and brain tumors. Neuropeptides, antibiotics, anticancer drugs and many CNS active drugs cannot cross blood brain barrier (BBB). Studies have revealed that when these drugs are loaded on to nanoparticles they not only cross BBB, but also exhibit decreased side effects. The drug can be dissolved, dispersed, encapsulated inside the nanoparticle or attached on to surface of nanoparticles. In 1995, dalargin was the first drug to be delivered across blood brain barrier (BBB) using polysorbate 80 coated nanoparticles. The size of nanoparticles is usually between 10-1000nm. For crossing BBB it should be less than 300 nm.

INTRODUCTION

In the past few years, several high profile global pharmaceutical companies have shutdown major research activities within the neuroscience area. This is because the development of new psychotherapeutic drugs has become a high risk activity with little success. CNS drug development takes considerable amount of time. Out of 5000 potential candidate molecules, only 250 reach pre-clinical evaluation. Out of 250 reaching the pre-clinical stage, 10 reach clinical development. Out of these 10 molecules entering clinical development, only one gets approved by the regulatory authorities and get to the market. The time for development of one drug molecule takes 12-15 years. The cost of developing a new drug is typically US$10-15 billion. Moreover, CNS drugs usually fail at later stage of clinical trials, after significant investment has been made (Wegner & Rujescu, 2013). The new drug molecule should possess desired pharmacological activity, selectivity at receptor site to avoid undesirable side effects, optimal bioavail-

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

ability, ability to penetrate the blood-brain barrier. The BBB and the efflux transporters are the main cause of failure of most of the CNS drugs under clinical trial.

Ehrlich and his colleagues very the first to describe the existence of blood-brain barrier (BBB) in 1885. They showed that intravenous injection of acidic dye tryptan blue was not able to color brain and spinal cord. This gave an indication of presence of some barrier which separated the CNS from rest of the body (Ehrlich, 1885). The existence of a barrier at the level of cerebral vessels was first postulated by Bield and Kraus (1898) and Lewandowsky (1900) based on the observation that the intravenous injection of cholic acids or sodium ferrocyanide had no pharmacological effects on the CNS, whereas neurological symptoms occurred after intraventricular application of the same substances. After the development of electron microscope, it was found that cerebral endothelial cells were morphologically different from other endothelial cells in the body. The tight junctions between the endothelial cells forms the cellular basis of BBB. The brain capillary endothelial cells are surrounded by astrocytes, microglial cells, pericytes. BBB protect brain from general circulation and toxic substances. Astrocytes are periendothelial structures which play an important role in brain homeostasis. They are involved in maintenance of potassium ion levels, inactivation of neurotransmitters, regulation and production of growth factors and cytokines (Ehrlich,1885). Damage to the BBB or alterations in transport systems may facilitate pathogenesis of many CNS diseases, including HIV-associated CNS dysfunction. HIV-1 infection can result in neuropathologic changes in about one half of infected individuals and also can result in damage to the BBB. HIV-1 and the HIV-1 viral proteins, Tat and gp120, cause alterations in the integrity and function of the BBB through both paracellular and transcellular mechanisms (McRae, 2016).

Mechanisms of Transport Across BBB

The transport of solute molecules across the BBB membrane takes place by four different mechanisms:

1. **Paracellular Diffusion:** This is a non-saturable and non-competitive process occurring between cells. The presence of tight junctions in brain endothelial cells greatly restricts paracellular diffusion. Only small water-soluble molecules can diffuse through the BBB.
2. **Transcellular Diffusion:** It is also non-saturable and non-competitive. And takes place across cells. Molecules which are highly lipophilic and have molecular weight less than 450 Da undergo transcellular diffusion.
3. **Carrier-Mediated Transport:** These carriers are membrane bound and facilitate active transport of specific nutrients across the BBB. Glucose transporters GLUT1 and GLUT3 are of great importance as glucose is main energy source of brain. Monocarboxylate transporters are another important carrier systems for lactate and pyruvate. Similarly specialized carriers exist for amino acids and vitamins. Drugs or prodrugs can cross BBB through this transport mechanism by mimicking nutrients (Ohtsuki & Terasaki, 2007).
4. **Receptor-Mediated Endocytosis:** It facilitates the transport of large endogenous proteins and hormones across the BBB. It is mediated by receptors present on the luminal side of the barrier. Specific receptors have been identified for insulin, insulin-like growth factors, angiotensin II, folates and transferrin. Lipids can also be internalized in the brain in the form of low-density lipoproteins (LDL), which are recognized and endocytosed by the endothelial cells, due to the expression of apolipoproteins on the surface of the LDL (Yoshikawa & Pardridge, 2001).

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

The massive brain microvasculature has a total surface area of 20 m^2 and a total length of 640 km. The brain capillaries present no fenestrae, few pinocytosis vesicles, and particular tight junctions, also known as zonula occludens, controlling the movement of molecules through the paracellular pathway. This comprises an almost impermeable barrier for drugs administered through the peripheral circulation (Kreuter, 2013). Only small molecules can diffuse through it. BBB prevents transport of many important drugs from blood to brain including anticancer drugs, antibiotics, drugs for treatment of Alzheimer's and Parkinson's disease. It has been a real challenge in developing drugs for CNS disorders (Jain, 2009). A number of methods have been developed to overcome this barrier. Chemical modifications of the drugs, such as increasing their lipophilicity, turn them more prone to be internalized in the brain. Osmotic opening of the tight junctions, direct surgical administration of drugs into the brain, use of prodrugs, use of carrier systems like antibodies or liposomes: Use of molecular tools to bind the drugs such as small immunoglobulins, liposomes or nanoparticles that will act as Trojan horses favouring the drug delivery in brain (Pardridge, 2015).

POLYMERIC NANOPARTICLES

In 1995, nanoparticles were first time used to deliver drugs across the BBB following intravenous administration. The underlying mechanism was found to be receptor-mediated endocytosis followed by transcytosis. Their was no evidence of tight junction opening of brain endothelial cells. Nanoparticles coated with surfactants like polysorbate-80 or poloxamers 188 take advantage of physiological receptor-mediated transport across the BBB. Once nanoparticles enter the blood, they get covered by a corona of biomolecules. These biomolecules are responsible for interaction of nanoparticles with the cellular processes. The physical adsorption of apolipoprotein A-I and /or E mediate interaction with LDL receptors on the BBB. The covalent attachment of apolipoprotein A-I and /or E or of transferring, insulin or antibodies against the respective receptors also enables a similar nanoparticle-mediated drug transport across the BBB (Ohtsuki & Terasaki, 2007).

Apolipoprotein E was chemically linked to human serum albumin nanoparticle (HAS-NP). Loperamide, which does not cross the blood-brain barrier but exerts antinociceptive effects after direct injection into the brain, was used as model drug. This preparation induced antinociceptive effects in the tail-flick test in ICR mice after i.v. injection. In contrast, nanoparticles linked to apolipoprotein E variants that do not recognize lipoprotein receptors failed to induce these effects. These results indicate that apolipoprotein E attached to the surface of nanoparticles facilitates transport of drugs across the blood brain barrier, probably after interaction with lipoprotein receptors on the brain capillary endothelial cell membranes (Michaelis *et al.*, 2006). HAS-NP with different vectors, transferrin, and apoE have been used in two independent series of experiments. Similar results were achieved for the delivery of loperamide to the CNS in both cases (Ulbrich *et al.*, 2009). Transferrin (Tf) is a single glycoprotein synthesized in the liver, and is the main iron-containing protein in blood plasma. Upon combination with Fe^{2+}, its molecular structure changes and it acquires binding affinity for the transferrin receptor (TfR) (Widera et al., 2003; Yang et al., 2009). TfR is widely expressed in capillary endothelial cells of the BBB, and targeted administration *via* the Tf-TfR pathway is a promising method of drug delivery (Xing *et al.*, 2016).

Polymeric nanoparticles are solid colloidal systems of 1-1000nm size, composed of biocompatible copolymers that have low solubility in water (Craparo *et al.*, 2011; Kumar *et al.*, 2010). Synthetic polymers like poly(alkyl cyanoacrylates); polyesters such as polylactides (PLAs); poly (D,L-lactide-co-

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

glycolate) (PLGA) have been used for preparation of nanoparticles. Nanoparticles made of PLA and PLGA are synthesized by emulsion-diffusion and precipitation, whereas poly(alkyl cyanoacrylates) nanoparticles are synthesized by emulsion polymerization and nanoprecipitation method (Craparo *et al.,*2011). Nanoparticles are able to transport substances adsorbed onto their surface or covalently bound or incorporated into their polymer matrix, or encapsulated in them. It is difficult to reveal localization of the incorporated substance, therefore the terms "nanospheres" and "nanocapsules" are not commonly used, instead the term "nanoparticles" is generally used (Denora *et al.*, 2009). Nanoparticles present in the blood are quickly cleared because of opsonization by RES cells. Decreasing the size of nanoparticles increases duration of their circulation in the blood (Pinto *et al.*, 2006). However, adsorption of surfactants on their surface has been shown to be more effective for prolongation of their circulation time in blood (Kreuter, 2001). Modification of the surface of the nanoparticles by adsorption onto their surface or covalent linking of hydrophilic polymers, such as PEG, polysorbate 80, or polysaccharides, leads to an increase in the circulation of nanoparticles in the blood, whereas incorporation of molecules that recognize cellular determinants helps in penetration of nanoparticles through the BBB (Kreuter *et al.*, 1995).

PLGA is a block co-polymer made of polylactic acid (PLA) and polyglycolic acid (PGA) that has been approved by the FDA and European Medicine Agency. PLGA has excellent biocompatibility, in the human body it is hydrolyzed into lactic and glycolic acids, which are naturally-occurring metabolites. PLGA nanoparticles can be easily modified to accommodate a range of functional or targeting options. However, PLGA NPs without modifications also have a number of intrinsic drawbacks. Their negative surface charge inhibits makes cellular uptake. They have a relatively short blood circulation time and they do not pass through the BBB without further modifications (Cai *et al.*,2016).

Polybutylcyanoacrylate nanoparticles were used to facilitate transport of drugs through the BBB (Kreuter *et al.*, 1995). Kreuter and Alyautdin, 2000 performed in vivo experiments that demonstrated the possibility for brain delivery of peptide dalargin using polybutylcyanoacrylate nanoparticles coated with polysorbate 80. It was shown in subsequent experiments with H^3-dalargin that the absence of the polymeric coating of nanoparticles significantly reduced the delivery of the peptide to the brain (Schroeder *et al.*, 2000). The polar hydrophilic drugs tubocurarine (Alyautdin *et al.*, 1998) and neostigmine, P-gp substrates loperamide (Alyautdin *et al.*, 1997) and doxorubicin (Steiniger *et al.*, 2004) and the nerve growth factor (NGF) a protein have also been delivered to the brain through the BBB using this transport system (Kurakhmaeva *et al.*, 2009). These data support the fact that adsorption of polysorbates onto the surface of nanoparticles leads to changes in the characteristics of nanoparticle distribution. Analysis showed that penetration of nanoparticles is provided by stimulation of receptor-mediated endocytosis; primarily, by interaction of nanoparticles with LDL receptors on brain endothelial cells (Wohlfart *et al.*, 2012). The reason for such interaction may be due to adsorption of endogenic LDL from the plasma by polysorbate 80. The role of apoE has been demonstrated by Michaelis *et al.*, 2006. Two types of albumin nanoparticles one coated with polysorbate 80 and other with covalently bound apoE on their surface exhibited approximately equal ability to transport drugs through BBB. It has been found that polysorbate absorbed on the surface of polymeric nanoparticles has three effects: it allows for an increase in the duration of nanoparticle circulation in the blood by decreasing the chance of being captured by RES cells; it indirectly stimulates receptor-dependent endocytosis; and it directly influences Tight junctions of the BBB (Kreuter, 2004; Kreuter *et al.*, 2003; Kreuter *et al.*, 2002).

Rivastigmine, a reversible cholinesterase inhibitor used for treatment of Alzheimer's disease. It was shown that, compared to the free drug, rivastigmine-loaded poly(n-butylcyanoacrylate) (PBCA) nanoparticles (Riv-NP), particularly after being coated with polysorbate 80 (Riv-NP + PS80), accumulated to

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

a greater extent in the brain. It was postulated by Wilson *et al.*, 2008 that this could translate into a better efficacy of rivastigmine. It was found that, compared to Riv-NP, Riv-NP + PS80 accumulates in a significantly lesser amount in the liver, which could potentially limit organ-specific toxicity and drug–drug interactions. Delivery of antineoplastic agents across the BBB has been shown to be improved by utilization of a nanoparticles. Gemcitabine, has proven to have beneficial effect on solid tumors such as non-small-cell lung cancer, pancreatic cancer, and breast cancer. Following incorporation into PBCA and coating with polysorbate 80 (Gem-PBCA + PS80),compared to gemcitabine alone, was found to have significantly improved antiproliferative activity on C6 glioma cells in an *in vitro* assay. The survival time was significantly increased in rats treated with Gem-PBCA + PS80 as compared to those treated with free gemcitabine (Wang *et al.*, 2009). Polymeric nanoparticles coated with polysorbate 80 have been used successfully to transport tacrine (Wilson *et al.*, 2008) and antitumor agent doxorubicin to the brain (Gulyaev *et al.*, 1999). It has been shown both *in vitro* and *in vivo* that polymeric nanoparticles penetrated the BBB, accumulated in the brain parenchyma resulting in strong antitumor effects (Kreuter and Gelperina, 2008). The polymers used as matrices for nanoparticles includes albumin, PLA, PLGA, chitosan, solid lipids, and polyethyleneimines. The main advantages of these polymers are low toxicity, biodegradability, presence of functional groups on the surface, processing stability, and the possibility to influence the excretion rate of drug molecules (Olivier, 2005). The development of novel and smart polymers have led to increase in number of transport vectors that can ferry drug molecules across BBB. Similar to the use of apoE as a vector for receptor-mediated transport, transferrin (OX26) or antibodies to transferrin receptor, insulin and antibodies to insulin, and TAT proteins have been used as targeting agents. Transferrin provides iron transport in the organism; therefore, there is a relatively high concentration of this protein in the plasma, which decreases its transport potential. Antibodies situated on the surface of nanoparticles interact with transferrin receptors in ECs, making it possible to deliver nanoparticle-receptor complex across BBB through transcytosis (Pardridge, 2006). Transferrin has been used to transport albumin nanoparticles containing loperamide through the BBB. The possibility of drug transport to the brain using antibodies to human insulin receptor was first demonstrated by Pardridge in monkeys in 1995. Ulbrich et al demonstrated, in 2011, the possibility for transporting the opioid agonist loperamide through the BBB in experiments using albumin nanoparticles with insulin attached to their surface. Antibodies to the insulin receptor inhibited transport of loperamide to the brain (Ulbrich *et al.*, 2011). TAT peptide is one of the most frequently used vectors for drug transport to the brain. This peptide, via a domain composed of nine to 16 amino acids, may penetrate biological membranes using mechanisms that are independent of transporter- or receptor-mediated transport (Torchilin, 2008) PLA nanoparticles, containing ritonavir and coated with TAT protein, increased the concentration of the drug in the brain 800 times (Rao *et al.*, 2008). Besides this, recent evidence suggests the usage of another cell penetrating peptide (CPP), syncytin-B (SynB), as a vector for drug transport across the BBB (Tian *et al.*, 2012). This group of investigators showed very promising data with nanoparticles that were conjugated to SynB peptide using PEG and gelatin–siloxane. Another protein, gH625, which is a membrane-perturbing domain in the glycoprotein gH of Herpes simplex virus type I, was conjugated onto polystyrene nanoparticles for transport across the BBB. This study was performed in vitro and can be applied to the design of one or more systems of drug delivery to the brain (Guarnieri *et al.*, 2013). Interesting data regarding CPP penetration, which delivered antibodies to the prion protein into mouse brain, were obtained (Skrlj *et al.*, 2013). Placing serotonin on the surface of a nanoparticle led to recognition by the serotonin receptor on the surface of cells, thereby stimulating endocytosis; in the same way, DNA was delivered to the cell (Gopal *et al.*, 2011). Both liposomes (Mora *et al.*, 2002) and

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

polymeric nanoparticles (Nowacek *et al.,* 2009) were successfully used for cell-mediated drug transport. This approach of drug delivery to the brain has several advantages. Targeting of drug to disease sites, resulted in prolonged drug half-lives and time-controlled drug release (Gendelman *et al.*, 2008). The concept of polymeric nanoparticles seems to be conventional, but surface conjugation of these carriers with peptides have improved their targeting capabilities as can be easily see in Table 1. It can be clearly seen that these versatile carriers can be developed as diagnostics for Alzheimer's disease.

Novel Non-Viral Vector for Brain Targeting

The application of viral vectors in drug delivery is restricted by issues such as toxicity, and their is utmost need for safe and effective treatment. Liposomes are a new non-viral vector for the delivery of drugs to

Table 1. Brain permeable theranostic polymeric nanoparticles

Drug/Bioactive Molecule	Polymer Used/ Stabilizer	Surfactant Coating	Particle Size	Results	References
Dalargin	Polybutylcyanoacrylate	Polysorbate-80	260 nm	Significant & Prolonged Anesthesia	Kreuter and Alyautdin, 2000

the brain, such as doxorubicin, which can be entrapped in the aqueous phase of the liposome (Schnyder et al., 2005; Xu, 2011; Gao et al., 2013). Brain-derived neurotrophic factor (BDNF) is widely expressed in the central nervous system, especially in the hippocampus and cortex (Bertrand, 2010; Qin, 2011). BDNF and its receptor TrkB play an important role in regulating various biological properties, including neuronal survival, differentiation, growth and plasticity (Ploughman et al., 2009; Tuinstra, 2012; Zhang, 2012). In the developing brain, endogenous BDNF levels are very low; therefore, in cases of brain injury (such as ischemia, degeneration and inflammation) during development, administration of exogenous BDNF is a promising treatment approach. However, as a macromolecular protein, exogenous BDNF cannot directly traverse the blood-brain barrier (BBB) or other biomembranes to exert its therapeutic function (Vijender, 2015). Recently it was investigated whether BDNF could be transported across the blood-brain barrier by tail-vein injection of liposomes conjugated to transferrin (Tf) and polyethylene glycol (PEG), and carrying BDNF modified with cytomegalovirus promoter (pCMV) or glial fibrillary acidic protein promoter (pGFAP) (Tf-pCMV-BDNF-PEG and Tf-pGFAP-BDNF-PEG, respectively). Both liposomes were able to traverse the blood-brain barrier, and BDNF was mainly expressed in the cerebral cortex. BDNF expression in the cerebral cortex was higher in the Tf-pGFAP-BDNF-PEG group than in the Tf-pCMV-BDNF-PEG group. This study demonstrates the successful construction of a non-virus targeted liposome, Tf-pGFAP-BDNF-PEG, which crosses the blood-brain barrier and is distributed in the cerebral cortex (Xing *et al.*, 2016).

Cell-Mediated Drug Transport

Immunocytes including mononuclear phagocytes (dendritic cells, monocytes and macrophages), neutrophils, and lymphocytes) are highly mobile; they have the ability to migrate across impermeable barriers and release their drug cargo at sites of infection or tissue injury. Thus immune cells can be exploited as trojan horses for drug delivery. Using cells as delivery vehicles enables targeted drug transport, and prolonged circulation times, along with reductions in cell and tissue toxicities. For successful cell-mediated drug delivery, high drug loading into cell-carriers, efficient preservation of entrapped therapeutic agents against disintegration and clearance in the host cells, drug triggered release at the site of action, efficient homing of cell-carriers to a disease site, safety of cell-based drug formulations for the whole organism are some of the prerequisite which needs to be achieved. The design of nanocarriers for cell-mediated drug delivery differ from those used for conventional drug delivery systems. Two different approaches are presently utilized in cell-mediated drug delivery: genetically modified cell-carriers producing therapeutically active molecules; and drug loaded cell-carriers used as "Trojan horses" to deliver the drug to the disease site. This disease combating strategy that can be applied to a spectrum of human infectious, cancerous, and degenerative disorders (Batrakova *et al.,* 2011).

To target circulating mononuclear phagocytic cells, negatively-charged nano-sized liposomes were formulated encapsulating serotonin, a BBB impermeable neurological drug. In vitro and in vivo studies confirmed the ability of monocytes to carry nano-sized liposomes loaded with serotonin across the BBB (Afergan *et al.*, 2008). There was also evidence of in vitro delivery of catalase to the brain using a polymeric nanocarrier. Catalase was immobilized on a polyethyleneimine-poly(ethylene glycol) copolymer, and such "nanozymes" were phagocytosed by bone-marrow-derived macrophages (Batrakova *et al.*, 2008). The polymer protected the enzyme from being activated inside the immune cell, while the macrophage delivered the antioxidant enzyme to the brain to reduce oxidative stress and increase survival of dopaminergic neurons in patients with Parkinson's disease.

Efflux Transporters in Brain

Efflux transporters contribute significantly in maintaining brain homeostasis by eliminating toxic endogenous and exogenous substances. The efflux transporters of the ATP-binding cassette (ABC) P-glycoprotein (Pgp) can actively transport large quantities of lipophilic drugs out of the brain capillary endothelial cells. Some of the other ABC efflux transporters are multidrug resistance protein (MRP) and breast cancer resistance protein (BCRP). ABC efflux transporters are beneficial in reducing or preventing adverse effects of drugs and neurotoxic substances. But they also limit distribution of drugs that are valuable in treating CNS disorders. Moreover, neurological disorders such as epilepsy may be associated with overexpression of ABC efflux transporters, resulting in resistance to therapeutic medication. Hence, modulation of ABC efflux transporters forms a novel strategy to enhance the penetration of drugs into the brain (Löscher and Potschka, 2005).

Another very popular ATP-dependent drug transport protein P-glycoprotein (P-gp) is present on the luminal side of BCEC. It is a 170-kDa membrane-associated glycoprotein that actively transports structurally diverse molecules. It has been established, both in vitro and in vivo, that BBB. P-gp can prevent accumulation of drug molecules in the brain, by expelling them from the cells. Inhibition of the P-gp function can be obtained through down-regulation of its expression at transcriptional or translational levels, or by altering membrane targeting after synthesis of the P-gp protein, or through chemical inhibition of transporter functions. The first two approaches have been less developed, whereas chemical inhibition of the transporter functions has been extensively studied for improving permeability across BBB (Tsuji and Tamai,1997; Schinkel, 1999). An alternative approach is use of nanoparticles to carry the drug into the endothelial cells by endocytosis, thereby bypassing the P-gp drug efflux mechanism (Miller *et al.*, 2008).

The activity of P-gp, is increased in pathological conditions like epilepsy, stroke (Spudich *et al.*, 2006; Yang and Rosenberg,2011*)*. This reduces drug efficacy. P-gp actively transport out phenytoin, levetiracetam, lamotrigine, and Phenobarbital ((Denora *et al.,* 2009*)*. In the case of HIV infection, transactivating transcriptor (TAT) proteins from virion stimulate P-gp activity (Hayashi *et al.*, 2005). Same is true for antitumor drugs like paclitaxel, vincristine and ivermectin. In transgenic mice lacking P-gp, the concentration of vincristine and ivermectin in the brain increased 80–100-fold than that in normal mice. Paclitaxel is effective on tumor cells in vitro, but does not show same activity in vivo because of P-gp efflux. The concentration of paclitaxel can be significantly increased by simultaneous administration of paclitaxel and an inhibitor of P-gp, PSC833 (Denora *et al.,* 2009*)*. The first-generation inhibitors of P-gp, verapamil, diltiazem and cyclosporine, are used to increase brain delivery of viral protease inhibitors, paclitaxel and itraconazole, docetaxel, digoxin, and imatinib. But, they had limitations, like low affinity to P-gp, toxic effects due to high doses of these inhibitors, and simultaneous inhibition of liver microsomal enzymes (CYP3A). A second-generation P-gp inhibitor, an analog of cyclosporine valspodar 10, has great affinity for the transporter, with reduced toxicity and decreased effects on liver microsomal enzymes. A third generation of P-gp inhibitors, including elacridar 11, zosuquidar 12, and tariquidar 13, are devoid of effect on liver microsomal enzymes (CYP3A). Modulation of BCRP/ABCG2 activity also has significant clinical importance due to the possibility of mutual overlapping with P-gp (Laquintana *et al.,*2009*).* Elacridar 11 and the proton pump inhibitor pantoprazole are known inhibitors of BCRP (Litman *et al.*, 2000). Inhibition of P-gp is desirable for delivery of therapeutic molecules but

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

would at the same time open the BBB to potentially toxic substances. This risk can be acceptable for the treatment of patients with cancer, but should be carefully weighed with long-term therapy of chronic CNS diseases (Alyautdin *et al.*, 2014).

ROLE OF NANOTECHNOLOGY IN TREATMENT OF BRAIN TUMORS

Glioblastomas belong to the most aggressive human cancers with short survival times. It is currently being treated with radiation therapy and surgery. One of the most important problems regarding the treatment of Glioblastomas is the presence of blood brain barrier (BBB) which inhibits the efficient drug delivery into central nervous system (Huse *et al.*, 2013). Nanotechnology can deliver therapeutic drugs into CNS by crossing the BBB. There are different types of nanoparticles (Nps) which can be manipulated for clinical applications as a treatment for CNS-related disorders (Pourgholi *et al.,*2016). Steiniger *et al.*, 2004 have shown that doxorubicin bound to polysorbate-coated nanoparticles crossed the intact blood-brain barrier, thus reaching therapeutic concentrations in the brain. Additionally, binding to nanoparticles may reduces systemic toxicity of doxorubicin. The standard therapy for GBM is surgery followed by radiation and chemotherapy with temozolomide (TMZ). Treatment of GBMs remains a challenge, largely due to the fast degradation of TMZ, inability to deliver an effective dose of TMZ to tumors, and lack of target specificity which may cause systemic toxicity (Zhang *et al.*, 2012). Recently Fang *et al.*, 2015 presented a simple method to synthesize a nanoparticle-based carrier that can protect TMZ from rapid degradation in physiological solutions and can specifically deliver them to GBM cells through the mediation of a tumor targeting peptide chlorotoxin (CTX). This nanoparticle, namely NP-TMZ-CTX, had a hydrodynamic size of less than 100 nm, exhibited sustained stability in cell culture media for up to two weeks, and could accommodate stable drug loading. The NP contains a biotin-functionalized chitosan core that is covalently conjugated with TMZ that were linked to GBM-specific, surface-bound CTX ligands with fast, stable, and stoichiometric biotin-neutravidin interactions (Petros and Desimone, 2010). NP-TMZ-CTX showed higher uptake in GBM cells and was more effective in cell killing than non-targeted NPs and free drug. It was further demonstrated that NP-TMZ-CTX can cross the BBB and deliver TMZ into avascular region of brain. NP-TMZ-CTX offers hope to deliver effective doses of TMZ specifically to GBM cells while minimizing dose-limiting toxicity on other healthy tissues. This NP-based delivery system can be broadly applied to various applications as it can be tailored to incorporate various therapeutics that are otherwise unstable or insoluble in physiological conditions (Fang *et al.*, 2015).

CONCLUSION AND FUTURE PROSPECTS

Biologics such as antibodies because of their large size are unable to cross BBB. They can be made to cross BBB by re-engineering them as an IgG fusion protein. The IgG is a monoclonal antibody against endogenous BBB receptor i.e transferring receptor. So the biologic is ferried into the brain by receptor mediated endocytosis. Many of ligand targeted nanomedicines for brain targeting have progressed into clinical trials. The fusion of classical pharmacology with nanotechnology has opened up many different

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

approaches for new generation of neuroactive drugs to access BBB. An example is targeted drug delivery to brain of BDNF using liposome as non-viral vector. Green synthesized nanoparticles can also be used in discovery of biomarkers and improvement of diagnosis. This forms the basis for new drug development for neurological disorders. It further explores new methods for drug delivery across blood-brain barrier. Nanotechnology based implants are being developed to facilitate regeneration of the nervous system. It is being speculated that femtolasers, nanorobots and other nanodevices will bring advancement in neurosurgery. Finally, the progress of BBB permeability of drugs and biologics are highly dependent on highly precise *in vitro* BBB models which have good prediction power. These models are extremely useful for investigating intracellular sorting mechanism of receptors. This requires microscopy at subcellular resolution. This will also help in studying vesicular compartments involved in transcytosis and finding new transcytosis receptors. All the molecules designed for BBB penetration cannot be tested in animals due to ethical considerations. Many models have been designed to mimic BBB *in vitro*. But none can replace *in vivo* investigations completely. Hence, great care should be exercised in the analysis and interpretation of the results obtained with cultured cells and extrapolating it to the native BBB *in vivo*.

Chapter 10
Engineered Gellan Polysaccharides in the Design of Controlled Drug Delivery Systems

Sabyasachi Maiti
Gupta College of Technological Sciences, India

ABSTRACT

Natural polysaccharides are getting increasing attention in the development of pharmaceutical dosage forms due to their encouraging reports on nontoxicity and biodegradability. Natural gums can also be engineered to have better materials for drug delivery system design. Gellan gum originates from microbial fermentation and has been declared as safe by US FDA for human consumption. It possesses gelling ability in presence of multivalent earth metal cations and thus enabled the design of mutiparticulate drug delivery systems in completely aqueous environment avoiding the use of organic solvents. Due to faster drug release profiles of divalent cation-induced gellan gum particles, nowadays chemically modified forms of gellan polysaccharide are currently being investigated for the controlled release of drugs. This chapter discusses the factors contributing to the varying gelling characteristics of gellan gum and the recent developments in its chemical modification towards the fabrication of novel controlled drug delivery devices.

INTRODUCTION

Polymers are compounds with high molecular masses formed by monomers. The word poly means ‘many’ and meros mean ‘units or parts’ in Greek. They consist of different functional groups. Because of their unique properties, polymers are extensively used in pharmaceuticals. The new technology in polymer-based drug release system offer possibilities in the administration of drugs. Pharmaceutically, these polymers are used as a binder in tablets, flow controlling agents in liquids, suspension and emulsions, as film coating agents to mask unpleasant taste of drug, to enhance drug stability, and to modify

the release characteristics of the drug. The rate of drug release from a matrix product depends on initial drug concentration and relaxation of the polymer chains, which overall displays a sustained release pattern (Uhrich, Cannizzaro, & Langer, 1999).

Natural polysaccharides and their derivatives represent a group of polymers widely used in pharmaceutical dosage forms. Various kinds of natural gums are used in the food industry and are regarded as safe for human consumption. These polysaccharides are obtained usually as plant exudates containing various sugars other than glucose and having significant quantities of oxidized groups in adjunct to their normal polyhydroxy format. In many cases, water-soluble polysaccharides are components of land and marine plants and their seeds. These material results from normal metabolic processes, and many times, they represent the reserve carbohydrate in that system (Bhardwaj, Kanwar, Lal, & Gupta, 2000). Natural gums are often preferred to synthetic materials due to their nontoxic nature, low cost, and free availability. Furthermore, natural gums have been modified to overcome certain drawbacks, like uncontrolled rate of hydration, thickening, drop in viscosity on storage, microbial contamination, and the like (Durso,1980).

Polysaccharides are a diverse class of polymeric materials of natural (animal, plant, microbial) origin formed via glycosidic linkages of monosaccharides (Shukla & Tiwari, 2012). Depending upon the nature of the monosaccharide unit, polysaccharides can have a linear or branched architecture. In addition to structural diversity, polysaccharides have a number of reactive functional groups, including hydroxyl, amino, and carboxylic acid groups, indicating the possibility for chemical modification (Liu, Jiao, Wang, Zhou, & Zhang, 2008). Moreover, polysaccharide molecular weight can vary between hundreds and thousands of Daltons, further increasing diversity (Saravanakumar, Jo, & Park, 2012). Also owing to their native presence within the body, most polysaccharides are subject to enzymatic degradation. Through enzyme catalysis, polysaccharides can be broken down to their monomer or oligomer building blocks and recycled for use as storage, structural support, or even cell signaling applications (Jain, Gupta, & Jain, 2007). For example, glycosidases are common, constituting 1%–3% of the human genome (Rempel & Withers, 2008), and can readily catalyze the hydrolysis of many different glycosidic linkages. In contrast to glycosidase, other enzymes (for example, hyaluronidase is specific for the polysaccharide hyaluronic acid) are more polysaccharide specific. Of note, some polysaccharides are particularly susceptible to degradation by lysosomal enzymes, including esterases, and proteases, following endocytosis pathway (Mehvar, 2003). Thus, enzymatic degradation provides a mechanism of release for therapeutics associated with polysaccharide-based carrier systems.

Mucoadhesion refers to the interaction of a material with a mucosal layer, such as in the gastrointestinal (GI) tract, nasal pathway, or airway. Many polysaccharides possess mucoadhesive property and thus, numerous investigators have explored their use for oral drug delivery. For neutral or negatively charged polysaccharides, hydrogen bonding provides the basis for mucoadhesion (Reddy, Mohan, Satla, & Gaikwad, 2011).

Any pharmaceutical formulation usually contains two types of ingredients one is the active ingredient and other components are excipients. The excipients help in the manufacturing of dosage form and also improve physicochemical parameters of the dosage form. They can influence drug release characteristics and preferably should be compatible, non-toxic, stable, economical etc. They are broadly classified as natural polymers and synthetic polymers. Due to their wide range of applications, the selection of polymer constitutes a vital step in designing any dosage form. Nowadays, due to many problems associated with drug release and side effects, manufacturers are inclined towards using natural polymers (Kulkarni, Butte, & Rathod, 2012).

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

They are amenable to chemical modifications, potentially biodegradable, and also biocompatible with few exceptions (Satturwar, Fulzele, & Dorle, 2003). The specific application of biopolymers in pharmaceutical formulations include their use in the manufacture of solid monolithic matrix systems, implants, films, beads, microparticles, nanoparticles, inhalable and injectable systems as well as viscous liquid formulations (Pandey & Khuller, 2004; Chamarthy & Pinal, 2008; Alonso-Sande, Teijeiro, Remuñán-López & Alonso, 2009). The polymeric materials have fulfilled different roles such as binders, matrix formers or drug release modifiers, film coating formers, thickeners or viscosity enhancers, stabilizers, disintegrants, solubilizers, emulsifiers, suspending agents, gelling agents and bioadhesives in these dosage forms (Guo, Skinner, Harcum, & Barnum, 1998).

Controlled drug delivery is the use of formulation components and devices to release a therapeutic agent at a predictable rate *in vivo* when administered by an injected or non-injected route. Controlled drug delivery occurs when a polymer, whether natural or synthetic, is judiciously combined with a drug or other active agent in such a way that the active agent is released from the material in a predesigned manner. The release of the active agent may be constant over a long period, it may be cyclic over a long period, or it may be triggered by the environment or other external stimulus. In any case, the purpose is to achieve more effective therapies while eliminating the potential for both under and overdosing. The role of many of the original controlled-release systems was to achieve a delivery profile that would yield a high blood level of the drug over a long period of time. With traditional tablets or injections, the drug level in the blood follows a profile in which the level rises after each administration of the drug and then decreases until the next administration. The key point with traditional drug administration is that the blood level of the agent should remain between a maximum value, which may represent a toxic level, and a minimum value, below which the drug is no longer effective. In controlled drug delivery systems, designed for long-term administration, remaining constant, between the desired maximum and minimum, for an extended period of time (Torchilin, 2001). Depending on the formulation and the application, this time may be anywhere from 24 hours (Procardia XL) to 1 month (Lupron Depot) to 5 years (Norplant) (Shaik, Korsapati, & Panati, 2012).

For decades microbial exopolysaccharides have been invaluable ingredients in the food industry, as well as having many attractive pharmaceutical and chemical applications. The biopolymer gellan is a more recent addition to the family of microbial polysaccharides that is gaining much importance due to its novel property of forming thermo-reversible gels when heated and cooled. It has applications in diverse fields in the food, pharmaceutical and many other industries (Giavasis, Harvey, & McNeil, 2000).

Gellan gum is an anionic, high molecular weight (5,00,000Da), deacetylated exocellular polysaccharide gum produced as a fermentation product by a pure culture of *Pseudomonas elodea* (Jansson, Lindberg, & Sandford, 1983), with a tetrasaccharide repeating unit of one α-L-rhamnose, one β-D-glucuronic acid and two β-D-glucose residues. The native polysaccharide is partially esterified with L-glycerate and acetate (Kuo, Mort, & Dell, 1986) but the commercial product Gelrite® has been completely de-esterified by alkali treatment (Morris, 1995; Kang, Veeder, Mirrasoul, Kaneko, & Cottrell, 1982). It usually contains small amount of nitrogen-containing compounds resulting from fermentation procedures. The glucuronic acid is neutralized by the presence of potassium, calcium, and magnesium ions. The relative concentrations of these ions will control the physical properties of the gum material such as gel strength, melting point and setting point. The production organism is an aerobic, gram-negative bacterium, which has been very well characterized and demonstrated to be non-pathogenic. This organism was found during an extensive screening programme seeking naturally occurring hydrocolloids with useful properties. Gellan gum has the characteristic property of temperature-dependent and cation-induced gelation. This

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

gelation involves the formation of double helical junction zones followed by a gellan gum aggregation of the double helical segments to form a three-dimensional network by complexation with cations and hydrogen bonding with water.

The acetyl groups in native gellan gum are removed by alkaline treatment to produce deacetylated gellan gum. Acyl substituents affect the rheology, and gel characteristics (Kang & Veeder, 1982). There are two types of deacetylated gellan gum differentiated on the basis of degree of deacetylation: high acyl gellan gum (partially deacetylated) and low acyl gellan gum (highly deacetylated) (Sanderson & Clark, 1983a). The high acyl form produces soft very elastic and non-brittle gels, while the low acyl form produces firm, non-elastic and brittle gels. In 1991, toxicological evaluation of gellan gum was done at the thirty-seventh meeting of the Joint FAO/WHO Expert Committee on Food Additives (JECFA) in Geneva. Results from a limited study on tolerance to gellan gum in humans indicated that oral doses of up to 200 mg per kg of body mass administered over a 23-day period did not elicit any adverse reactions. Toxicological studies show that gellan gum is relatively nontoxic. An acute oral toxicity test on rat found that the LD_{50} of gellan is higher than 5000 mg/kg, and an eye irritation test indicated gellan to be safe for eye contact. Such evidence led to gellan gum being given FDA approval for use in foods on November 25, 1992 (Pszczola, 1993).

This chapter discusses the gelling properties of gellan gum, background information on gellan gum-based drug delivery systems, their merits, and demerits, factors controlling gelling behavior of gellan gum, and the latest developments in the area of controlled drug delivery system design using modified gellan polysaccharides.

BACKGROUND

In the design of pharmaceutical dosage forms, naturally occurring polysaccharides are currently being preferred over their synthetic counterparts because they are nontoxic, biodegradable, freely available, and less expensive (Bhardwaj et al., 2000). Over the last few years, a great deal of attention has been paid to the development of polysaccharide-based hydrogel beads through ionotropic gelation technique. They have been found useful as potential carriers for controlled drug delivery. One of the advantages of this technique is that the drug encapsulation in the beads can be accomplished in an eco-friendly aqueous environment (Patil, Kamalapur, Marapur, & Kadam, 2010). In addition, multiunit systems avoid the vagaries of gastric emptying and different transit rates through the gastrointestinal tract, thereby, releasing drugs more uniformly and preventing exposure to a high drug concentration, when compared to single unit dosage form on chronic dosing (Follonier & Doelkar, 1992). The anionic biopolymer sodium alginate (Das & Senapati, 2008; Kikuchi et al., 1999; Yegin et al., 2007) has been investigated in detail for its unique nature of forming hydrogel beads with divalent calcium ions. However, calcium alginate beads erode/disintegrate rapidly in simulated intestinal fluids leading to quick release of theloaded drugs (Acarturk & Takka, 1999). Further, the gel strength of alginate beads was improved by the formation of polyelectrolyte complex with positively charged amines such as poly-l-lysine (Ueng et al., 2000), polyethyleneimine (Halder, Maiti, & Sa, 2005), and chitosan (Anal & Stevens, 2005) for the controlled delivery of drugs. But the results were not so encouraging. Chitosan is at the origin a neutral polysaccharide whose amine functional group can be protonated in acidic pH conditions and become one of the little polysaccharides which are positively charged. The ability of chitosan to form hydrogel beads in presence of negatively charged sodium tripolyphosphate has also been investigated for controlled drug

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

delivery (Aydin & Akbu˘ga, 1996; Srinatha, Pandit, & Singh, 2008). However, higher porosity of sodium tripolyphosphate/chitosan beads led to rapid release of drug in acidic dissolution medium (Gupta & Ravi, 2000). Even, the pectin beads have some drawbacks due to their rapid *in vitro* drug release (Bodmeier, Oh, & Pramar, 1989). Thus, it was evident that none of the polymeric bead systems seems suitable as an oral controlled release system. Due to its ability to form hydrogel beads in presence of divalent cations, particularly Ca^{+2} ions, gellan gum has been investigated for the controlled release of various kinds of drugs. Gellan gum gels are stable in low pH solution but swell in weakly basic solutions and calcium gellan allowed releasing the drug rapidly in phosphate buffer (El Fattah, Grant, Gabr, & Meshali, 1998).

In a study by Reddy and Tammishetti (2002), the efficiency of divalent and trivalent metal ions to form durable carboxymethyl guar gum beads was compared. They reported that due to higher valency, the cross-linking rate for trivalent aluminum (Al^{+3}) ions with carboxymethyl guar gum was faster than divalent calcium (Ca^{+2}) ions. The optimum salt concentration that provided maximum bovine serum albumin retention in the beads was found to be much lower for Al^{+3} ions. Furthermore, the beads cross-linked with Al^{+3} ions released the protein over a longer duration in simulated intestinal fluid, than those cross-linked with Ca^{+2} ions. Thus, the faster cross-linking rates with Al^{+3} ions could be very useful to load higher percentage of drug into the beads; otherwise the loaded drug would escape into cross-linking medium with time. Considering relatively fast drug release rate of Ca^{+2}/gellan beads in phosphate buffer solution, a novel glipizide-loaded bead system was developed by Maiti et al. (2011) through ionotropic gelation of gellan with trivalent Al^{+3} ions A maximum of 97.67% drug entrapment efficiency was achieved. The beads released only 10% drug in acidic medium in 2h; however it was found 38-47% for Al^{+3}/gellan beads in weakly alkaline medium. Al^{+3}/gellan beads could be useful carriers for the controlled oral delivery of glipizide.

Gellan gum has the potential to form gels in presence of mono- or divalent cations. Because of the presence of free carboxylate groups in GG, it becomes anionic in nature and thus, would possess the characteristic property of undergoing ionic gelation in the presence of mono- and divalent cations. However, the affinity for divalent cations is much stronger than the monovalent cations (Sanderson & Clark, 1983b). The mechanism of gelation involves the formation of double helical junction zones followed by aggregation of double helical segments to form a three-dimensional network by complexation with cations and hydrogen bonding with water (Grasdalen & Smidsrød, 1987).

This property has enabled possible applications of GG in the field of drug delivery. GG alone or its modified form has been studied extensively as a vehicle for ophthalmic delivery of drugs (Sanzgiri et al., 1993; Rozier, Mazuel, Grove, & Plazonnet, 1997; Carlfors, Edsman, Peterson, & Jornving, 1998) and other sustained release formulations viz. tablet binder (Ike-Nor, Ofoefule, & Chukwu, 2006), disintegrants (Antony & Sanghavi, 1997; Shah, & Jani, 2010), implantable films (Li, Kamath, & Dwivedi, 2001), and especially oral hydrogel beads (Santucci et al., 1996; Kedzierewicz, Lombry, Rios, Hoffman, & Maincent, 1999; Singh & Kim, 2005; Agnihotri, Jawalkar, & Aminabhavi, 2006; Babu, Sathigari, Kumar, & Pandit, 2010).

In view of the characteristic property of cation-induced gelation, it has been widely used in the formulation of *in situ* gelling ophthalmic preparations (Sanzgiri et al., 1993; Rozier et al., 1997) as well as *in situ* gelling oral sustained release formulations (Kubo, Miyazaki, & Attwood, 2003; Miyazaki, Kawasaki, Kubo, Endo, & Attwood, 2001; Miyazaki, Aoyama, Kawasaki, Kubo, & Attwood, 1999). Quigley and Deasy (1992) developed the sustained release beads containing GG for controlled release of sulfamethizole prepared by the hot extrusion method into the chilled ethyl acetate. The GG beads containing salbutamol sulfate was also studied for sustained release applications (El Fattah et al., 1998). Recently,

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Kedzierewicz et al. (1999) have developed the GG beads for the controlled release of propranolol hydrochloride and found that the drug release was rapid. However, the ionotropic gelation with GG offers new opportunities in the field of bioencapsulation. Chan et al. (2002) recently reported that a combination of calcium and zinc ions could produce more sustained release of drugs from the alginate microspheres compared to calcium ions alone. Agnihotri et al. (2006) prepared and evaluated gellan gum beads. Gellan gum beads containing cephalexin were prepared by extruding the dispersion of cephalexin and gellan gum into a solution containing a mixture of calcium and zinc ions (counterions). Beads were prepared by changing experimental variables such as pH of the counterion solution and amount of cephalexin loading in order to optimize process variables on the final % drug entrapment efficiency, release rates, size, and morphology of the beads. Beads were spherical in shape, with the average bead size ranging from 925 to 1183 μm as measured by the laser light scattering technique. Cephalexin entrapment of up to 69.24% was achieved. *In vitro* release studies were performed in 0.1N HCl or pH7.4 phosphate buffer and the release of cephalexin was achieved up to 6h.

Alhaique et al. (1996) prepared gellan capsules by Ca^{+2} induced gelation of this polysaccharide around a core containing starch, calcium chloride and a model drug. Results obtained indicated that gellan is suitable for the formulation of sustained release capsules and that solvent uptake by the dried capsules is most likely the main factor capable of affecting the rate of delivery from the tested preparations.

Kedzierewicz et al. (1999) prepared the beads according to the technique of ionotropic gelation. Gellan gum beads of propranolol hydrochloride, a hydrophilic model drug, were prepared by solubilising the drug in a dispersion of gellan gum and then dropping the dispersion into calcium chloride solution. The droplets formed gelled beads instantaneously by ionotropic gelation. The drying of the gel beads was carried out by either freeze drying or oven-drying at 37°C for 24h. Very high entrapment efficiencies were obtained (92%) after modifying the pH of both the gellan gum dispersion and the calcium chloride solution. The drug release from gellan gum beads (2.09-3.35 mm) was studied. The beads could be stored for 3 weeks in a wet or dried state without modification of the drug release. Oven-dried beads released the drug somewhat more slowly than the wet or freeze-dried beads. The drug release from oven-dried beads was slightly affected by the pH of the dissolution medium. Gellan gum could be a useful carrier for the encapsulation of fragile drugs and provides new opportunities in the field of bioencapsulation.

In order to evaluate the influence of the dissolution medium on drug release, the results obtained in buffer at pH6.8 were compared with results from a medium at pH2.0. The results showed that the wet beads released the drug (maximum 80%) in 15 min in both dissolution media. In contrast, drug release from oven-dried beads was slightly affected by the pH. This small increase in the delivery rate observed after 7min in the acidic environment cannot be related to the different solubilities of the drug at pH 2.0 and 6.8, because the maximum amount of drug released from the wet beads was the same in the two dissolution media. It could be explained by modifications of the gel structure due to the competition between H^+ and Ca^{+2} ions which could affect the swelling rate of the beads and consequently the penetration of the solvent into the beads. Indeed, reduced ionization of carboxyl group results in decreased polymer extension in aqueous medium and a modification of gel structure, which affects the overall release mechanism, may occur (Deasy & Quigley, 1991). This hypothesis was supported by the non-swelling of the beads in medium at pH2.0. Although the drug was released more quickly in medium at pH2.0, the total amounts released were the same in the two media and never greater than either 50% for the beads prepared with the gum dispersion at normal pH or 80% when the gum dispersion was alkalinized to pH12.

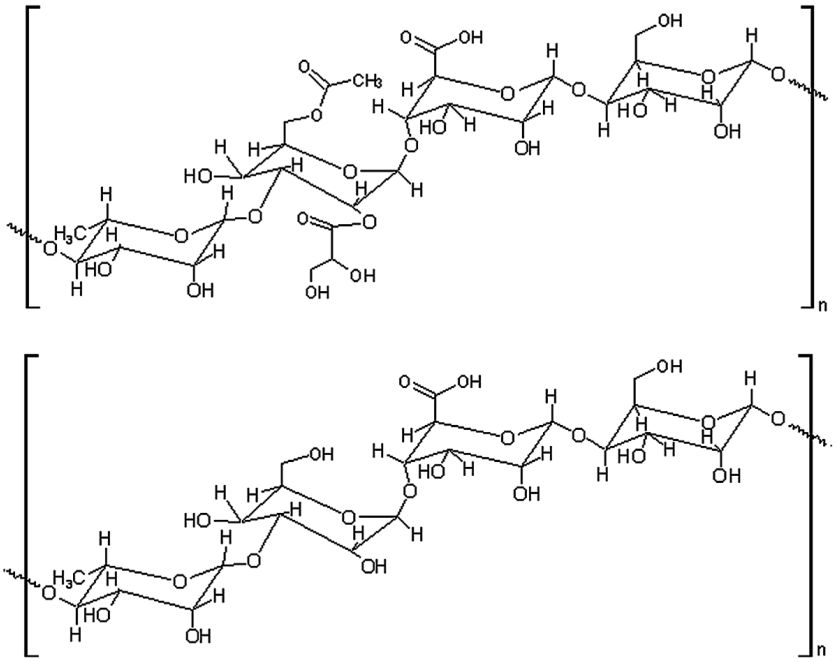
Low-acyl gellan is cross-linked more effectively with divalent cations than the monovalent cations (Morris, Gothard, Hember, Manning, & Robinson, 1996). Divalent metal ions bind to pair of carboxylic

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

group on nearby helices, whereas monovalent metal ions bind individual helices (Tang, Tung, & Zeng, 1996). The strongest gellan gels were obtained when the [cation]/[carboxylate] ratio corresponds to 0.5 for divalent and 10-30 for monovalent. At optimum concentration of respective cations, gellan form stronger gel with Ca^{+2} than Mg^{+2}. Low-acyl gellan forms gel at temperatures between 30 and 50°C. The high-acyl gellan has poor aggregation properties; it gels at around 70°C. Low-acyl gellan forms hard and brittle gel, whereas high-acyl gellan forms soft and elastic gel. Below pH3.6, gellan forms acid gel, which has lower modulus and hardness value.

The high-acyl gellan has poor cation-mediated aggregation. The acetyl groups present on the surface of the duplex block helix-helix aggregation, and the steric effect of bulky glyceryl group repels the carboxylic groups, making it incapable of accommodating site-bounded cations (Mortika, Fukuba, Kumeno, Nakahma, & Nishinari, 1991).

Patil et al. (2006) prepared gellan beads by ionotropic gelation method which involves very mild processing conditions and can be accomplished in an aqueous, organic solvent-free environment. The drug-loaded beads were spherical with size range of 0.85-1.8 mm. The drug entrapment efficiency of various batches was in the range of 72.52-92.74%. Calcium-gellan beads containing diclofenac sodium showed pH-dependent swelling and drug release properties. Swelling and drug release were significantly higher in pH7.4 phosphate buffer than 0.1N HCl. The swelling ratio for beads was up to 22 and 3 for phosphate buffer and 0.1N HCl, respectively. Cumulative diclofenac sodium release from calcium-gellan beads was 12-35% in 0.1N HCl within 2h, whereas complete drug release was observed within 3-4h in pH7.4 phosphate buffer. Studies indicated that, in addition to drug: polymer ratio, pH of cross-linking solution and speed of agitation also influence the formation and properties of calcium-gellan beads. The pH of manufacturing liquid is more important for drugs having pH-dependent solubility and gums having pH-dependent gelling. The effect of speed of agitation is more influential for the polysaccharides showing slow rigidization during cross-linking process. Release of diclofenac sodium from calcium-gellan beads in phosphate buffer was not only dependent on drug solubility but also governed by formation of drug precipitate, which occurred during processing.



The native form of gellan gum contains two acyl substituents, namely acetate and glycerate, both of which are located on the same glucose residue and, on average, there is one glycerate and a half acetate group per every tetrasaccharide repeating unit (Figure 1).

The varying substitutions lead to a difference in the gelling potential and, therefore, microencapsulation efficiency of its native and deacetylated forms (Chandrasekaran, Radha, & Thailambal, 1992). The gelling mechanism of gellan gum is inducible by cations as well as temperature dependent. In aqueous solution, the gelation of gellan gum is usually accompanied by a two-step process, which involves formation of double helices from random coil chains ('coil-to-helix transition') and an aggregation of pairs of double helices. Furthermore, the coil-helix transition is greatly affected by the electrostatic interaction with co-existing cations in the solution (Kanesaka, Watanabe, & Matsukawa, 2004), whereas the aggregation behaviour appears to be affected by the pH of solution (Horinaka, Kani, Hori, & Maeda, 2004). In the case of monovalent cations, the gelation is mainly contributed by the screening of the electrostatic repulsion between the ionized carboxylate groups (COO-) on the gellan chains (Nakajima, Ikehara, & Nishi, 1996).

On the other hand, in the case of divalent cations, the gelation and aggregation of gellan gum occurs via a chemical bonding between divalent cations and two COO- groups belonging to glucuronic acid molecules in the gellan chains, in addition to the screening effect. Although a great deal of effort has been made in understanding the gelation mechanism of gellan gum in the presence of various monovalent

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Chemical structure of native gellan gum (top) and deacetylated gellan gum (bottom) (O'Neill, Silvendran, & Morris, 1983)

and divalent cations; only a few studies have explored the microencapsulation efficiency of gellan gum in the presence of divalent cations other than Ca^{+2} (Tang, Tung, & Zeng, 1997).

Singh & Kim (2005) evaluated the effects of calcium (Atomic number=20), magnesium (12), copper (29), zinc (30) and barium (56) ions on the encapsulation efficiency of deacylated gellan gum using azathioprine as a model immunosuppressive drug. The information from this study is not only relevant from a microencapsulation perspective, but also from a therapeutic point of view, as both azathioprine and certain transition metals (e.g. copper) have been suggested to have anti-rheumatic properties (Fini, Feroci, & Fazio, 2001).

Spherical beads containing azathioprine were prepared from deacetylated gellan gum by ionotropic gelation method. One molar solution of various divalent chlorides ($MgCl_2$, $BaCl_2$, $CaCl_2$, $CuCl_2$ and $ZnCl_2$) and two additional concentrations of $CaCl_2$ (2.5M and 5.0M) were used as ionotropic media. Drug solubility was also determined in these ionotropic media. Solubility in various divalent chloride solutions (1.0M) suggests that azathioprine forms complex with Ca^{+2}, Zn^{+2}, and Cu^{+2}, while there might be a formation of poorly water-soluble chelates with Mg^{+2} and Ba^{+2} as solubility in these media were less than in deionized water. The encapsulation efficiency of gellan gum was much higher in the presence of transition elements (Cu^{+2} and Zn^{+2}) when compared to alkaline earth metal ions (Ca^{+2}, Mg^{+2} and Ba^{+2}). Higher concentrations of Ca^{+2} decreased the encapsulation efficiency of gellan gum in a nearly proportional manner. The correlation between encapsulation efficiency and pH of the ionotropic media was negative, although the solubility of azathioprine seems to be independent of the pH of the ionotropic medium. Overall, the results suggested that drug encapsulation efficiency of deacetylated gellan gum was largely affected by the concentration and nature of various divalent cations (e.g. atomic number, valency or electropositivity, co-ordination property, etc.) and pH of the ionotropic medium (Singh & Kim, 2005).

Gellan beads have the following advantages: i) nontoxic when taken orally ii) since the dried gellan beads have the property of reswelling, they can act as controlled release system iii) since their property of reswelling is susceptible to environmental pH, acid sensitive drugs incorporated into the beads would be protected from gastric juice (Coviello, Matricardi, Marianecci, & Alhaique, 2007).

However, porosity gives gellan beads not only fast release of incorporated drugs but also a very low efficiency of incorporation of low molecular weight drugs except for sparingly soluble drugs. Therefore, it appears that gellan beads can be used for a controlled release of sparingly water soluble drugs or macromolecular drugs. Multiparticulate delivery systems spread out more uniformly in the gastrointestinal tract and reduce the local irritation with respect to single unit dosage forms, such as tablets.

Babu et al. (2010) explored the possible applicability of gellan macro beads as an oral controlled release system of a sparingly soluble drug, amoxicillin. They investigated the effect of drug loading, stirring time, polymer concentration, electrolyte ($CaCl_2$) concentration, curing time etc. influencing the preparation of the gellan gum macro beads and the drug release from gellan gum beads. Optimal preparation conditions allowed 91% drug incorporation efficiency (gellan gum: 2%w/v; amoxicillin: 2%w/v; $CaCl_2$ concentration: 0.2M; and curing time: 5min). The gellan beads are stable in low acidic pH but swell and disintegrate in intestinal pH. The swelling and disintegration of calcium gellan beads are dependent on the pH of the dissolution medium and solubility of the drug entrapped in the gellan beads. The release rate of amoxicillin from gellan beads was in the following order: 0.1N HCl> phosphate buffer>distilled water. Amoxicillin was released from gellan beads similar to ibuprofen as in earlier studies although alginate beads are not swelled and disintegrated in gastric fluids (Lee & Min, 1996).

The percent of amoxicillin released in 0.1N HCl was higher due to higher solubility when compared to lower solubility in phosphate buffer. The shape of the gel beads did not change in appearance even on completion of drug release studies. This suggests that the gel structure was maintained throughout the release process. The rapid drug release from gellan matrices in acid medium can also be explained by a change in the matrix properties on contact with acid. The calcium ions in gellan beads were totally discharged in an acid environment and the carboxyl groups were shifted to an un-ionized form. This might alter the matrix properties, including the release characteristics of the incorporated drug. The swelling of gellan matrices in phosphate buffer (pH6.8) resulted from the exchange of hydrogen ions with sodium ions of the dissolution medium (Kim & Lee, 1992). The rapid swelling and aqueous solubility of gellan and amoxicillin, respectively, might be the cause of the increased drug release in phosphate buffer than in distilled water.

When gellan beads are placed in the dissolution media, three processes occur. First, the gellan beads imbibe water, rehydrate and perhaps swell. Second, as water penetrates the gel network, amoxicillin saturates the water in the gel. Third, amoxicillin diffuses through the water filled gelled network. On both a molecular and macroscopic scale the gellan beads are porous. The cross linked regions create a three-dimensional pore structure which will be filled with the medium. If calcium forms more extensive cross linking (at increasing calcium concentration), the molecular porosity may be reduced and both the extent of rehydration and the rate of drug release are reduced. During drug release, the gellan beads become macroscopically porous because the dissolved drug particles would leave water filled cavities in the gel. A significant number of the drug particles originally suspended in the gellan beads would be in physical contact with each other and the individual cavities left after dissolution would become continuous water filled tortuous channels. The formation of the channels depends on the extent of drug loading in the gellan beads. The percolation limit, the drug load above which the channels become continuous, has been estimated to be 30-40% (Fernandez-Hervas, Vela, Holgado, Cerro, & Rabasco, 1995).

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Release study of the gellan beads in all three media showed an initial burst concentration of amoxicillin. This may be due to crystals of the drug on the bead surface or may be due to an unequal distribution of drug within the gellan beads which results in slightly higher concentration of drug at the surface of the gellan beads. These may arise as follows. When gelation occurs, water is expelled from the gellan beads because the gel contracts during cross linking. Furthermore, as the gellan beads are dried, water migrates to the bead surface. These water fluxes may carry amoxicillin molecules and alter the drug distribution within the gellan bead, which will be reflected as an increased concentration of drug particles on or just beneath the surface of the dry gellan beads. Since water uptake by the gellan beads during release and dissolution of amoxicillin occurs radially inwards, the initial rate of release is high. The rate decreases with time because of the greater diffusional path length and possibly because of the lower concentration of amoxicillin towards the bead centre. The radial pattern of drug dissolution in the gellan is visible as a translucent gel layer at the edge surrounding a solid drug core.

Change in curing time did not significantly affect the release rate constant, but drug concentration, polymer concentration and electrolyte concentration significantly affected the release rate of amoxicillin from the beads. The gellan macro beads may be suitable for gastro retentive controlled delivery of amoxicillin. The encapsulation efficiency of amoxicillin beads increased as the polymer and drug concentration were increased. The entrapment efficiency was determined as a function of different initial amoxicillin (0.5 - 2.0 g) loading. Around 90% of amoxicillin was incorporated when the initial drug loading was at 2% (w/v); the entrapment efficiency increased with increasing drug concentration. Although the entrapment efficiency values seem low, it has to be kept in mind that the encapsulation process is carried out in an aqueous environment, where the drug is sparingly soluble. The entrapment efficiency of amoxicillin also increased as a function of the polymer concentration (1-3%, w/v). Approximately 84% of amoxicillin was incorporated at the polymer concentrations 3.0 percent (w/v). Since the amount of the drug extracted depends on the duration for which the beads remain in the cross linking solution, the duration of the cross linking process has to be strictly determined. To assure the reproducibility of drug loading, the curing time was maintained constant (5 min) in the preparation. When the percent of drug (0.5 to 2%) and polymer (1 to 3%) were increased the beads were still round but their diameter increased with the percent of drug and polymer. This effect can be explained by an increase in the viscosity of the gellan solution which therefore flowed more slowly out of the syringe. Consequently, the drops and then the beads had a larger diameter. The entrapment efficiency of amoxicillin into gellan beads was studied as a function of curing time. Excessively long curing time might result in low entrapment efficiency of soluble drugs in gellan beads. Due the overall aqueous environment, the curing time may be one parameter strongly influencing the entrapment efficiency. Therefore, in order to decrease the leakage of the incorporated amoxicillin in to the calcium chloride solution during bead preparation, the curing time was reduced from 15 min to 5 min. It was observed that curing for 5 min gave good entrapment efficiency (84.4%) and proper gelling of the polymer. Increasing the curing time from 5 to 15 min resulted in low entrapment efficiency and consequently decreased size of beads. The drug loading decreased as the concentration of cation was increased (0.1-0.4M). As gelation proceeds, water is expelled due to cross links formed by the cations. Therefore a more cross linked structure may show a larger water loss. Dissolved portion of amoxicillin in the beads could be lost from the gellan beads during curing by simple diffusion and the expulsion of water will cause convective loss of drug molecules (Ostberg, Lund, & Graffner, 1994). The mean diameter of gellan beads decreased with increased concentration of calcium, due to more extended gel bead shrinkage, caused by syneresis, during curing in a similar manner to calcium alginate (Oestberg & Graffner, 1992).

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Release of amoxicillin from gellan beads cured for 15 min was somewhat slower than that from beads that had been cured for 5 and 10 min. However, the pattern of release showed very little variation between gellan bead samples cured for longer than 5 min. Therefore, it appears that the optimum curing time of the gellan beads could be taken as 5 min, as there is no statistically significant difference in the release rates of bead with curing times between 5 and 15 min ($p > 0.05$). The release from gellan beads made at 0.4M calcium chloride solution was lower than gellan beads made at 0.2 and 0.1M calcium chloride solutions. The release rate of amoxicillin in phosphate buffer was increased with drug loading. The increase in drug release from beads containing high concentrations may be due to the decrease in the polymer/drug ratio. As polymer concentration increased, the release rate decreased due to hindrance of swelling and disintegration of gellan beads in intestinal fluids]. Increased gellan density per unit volume may also result in decrease in the mesh size within the gel, affecting amoxicillin release. This result is consistent with that of Kikuchi et al. (1997) for alginate beads.

The potential role of gellan in controlled drug release and adsorption in stomach has also been examined. Wataru et al. (2003) studied sustained delivery of paracetamol by gellan and sodium alginate formulations, and reported that the bioavailability of paracetamol from the gels formed *in situ* in the stomach of rabbits following oral administration of the liquid formulations prepared from gellan gum and sodium alginate was similar to that of a commercially available suspension containing an identical dose of paracetamol. Use of gellan gum for controlled bioavailability of ophthalmic formulations has also been proposed. Sanzgiri et al. (1993) have shown that gellan-based ophthalmic solutions have longer residence time in tear fluid than saline solution. Sidda et al. (2007) formulated *in situ* gellan gum-based gels with ciprofloxacin hydrochloride as a drug. The gel formulation containing both ciprofloxacin and gellan gum showed a prolonged drug release pattern. Gellan gum was evaluated as a binding agent in lactose-based tablets containing metronidazole or paracetamol. The binding properties of the gum were compared with acacia and gelatin. Granules were prepared by the conventional wet granulation method. The results indicated that though the hardness of tablets containing gellan gum was lower than that containing gelatin or acacia, gellan gum can be employed in the formulation of normal release of metronidazole and paracetamol with moderate hardness, low friability and good disintegration and dissolution properties (Ike-Nor et al., 2006).

Due to its characteristic property of temperature-dependent and cation-induced gelation, gellan has been used in the formulation of eye drops which gelify on interaction with the sodium ions naturally present in the eye fluids. Gelrite® solution, a novel ophthalmic vehicle, gels in the presence of mono or divalent cations. In the conjunctival sac 'ion-activation' of the sol/gel transition is accomplished by the lacrimal fluid. A 0.6% Gelrite® vehicle has been compared to an equiviscous solution of hydroxyethylcellulose (HEC) using timolol maleate as a drug probe. *In vitro* release rates of timolol from HEC and Gelrite® gel were similar. *In vivo*, the formation of the gel in the presence of tear fluid cations prolonged precorneal residence time and increased ocular bioavailability of timolol in the cornea, aqueous humor and iris and ciliary body of albino rabbits (Rozier, Mazuel, Grove, & Plazonnet, 1989).

A methylprednisolone (MP) ester of gellan (gellan-MP) was synthesized. Sustained release dosage forms evaluated were gellan-MP films, gellan films with physically incorporated MP and eye drops of MP suspended in a 0.6% w/w/ gellan dispersion in water. The control dosage form was a suspension of MP in normal saline. *In vitro* release of MP from the test dosage forms was determined in a pH 7.4 phosphate buffer at 32 °C using a rotating bottle apparatus. MP concentrations in the tear fluid of New Zealand white rabbits were measured after ocular application of the dosage forms. Compared with the MP suspension control, the gellan-MP films yielded an approximately 4-fold higher area under tear

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

fluid concentration vs time curve, AUC_{0-8h}, but exhibited a tendency to slip out of the eye due to a high degree of swelling. The *in vivo* release from films containing physically incorporated MP showed higher variability and provided mean AUC_{0-8h} values approximately equal to the control values. The gellan eye drops containing MP yielded 2.6-fold higher AUC_{0-8h} values than the control and also provided ease of administration. Gellan solutions might thus provide a versatile vehicle for ocular sustained release of drugs (Sanzgiri et al., 1993).

Recently, gellan based intra-gastric *in situ* gelling system for controlled delivery of amoxicillin has been reported (Rajinikanth, Balasubramaniam, & Mishra, 2007). The aim of this study was to develop a new intra-gastric floating *in situ* gelling system for controlled delivery of amoxicillin for the treatment of peptic ulcer disease caused by *Helicobacter pylori* (*H. pylori*). Gellan based amoxicillin floating *in situ* gelling systems (AFIG) were prepared by dissolving varying concentrations of gellan gum in deionized water containing sodium citrate, to which varying concentrations of drug and calcium carbonate, as gas-forming agent, was added and dissolved by stirring. The formulation variables like concentration of gellan gum and calcium carbonate significantly affected the *in vitro* drug release from the prepared AFIG. The *in vivo H. pylori* clearance efficacy of prepared AFIG in reference to amoxicillin suspension following repeated oral administration to *H. pylori* infected Mongolian gerbils was examined by polymerase chain reaction (PCR) technique and by a microbial culture method. AFIG showed a significant anti-*H. pylori* effect in the *in vivo* gerbil model. It was noted that the required amount of amoxicillin for eradication of *H. pylori* was 10 times less in AFIG than from the corresponding amoxicillin suspension. The results further substantiated that the prepared AFIG has feasibility of forming rigid gels in the gastric environment and eradicated *H. pylori* from the gastrointestinal tract more effectively than amoxicillin suspension because of the prolonged gastrointestinal residence time of the formulation.

Another latest report was associated with the use of a blend of two natural polymers for ionic crosslinking and obtaining hydrogel beads (Prezotti, Cury, & Evangelista, 2014). Gellan gum/pectin mucoadhesive beads containing ketoprofen were prepared by ionotropic gelation using Al^{+3} as crosslinker. Beads having diameter of 728-924μm exhibited a drug entrapment efficiency of 52.22–88.78%. The erosion of beads was greater in acid media while swelling was more pronounced in pH7.4. Drug release was dependent on pH and was 20-34% in pH1.2 acidic medium, while in pH7.4 buffer solution; the drug release was sustained up to 6h.

Thorough literature scrutiny suggested that deacylated gellan gum can be used for the design of sustained release ophthalmic preparation and oral hydrogel beads due to its Calcium ion induced gelling ability. However, the prior art suggested that calcium gellan beads alone could not control the drug release for a longer duration which is desirable from better therapeutic point of view. Some remedial actions were taken by some workers with the variation in type and concentration of gelling ions and other formulation/processing variable. However, these changes were still insufficient for gellan beads to be suitable for the controlled delivery of drugs. Lot of workers put their effort to make effective controlled drug delivery systems for a variety of drugs, each having their own advantages or disadvantages. Therefore, it would wise decision if some chemical modifications can be done on the native gellan gum and the drug delivery systems be designed.

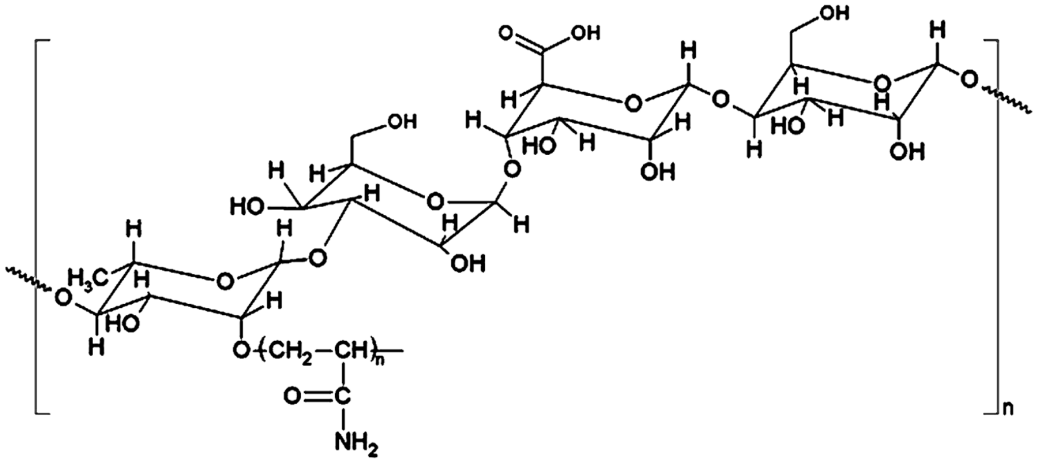
MODIFIED GELLAN POLYSACCHARIDE IN DRUG DELIVERY

Recalling the drawbacks of metal ion induced gelled beads in the inability to control drug release rate in simulated gastrointestinal fluids, this section has been devoted to highlight the recent advancements in the field of drug delivery using chemically modified gellan polymer. This section has been described under different subhead according to different type of chemical modifications that have been done to overcome accompanying problems of calcium gellan beads.

Grafted Gellan



Recently, the polyacrylamide-grafted copolymer of natural polysaccharides has entered the arena of prolonged drug delivery. Graft copolymer is described as a macromolecular chain, where the main polymer backbone has branches of another polymeric chain emanating from different points along its length (Zohuriaan-Mehr, 2005). It can easily be converted into its ionic form through hydrolysis of the side chain amide groups resulting in pH-sensitive or smart copolymer (Kaur & Chatterji, 1990; Qiu & Park, 2001). However, its degree of pH sensitivity depends on the number of ionisable functional groups (Soppimath & Aminabhavi, 2002). This fascinating technique may be considered as an approach to achieve novel polysaccharide-based materials with combined properties of natural and synthetic polymers. Furthermore, the evolution of ionotropic gelation technique has enabled their preparation in multi-particulate form in an aqueous, eco-friendly environment without the need for expensive, toxic organic solvents. As the pH of the GI tract varies from acidic (stomach) to weakly alkaline (intestine), the smart hydrogel particles can dictate swelling, and consequently release the drug from their network (Satish, Satish, & Shivakumar, 2006).

Maiti and his coworkers (2012) synthesized gellan gum (GG) graft copolymer and developed hydrogel beads for controlled delivery of salbutamol sulfate. Acrylamide was grafted onto GG polymer by free radical polymerization following the method reported earlier (Pourjavadi, Sadeghi, & Hosseinzadeh, 2004). Initially, 100 ml of 1% (w/v) GG solution was prepared in a 500-ml three-necked round bottom flask by flushing a slow stream of nitrogen gas and gently heating to 80°C for 4h. Then, 0.12 mol of acrylamide and 0.002 mol of ammonium peroxodisulphate were added to the reaction flask and nitrogen was purged for 1h to allow the grafting reaction. The resulting graft copolymer was then filtered, re-precipitated with methanol for removing the un-reacted monomers, and dried at 50°C. The copolymer was hydrolyzed in 0.9M NaOH solution at 75°C for 1h and purified in methanol. The hydrolyzed copolymer beads were prepared by ionotropic gelation with aluminium ions. The smart hydrogel reticulates (1.43-1.56 mm) seemed spherical and showed a maximum of 65% drug retention. The drug release rate was inversely proportional to $AlCl_3$ strength in simulated intestinal milieu (pH7.4), but approximated a proportional relationship with drug load. The hydrogel particles liberated only 10–17% content in simulated gastric milieu (pH1.2) in 2h. The release data correlated well with the pH-dependent swelling of hydrogel and indicated the anomalous drug diffusion mechanism. They concluded that smart hydrogel had the potential to prolong drug release mimicking the variable pH of the gastrointestinal tract.

The graft copolymer of acrylamide and gellan gum was prepared by microwave-assisted (at 480 W), free radical induced polymerization method by Vijan et al. (2012). The probable chemical structure was given in Figure 2. Tablets were prepared by wet granulation method and an anti-diabetic drug metformin hydrochloride was incorporated in grafted gum along with excipients (PVP-K 30). *In vitro* studies showed extended drug release up to 8h. They suggested that microwave assisted cerric (IV) induced

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Possible structure of poly (acrylamide) grafted gellan copolymer

graft co-polymerization is an easy, efficient, less time consuming and reproducible (due to the supply of fixed energy form microwave) method for the development of graft co-polymer which can be used as an rate controlling polymer for the development of sustained release dosage from.

Covalently Crosslinked Gellan

Chemical crosslinking of polysaccharide is highly versatile method with good mechanical stability. During crosslinking counterions diffused into the polymeric and crosslinking agent reacts with polysaccharides forming either intermolecular or intramolecular linkages. The gellan gum-based drug delivery devices were reported by Maiti et al. (2011).

Due to relatively faster drug release from Ca^{+2}/gellan beads in phosphate buffer solution, a combination of ionotropic gelation with trivalent Al^{+3} ions and covalent cross-linking with glutaraldehyde (GA) was adopted for designing a novel hydrogel bead system. Glipizide (30%, w/w) was dispersed uniformly into 1.25% (w/v) gellan gum aqueous solution and extruded dropwise into slightly agitated 5% (w/v) aluminum chloride ($AlCl_3$) solution containing 0.08% (w/v) Tween 80. Following an incubation period of 10 min, the beads were isolated and air-dried. The beads were then treated with glutaraldehyde (GA) solution (pH2.0) at 50°C for 2h. The cross-linked beads were removed and washed with distilled water repeatedly to remove non-reacted GA. A maximum of 97.67% drug entrapment efficiency was achieved; however GA-treatment reduced the same by 11.89%. All the beads released only 10% drug in acidic medium in 2h; however it was only 15% for GA-treated beads in weakly alkaline medium. The anomalous drug transport mechanism shifted to super case II transport for GA-treated beads, where the polymer relaxation phenomenon was dominant. They stated that GA-treated beads could be useful carriers for the controlled oral delivery of glipizide.

Later on, Kulkarni et al. (2013) developed simvastatin-loaded gellan gum-carrageenan composite polyspheres by ionotropic gelation/covalent crosslinking method. The polyspheres had rough and dense surface. The drug entrapment efficiency of the particles prepared by ionic crosslinking was higher than those prepared by dual crosslinking. The *in vitro* drug release study indicated that the ionically cross-

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

linked polyspheres discharged the drug quickly whereas, dual crosslinked polyspheres extended the drug release for longer period. The polyspheres effectively reduced the elevated total serum cholesterol and triglycerides in Wistar rats.

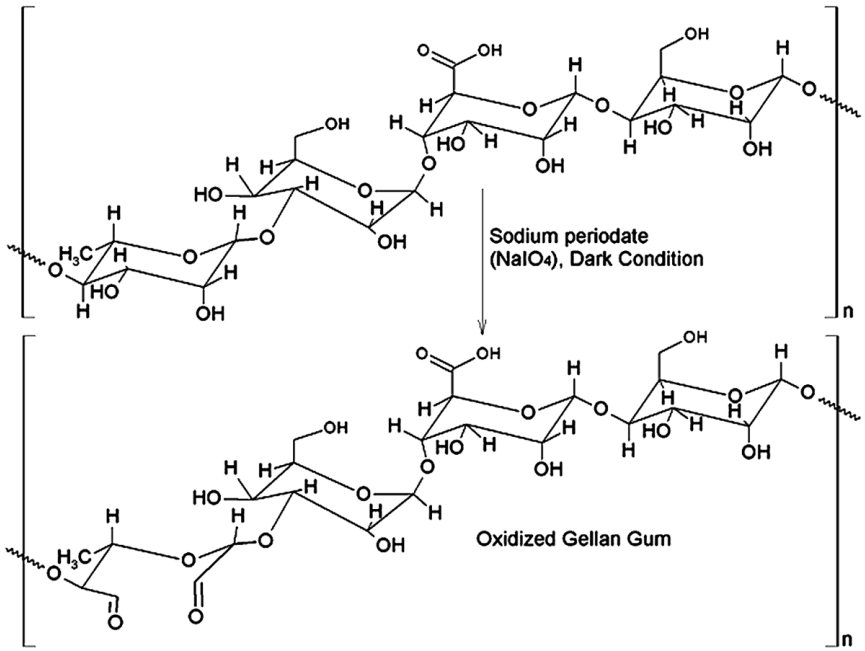
Complex Coacervation

During the last ten to twelve years the focus of a number of pharmaceutical scientists has been on the use of polyelectrolyte complex (without the need of toxic crosslinkers) for the sustained/modified delivery of drugs. Use of cationic chitosan in the formation of polyelectrolyte formation with anionic polymers is not new. Polyelectrolyte complexes of chitosan with pectin, xanthan, alginate, gelatin, hyaluronic acid etc have been extensively reported in the literature. However, very few articles have been found reporting the formation of gellan-chitosan polyelectrolyte complex (PEC). Dixit et al. (2011) explored their potential for oral sustained/controlled/ stomach specific delivery of water soluble and insoluble drugs. They prepared beads by extruding aqueous solution of gellan gum (with or without drugs) into chitosan solution (pH3.5). Prepared beads exhibited poor encapsulation and burst release for metronidazole, while very high encapsulation and extended release was observed for metronidazole benzoate in simulated gastric fluid (pH1.2). From metronidazole base containing formulations, almost all the drug was released within 2h. Overall, gellan-chitosan beads showed poor retardant capacity of drug release for metronidazole whereas good retardant capacity was observed for metronidazole benzoate.

Floating emulsion PEC beads (gellan gum-gelucires-chitosan) were prepared by combining the complex coacervation technique with emulsion gelation (Dixit, Verma, Mishra, Verma, & Pandit, 2012). Here, an emulsion of gellan with gelucire 39/01 and 50/13 containing $CaCO_3$ (with or without drug) was extruded dropwise into chitosan solution (0.6% w/v) and were isolated after 15min and then dried. Floating gellan-chitosan PEC beads were prepared in the similar manner but without gelucires. The beads showed excellent buoyancy along with significantly improved encapsulation efficiency (92.78%) and sustained release of metronidazole for 8h when compared to floating gellan-chitosan PEC beads prepared in the similar manner but without gelucires. Experimental data showed that floating emulsion PEC beads may form a potential stomach site specific drug delivery system for the delivery of highly water soluble drugs with an absorption window in the upper gastrointestinal tract.

Oxidized Gellan

Polysaccharide-based hydrogels have been proven promising in tissue engineering applications due to their good biocompatibility, controllable properties and abundance, and are therefore in great demand as therapeutic cell vehicles. For tissue engineering purposes, however, gellan-based hydrogels need to be modified in order to meet the requirement of encapsulating living cells while maintaining their injectability, because the gelling point of this temperature-dependent gel is too high (above 42°C). In the presence of cations (e.g., Na^+, K^+, and Ca^{+2}), aqueous solutions of gellan undergo thermo-reversible gelation when cooled to below $T_{gelation}$, forming a gel that is stable below $T_{melting}$. Therefore, the gellan solution is theoretically available to be injected into a defect site and form a gel *in situ* by cooling treatment. But in physiological cationic conditions, the $T_{gelation}$ of commercially available and unmodified gellan is too high (>42°C), and must be decreased to suspend the mammalian cells at physiological temperature (37.5°C) for injectable purposes. Gellan (Phytagel) was mixed with deionized water (5g gum powder in 500 ml) and heated to 70°C for 3–5h to obtain a homogeneous aqueous solution. After the gellan solution was



EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

cooled to 40°C, sodium periodate (0.25 M $NaIO_4$) was then added at different dosages (3-7.2ml) with gentle stirring and reacted for 1–120h to achieve various oxidization degrees. An equimolar ethylene glycol was added at predefined reaction time points to stop the oxidation reaction. The resulting solution was purified by Sephadex G25 SEC. Finally the product was lyophilized. The chemical structure of oxidized gellan gum was predicted in Figure 3. Chondrocytes were then seeded into the modified gellan gels. Their cytocompatibility and the capability to promote *in vitro* tissue regeneration were evaluated. Notably, chondrocytic constructs based on modified gellan gel were kinetically monitored for 150 days which showed superiority for long-term cartilaginous development in terms of many aspects such as cell proliferation and specific matrix formation. They showed that modified gellan was able to retain the chondrocytes viability, enhance the extracellular matrix (ECM) secretion and maintain normal phenotype. A novel injectable hydrogel was successfully developed basing on gellan gum, the molecular size of which had been chemically reduced and optimized to alter the working gelling point to the cell-favorable range and simultaneously maintain the injectable processability for transplantation. The chondrocytic cell-laden gellan gel was kinetically tested for nearly half a year. The results indicated that such modified gellan gels have superior performance in long-term culture *in vitro* in comparison with other popularly employed gels such as agarose. This new hydrogel-based scaffolding system was capable of providing a promising platform for cartilaginous regeneration (Gong et al., 2009).

Interpenetrating Polymer Network (IPN)

A considerable interest has been given to the development of IPN hydrogels for the controlled release of drugs. An IPN is a composite of two polymers, which is obtained when at least one polymer network is synthesized or cross-linked independently in the immediate presence of the other. Such systems are

Figure 3. Periodate oxidation to cleave the adjacent dihydroxyl groups in the gellan polysaccharide chain

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

known to increase the phase stability and, thus, enhance the mechanical properties of the final product. Agnihotri and Aminabhavi (2005) developed IPN of gellan gum for oral controlled drug delivery of carvedilol, an antihypertensive drug. Gellan gum and poly (vinyl alcohol) IPN microspheres containing carvedilol were prepared by the emulsion cross-linking method. In this method, poly (vinyl alcohol) was dissolved in hot water at 80°C, and after cooling, gellan gum was added (total polymer concentration was 4%, w/v). Carvedilol was dissolved in 2ml absolute alcohol and slowly added to the above polymer solution under stirring. This produced a fine precipitation of carvedilol, which was stirred further to get a uniform suspension. This solid-in-water suspension was emulsified into light liquid paraffin in the presence of 0.5% Span 80 at 300 rpm for 5 min. Then, glutaraldehyde (GA) and 1 ml of 5N HCl was added slowly, and the reaction was continued for 2h. Hardened microspheres were separated by filtration and washed with *n*-hexane followed by acetone. The microspheres were dried at 50°C for 24h. Carvedilol, Scanning electron microscopy confirmed the spherical nature and smooth surface morphology of the microspheres. Mean particle size of the microspheres ranged between 230 and 346 mm. Carvedilol was successfully encapsulated up to 87% in the polymeric matrices. The drug release continued up to 12h in simulated intestinal fluid. It was found that the drug release rate relied upon the amount of GA used for cross-linking, i.e., drug release was slower for those formulations in which a lower amount of GA was used compared to those in which a higher amount was used. This was due to higher cross-linking density of the matrix which hindered the easy transport of drug molecules through the matrix. It was seen that carvedilol release from the microspheres was faster in the case of simulated gastric fluid compared to simulated intestinal fluid. This was attributed to higher saturation solubility of carvedilol in gastric fluid compared to intestinal fluid.

Thermoresponsive gellan gum-poly(*N*-isopropylacrylamide) semi-interpenetrating polymer networks was prepared by Mundargi et al. (2010) and evaluated the controlled release property of atenolol, an antihypertensive drug from this network. Scanning electron microscopy indicated spherical nature and smooth surfaces of the microspheres with some debris attached on their surfaces. Mean particle size was between 34 and 76 μm. *In vitro* drug release performed at 25°C and 37°C indicated temperature-dependency of drug release, which was extended up to 12h. The reports on IPN systems were encouraging and thus, had a splendid outlook in the design of gellan-based controlled drug delivery devices.

Amphiphilic Copolymer

Like low molecular weight surfactant molecules, amphiphilic copolymer can also form micellar structures with higher physical stability and can also solubilize poorly soluble drugs in the micellar core and therefore can act as controlled drug delivery carriers. Maiti et al. (2014a) prepared gellan copolymer by conjugating hydrophobic cetyl group to the backbone of native gellan polymer. Native gellan polymer (3%, w/v) was dispersed in DMF and stirred for 1.5h. To this, sodium hydride (1.67%, w/v) was added at 10°C. After 20min, cetyl chloride dispersion in DMF (6.67%, w/v) was added to the resulting polysaccharide mixture and stirred continuously for additional half an hour. Then, the reaction product was transferred into 50ml of water and adjusted to pH7.0 with controlled addition of 0.01N glacial acetic acid. Cetyl gellan copolymer thus formed was separated by filtration, washed with ethanol for purification and oven-dried at 40°C. The reaction scheme can be briefly described as follows:

$$\text{Cetyl alcohol} + SOCl_2 = \text{Cetyl chloride} + SO_2 + HCl$$

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$\text{Polysaccharide} - OH + NaH = \text{Polysaccharide} - ONa + H_2$$

$$\text{Polysaccharide} - ONa + \text{Cetyl} - Cl = \text{Polysaccharide} - O - \text{Cetyl}(C_{16}) + NaCl$$

Gellan alkoxide was formed when gellan gum reacted with sodium hydride. In order to remove excess hydride, the final product was dispersed into water. In contact with water, NaH converted into sodium hydroxide (NaOH), and released traces of hydrogen gases. Finally, etherification reaction between gellan alkoxide and cetyl chloride yielded the desired amphiphilic copolymer. Considering stability aspects, the copolymer micelles seemed suitable for practical purposes due to its low CAC value (1.02mg/l). Higher CAC value was reported for dextran-*g*-poly (ethyleneglycol)-C_{16} polymer (6.5-12.5mg/l) (Francis, Cristea, Yang, & Winnik, 2005) and stearic acid-*g*-chitosan copolymer (8.5 mg/l) (Li et al., 2008).

The micelles were prepared by dispersing the amphiphilic copolymer in distilled water. The drug was loaded into micellar core by solvent evaporation method. Both drug-free and drug-loaded micelles looked spherical in water. It was argued that driving force behind self-association of amphiphilic molecules was related to reduction of free energy of the system upon removal of hydrophobic fragments from the aqueous surroundings and subsequent formation of micellar core. The z-average diameter of the drug-loaded micelles ranged between 1287nm and 1599nm. However, cyclosporine-loaded dextran-*g*-poly (ethylene glycol)-C_{16} copolymer micelles showed relatively smaller diameter (10-22nm) (Francis et al., 2005). The mean size of drug-loaded stearic acid-*g*-chitosan copolymer micelles was 173.7nm (Li et al., 2008). Self-assembled poly (ε-caprolactone)-*g*-dextran nanoparticles had an average diameter of 80-128nm (Bajgai, Aryal, Lee, Park, & Kim, 2008). Probably, gellan polysaccharide and cetyl chains induced larger steric hindrances over a larger volume for the polymer of higher molecular weight (Baldwin & Chien, 1988) and thus led to the formation of higher particle size. Hydrophobic simvastatin solubilized into core of the copolymer micelles to an extent greater than its intrinsic water solubility (2.54μg/ml). Increasing copolymer: drug weight ratio above 1:1 actually led to reduction of water solubility of the drug. The micellar solubility of drug was highest at the lowest copolymer: drug weight ratio (1:1). Compared to its inherent solubility, the micellar solubility was increased by ~355 fold. At the end of 8h, a maximum 60% drug was found to release in phosphate buffer solution. The micellar carriers could control hyperglycemia for a prolonged period.

Further, the work of Maiti et al. (2014b) demonstrated the drug solubilization power of a novel amphiphilic gellan co-polysaccharide. Anti-rhinitis micellar solution of budesonide was prepared. Herein, a long alkyl chain (C18) was successfully grafted onto gellan polysaccharide by etherification reaction. The dispersion of co-polysaccharide in water led to formation of spherical, nanomicellar structures. Depending upon the co-polysaccharide: drug weight ratio (1:1, 1:2 and 1:3), a maximum drug loading (>95%) was noted at the lowest level. The nanomicelles were in the range of 371–750 nm and showed negative zeta potential (48.3 to 67.2 mV) values indicating their stability in aqueous system. They exhibited a longer dissolution profile in simulated nasal fluid (pH 5.5). The co-polysaccharide micellar system showed potential in controlling intranasal delivery of budesonide for the symptomatic relief of anti-rhinitis (Maiti, Chakravorty, & Chowdhury, 2014).

FUTURE DIRECTIONS

The polysaccharide can be modified in different ways in order to get functional biomaterials for controlled drug delivery. The development of pure modified polymers, free of residual toxic chemicals used in the synthetic process is a challenge to the pharmaceutical scientist before designing novel drug delivery systems. The biopolymers resemble natural living tissue more than any other class of synthetic biomaterials due to their high water content; furthermore, the high water content of the materials contributes to their biocompatibility. In this regard, the gellan gum can be carefully modified as a suitable material for tissue engineering applications. Though natural polymers are biodegradable, their modified forms may not show biodegradability and biocompatibility. The tailored materials must be evaluated for these properties. Some polysaccharides may possess innate bioactivity and hence, its derivative should be evaluated for any possible bioactivity and toxicity profiles. The most exciting opportunities in polymer drug delivery lie in the arena of responsive delivery systems to deliver a drug precisely to a targeted site. The "intelligent" or "smart" polymers that respond to external stimuli may play important role in drug delivery since they may dictate not only where a drug is delivered, but also when and with which interval it is released thus, new synthetic methods have been used to prepare homo-and co-polymeric hydrogels for a wide range of drug, peptide, and protein delivery applications.

Novel graft, block and comb -like copolymers can be synthesized for several interesting applications of such systems in the treatment of diabetes, osteoporosis, cancer or thrombosis. Moreover, several types of linkages can be made depending on the desired speed of cross-linking and biodegradability of the resulting conjugates. New promising methods of delivery of chemotherapeutic agents using hydrogels can also be developed. Now, it is not hard to say that a new generation of drug delivery systems can be developed by scissoring the gellan gum structures. However, the modification techniques can also be applied to other polysaccharide also and we can get better material for drug delivery. Besides, the *in vivo* evaluation of modified material-based delivery systems will be one of the future directions, in order to fully understand their biological fate and *in vivo* drug delivery efficacy. Successful development of the novel formulations using modified polysaccharides will obviously require assimilation of a great deal of emerging information about the chemical nature and physical structure of these new materials and regulatory considerations. Depositing billions of drug molecules in the blood or gut and allowing the hapless molecules to locate their target, by uncontrolled diffusion, is surely a therapeutic strategy of yesterday and not of tomorrow. Guiding sufficient numbers of molecules in sufficient time directly to their targets is the future. Biopolymers may help this endeavor and will continue to enable this effort in the foreseeable future.

CONCLUSION

Natural polysaccharides have received increasing interest year after year due to their nontoxic and biodegradability. In this chapter, it was clearly seen that more and more new functional gellan gum materials have been synthesized in order to control the drug release in simulated biological fluids. Their highly porous structure can easily be tuned by controlling the cross-linking density in gel matrix and by synthesizing novel materials.

The selection of polymer plays an important role in drug manufacturing. But, while selecting polymers care has to be taken regarding its toxicity, drug compatibility and degradation pattern. Chemical

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

modification of polymers enables the development of new drug delivery systems which improves the therapy and treatment. The large variety of applications as well as the steadily increasing number of research workers engaged in studies of Gellan gum due to their unique properties, have made significant contributions to many types of formulations and suggest that the potential of Gellan gum as novel and versatile will be even more significant in future.

KEY TERMS AND DEFINITIONS

Amphiphilic: Chemical compound possessing both hydrophilic (water-loving) and lipophilic (fat-loving) properties.

Complex Coacervation: Refers to the formation of a dense macroion-rich phase when solutions of two oppositely charged polymers are mixed.

Controlled Release: Release of drugs in biological fluids in a predictable manner over an extended period.

Engineered Polymer: The materials obtained after scissoring the native polymer by chemical reaction.

Graft Copolymer: Macromolecular chain with one or more species of block connected to the main chain as side chain.

Hydrogels: Natural or synthetic polymer network that imbibes water and swell but do not dissolve in aqueous biological fluids.

Ionotropic Gelation: A process where polymeric chain is cross-linked with multivalent cations. These may include, calcium, zinc, iron and aluminium.

Natural Polymer: Refers to high molecular weight substances of natural origin (plant, algae, microbial, marine) whose structure is composed of multiple repeating units of sugar moieties.

Polysaccharide: Polymeric carbohydrate molecules composed of long chains of monosaccharide units bound together by glycosidic linkages.

Chapter 11
Improving Pharmaceutical Care through the Use of Intelligent Pharmacoinformatics

Tagelsir Mohamed Gasmelseid
International University of Africa, Sudan

ABSTRACT

The expansion of drug-related problems urged healthcare organizations to adopt Pharmacoinformatics to signal, analyze and report Adverse Drug Reactions (ADRs). Data for this study have been compiled from local and international sources such as WHO. The study resulted into the development of an intelligent multi-agent decision support system including a process model, a multi-agent architecture and an integrated data processing model with clear description of agent functionalities. The model reflects three main modules: a data capture and update module, diagnosis module and a pharmaceutical care and drug monitoring module. The study also reflected on the practical and managerial environment of the model and the basic considerations to be taken into account. The study also provided some important recommendations.

INTRODUCTION

The use of information systems for the improvement of healthcare is gaining paramount importance. They increase information accessibility to healthcare providers (Makus, 2001) and increased convenience for patients (Fitzgerald, Piris & Serrano, 2008; Glaser & Foley, 2008). Their deployment by pharmaceutical care assists in the assessment and management of therapeutic outcomes in patients as well as in detecting, signaling, evaluating, and solving potential and actual drug-related problems (including adverse drug events or drug interactions). Within the context of a wider hospital management system, the use of information systems to assist in pharmacy-related decision making is known as "pharmacoinformatics". In addition to databases, such systems make use of different technological settings (including informatics, the internet, and interactive technologies) to assist in improving pharmaceutical care, patient safety and enhancing hospital management processes. They aim at improving the capacity of clinical practitioners

to efficiently acquire and develop new treatment strategies. The use of such systems by practitioners tends to focus on three main areas: facilitating information exchange, detecting and managing adverse drug events and enabling the supply chain management process.

However, despite the potential outstanding benefits to be gained by hospitals as a result of the deployment of powerful pharmacoinformatics applications, the realization of such applications is still limited. Currently, pharmacoinformatics applications are used as sub-modules of the corporate information system. Their roles tend to be limited to stock control, monitoring drug availability and issuance at outpatient and ward pharmacies. Even for stock control, there seems to be no emphasis on the use of electronic ordering and procurement processes for which no standard operating procedures exist. The analysis of drug therapies and management of prescription inconsistencies are not supported by the current pharmacoinformatics applications in use. Moreover, there is a considerable lack of emphasis on developing and deploying information systems for signaling and detecting adverse drug events manifested in patients and recorded by healthcare professional. While the role of Pharmacovigilance centers in analyzing and managing adverse drug reactions is fundamental, there is a considerable lack in using information systems to establish relationships between such centers and hospitals through which adverse events can be reported and tracked. As a result, hospitals tend to miss the technical support provided by national Pharmacovigilance centers.

Therefore, the aim of this project is to develop a reference multi-agent pharmacoinformatics model to assist in detecting adverse drug events and drug interactions, as well as improving hospital management. The model will be based on the use of multi-agent technologies which has proven to be suitable for tackling large, real-world problems (Gasmelseid, 2006).

1. PROJECT'S OBJECTIVES

This project highlights the different Pharmacoinformatics channels that have been used (by both healthcare professionals and patients) in hospital management and the provision of pharmaceutical care which involves identifying, solving, and preventing potential or actual drug-related problems (DRPs) with regards to a patient's drug therapy.

Despite the fact that there are a number of different approaches to the development of Pharmacoinformatics applications used for decision support, there is a general agreement that decision support systems are developed most successfully by an interactive, prototyping approach. The suitability of this approach for this project stems from the fact that complete information requirements of stakeholders are difficult to identify in advance and may change significantly over time. To achieve the aims of this project emphasis will be made on:

1. The articulation of the issues which can potentially affect hospital management processes and the quality of pharmaceutical care in public hospitals in pursuit of providing insights into how Pharmacoinformatics can potentially affect the future of healthcare.
2. The development of a process mode (including all decision models and processing functions relevant to the organization as a base for the transformation of data into information) and
3. The development of a data processing model (establishing relationships between the system's structure and dynamics.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

2. PROJECT'S SIGNIFICANCE

The significance of the study originates from the following considerations:

1. This study deals with the context of healthcare with emphasis on the improvement of pharmaceutical care processes as basic elements in the delivery of improved healthcare services.
2. The growing importance of the deployment of advanced information systems in response to the fundamental changes exhibited in the healthcare system and its subsystems. The growing incidence of medical errors and adverse drug events, the complications of communications among medical professionals in many hospitals (mainly physicians and pharmacists), and the escalation of drug procurement costs, are signs that motivate the emphasis on pharmacoinformatics.
3. The emergence of new business models in response to technological advancements, increasing use of medical informatics and communication systems and technologies.

3. METHODOLOGY

The methodology for this study is generally a descriptive analytical survey with both inductive and deductive methods applied. Due to the nature of the study a number of other methods and empirically driven theories capable of dealing with the topic in question, both quantitatively and qualitatively, could also be used. The use of several methods and instruments of research is to allow some flexibility in order to capture the specific relations between the main variables and the factors affecting them. To account for the diversity of information across the different managerial landscapes and to ensure the validity of the instruments of research, Anthony's taxonomy of managerial levels is adopted. The project also made use of the concepts of "information modeling" and agent oriented software engineering methodologies and other "process-centered" and "resource-oriented" approaches for the articulation of variables and the development of the entire model and its corresponding modules.

The majority of the project's data is collected from electronic sources of many healthcare organizations and regulatory agencies such as the National Pharmacovigilance Center at the Food and Drugs Authority (FDA) at the Ministry of health. The study also used a variety of tools and methods of analysis of data provided by international organizations such as WHO. The tools include data matrix, tables, diagrams, models and output of computer programs. To achieve the aims and objectives of this study, data has been compiled from the use of questionnaires and interviews with key personnel in different healthcare organizations across the kingdom. In order to reduce the variance of estimators and gain sampling precision, the technique of optimum allocation has been used.Despite the fact that a wide number of approaches can be used for the development of agent-oriented information systems, the multi agent distributed reference framework proposed in this study follows TROPOS agent oriented software engineering methodology. To improve the face validity of the methods of research as well as the outcomes of the study, close consultation and review for the whole project is done by different experts in many international universities.

4. REPORT STRUCTURE

This report falls in nine main parts. Part one through part five provide a basic introduction about the main thread of the project and the context of problems to be investigated, project objectives, significance of the project, methodological framework and report structure. Part six is devoted for the development of a conceptual framework guided by a synthesis of related work. While part seven shows the description of the proposed pharmacoinformatics reference model, part eight and nine provide some discussion and recommendations.

5. SOFTWARE AGENTS

Software agents' technology is witnessing an increasing deployment in different sectors such as healthcare, e-business, environmental management, entertainment, telecommunications, e-banking and e-learning, among others. There is a general consensus that software agents interact autonomously and share resources to achieve objectives assigned to them by their users and/or other agents, they also operate individually to achieve personal objectives. Resource sharing and objective realization usually take place within the domain of a specific organizational structure. Because there is no agreement about what constitutes "agency", the conceptualization of agent-based applications and modeling tend to be done by focusing on the qualities possessed by software agents such as autonomy, learning, intelligence, proactivity, reactivity and social ability, among others. Moreover, such qualities-based characterization of agents has been used to develop a typology for agent types as mobile, interface, information, broker, recommendation agents, among others. Software agents' technology has been widely used to perform different tasks and automate different processes in e-commerce, environment, e-banking, airlines, communication and industry.

Software agents are software entities that perform some tasks on behalf of their users, other agents or programs with some degree of autonomy using the appropriate information and communication platforms. Their roles include task delegation, users training, event monitoring, information search, matchmaking and filtering (Gasmelseid, 2009a). They possess important properties such as autonomy, social ability, reactivity and pro-activeness, learning, mobility, benevolence, rationality, independence, cooperation, reasoning, intelligence and adaptivity (Lisa et al, 2001; Persson et al, 2001; Bonarini & Trianni, 2001; Hu & Weliman, 2001). According to Wooldridge and Jennings (1995), autonomy, which represents the main quality, reflects the capacity of agents *to* operate without the direct intervention of humans or others, and have some kind of control over their actions and internal state. Social ability denotes the need that agents should be able to interact with other agents (and possibly humans) via some kind of agent-communication language. Reactivity reflects the ability of agents to perceive their environment and respond in a timely fashion to changes that occur in it. This environment may be the physical world, a user via a graphical user interface, a collection of other agents, the Internet, or perhaps all of these combined. Pro-activeness denotes the ability of agents to act in response to their environment and exhibit goal-directed behaviour by taking the initiative.

Different ways have been used to classify software agents in accordance with their agency attributes and functions. According to Ponnurangam (2005), software agents can be broadly classified into two categories: user agents (direct task-oriented) and service agents (implicit task assistance). Alternatively, agents may be classified according to the tasks they perform, their control architecture, the range and

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

effectiveness of their actions, the degree of sophistication of their internal states, or the environment in which agents find themselves (Anumba & Newnham, 2000).

Especially for complex systems, software agents tend to be deployed in the form of a multi-agent organization in which multiple agents interact and exchange information in a decentralized and "social" manner to solve larger and complex problems. Applications such as electronic commerce, traffic control, health care provisioning, portfolio management and telecommunications, prove to be suitable for complex, distributed problems involving a multiplicity of interconnected processes whose solutions demand the allocation of fusion of information and expertise from demographically distributed sources (Sycara 1998). A multi-agent system can be defined as a collection of possibly heterogeneous, computational entities, having their own problem-solving capabilities, and which are able to interact in order to reach an overall goal (Oliveira, et al, 1999). According to Ferber (1999), a multi-agent system is composed of an environment (a space), a set of situated objects (agents) with the possibility of being associated with a position in the environment). It also includes an assembly of agents representing the active entities, an assembly of relations that link objects together. The assembly of operations it includes allows agents to perceive, produce, transform, and manipulate objects in the set of objects and operators with the task of representing the application of these operations and the reaction of the world.

According to Anumba et al (2003), there are several common ways of structuring the agent organizations:

1. **Organizational Structuring:** In which all agents share the same explicit end goal. Due to the fact that only one agent possess a global view of the full task, it is very difficult for peer agents with different goals to resolve their difficulties.
2. **Contracting:** Where a manager agent breaks the entire problem into component problems and then announces each task for contracting agents to make their bids. The manager then reviews the bids and awards the contract. Since contract nets are best used when the problem can be broken down via a well-defined hierarchical nature into a set of tasks, planning has to be done centrally.
3. **Multi-Agent Planning:** Which involves a central arbiter who reviews all potential plans of individual agents and resolve conflict when they exist.
4. **Peer-to-Peer Negotiation:** Where agents communicate directly with each other in the pursuit of achieving both individual and collective goals.

Multi-agent concepts incorporate technological, organizational and decision making issues that support the realization of the objectives of collaborative work in a wider socio-organizational context. In such a context, the objectives of the collaborating parties and their tasks are represented in terms of agents. Such representation goes hand-in-hand with the measures that govern the organizational structure, division of labor and hierarchy of responsibilities at different decision making and organizational levels. Therefore, the agent organization reflects the organization of task assignments together with their related hierarchy of command and goal congruence mechanisms. The diversity of organizational settings, therefore is reflected in the type and functionalities and privileges of the agents interacting within the entire multi-agent organization. The potential and applicability of multi-agent paradigm to support collaborative work is driven by the following considerations. Especially in complex situations, multi-agent configurations facilitate collaboration and manage tasks through the shift of some collaboration tasks to agents and allowing some space for wider interactions and the production of user-created content. Throughout the collaboration process, the collaborating parties can mainstream their tasks in a functional

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

way by using functional and task-oriented agents such as the information and interface agents without breaking organizational chains of command. They also contribute to the negotiation of tasks and the use of cooperative distributed applications.

Different software engineering methodologies have been used for the design and development of multi-agent systems such as Gaia, TROPOS, MESSAGE and Multi-agent Systems Engineering methodology (MaSE), among others (Gasmelseid, 2013). While some of the available AOSE methodologies represent an extension to and/or application of existing "conventional" software engineering methodologies (especially object oriented) to agent oriented applications, others have focused on defining a number of models that use the basic guidelines of agent theory as a guide for analyzing and designing agent oriented applications and systems (Iglesias et al, 1998; Wooldridge, et al, 2000; Odell et al, 2000; Kendall, 1999; Lind, 1999). Gaia methodology deals with both the societal (macro) and agent (micro) level aspects of information system design. The main concepts in Gaia are divided into two categories: "abstract" and "concrete". At the high level of conceptualization, "abstract" concepts involve the definition of roles including protocols, permissions, activities and responsibilities. On the other hand, "concrete" concepts put more emphasis on the articulation of agent types, services and acquaintances. The outcomes of the analysis phase are used as inputs for design phase which focuses on creating an agent-based model.

TROPOS methodology pays more attention to understanding the organizational context of the multi-agent information system by focusing on the very early phase of software development in which the system as well as it's context are studied as a larger social-technical system (Bresciani, et al, 2002*;* Perini, et al, 2001; Giunchiglia et al, 2001; Giunchiglia et al, 2002). It includes five phases of software development: early requirements analysis, late requirements analysis, architectural design, detailed design and implementation. Being an organizationally-oriented methodology, TROPOS tries to improve the ability of designers to justify the entire multi-agent system as well as its "traceability" dimensions by enabling artifacts produced during later phases to be clearly referred back to artifacts or requirements produced earlier. MESSAGE methodology is more oriented towards knowledge representation. Most of the knowledge level entity concepts of the MESSAGE methodology fall into three main categories: "Concrete-Entity", "Activity", and "Mental-State-Entity" (Caire, et al, 2001). The main types of Concrete-Entity are: agents, organizations, roles, and resources. The main types of Activity are: tasks, interaction and interaction protocols. The basic type of Mental-State-Entity is the goal. A goal (whether intrinsic or transient) associates an agent with a situation in terms of a rule-based utility function. An analysis model in MESSAGE is contingent upon a number of views describing organization, goal-task, agent-role, interaction, and domain. The Prometheus methodology consists of three phases: system specification, architectural design and detailed design (Padgham & Winiko, 2002a; 2002b). The system specification phase, involves two activities: determining the system's internal and external environment (in terms of percepts denoting incoming information from the environment and actions by which an agent affects its environment), and determining the goals and functionality of the system. The architectural design phase involves three activities: defining agent types, designing the overall system structure, and defining the interactions between agents. The internals of each agent and how it will accomplish its tasks within the overall system are addressed in the detailed design phase which focuses on defining capabilities, internal events, plans and detailed data structure for each agent type identified in the previous step. Multi-agent Systems Engineering methodology (MaSE) is similar to Gaia with respect to generality and the application domain supported, but in addition MaSE goes further to support for automatic code creation through the MaSE tool (DeLoach, 1999; Wood & DeLoach, 2000). It is divided into seven phases: goal

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

capture, application of use cases, goal refinement, agent classes' creation, conversations construction, agent class assembly and system design.

Some of these methodologies have been criticized for their limited deployment due to the lack of maturity and their failure to capture the autonomous and proactive behavior of agents, as well as the richness of the interactions (Zambonelli, 2001). Current agent-oriented methodologies focus mainly on multi-agent systems analysis and design, but without providing straightforward connections to the implementation of such systems (Wooldridge, et al 2000; DeLoach, et al 2001). Some of the existing software development techniques are characterized with a fundamental mismatch between the concepts used by object-oriented developers and the agent-oriented view (Wooldridge, 1997). In particular, extant approaches fail to adequately capture an agent's flexible, autonomous problem-solving behavior, the richness of an agent's interactions, and the complexity of an agent system's organizational structures. Most of these methods feature a technology-driven, model-oriented and sequential approach for the development of multi-agent applications that may not be always adequate for the development of agent-oriented systems. Most of them assume (in advance) the suitability of multi-agent technology for the entire problem domain. While the model orientations of methodologies are obvious, the process of model coupling and integration process does not explicitly reflect the links between models (Lind, 1999). Besides as the main issues to be addressed by agent oriented software engineering methodologies (such as autonomy, reactivity, proactive-ness and social ability), the concern for mobility have been growing over time (White, 1997). In spite of the growing diffusion of mobile agent technology, little research has been done to settle "design" directions to be followed in order to determine when mobile agents are convenient to be used or not. However, the current agent oriented software engineering methodologies used for developing multi agent systems do not provide methods to determine in which cases mobile agents should be used. Many of the existing methodologies intentionally do not support intelligent agents; rather, they aim for generality and treat agents as black boxes.

Except for the case of TROPOS and to some extent Gaia, AOSE methodologies tend to focus on system design (basically definition of agents, capabilities and communication) without providing a thorough understanding of the "actual problems" facing decision makers, the causes and consequences of these problems and whether the use of multi agent systems can contribute to the solution space envisioned. Because these methodology are characterized by the limited communication between the "decision maker" and the "designer" and the fact that agent technology has already been decided in advance to be the appropriate paradigm for solving problems, the chance of developing systems on the basis of "imagined" potentials of designers is highly probable.

The use of MESSAGE methodology results into a large amount of data and demands additional processing resources (time, cost and skills) in a way that complicates the process of system design because it is necessary to undertake resource-consuming investigations of the interactions among different "views" and associating them with corporate objectives. Such a consideration may result into complexities with regards to information update and system maintenance. Because of the complex view-coupling process any mistake that exists at later stages of the system development process demands intensive rework that delays design. Although the methodology does not provide in depth emphasis on "problem analysis" and the early phases of decision making, the process of coupling problem dynamics with agent capabilities will be cumbersome. While the process of system analysis and design require extensive user involvement to enrich and enable the articulation of system linkages and agent functionalities, they validity of such methodology will be seriously threatened if such involvement is not maintained appropriately.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Prometheus methodology does not provide emphasis on the early phases of decision making (decision intelligence and problem-objective orchestration) therefore, the resulting system specifications are not directly related to the basic "information requirements" of the users who "delegate" some of their authorities to "agents. As it is the same limitation in conventional system development and engineering methodologies, the entire system dynamic will be based on the designer's perception of "what will be his information requirements if he were the decision maker for whom the entire agent module or organization provides support" rendering the entire agent-oriented applications to be "operationally" out right failures although "technically sound" and reduce their applicability with regards to the provision of appropriate decision support. Although Prometheus is regarded as supporting the development of intelligent agents in accordance with goals, beliefs, plans, and events (Padgham & Winikoff, 2002), many other methodologies treat agents as "simple software processes that interact with each other to meet an overall system goal" (DeLoach, 2001). Like other methodologies, Prometheus is envisioning implementation through the emphasis on the "automation" of the stages of the methodology rather than the "implementation" of the target system.

Although Gaia is viewed as being neutral with respect to both the target domain and the agent architecture, it does not present a procedure to guide roles and protocols identification when building agent-based systems when it is regarded as an organizational design process. While the analysis models used in Gaia methodology are based on well-defined concepts, they only represent a subset of the concepts required for agent oriented analysis with the design models remain not clearly explained. Although it has been proven as a good approach for developing closed domain agent-systems, the above mentioned restrictions delimit its applicability to open and unpredictable domain of internet applications. The methodology has been extended by adding some organizational concepts such as organizational rules, structures and patterns (Zambonelli et al, 2001).

Because the MaSE methodology is similar to Gaia with respect to generality and application domains supported, it inherits the same limitations. The "process" of using the MaSE methodology tends to be oriented towards the "tool itself" by focusing on the use of diagrams rather than focusing on the orientation of the whole process directed towards the investigation and solution of decision-making problems. On the other hand, MaSE methodology has been characterized by a long system development process that complicates the process of integration in addition to the fact that it does not support the initial phases of decision making.

Multi-agent systems have been widely used in the healthcare sector because they possess a higher capacity to address complex and distributed problems involving a multiplicity of interconnected processes, users, information sources, and locations. The development of agent organizations in the healthcare sector tend to be structured in accordance to organizational structures characterized in functional terms in which superior agents are supported by subordinate ones (e.g., information, interface, task, etc). Superior agents have the capacity to act as "task mangers" to ensure the effectiveness of the entire agent organization in the achievement of corporate objectives based on the functionalities of their corresponding subordinate agents responsible for task performance. While in some cases pharmaceutical care applications are addressed within the context of a wider hospital information system (as a sub-module), there has been a tendency to address pharmacy-related issues in separate applications, such as the use of multi-agent systems for monitoring and reporting of adverse drug events, electronic prescriptions, managing drug therapies and mainstreaming pharmaceutical procurement activities, among others.

The use of software agents in healthcare has been widely cited in e-health, electronic medical records as well as functional applications supporting medical and paramedical business units (e.g., pediatrics,

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

internal medicine, geriatrics, pharmacy, nursing, intensive care and emergency, obstetrics, etc.) at the level of hospitals. The use of multi-agent systems in healthcare allows for the realistic modeling of complex, heterogeneous and distributed medical and healthcare systems and environments. They are used to improve the performance of a computerized system in terms of interoperability, scalability and configurability (David, David, & Antonio, 2010), information integration (Yifeng & Bhattacharyya, 2010; Kostkova, et al 2003; Bodenreider, 2004), task automation (such as scheduling of meetings, negotiation and learning (Bireshwar & Mishra, 2010; Hokyin, Minhong, & Huaiqing, 2011).

Godo et al (2003) used the multi-agent systems to monitor the prescription of restricted use antibiotics within the context of an electronic Institution (i.e., hospital) incorporating agents, roles, dialogic framework, scenes, and performative structure. The architecture included six types of (functional) agents: patient (a.k.a guardian angel), physician secretary, laboratory manger, pharmacy expert, and nurse agents. Different scenes were used to address communication among the agents such as: Patients Room, Physicians Room, Laboratory, Pharmacy, Dialog scene, Waiting Room and halls. Based on the patient information acquired from the electronic medical record, the entire agent structure focuses on three main functions: antibiogram authorization, antibiogram results and modification of the entire electronic medical record. However, despite its advantages, the architecture has a limited scope to provide comprehensive pharmacoinformatics assistance.

The use of multi-agent systems for the analysis and signaling of adverse drug events originates from the need for collaboration and exchange of complementary skills from different experts (e.g., epidemiologists, biostatisticians, pharmacists and physicians) for the analysis and interpretation of reports, collecting additional relevant information, and drawing reliable conclusions (Yanqing et al, 2005). Yanqing et al, (2007); (2010) used intelligent agents with a fuzzy recognition-primed decision model to develop a distributed adverse drug reaction detection system. They proposed a multi-agent framework for early detection of adverse drug reactions (ADRs) by utilizing electronic patient data distributed across many different sources and locations. In this framework, intelligent agents assist a team of experts based on a well-known human decision-making model called Recognition-Primed Decision (RPD). They generalized the RPD model to a fuzzy RPD model and utilize fuzzy logic technology to not only represent, interpret, and compute imprecise and subjective cues that were commonly encountered in ADRs but also to retrieve prior experiences reported by patients, physician and hospitals by evaluating the extent of matching between the current situation and a past experience.

Multi-agent systems have also been widely used for the management of supply chains using different technologies (Pathak et al. 2000; Fu & Piplani, 2000; Frey et al., 2003; Davidsson & Wernstedt, 2004; Walsh & Wellman, 2000; Lu & Wang 2008). Govindu and Chinnam (2007) proposed a generic process-cantered methodological multi-agent supply chain management framework to simplify multi-agent systems (MAS) development for supply chain applications. Shirazi and Soroor (2007) presented architecture for strategic information systems. Turcu et al. (2008) discussed the use of multi-agent systems and radio frequency identification (RFID) technologies in healthcare to track pharmaceuticals from the manufacturer, distributor, and pharmacy to the point of administering medications to the patient. Trappey et al. (2009) presented a multi-agents system collaborative production system to support the collaborative and autonomous mold manufacturing outsourcing processes. Seyed et al (2010) focused on merging remote sensing data and population surveys in large, empirical multi-agent models. Gottfried et al, (2011) combine a multi-agent framework with ontology-driven solutions to support and automate the procurement process. Gaurav Jetly et al (2009) developed a multi agent system to simulate the supply chain of the pharmaceutical industry.

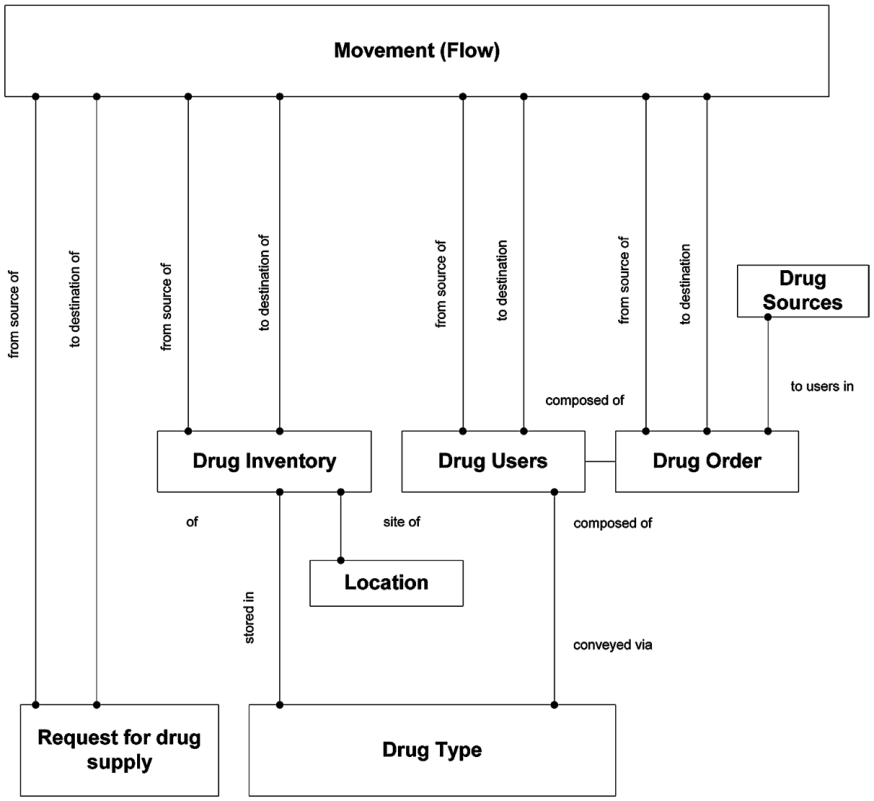
6. MODEL DESCRIPTION

Process Modeling

The use of multi-agent systems is guided by a wide range of agent oriented software engineering methodologies. Using TROPOS, Figure 1 shows the context of interaction among the stakeholders involved (directly or indirectly) in the process of pharmaceutical decision making. Patients, physicians, pharmacists and other supporting departments constitute the stakeholders whose interactions are reflected in the functionality of the multi-agent organization and its model.



Following a process-cantered approach, the flow of analysis depicted in Figure 2 reflects the set of flows that take place to facilitate communication between patients, physicians, pharmacists and other departments. The flow also depicts the movement of requests and orders in order to ensure drug availability for treatment. As shown in Figure 2, the central entity in the relational conceptualization is the drug order initiated and itemized by the physician (in the form of a prescription), hospital, outpatient or ward pharmacies. It represents an authorization to provide a specified type and quantity of a specified drug from a specific drug source to a specific user. Drug inventories exist at different locations such as hospital, outpatient and ward pharmacies and are capable of satisfying all drug orders using different drug types. The entity representing transactions that moves drugs in, out and through the entire pharmacy network is a movement or a flow. When drugs (flow) are provided against a drug order (prescription), a flow (movement) is recorded by the drug provider from a particular location (e.g., outpatient pharmacy). Should there be an excess flow (drugs) provided by mistake to a patient, it should be monitored and addressed by the "providing" location or other entities in the hospital during the medication course. This

Figure 1. Stakeholders representation and involvement

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Flow analysis in pharmaceutical care systems

may entail another kind of movement transaction to record it. When "stock control" is carried out (with adjustments increasing or reducing the stock balances at different hospitals), an increase can be recorded as a movement to the "inventory" with no "from source of" being indicated and a decrease recorded as a movement from the "inventory" with no "to destination of' being identified.

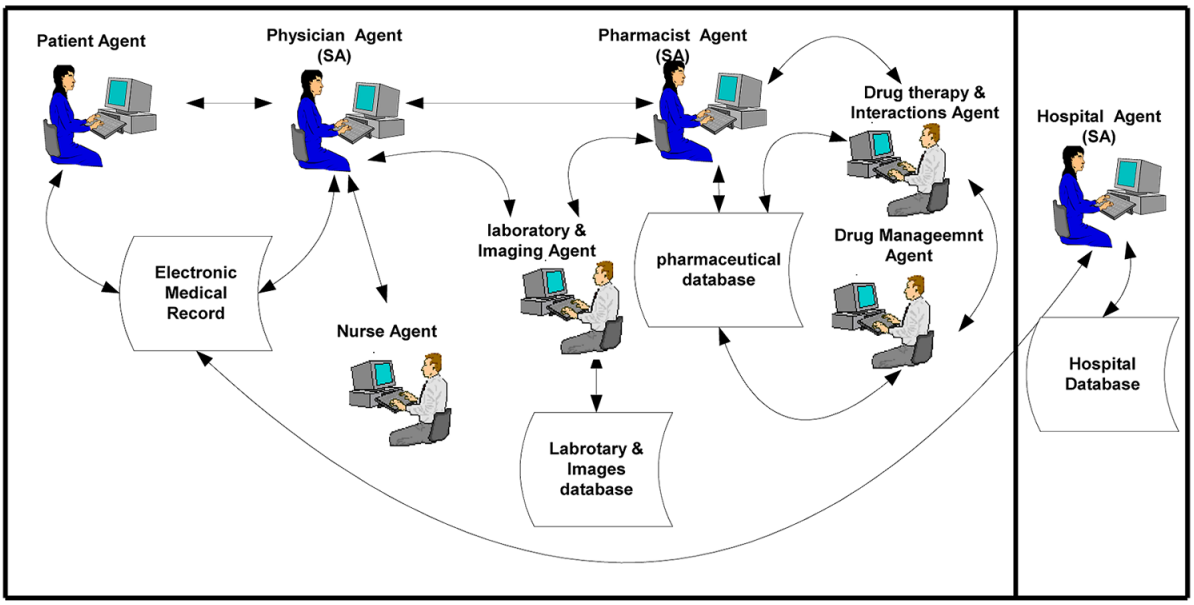
Multi Agent Architecture

The proposed multi-agent architecture follows the superior-subordinate structure that incorporates superior and subordinate functional agents. It includes interface agents (providing access to databases and knowledge-based systems), information agents (enabling communication and information exchange among health care practitioners), and functional agents (human agent assistants such as physician and pharmacist). In their functional capacity, software agents can assist in the procedure of revising a therapy (getting clinical information, deciding alternative therapies, etc.),

As shown in Figure 3, the proposed multi-agent reference pharmacoinformatics model includes two types of agents:

1. Superior agents representing health organizations (such as hospitals, Pharmacovigilance centres and Food and Drug Authorities (FDAs).. Such agents act on behalf of their organizations as well as their supporting subordinate agents assisting in the implementation of hospital-wide functions

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use



organized in business units such as surgery, paediatrics, etc. The communication process is essential for the assistance in the management of the entire health organization (such as a hospital) or coordination of health organization efforts such as Pharmacovigilance centres and FDAs. In addition to the facilitation and management of internal and external communication, superior agents are responsible for ensuring that organization-wide databases, such as electronic medical records (EMRs), are managed and appropriately accessed.

2. Subordinate agents providing support to their corresponding superior agents as "functional", "information" or "interface" agents. Agents that support departments, physicians, pharmacists and nurses, among others, are examples.

The functionality description of each agent is provided below.

1. **The Hospital Agent (HA):** This is the superior agent responsible for the corporate management of the entire hospital. It works with other supporting subordinate agents who act in the capacity of superior agents for their corresponding subordinate agents. In its capacity as a main superior agent, the hospital agent directs all other agents towards the realization of corporate objectives and represents a link between the agents interacting inside the hospital and other agents or entities in the external environment. To do so, it should be able to access all functional databases and investigate the role of agents and their operating procedures in facilitating joint functionality.
2. **The Patient's Agent (PA):** This is the patient's main agent responsible for exchanging information between the patient and other agents or personnel in the entire healthcare organization, including physicians, medical records, the pharmacy and laboratory. In addition, it allows an interface exchange between the patient, the pharmacist and the physician in case of problems with regards to drug management, after-discharge complexities, and reactions and alerts in relation to appointments, drug usages and confirmations. It also helps in reporting and signaling adverse drug reactions.

Figure 3. Multi-agent architecture

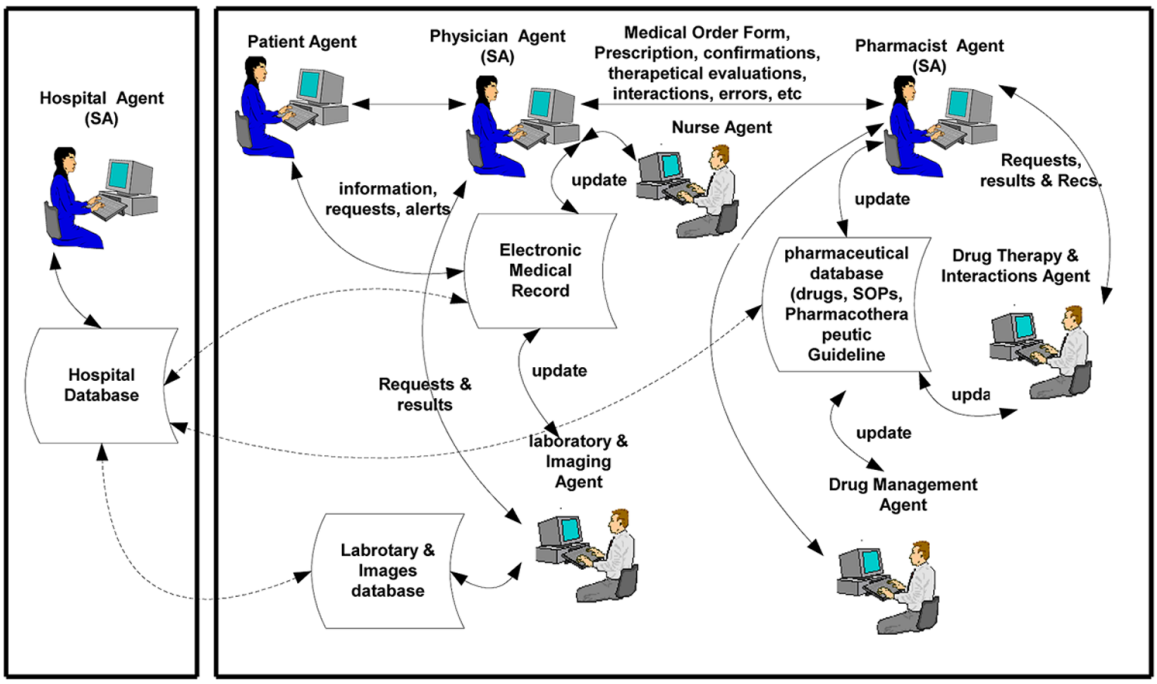
EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

3. **The Physician Agent (PhA):** This is the agent that supports physicians with regards to their processes, functions, schedules and communication. It allows an interface between the physician, patients, pharmacists, nurses and other laboratory experts dealing with microbiological analyses, pharmaceutical screening and drugs ordering, modification and administration. Exchanging alerts among physicians and other experts, such as pharmacists and patients, are also addressed. The agent also interacts with the patient's agent with regards to appointments, diagnosis, reporting of adverse drug reactions (especially post-discharge) and the confirmation and modification of drugs.
4. **The Laboratory and Images Agent (L&IA):** This is the agent that supports data acquisition, processing and communication to support laboratory and imaging professionals in the hospital. It takes care of the laboratory data (laboratory test requests and results), as well as imaging requests and results. The L&IA updates of the entire laboratory and imaging database and improves the availability and accessibility of information in a comprehensive hospital information system. It interacts with other agents such as the PA, PhA and PrA with regards to the requests and results of laboratory test requests.
5. **The Pharmacy Agent (PrA):** This is the main agent in the pharmaceutical setting because of its functional expertise. In addition to its role in enabling the implementation of pharmaceutical functions, it plays a significant role in facilitating information acquisition and communication, analysis, reporting and recommendation of different alternative medication scenarios using technical expertise and patient's data. It liaises between the hospital agent and its subordinate agents with regards to drug therapies, pharmaceutical and medical analyses, as well as signaling, analyzing and reporting of adverse drug reactions. Since it is responsible for the management of pharmaceutical care at the level of the entire health organization, the pharmacy agent gets support from the following subordinate task agents:
    a. **Drug Therapy and Interactions Agent (DT&I):** The drug therapy and interactions agent works as a subordinate agent for the pharmacy agent. It uses information from the patient's EMR, medical and laboratory test results, and prescription records to assist in managing drug therapies. In addition to reporting drug therapies and confirming them, this agent has the responsibility to recommend changes in medications and drugs based on a data-mining algorithm. It is responsible for screening drug therapies and signalling adverse drug reactions occurring for hospitalized and discharged patients throughout the medication process, in collaboration with the PA and PhA. Upon verification, this agent informs the pharmacy agent to take necessary actions.
    b. **Drug Management Agent (DMA):** The drug management agent acts as a subordinate agent for the pharmacy agent and is responsible for drug management at the level of the hospital, outpatient and ward pharmacies, where it manages drug availability, procurement, ordering and removal of near-expiry drugs. Pharmacy data recorded by the DMA at the level of the hospital pharmacy include name of drug, drug's serial number, drug code, drug components, drug close substitute, dose, quantity available in pharmacy, producing company (with updateable contact address), drug importing company (with updateable contact address), drug's date of production, expiry date, drug food interactions, drug-drug interactions, pharmacist on duty, etc.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

6. **The Nurse Agent:** This is the subordinate agent responsible for collecting medication instructions from the physician agent and managing drugs by monitoring drug availability in wards in accordance with the medical order forms forwarded to it. This agent uses a standard operating procedure to monitor and request routine drugs and ad-hoc requests in collaboration with the DMA.

Multi-Agent Pharmacoinformatics Data Processing Model



The reference model is implemented through three main modules:

1. Data capture and update (implemented through the functionalities of the agents representing the patient, physician, laboratory and images, and nurses),
2. Diagnosis (implemented through the agents representing physicians and pharmacists), and
3. Drug monitoring (therapies, interactions analyses and requests for supply implemented through the agents representing physicians and pharmacists). The interactions shaping the functionality of these modules are shown in Figure 4. In addition to using different colors to differentiate among superior and subordinate agents, superior agents are labeled with (SA).

Data Capture and Update Module

The process starts with the use of the patient agent to make appointments at the hospital and provide basic information to establish the electronic medical record, which consists of standard set of data about the patients, their diseases and diagnoses, and therapies. For purposes of patient identification, this module

Figure 4. Data processing model

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

captures the name, age, addresses of the patient and his/her closest relative(s), the department, room number, room phone, equipments used for the patient in the room (if any), medical records and reports, medical images and the treating physician. Diagnosis data include the patient's medical history, current disease diagnosis and its causes. Current and previous therapies include the current drug(s) used by the patient, dosages, frequencies, types of administration, and start and dates of treatment. Some of these data elements are generated after the consultation by the physician agent as a part of EMR updates. Any change on the patient's electronic medical record done by other staff (such as nurses and image specialists) and their corresponding agents takes the form of data input (e.g. imaging requests or medication instructions) in response to requests made by the physician agent. Updates originating from the pharmacist and his/her corresponding agents concerning any comments about drugs and drug therapies that delay its issuance are a result of the physician agent's approval and authorization. The delay in drug issuance then leads to an automatic update of the electronic medical record that will not require the approval of the physician anymore.

Diagnosis Module

Upon the completion of diagnosis, a prescription is made by the physician and communicated to the patient with a copy to the pharmacy. The issuance of the prescription automatically updates the electronic medical record and informs both the patient agent and the pharmacy agent.

Pharmaceutical Care Analysis and Drug Monitoring Module

This is the module managed through the pharmacy agent and its subordinate agents. It is the core module of the entire multi-agent pharmacoinformatics module as it includes the analysis of drug therapies, detection and signaling of drug interactions and adverse drug reactions, and maintaining drug availability at the different levels of the pharmacy (hospital, outpatient and ward). Upon the receipt of a copy of the prescription by the pharmacy agent, the following supporting agents are activated: the drug allergy and interactions agent (to examine drug therapies) and the drug management agent (to examine drug availability). This process is complex and requires the integration between the pharmaceutical database, electronic medical record and other agents such as the physician agent and the laboratory and images agent for further examination and confirmation.

The pharmaceutical database constitutes information about the:

1. Standard operating procedures that govern the examination of medical documents and requests coming to the pharmacy department, such as medical order forms and requests for drug supplies placed by different units in the hospital. These procedures also govern the interaction between the pharmacy department and other units in the form of document exchanges and requests placed to other internal units (e.g. laboratory) and external organizations (e.g. suppliers, ministry of health and Food and Drug Authority (FDA)). While such procedures are generally related to the functionality of the pharmacy department, they remain an essential part of the hospital standard operating procedures.
2. Hospital Therapeutic Guide, which includes information about all routine drugs and medicines used in the hospital, as well as guidelines for acquiring and managing ad-hoc drugs. It also includes

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

detailed recording of drug attributes such as correctness of drug types, dosage, route of administration, frequency, length of use etc.

3. Allergy and microbiological information necessary for making associations between prescribed drugs and diseases, for example, isolated pathogen micro-organisms, and their corresponding sensitivities.
4. Drug groupings created in accordance with diseases and the data individual patients. Each group includes all drugs related to a particular disease (in accordance to drug pharmaceutical attributes and laboratory analyses) for patients with certain allergies and symptoms.

Upon the receipt of the order by the PrA, it examines its "procedural context" and its compliance with the standard operating procedures. Orders in compliance with such procedures are communicated for the corresponding subordinate agents. Non-complying prescriptions are returned by the PhA for further analysis. The DTIA access all prescriptions approved by the PrA. It consults the pharmacy database, HTG, and the patient's electronic medical record to screen order attributes such as appropriateness of drug types, dosages, routes of administration, frequencies and lengths of use; and reports any inconsistencies to the pharmacy agent. These inconsistencies are then communicated to the PhA for further examination. Once the drugs are considered suitable, the DTIA recommends the issuance of these drugs. The DMA examines the availability of drugs by screening and updating the HTG, and drug inventory of routine and ad-hoc drugs. Based on the laboratory and/or diagnostic analysis results posted in the electronic medical record, the PrA can now provide some recommendations to the PhA, such as dosage adjustments, changes in prescribed drugs, and use of medicines. Upon the confirmation of the PhA, the PrA approves the order and interacts with the PhA to update the electronic medical record and the PA for drug administration.

In case of suspected adverse dug events, the DTIA examines the results of general lab analysis of the patient by accessing his/her electronic medical record and informs the PrA to warn the PhA in case of orders prescribed without general lab analysis. The process is also applicable for the detection and signaling of adverse drug reactions reported to the PrA through the PhA in accordance with a signal originating from either the PA or other medical staff involved in medical activities in wards. The (DAIA) examines the event and gives an initial assessment whether it is Type (A) or (B) or (C). In case of type (A), the recommendation posted to the PrA focuses on improving dosage characteristics, since a large proportion of adverse drug reactions are dosage-based and related to the pharmacokinetic properties of drugs. In case of Type (B) detected adverse drug reactions, the DAIA recommends the PrA to consult with both the PhA, and L&IA for further shared discussions because Type (B) events are generally related to the patient's reactions and tend to be allergic, idiosyncratic, immunological, or non-immunological (Meyboom et al, 2000). The same consultation process is required to address Type (C) events since they tend to be serious and may result in significant implications on public health. They originate from the impacts of drugs used for improving the quality of life of patients with serious chronic diseases. The PrA also informs the HA about all reported adverse drug reactions and interactions so as to communicate them to the National Pharmacovigilance Centre.

Drug Management Module

This is the module managed by the Drug Management Agent (DMA) in collaboration with the Nurse Agent (NA), which gets information from the physician agent. The basic aim of this module is to ensure

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

the availability of suitable drugs included in the HTG. The nurse agent is concerned with monitoring drugs for patients in wards and ordering them on regular and ad-hoc bases. In the case of regular drugs (i.e. drugs included in the hospital's drug list and HTG, the nurse agent (NA) examines the ward repository for the drugs included in the prescription made by the physician and prepares it for the patient's treatment (if available in stock). If not, it posts a request to the Drug Management Agent (DMA) through the pharmacy agent to screen for drug availability and prepare the medicine for delivery to the requesting ward or post a request (through the hospital agent) for the FDA (in case of public hospitals) or suppliers (in case of private ones) and deliver it to the ward upon arrival. In case of ad-hoc requests, the NA (in consultation with the physician agent) sends the prescription to the pharmacy agent for examination and ordering. In case of detected inconsistencies, if any, the physician agent is informed with recommendations. Upon the receipt of confirmation from the physician agent, the pharmacy agent follows the standard operating procedures to acquire the drug and deliver it to the requesting wards. The DMA monitors drug availability and controls stock at the level of ward repositories and outpatient pharmacies. Such systems provide information about drug orders for in-patients, availability statuses of the drugs through alerts such as 'No quantity', 'Near expiry', 'Re-order', 'restrictions' and requests for authorization and Verification.

7. DISCUSSION

The area of focus of the project is a new research domain where over years, the question of pharmacoinformatics is being misinterpreted and misunderstood by dealing at the process of pharmaceutical care as a function in the entire hospital management process. The study has cleared some of the methodological doubts and gaps with regards to the crystallization and conceptualization of the term by relating it to process of decision making rather than the use of computers in drug production.

The study focused on the development of a multi agent reference pharmacoinformatics model in pursuit of improving hospital management through improved The use of intelligent agents for the improvement of pharmaceutical care processes at the hospital level is gaining importance due to several reasons. The outstanding capabilities shown by intelligent agents in addressing complex problems provide significant assistance to the healthcare in general and pharmacy information systems in particular. Being used as stand-alone applications or within the context of a wider hospital information systems, the use of multi agent pharmacy-related information systems are gaining paramount importance due to their growing roles in improving the acquisition and exchange of drug-related information, examining drug therapies and interactions and integrating information.

The practical managerial context of the model is shown in its potential benefits in improving communication between physicians and other professionals (such as nurses and laboratory) on the one hand and between the physician and the pharmacist, a relation that tend to be complicated in real life. The outcome of such improved communication should be reflected in the quality of medical services and pharmaceutical care as it creates a conducive environment for negotiation, accountability and coordination. The prescription of (suitable) drugs will guided by a pharmaceutical cross check that investigates and alters the compliance with procedures (standard operating procedures) and requirements (such as microbiological analysis) in a way that minimizes medical errors and the occurrence of adverse drug reactions. This will eventually improves signaling and analyzing adverse drug and exchanging information with national Pharmacovigilance centers and attracting technical support.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

However, many issues need to be addressed. The process of agent interactions, consultation and information exchange calls for a clear role description especially for agent-assigned tasks and user-based intervention in accordance with the degree of autonomy allowed for the entire software agent. Semantics, ontologies and knowledge representation are also important considerations that need to be addresses in the light of the problem domain and solution spaces envisioned. Moreover, the preparedness of the medical staff to use intelligent tools and interact in an agent-based organization, willingness to provide inputs and comply with continuous improvement and security requirements are also important issues.

8. RECOMMENDATIONS

In the light of the work done and its outcomes, the following recommendations can be made to help healthcare organizations (hospitals, FDAs, Pharmacovigilance Centres and ministry of health) improve their efficiency in providing high quality pharmaceutical care services:

1. Restructuring hospital-wide processes to reflect the central role of pharmaceutical functions and incorporating clear standard operating procedures to ensure the incorporation of suitable tasks and activities.
2. Adopting an integrated approach for the crystallization of pharmacoinformatics very early in the medication process to ensure its involvement in the analysis of drug therapies, cross-checking prescriptions, alerting physicians and other medical professionals about the non-existence of drug prescription pre-requisites such as general lab analysis and recommending change of drug regimens and the use of free-use drugs wherever applies.
3. Making pharmaceutical care processes more patient oriented to optimize the utility matrix of the stakeholders in the entire healthcare system. As a result, the pharmacoinformatics can be of high importance in improving the knowledge of patients about drugs, the dysfunctional consequences of adverse drug events and their capacity and willingness to report such events.
4. Developing clear hospital-wide information system strategies and information security policies to facilitate effective communication among medical professionals, interactions with patients and, most importantly, interactions with the National Pharmacovigilance Centre of the Federal Food and Drug Authority at the Ministry of Health.

KEY TERMS AND DEFINITIONS

Adverse Drug Reactions: Complications that occur as a result of drug-related or patient-related factors.

Autonomy: The capacity of agents *to* operate without the direct intervention of humans or others, and have some kind of control over their actions and internal state.

Electronic Medical Record (EMR): The record created by healthcare providers to include all patient-related and medication-specific information that can be used for medical examination, prescription and investigation. Usually it is referenced using the patient's name or number as a key filed.

Healthcare Business Units: All departments and sections that are specialized in the provision of healthcare service at the level of service provision such as specialized departments in hospitals. They constitute the base of the management of pharmaceutical services and the identification of agent-based functionalities.

Information Systems: The collection of physical resources (hardware, software, telecommunication and database) and personnel (such as analysts, designers, developers and programmers) involved in the acquisition, storage, processing, dissemination and provision of information to enable decision makers achieve organizational objectives effectively and efficiently.

Multi-Agent System: A collection of, possibly heterogeneous, computational entities, having their own problem-solving capabilities and which are able to interact in order to reach an overall goal.

Pharmaceutical Care: The set of activities, processes and procedures carried out at different levels of the health care chain in pursuit of improving the quality of pharmaceutical interventions and decisions made.

Pharmacoinformatics: The use of computer based applications for the provision of information and implementation of tasks to assist medical policy makers and professionals in healthcare organizations to control and monitor drug therapies, prescription, use, signaling and analyzing of adverse drug events and stock control.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Reactivity: The ability of agents to perceive their environment and respond in a timely fashion to changes that occur in it.

Software Agents: Computational entities that interact and cooperate together and use resources collectively in order to achieve their own objectives or the objectives of their owners or other agents.

Superior Agents: High rank software agents operating within the context of the entire software organization. Their basic aim is to ensure that all subordinate agents contribute to the realization of the corporate objective to be met by the multi-agent organization. They exercise control and direction upon their subordinate agents and communicate on behalf of them.

Chapter 12
Personalized Medicine in the Era of Genomics

Navneet Kaur Soni

Nitin Thukral
Delhi Technological University, India

Yasha Hasija
Delhi Technological University, India

ABSTRACT

Personalized medicine is a model that aims at customizing healthcare and tailoring medicine according to an individual`s genetic makeup. It classifies individuals that differ in their susceptibility to a particular disease or response to a particular treatment into subpopulations based on individual's unique genetic and clinical information along with environmental factors. The completion of Human Genome Project and the advent of high-throughput genome analysis tools has helped in building and strengthening this model. There lies a huge potential in the implementation of personalized medicine to significantly improve the clinical outcomes; however, its implementation into clinical practice remains slow and is a matter of concern. This chapter aims at acquainting readers with the underlying concepts and components of personalized medicine supplemented with some disease-based case studies, discussing challenges and recent advancements in the implementation of the model of personalized medicine.

INTRODUCTION

Personalized medicine is one of the most exciting topics revolutionizing healthcare industry today. It is a concept that has the potential to transform medical interventions by providing effective, tailored therapies based on the genetic profile of an individual by utilizing vast information contained in our genetic code. It simply means studying the person in the framework of disease rather than just studying the disease itself. The kind of genetic makeup a person has, the kind of protein produced in them and bio-signatures or biomarkers present in their genome are considered while tailoring treatment for an

individual. Offering right drug to the right disease at the appropriate time with the optimal dosage is what is required to improve clinical outcomes and this is what personalized medicine stands for (The Case for Personalized Medicine, 2014)

Traditionally healthcare industry followed a reactive approach to treatment, in which the treatment only begins after signs and symptoms appear. The same prescription is given to different people suffering from the same disease. The physicians only considered family history, social-economic and environmental factors. As a result, every year large number of people die due to severe effects of the medicine and even larger gets hospitalized from adverse effects of medication (ADR-Adverse Drug Reaction). According to a report, patient's response rate to medicines can be as low as 20% depending upon the drug (range= 20-75% response rate). The pharmaceutical industry is still developing medicine based on the observation and the mechanism of the disease. Thus, just treating the disease and not the person.

The modern medical treatment focusses on patient`s disease to investigate exactly the state and the pathophysiology of disease, in order to "select" the most appropriate medication. "One drug size fits all" paradigm has lost its validity and it is also clear now that the drug response varies from patient to patient. Genetics play an important role in individual`s response to a drug and in deciding optimal drug dose. So we have a model that takes into consideration all the aspects affecting a person`s state of health from genetics to lifestyle, termed precision or personalized medicine. The following quote can easily summarize the concept behind personalized medicine *It's far more important to know what person, the disease has than what disease the person has* (Hippocrates of Cos (c. 460 BC – c. 370 BC)).

The development of personalized medicine as an approach to medicine, and as a new dimension in medicine, took off when the human genome was sequenced in 2001. A tectonic shift has started since then which is though subtle and perhaps imperceptible for ordinary individuals, but it is bound to influence the entire backdrop of how we look at our physical and emotional well-being. Modern techniques and the completion of Human Genome project have made it possible to understand the genetic part of the diseases and helped in making significant advancements in the drug development process. Personalized medicine is the new paradigm shift in the field of drugs or medicine which formulates treatment or medicine following genetic testing, proteome profiling, and metabolomic analysis to identify the impact of genetic variations on drug response. However, personalized medicine also requires doctors to collect the patient`s personal information including the genotype, so as to understand the nature of the particular patient. Based on which the doctor will decide the most suitable medical treatment for that particular patient.

In particular, each person has different ability of drug metabolism owing to the activity of their metabolic enzymes. For instance, if a person has very weak enzymatic activity, the drug will not get completely metabolized and its concentration in the blood increases. Contrary to this, if a person has very strong enzymatic activity towards a particular drug, the drug gets metabolized very quickly and its concentration in the blood would remain low. In simpler words, when several patients are prescribed the same dosage of a drug, the actual effect of the drug would vary depending on its enzymatic activity and thus its genotype. Based on this observation, a new process of drug development requires studying the effectiveness of the drug against the genotype, including the adverse effects.

The whole genome is sequenced using next generation sequencing methods and the obtained genomic reads are then filtered, aligned and variants identified. Variants and Mutations are then annotated using publically available bioinformatics resources. Personalized treatment could then be suggested based on the biomarkers present and other molecular aspects.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

It could be possible to assess patient`s susceptibility for diseases such as high blood pressure, stroke, diabetes, cancer etc. On the basis of the collected information, a new type of medical treatment, called "preventive therapy" to prevent these risks is developed. This implies that even though a person is identified as susceptible to a particular disease based on the genomic examination, changes to prevent the disease by performing the preventive therapy which is designed on the basis of personal information, still prevails. The preventive therapy is expected to gain more importance in the near future.

One of the earliest and most important examples of precision medicine is related to breast cancer. In about one-third of the breast cancer patients, HER2 protein is overexpressed which is non-responsive to standard therapy. FDA has approved Trastuzumab for patients with such condition and research in further years showed that it reduced recurrence by about 52% in combination with chemotherapy (The Case for Personalized Medicine,2009). Another example of personalized medicine is known in melanoma. It is shown that a mutation exists in gene BRAF encoding for protein B-Raf, which is responsible for sending signals inside cells for directing its growth in the majority of melanoma patients. Vemurafenib, an inhibitor of B-Raf and the companion BRAF V600E mutation test were approved in 2011 for the treatment of these melanomas. Vemurafenib is only beneficial for patients with a positive test for BRAF V600E mutation (Ascierto et al., 2011).

A non-invasive genetic diagnostic test is available as an alternative to endomyocardial biopsy for heart transplant recipients to help manage the care of patients post-transplant. This test may be helpful for longer-term patient management as it will aid in predicting the risk of rejection and prescribing more precise immunosuppressive drug regimes.

The prevailing medical treatment is exercised majorly in large centralized hospitals where the focus is on "patients of the average population". However, when it comes to personalized medicine, the current medical system may fall short in expectations. If a patient particularly requires the personalized or the preventive therapy, a modern system would be required to fulfill the requirements. In future, a new system is believed to be a reality with the combination of a "family doctor" and a large centralized hospital. In this system, the role of the family doctor would be to convince the patient and establishing mutual trust as well as understanding the patient`s characteristics. On the other hand, the centralized hospital equipped with an advanced and the latest technologies and instruments would be dealing with the patients whom family doctor is unable to handle.

Personalized Medicine or Precision Medicine is a model that customizes and tailors medication according to an individual's genetic information and determines its predisposition to a particular disease or condition. With the help of personalized treatment model, the healthcare industry will be seen shifting its focus from illness to wellness, and from curing disease to maintaining health. The realization of this model is not without challenges such as lack of infrastructure to support the requirements of this model, the lacking recommendations for the implementation and follow-up of personalized therapy, ethical, legal and social issues, economic issues. But on the whole, it seems evident from the outcomes of the traditional trial and error medicinal approach, that personalized medicine was not a promise made hastily, but a realizable dream. Although the investment in precision medicine is not trivial, it is providing the foundation and systematic methods for prospective progress.

This chapter explains the very concept and the key components of the personalized therapy, dwelling deep into behind the scene factors affecting the implementations of the model of personalized medicine. The chapter also focuses on the advancements in other branches of science such as nanotechnology, metabolomics, molecular biology, immunoinformatics and bioinformatics which has significantly added more value to this model.

PHARMACOGENOMICS AND PHARMACOPROTEOMICS: KEY COMPONENTS OF PERSONALIZED THERAPY

Pharmacogenomics (PGx)uses 'omics' approaches that have led to a revolution in unraveling the underlying cause and mechanism of disease susceptibility, thus providing enormous potential for novel therapeutic strategies.

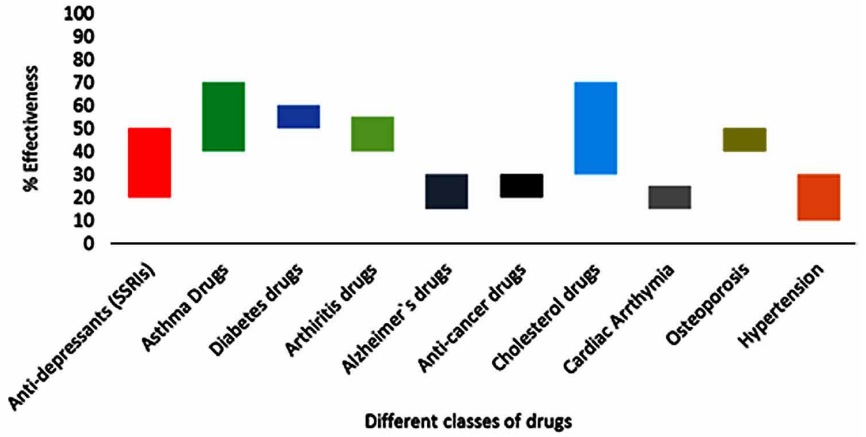
In general, pharmacogenomics can be defined by splitting the word into two words:

1. **Pharmacology**: The science of drug development and discovery, and
2. **Genomics**: The study of genes and their functional aspects.

Pharmacogenomics – the study of how genetic differences among individuals or alterations in gene expression that are linked to pharmacological function and therapeutic response. It is also sometimes referred to as science differentiating how individual's genetic makeup influences a person's reaction to drugs. The therapeutic response in many disease processes is gene-specific and multifactorial. Therefore, tailoring medication based on patient genomes maximizes efficacy and compliance while avoiding side-effects and drug-drug interactions. Basically, genomics knowledge would help optimize drug therapy for patients that would deliver the best results based on the patient's genotype. Thus, separating responders from non-responders and predicting the efficacy and toxicity of the drug.

PGx involves better pharmaceutical outcomes for patients and possibly finding the right mix of therapy thereby reducing the need for polypharmacy. "Pharmacogenomics" should be implemented in drug development Pipeline. It is introduced in Phase IIA/IIB of clinical trials with the aim of accelerating and facilitating the development of new molecules while reducing the associated risks and costs (Adams, 2008). Thus, aids in understanding how genetic variation among individuals contributes to differences in reactions to the drugs.

PGx play the following role in clinical trials**:**



- Identification of variations in a large number of genes that affect drug action.
- Stratification of Patients in Clinical Trials according to genotype.
- Prediction of optimal doses of the drug in different patient populations.
- Reduction in Drug Development time by predicting the populations having good efficacy.
- Prediction of adverse reactions or therapeutic failures based on the Genotype of the patient.
- Prediction of Drug-Drug interactions

In PGx, genomic information is used to study individual responses to drugs (Adams, 2008). The two major determinants for studying drug action in individuals are:

1. How much of a drug is needed to reach its target in the body – *Pharmacokinetics.*
2. How well the target cells such as heart tissue, liver respond to the Drug- *Pharmacodynamics.*

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

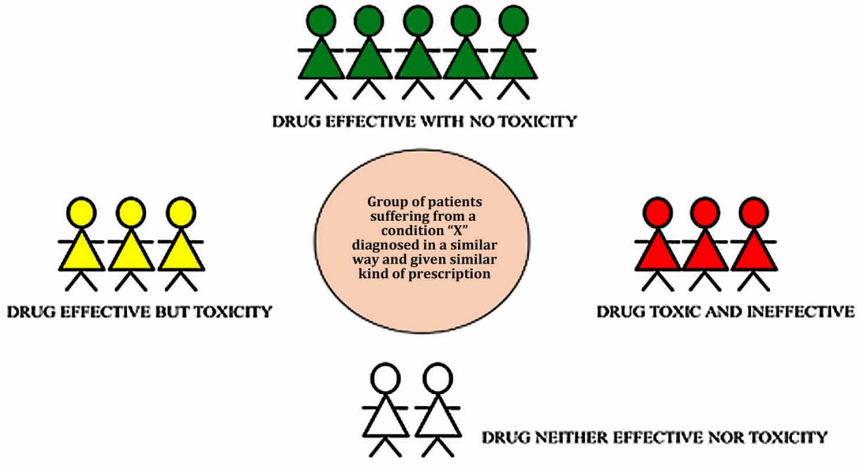
Figure 1. Advancement in PGxhas allowed for more tailored treatment for a wide range of health problems, including cardiovascular diseases, cancer, HIV/AIDS etc.

Factors Affecting Response to Medication

Genetic variations are not the only determinant of variations in response to the medications but age, sex, diet, intake of supplement drugs can each influence individual`s response to a medication (Personalized Medicine, Coriell Personalised Medicine Collaborative).

Non-Genetic Risks

- Interactions between drugs and lifestyle factors.
- A person's Gender, Age, and Weight.
- Drug-Drug Interactions like taking clopidogrelas a combination therapy with proton pump inhibitors like Prilosec (commonly used to treat heartburn) reduces the clopidogrel effectiveness in preventing blood clots.
- Interact of existing Medical conditions with Medications. For example, a person that has hypertension or high blood pressure cannot take many anti-inflammatory drugs, such as aspirin and steroids, as they could cause an unsafe rise in blood pressure.
- Environmental risk factors such as sun exposure, air quality, and job-related hazards involving exposure to chemicals, radiation, and carcinogens.



Genetic Risks

Family History for a particular disease may increase the risk of developing a disease.

As pharmacogenetic testing become widely recognized and easily available, precision medicine will make use of the obtained genetic information to evaluate the multifaceted representation of variability in drug response and manifestation of side effects. In conclusion, while adopting pharmacogenomic testing for the design of personalized prescriptions still has hurdles to cross for integration into clinical practice, but the knowledge of drug response at the molecular level, risk factors, and disease susceptibility can increase the susceptibility towards achieving the aim of Precision Medicine.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Different set of population respond differently to same treatment owing to their genetic differences

Potent Applications

The application of PGx has focused on the studying genetic variations in the population to explore linkages between genes, diseases, and environmental factors, and developed new therapies and diagnostic tests. One such application is mentioned below.

Anti-cancer therapy was the foremost area of medicine to use PGx. Nowadays it is common to treat certain cancers by testing the tumor tissue for its genetic "signature" (Squassina et al., 2010; Xie & Frueh, 2005). The information obtained thus can be helpful for doctors to prescribe the effective therapy based on the tumor's specific genetic makeup. A successful example of this approach was observed in leukemia treatment, breast cancer treatment, and colon cancer treatment. The most promising applications of PGx has also been implemented in defining the risk for adverse effects, dosages and response to medications in Cardiovascular Diseases, Psychiatric Diseases, Infectious Diseases.

Pharmacogenetics (PG)

Most of the articles use the term Pharmacogenetics (PG) and Pharmacogenomics interchangeably though they only differ in the initial approach of science. Pharmacogenetics begins with the unexpected drug response to a given therapy and investigates the genetic cause behind it whereas PGx begins with identifying genetic differences with a population to explain the observed response to certain drugs or to define the susceptibility to a disease.

Potential benefits of PG include discovery and development of drugs for targeted therapies and with minimized adverse effects, more accurately determining drug dosages and development of amalgamated DNA vaccines that could activate the immune system to have the benefits of multiple vaccines with reduced infection risks. It is currently being used for evaluating drug responses in a number of diseases such as cardiological disorders, respiratory syndrome and neurological conditions, investigating fast and slow metabolizers in respect to commonly consumed drugs. It has certain limitations as well. Multiple genes could be responsible for determining the drug response to a drug, thus making drug development process tedious. Identifying genetic variations in each of the individuals that may influence drug me-

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

tabolism is very difficult and time-consuming task (Pharmacogenetics/Pharmacogenomics, Fact sheet 25 NSW Government Health).

PG is the study of specific SNPs in specific genes with known functions that could be linked to drug response. Pharmacogenetic testing involves examining SNPs identified in advance, that are linked to Neurotransmitters, receptors or growth factors. Pharmacogenetic testing is an alternative to "Hit-&-Miss" approach of prescribing any drug. The knowledge of patient drug metabolizing gene variants (poor metabolizers, rapid metabolizers, and ultra-rapid metabolizers) can help in finding the appropriate therapy and optimal dosage of many of the commonly prescribed drugs, including Antidepressants, Beta blockers, Warfarin (Scott, 2012).

Determining Drug-Drug Interactions

The wider use of Pharmacogenetic testing is an opportunity for prescribing safety and efficacy. It is a very important and useful tool in predicting which drug will be effective in various patients. For instance, the drug "Plavix" is the best-selling prescription drug that blocks Platelet reception. It is being given to patients who had received a stent in the coronary artery to prevent clotting but Genome Wide Association Studies (GWAS) have identified the gene CYP2C19 in those who are unable to metabolize Plavix (Pharmacogenetics, Wikipedia)

Applying Pharmacogenetics into Clinical Practice

When physicians are equipped well evaluating a patient's genetic make-up will help them diagnose more accurately and prescribe the right drug. The variation extends among people beyond our phenotype (Pharmacogenomics, The University of Utah).

Case Study: An 18-year old person "X" who has been diagnosed with Leukemia type of Cancer involving the bone marrow and blood cells. His doctor wants to start his Chemotherapy as soon as possible.

"Purinethol" is a common chemotherapy drug. It incorporates itself into cancer cells and killing them. While most patients were benefitted from the drug, doctors knew that it canal so cause severe and fatal side effects in certain patients. Previously doctors were unable to understand that why these patients responded so negatively to the drug. After a long time, they discovered that TPMT (Thiopurine Methyltransferase) enzyme is responsible for metabolizing and inactivating the drug, Purinethol. The people also vary in their TPMT enzyme activity level. Because Purinethol is a toxic substance, it is important that it should only remain in the body for a limited amount of time, affecting mainly cancer cells and not the healthy cells. Therefore, before prescribing the drug, it is critical for doctors to know if a patient has enough TPMT enzymes to effectively inactivate Purinethol. If patients are unable to break down Purinethol they will suffer toxic side effects. About 89% of the population has the ability to fully breakdown the toxic anti-cancer drug. This population carries the variation in TPMT responsible for maximum enzymatic activity and will be resistant to severe ill-effects from Purinethol. 10.66% of the population has a TPMT variation with partial activity, leading to the less efficient breakdown of Purinethol. Thus, they will suffer severe side-effects if given a full dose of the drug. However, they will benefit from a much lower dose. 0.33% of the population has TPMT with insufficient enzymatic activity. As a result, Purinethol breakdown will not occur to the greater extent and the toxic substance will persist in the body. So they will suffer fatal side-effects if given any Purinethol.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Therefore, knowing which genetic variant of TPMT the person "X" has will influence his treatment tremendously. To determine the dosage of Purinethol that "X" will need, his doctor takes a DNA sample from his blood and sends it to a lab. After running a diagnostic test based on SNP Profiling, it was determined that person "X" has 'partial TPMT activity' variation. With this knowledge, he can confidently start "X" on a reduced dosage of Purinethol.

This case study illustrates just one-way doctors can apply PG into clinical practice to deliver with the correct dosage of a chemotherapeutic drug.

Pharmacoproteomics (PP)

Pharmacoproteomics is another key component of personalized medicine along with PG and PGx that uses proteomic technologies to discover and develop novel drugs. Genotyping just provides variations at the DNA level whereas pharmacoproteomics is the functional representation of those variations. Designing therapeutic strategies on the basis of differential protein expression would be more beneficial than just based on genetic polymorphism. Protein chips like microarray chips will be used more frequently in the near future in clinical diagnostics, particularly in Point of Care diagnostics. Proteomics will help in the development of molecular diagnostics, Characterization of complex disorders thereby defining a targeted therapy for a particular biomarker, Drug discovery and development, designing precision medicine based on proteomic profile rather than genetic polymorphism.

PP will be a useful adjunct to PGx and PG in developing the model of personalized medicine by connecting genotype with the phenotype and classifying the patients into responders and non-responders. Several important applications of Pharmacogenomics are already in clinical practice and some of them have the FDA approval (for example, cetuximab/panitumumab and KRAS; vemurafenib and BRAF; warfarin and CYP2C9/VKORC1; abacavir andHLA-B*5701; carbamazepin and HLA-B*1502; thiopurines and TPMT) (Meyer, Zanger, & Schwab, 2013)

METABOLOMIC ANALYSIS FOR PERSONALIZED MEDICINE

Despite technological advancements and enormous financial inputs, PGx has the success that has limitations too like in predicting drug response with absolute certainty using biomarkers. This can be attributed to the fact that PGx takes into account only genotypes and not the phenotypes, which is the result of interactions between genotype and environmental factors such as diet, gut microbiome, nutrition, age, sex, dietary supplements, and lifestyle. Therefore, it becomes critical to determine individual`s phenotype in deciding the correct drug and optimal dosage and thus predicting the response to a given therapy.

The metabolomic/metabolic profiling takes into account the influence of individual`s physiological state, microbiome diversity and functional composition, genetic polymorphism and other environmental factors. Thus, could be useful in predicting the possible outcomes following a therapeutic intervention. A new approach called Pharmacometabolomics is emerging that combines the effect of metabolic profiling and metabolite assessment tools for linking the inherent variations in the metabolite and drug efficacy. Some reviews have typically described the potential of metabolomics, especially pharmacometabolomics in clinical trials and thus personalized medicine (Nicholson, Wilson & Lindon, 2011; Nicholson, Everett & Lindon, 2012).

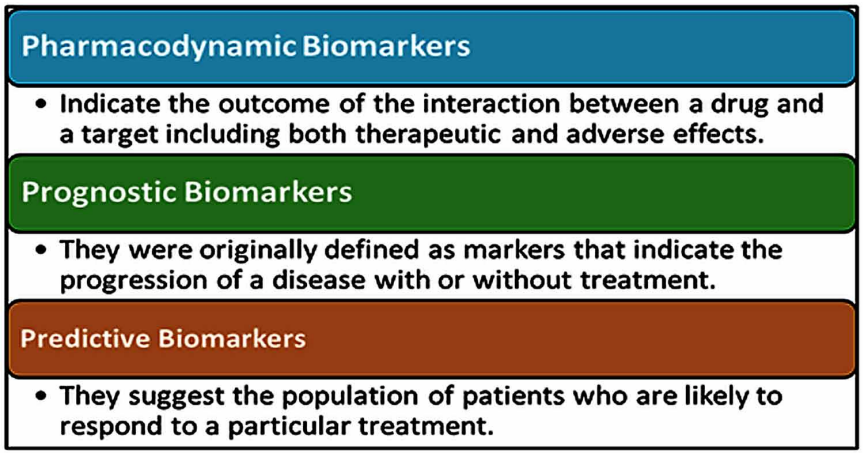
EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

One advantage that pharmaco-metabolomics enjoys over the other 'omics' technologies is that the metabolic profile represents the phenotype of the organism and reflects the overall biological impact which no other technology represents. It involves metabolite profiling of the biofluids or fecal extracts in the pre-dose and post-dose individuals to envisage his/her responses for a therapeutic intervention and in the process identifies surrogate markers for subsequent therapies. Furthermore, it is also capable of providing useful drug pharmacokinetic and drug metabolite information for an individual, which can provide a mechanistic understanding of variations in responses.

Pharmacometabolomics along with other 'omics' technologies can be helpful in determining response phenotype, evaluating toxicity and predicting individual response to targeted drug therapy (Kaddurah-Daouk et al., 2010). For example, metabolic profiling was employed to investigate the metabolic pathways of ritonavir which is a protease inhibitor used with HIV chemotherapy (Li, Lu & Ma, 2011). Four bioactivation pathways associated with CYP3A were found to be related to ritonavir-induced toxicity. Additional data obtained from pharmacokinetics for a drug could provide relevant information to determine individual responses for the drug. Recently, to profile pre and post-dose urinary metabolites scientists applied metabolomics approach in individuals given a single toxic dose of APAP-s (acetaminophen sulfate). It was discovered that human subjects with high pre-dose levels of p-cresol (metabolites related to human gut microbiome) had lower concentrations of APAP-S, which is due to the competition of the binding site to the sulfotransferase enzyme. The individuals with lower pre-dose urinary concentrations of p-cresol might be more susceptible to APAP-induced toxicity since less APAP will be conjugated with sulfate to produce APAP-S. The findings indicated that each individual, colonized by a unique assortment of trillions of microbes, could respond to a drug differently, either beneficially or adversely. This study demonstrates that evaluation of metabolic phenotype by metabolic profiling could play an important role in drug toxicity and metabolism, as well as in personalized healthcare system (Clayton et al., 2006).

BIOMARKERS

The sole aim of precision medicine is to utilize the growing understanding of biology so that patients receive the right drug for their disease, at an accurate dose and in adequate time. But personalizing medication includes the use of different biomarkers driven by a decision-making process in which a diagnostic test is essential.



Biomarkers are organic substances that are known to indicate certain biological processes. A biomarker is a term used to indicate a measurable character that can indicate a biological state. Biomarkers vary from one branch of science to others. In the field of medicine, biomarkers such as DNA (copy number variations, methylation states, and mutations), RNA (mRNA, microRNA), Protein (phosphorylation sites, post-translational modifications), polysaccharides, metabolic products, single nucleotide polymorphism and gene variants and cells serve to diagnose diseases (Escamilla, 2013). Tests that screen for biomarkers can help medical practitioners to learn more about the patient's condition, for example, if he or she is afflicted with a certain type of cancer or is he/she at greater risk of suffering a heart attack. In medical diagnostics, biomarkers also serve to detect gene mutations that can cause diseases.

Ideal biomarkers for use in diagnostics and prognostics, and for drug development and targeting, should be measurable, safe, modifiable upon treatment, consistent across different populations, highly specific and sensitive (Issaq, Waybright & Veenstra, 2011).

Clinical Biomarkers can also be categorized as shown in Figure 3.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Biomarker classification
(Drucker & Krapfenbauer, 2013; Buyse, Sargent, Grothey, Matheson, & de Gramont, 2007)

DNA Sequence-Based (SNPs) Biomarkers

Identifying, cataloging and studying small genetic variations among humans will lead to more efficient drug therapies. Reliable SNPs could serve as biomarkers to predict the response of various drugs.

SNP is defined as the single base change occurring in the DNA sequence such that it is present in at least 1% of the population. SNPs can be of two types:

- **Synonymous SNPs**: The single base change occurring at the DNA level will not reflect in the protein sequence as one amino acid can be coded by different codon triplets.
- **Non-Synonymous SNPs**: The single base change occurring at the DNA level will reflect in the protein sequence, thus leading to altered protein. These SNPs are of much importance in personalized medicine approach.

Finding and Identifying SNPs

It is generally done by following two major approaches:

1. **Genomic Approach:** Large scale projects are started to sequence the whole genome of a large number of people and compared their genome to identify the differences in the sequences. It requires a lot of financial, scientific and computational input to generate as well as store and analyze data. Scientists identify SNPs mainly by two methods:
   - Sequencing complete DNA of a large number of people and then a comparison of results.
   - Primer extension Method.
2. **Functional Approach:** Scientists select a particular disease, then select the genes associated with it, examine them in different sets of people i.e. patients who respond to a drug and the patients who don`t respond to the drug.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

SNPs are categorized into two main categories when studying them in relationship to their effects on drug:

- **Linked SNPs**: They resides on intergenic or intron region but do not affect the function of the protein encoded by the gene. They have some relationship to drug response.
- **Causative SNPs**: These are those SNPs that affects the function of the protein and corresponds to a disease or abnormality or influence the person`s drug response. These are further of two types:
  - **Non-Coding SNPs:** They are present in the regulatory regions of the gene and they affect the gene expression.
  - **Coding SNPs:** They are present in the coding regions or within a gene, change the amino acid sequence in the protein and alters the protein function. [36]

Haplotypes (or Haplotyping)

Characterizing the combination of SNPs in a fragment of DNA. Most of the time a single SNP does not reveal everything about a person. Haplotypes influence the drug response and can be a more accurate predictor of phenotypes than SNPs.

Pharmacogenetics studies on candidate gene have been performed based on haplotype approach. Positive results have been obtained. This approach has also been applied to clinical trials making it the first genetically personalized medicine approach.

Companion Diagnostic (CDx)

Measurement of different markers (RNA, DNA, and/or proteins) needs different diagnostic assays; therefore, different qualification and validation strategies are needed. Pharmaceutical companies are increasingly looking to develop a drug and diagnostic test simultaneously, in a process referred to as drug-diagnostic-co-development, also called companion diagnostic (CDx), to significantly define the appropriate patient population for treatment. A companion diagnostic test is essentially a biomarker test that enables better decision making on the use of a therapy. In other words, they are often developed concurrently with a therapeutic, but can also be developed to optimize treatment with a therapeutic that has already been approved (Simoncelli, 2013). Pharmaceutical and device sponsors have become increasingly interested in pursuing "co-development" strategies for the development of a therapeutic product and an accompanying IV-D companion diagnostic device. As described earlier, the concept of co-development was first applied in 1998, when the approval of the therapeutic Trastuzumab (Herceptin), was paired with approval of an immune histochemical IVD companion diagnostic device (HercepTest™) that measures expression levels of human epidermal growth factor receptor 2 (HER-2) in breast cancer tissue (Elkin et al., 2004).

The goal here is to increase the safety and the efficacy of the drug (Buyse et al., 2007). CDxis increasingly important tools in drug development because they have following advantages:

1. Reduced costs through pre-selected (smaller) patient population;
2. Improved chances of approval through more focused therapies;
3. Offer better outcomes, less toxicity, and fewer treatment delays;

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

4. Significantly increased market uptake;
5. Added value for core business (late phase);
6. Regulatory trend to have CDx mandatory.

Tafinlar/Mekinist/THxID BRAF test: In May 2013, FDA approved Tafinlar (dabrafenib) and Mekinist (trametinib) for patients with advanced or unresectable melanoma, the leading cause of death from skin disease. The FDA approved Tafinlar and Mekinist with a genetic test called the THxID BRAF test, a companion diagnostic that will help determine if a patient's melanoma cells have the V600E or V600K mutation in the BRAF gene. Approximately half of melanomas arising in the skin have a BRAF gene mutation. Tafinlar is intended for patients whose tumors express a single BRAF gene mutation, V600E. Mekinist is intended for patients who express that mutation or the V600K mutation (Simoncelli, 2013).

A list of companion diagnostics that have been approved to date can be viewed athttp://www.fda.gov/MedicalDevices/ProductsandMedicalProcedures/InVitroDiagnostics/ucm301431.htm.

But actual co-development seems to be a rare phenomenon until now because of following reasons:

1. Clinically useful biomarkers are usually established late in the drug validation process because it is quite difficult to find clinically useful predictive biomarkers early on in a drug development program, simply because they can only be determined on the basis of the patients' responses to the drug. A number of biomarkers, such as KRAS and EGFR mutations, could only be established after a sufficient number of patients for a Phase III trial had elicited a better understanding of differential drug response. And still 30% of the drugs fail during Phase III, diagnostic manufacturers will not be able to afford the huge investment in the development of companion diagnostics (Collins, 2013).
2. The worlds of drug development and diagnostics, although both part of health care, are parallel universes in many ways. In general, they have different development timelines, product lifecycles, return on investment, customers, and regulations. Drugs are valued and reimbursed as products, typically of high value. Diagnostics are valued and paid for as services, typically at a much lower value. Drugs are protected by patents, but in the companion diagnostic arena, biomarkers are considered to be within the public domain and there is less emphasis on intellectual property. It is even debated whether biomarkers should be patented at all because biomarkers are not invented but already exist in cells.
3. The challenge of timing and alignment of the development strategies of the two products: if the diagnostic is going to be used to select patients for the trial, an analytically validated test should be available at the time of initiation of the trial. This can be challenging since sometimes the need for the companion diagnostic may not be evident until late in the development of the drug, or the need to change the test might arise during the course of the trial. The purpose of the trial is not only to assess the safety and effectiveness of the drug but also to investigate the performance of the diagnostic in that specific therapeutic context. A test that does not perform adequately may negatively impact the outcome of the trial and harm patients. Changes made to the test after initiation of the trial can make it difficult if not impossible to interpret the study results (Simoncelli, 2013).
4. Lastly, is the design of the trial itself. Identifying patients at the beginning who are most likely to benefit from a drug or biological product (or excluding those likely to suffer toxicities) can allow for smaller, faster, and less expensive clinical trials with a higher likelihood of success. However, there are some challenges associated with designing very small trials, such as being able to build insufficient statistical power to yield convincing results. Designing a trial to test whether a drug

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

is effective for a subpopulation of patients also sometimes raises complex technical and ethical questions about whether to include marker-negative patients (i.e., those that are note expected to benefit from the drug) in the trial (Simoncelli, 2013).

Improvised treatment strategies and healthcare expenditure may reduce up to a greater extent with successful biomarker discovery and validation. For example, the American Society of Clinical Oncology estimates that routinely testing people with colon cancer for mutations in the K-RAS oncogene would save at least US $600 million a year (Drucker & Krapfenbauer, 2013). On the other side, thousands of projects in the course of potential biomarker discovery projects have been proposed, but only a few clinically useful biomarkers have been successfully validated for routine clinical practice (Poste, 2011). The following are the major pitfalls in the translation from biomarker discovery to clinical utility:

1. Lack of making different selections before initiating the discovery phase.
2. Lack in biomarker characterization/validation strategies.
3. Robustness of analysis techniques used in clinical trials.
4. The lack of characterization and validation of technologies such as protein chip, multiplex, etc. Besides technical characterization, it also needs quality requirements for correct characterization of the predictive value of biomarkers.
5. **Regulatory Hurdles:** Each of these details is hardly documented and can dramatically affect the predictive response of biomarker results. However, the selection of useful biomarkers must be carefully assessed and depends on different important parameters, such as on sensitivity (it should correctly identify a high proportion of true positive rate), specificity (it should correctly identify a high proportion of true negative rate), predictive value etc. Unfortunately, biomarkers with ideal specificity and sensitivity are difficult to find. One potential solution is to use the combinatorial power of different biomarkers, each of which alone may not offer satisfaction in specificity or sensitivity. Besides traditional immunoassays such as ELISA, recent technological advances in protein chip and multiplex technology offer a great opportunity for the simultaneous analysis of a large number of different biomarkers in a single experiment, which has expanded at a rapid rate in the last decade.

NANOBIOTECHNOLOGY IN PERSONALIZED MEDICINE

Nanobiotechnology is also an important contributor in the refinement of various molecular diagnostic technologies, biomarkers identification and other diagnostic and therapeutic technologies and useful field of science for personalized medicine.

Nanobiotechnology and Biomarkers

As already discussed in the previous chapter what biomarkers are, how important they are in personalized medicine approach and how important it is to identify novel biomarkers, Nanomaterials can be used for bio-labeling for identifying and characterizing biomarkers. Various new composites have shown high potential for cell labeling. One of such composite is made of biocompatible, water-soluble having fluorescence and being stable is nature silver dendrimernanocomposite for labeling cells in various *in-vitro*

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

studies. Trials using quantum dots for molecular labels for detecting early signs of tumors and tracking drug efficacy and efficiency have shown significant results.

Nanoproteomics which is the application of Nanobiotechnology in proteomics helps in improving available protocols/procedures and analyzing less abundant proteins. Using Nanobiotech, we may design and build devices that can be implanted in the body to detect and identify biomarkers, thus enhancing the diagnosis of various diseases. It is now possible to mold certain known nanoparticles to selectively attach to a small set of biomarkers and help in sequestering them (Geho, Jones, Petricoin, & Liotta, 2006).

NanoDiagnostics

It refers to the appliance of nanotechnology in molecular diagnostics. It is believed that the use of nanotechnology in molecular diagnostics will enhance the sensitivity (Emerich, & Thanos, 2006). Nanopore technology has already been available to sequence single molecule of DNA providing higher sensitivity and offers correlation between gene and its expressed proteins with specific disease using not reusable and portable nanodevices. Molecular diagnostic tests used to detect and measure the activity of biomarkers will become speedier and reliable. Tagging of biomolecules with nanoparticles will provide an additional edge. It is viewed that nanotech has potential application in Point of Care (POC) diagnostics and thus will be helpful in personalized treatments.

Nanobiotechnology in Discovering and Delivering Personalized Medicine

Nanobiotechnology is making a noteworthy contribution to the pharmaceutical industry in developing personalized medicine. Nanobiosensors and Nanobiochips are being used for improving drug development process. Drug delivery to the targeted tissue/organ with precision is important for personalized medicine. Using nanocarriers in conjugation with ligands and aptamer allows precise targeting and improved clinical efficacy (Debbage, 2009). Nanobiotech will improve detection of cancer biomarkers. Scientists have applied Alpha-mu-beta 3 targeted paramagnetic nanoparticles for safely finding very minute regions of angiogenesis associated with cancer (Schmieder, Winter, Caruthers, Harris, Williams et al., 2005).

The contrast of MRI scans was enhanced by using particle filled with thousands of molecules of metal. The surface of each particle is coated with a substance that could connect to newly emerging blood vessels at the site of cancer, thus enabling detection of sparse biomarkers. Additionally, nanoparticles used for detection could also be used for precisely delivering doses of anti-cancer medication directly at the target site avoiding side-effects, thus posing another advantage of using nanoparticles. Furthermore, it would be easy for the physicians to evaluate MRI scans, thus fulfilling certain important criteria of a personalized therapy such as timely detection and amalgamation of diagnostics with therapeutics.

Similarly polyvalent dendrimers can be conjugated with several biofunctional moieties for targeting cancer cells. One such example is conjugating dendrimers with folic acid using complimentary DNA oligonucleotides to produce clustered molecules for targeting folate receptor overexpressing cancer cells (Choi, Thomas, Kotlyar, Islam, & Baker, 2005).

Investigations on multifactorial and multiplex nanoparticles linked with antibodies or other small molecules are speeding up for being using them to target malignant tumors with higher sensitivity and affinity (Cho, Wang, Nie, Chen, & Shin, 2008; Wang, Shin, Simons & Nie,2007).

Nanobiotech, when applied to the nervous system, will help us in improving our understanding of neurological disorders and help us design drug delivery systems for them (Jain, 2005). The first and

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

foremost thing in applying nanobiotechnology to neurological disorders is to understand the pathomechanisms of it. The development of targeted drug delivery systems to brain that crosses blood-brain barrier is another important component of personalized treatment (nanobiotechnology-based drug delivery to the central nervous system).

NanoBiotechnology has already started establishing its foothold in the area of cardiovascular disorders diagnosis and treatment using targeted drug delivery (Wickline, Neubauer, Winter, Cauthers, & Lanza, 2006; Iverson, Plourde, Chnari, Nackman, & Moghe, 2008). For example, using perfluorocarbonnano particles for visualization and targeted drug delivery in cardiovascular disease. Such nanoparticles will ensure that the drug reaches the target and a subsequent molecular influence is taking place, a vital component of personalized treatment. For instance, with the technological improvement, it would be possible to screen and target biomarkers associated with atherosclerotic lesions expansion.

The main aim to personalized medicine is to improve healthcare and nanobiotechnology is surely all set to play an important role in it. Advancement in technology and availability of cheaper nanomaterials will surely help in cheaper and reliable molecular diagnostic technologies and personalized treatments. Both nanomedicine and personalized medicine will continue to advance and will play an important role in the development of healthcare industry towards personalized medicine. Safety and regulatory issues along with ethical and economic issues are being resolved. It is believed that nanotechnology will pace up the development of personalized medicine by integrating diagnostics with therapeutics.

BIOINFORMATICS TOOLS AND DATABASES AIDING PERSONALIZED MEDICINE

Systems biology along with the key components of personalized medicine i.e., pharmacogenomics, pharmacogenetics, and pharmacokinetics are developing as one of the most promising fields that give a complete understanding of diseases and enable targeted therapy. Although, there are a lot of hurdles that has to be overcome while preparing for personalized medicine (Yan, 2010). Few of the challenges are:

- The scientific challenges, such as determining which genetic markers have the most clinical significance, limiting the off-targeting effects of gene-based therapies, and conducting clinical studies to identify genetic variants that are correlated with a drug response.
- The policy challenges, such as finding a level of regulation for genetic tests that both protects patients and encourages innovation.

In order to make progress, the NIH and the FDA will invest in advancing translational and regulatory science, better define regulatory pathways for coordinated approval of co-developed diagnostics and therapeutics, develop risk-based approaches for appropriate review of diagnostics to more accurately assess their validity and clinical utility, and make information about tests readily available.

Translation of scientific discoveries into better therapeutic outcomes requires better information and workflow management, efficient literature and resource retrieval, and communication improvement. Translational bioinformatics is a powerful method to bridge the gap between systems biology research and clinical practice which provides biological and medical information to allow for individualized therapy. Such computational approaches encompass the development and application of informatics techniques in the biological sciences (Chang, 2005). It serves following purposes:

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

- It would enable the identification of biomarkers based on systemic analyzes.
- It enables researchers to search online biological databases and use the biological information in their medical practices. For instance, the data obtained from a microarray is extremely complicated and bioinformatics aids in selecting appropriate software to analyze the microarray data for medical decision making.
- It can improve the understanding of the correlations between genotypes and phenotypes.
- It would enable novel insights of interactions and interrelationships among different parts in a whole system.
- In translational bioinformatics biological databases have been managed in EHR to improve health care and clinical practice moves toward personalized medicine. Bioinformaticians hope to pull all available genomic data into electronic health records (EHRs) that also consider the effects of genetic mutations. The EHRs will allow researchers to assess the contribution of genomic variations to disease (Schmidt, 2003). A virtual patient system has been developed and used to model obesity, diabetes, and asthma.
- Methods based on data integration, data mining, and knowledge representation can provide decision support for both researchers and clinicians.

Moreover, advances in molecular-based information have led to a deeper understanding of the complexity of life. Translational bioinformatics using the high volume of biological information will contribute to changes in practice standards in healthcare systems. It is believed that bioinformatics tools will provide potential benefits to patients by means of improved healthcare, disease prevention and health maintenance as we move towards the era of personalized medicine.

IMMNUNOINFORMATICS AND PERSONALIZED MEDICINE

Immunoinformatics refer to the use of bioinformatics to study immunology. The immune system plays a critical role in the precision medication advance for some chronic, infectious and inflammatory immune-mediated diseases. The genetic capability to generate a diversity of adaptive immune responses is critical to fighting pathogens and differentiates between self and non-self-components. This diversity will also aid in defining patient subgroups for individualized vaccine or drug development. The accumulation of huge amount of immunological relevant information requires efficient informatics methods for analyzing data and its management.

Research areas of Immunoinformatics are:

- Immune system response modeling and simulation of laboratory experiments.
- T-cell and B-Cell epitope prediction.
- Host-pathogen interaction.
- Identify novel functions of existing genes.
- Performing NGS and RNA-Seqin healthy and diseased states.
- Epigenetic Studies (Allergy prediction)
- Design and engineering of immune therapeutics and diagnostics.
- *In silico* vaccination

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. List of bioinformatics tools, databases used in different fields of personalized medicine

S.No.	Program/Databases	Description
Software for Analysis of Microarray Data		
1	Cluster	For clustering, SOM
2	TreeView	Graphically browse and analyzes results of clustering
3	ScanAlyze	Processes fluorescent images of microarrays
4	ArrayMiner	Set of analysis tools
5	Expression Profiler	Analysis & clustering of gene expression data
6	GeneX-Lite	Integrated toolset, provides an interface to RDBMS
7	BASE	Microarray database and analysis platform
8	dChip	Analysis of oligonucleotide arrays
9	ArrayDB	Mining and analysis of microarray data
Proteomics Strategy Tools		
1	ExPASy (Expert Protein Analysis System)	Analyzes protein sequences and structures
2	PROSITE	Protein database describing protein domains, families, and functional sites
3	Swiss-Prot	A manually curated protein sequence database
4	SWISS-3DIMAGE	An image database provides high-quality pictures of biological macromolecules with known 3D-structure
5	ENZYME	Repository of information relative to the nomenclature of enzymes
6	Protein Explorer	Software to display the protein structure
7	Cn3D	A structure viewer and a helper application
Pharmacogenomics Strategy Tools		
1	dbSNP (The database of Single Nucleotide Polymorphisms)	Free public archive for studying genetic variations.
2	OMIM (Online Mendelian Inheritance in Man)	Catalogues all the known diseases with a genetic component
3	dbGaP (The database of Genotypes and Phenotypes)	Archives the results of the studies of interaction of genotype and phenotype
4	PharmGKB (Pharmacogenomics Knowledgebase)	Encompasses clinical information including dosing guidelines and drug labels, potentially clinically actionable gene-drug associations
Systems Biology Strategy Tools		
1	KEGG (The Kyoto Encyclopedia of Genes and Genomes)	A knowledge base for systematic analysis of gene functions, linking genomic information
2	AfCS (Alliance for Cellular Signaling)	A large-scale collaboration designed to answer global questions about signaling networks
3	STKE (Signal Transduction Knowledge Environment)	Combines the traditional, albeit electronic, publishing of articles, such as reviews, perspectives, and protocols, with tools for organizing and collating information in the cross-disciplinary field of signal transduction

Out of above-mentioned research areas, the most studied is the T-cell and B-cell epitopes prediction because they play a crucial role in disease understanding, host-pathogen interaction, antimicrobial target discovery and vaccine design (Bette, Montiago & Karina, 2006). Epigenetic studies provide the understanding of how environmental changes can affect complex immune diseases such as allergy.

With the help of Immunoinformatics, we can develop personalized medicine for chronic, infectious and inflammatory immune-mediated diseases.

DISEASE-BASED CASE STUDIES ON PERSONALIZED MEDICINE

Several genes have been found responsible for variations in drug response and metabolism among different individuals. The most important and common among them are the *Cytochrome P450* (*CYP*) genes. These genes encode enzymes involved in regulating in one way or the other the metabolism of about three-fourth of the prescribed drugs. Individuals carrying variations in certain *CYP* genes often differ in their ability to metabolize the drug. There are a number of other genes that affect drug response such as the ones encoding the regulatory molecule`s receptors, growth hormones, structural proteins, transcription factors and some cellular proteins. Diminished drug response and occurrence of adverse drug reactions (ADR) can often be due to polymorphism in these genes. Polymorphism in these genes can either hyperactive or inactive their protein proteins; or disable or interfere with the functioning of their protein, thus forcing physicians to discontinue the medication. A list mentioning drugs, and genetic variations affecting their response or safety, is available at U.S. Food and Drug Administration website for physicians, researchers and individual`s reference (Pharmacogenetics, FDA)

Also, it has been observed that certain drugs can lead to changes in the phenotype of individuals and influences the metabolizing capacity of enzymes by mimicking the effect of genetic variations. Quinidine is a known inhibitor of CYP2D6 activity. In case if an individual is prescribed quinidine, then he/she will be a poor metabolizer of CYP2D6, compared to someone who carries a loss-of-function polymorphism in *CYP2D6*. In those patients, drugs requiring the activity of CYP2D6, such as atomoxetine, will not

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

be metabolized at the same rate as in most people. Mimicking the effect of genetic variations is also a known phenomenon in certain foods. For example, grapefruit juice, an inhibitor of CYP3A4 can lead to poor metabolism of drugs like diazepam, requiring the activity of CYP3A4.The following three case studies illustrate three categories for which pharmacogenomic knowledge can help take better decisions for medication respectively.

Case Study 1: In Predicting and Preventing Adverse Drug Reactions

Aman, a 30-year-old man has recently been diagnosed of HIV infection. Before initiating Abacavirantiretroviral therapy, his physician decided to go for genetic testing to determine whether he carries any relevant variation. The test confirmed the presence of the *HLA-B*5701* allele.

How did genetic testing help Aman and his physician?

Abacavir (Ziagen) marketed by GlaxoSmithKline is a nucleoside reverse transcriptase inhibitor often used in amalgamation with other antiretroviral medication to treat HIV infection. An immunologically-mediated hypersensitivity reaction is known to occur in about 5–8 percent of patients taking Abacavir, usually during the first six weeks after initiation of therapy. (GlaxoSmithKline. Ziagen, product labelling. 2010)

Knowing that Aman carried the *HLA-B*5701* variation and he would likely experience a hypersensitivity reaction and would develop fever, rash, nausea, and fatigue if he is given Abacavir, thus, the physician would avoid prescribing him Abacavir.

Case Study 2: To Predict Effectiveness

JS, a 55-year-old man recently had an acute myocardial infarction. The physician recommended him anti-platelet therapy and prescribed clopidogrel. 6-months following the anti-platelet therapy, JS surprisingly suffered another acute myocardial infarction. The physician suspected that clopidogrel therapy may have been ineffective or less effective. Following genotyping it was found to carry a variation on *CYP2C19*.

How would genetic testing help JS and his physician?

Clopidogrel is a prodrug and it is converted to an active metabolite by cytochrome P450 enzyme, CYP2C19 to exert its anti-platelet properties. Individuals carrying certain variations in CYP2C19 are considered poor metabolizers and show decreased ability to convert clopidogrel into its active metabolite (Shuldiner, O'Connell, Bliden, Gandhi, & Ryan, 2009). Further, these patients are more likely to have an ischemic event following clopidogrel therapy (Mega, Close, Wiviott, Shen & Hockett, et al., 2009). It was found that JS carried a variation in its *CYP2C19*. This variant has been known to be associated with the diminished antiplatelet effect of clopidogrel. The physician would have to re-examine him and consider giving him some other anti-platelet therapies, thus decreasing his chance of getting another cardiac attack.

Case Study 3: In Predicting Optimal Dose

Mitchell, age 66, has been recently diagnosed with atrial fibrillation. The physician recommended her warfarin therapy in order to reduce the risk of further getting any stroke and leading to other thrombotic events. In order to estimate the optimal dose, the patient has to undergo INR monitoring every day until a stable dose is determined, and then every few weeks thereafter for maintenance monitoring.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

How would genetic testing help Mitchell`s physician to determine the optimal dose for her?

The most commonly prescribed anti-coagulant is Warfarin (Coumadin), to treat and prevent thrombosis. CYP2C9 enzyme metabolizes it and further action by the enzyme VKORC1 mediates its anticoagulant effect. It is observed that polymorphism in the *CYP2C9* gene causes some individuals to slowly metabolize warfarin and increasing the half-life of the drug, resulting in higher than usual blood concentrations of warfarin and greater anticoagulant effect. On the other hand, certain variation in the VKORC1 gene reduce the activity of the enzyme encoded by it and subsequently decreases the production of coagulation factors. The blend of reduced warfarin metabolism caused by *CYP2C9* gene polymorphism and subsequent decreased coagulation due to *VKORC1* gene variations has been found to increases the chances of bleeding during warfarin therapy. Warfarin has a narrow therapeutic index; variations in *CYP2C9* and *VKORC1*, in addition to several other patient characteristics, make it difficult to predict the effective dose. (Reider, Reiner, Gage, Nickerson, & Eby, et al., 2005) (Bristol-Meyers Squibb Company. Coumadin (warfarin sodium) product labeling 2010). If Mitchell carries any mutation on *CYP2C9* and *VKORC1* genes then it would be difficult to optimize the dosage for warfarin but surely it would surely reduce the risk of bleeding. This would help thephysician to decide more appropriately decide the initial dosage.

The following case study which will demonstrate the application of personalized medicine/genetic testing in efficiently treating dreadful diseases.

Case Study 4

A clinician sends two samples for molecular analysis of the patients suffering from Chronic Myeloid Leukemia (CML) and been administered a drug called Imatinib, showing clinical signs of drug resistance. The samples are sent to the laboratory to confirm drug resistance and investigate the reason for drug resistance. A standard laboratory test called "IRMA" was performed to detect a point mutation in chromosome 9, as it is a known prognostic factor for drug resistance. One of the samples showed a positive result for IRMA and other showed a negative result.

How would one go through the rest of the process for personalized medicines for these 2 patients?

First of all, we have to identify all the other biomarkers present in the patient`s genome and understand their effect on the drugs available. For CML, not all the biomarkers are known yet, so it calls for studies regarding biomarkers. One such biomarker has been identified as single nucleotide polymorphisms of ABCB1. Also, one marker is surrogate for the other. Depending upon the biomarkers or the variants present in the patient we can go by tailoring a treatment specific to that patient only.

ELSI (ETHICAL, LEGAL, AND SOCIAL IMPLICATIONS) OF PERSONALIZED MEDICINE

Introduction to Ethical Issues

Ethical issues of personalized medicine are based on PG, genetic information and impact on healthcare. We need to take care how the personal information of the patient, genetic information and information important for pharma companies flows during the implementation of personalized medicine approach. It is recognized that there are a number of barriers that need to be addressed before PGx will be part of routine clinical care.

Ethical Aspects of PG

Some of the ethical issues that are bound to rise by PG in implementation of personalized medicine are:

- When the geneticists can predict which patients are likely to benefit from the available pharmacotherapy and which are less likely, the issue of inequality may arise. We have to ensure that equality remains in medical healthcare.
- Confidentiality of patient`s Genetic information. Protecting patient privacy is one of the most important concerns that must be addressed before implementation of individualized medicine in clinical practice and just about everyone agrees that patients have a right to keep details about their health private from most people (even if not from, say, their insurance company or in some cases state or local governments).
- Another issue is to protect the right of a medical practitioner or scientist to reject a patient the available therapy on the basis of its genetic makeup.
- Cost is also a significant ethical issue as well. Still millions of people are without health insurance today, and many more have insurance plans that cover only the most basic things. How can 'payers' provide access to personalized medicine to everyone?

Ethical Aspects of Genetic Information

It covers the following aspects:

- **Ethical Issues of Whole Genome Analysis**: A large amount of data generated by genetic studies and their analysis predicting the patient`s response to different disease and the diseases they are likely to develop can have ethical issues as to what information is to be revealed to the patient and what is to be concealed.
- **Privacy Issues in Personalized Medicine:** As personalized medicine approach involves dealing with the complete information about a person, privacy issues are bound to rise. The patient might not be comfortable in sharing his/her personal information either due to social issues or some personal/moral issues. The information generated from genetic analysis of patient`s data may not be emotional good for the patient and physician might try to conceal it for better treatment of the patient. Sometimes the patient is reluctant to reveal his information even before the diagnosis is done.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Molecular tests challenge two aspects: How comprehensive these tests are and how the access to this information is regulated:

- Accessibility of diagnostic tests and targeted treatments within and across countries with companies seeking orphan status for new targeted treatments.
- Patients' understanding and patients' role in future decision making.
- **Human Dignity:** Potential for stigmatization and discrimination.
- **Human Integrity:** How this affects moral convictions, preferences, and commitments
- **The Input-Output Problem:** Though personalized medicine aims at segregating populations into small subgroups based on their genotype and response to drug or susceptibility to a disease but in all these studies racial and ethnic minorities have been left unexplored. Even the GWAS studies take in account only European or in some cases Asian populations. The proportion of GWAS conducted with minorities suffered from health disparities. The input–output problem arises because allele frequencies and environmental exposures tend to vary among population groups (Fullerton, 2011). Because of this, the assumptions that inform personalized medicine practice in well-studied populations are not necessarily generalized to poorly studied populations.

Regulatory Aspects

All the above ethical issues need to be resolved for efficient implementation of personalized medicine approach in the healthcare industry. Regulatory authorities have to set some standards for this approach and ensure that the rights of the patient, physician, and Pharma companies are protected as well as ensuring that personalized medicine approach does not create any social differences (King, Casavant, & Lang, 2013).

Role of Regulatory Authorities

- Sometimes the patient is reluctant to reveal his information even before the diagnosis is done, in that case, it is needed to be ensured that patient is properly supported and informed about the personalized medicine approach.
- Medical products should be carefully evaluated to find out their benefits and risks.
- Regulatory authorities should remain updated about the new technology and must keep the pharma companies on the toes to inform the author about each and every aspect of drug development.
- Provide clarity to the pharma industry and the consumer/patient about the recent therapies available in the market.
- They should address "pipeline" problems about the drugs by identifying the opportunities for streamlining the processes.
- Scientific barriers, regulatory issues and ethical issues have to be tackled beforehand so that there is the smooth implementation of personalized medicine in clinical practice.

The need of an hour is to expand the amount of work and effort to address ELSI. This requires expanding our current list of experts in the field of bioethics and clinical policies along with collaborations with quality control experts, health economists, and strategists. It is also clear that new approaches towards

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

informed consent, intellectual property, protection of individual`s privacy and data required to be established for facilitating the suitable and active application of new technologies to personalized medicine (Brothers, & Rothstein, 2015).

CHALLENGES IN THE JOURNEY TOWARDS PERSONALIZED MEDICINE

As every coin has two sides, personalized medicine too has another side to it. There is a need to take care how the personal information of the patient, genetic information and information important for pharma companies flows during the implementation of personalized medicine approach.

Whenever a new technology or a model is found, there are always some concerns in its implementation in the initial phase. Personalized medicine model`s implementation also have some concerns and limitations:

Economic Limitations

- Personalized medicine could raise issues for those who pay for treatment, people in developing countries like India. The cost of new assessment tests and personalized medication is more and predictive potential of personalized medicine could add more to the expense after the disease has been detected. Though health insurance is not a trending business in India, as the insurance premium are based on actuarial statistics that apply to large and predictable population, insured people might have to end up paying more for getting an insurance.
- It is difficult to convince pharma companies to manufacture drugs according to a group of people carrying a certain genotype. Pharma companies see more benefits in producing traditional drugs that work on 50-60% of the population and still being prescribed to patients who do not respond to it or have side effects after consuming these medicines.
- Genome-wide association studies (GWASs) have been used to assess the SNPs with many important common diseases. But only a limited number of variants have been characterized, and understanding the functional relationship between associated variants and phenotypic traits has been difficult. SNP Prediction methods are not to be solely relied on as they don`t provide much information about the pathophysiology of the diseases. So we have to switch to the wet lab and conduct experimental tests to validate genetic predictions. As we know Laboratory validations are always expensive and time-consuming and so there is a need for fast and accurate methods for gene prioritization.

Limitations in Identifying Disease Biomarkers

- To unravel DNA variants so as to predict common, complex diseases that result from a combination of genes and environmental factors will require cost-effective, high-throughput genotyping; large, well-characterized patient populations; sophisticated computational methodologies; and a detailed understanding of the biological pathways of disease.
- Uncovering mRNA and protein markers for application in screening, diagnosis & prognosis and monitoring of disease will have its own set of challenges. Access to optimal relevant tissues might not be possible for many diseases. Proteomic technologies still need further development, because

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

computational approaches for analyzing massive amounts of gene and protein profile data. To realize the vision of personalized medicine, the agenda for medical and pharmaceutical research must include the assembly and integration data from many sources on large numbers of patients. Clinical investigations should incorporate genotyping and molecular profiling technologies along with traditional clinical data collection and should establish a repository of patient samples where possible.

- New molecular markers might face many hurdles before they can be implemented in patient care. The issues range from FDA regulation and acceptance of these new markers to developing tractable assay platforms, to resolving issues around the ethical, legal and social implications of obtaining highly sensitive genetic information. Foremost among these, in our opinion, is the education and engagement of physicians and patients in the paradigm shift to objective, quantitative marker-based clinical care. If appropriate patient management systems, integrated databases, educational tools and genetic counseling are not in place, then it will be difficult to realize the significant benefits forecast from this approach.

Bioinformatics Challenges

- **Processing Large-Scale Robust Genomic Data:** Sequencing technologies are becoming affordable and are replacing the microarray-based genotyping methods, which were limited to interrogating regions of known variation. Now a whole genome can be sequenced in less than 15 days with an error rate of ~ 1 error per 100 kb. Even such low error rates can lead to a significant number of errors, which is around ~30 000 errors in a 3 GB human. The error rate from these technologies is a source of significant challenges in applications, including discovering novel variants (Fernald, Capriotti, Daneshiou, Karczewski, & Altman, 2011). Whenever a novel variant is identified, it will still have to be verified due to this false positive rate. Even high-quality sequence reads must be placed into their genomic context to identify variants, which is an active area of research since, for example, different mapping and alignment algorithms often yield different results. Because de novo assembly (Shendure & Ji, 2008) is slow and complicated by repetitive elements, sequences are usually mapped to a genomic reference sequence instead. Algorithms such as BLAST (Altschul, Gish, Miller, Myers, & Lipman, 1990) or Smith–Waterman (Smith & Waterman, 1981) have been traditionally used, but their execution speed depends on the genome size. While individual queries may only take seconds per CPU, aligning 100 million of them would require more than 3 CPU years.
- **Interpretation of the Functional Effect and Impact of Genomic Variation:** After genomic data has been processed, the functional effect and the impact of the genetic variations must be analyzed. Genome-wide association studies (GWASs) have been used to assess the statistical association of SNPs with many important common diseases. These methods are providing new insights, but only a limited number of variants have been characterized, and understanding the functional relationship between associated variants and phenotypic traits has been difficult (Frazer, Murray, Schork & Topol, 2009).The important resources for obtaining SNP data are adbSNP database, Online Mendelian Inheritance in Man, Human Gene Mutation Database. But such prediction methods do not provide any information about the pathophysiology of the diseases and so experimental tests are required to validate genetic predictions. Laboratory validation is expensive and time-consuming and so there is a need for fast and accurate methods for gene prioritization.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

- **Integrating Systems and Data to Capture Complexity:** Given the complex phenotypes involved in personalized medicine, the simple 'one-SNP, one-phenotype' approach taken by most studies is insufficient. Most medically relevant phenotypes are thought to be the result of gene–gene and gene–environment interactions (Manolio et al., 2009). For example, drug response often depends on multiple pharmacokinetic and pharmacodynamic interactions, which form a robust and tolerant system with highly polymorphic enzymes and many interaction partners (Wilke, Reif & Moore, 2005). As a result, of this complexity, a drug–response phenotype of interest is likely to depend on many genes and environmental factors. Basic GWAS approaches for pharmacogenomics have given some success. There is concern that pharmacogenomics GWAS themselves are susceptible to many limitations: insufficient sample size, selection biases for genetic variants, environmental interactions that may affect the outcome measures and multiple gene–gene interactions that may underlie unexplained effects (Motsinger-Reif et al., 2010).
- **Making it All Clinically Relevant:** The ultimate challenge for this research is to apply the results for improved patient care. Much of this research has yet to be translated to the clinic. In fact, many physicians are unprepared to incorporate personal genetic testing into their practice and it is unclear how to best apply research results to improve patient care (McGuire & Burke, 2008). Bioinformatics also translates discoveries to the clinic by disseminating discoveries through curated, searchable databases like PharmGKB, dbGaP, HGMD, OMIM (Mailmanet al., 2007; Thorn, Klein, & Altman, 2010). A major bottleneck for these databases is manual curation of the data. Biologically and medically focused text mining algorithms can speed the collection of this structured data, such as methods that use sentence syntax and natural language processing to derive drug–gene and gene–gene interactions from scientific literature (Garten, Coulet, & Altman, 2010). These databases and methods need to be developed and used carefully. All these data sources are susceptible to errors and so validation of data is essential, especially before the information is applied in the clinic. Finally, there are challenges and opportunities for bioinformatics to integrate with the electronic medical record (EMR) (Busis, 2010). For example, the BioBank system at Vanderbilt links patient DNA with a de-identified EMRs to provide a rich research database for additional translational research in disease–gene and drug–gene associations (Denny et al., 2010; Roden et al., 2008).

Other Limitations

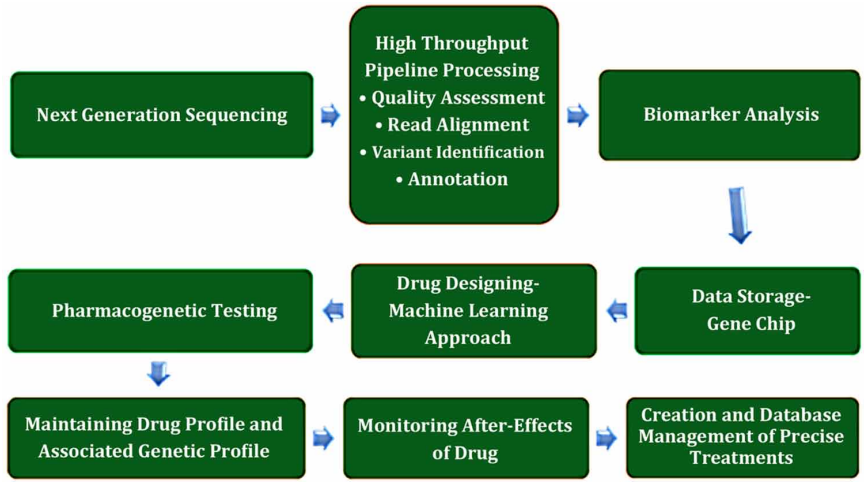
- **Limited Understanding of the Intrinsic Biology of Disease:** The tools of the last two decades have left us overflowing in data, yet we still have a relatively limited understanding of what it all means. Its implementation in clinical practices remains in its infancy. Scientific understanding will likely remain the most important limiting factor for the momentum of this field. Physicians will have to be well equipped with the knowledge of genomics and proteomics to understand the new data.
- **Common Conditions Involving Multiple Genes/Biomarkers:** Common conditions are often influenced by multiple genetic, as well as environmental and social factors, in ways that are not yet well understood. Realization of the benefits of personalized patient management for common conditions affected by multiple genes will be a complex process that will depend on substantial investment in clinical research well beyond the initial demonstration of gene-disease correlations (Simoncelli, 2013).

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

- **An Outdated Disease Classification System:** Currently used disease classification systems define diseases primarily on the basis of their signs and symptoms. These systems do not easily accommodate emerging information about disease mechanisms, particularly when it is at odds with traditional physical descriptions. As a result, many disease subtypes with distinct molecular causes are still classified as one disease, while multiple, different diseases that share a common molecular cause are not properly linked. The failure of our outdated disease classification systems to incorporate optimally new biological insights serves as a fundamental barrier to progress in personalized medicine. The National Academy of Sciences has called for the creation of a "New Taxonomy" of disease that is designed to advance our understanding of disease pathogenesis and improve health and that defines and describes diseases on the basis of their intrinsic biology in addition to traditional signs and symptoms. (National Research Council: Committee on a Framework for Developing a New Taxonomy of Disease. (2011). Toward Precision Medicine: Building a Knowledge Network for Biomedical Research and a New Taxonomy of Disease. Washington, DC: The National Academies Press).
- **Lack of Infrastructure:** Costs of genetic sequencing have plummeted over the past decade, resulting in an explosion of information. Yet, while information is becoming easier and easier to obtain, the infrastructure to collect, analyze, integrate, share, and mine that information remains lacking.
- **Clinical Implementation of New Diagnostics:** Many clinicians have been reluctant to use new diagnostics. Part of this reluctance may be due to the ongoing controversy over clinical utility and the fact that biomarker clinical utility can often be a moving target. Clinicians also commonly face the general problem of "information overload," making adoption of new tests difficult without decision-support tools in place that could be accessed to help the clinician to identify, order, and interpret the appropriate tests.
- We don`t know whether it will be a good idea to inform an individual that he/she is likely to develop a disease or is suffering from a disease for which there is no cure.
- Realization of personalized management in diseases with multiple genes affecting the diseased state is a complex process and will ask for higher financial input as well as in-depth clinical research.
- *Poor sequence quality* from sequencing technologies is a challenge in discovering novel variants. Moreover, it is difficult to detect INDELS, Copy number variants, and structural variants. The cost of sequencing is another major concern. Efforts are being made to reduce the cost of sequencing the whole genome under $1000.

CURRENT STATUS AND FUTURE IMPLICATIONS OF PERSONALIZED MEDICINE

Personalized medicine has just moved out of its infant shell and it is expected that it will enter its teen years by the end of this year. It is of outmost important that we design and device strategies for efficient implementation of the personalized medicine model in clinical practice. Currently, personalized treatment is employed in only few of the diseases such as Cancer, cardiovascular disorders, respiratory syndrome and psychiatric maladies. Most research and success has been achieved in case of anti-cancer therapies. But to reciprocate the success in other disorders, we need to work on areas such as lowering



EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

down the cost of sequencing, applying exome sequencing for better diagnosis and treatment, improving the available infrastructure for the implementation of personalized medicine in clinics and all these is to be supported by new regulatory policies. New technology, new models require new regulatory policies to ensure safer and smoother implementation. Government and regulatory authorities like FDA have to draw in more stern regulations for personalized medicine thus ensuring the availability of safe and effective diagnostics. The regulatory science has to catch up with all that is happening in relation to personalized medicine and help in its faster, safer and regulated implementation. Drug labeling provides important information about the drug which is useful for both clinician and the patient. As personalized medication will be designed for a group of population, product labeling becomes important. Integration of nanobioscience and high throughput proteomics techniques with personalized medicine and development of point of Care Medication.

A good amount of work on electronic health records is being carried out in the USA along with an additional emphasis on the storage of genetic data and developing point-of-service prompts to assist busy clinicians in identifying and utilizing relevant genomic data at the proper time in diagnostics or treatment planning. A 10 years down the line we could reach a point where the analytical validity of sequencing technologies are high, with the easy ability to access and clinically interpret genomic information, and knowledge about patient responses to genomic information.

Owing to recent developments with respect to personalized medicine, it is expected that this model will eventually be turned into clinical practice by the end of this decade. Besides the application of PG and PGx, pharmacoproteomics will gain more application in identification of novel biomarkers, designing new drugs in accordance with the protein profile and understanding disease pathophysiology. By combining the three key components of personalized medicine, it would be possible to strictly define responsive populations and effectively monitor drug responses. Protein chips are expected to make it to the clinics within next five years thus aiding point-of-care diagnostics.

Figure 4. Flow chart for the case study 4

Efficient Next Generation Sequencing (NSG)

1. High-Throughput Pipeline Processing. Better and efficient bioinformatics tools for quality assessment, alignment, and variation calling.
2. Database for identifying biomarkers.
3. Storing the patient`s data in a Gene Chip. It will give easy an access to the Clinician.
4. Designing a probable drug molecule through machine learning.
5. Virtual Biological systems that will analyze the drug path, molecular interactions, signal transduction pathways and some other parameters.
6. A complete profile of the drug will be generated.
7. Store the Drug profile in association with a genetic profile in a database or some records.
8. Administer the drug, if found suitable for a group of patients.
9. Analyze the After effects. A Chip will keep the record of the patient`s physiological parameters.
10. Create and manage a database of such personalized treatments.

CONCLUSION

This chapter has tried to present the very model of personalized medicine from different angles, emphasizing on its key components, its potential applications and trying to identify issues that may arise during implementation of such a model in clinical practice. It also summarizes the current developments and future potential of personalized medicine.

We believe it would be fair enough to say that personalized medicine has started spreading out its wings. It has the potential to re-define the approach we have about identifying and managing health problems. It has already shown it significant impact on the healthcare industry. Since personalized medicine has the potential of revolutionizing patient care targeting patient population; avoidance of drug-related toxicities and optimization of costs in non-responder patients; reduction in the cost of drug development, and reduction in patients to be tested in clinical trials. There lies a huge potential in the application of precision medicine to significantly improve the clinical outcomes in terms of treatments, prevention strategies, medication types and dosages- that may have inter-individual variability. However, the wider impact hasn`t been achieved yet despite of being increasingly recognized in literature and many disease cases in humans. High sequencing cost, lack of infrastructure support for scientists and physicians, ELSI, lack of regulatory measures and economic factors additionally are hindering the translation of this model into reality. In short, we could say that though catering medicine specifically to an individual`s requirement is a farfetched but certainly possible reality following more research, high financial investments and establishing more systematic guidelines.

KEY TERMS AND DEFINITIONS

Biomarker: It is measurable indicator for a biological state or physiological condition.

Personalized Medicine: An approach followed for disease prevention and treatment that takes into account differences in people's genes, environments and lifestyles.

Pharmacodynamics: The study of the biochemical and physiological effects of drugs on the body and the mechanisms of drug action and the relationship between drug and response.

Pharmacokinetics: It refers to the study of drug pathway inside the body. It involves studying absorption, metabolism, distribution and excretion of a drug.

Pharmacoproteomics: It refers to the use of proteomic technologies in drug development and molecular diagnosis. It helps more clearly demarcate patient-to-patient variations as compared to genotyping.

Risk Assessment: It refers to identifying sensible measures to control the risks associated with different trials especially where live organisms are involved.

Chapter 13
Role of Resveratrol (RES) in Regenerative Medicine

James A. Stokes III
Alabama State University, USA

Manoj K. Mishra
Alabama State University, USA

ABSTRACT

Within the last quarter century, technology has been a major catalyst of the advancement in various fields of scientific knowledge, particularly medical research. This new enlightenment has spurred the exploration of alternative treatment methods to some of society's most problematic diseases. One such innovative treatment is the use of Resveratrol (RES) to treat a number of pathophysiological conditions. RES is a natural polyphenolic compound found in the skin(s) of blueberries, red grapes (a major constituent of red wine), some vegetables, and even peanuts. The compound has a number of potent regenerative properties, which include: anti-aging, anti-inflammatory, and antioxidative. Research has confirmed both in vivo and in vitro RES's beneficial applications to numerous diseases. This chapter centers on its unique healing powers and beneficial applications against myriad debilitating conditions.

INTRODUCTION

Recent scientific studies have revealed that conditions affecting the circulatory, muscular, skeletal, and other organ systems such as multiple sclerosis, heart disease, and diabetes have their origins rooted in a low-nutritious western diet. This emerging problem has led to the advancement in medical ingenuity such as regenerative therapeutics (Hubmayr 2013). For example, researchers have implemented the use of stem cells harvested from umbilical or fetal cord blood in an attempt to generate newly functional tissues (Hubmayr 2013; Bouros and Laurent 2012 ; Kolios and Moodley 2013; Liu et al. 2013; Viswanathan and Joshi 2013). Despite its potential benefits many take issue with this new technology due to the perceived unethical nature in which the cells are acquired. Therefore, research into alternative life-restoring compounds such as resveratrol (RES) and its conjugation with novel nanoparticles have presented the

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

scientific community with a viable alternative to the mainstream medicines. RES is a naturally occurring polyphenolic compound found in the skin of red grapes, blueberries, select vegetable foods, and even peanuts (Zunino and Storms 2009; Sha et al. 2009; Kao et al. 2009; Trincheri et al. 2008; Sun et al. 2008; Shakibaei et al. 2008; Roccaro et al. 2008; Juan et al. 2008; Martin et al. 2004; Larrosa et al. 2003; Radhakrishnan et al. 2011). It is a powerful and versatile compound with potent regenerative properties including anti-oxidative, anti-inflammatory, and anti-aging. Combining the many beneficial properties of RES with unique nanotechnology, such as carbon nanoparticles, could give scientists the ability to enhance RES's inherent regenerative powers by increasing the stability of the compound *in vivo*, allowing it to deliver therapeutic effects over an extended period of time. Nanodiamonds (NDs) have been incorporated into the research of revolutionary drug-delivery system(s). These microscopic carbon compounds are harvested from the residue of explosive mixtures such as trinitrotoluene (TNT) and dynamite. The raw material is chemically refined and functional groups such as carboxyl (COOH), hydroxyl (-OH), and ketones (C=O) are incorporated onto the surface of the ND. This gives researchers the flexibility to conjugate a wide variety of therapeutic agents such as RES, creating an effective drug-delivery vehicle. This carrier system when introduced *in vivo* allows RES to remain intact and be released in a time-dependant manner. The agent conjugated to the surface of the ND is released only in response to a change in physiological conditions, specifically a drop in pH from basic to acidic [Hubmayr 2013; Figueiro et al. 2013; Li and Ye 2006]. This pioneering technology would allow physicians to decrease both the dosage and amount of times required to treat patient(s) suffering from debilitating conditions such as cancer. Previous clinical studies have demonstrated RES's impressive therapeutic capabilities and minimal side effects because it is a natural chemical (Mohanty et al. 2013; Liang et al. 2013; Borriello et al. 2014; Lachenmeier et al. 2014; Cottart et al. 2014). RES's natural regenerative properties and negligible toxicity makes it an extremely attractive option in the arduous pursuit for health and longevity. Many who have worked closely with RES are fascinated by its ability to operate through a variety of cellular biochemical pathways and mediate positive immune responses. Clinical data has shown that the administration of RES has restored significant functionality and vitality to target organs and tissues (Zhang et al. 2007; Sareen et al. 2007; Lee et al. 2007; Horvath et al. 2007; Hambrock et al. 2007; Gill et al. 2007; Ahmad et al. 2007).

(RES) RESTORES GROWTH OF CARDIAC STEM PROGENITOR CELLS (CSPC)

There have been numerous studies documenting RES's incredible ability to regenerate tissues. One such study investigated the effects of the application of RES to replenish degenerating cardiac tissue. As in the case of many pathophysiological conditions the common underlying cause for its manifestations is the quality of diet. The debilitating condition of diabetes mellitus is a result, among other mitigating factors, of a poor diet high in processed sugars and foods with little to no nutritive value. The onset of Diabetes can cause an imbalance in other organ systems via metabolic derangements that accompany the primary condition. Diabetic cardiomyopathy (DCM) is characterized as a disorder in the muscles of the heart which can lead to poor circulation and other complications (Delucchi et al. 2012). Evidence shows that high glucose levels leads to the hindered differentiation, migration, and adhesion of cardiac stem progenitor cells (CSPC) for the rejuvenation of worn or dying mature cardiac cells (Delucchi et al. 2012). This produces a net loss of cardiac cells because not enough new progenitor cells are able

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

under stressful diabetic conditions to replace the cells that are lost over time. RES has been documented to restore positive growth back to the subpopulation of CSPC and improve cardiac tissue function and other model systems (Delucchi et al. 2012; Figueiro et al. 2013; Jana et al. 2009; Busanello et al. 2012; Schlachterman et al. 2008).

RES INCREASES MATRIX MINERALIZATION OF ADIPOSE STEM CELLS (ADSC)

In a separate study investigators examined the proliferative effects of treating both rat and human adipose derived stem cells (rADSC and hADSC, respectively) in a 3-D environment (polycaprolactone, PCL) with RES. The work revealed that the pre-treating or pre-conditioning of ADSCs significantly increased the osteogenic potential in both cell lines as compared to that of untreated ADSCs. However, variables such as species type, specific dosage(s), and various time-points all factored into the degree of cell mineralization/differentiation caused by RES (Dosier et al.). According to the study, increased matrix mineralization was observed at 12.5 μM RES concentration at four weeks. Concentrations of RES higher than 12.5μM proved to have an overall toxic effect on both rADSCs and hADSCs; as a result decreased matrix mineralization was observed (Dosier et al.). Surprisingly, the low concentration of 6.25μM RES yielded the greatest amount of mineralized matrix suggesting that lower concentrations/doses are more effective at sustaining the model cells and producing mineralized matrix over a prolonged period of time. Higher doses (i.e. 12.5μM RES) proved to be more efficient at shorter time-points. The results confirm RES's proliferative/life generating capabilities (Dosier et al. 2012).

RES EXHIBITS CYTOPROTECTIVE PROPERTIES OF LIVER CELLS

The liver is the second largest organ in the human body and plays a critical role in maintaining the metabolic homeostasis of an organism. Important functions related to immune system response, the neutralization of many toxic elements, metabolite(s)/nutrient synthesis, and digestion are managed directly or indirectly by the liver (Matsumoto and Nakamura 1992; Bouwens et al. 1992). In fact, one can consider liver as the "processing plant" of the body in most organisms. Many diseases and toxins that target/affect the liver will have a negative impact on the overall health and vitality of the affected organism(s). These conditions can be fatal, for example, cirrhosis of the liver due to the ingestion of toxins or pollutants can cause a condition where viable liver tissue is replaced by nonfunctional scar tissue. However, recent research has shown that among the many other beneficial properties of RES it also demonstrated the ability to prevent and even reverse liver damage. The administration of RES to murine model cells have shown to protect against oxidative stress and exhibit hepatoprotective activity against agents of acute and chronic liver damage. At low doses RES decreases ischemia-reperfusion-induced liver injury and protects hepatocytes against oxidative complications (Roy et al. 2011). Quantitative data showed that the liver and body weights of rat specimens treated with RES showed comparable weights with that of specimens in the normal control group. Furthermore, RES displayed protective properties against certain histopathologies caused by carbon tetrachloride (CCL4) in the liver. The numbers of hepatocyte nodules (aggregates of liver cells enclosed by collagenous fibers) were significantly less in specimens treated with RES than the group induced with the agent CCL4 (Roy et al. 2011). These nodules are prominent

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

in damaged livers and replace the normal architecture of the organ, and RES both decreased the number and development of these nodules. RES mitigated the toxic effects of CCL4, the liver of specimens treated with RES exhibited fewer necrotic zones and the arrangements of liver cells were similar to that of the normal control group. Additionally, RES inhibited the secretion of pro-inflammatory cytokines of tumor necrosis factor-alpha (TNF-α) and interleukin-6 (IL-6); therefore, eliminating complications resulting from inflammatory immune responses (Roy et al. 2011; Cerqueira et al. 2013).

RES REVERSES THE PROGRESSION OF AGE-RELATED MACULAR DEGENERATION (AMD)

Additional research data further substantiates RES's versatility and wide-spectrum mediatory capabilities. One such study implemented a RES based nutritional supplement named Longevinex (L/RV) to treat individuals afflicted with age related macular degeneration (AMD). Those of the sample test group were United States veterans of one of three major conflicts (World War II, Korean, or Vietnam wars). AMD is a debilitating condition characterized by the progressive deterioration of the macula of the eye, which can lead to a significant loss of sight at the center of one's vision. The results of this investigation show that the L/RV supplement reversed the symptoms of AMD as well as other systemic co-morbidities. Octogenarians observed improvements in subjects' hearing, blood pressure, and vitality after treatment with the resveratrol-based supplement. Conversely, after cessation of treatment with L/RV investigators observed a regression in the improving conditions of the subjects (Richer et al. 2013). In a normally active eye the retina, photoreceptors, and other important cells that are worn are regularly replenished with new cells. The tissues of the eye are continuously supplied oxygen and nutrients by blood vessels. However, the pathogenesis of AMD is characterized by inflammatory and oxidative conditions which hinder the regenerative capabilities of the eye. In mammalian species damage to photoreceptors and internal neurons of the eye are rarely replaced or regenerated. However, this was not the case when L/RV was administered to patients. Investigators recorded growth of glial cells and improvement in visual functionality (Richer et al. 2013). RES was shown to neutralize AMD disease progression and produced moderate improvements in the condition of many of the subjects. Although more extensive research is needed to confirm these preliminary results one cannot deny the beneficial impact of RES treatments (Richer et al. 2013).

RES ADMINISTRATION PREVENTS CELLULAR SENESCENCE

Endothelial progenitor cells (EPCs) are critical to the restoration and upkeep of endothelial tissues (Krautkramer et al. 2014; Kaur and Bajwa 2014; Sommese et al. 2014; Basile and Yoder 2014). Systemic metabolic abnormalities caused by chronic conditions such as hypertension and diabetes are major contributing factors to the impairment of EPC proliferation and cellular activity. As we will continue to see in this chapter, RES can initiate a wide range of beneficial physiological effects. RES possesses the ability to protect and regenerate many tissues of the body including cardiovascular, liver, and bone. Clinical data have revealed RES's ability to neutralize and reverse complications associated with condi-

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

tions such as cardiovascular disease and diabetes both of which diminish the vitality of EPCs. Additionally, the dose and time dependent administration of RES *in vitro* have been documented to increase the proliferation, migration, and cellular adhesion of progenitor cells. Research has revealed that there are many causative agents to cellular aging (senescence); one of the more widely investigated causes of senescence is the decrease in telomerase activity. Telomerases are ribonucleoproteins that incorporate DNA sequence repeats to the 5' ends of eukaryotic chromosomes (Zappulla and Cech 2006; Li and Ye 2006; Hamma et al. 2005; Lee et al. 2003; Blackburn 2000; Collins 2000). These incorporated regions of DNA repeats are noncoding and prevent the loss of DNA from chromosome ends during replication (Xia et al. 2008). Many scientists proclaim that the malfunction of telomerases is a key initiating factor that triggers cellular senescence. Recent publications have shown RES to inhibit EPC senescence in a dose dependent manner with the greatest efficiency observed at 50μM. However, cellular senescence increased at high concentrations of RES, namely 100μM hinting at cytotoxic effects of RES at high doses, which confirms the findings of related research (Xia et al. 2008). Through the analyzation of various experimental assays RES demonstrated the ability to increase the proliferation/migration of EPCs and upregulate telomerase activity (Delucchi et al. 2012; Xia et al. 2008; Lefevre et al. 2007).

RES INCREASES MYELINATION OF NERVE CELLS

The myelin sheath (a plasma membrane that encases the axon of nerve cells) originates from the Schwann cells (SC) of the peripheral nervous system (PNS) (Payne et al. 2012; Zhang et al. 2012; Baird and Furek 2012). It is critical for a properly functioning nervous system. Information received from external stimuli is processed rapidly via the sheath along the axon of the nerve cell and initiates an appropriate response. SC health and vitality is fundamental in the production and maintenance of the myelin sheath. Pathologies of the PNS can lead to the deterioration of SCs and by default the myelin sheath resulting in the manifestation of clinical symptoms associated with malfunctioning nerves (Payne et al. 2012; You et al. 2013; Chen et al. 2013; Ho et al. 2012). Therefore, research into compounds that possess the ability to enhance the proliferation and regeneration of both of these structures are of the utmost importance. Scientific have researched the effects white and red wine, the latter which consist of RES, on the generation of SCs using an embryonic murine tissue model. According to various publications, red wine contains an approximate tenfold higher concentration of phenolic compounds as compared to white wine. Compounds such as catechin, epicatechin, gallic acid, anthocyanins, and RES were not even detectable in white wine (Stettner et al. 2013). The addition of both wines to model nerve cells resulted in the increase of myelin synthesis, but cells treated with red wine experienced significantly higher levels of myelination. This result is mostly likely due to the higher prominence of phenolic compounds, most notably RES, found in red wine. Additionally, investigators administered red wine exclusively to murine model cells and analyzed the effectiveness of different RES concentrations within red wine. The work revealed that RES introduced at higher doses in fact decreased myelination, "High RES concentrations (>mg/1) lead to a significant decrease of myelin synthesis, whereas RES administered in a lower concentration (~0.5 mg/1) resulted in a significant increase of myelin production (Stettner et al. 2013). These results confirm data from previous studies, which is that the administration of RES in moderate to low doses is most effective in myelin synthesis (Stettner et al. 2013; Wu and Ren 2009).

CONCLUSION

The information expounded upon in this discussion and other documents not covered in this chapter well establish RES's regenerative capabilities. RES is truly an amazing compound fashioned by Mother Nature that offers many curative properties with little to no side effects which makes it such an attractive alternative to traditional medical treatments (Zunino and Storms 2009; Sha et al. 2009; Sun et al. 2008; Shakibaei et al. 2008; Larrosa et al. 2003; Alkhalaf et al. 2008; Ma et al. 2007; Li et al. 2007; Garvin et al. 2006; Uguralp et al. 2005; Su et al. 2005; Rigolio et al. 2005; Pozo-Guisado et al. 2005; Ito et al. 2003; Pozo-Guisado et al. 2002; Morris et al. 2002). Research into the healing powers of Natural compounds such as RES could usher in a new era of medical research and play a major role in revealing some of the root causes of chronic diseases ailing populations worldwide. Future research into exactly how RES mediates such powerfully positive biological effects will endow the scientific community with the knowledge of how to most effectively leverage this amazingly versatile compound against systemic health problems within society.

KEY TERMS AND DEFINITIONS

Cytokine: Various proteins secreted by cells that elicits effects/actions on target cells.

In Vitro: Within a controlled experimental system.

In Vivo: Within a live organism/specimen.

Nanodiamonds (NDs): Carbon nanoparticle (diamond allotrope) harvested from explosive mixtures such as trinitrotoluene (TNT) and dynamite.

Physiological: Of or pertaining to the normal biological functioning(s) of an organism.

Regenerative: The tendency to reform, renew, or replace.

Resveratrol: Polyphenolic compound found in the skin of red grapes, blueberries, select vegetable foods, and peanuts. Used medicinally as an anti-oxidant and anti-inflammatory.

Chapter 14
Strategies for Expanding Access and Improving the Quality of Pharmaceutical Services

Marcus Vinícius Dias-Souza
Federal University of Minas Gerais, Brazil

ABSTRACT

Pharmaceutical services are among the most accessible healthcare assistance systems worldwide, being provided generally in enterprises like Drugstores and Compounding Pharmacies. Pharmacists are highly accessible healthcare professionals considering also the availability, geographic distribution and location of pharmaceutical enterprises. However, there are several challenges for providing these services for patients with limitations such as low education, difficulties on reaching the Pharmacist, and the need for individualized monitoring (due to the complexity of therapy). Reports of low quality services are growing worldwide, and in order to expand access and improve the quality of pharmaceutical services, Pharmacists must move from being medication dispensers with focus in administrative management to a clinically-oriented practice with a humanistic view. The aim of this chapter is to make an approach on the implementation of effective strategies and ways to improve the quality of Pharmacists' work as specialized healthcare providers.

INTRODUCTION

If Pharmacists do not take their place in science and in professional practice, our future is condemned to be like inflammation and apoptosis. (Personal communication with Professor Flávio Figueiredo, Pharm.D, MSc).

Perception and satisfaction of patients with healthcare services are increasingly being considered important parameters to assess the quality and competence of care providers and the outcomes and impacts of their services in patients' health and in society. The World Health Organization (WHO) defines quality of care as the coverage to which the care provision achieves the most favorable outcomes when balancing risks

and benefits in a given financial setting, and because of the worldwide rise in medication use in recent years, this subject has gained more attention among Pharmacists and pharmacy practice research (Schulz et al., 2001; Kheir et al., 2004; Patwardhan et al., 2014; Sakharkar et al., 2015; Shemeikka et al., 2015).

Pharmacy profession has improved to include the provision of services beyond the traditional role of medication dispensing. Pharmacists are highly accessible healthcare professionals considering also the availability, geographic distribution and location of pharmaceutical enterprises like drugstores and compounding pharmacies. Historically, the main role of pharmacy is to dispense medications and provide patients enough instructions regarding their correct use. The Pharmacist is usually the first professional addressed by a patient with minor or complex health issues, commonly due to the scarcity of physicians, or even due to financial barriers to private clinical services when public healthcare services cannot address patients' needs. Conversely, in spite of this context, differently from other health professionals, providing patient care is not an imperative activity for Pharmacists, as several technical fields of the profession (comprising both privative and non-privative activities) do not necessarily involve direct contact with patients (Hepler, 1996; Schulz et al., 2001; Kheir et al., 2004; Wiley et al., 2014; Penm et al., 2015).

The World Health Organization has pointed that more than half of the world population cannot access the medication they demand. Prices are often too high for people or health systems to afford, and therefore, spends on medicines are a major part of the total healthcare budget. Governments must control the cost of drugs through specific policies and make sure that essential medicines are not overpriced. Also, policies for pharmaceutical services must be included, given that the Pharmacists are the most appropriate professionals to provide the correct and safe use of medications, and to analyze, consider and include pharmacoeconomic and pharmacoepidemiological factors in the organization of drug dispensing (Malone et al., 2001; Murray et al., 2009; Penm et al., 2015).

In some countries, in addition to counseling patients on appropriate drug administration, dosage, side effects, storage and interactions, Pharmacists are allowed to prescribe over-the-counter and other types of medications in several countries, such as phytotherapics and homeopathic products, what can help patients to take decisions on self-treatment with medications. This helps to explain in parts why patients often seek advice in pharmacies, and frequently do not consider a physician consultation, which are also, sometimes, not accessible for patients, generally due to the scarcity of professionals. Nevertheless, there are several challenges for providing these services for patients with limitations such as low education, difficulties on reaching the Pharmacist, the need for individualized monitoring (due to the complexity of therapy), and reports of low quality services are growing worldwide. These facts have been requiring Pharmacists to rethink the way in which pharmacy practice is performed (Lewin, 2013; Sakthong et al., 2013; Sakharkar et al., 2015; Fisher et al., 2015; Malewski et al., 2015).

Pharmacy is a very dynamic profession, given that patients' and society needs regarding drug therapy are changing continually. Evidence-based pharmacy practices are the key to provide effective pharmaceutical services and to improve the quality of healthcare as a whole. In this sense, Pharmacists must move from being medication dispensers with focus in administrative and logistics management, to be patient-focused and clinically-oriented care providers, with more responsibility and commitment to improve their technical knowledge, but with a humanistic view of practice. Thus, the aim of this chapter is to discuss the implementation of effective strategies to expand the access of patients to pharmaceutical services focusing in PC, and ways to improve the quality of such services. Data regarding patients' views and satisfaction with Pharmacists' performance as a specialized healthcare provider, and Pharmacists' perception of receptiveness and evolution of patients will be also discussed in light of evidence-based practice (Straus, 2007; Sakharkar et al., 2015; Cho et al., 2015; Malewski et al., 2015).

BACKGROUND

Pharmaceutical Services: In Way of Changes

Pharmaceutical services are generally designed in agreement to medicines policies in order to ensure access, affordability, and delivery of essential medicines to the population. Usually, they comprise medication dispensing, counseling on rational use, and logistic organization of dispensing services accordingly to local epidemiologic data. Strategies for the rational use of medications are than planned to promote safe and cost-effective treatments, considering regulatory and quality standards defined by local laws. Pharmacists should, therefore, develop mechanisms for regular review or new proposals of formularies, guidelines and policies regarding drug dispensing and prescribing; therefore, developing trained human resources for this field is of paramount importance, and efforts have been made in several institutions to provide this improvement in different levels of pharmaceutical education, such as PharmBSc (Bachelor of Science in Pharmacy), PharmMS (Master of Science in Pharmacy) and PharmD (Doctor of Pharmacy) (Vijayanarayana et al., 2014).

Pharmaceutical services are among the most accessible healthcare assistance systems worldwide, being quite often provided without additional charges (beyond medication prices) by Pharmacists in enterprises like Drugstores and Compounding Pharmacies; yet, some of these services can be charged, for instance, pharmaceutical consultations, the time spent in blood pressure measurements or preparation of healing bandages. The published experience on the traditional way that pharmaceutical services are established and offered to the population has shown that they have historically been working relatively well for patients in conditions such as: a) common and controlled acute or chronic diseases, b) use of not many medications (like two or three formulations), c) simple therapeutic schemes, and d) adequate education level to understand pharmaceutical advising on rational use of medications (Straus, 2007; Citrome, 2011; Fisher et al., 2015; Gabr & Shams, 2015).

However, what can Pharmacists do to patients with limitations such as low literacy, difficulties on reaching the Pharmacist, or unusual needs like individualized care and monitoring for complex diseases and/or drug therapies?

The answer is neither simple nor easy, and varied barriers can be mentioned. However, these difficulties can be overcome with adequate strategic planning, training and management. In this chapter, I will present different strategies for improving and expanding pharmaceutical services which have provided encouraging results that strongly indicates their effectiveness in providing pharmaceutical services with equity, justice, and addressing patients' needs.

PHARMACEUTICAL CARE

Overview of the Implementation Process

Since the 1990s, Pharmaceutical Care (PC) has been described as an important service and element of pharmacy practice and healthcare, in which Pharmacists are responsible for the quality. Because of the extension of this subject, the approach of this chapter is limited to demonstrate how PC can influence pharmaceutical services to become more accessible and with a broader coverage of patients.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

PC is a pharmaceutical service designed to achieve definitive therapeutics outcomes through preventing or solving drug related problems, and is generally defined as a direct provision of drug related care by the Pharmacist through health education, in order to improve patients' quality of life when using medication. It represents a shift of practice in pharmacy from being drug product-oriented to a patient-oriented view (Hepler & Strand, 1990; Penna, 1990; Cipolle et al., 2004; Dias-Souza & Barros, 2012c). As described by Hepler (1996), PC services comprise:

1. Recognition and correct identification of clinical conditions requiring safe and efficient drug therapy;
2. Prescribing for definite outcomes;
3. Dispensing and patient counseling, involving the patient or family/caregiver in all decisions;
4. Monitoring and management of outcomes;
5. Documentation of all actions.

PC activities also include medication dispensing, providing education on drug use through patient counseling, drug use monitoring, preparation of formulations for parenteral nutrition, monitoring adverse drug reactions, development of drug use guidelines, and cooperation with the healthcare team; these are offered in a mutually beneficial exchange way, in which the patient asks and consents to be supported by the Pharmacist regarding pharmacotherapeutics needs, and the Pharmacist accepts the responsibility to provide drug therapy support with competence and commitment. The Pharmacist provides this service for one patient each time, but groups can also be reached by PC services, in consultations that vary in time and frequency according to the patient's needs (Dias-Souza & Barros, 2012a; Alturkia et al., 2013; Cheng et al., 2015).

The steps of pharmaceutical consultations include (but are not limited to):

1. Collection and organization of patient-specific information (such as demographic data, body mass index and blood pressure);
2. Identification of health problems;
3. Analysis of all the medication being used, in order to identify potential drug-related problems (DRP) like dosage form, therapeutic schemes, administration, and drug-drug and drug-food interactions;
4. Patient counseling on pharmacological and non-pharmacological management of the disease;
5. Monitoring of the desired outcomes through clinical investigations.

These steps will be discussed in the following paragraphs.

In PC services, the Pharmacist work in concert with the patient and other healthcare professionals to promote health, prevent diseases, and to assess, monitor, and when necessary, modify medication use in order to assure that drug therapy regimens are adequate, safe and therefore, effective. PC services should optimize quality of life regarding drug therapy, and achieve positive and definitive clinical outcomes within realistic financial expenditures (Malone et al., 2001; Wait, 2005; Straus, 2007).

The implementation of PC depends essentially on data collection and documentation systems that register patients' information, such as demographic data and clinical history, communications with other professionals like nutritionists, physician in charge, dentist, and also for scientific research purposes, like the study of medication use profile. Moreover, specific equipments are needed to assess drug therapy adherence and effectiveness, and also patient education materials, as described in the previous section.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Interactions between the Pharmacist in charge and the patient (and the family and/or caregivers, when necessary) should occur to assure efficient mutual communication and cooperation, and that the decision making process on drug therapy is shared by the Pharmacist and the patient. The Pharmacist uses technical knowledge and skills to optimize drug therapy and the patient agrees to supply personal information and actively participate in the process of PC (Pispati, 2003; Cohen et al., 2009; Schmelz et al., 2010).

Nevertheless, varied barriers have been described for the implementation and success of PC services (Schulz et al., 2001; Lada and Delgado, 2007; Maher et al., 2011; Kaufmann et al., 2015; Kuhmmer et al., 2015; Pauwels et al., 2015; Srivastava & McGuire, 2015), and some of them will be briefly presented:

- **Access to Effective Drug Information Resources:** Some professionals have scarce training in searching for evidence-based data in articles, for example. This can be overcome with specific training in articles search platforms;
- **Access to Full Patient Information:** This happens especially when the Pharmacist is dealing with the caregiver and not directly with the patient, or when the patient has some type of limitation that affects this parameter;
- **PC Courses in Graduate and Undergraduate Curricula:** Many pharmacy faculties still do not give attention to social activities of Pharmacists;
- **Comprehensive Understanding to Care Concepts:** PC is still often regarded as pharmaceutical assistance and vice-versa;
- **Continuity of Quality Improvement:** The lack of interest and motivation for quality improvement is very common when the Pharmacist is not properly valued;
- **Counseling Guideline or Plan for Effective Patient Counseling:** This is a critical point in PC: although patients have different needs, all steps in PC must be standardized when possible, to guarantee that care will be delivered to all patients in a similar way;
- Disparity of cultures and believes, often affecting the use of medication;
- **Poor Documentation of the Provided Care:** For an effective follow-up, all actions must be registered and properly saved;
- **Fear of Change to New Profession and Poor Education in Communication Skill:** The lack of training in these is the most critical issue regarding human resources in PC. However, it is possible that trainings with strategies like the simulated patient may help to improve this ability;
- Education in skills needed to deal with technology;
- Financial capital to start the service;
- Improper utilization of registration formularies;
- Inadequate private counseling area;
- **Lack of Insurance Assistance:** Most insurance services world-wide do not cover pharmaceutical services at all;
- **Legislation Barriers:** In some countries, pharmacy clinical practice is still poorly regulated, what may cause doubts when implementing PC;
- **Pharmacy Location:** Sometimes, the location makes it difficult for patients to reach the Pharmacist;
- **Professional Resistance to Interactions with the Pharmacist:** Often, some prescribing or care professionals do not interact with the Pharmacist. A good alternative is to try a personal contact and provide scientific literature as an ice breaker;

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

- **Patient Interest:** Not all patients will be interested in PC. When the patient is adult and in his own, there is not much to do but to show the advantages of PC. When the patients demands family or caregiver support, it is important that the Pharmacist clearly shows how much the service can help the improvement of quality of life, promote financial savings and adequations on the use of medication;
- **Patient Literacy and Socioeconomic Status:** This is also critical for the patient that demands instructions. Memorizing is not always possible because of the load of information. However, some alternatives will be shown further in this chapter;
- **Profession Fees to Reward Care Services:** PC services are charged in some countries. Although it is a fair practice, not all patients with real need of PC services can afford them;
- **Software for Medication Assessment Support:** To avoid handwritten formularies, softwares for registration of the activities are necessary;
- Space and layout within the pharmacy;
- Trained Staff.

Pharmacists must collect subjective and objective information regarding the patient's general health status, past medical history, medication use history, social habits history (like alcohol use, smoking), diet, physical activities routine history, history of the current clinical condition, financial and insurance status, when necessary. To perform this, Pharmacists should ask patients for access to medical prescriptions, charts and reports, and should create health/physical assessment instruments. Some validated instruments have been published elsewhere, and often, adaptations are not required. Furthermore, interviews with family members or the caregiver are important, mainly for pediatric or senior patients. Other healthcare providers including physicians, nurses, and mid-level practitioners should also be contacted when necessary. All this information will form the basis for decisions on the development and modification of therapeutic schemes. Therefore, patient data must be updated, accurate, complete, organized and recorded with operational standard procedures, to assure that they are readily retrievable and recorded confidentially (Stewart et al., 1995; Hepler, 1996; Cipolle et al., 1998; Isetts et al., 2003; Dias-Souza et al., 2012a; Holtzman et al., 2015; Kaló et al., 2015).

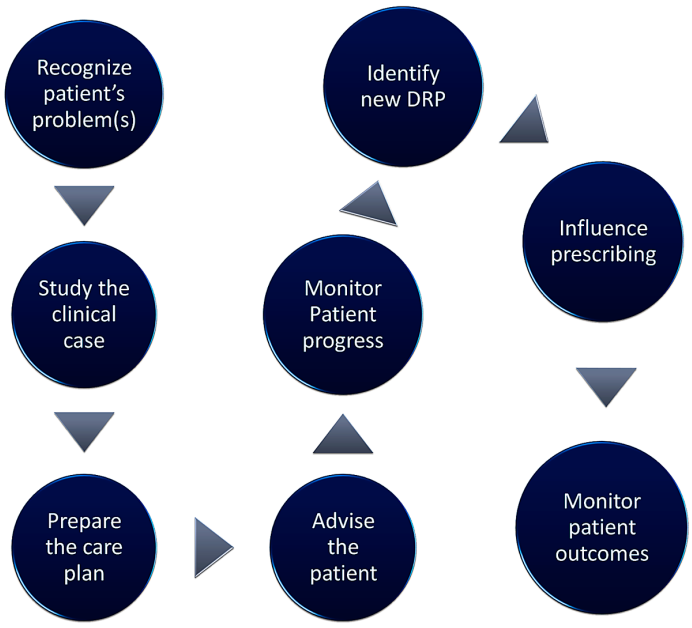
Pharmaceutical consultations have professional limitations such as providing diagnosis; however, the experience of patients in pharmaceutical consultations generates opinions and views for both patients and Pharmacists, which are important tolls to evaluate and optimize the quality of services and to assess the need for new services. To perform PC services, Pharmacists must have characteristics like being a caregiver, communicator, decision-maker, teacher, researcher, leader, and manager, in order to offer individualized care to patients (Hepler, 1996; Cipolle et al., 1998). Conversely, the experience reported in the literature describes lack of training in such abilities during academic life (Sakharkar et al., 2015).

All the information is then evaluated and a drug therapy plan is developed with the patient. Based on a thorough understanding of the clinical picture of the patient and the treatment options available and affordable, the Pharmacist plans an outcomes-oriented drug therapy plan. For this, the Pharmacist considers not only clinical aspects of the disease, but also psychological and social consequences, including the complexity of therapy and alternatives to improve patient adherence (Hepler & Strand, 1990; Cipolle et al., 2004; Weiss et al., 2015).

Regarding medication use, the patient should be instructed about side effects, important negative or positive interactions with food and other medication, and eventually, of other therapeutic options and non-pharmacological complementary alternatives. The therapeutic therapy plan must be documented in

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

the patient's pharmacy record and communicated to the patient's other healthcare providers when necessary. The therapeutic plan must be completely explained to the patient, including the responsibilities shared with the Pharmacist. Information should be provided to the patient at a level that the patient will understand; thus, appropriate language should be used, avoiding, for example, detailing drug mechanism of action. At the end of the consultation, the patient must know how to take the medication, why it is being administered, for how long it will last, risks and benefits of the use and what other health-related behaviors can increase quality of life (Seybert et al., 2008; Dias-Souza & Barros, 2012b; Dias-Souza & Barros, 2012c; Ross et al., 2015).



A short guide on how to start a PC consultation will be described as follows, and will be summarized in Figure 1:

Data Collection

An initial interview should be conducted with the patient/family/caregiver for establishing a professional working relationship and to open the patient's record, with confidentiality and privacy. In this first interview, all patient's needs concerning drug therapy should be met, therefore, sufficient time (often 30 to 60 minutes) is spent to assure that questions and answers are provided without embarrassment or hurry. The interviewee should be comfortable with the questions, and for scientific and professional protection of both Pharmacist and patient, a consenting form approved by an Ethics committee should be signed by them (Penna, 1990; Kroenke, 2001; Cadogan & Ryder, 2015).

Standard procedures should be used to systematically record patient-specific subjective information, including health and activity status, past medical history, medication history, social history (including economic situation), family history, and history of present illness. Patients' perceptions, thoughts, beliefs

Figure 1. PC consultation flow summary. Modified from Hepler (1996).

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

and feelings of the diseases should be included on the formulary. When necessary, physical assessment techniques like blood-pressure monitoring, capillary measurements of lipids and sugars, should be appropriately performed to obtain patient-specific objective information (Toubro et al., 1999; Schwartz et al., 2008; Sancar et al., 2011; Safaeian et al., 2015).

The Pharmacist must guarantee that patients' records are properly organized, kept updated, and with all important points discussed in all consultations.

Evaluation of the Information Obtained at the Interview

After the patient left the consultation office, the Pharmacist begins an evaluation of the subjective and objective information gathered from the patient and 1) investigates what drug-related problems are happening or can happen in the current clinical picture; 2) analyses opportunities for optimizing the safety, effectiveness, and financial aspects of the drug therapy; 3) discuss the conclusions with the patient in the second consultation. The discussions with the patient, as necessary and appropriate, should guarantee an appropriate understanding of the clinical picture, treatment strategies and administration schemes, and what will be necessary to do for an effective management (Hepler, 1996; Cipolle et al., 1998; Cipolle et al., 2004; Cheng et al., 2013; Al-Quteimat & Amer, 2014).

Preparation of the Care Plan

This preparation happens during step b. The Pharmacist identifies, evaluates and then chooses the most appropriate actions to improve and/or assure the safety, effectiveness, and/or cost-effectiveness of current or planned drug therapy, and to minimize the existing or potential drug-related problems. The care plan is prepared according to the desired outcome. The plan may include work with the patient as well as with other health professionals to provide therapy protocol adjustments or to modify prescribed drug therapy, implement clinical monitoring, recommend alterations on diet, add non-prescription medications or non-pharmacological treatments, or recommend a visit to a specific professional (Spencer et al., 2005; Montgomery et al., 2008; Petrillo et al., 2011; Vijayanarayana et al., 2014).

For each identified problem, the Pharmacist should consider each of the patient's needs and determine the desirable and mutually agreed outcome and incorporate these to the care plan. The plan may include specific disease state and drug therapy endpoints and monitoring endpoints. The Pharmacist reviews the plan and desirable outcomes with the patient and with other healthcare professionals when it is necessary (Odedina & Segal, 1996; Campbell & Saulie, 1998).

Implementing the Care Plan

The Pharmacist take the steps necessary to implement the plan, which include contacting other health professionals when necessary for any modifications on drug therapy, counseling the patient and/or the caregiver about the correct use of the medication and all problems associated to the incorrect use, coordinate the acquisition of medications and related supplies and begin the clinical monitoring. The Pharmacist should maximize patients' understanding and involvement in the care plan, guaranteeing that the parameters for drug therapy monitoring like blood pressure, molecular markers, blood glucose and cholesterol testing, are made and understood by the patient, family and the caregiver (Moore, 1998; Spitzer et al., 2001; Diez-Quevedo et al., 2001; Ojasalo, 2001).

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

The patient should be instructed on how to properly use all medications and related products when necessary. Information should be provided to the patient in an easy way to understand. All this information must be registered in the pharmacy record, as well as the steps taken to implement the plan including the appropriate baseline monitoring parameters (Knapp et al., 2004; Spencer et al., 2005; Austin et al., 2006, Nkansah et al., 2008).

Monitoring Outcomes and Modifying the Care Plan

The Pharmacist should review subjective and objective monitoring parameters in order to determine if the desired outcomes will be achieved as outlined in the drug therapy plan. If any problems are detected, the Pharmacist must make the required modifications with the patient, family and caregiver. As progress towards outcomes is achieved, the Pharmacist should provide positive reinforcement and update the care plan. The Pharmacist uses appropriate professional judgment to assess the need to notify other healthcare professionals involved in the patient's case about the registered evolutions (Classen et al. 2002; Brown et al., 2003; Cranor & Christensen, 2003; Malone et al., 2003; Osterberg & Blaschke, 2005; Scuffham et al., 2008; Fiz et al., 2011)

Establishing evidence-based practice is important for effective, updated and relevant PC services. Furthermore, the implementation of PC is relevant to patients because not only drug therapy will be optimized, but complex pharmacological regimens prescribed may be restructured or simplified by the Pharmacist in order to make it more understandable to the patient. This becomes even more important when we consider that a single patient may visit more than one physician in a given clinical condition and get different prescriptions, and the communication among them about drug prescription is often insufficient. Additionally, medication costs often consume a significant proportion of patients' and public health financial resources, what makes PC services economically relevant. Different pharmacoeconomics analysis described that significant financial savings could be achieved by patients, institutions and health insurances through PC services (Isetts et al., 2003; Kiel & McCord, 2005; Morello et al., 2006; Nkansah et al., 2008; Dias-Souza & Barros, 2012b; Lewin, 2013).

Different methodologies of PC have been used worldwide, and the most explored (and published) will be presented briefly:

A. **PWDT (Pharmacists Workup of Drug Therapy):** In this method, patients are assessed by a single Pharmacist for the all drugs used for any health problems that the patient might be affected by, and the DRP are analyzed for each formulation used. Therefore, if the patient has migraine and diabetes, the same Pharmacist is responsible for optimizing the drug therapy of both diseases (Isetts et al., 2003; Kiel & McCord, 2005).
B. **TOM (Therapeutic Outcomes Monitoring):** In this method, patients are assessed by more than one Pharmacist for the drugs used for each health problem that the patient might be affected by, and the DRP are analyzed for each formulation used. Therefore, if the patient has asthma and arthritis, a specialist Clinical Pharmacist in asthma and another, specialist in arthritis, shall be visited (Dias-Souza & Barros, 2012b; Dias-Souza & Barros, 2012c)
C. **Dáder:** This method was developed by a Spanish group of PC headed by Maria José Fáus-Dáder, and has similarities with PWDT in its organization and coverage of diseases, but DRP are analyzed in a different way. This method is widely used also in Latin America (Amariles et al., 2012).

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Other methodologies for PC services include FARM (Findings, Assessment, Resolution and Monitoring), DOT (Direct Observed Treatment), and SOAP (Subject, Objective, Assessment, Planning) (Amariles et al., 2012).

Providing Written Information in PC

A critical point regarding PC is that most of the counseling offered by Pharmacists to patients is provided orally, and hardly ever the patient or the Pharmacists take notes of the information in a standardized and validated way. As a result, patients may misunderstand or forget important details like drug onset of action and side effects, leading to poor compliance problems and negative results. Doubts regarding the need for therapy may arise and complex therapeutic schemes, usually difficult to be managed by patients without professional support, also contributes to poor compliance. The use of written and/or pictorial aids and other educational approaches is still scarce in pharmacy practice, and here, I would like to encourage the reader to explore this resource to improve the access of patients to pharmaceutical services. In this sense, previous works of our group provided evidence of the relevance of written information for patient counseling and education on drug administration (Worley-Louis et al., 2003; Worley et al., 2007; Seybert et al., 2008; Dias-Souza & Andrade, 2010; Dias-Souza & Barros, 2012c, Khan et al., 2013).

A clinical case of chronic pain in an elderly patient had drawn our attention at first: because of the use of several medications, the patient had difficulties in administrating them correctly, and several interactions were detected in the first pharmaceutical consultation. We reorganized the therapeutic scheme and provided handwritten information in a simple and accessible language such that the elderly patient could easily understand. As the clinical monitoring followed, the evolution of the patient was positive and pain was finally under pharmacological control. We recommended physical therapy sections for the patient, and advised for a clinical-functional assessment by a Physiotherapist (Dias-Souza & Andrade, 2010).

Nevertheless, all this was directed for a single patient. How to deal with several people that simultaneously demand specific written information like this patient? And how to do this for so many possible medications – isolated or combined – in compounding pharmacies or drugstores? A possible answer comes in a study developed by our group. The development of drug use instructional cards (DUIC) for different pharmacological groups and its use in compounding pharmacies was described in 2012 for the first time (Dias-Souza & Barros, 2012c).

The DUICs were developed due to a rising demand of basic advising on the correct use of medications on the pharmaceutical setting where the work was developed (a Brazilian compounding pharmacy located at the state of Minas Gerais). Using patients' complaint formularies (PCF) – a document that the good manufacturing practices (GMP) laws from the National Sanitation Regulatory Agency (ANVISA, an agency equivalent to the FDA in the U.S.A.) obligate compounding pharmacies to have in order to register any complaints from patients or clients – we have explored the most frequent drug-related problems to delineate how the DUICs should be designed. The parameters we considered were:

1. Drug-drug interactions
2. Drug-food interactions
3. Correct way and time of administration
4. Storing the dosage form
5. Experienced side effects and potential toxicity

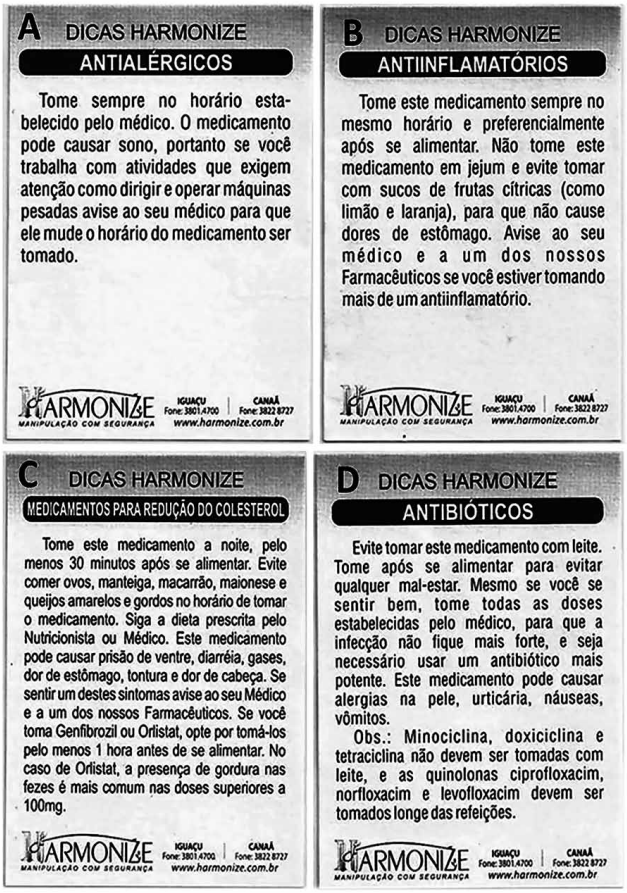
EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

After analyzing these data, we performed an extensive literature review for collecting technical information for correct drug using, regarding:

1. Most common drugs and indication;
2. Pharmacokinetics and metabolism;
3. Drug-drug interactions (obtained at the drug interaction checker in Medscape website);
4. Drug-food interactions;
5. Basic Nutritional Support;
6. Best time of administration;
7. Pregnancy, lactation and fertility impairment warnings;
8. Contraindications;
9. Common Clinical Adverse Reactions.

DUICs were then developed for the following groups:

1. Antihistamines;
2. Antimicrobials;
3. Anti-hypertensives;
4. Anti-lipemics;
5. Proton pump inhibitors
6. Non Steroidal Anti-inflammatory Drugs (NSAID);
7. Psychotropic drugs



After, the design was created and adjusted for the size of the document, such that it could be attached to the medication that was dispensed through the delivery service or at the counter. DUICs samples (in Portuguese) are shown in Figure 2.

We showed through our data that the DUICs not only were effective in counseling patients in a standardized way, but also improved telepharmacy services: the basic instructions provided in the DUICs could be assimilated by non-Pharmacists attendants, and some basic information about drug use could be rapidly provided for patients. Although the DUICs were planned (and are still being used) for compounded medication, the same instructional material can be adapted for industrialized medication, for which, information commonly found on package inserts has been described as poorly designed by professionals and not completely understood by patients. Also, patients often describe that written information on prescription drug labels are confusing or incomplete.

To overcome these problems, Kripalani et al. (2007) developed illustrated medication schedules for helping low-literacy patients to administrate medications correctly. The development of the cards design began by raising the needs of the patients through surveying local Pharmacists by telephone and posted emails on national pharmacy list servers, asking about the use of medication aids, visuals, or other patient education tools. Physicians with expertise in medication adherence, patient education, and literacy helped to draft the cards, using pictures to illustrate instructions to follow drug therapy schedules. A multidisciplinary team of healthcare providers then reviewed the content and format of the design draft. Twelve patients of different age and educational attainment reviewed sample pill cards to provide input into the types of pictures used, the size of the text and overall document, and the desired content. The instrument could maximize comprehension across levels of health literacy, providing only the most es-

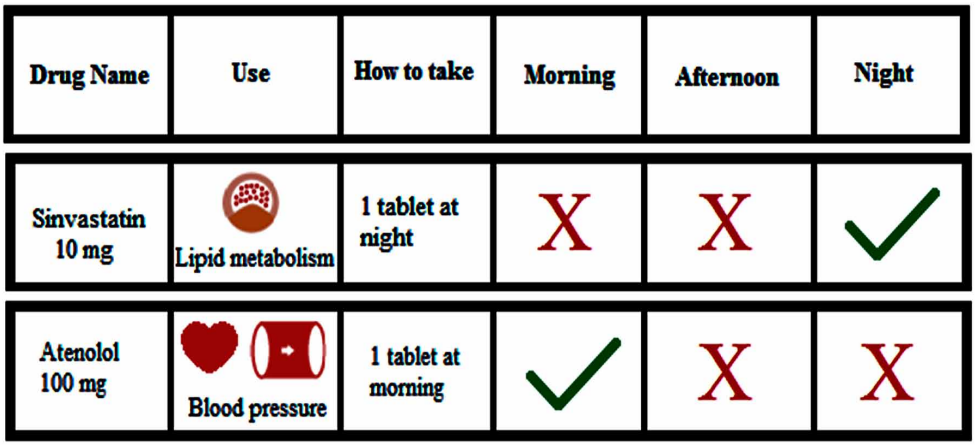
Figure 2. DUIC samples (available only in Portuguese) developed by Dias-Souza & Barros (2012c): a) antihistamine drugs; b) NSAID; c) antilipemic drugs; d) antimicrobials. DUICs are still being distributed for patients that are costumers of the compounding pharmacy where the study was conducted

sential medication instructions like name, purpose, appearance, and time of administration. Patients with inadequate or marginal literacy skills, less than high school education, or cognitive impairment were most likely to refer to the card on a regular basis initially and after 3 months. Patients found it easy to understand and helpful for remembering important medication information, such as the name, purpose, or time of administration.

Kassardjian et al. (2008) validated a Pictorial Representation of Illness and Self Measure (PRISM) as a measure of suffering in patients with chronic non-cancer pain. Patients were recruited from 2 hospital pain clinics, and the majority of them were middle-aged women, in whom chronic pain is more prevalent and also more treated with medication. For that task, patients were shown a letter size white paper with a fixed yellow circle glued in the bottom left-hand corner of the piece of paper. Then, they were asked to imagine that the paper represented his/her life and that the yellow disk represented his/her concept of self. They were given a red paper disk representing their pain and asked to glue it in a location related to the "self" disk, reflecting the impact of pain into their lives. The same request was made regarding work, family, spouse/partner and recreation. Patients glued the disks onto the page in whatever order

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

they wanted. Blind patients also completed the task, indicating that it also behaved as a tactile tool. Eight main parameters were assessed: Physical functioning, role-physical, bodily pain, general health, vitality, social functioning, role-emotional, and mental health. Higher scores in a scale of 0–100 indicated better health-related quality of life. Different situations were identified using this PRISM system: Patients reported that their close relatives were a negative influence to the treatment because they were overly controlling, or did not believe in the state of disability due to pain. Patients with high scores felt controlled by partners or family members, or emotionally distant from them. It was also reported by group of patients that their partner and family have either very little influence over their lives, or a significant negative influence. Patients found PRISM thought-provoking, and it was described by the authors as a quick, simple, and manageable tool for patients with chronic pain to complete.



A randomized blind trial comparing picture-based versus prose-based information pamphlets was conducted by Thompson et al. (2010). The authors compared memory, comprehension, and preference for medication information presented in a prose-based medication information pamphlet versus a pictorial-based information pamphlet. Specific information regarding methotrexate was used in this study. A total of 100 participants aged 18–65 years of age, who had not completed high school, could read English, and had no prior knowledge about methotrexate were included. The (better) effects of pamphlet type were assessed using immediate free recall, cued recall and comprehension. In the end, each participant was shown a card displaying both the picture and prose-based pamphlets and asked to decide which pamphlet they felt to be most visually appealing, which they would rather receive, which looked more useful, and which was easier to read. According to the statistical analysis, no differences were detected between picture and prose pamphlets in free recall, cued recall, and comprehension either immediately or after a 1-week interval, and the pictorial pamphlet was preferred over the prose-based pamphlet.

Mohan et al. (2013) conducted research with focus groups and interviews with Latino patients with diabetes at two safety net clinics in the USA to understand medication taking practices and perceptions of illustrated medication instructions. They explored PictureRx™, a software platform that generates illustrated, patient-centered medication lists in a daily medication schedule. The following essential information for patients is included: name, dose, frequency, purpose, and special instructions when needed. The design of PictureRx cards (Figure 3) was evidence-based, drawing on research and best practices for the creation of patient education materials with illustrations for medication instructions and other health-related information. Patients reported confidence in being able to take medications and expressed preference for illustrated medication instructions, which could overcome patients' difficulties on administrating the medication.

Pictorial representations of clinical scenarios for asthmatic patients and of commonly used inhalers devices were developed by Roberts et al. (2010). Initial images were developed, designed and reviewed in consultation with medical and nursing respiratory members of staff before testing it with patients. A computerized software package was developed for the preparation of personalized asthma action plans during a consultation: the health professional should select the options according to the patient's needs. Following a series of sequential screens, the professional identifies appropriate images and scenarios to build a plan. In the end, a pictorial action plan is generated, which should be printed and provided to the patient. The software package automatically checks dosages used, and maximizes inhaled therapy. When the patient uses peak flow for self-monitoring, the program calculates the personalized action levels based upon the reported best peak flow. Users can print out a picture only plan, a words only version or a plan containing pictures and words. According to the authors, the pictorial care plans are

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Adapted schematic sample of how the charts for drug information are disposed on the works developed by Kripalani et al. (2007) and Mohan et al (2013)

quickly prepared to be printed for the patient to take away in several formats, and the data can be stored in the patient's record.

A recent work evaluated the efficacy of a pictorial medication sheet to improve adherence in patients with heart failure and cognitive impairment (Hawkins & Firek, 2014). A total of 36 patients were enrolled. Four study visits spread over approximately four months were performed. At visit one, subjects were asked to bring in all of their regularly prescribed medication for a direct count of administered tablets. After 30 days, in visit two, another tablet count was performed, and adherence was estimated. The subject then received a customized pictorial medication sheet with brief instruction on how to use the pictorial medication sheet that represented their actual prescribed medication regimen. Subjects were asked to use the new sheet in place of any prior medication instruction sheet they may have been using. The medication sheet included of images of the subject's current medications printed in full color and dose range, arranged in columns for morning, noon, and evening administrations. Descriptions of the medication name, indication and dose were also included. Authors reported that although medication adherence was poor, statistically significant improvements (described in tablets counting) were detected after the interventions.

Nevertheless, written information must be used properly, and should be used regardless of problems not related to the patient. A negative example in this sense was described. Hamrosi et al. (2013) examined and compared the use and provision of written medicine information in Australia, focusing in Consumer Medicine Information (CMI) - available for medicines as package inserts, computer prints, or leaflets - by Pharmacists and consumers. The reasons surrounding readership and provision of the CMI and comparisons on its use by both consumers and pharmacists were also investigated. A total of 1000 consumers and 1100 Pharmacists were interviewed by postal or telephone surveys. The authors found that 66% of consumers usually read the CMI looking for information regarding side effects and clinical use of the medication. Reasons mentioned for not reading the CMI comprised previous experience with the medications, enough information was provided verbally from the Pharmacist, and also that the document was too long or contained too much information. Interestingly, the disparity detected by the authors amongst the types of written medicine received by patients and provided by pharmacists is strongly suggestive of incomplete/inadequate (or both) provision of pharmaceutical services. Almost

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

90% of pharmacists reported providing package inserts, but 88% of consumers reported receiving them when provided with written medicine information. Personalized computer-generated CMI was provided by 99% of pharmacists, but only 37% of consumers reported receiving it. Around 40% of pharmacists and 25% of GPs (n = 45) also reported providing loose leaflets/brochures yet only 7% (n = 47) of consumers reported receipt.

Telepharmacy Services

In this section, I would like to introduce the need and the context of telepharmacy services, a powerful tool for expanding pharmaceutical services when used correctly. According to the World Health Organization (WHO, 2010), telemedicine is defined as the delivery of healthcare services, where distance is a critical factor using information and communication technologies for the exchange of information for diagnosis, treatment and prevention of diseases, research and for the continuing education of healthcare providers, all in the interests of advancing the health of individuals and their communities. Telepharmacy, following the example of telemedicine, offers pharmaceutical services at a distance, i.e., with the Pharmacist and patient communicating through telephone, videoconferencing systems such as Skype®, or any online communication system such as WhatsApp® and social networks. Online chat services available at the website of the pharmacy are also a good alternative.

And why this is important? Telepharmacy technologies can improve patient access to pharmaceutical services beyond remote medication dispensing, including PC. This sort of communication is especially important when the patient cannot reach the Pharmacist due to several possible limitations like mobility issues (the patient does not have access to a vehicle), or if the patient is affected by a disease that impairs the patient to meet the Pharmacist (Garrelts et al., 2010).

Nevertheless, to use this sort of service, a Pharmacist must work exclusively on it, and must have trained people on using the system for technical support or as workmates, to make the service work in a normal flow. In this service, patients can be advised about any aspects of the medication. Also, as some are not comfortable on going to the pharmacy for several reasons (embarrassment on talking to the Pharmacist face-to-face about the health problem, embarrassment on talking about it in public), the service may make the patient more comfortable on talking to the Pharmacist through typing or by phone.

Bynum et al. (2001) assessed the effect of telepharmacy counseling and using interactive compressed video, on how to use the asthma inhaler and patient satisfaction among adolescents with asthma. The telepharmacy service provided accessible education regarding asthma inhaler techniques for adolescents.

Moser et al. (2004) found 4136 documents using the search term “telemedicine” in MEDLINE from 1964 to 2003. They reported significant correlations between publications per million inhabitants and GDP per capita. Fatehi and Wootton (2012) examined the occurrence of the terms “telemedicine”, “telehealth”, and “e-health” in the Scopus database and a total of 11.642 documents were found in 2012. They found that “telemedicine” was the most common term with 8.028 documents.

Stubbings et al. (2005) described a telepharmacy call center service that was developed at a multidisciplinary health service through collaboration among the health professionals and the health plan to care for patients with medication-related questions. Pharmacists work close to physicians, nurses, and service associates of the call center. The team answered approximately 1.200 calls daily, regarding their transition into the health insurance plan and drug therapy questions. The service improved the quality and cost-effectiveness of drug therapy regimens and significant cost savings were registered.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

The group of Lam et al. (2009) reported telepharmacy-related services and outcomes in western Washington State (USA) from 2007 to 2008. Five network clinics without in-house pharmacies were remotely connected to a central pharmacy to provide telepharmacy services, and automated drug dispensing system (ADDS) units, webcams, and electronic medical charts were used to provide remote medication order processing/dispensing, patient counseling, refill authorizations, and medication assistance referral services. Patient demographics, numbers of dispensed medications, patient consultations, and refill authorizations were registered, and service referrals, Pharmacist feedback and workflow changes as well. Antimicrobial drugs were the most frequently dispensed medication, and Pharmacists described webcam-enabled interviews as an excellent method for better privacy and longer counseling.

Garrelts et al. (2010) implemented a telepharmacy service at five hospitals from a Catholic, nonprofit, integrated delivery network health system. Telepharmacy services were provided by a team of Pharmacists employed by the health system. Using a virtual private network or terminal server, Pharmacists directly accessed hospital servers and information systems to conduct their work. The time spent in routine orders of medication reduced significantly after telepharmacy services were implemented. The number of clinical interventions documented increased and annual savings reached 1 million dollars.

Sankaranarayanan et al. (2014) documented remote Pharmacist interventions for patients at eight rural hospitals in the Midwestern United States during prospective prescription order review/entry from 2008 to 2011. Remote Pharmacists' interventions were divided in three broader-level definitions: (a) interventions in interactions and potential interactions, contraindications, adverse effects, drug product selection, drug regimen and recommendations, (b) patient medication management regarding therapy review and action, and (c) health system-centered medication use process, regarding medication prescribing, transcribing and documenting, administering, and monitoring clinical results. Frequencies of intervention levels were compared by year, hospital, remote Pharmacist, and hospital pharmacy status. Frequency of interventions significantly increased each year, and differed significantly across the hospitals, suggesting that patients' needs were addressed particularly.

Service Quality Perspectives

The quality of healthcare services, included the ones provided by Pharmacists, is a topic of intense discussion. The aim of this section is to briefly present important aspects of the services that should be focused such that patients' perspectives are built on positive experiences.

As mentioned, Pharmacists are key professionals to improve medication compliance among users, given their availability of contact with patients, specific knowledge and skills. The burden of several diseases can be reduced through improving medication compliance, and the implementation of clinical pharmaceutical services has positive impacts on patient care, satisfaction and perspectives on these services. Patients' perceived quality of interaction with the Pharmacist, service facilities and outcomes have a significant effect on a patient's choice to use the medication or not (Khan et al., 2013; Al-Quteimat et al., 2014; Fisher et al., 2015).

Managing quality is clearly not a simple task, given that not only technical and regulatory points of clinical services are involved, but values, knowledge and behavior of the Pharmacists regarding patient care are included. Although there is some agreement on how Pharmacists can manage patients' therapy-related needs, there is less agreement on whether the pharmacists are able to meet those needs. Services are generally designed to be broad enough to meet several clinical needs of patients - such as the so called cognitive services (characterized by direct interaction between patient and pharmacist, making

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

use of the pharmacist's knowledge), however, due to the exposed reasons, patients' perspectives of the services are variable. Also, standards to evaluate services vary among patients, once previous experiences are the starting point. All this data, however, is essential for understanding patients' interaction, satisfaction and trust in the Pharmacist (Cho et al., 2015; Malewski et al., 2015; Gabr & Shams, 2015).

Understanding the intricate communication between these features helps us to improve the quality of services. Clinical effectiveness, safety, positive outcomes, patient experiences (self-rated health), proximity, availability and access are the main items to build patients perspectives of the services. However, the pressures for the development of adequate and efficient services can sometimes present divergent logics considering the economic aspects of an enterprise. This technical difficulty should be overcome and negotiated in a way that economic needs of productivity are in line with professional and patients' values regarding high quality health services. This is not a simple endeavor, but in a middle-term perspective, these actions support the growth of the enterprise, as more people tend to look for the service after patients spread the word about the experiences with the service (Dias-Souza & Barros, 2012a; Kaufmann et al., 2015; Kuhmmer et al., 2015).

When patients are engaged in the development of services, it is more likely that they will use these services more frequently (whenever it is necessary) and will be more compliant to recommended treatment plans, leading to the expected health outcomes. The existence of high quality patient-centered services based on reliable and safe patient-Pharmacists relationships, the convenience and ease of access to services and the responsiveness to their therapeutic needs - and when adequate, the quick and safe provision of medication supply, are elements of paramount importance for patients' compliance and development of positive perspectives. These are also important requirements of the patient and caregivers as clients of the pharmaceutical enterprise, especially if the clinical services are charged. Young, highly educated consumers and recently diagnosed patients tend to consider these items with even more importance (Ross et al., 2015; Safaeian et al., 2015).

CONCLUSION

Strategies on expanding and improving pharmaceutical services have been presented in opportunities that are still poorly explored in daily practice: the provision of written information for patients and telepharmacy services. Written information may help patients to remember and reinforce how medication should be correctly taken, and in case of low literacy, alternatives of pictorial support were discussed. Telepharmacy services may help patients and health professionals to quickly reach the Pharmacist and solve drug-related problems, especially when there mobility issues. The implementation of these services in PC context is not a simple endeavor; however, to overcome the technical difficulties, the Pharmacist must work together with patients, families and caregivers, generating solid services, and along with other health professionals. This team work is the key for improving and expanding pharmaceutical services.

ACKNOWLEDGMENT

The author is thankful to GPqFAR (*Integrated Pharmacology and Drug Interactions Research group*) scientists and students, for the outstanding work developed so far. MVDS is head of GPqFAR and is currently at the Federal University of Minas Gerais, Brazil; his research is supported by grants from Fundação de Amparo à Pesquisa do Estado de Minas Gerais (FAPEMIG).

KEY TERMS AND DEFINITIONS

Drug-Related Problems: Any problem on drug therapy, such as side effects, high cost, allergies, poor adhesion to therapy, etc.

Pharmaceutical Care: A model of pharmacy practice in which the Pharmacist takes the responsibility of the pharmacological treatment of a patient and optimizes it, preventing drug-related problems.

Pharmaceutical Consultations: An ambulatorial service provided by the Pharmacist to conduct clinical interviews and assessment; however, no clinical diagnosis of diseases is made.

Pharmaceutical Counseling: A pharmaceutical service to provide patients the most relevant information on the best way of drug use.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Pharmaceutical Enterprise: Any place where a Pharmacist works with medication or subjects related to medication, like manufacturing industries, compounding pharmacies or drugstores.

Pharmaceutical Services: Activities developed by the Pharmacist for the wellbeing of a patient, considering (or not) drug use.

Phytotherapics: Plant-based natural products.

Side Effects: Adverse reactions due to incorrect or even correct use of medications.

Chapter 15
An Overview of Therapeutic Applications

Sandeep Waghulde
University of Mumbai, India

Pravin Naik
University of Mumbai, India

ABSTRACT

Over the last few years' great advances have been made on the development drug delivery systems for different purposes for targeting the diseased conditions. Novel drug delivery originates from polymers or associated with some devices is generally related with the emergence of novel characteristics. These changes are what eventually comprise the value of drug delivery system and Novel drug delivery system. Novel properties become existed without making new materials. Novel drug delivery system comparable to traditional system, following Targeted Drug Delivery System (TDDS) is also called targeting drug system. A new drug delivery system makes the drugs densely gather pathological-change structures, and has an improved healing effect and less toxic side effects. The drugs can improve the strength of pharmacological action and reduce the bad effect all over the body, for they release in the target organs.

INTRODUCTION

The method of treating infection and illness as we enter in next era twenty first century includes the subsequent forms of treatment a. surgery, b. psychotherapy, c. physical therapy, d. radiation and e. chemo or pharmacotherapy. The most commonly used is treatment method (Banker, Siepmann; Rhodes, 2002).

Novel drug delivery system whether it originates from polymers or associated with some devices is generally related with the emergence of novel characteristics. The most extensive results of their minute size, dosage form or targets are without distrust the change in their final properties. Next in significance are changes in other properties, both physical and chemical. These changes are what eventually comprise the value of drug delivery system and Novel drug delivery system. Novel properties become existed without making new materials.

Role of Targeted Drug Delivery System (TDDS)

Novel drug delivery system comparable to traditional system, following Targeted drug delivery system (TDDS) is also called targeting drug system'. A new drug delivery system makes the drugs densely gather pathological-change structures, and has an improved healing effect and less toxic side effects. The drugs can improve the strength of pharmacological action and reduce the bad effect all over the body, for they release in the target organs (Chaturvedi et al., 2011).

Carrier-mediated drug delivery has emerged as a powerful line of attack for the action of various pathologies. The therapeutic index of conventional and novel drugs is enhanced via the increase of specificity due to target of drugs to a particular tissue, cell or intracellular segment, the control over release kinetics, the protection of the active agent or a combination of the above. Nanoparticles (NPs) were proposed as drug carriers over 30 years ago and have received increasing attention since, mainly due to their stability, improved loading capabilities and control over physicochemical properties. The unique pathophysiology of solid tumors allows passive accrual of NPs at these sites upon intravenous injection. Furthermore, stealth NPs with long circulation times is better organized in reaching tumor tissue.

Drug activity is a result of molecular interaction(s) in certain cells; it is therefore easily deduced that it is essential for the drug to reach one way or another site of action following administration (oral, intravenous, local, transdermal, etc.) at sufficient concentrations. The systematic field dealing with this issue is known as drug delivery and has fundamentally the following aim: to deliver the drug at the exact place, at the right concentration for the right period. This is not possible by simply selecting a suitable administration route, or if such administration causes patient uneasiness, strategies based on the involvement of the drug with a carrier. Additional motivations for such approaches include the reduction of required resources for therapy, accomplished by an increase of the drug's therapeutic index and the prevention of frequent, unpleasant or expensive treatments.

Role of Drug Delivery System Other than TDDS

Drug delivery systems, ranging from implantable electronic devices to single polymer chains, are required to be well suited with processes in the body (biocompatibility) as well as with the drug to be delivered. DDS alter the biodistribution and pharmacokinetics of the associated drug: that is the time-dependent proportion of the administered dose in the different organs of the body. Furthermore, obstacles arising from little drug solubility, degradation (environmental or enzymatic), fast clearance rates, non-specific toxicity, in ability to cross biological barriers, just to mention a few, may be dealing by drug delivery system. Overall, the challenge of increasing the therapeutic outcome of drugs, with a simultaneous minimization of side effects, can be tackled from side to side-appropriate design and engineering of the DDS, in a case-to-case manner (Kelner, 2005; Mann et al, 2001; Pathak et al, 1992).

Even the most difficult part in all Drug delivery systems development actions, the accomplishment of release of the drugs, can be controlled suitably. This is true of both Drug delivery systems and novel drug delivery systems. Because of the extensive history of development, there has been profusion of time to develop perfect Drug delivery systems to novel one. One decisive finding opened up completely novel strategies for both traditional systems and Drug delivery systems the make use of polymers, frequently consisting of organic molecules. Such interesting molecules not only support the delivery systems by their kinetic and size-limiting function; they also make the drugs soluble in solvents, depending on the chemical character of the delivery systems.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Role of Novel Drug Delivery Systems (NDDS)

However, novel drug delivery systems have also had a notable revival after a hundred years' sleep. This is in particular true of delivery systems. Apart from leading to an increase in our information of delivery systems, these offer unimagined application possibilities. Although novel delivery systems are currently, being used in numerous industrial and medical applications, organized research into the novel delivery systems of drugs needs some attention.

It is apparent, for any variety of chemical approach, that dependence on the present-day pattern of information exchange in logic fundamentals or memory devices will entail defect-tolerant computer architectures with suitable, intellectual software. On the other hand, it may be promising to develop other routes which require more complex architectures and unlike principles of information exchange where the problems associated with idleness, current density, recital speed, and especially contact confrontation and charge redistribution at the lead-to-molecule interface are less relevant (Schmid, 2011).

Role of Novel Drug Delivery Systems with Its Different Application

Most of the anti hyperlipidimic drugs have reduced water solubility hence poor dissolution, which lead to reduced bioavailability. Therefore, when these drugs are given in predictable dosage forms they do not meet the therapeutic requirements therefore are given in large doses, which show the various side effects. Therefore, it is the essential to formulate that type of dosage form in which the drug shows better bioavailability and not as much of side effects (Farooq et al, 2013). Researchers are going on in this field and a variety of novel drug delivery systems are formulated and evaluated which have exposed the intensify the bioavailability of these drugs. Some of the novel drug delivery systems for antihyperlipimic drugs are:

1. **Self-Micro Emulsifying Drug Delivery System:** Self-emulsifying formulations enhance readily in the GI tract, and the digestive motility of the stomach and the intestine make available the agitation essential for self-emulsification. Lovastatin is inadequately soluble in gastric fluid when administered throughout predictable dosage forms like tablet, so SMEDDS are formulated to enhance the solubility of drug in gastric fluid and therefore improving the bioavailability by rising gastrointestinal absorption through passive diffusion. Fenofibrate is a (BCS) Class II drug with a high dose number. Thus, has little oral bioavailability due to its solubility and dissolution limits. An optimized SMEDDS formulation consisting of Labrafac CM10 (31.5% wt/wt), Tween 80 (47.3% wt/wt), PEG 400(12.7% wt/wt), and fenofibrate (8.5% wt/wt) has been developed with an improved dissolution rate, increased solubility therefore, improved bioavailability of a poorly water-soluble drug. Supersaturated drug delivery systems include the drug in a high-energy or rapidly dissolving form, which allows the solution to have drug concentrations higher than the solubility limit. (Cowan-Lincoln)
2. **Ternary Solid Dispersions:** Solid dispersions have been generally used to enhance the solubility, dissolution rate, and bioavailability of poorly soluble drugs. There are different types of solid dispersion systems categorized according to the physical states of the drug and the mover in the systems. It may be a molecular solid solution, a dispersion of amorphous or crystalline drug particles in an amorphous carrier matrix or an arrangement of a solution and distribution of solids. Fenofibrate compound is almost insoluble in water and has high lipophilicity. Therefore, the dissolution rate

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

of fenofibrate is likely to limit its absorption from the gastrointestinal tract. The solid dispersion of the fenofibrate was prepared by spray drying method using Poloxamer 188 as carrier and TPGS as surfactant shows highest solubility improvement of fenofibrate. Solid dispersion along with an adsorption method that employs a water-soluble adsorbent can be used to improve the dissolution of Ezetimibe, which may effect from the combined effect of hydrophilic carriers and improved surface area. Many drugs can be given in such form which will improve the efficiency of the drug. (Bhise, 2011; Parmar et al, 2011)

3. **Nano Suspension:** Nano suspensions not only increase the surface area but also at the same time enhance the saturation solubility and the solution velocity by raising the vapor pressure of the particles. Here the dissolution velocity slowly is improved due to decrease in the diffusional distance on the surface of drug nanoparticles. The saturation solubility gets affected through in situ generation of energies throughout alter of drug microcrystals to nanoparticles. Fenofibrate is a Nano suspension currently marketed in the name of Tricor. Nanosuspensionsmake use of some technique to decrease the particle size to the nano level which help to enhance the solubility of the drug suitable to small particle size. (Selvamuthukumar et al, 2012)
4. **Ion Exchange Resins:** Cholestyramine resin USP, when used as an active ingredient, binds bile acids; this leads to replacement of bile acids; through improved metabolism of serum cholesterol resultant in lowered serum cholesterol levels. Ion exchange resins no uncertainty are very effective in improving the bioavailability of the drugs but due to the use of some polymers it also enhances the charge of the delivery system. (Pande et al, 2011; Srikanth et al, 2010)
5. **Nanosponge Drug Delivery:** Nanosponges are a new class of materials and prepared of microscopic particles with few nanometers wide cavities, in which a huge variety of substances can be encapsulated. These particles are capable of carrying equally lipophilic and hydrophilic substances and of enhancing the solubility of poorly water-soluble molecules. This technology offers entrapment of ingredients and is supposed to decrease side effects by controlling the release, develop stability, enhance elegance and enhance formulation flexibility. These complexes can be also used to enhance the dissolution rate and solubility, to cover unpleasant flavors and to convert liquid substances to solids. By calculating the ratio of polymer to the cross-linker the particle size and release rate can be modulated. Nanosponges facilitate the insoluble drugs, protect the active moieties from physicochemical degradation, and controlled release. Atorvastatin, Fenofibrate, Glibenclamide, Glipizide, Lovastatin can be formulated into nanosponges. Nanospongesdevelop the solubility of the drugs efficiently but the technology employed in this process is not cost effective as this technique utilizes some polymers which are costly in nature. (Sharma & Pathak, 2010)
6. **Nanoparticle Formulation:** Nanoparticulate drug delivery as the biological dimension of nanotechnology has been developed, which may help generate useful formulations of OA for clinical applications. Nanoparticulate drug delivery system increases the dissolution rate and bioavailability of OA, providing a practical formulation method for clinical applications. (Chen et al, 2011)
7. **Mucoadhesive Microcapsules:** Simvastatin (SV) is a cholesterol-lowering agent that is resulting synthetically from a fermentation product of *Aspergillus terreus* and is widely used to treat hypercholesterolemia. Microcapsules of Simvastatin were prepared by complexation with HPBCD and by this means including this complex in the polymeric matrix by make use of orifice gelation method resulted in more improved drug delivery. (Bal et al, 2012)
8. **Pulsatile Drug Delivery System:** Pulsatile Drug Delivery System is helpful in the diseases in which the drug release is timed to counterpart rhythms of the disease to optimize the beneficial

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

effect and reduce the side effects. Circadian rhythm occurs during hepatic cholesterol synthesis, which is higher during the night than daylight and diurnal synthesis represent upto 30-40% of daily cholesterol synthesis. The maximal production occurs in the morning. So there is a regular require for new delivery systems that can offer improved therapeutic benefits to the patients by delivering drug at the right time, right place & in right amounts to correspond with circadian rhythm of body. These dosage forms offer several advantages, such as almost stable plasma drug level without any fluctuations, decrease in dose of drug, decreased dosage frequency, least side effects, and enhanced patient compliance. Various systems like capsular system, osmotic system, and single multiple unit system based on the use of soluble or erodible polymer coating and use of repturable membrane. (Rajput et al., 2012; Rasve et al, 2011)

Ternary solid dispersion and ion exchange resins are the systems which improve the solubility of drugs largely and hence the bioavailability but it utilizes the variety of polymers which are costly in nature hence they may enhance the cost of the medication. Gastric floating drug delivery system is helpful in improving the solubility of those drugs, which are less soluble in acidic pH, and the drug waste is much more. This system is helpful in prolongs the gastric retention of the drugs and therefore increases the solubility of the drugs. While as pulsatile drug, delivery system is the system, which responds to the circadian rhythms of the body, and as a result, this system is very useful because cholesterol synthesis depends on circadian rhythms. SMEDD Scan is used to improve the solubility of the drugs by lessening the particle size in the emulsion base, which will efficiently enhance the bioavailability of the drug. Among all the systems above SMEDDS seems to be the most successful delivery system for antihyperlipidemic drugs because it is very easy to formulate and does not require any costly polymers, which make it effective in therapy as well as in cost. Many other novel drug delivery systems can be used to enhance the efficiency of these drugs.

Role of Novel Drug Delivery Systems in Cancer

Over the past several years, great advances have been made on expansion of novel drug delivery systems of anticancer drug (NDDS). The selection of novel formulations like polymeric nanoparticles, nanocapsules, liposomes, phytosomes, nanoemulsions, microsphere, hydrogels has been reported using bioactive and plant extracts. The novel formulations are reported to have extraordinary advantages over conventional formulations of anticancer, which include improvement of solubility, bioavailability, and protection from toxicity, improvement of pharmacological activity, improvement of stability, better tissue macrophages distribution, sustained delivery, and protection from physical and chemical degradation. (Kushwaha et al, 2012).

Role of Polymers in Drug Delivery Systems

Multiple synthetic and natural biodegradable polymers have been investigated for these purposes, with polyesters, polyether's, poly amino-acids, polysaccharides, and proteins (Medina et al, 2004). These polymers are employed as injectable drug delivery system, and especially as injectable drug delivery system for cancer chemotherapy, and have been investigate dynamically so as to reduce the toxic side effects and increase the carcinostatic pharmaceutical effects (Heller & Hoffman, 1996).

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Methods of local administration of drug delivery system, nanoparticles (Barraud et al., 2005; Brannon-Peppas & Blanchette, 2012; Panyam & Labhasetwar, 2003), microspheres(Freiberg & Zhu, 2004; Kakinoki et al., 2003), polymeric micelles (Hrubý et al., 2005; Nishiyama et al, 2005; Rapoport et al, 2003), liposomes (Abraham et al., 2005; Goyal et al., 2005; Kaneda, 2000; Saul, et al., 2003), and hydrogel systems (H. He et al, 2004; Ruel-Gariepy & Leroux, 2004)for targeting and controlled release have been investigated with non-biodegradable polymers. However, the targeting drug delivery system has not been acceptably achieved. Accordingly, the injectable in situ formulating a drug delivery system with hydrogel system, that demonstrates a sol–gel transition in a physiological environment, has many uses (Packhaeuser et al, 2004). For example, water-soluble polymers with stimuli responsiveness have been widely used as injectable drug delivery system.

For the last few years, novel drug delivery systems have been investigated to conquer the control of the conventional systems. Cancer chemotherapy and DNA-based vaccines have been well known as special areas of need for improved drug delivery. Lipoproteins as drug delivery systems have turn out to be an attractive area of research and they are considered admirable candidates as novel drug delivery systems. Herbal drugs have massive therapeutic impending, which should be explored through some significance additional drug delivery systems. Lipid solubility and molecular size are the major restraining factors for drug molecules to pass the biological membrane to be absorbed systematically follows oral or topical administration. Several plant extracts and phytomolecules, despite having exceptional bioactivity in vitro show fewer or no in vivo actions due to their poor lipid solubility absorption and reduced bioavailability. Standardized plant extracts or mainly polar phytoconstituents like flavonoids, terpenoids, tannins, xanthones when administered through novel drug delivery system show much improved absorption profile, which enables them to cross the biological membrane, resulting enhanced bioavailability. Hence, extra amount of active constituent becomes present at the site of action (liver, brain, heart, kidney, etc.) at similar or less dose as compared to the conventional plant extract or phytomolecule. Therefore, the therapeutic action becomes improved, more detectable and prolonged. Several excellent phytoconstituents have been successfully delivered using NDDS. Hence, there is a great potential in the development of novel drug delivery systems for the plant actives and extracts.

Previously used for simple encapsulation of cells or drugs, in homogenous materials, today's hydrogels are new complex smart polymers with different types of ligands and cross-links allowing for highly regulated structures and different bio responsive functionalities. Hydrogels that undergo swelling changes in response to specific biomolecules have become ever more important because of their potential applications in the development of biomaterials and drug delivery systems and the biomedical applications of the hydrogels. We concentrate on the bio responsive hydrogels and sensors, also introduces the physical background of the special properties of stimuli-responsive hydrogels; use of the variety of transducers describing changes in physical properties of the hydrogels. It considers the opportunity of using artificial neural network models to identify model for swelling behavior as new techniques.

Molecular imprinting involves forming a pre-polymerization complex between the template molecule and functional monomers or functional oligomers (or polymers) (Lim & Sun, 1980) with detailed chemical structures interrelate with the template either by covalent (Wulff, 1995), non-covalent chemistry (Kirsch, et al, 2000). Formerly the pre-polymerization complex was formed, the polymerization reaction occurs in the presence of a cross linking monomer and an appropriate solvent which controls the overall polymer morphology and macro porous structure. Once the template is removed, the product is a hetero polymer matrix with specific known elements for the template molecule. It is explaining the upcoming

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

field of molecular imprinting and designed molecular recognition (Takeuchi & Haginaka, 1999). The macromolecular architecture must be planned in a different way than more traditional dense network and must contain a spatially varying cross-linking density (micro and macro-porous regions). A density fluctuation in the polymer network generates regions or microgels of localized higher cross-linking, which contain an effective imprinting structure and suitable rigidity to produce enough specificity (areas or patches of recognition).

Hydrogel Applications (Kalshetti, et al, 2012)

1. Biological molecules can be covalently built-in into hydrogel structures.
2. Hydrogels has mechanical properties, which are highly elastic, and elasticity can be tailored by modifying cross-link densities.
3. Hydrogels provide appropriate semi wet and three-dimensional environments for molecular-level biological interactions.
4. Many hydrogels shows inert surfaces that prevent nonspecific adsorption of proteins, known as antifouling.
5. Hydrogels can be designed to alter properties due to externally useful factors, such as temperature, ionic strength, solvent polarity, electric /magnetic field, light, or small biomolecules.

The objective of every drug delivery system is to give a therapeutic amount of drug to the proper target site in the body and then maintain the desired drug concentration. A well-designed controlled drug delivery system can overcome some of harms of conservative therapy and improve therapeutic efficacy of the given drug. There are various approaches in delivering therapeutic substance to the target site in sustained and controlled release fashion. One such approach is using microspheres as carriers for drug. Microspheres are characteristically free flowing powders consisting of proteins or synthetic polymers, which are biodegradable in nature ideally, have particle size less than 200μm.Various synthetic and natural materials are used for the preparation of microspheres. These are prepared by techniques like Single emulsion, Double emulsion, Polymerization, Phase separation co-acervation, Emulsion solvent evaporation and solvent diffusion. Microspheres are having wide range of applications because of controlled and sustained release. Most important use is that it is used for targeting tumours usinganti-cancer drugs. It is important carrier for safe and effective in vivo drug delivery (see Table 1). (Kotta et al., 2012; J. Silva et al., 2014; Thiagarajan, 2011)

Role of Microencapsulation in NDDS

Microencapsulation is used to alter and delayed drug release of pharmaceutical dosage forms. A well-planned controlled drug delivery system can overcome the problems of traditional therapy and improves the therapeutic efficacy of a drug. It is the dependable way to deliver the drug to the target site with specificity, if modified, and to retain the desired concentration at the site of interest without untoward effects. Microspheres received much attention not only for extended release, but also for targeting of anticancer drugs to the tumor. The objective is to draw attention to the potential of microencapsulation technique as a vital method in novel drug delivery. Polymerization is a relatively new microencapsula-

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Microsphere applications

Type of Microspheres	Applications
Bio-adhesive microspheres	Buccal, oral, ocular, nasal, colonic drug delivery Nasal - Gentamicin, Insulin (Farraj et al.,1990), GI –Glipizide (Kyyrönen et al., 1992) Colonic – Insulin (Geary & Schlameus, 1993), Ocular - Methyl prednisolone (J. Patel et al., 2004)
Magnetic microspheres	Used in DNA analysis, cell isolation, protein purification and targeting drugs to tumour sites(Doxorubicin) (Pawan& Hemchand, 2009)
Floating microspheres	Carriers for drugs like antiviral, antifungal and antibiotic agents (so called absorption windows), non-steroidal anti-inflammatory drugs, Prednisolone, Lansoprazole (Garima Chawla et al., 2013; Shirwaikar et al., 2006)
Radioactive microspheres	For diagnostic purpose - Diagnostic radio embolization: 99mTc-macroaggregated human serum albumin (MAA) (Ercan, 1992), Thrombus imaging in deep vein thrombosis: 99mTc-sulfur colloid (Knight, 1986) For therapeutic purpose – Radio embolization of liver and spleen tumours: 90Ymicrospheres, Local radiotherapy: 212Pb-sulfur colloid (Russell et al., 1988).
Polymeric microspheres Vaccine delivery:	Hepatitis, Influenza, Pertussis, Diphtheria toxoid (Haefeli et al., 1992), Oral drug delivery of easily degraded drugs: Gene therapy with DNA plasmids; delivery of insulin, LHRH Controlled drug delivery after local application: Release of proteins, hormones and peptides over extended times

Prasanth, et al., 2011; Ramteke et al., 2012.

tion technique utilizes polymerization technique to from protective microcapsule coatings in situ. The methods involve the reaction of monomeric units located at the interface existing between a core material substance and a continuous phase in which the core material is dispersed. The continuous or core material supporting phase is usually a liquid or gas, and therefore the polymerization reaction occurs at a liquid-liquid, liquid-gas, solid-liquid, or solid-gas interface (Venkatesan et al., 2009). Microspheres are typically free flowing powders consisting of synthetic polymers which are biodegradable in nature and ideally having particle size less than 200 μM (N. Jain, 2002). There are many reasons why drugs and related chemicals have been microencapsulated (N. K. Jain, 1997; Lachman et al., 1986).

The technology has been used widely in design and proposes of controlled release and sustained release dosage forms.

1. To mask the bitter taste of drugs like Paracetamol, Nitrofurantoin, etc.
2. Many drugs have been microencapsulated to reduce gastric and other G.I. tract irritations. Sustained release Aspirin preparations have been reported to cause significantly less G.I. bleeding than conventional preparations.
3. A liquid can be converted to a pseudo-solid for easy handling and storage. e.g. Eprazinone.
4. Hygroscopic properties of core materials may be reduced by microencapsulation e.g. Sodium chloride.
5. Carbon tetra chlorides and a number of other substances have been microencapsulated to reduce their odor and volatility.
6. Microencapsulation has been employed to provide protection to the core materials against atmospheric effects, e.g. Vit. A. Palmitate.
7. Separation of irreconcilable substance has been achieved by encapsulation.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Role of Nanoemulsions in NDDS

Nanoemulsions are novel drug delivery systems containing emulsified oil and water systems with mean droplet diameters ranging from 50 to 1000 nm. Usually, droplet size is between 100 and 500 nm and can exist as oil-in-water (o/w) or water-in-oil (w/o) form, where the core of the particle is either oil or water, respectively. Nanoemulsions are made from pharmaceutical surfactants that are generally regarded as safe (GRAS) (Chime et al., 2014).

The major advantages of nanoemulsions as drug delivery carriers comprises of increased drug loading, improved drug solubility and bioavailability, reduced patient variability, controlled drug release, and protection from enzymatic degradation (Kotta et al., 2012). A range of novel strategies are currently being developed for capable delivery of poorly water-soluble drugs, such as the formulation of amorphous solid form, nanoparticles, microemulsions, solid dispersions, melt extrusion, salt formation and formation of water-soluble complexes. Among all, the most accepted approach is the lipid-based formulation approach (Dixit & Nagarsenker, 2008; Shafiq et al., 2007).

Recently importance of nanoemulsions have become increasing as good vehicles for the controlled delivery of cosmetics and for the optimized dispersion of active ingredients in particular skin layers. Nanoemulsions are suitable in cosmetics because there is no chance of creaming, sedimentation, flocculation or coalescence, which is observed within microemulsions. The incorporation of potentially nauseating surfactants can be avoided by using high-energy equipment during manufacturing process. PEG free nanoemulsions for cosmetics have also been developed and formulations shown good stability (Chime et al., 2014; Lovelyn & Attama, 2011; Thiagarajan, 2011).

A characteristic of the nanoemulsions is their highly selective toxicity to microbes at concentration range that are non-irritating to skin or mucous membrane. The safety range of nanoemulsions is because of the minute amount of detergent in each droplet, so far when acting in concert; these droplets have enough energy and surfactant to destabilize targeted microbes without affect healthy cells. Nanoemulsions can get a level of current antimicrobial activity, which can only be formerly achieved by systemic antibiotics.

The US Army (RestOps) checked the broad-spectrum nanoemulsions on surfaces in Dec 1999 for decontamination of Anthrax spore. It was checked again by RestOps in March 2001 as a chemical decontamination agent. This tool has been tested on gangrene and clostridium botulism spores, and can even be used on infected wounds to salvage limbs. The first applications as vaccine, an influenza vaccine and an HIV vaccine, can proceed to clinical trials. The nanoemulsion causes proteins useful to the mucosal surface to be adjuvant and it help uptake by antigen presenting cells. This results in the significant systemic and mucosal immune response due to that the production of specific IgG and IgA antibody as well as cellular immunity. Research has been ongoing to complete the evidence of concept in animal trials for other vaccines including Anthrax and Hepatitis B. The University of Michigan has licensed this technology to NanoBio (Chime et al., 2014).

Another interesting application, which is experiencing an active development, is the use of nanoemulsion formulations, for controlled drug delivery and targeting (Wang et al., 2007). The development of magnetic nanoemulsions is an innovative approach for cancer therapy. These can transport photosensitizers as ifFoscan® to deep tissue layers crossways the skin thereby inducing hyperthermia for subsequent free radical generation. This method can be used for the treatment of cancer in the type of photodynamic therapy (Primo et al., 2007).

Among the possible delivery systems, the use of nano based carriers hold a great promise to protect the biomolecules, promote nanocarrier interface with mucosa and to direct antigen to the lymphoid tis-

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

sues. As a result, the use of nanoemulsions in intranasal drug delivery system is set to transport about important results in targeting drugs to the brain in treatment of diseases correlated to the central nervous system (Clark et al., 2001). Major clinical and pre-clinical trials have therefore been carried out with parenteral nanoemulsion based carriers. The advances in these novel drug delivery systems have been reviewed by Patel and Patel (R. Patel & Patel, 2010). Nanoemulsions overloaded with thalidomide have been synthesized where a dose as low as 25mg leads to plasma concentrations which can be therapeutic (Araújo et al., 2011). However, a significant reduce in the drug substance of the nanoemulsion was observed at 0.01% drug formulation after two months' storage which could be overcome by the addition of polysorbate 80. Chlorambucil, a lipophilic anticancer agent has been used against breast and ovarian cancer. Lipid formulations are used to treat cardiovascular diseases since they accrue in the walls of injured vessels, transporting the drug to the place of vascular injury and to protect it from rapid inactivation by the lungs (Hoshi, 1996; Igarashi et al., 2001; Momma, 1996; Scheffler et al., 1996). Nanoemulsions are proposed for numerous applications in pharmaceuticals as drug delivery systems because of their ability to solubilize non-polar active compounds. Future perspectives of nanoemulsion are very hopeful in diverse fields of therapeutics or application in development of cosmetics for hair or skin. One of the versatile applications of nanoemulsions is in the part of drug delivery where they act as efficient carriers for bioactive, facilitating administration by various routes.

Role of Microbubbles in NDDS

Ultrasound-mediated microbubbles destruction has been planned as a novel method for noninvasive delivering of drugs and genes to different tissues. Microbubbles are used to carry a drug or gene until a specific area of importance is reached, and then ultrasound is used to burst the microbubbles, causing site-specific delivery of the bioactive materials. In addition, the capacity of albumin-coated microbubbles to adhere to vascular regions with glycocalix damage or endothelial dysfunction is another probable mechanism to deliver drugs even in the absence of ultrasound. Microbubbles that give those therapeutic properties and some important aspects of ultrasound parameters that are known to control microbubble-mediated drug delivery (Majumdar & Chowdhury, 2010).

In addition, current studies relating this novel therapeutic use of microbubbles (Majumdar & Chowdhury, 2010; Tsutsui, Xie, & Porter, 2004) have shown that microbubbles targeted to AlphaV, BetaIII can be used to measure the temporal expression of this integrin in association with angiogenesis. A contrast agent targeted to endothelial- based markers of angiogenesis might be used to develop diagnosis and treatment of disorders affected by angiogenesis. Other endothelialbased targets such as P-selectin might be shown to develop targeted imaging agents for detecting inflammation. Vulnerable plaques are those that have been infiltrated by macrophages, and are undergoing inflammation (Majumdar & Chowdhury, 2010). Inflammation can show the way to rupture of vulnerable plaque and formation of thrombus, as in stroke and myocardial infarct. Vulnerable plaques may lie unknown as unseen threats, liable to cause morbidity and sudden death.

Microbubbles accelerate the rate of SonoLysis. Improvement is greater for the targeted molecular ultrasound contrast agent, MRX-408, than for the non-targeted agent. Hynynen has shown (O'Reilly & Hynynen, 2012) that intravenous doses of microbubbles and transcranial function of ultrasound can be used to reversibly open the blood brain barrier. Laser-induced bubble formation around nanoparticles may play a crucial role in selective laser nanophoto thermolysis of cancer cells targeted with nanoparticles. Progress in cardiovascular gene therapy has been vulnerable by concerns over the safety and practicality

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

of viral vectors and the ineffectiveness of current nonviral transfection techniques. Ultrasound exposure (USE) enhances transgene expression in vascular cells by up to 10-fold after naked DNA transfection, and enhances lipofection by up to three-fold. The presence of gas in the gene-filled microbubble allows ultrasound energy to "pop" the bubble. An energetic wave is then created which allows the genetic material to enter surrounding cells (Lawrie et al., 2000).

Microbubbles are presently used clinically as contrast agents in ultrasound (US) diagnostics and experimentally as drug or nucleic acid carriers. The protective blood-brain barrier blocks many drugs from acting on brain cells. Now, a new technique for delivering drugs directly to the affected area may enhance the effectiveness of chemotherapy in brain tumors and reduce its toxic effect on healthy cells. Researchers at the University of California are developing a novel technique that uses ultrasound and drug-laden "microbubbles" to deliver concentrated chemotherapy drugs to the inner lining of blood vessels. Doctors already use ultrasound to recognize tumors and leads to biopsy procedures. Ultrasound pulse sequences can also guide micro-packaged medications to specific parts of the body (Shortencarier et al., 2004).

The purpose of nanotechnology in the field of health care has come under great attention in recent times. There are many treatments today that take a lot of time and are also very costly. Using nanotechnology, quicker and much cheaper treatments can be developed. By performing further research on this technology, cures can be found for diseases that have no cure today. We could make surgical instruments of such accuracy and precision that they could operate on the cells and even molecules from which we are made - something well beyond today's medical technology. (Bhowmik et al., 2009)

Role of Vesicular Systems in NDDS

Novel drug delivery attempts to either sustain drug action at a fixed rate, or by maintaining a relatively constant, effective drug level in the body with related minimization of undesirable side effects. The vesicular systems are highly ordered assemblies of one or several concentric lipid bilayers formed, when certain amphiphillic building blocks are confronted with water. The vesicular system such as liposomes, niosomes, sphingosomes, ethosomes, transferosomes and pharmacosomesare used to develop the therapeutic index of both existing and new drug molecules by encapsulating an active medicament inside vesicular structure in one such system. It prolongs the existence of the drug in systemic circulation and finally reduces the toxicity. Such different systems are widely used in gene delivery, tumor targeting, oral formulations, in stability and permeability problems of drugs. Now a day's vesicle as a carrier system have become the vehicle of choice in drug delivery and lipid vesicles were found to be of value in immunology, membrane biology and diagnostic technique and most recently in genetic engineering (Jadhav, et al., 2012).

Different types of pharmaceutical carriers such as particulate, polymeric, macromolecular and cellular are present. Particulate type carrier also known as colloidal carrier system, includes lipid particles (low and high density lipoprotein-LDL and HDL, respectively), microspheres, nanoparticles, polymeric micelles and vesicular like liposomes, sphingosome, niosomes, transferosomes, pharmacosomes, virosomes (Sezaki & Hashida, 1985).

The cells of RES preferentially take up the vesicles. The uptake of niosomes by the cells is also by circulating serum factors known as opsonins, which mark them for approval. Such limited to a small area drug accumulation has, however, been exploited in treatment of animal tumors known to metastasize to the liver and spleen and in parasitic infestation of liver (Malhotra & Jain, 1994).

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Niosomeshave been used for studying the nature of the immune response provoked by antigens. Brewer and Alexanderhave reported niosomes as potent adjuvant in terms of immunological selectivity, small toxicity and stability (Brewer & Alexander, 1992).

Transferosomes improve the site specificity, overall drug safety and lesser the doses quite a lot of times than the currently available formulations for the treatment of skin diseases. Because of their excellent penetration power and flexibility, transferosomes formulations are used for useful delivery of non-steroidal anti-inflammatory agents like ibuprofen and diclofenac. Transferosomes not only enhance the penetration of diclofenac through intact skin, but also transfer these agents directly into the depth of the soft tissues under the application site (Cevc, 1996).

Ethosomes have high penetration rate through the skin as compared to liposomes therefore these can be used commonly in place of liposomes. Although, the exact mechanism for better penetration into deeper skin layers from ethosomes is still not clear. The synergistic effects of combination of phospholipids and high concentration of ethanol in vesicular formulations have been recommended to be responsible for deeper distribution and penetration in the skin lipid bilayers. The size range of ethosomes may differ from tens of nanometers to microns (Dayan & Touitou, 2000; S. Patel, 2007). Ethosomesare mainly used as replacement of liposomes mainly for the transdermal route of drug delivery.

Sphingosomes solve the major disadvantage of vesicle system (liposomes) like less stability, less in vivo circulation time, low tumor loading efficiency in case of cancer therapy. Sphingosomes are clinically used delivery system for chemotherapeutic agent, biological macromolecule and diagnostics. Due to flexibility in size and composition, different types of sphingosomes have been developed (Saraf, Gupta, Kaur, & Saraf, 2011). Sphingosomal products such as Marqibo(TM) (sphingosomal vincristine) are loaded with active, cell cycle-specific anticancer agents that may help from increased targeting and longtime drug exposure at the tumor site. Vincristine, vinorelbine and topotecan are approved cancer therapies which have been chosen for sphingosomal formulation specifically for their ability to help from this novel encapsulation.

Pharmacosomes are the colloidal dispersions of drugs covalently bound to lipids and may be present as ultrafine vesicular, micellar or hexagonal aggregates, depending on the chemical structure of the drug–lipid complex (Semalty, Semalty, Rawat, Singh, & Rawat, 2009). Because the system is formed by involving a drug (pharmakon) to a carrier (soma), they are called pharmacosomes. Any drug possessing a free carboxyl group or an active hydrogen atom (–OH, NH2) can be esterified (with or without a spacer group) to the hydroxyl group of a lipid molecule, thus generating an amphiphilic prodrug, which will facilitate membrane, tissue, or cell wall transport, in the organism. Any drug with a definite cut-off molecular weight may be formulated as pharmacosomes provided it has active functional groups to integrate with the vesicle-forming amphiphilic molecule.

Various amphipathic liponucleotideprodrugs, 1-β-D-arabinofuranosylcytosine 5'-Diacylglycerols (Ryu et al., 1982) (containing either dimyristoyl, dipalmitoyldistearoyl free fatty acid side chains) and determined the aggregational and morphological character of their sonicated dispersions in relation to alter in temperature. The sonication at low temperature gave turbid solutions containing big bilayer sheets. On increasing the temperature, a transition temperature (tg) was reached at which a stable three dimensional cross-linked network of small interlocking bilayer stacks was formed. Sonication at the temperature close up to tg produced small disc-shaped micellar structures. These micelles were shown to be present in another aggregational equilibrium consisting of stacking-destacking process. In contrast, the prodrug containing unsaturated fatty acid chain gave multilamellar liposomes. Improved biological activity after incorporation of drug into pharmacosomes was found in case of Taxol and Cytarabin.

Role of Nanocarriers in NDDS

Nanocarriers with optimized physicochemical and biological properties are in use up by cells more easily than larger molecules, so they can be effectively used as delivery tools for currently existing bioactive compounds (Suri, Fenniri, & Singh, 2007). It is usually accepted that nanoparticles with a hydrodynamic diameter of 10–100 nm have best possible pharmacokinetic properties for *in vivo* applications. Smaller nanoparticlesare subjects to tissue extravasations and renalclearance whereas larger are rapidly opsonized and removed from the bloodstream *via* the macrophages of the reticuloendothelial system (Cole et al., 2011).

Once the drug-nanocarrier conjugates reach the diseased tissues, the therapeutic agents are released. A controlled release of drugs from nanocarriers can be achieved during changes in physiological environment such as temperature, pH, osmolality, or *via* an enzymatic activity. Nanocarriers used for medical applications have to be biocompatible (able to integrate with a biological system without eliciting immune response or any negative effects) and nontoxic (harmless to a given biological system) (Wilczewska et al., 2012).

SLN (solid lipid nanoparticles), NLC (nanostructured lipid carriers) and LDC (lipid drug conjugates) are types of carrier systems based on solid lipid matrix, i.e., lipids solid at the body temperature (Wissing et al., 2004). They have been exploited for the dermal (Abdel-Mottaleb et al., 2011), peroral (Muchow et al., 2008), parenteral (Nayak et al., 2010), ocular (Attama et al., 2007), pulmonary (Liu et al., 2008), and rectal (Sznitowska et al., 2001) delivery.

The application of biodegradable nanosystems for the development of nanomedicines is one of the most successful ideas. Nanocarriers composed of biodegradable polymers undergoes hydrolysis in the body, produces biodegradable metabolite monomers, such as lactic acid and glycolic acid. Kumari et al. (Kumari et al., 2010) reported a minimal systemic toxicity related with using of PLGA for drug delivery or biomaterial applications. Such nanoparticles are biocompatible with tissue and cells (Panyam & Labhasetwar, 2003). Drug-biodegradable polymeric nanocarrier conjugates used for drug delivery are stable in blood, non-toxic, and non-thrombogenic. They are also non-immunogenic as well as non-pro inflammatory, and they neither activate neutrophils nor affect reticuloendothelial system (des Rieux et al. 2006).

Silica materials used in controlled drug delivery systems are classified as xerogels (Czarnobaj, 2008) and mesoporous silica nanoparticles (MSNs), e.g., MCM-41 (Mobil Composition of Matter) and SBA-15 (Santa Barbara University mesoporous silica material) (Wei, Hu, & Zhang, 2010). They exhibit several advantages as carrier systems, including biocompatibility, highly porous framework and an ease in terms of functionalization (Amato, 2010). Among inorganic nanoparticles, silica materials are the carriers which most often are chosen for biological purposes (Slowing, Trewyn, Giri, & Lin, 2007). Xerogels used in controlled drug release (Quintanar-Guerrero et al., 2009). Phenytoin (Fidalgo et al., 2009), doxorubicin (Prokopowicz et al., 2010), cisplatin (Katarzyna et al., 2007), metronidazole (Katarzyna et al., 2012), nifedipine (Maver et al., 2007), diclofenac (Katarzyna Czarnobaj & Czarnobaj, 2008), and heparin (Ahola et al., 2001) are examples of drugs which have been loaded into xerogels using this technique.

The best known types of mesoporous silica nanomaterials are MCM-41 with a hexagonal arrangement of the mesopores and SBA-15 with a well-ordered hexagonal connected system of pores. The MSNs, in comparison with xerogels, possess more homogenous structure, lower polydispersity and higher surface area for adsorption of therapeutic or diagnostic agents (Di Pasqua et al., 2009). The mechanism of drug loading into mesoporous silica material is a chemical or physical adsorption. By these processes, diverse

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

types of drugs, including anticancer drugs (Q. He et al., 2011), antibiotics (Li et al., 2010), and heart disease drugs (Popovici et al., 2011) have been embedded into MNSs.

Carbon nanocarriers used in DDS are differentiated into nanotubes (CNTs) and nanohorns (CNH). CNTs are characterized by unique architecture formed by rolling of single (SWNCTs – single walled carbon nanotubes) or multi (MWCNTs – multi walled carbon nanotubes) layers of graphite with an enormous surface area and an excellent electronic and thermal conductivity (Beg et al., 2011). Drug release from carbon nanotubes can be electrically or chemically controlled. To prevent the unwanted release of the drug, the open ends of CNTs were sealed with polypyrrole (PPy) films [129]. Homing devices, i.e., folic acid [130] and epidermal growth factor (Bhirde et al., 2009), were attached to improve selectivity of such drug delivery systems. Newer studies have pointed out the similarity in carcinogenic potential between CNT and asbestos. (Poland et al., 2008). Carbon nanotubes have been shown to cause necrosis or apoptosis of macrophage cell lines and changes in cell morphology (Jia et al., 2005). Radomski et al. (Radomski et al., 2005) studied the effects of engineered carbon nanoparticles (MWCNT and SWCNT) on human platelet aggregation *in vitro* and rat vascular thrombosis *in vivo*. Incubation of platelets with carbon nanomaterials caused platelet aggregation with little or no granular release.

Therapeutic activity of diverse drugs incorporated into iron oxide nanocarriers have been tested and reported. Magneic Nano Particals have been examined for multitasking treatment as biosensors (diagnosis) and drug carriers (therapy) simultaneously. Concomitant use of magnetic resonance or magnetofluorescent imaging and targeted therapy (*via* conjugation of targeting moieties) can enhance effectiveness of cancer therapy (Chomoucka et al., 2010). Magnetic nanoparticles promote activation of phagocytotic and cytokine-release functions of macrophages (Dobrovolskaia& McNeil, 2007). Gas vesicles were observed in MNPs treated cells with increased granularity of the cells (Mahmoudi et al., 2010). Magnetite nanoparticles have the potency of causing oxidative DNA lesions in cultured A549 cells (the human lung epithelial cell line) (Karlsson, Cronholm, Gustafsson, & Moller, 2008). They also cause transient increase of ALT (serum alanine aminotransferase), AST (aspartate aminotransferase), and ALP (alkaline phosphatase) levels. (Jain TK et al., 2007)

Most of the applications of nanotechnology in medicine are still under development nanocrystalline silver is used already as an antimicrobial agent in the treatment of wounds. Qdots will be useful to identify the location of cancer cells in the body. Use of nanoparticles that can deliver chemotherapeutic drugs directly to cancer cells which minimizes damage to the healthy cells. Nanoshells concentrate the heat from infrared light to destroy cancer cells with minimal damage to surrounding healthy cells. Nanotubes used in the broken bones to provide a structure for newbone material to grow. Nanoparticles that can attach to cells infected with various diseases and permit a doctor to identify, in a blood sample, the particular disease (Bhowmik et al., 2009).

Nanomedicine refers to future developments in medicine that will be based on the ability to build nanorobots. In the future, these nanorobots could actually be programmed to repair specific diseased cells, functioning in a similar way to antibodies in our natural healing processes. Nanomedicines would be able to eliminate of bacterial infections in a patient within minutes as an alternative of using treatment with antibiotics over a period of weeks, also able to perform surgery at the cellular level, removing individual diseased cells and even repairing defective portions of individual cells. Significant lengthening of the human lifespan by repairing cellular level conditions that cause the body to age.

Nanoparticles can be planned with a structure very similar to the bone structure. An ultrasound is performed on existing bone structures and then bone like nanoparticles are created using the results of the ultrasound (G. A. Silva et al., 2004). The bone-like nanoparticles are inserted into the body in a

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

paste form (Adhikari, Kundu, & Rao, 2013). When they arrive at the fractured bone, they accumulate themselves to form an ordered structure which later becomes part of the bone.

Another key use for nanoparticles is the treatment of injured nerves. Samuel Stupp and John Kessler at Northwestern University in Chicago have made tiny rod like nano-fibers called *amphiphiles*. They have kept capped with amino acids and are known to spur the growth of neurons and prevent scar tissue formation. Experiments have shown that rat and mice with spinal injuries recovered when treated with these nano-fibers.

The use of RNA interference (RNAi) to down regulate several targets has emerged as a treatment modality of exceptional promise for cancer treatment (Fire et al., 1998). The RNAi approach uses small RNA molecules which bind to messenger RNAs (mRNA) by complementary base pairing, to induce degradation of the mRNA and/or block protein synthesis. The small RNA molecules are included and processed into cellular RNA processing machinery to induce their inhibitory effects in one RNAi-based therapy modality, a 21-27 base pair double stranded RNA (siRNAs) is introduced into the cells, where it binds to its specific complementary mRNA sequence and inhibits protein synthesis (this effect is commonly called RNA silencing) (Elbashir et al., 2001). SiRNAs are designed to target only one gene which is normally over expressed in cancer cells compared with normal cells. As a result, it is highly desirable to use siRNAs targeting key genes involved in cancer cell migration, invasion, and metastasis. Before RNAi discovery, sequence-specific inhibition of gene expression was possible using nucleic acid-based antisense technology. One of the major advantages of RNAi over antisense based approaches is that the RNAi depends on the cellular machinery to target complementary transcripts resulting in efficient and potent down-regulation of gene expression (Aagaard & Rossi, 2007). Furthermore, the use of the RNAi strategy is highly specific when modulation of a particular target is desired. In this scenario, lower side effects are expected compared to conventional chemotherapy.

CONCLUSION

In this chapter we explore different therapeutics applications of different Novel Drug Delivery System which will be providing complete set of information about drug delivery systems are being of great concern due to their sole purposes. The significance of different drug delivery and targeted drug therapy is to carry a drug directly to the centre of the disease under physiological condition and thereby treat it purposely, with neither effect on the body. This is particularly significant in cancer chemotherapy and enzyme substitute treatment. Drug targeting is the delivery of drugs to receptors or organs of the body to which one hopes to deliver the drug entirely. The targeted delivery of drugs is truly a very inviting aim because these supply one of the most potential ways to develop therapeutic index of the drugs. Previous work done between late 1960s and the mid-1980s stressed the need for drugs carrier system originally to alter the pharmacokinetics of the before proven drugs whose efficacy might be improved by changing the rates of metabolism in liver or clearance by the kidneys. These approaches commonly were not focused to achieve site specific or targeted delivery such as getting a cytotoxic drug to cancerous tissue while sparing other normal, though equally sensitive tissue with the progress in the carrier technology the issue of delivering either single or the entire carrier to the specific site has been addressed during the last few years. The effective use of applications in targeted drug delivery relies on a number of different factors all play a key role in determining the effectiveness of magnetic drug delivery.

Chapter 16
Bioinformatics and Its Therapeutic Applications

Sarvesh Kumar Gupta
IIIT Allahabad, India

Kamal Kumar Chaudhary
IIIT Allahabad, India

Nidhi Mishra
IIIT Allahabad, India

ABSTRACT

Bioinformatics has emerged as a major element in contemporary biomedical and pharmaceutical region. Bioinformatics deals with growth in biological data and has led to development of many databases. Bioinformatics deals with collection of data that is relevant clinically and these days separate term clinical information has come up. Data mimics are another field which is gaining importance. This chapter shall deal with introduction of bioinformatics and its applications in medicine and health care.

INTRODUCTION

Bioinformatics is an applied science including computer science and Biological related research area. There is model change in biological research approach used in computer application (Bayat, 2002) many software tools and computational mathematics model in different field experiment in a high labeled (Cohen, 2004). Bioinformatics introduces the exponential development in life science including chemical and biological data development of primary database and secondary database protein sequencing, nucleic acid sequencing and many structures (Altman, 1998). Some of the known database including Protein database, gene database, zinc database, Swissprot database, CATH database, SCOP database and PIR database etc. These databases are easily available in many private internet Server Company and government domain information. Essential research and protein modeling is completed using these database with helpful for the protein sequencing analysis tool like FASTA, BLAST,CLUSTALW etc. and the protein modeled structure are visualized in using (Russo, 2000) Bioinformatics work as im-

portant role in mixture of broad disciplines of biological organ/tissue to understand the organ complex mechanisms of the body cell. Bioinformatics is also the way in which Pharmaceutical investigation, biomedical investigation and health science use the information technology in their testing proof. The complete process of biological and information data collection to analysis of the proof result such testing may be classified under the specific area named –cheminformatics, Pharma co-informatics and clinical information (Wooley, 1999) (Figure 1).

WHAT IS BIO-INFORMATICS

Bioinformatics research and development studies two important information technology steps in modern biology. The first is the step of proteomic &genomics information from the DNA and RNA of an individual *Homo sapiens* organism up to the characteristics of a population growth of such organisms (Altman, 1998). The second is the steps of practical information from observed biological activity phenomena to models that explain them and then to new experiments in order to test these models. The discipline of bioinformatics has its roots in a number of activities, including the body organization of DNA & RNA sequence and protein three-dimensional structural data collections in the 1960's and 1970's (Langridge, 1974). It has become a booming academic and industrial enterprise with the introduction of biological experiments that rapidly produce massive amounts of data (such as the multiple genome sequencing projects, the large scale analysis of gene expression, and the large scale analysis of protein-protein interactions). Basic biological science has always had an impact on clinical medicine& pharmaceutical (information systems), and is creating a new generation of epidemiologic, diagnostic, prognostic, and treatment modalities. Bioinformatics efforts that appear to be wholly geared towards basic science are likely to become relevant to clinical informatics & pharmaco informatics in the coming decade. For example, DNA sequence information and sequence annotations will appear in the medical chart with

Figure 1. Interaction of disciplines that have contributed to the formation of bioinformatics (source- Science, medicine, and the future: Bioinformatics, a new interdisciplinary science, is essential to managing, understanding, and harnessing clinical benefit from new genetic data.)

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

increasing frequency. The algorithms developed for research in bioinformatics will soon become part of clinical information and chemo informatics systems.

Bioinformatics is a discipline/sub discipline has been recognized for less than 10 years. The first efforts in bioinformatics can be traced back to the early application of computers to biology in the 1950's and 1960's. The early applications of computers to molecular biology were for graphical rendering of three-dimensional molecular structures and the creation of databases of molecular sequence and three-dimensional structure information. Bioinformatics can generally be defined as the study of how information technologies are used to solve problems in biology. The precise definition of bioinformatics is a matter of some debate. The most narrow usage of the term refers to the creation and management of biological databases in support of genomic sequences. The most broad usage includes essentially all applications of computers and information sciences to problems in biology. Bioinformatics is based on the fundamental example of molecular biology: genomics and proteomics information is stored in sequences of DNA bases. Finally this concept of molecule sequencing including molecule storage and analysis is important and central biological data and does not occur in many other area of information technology.

Bioinformatics and Its Scope

Bioinformatics uses modern approaches in the area of life science, computer science and information science including communication technology, computer technology and information technology to problem defined in one or more area in pharmaceutical chemistry, biotechnology and life science. Bioinformatics is data stored in big amount and find out data analysis in data mining have occur main issues for pharma analyst and biological scientists due to fast development in quantitative data in life science such as complete proteomic and genomics of life science species including homo sapiens (human) genome, protein 3-D structure, metabolic pathway and protein sequencing database related information. Advances in bioinformatics particularly the internet source and approach ever increasing information in life science and biotechnology. Functional genomics and proteomics development of new pharmaceutical target and vaccine other pharmacogenomics and biochemical molecule diagnostic kit are many of the field in which bioinformatics has developed in essential part of research and development. The knowledge of multi database, tool to carry out data analysis and design of pharmaceutical molecule and life science system in computer work place as well as in network atmosphere has occur important for any candidate of bioinformatics. Bioinformatics is the multi-disciplinary field and has developed so more than one divides it into Biochemical molecular bioinformatics, sepsis bioinformatics and organelle bioinformatics. Therefore bioinformatics research and development unit are being founded in many pharmaceutical industry, biotechnology laboratory and even in other traditional company introduced in life science (biological). Bioinformatics is thus determined in many numbers of opportunities in this field.

Bioinformatics is introduced with database design, data modeling and data analysis. Data creating is done not only for copy material but also from networking source. Database in life science are mainly multi organized in affiliated database development.

Bioinformatics Tool

The main tools of bioinformatics function are online various related server and computer software like Schrodinger, Auto dock. The fundamental action of molecule sequencing of protein and DNA molecule using different types of software program and biological database easily available on the web server.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Bioinformatics is a developed science and every day there is improvement in every branch of life science and computer science, and today bioinformatics expert use in various complex software programs for recovering, molecule prediction, molecule analysis, molecule protein and DNA sequencing data (NCBI, http://www.ncbi.nlm.nih.gov).These are major class of bioinformatics tool they are using data Ming software and genomics & proteomics sequencing database tool, homology and protein functional analysis tool:

- Homology and Similarity Tools
- Protein Function Analysis
- Structure Analysis
- Sequencing Analysis

Some Example of Bioinformatics Tool

- BLAST (Basic Local Alignment Search Tool)
- FASTA
- EMBOSS (European Molecular Biology Open Software Site)
- crustal W
- RasMol
- Prospect
- Pattern Hunter
- COPIA (Consensus Pattern Identification and Analysis)

Application of Programmers in Bioinformatics

- Bio Java
- Bio Perl
- Bio XML
- Bio cobra
- Ensemble
- Bio Perl-db
- Bio Python & Bio Java

CONVERSION OF 2D TO 3D

Chemsketch and CORINA are easy conversion software's and biological data based program system. They create natural data base library in SDF File format convert into 3D for screening which is taken as input. And hydrogen atoms are added (e.g. Ions in salts) and all molecules are neutralized. Structures that couldn't be converted are excluded from the 3D output file but written to a find out error file. The output file is also formatted in MDL SDF File format.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

DOCKING TOOL

Schrodinger Software

Schrödinger software arrangement in drug design is software applied for ligand molecule and structure molecule based methods. Schrödinger deliver actual, creditable and high achievement computational dependent technology to solution in life science and other applied science research. Maestro is the unified interface for all Schrödinger software products. Schrodinger software are Supplier L.L.C., US. Following software products of Schrödinger are usually installed.

- Glide
- Desmond
- Q Site
- Maestro
- Site Map

Glide

Glide is all about the ligand and receptor complex docking studies. Glide tool response has good speed and accuracy for virtual screening of compounds. Virtual screening is performed by the help of various phases such as HTVS, SP and XP. Glide tool is most common advanced scoring energy function.

Desmond

Desmond tool performs molecular dynamic simulation for ligand complex molecule of proposed ligand and protein. Molecular simulation dynamics provides natural environment and finds out biological system movement at atmospheric condition. Technical and Pharmaceutical industries take up molecular dynamic simulations from time to time to study computational simulations for knowing stability of bound protein.

Q-Site

Q Site is applied for Quantum mechanism studies, to demonstrate the interaction point of a target, active site and protein molecule interaction function to the comfort of the system. Classical molecular mechanism (MM) process cannot be defined by the electrostatic force change condition of reaction and finding out ligand receptor interaction. Quantum mechanism (QM) is expected to study active chemical molecule affect of transition metal with a protein in atmospheric conditions.

Maestro

Maestro tool is the undivided interaction for all Schrodinger tool and most commonly selected analysis tool. Maestro tool has been developed for chemical molecule simulation and is used in pharmaceutical company and research institute. Maestro tool is computational technology visualization function. Maestro tool is used to find out chemical molecule properties with intramolecular interaction. Maestro tool are used in advanced computational science in drug discovery.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Site Map

Site map is a tool for identification of binding site and characteristic visualization tool. It is easy to use and finds out good ligand binding site corresponding to that area of drug design. Site map is based on proven algorithm for active bind position identification and assessment and can help in research associated to actual point of binding site.

ORGANISM INFORMATION BIOINFORMATICS DATA

The concept of under based many research development procedure in bioinformatics is that big database can be created side by side depending on chemical and biological analogs, for example proteomic and genomic DNA and protein sequence gene (Pedersen, Jensen, Brunak, Staerfeldt, & Ussery, 2000).An essential aspect of management of big amount of database is in developing procedure for doing comparative study between different molecules in biological data and identifying related bimolecular data. We introduced major data base that provide primary source of bioinformatics and introduced in secondary data base in order to colony the data. These are classified correlation between genomic, proteomics and its derivative product (Luscombe, Greenbaum & Gerstein, 2001). There are common term to define the correlation between pair of protein sequence and gene sequence. The two classes can be some time difficult to different especially if the relation between the two proteins is distance (Russell, Saqi, Sayle, Bates & Sternberg, 1997, 1998). Protein that are relation between gene duplication and genome (Fitch, 1970). Normally orthologs contain the same work (Tatusov, Koonin, & Lipman, 1997).The important notation of these area observations is limited for different organism (Gerstein & Hegyi, 1998; Skolnick & Fetrow, 2000) (Table 1).

MOLECULE INFORMATION BIOINFORMATICS DATA

The type of bioinformatics data that are analysed in range of subject and that are consider to relative to that area. We also give near about value introduced in size of biological data base being discussed. Source of information in bio informatics may be defined to raw material in DNA sequencing, genome molecule sequencing, macromolecule protein structure and all other genome bioinformatics data. Basic DNA molecule sequencing is initial stage four base character comparing gene base pair, each generally more than 1000 base pair large. The gene bank stock of nucleic acid sequence latest holds a 9.5 million base pair data base. The protein sequencing strings of 20 amino acids. At time presented 300,000 known protein sequence, with a typical bacteria protein contenting near about 300 amino acids. Macro molecular data represents more information. Latest the big data base for bacteria has made near about 20 times analysis for 6000 gene (Holstege et al., 1998) (Table 2).

ACCOMPLISHMENTS OF BIOINFORMATICS

There are two categories of accomplishments of bioinformatics that can be credited to bioinformatics. The first categories are an empirical principal that have become accepted by this field and generate context

(source-What is bioinformatics? An introduction and overview" Yearbook of Medical Informatics 2001")

which guides both training and research development. The second categories are particular biological database and algorithm that have been evolved and which are service to Biological science.

1. The molecular structure of protein in evolution contains more changes like mutation, dilation and insertion of building blocks amino acid protein to the sequence. There are many similar chemical and biological structures with many different sequences (Lesk & Chothia, 1980).
2. Chemical and biological sequence can be aligned using algorithm based dynamic program. These mathematically choice alignment are most reliable when the similarity between sequences is high (>30% identical), but become less reliable in the range below 25% (Chung & Subbiah, 1996).
3. Probabilistic model of protein sequencing model known as hidden markov model can sensitively characterize a class of related sequence (Durbin, Eddy, Krogh, & Mitchison, 1998).
4. Different in both host and DNA pathogen genetic information can be used to comprehend which proteins are involved in diseases.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Sources of data used in bioinformatics, the quantity of each type of data that is currently

Biological Data Source	Biological Data Size	Bioinformatics Topics
Raw DNA sequence	8.2 million sequences (9.5 billion bases)	Separating coding and non-coding regions Identification of introns and exons Gene product prediction Forensic analysis
Protein sequence	300,000 sequences (~300 amino acids each)	Sequence comparison algorithms Multiple sequence alignments algorithms Identification of conserved sequence motifs
Macromolecular Structure	13,000 structures (~1,000 atomic coordinates each)	Secondary, tertiary structure prediction 3D structural alignment algorithms Protein geometry measurements Surface and volume shape calculations Intermolecular interactions Molecular simulations (force-field calculations, molecular movements, docking predictions)
Genomes	40 complete genomes (1.6 million – 3 billion bases each)	Characterization of repeats Structural assignments to genes Phylogenetic analysis Genomic-scale censuses (characterization of protein content, metabolic pathways) Linkage analysis relating specific genes to diseases
Gene expression	largest: ~20 time point measurements for ~6,000 genes	Correlating expression patterns Mapping expression data to sequence, structural and biochemical data
Other data Literature Metabolic pathways	11 million citations	Digital libraries for automated bibliographical searches Knowledge databases of data from literature Pathway simulations

(2000) available, and bioinformatics subject areas that utilize this data.
(Source-What is bioinformatics? An introduction and overview" Yearbook of Medical Informatics 2001")

The effect of bioinformatics has also been made with the improvement of algorithm and biological database that are generally used some of which were developed by bioinformatics developer/researcher and other important bioinformatics resources and modern bioinformatics tool. The physician is not decided which symptom the patient may have and conformed to go on the web site server to investigate the known genetic syndrome related with disease. Today physician cross web site server to gather biological information in the following manner.

1. The physician first goes to the NCBI (National center for Biotechnology Information) web site server page. Today NCBI maintains a large number of biological database and molecular medicine database.
2. The molecule genetic gen data bank is then approach forms the molecule protein sequence to see the detailed molecular sequence of DNA base that encoded for the gene.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

THERAPEUTIC APPLICATION

Bioinformatics has several therapeutic applications. Some of which are discussed below. The application of bioinformatics is in - Preventative medicine, Gene therapy, Antibiotic resistance, Evolutionary studies, Waste cleanup, Biotechnology, Climate change Studies, Alternative energy sources, Crop improvement, Forensic analysis, Bio-weapon creation, Insect resistance, Improve nutritional quality, Development of Drought resistant varieties and Vetinary Science.

BIOINFORMATICS USED IN DATA MINING

In bioinformatics there is huge amount of data to deal, in order to deal with this huge amount of data some techniques are required to sustain this huge amount of data properly. In this sense DATA MINING software provide huge contribution.

Some of the applications are as follow –

1. Finding the gene in large DNA molecule.
2. Domain Finding
3. Protein and gene interaction recognition
4. Motif Detection

For example Microarray technology is used to predict the patient health behavior. On the basis of genotypic behavior of patient, the survival time of the patient and the disease in the patient is recognized i.e. very useful in disease estimation or analyzing. The data mining tool provide machine learning technology for analyzing massive amount of data i.e. peptide identification of mass spectroscopy.

These are main task of data mining:

- **Classification:** provide tools for classification of data based on requirement of experimental purpose i.e. Classes are predefined in it.
- **Estimation:** Given some input data, it helps in estimating the value of some unknown parameter.
- **Prediction:** it is similar to the classification and estimation but the records are classified based on the behavior of future.
- **Association Rules:** this rule helps to determine the dependency between the records so that the similar thing can come up together.
- **Clustering:** is a process of dividing the large population into small-small group containing the similar feature?

Description & visualization the above classified data is now is shown by using the some of visualization technique.

Learning by using these tool fall out under two categories

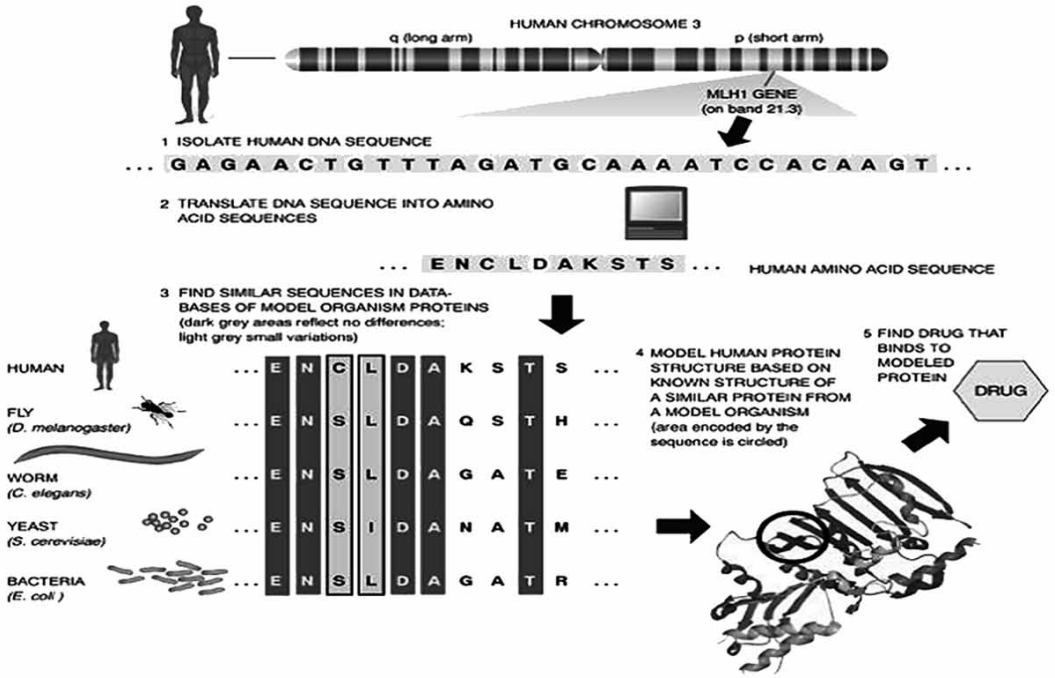
- Supervised learning
- Unsupervised learning

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

The classification, estimation, prediction are the example of supervised learning. Supervised means there is guideline to perform the task.

The next three task – association rules, clustering and description & visualization comes under the the categories of unsupervised learning.Unsupervised learning means there is no any definite guideline to perform the task.

BIOINFORMATICS AND DRUG DISCOVERY



Today various type of disease is now known. Today more than 14 to 15 million death every year occur in developing countries as per WHO report. Most death from infectious disease occurs in developing countries like Ebola, malaria, H1N1 etc. (Clark & Pickett, 2000). Such drugs are high in cost and not easily available for developing world. The drug development of low cost and good quality drug for a different type of diseases is one of the most common problems faced by pharmaceutical industry or research institute. The solution to problem drug design is use of bioinformatics. Pharmaceutical company research and development of new drug using bioinformatics tool and various techniques reduces time and cost of pharmacological agent. Computational procedure are used for the forecast of drug similarity which is nothing but the molecules identification of hit molecule that will probably prove to be drug in later stage of drug discovery and development (Shortliffe & Blois, 2000). The pharmaceutical research institute and pharma industry‘s point of view bioinformatics is a key to drug design. It reduces the number of molecule trial in the screening of drug molecule and identifies potential drug receptor for the specific diseases using computational server workstation and bioinformatics tool. The application of bioinformatics in genomic and proteomic sequence has opened up a new area in pharma co informatics, pharmacogenomics which is the study of molecular genetics basis for the different type of drug design (Figure 2).

BRIEF HISTORY OF COMPUTER AIDED DRUG DESIGN

2000’s: Vast information handling technology (pharmacogenomics)
1990’s: First Computer based genomic assembly or Genomics based target selection
1900: Human Genome Project, Bioinformatics, Combinational chemistry and HTVS (High throughput virtual Screening)
1900: Receptor based and locks and key principal [(1909) P. Ehrich and (1894) E. Fisher]
1980: Beginning of Computer aided drug design, Computer graphics, X-ray crystallography, and Multidimensional NMR, Molecular Modeling and Molecular computational biology.
1980’s: First computer based docking
1980’s: Data based combinatorial libraries including information technology
1970: QSAR (Quantitative Structure Activity Relationship) including 2-Dimentional and retrospective analysis.
1960’s: Review the target or drug interaction

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Above is a schematic outlining how scientists can use bioinformatics to aid rational drug discovery.
(Source-What is bioinformatics? An introduction and overview "Yearbook of Medical Informatics 2001")

COMPUTER AIDED DRUG DESIGN

Computer based drug design including Structure or ligand based drug design; rational drug design and intelligent drug design are very typical and longtime processes developed in last 12to15 years (Richards, 1994). Today computer aided drug design (CADD) works on various types of algorithm based software and working technology in a very short time for drug development and gives a hypothetical result. And it has led to development of a branch called Bioinformatics (applied science). (Clark & Pickett, 2000). Today entire scientific community, most pharmaceutical research and development companies including biotechnology research development laboratories and research institute use computational based design software tools. Because of low cost involved by their use in drug development (Zeng, 2000). Computer aided drug design is of two types: structure dependent drug design and ligand based drug design. Structure based drug design; main hypothesis is by this influence the potent molecule's capability to interact by hydrogen bond with special protein pulls a required biological impact which depends on its capability to favorably interact with a specific binding site on that molecular protein. And other ligand based computer aided drug design depends on ligand and involve the analysis of ligand molecule known/unknown to interact by hydrogen bond with target ligand and active molecule. Compounds found by ligand based virtual screening method are again and again more potent molecule (Klebe, 2000). The latest development is human immunodeficiency virus (HIV) potent inhibitor which has convincingly demonstrated the impact and the relevance of structure-based approaches to the discovery of new drugs (Lipkowitz & Boyed, 1996).

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

ADMET Properties

The pharmacological activity in our body or tissue, pharmaceutical compound has to pass through physiological barriers such as the BBB (blood brain barrier), gastrointestinal barrier, microcirculatory barrier and plasma member barrier before passing to blood circulatory system. Pharmaceutical compound are subsequently transported to effective receptor site for distribution into organs and tissue by specific pocket site and other wastage material out of the body this process is called excretion. ADMET (Absorption, Distribution, Metabolism, Excretion and toxicity) properties check out biological activity of pharmaceutical compound (Song, Lim, & Tong, 2009). Drug development for novel pharmaceutical agent is filtering out one compound out of several screened compounds, and this reduces long time and cost for research and development. Today pharmaceutical industry and biotechnology laboratory develops several potential ligands and checks out ADEMT properties at every stage of drug development (Veselovsky & Ivanov, 2003).

Pre-Filtering

Initial step in ligand virtual screening is screening the generated library by the Lipinski's Rule of Five (Lipinski, Lombardo, Dominy, & Feeny, 2001; Kerns, & Carte, 2009). Lipinski's rule work depends on the analysis of profiling the calculated physical property-

- Maximum five hydrogen bond donor nature
- Molecular mass less than 500Da
- Octanol water partition coefficient less than five
- More than 10 Oxygen and Nitrogen atom accepter
- No. of rooted bond less than ten

Molecule chemical structure characteristic eligible of optimization and designed by combinatorial ligand and medicinal chemistry-

- ADME properties is good
- No toxic substructures

Thus lead molecule chemical structures are the starting point for drug development. The meaning of leads molecule structure requires at least one marketed preparation drug design based on this particular lead molecule structure (Clark, & Pickett, 2000).

Design of Combinatorial Natural Compound Library

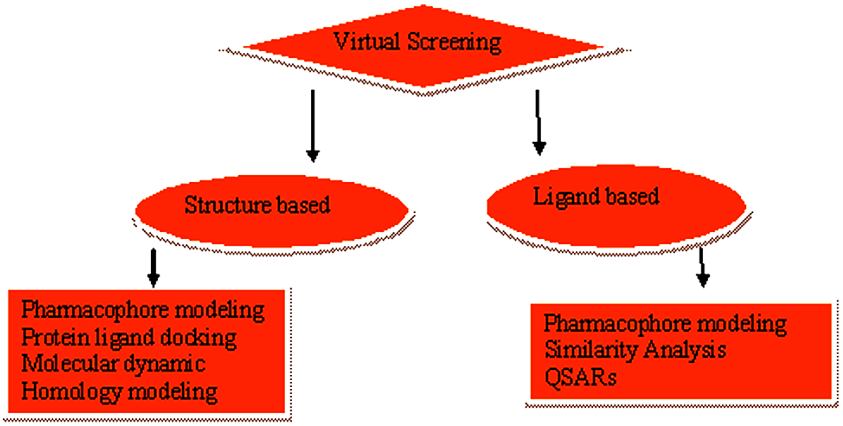
Virtual high through screening use used in high performers computational to virtual screening large ligand molecule data base compound for most potent inhibiter screen. The performers a how ever virtual combinatorial library must be possible for natural library screening. Virtual screening can be earned in variation of molecule size and drug design inclusive of general virtual screening library that can be used to screen data base against proposed protein, selected library this are designed structure for a data base of

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

related proposed target. And proposed target data base libraries that are specific structure designed for a single potent target. At last finally proposed data base methods is called generated data base (Sliwoski, Kothiwale, Meiler & Lowe, 2014).

Virtual Screening

Virtual screening is a standard process in drug discovery and selection of most potent chemical molecule structure this process involved in computer aided drug design. VS basically meninges data base library screen again proposed target protein molecule high energy scoring function in selection of data base library. This time Meany drug rejected in clinical trial phase because the drug is not potent for receptor. And pharmacokinetic including absorption, distribution metabolism, excretion and toxicology based blamed and reject clinical trial phase. The term virtual screening has been define in process computational based large data base chemical compound analysis and best compound selected. Virtual screening following the principal of Lipinski rules used in drug deployment. The selection of an applicable virtual screening process depends on much point e.g. on the availability of structure based biological information of the proposed target protein molecule and other selected ligand molecule the size of data base used for virtual screening and computation based resources. Virtual screening method can be categorized in two parts first part is ligand based and second part is protein structure based (Clark & Pickett, 2000) (Figure 3).



Ligand-Based

Ligand based drug development ligands bind to specific biological target. Mainly ligand based virtual screening procedure are QSARs, pharmacophore based modeling and similarity analysis.

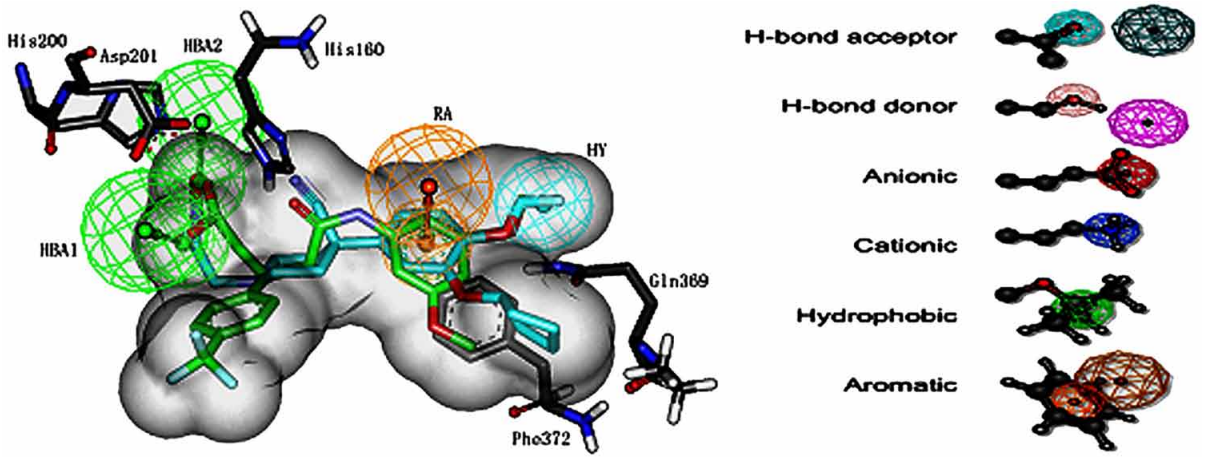
Ligand Base Pharmacophore Modeling

Pharmacophore modeling introduced by Paul Ehrlich time duration the late 1800s (Schueler, 1960). The word pharmacophore coined by Schueler introduced in his book Drug design and Chemo biodynamics, a molecular structure that carry the essential features responsible for drug pharmacological activity

Figure 3. Virtual screening method application in drug development.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

(Schueler, 1960).International Union of Pure and Applied Chemistry (IUPAC) introduced the term pharmacophore in 1997, Pharmacophore is the ensemble of electronic and steric features that is necessary to ensure the optimal supramolecular interactions with a specific pharmacological target and to block its pharmacological activity. Computational pharmacophore structure is generally involved to generate novel initials point for drug development research center (Wermuth, Ganellin, Lindberg, & Mitscher, 1998). Many category of pharmacophore modeling based ligand development, such as Discovery of studio/Catalyst, phase (Leach, Gillet, Lewis, & Taylor, 2010). Ligand Scout and MOE (Dixon et al., 2006). These chemical ligand based can be labeled hydrogen bond accepter or donor, cation, anionic, hydrophobic or aromatic and any probity aggregate (Wolber, & Langer, 2005) (Figure 4).



Similarity Analysis

Similarity search based algorithms use full techniques are finger print similarity analysis (2D finger print) or Electrostatic similarity analysis (3d shape) to find out similarity of a pharmacological activity query ligand with a biological data base. Fundamental developed for ligand chemical structure search, finger print similarity analysis very popular technique for conclusion of chemical molecular similarity between ligand based chemical compound (Gund, 2000). Finger print of data molecule similarity performed used in a coefficient score (Leach & Gillet, 2003).most popular finger print similarity analysis algorithms include ECFPs (Scitegic Extended Connectivity Fingerprints), 2D mol print and daylight finger print (Duan, Dixon, Lowrie, & Sherman, 2010).

Quantitative Structure Activity Relationship (QSAR)

Quantitative Structure Activity Relationship (QSAR) defined the mathematical correlation between structure characteristic and pharmaceutical target properties of ligand database (Perkins, Fang, Tong, & Welsh, 2003; Verma, Khedkar, & Coutinho, 2010) (Table 3).

Figure 4. Pharmacophore mapping of ligand and compound predicted by molecular docking.

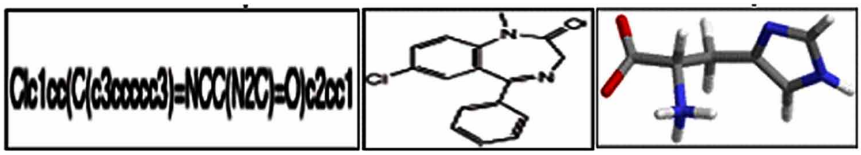
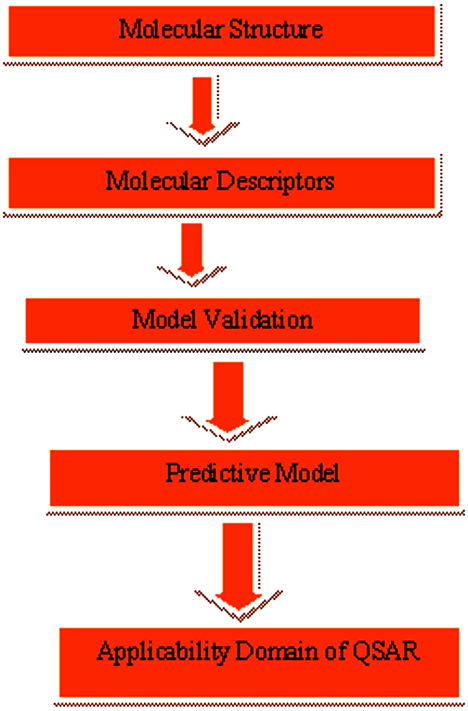
Summaries of QSAR studies in literature	Journal Quantitative Structure-Activity Relationship



Hence in contrast to hit drug development technique such as pharmacophore based modeling, QSAR are commonly used in the optimization phase of drug development (Fischer, 2008). QSAR technique 1st time introduced Corwin Herman Hansch (father of QSAR concept) in 1860 (Hansch, 1969) and this technique improved by two scientists Crum Brown and Fraser in 1865 expressed the idea chemical structure and relationship activity(Crum –Brown & Fraser,1969; Richet, 1893; Meyer, 1899; Overton, 1901).

Different type molecule structure like one dimension, two dimension, three dimensions and multidimensional Quantitative Structure Activity Relationship (QSAR) based have been design time period the past separate decades (Lill, 2007).one dimensional QSAR defined biological activity by correlation of the pharmaceutical ligand physicochemical properties eg.log P value. And two dimensional QSAR structure character of pharmaceutical ligand compound relation between structures based eg.2D-Pharmacophore (Lill, 2007).In three dimensional Quantitative structure activity relationship (QSAR) congeniality is correlated with the three dimensional structure of pharmaceutical ligand eg- CoMFA. CoMFA (Comparative molecular field analysis) is defined the 3Dimenstional visualization of electrostatic field and steric of pharmaceutical ligand molecule bioactive conformation and protein ligand binding (Cramer, Patterso, & Bunce, 1989). Three dimensional Quantitative Structure Activity Relationship used tool CoMSIA (comparative molecular similarity indices analysis) procedure calculation pharmaceutical ligand field characters like hydrogen bond accepter, hydrogen bond donor and hydrophobicity to created 3-dimenstional Quantitative structure activity relationship models (Klebe & Abraham, 1999) (Figure 5).

QSAR Modeling Process



Quantitative structure activity relationship modeling process mainly five phases (Figure 6).

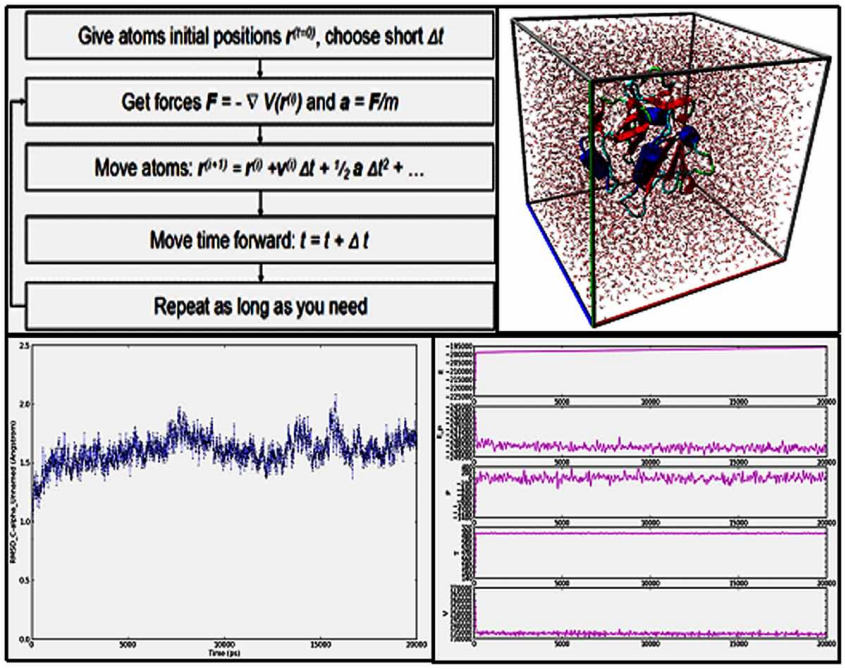
Structure Based Virtual Screening



Structure based Virtual screening applied for drug development process pharmacological ligand target is available for three dimension ligand structure data. Structure based virtual screening interaction on ligand and protein and tool for optimization and hit drug development (Waszkowycz, 2008).

Molecular Dynamics Simulation

Molecular dynamic simulation is docking complex computational simulation method. Molecular dynamic come up of the first simulation method form the search function to the molecular dynamic of liquid phase introduced by Alder, Rahman and Wainwright in the later 1950s and early 1960s. There are two main category of molecular dynamics simulation process. In the classical working output to molecular dynamics simulation partials are treated as classical object, homologues much the ball and stick model. Molecule atom approach to soft ball and elastic stick corresponding to bond (Sandeep, Priyadarshini, Pradhan, Munikumar, & Umamaheswari, 2012). The rule of classical work defines the dynamic of the method. The first principal of molecular dynamic simulation started in 1980 with the seminal work of car and Parinello accepted finally in to account the quantum nature of the chemical bond. Quantum molecular dynamics simulation performs an important correction over the access and they are used in given information on a number of biological problem. Computer molecular dynamic simulation act as a pool between microscopic distance and time parameter and microscopic earth sphere of the laboratory we provide a conjecture at the interaction between molecule particles and receive correct prediction of high amount characteristic. A molecular dynamic simulation is illustrated with figure (Figure 7).

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 7. A simplified description of molecular dynamics simulation.

Protein Ligand Docking

The Docking method is calculation of energy in complex including ligand and protein molecule. There are two role of docking research first is protein structure modeling and second is prediction information of biologically activity of ligand molecule. Docking is selection of scoring faction energy interact between ligand and protein ranking. Molecular characteristic such as hydrophilic nature, hydrogen bonding and electro static force as well as weight combination have been obtain a completely automated arrangement of molecule. Docking is basically work for accurate proposed structural modelling and correct prediction of the biological activity (Virtanen, 2013). The protein ligand docking development manly divided in two phase first know pocket site of pharmaceutical ligand docking development process and other randomly pharmaceutical ligand binding and using scoring faction of ligand docking energy (Kirchmair, Markt, Distinto, Wolber, & Langer, 2008).

Structure Based Pharmacophore Modeling

Structure based Pharmacophore modeling used in the geographical information related to the pharmaceutical ligand protein target to create a topologically characterization of pharmaceutical ligand protein interaction (Leach, Gillet, Lewis, & Taylor, 2010).Three dimensional structure information on the pharmaceutical ligand protein is mainly got from multidimensional or X-ray crystallography spectroscopy and NMR. It is necessary to secure the credibility of the ligand bind site residues and pharmaceutical ligand co-ordinate by visually check out theirs degree of fitness to the corresponding electron density graph available for illustration at the Uppsala Electron Density Server (Kleywegt et al., 2004).Structure

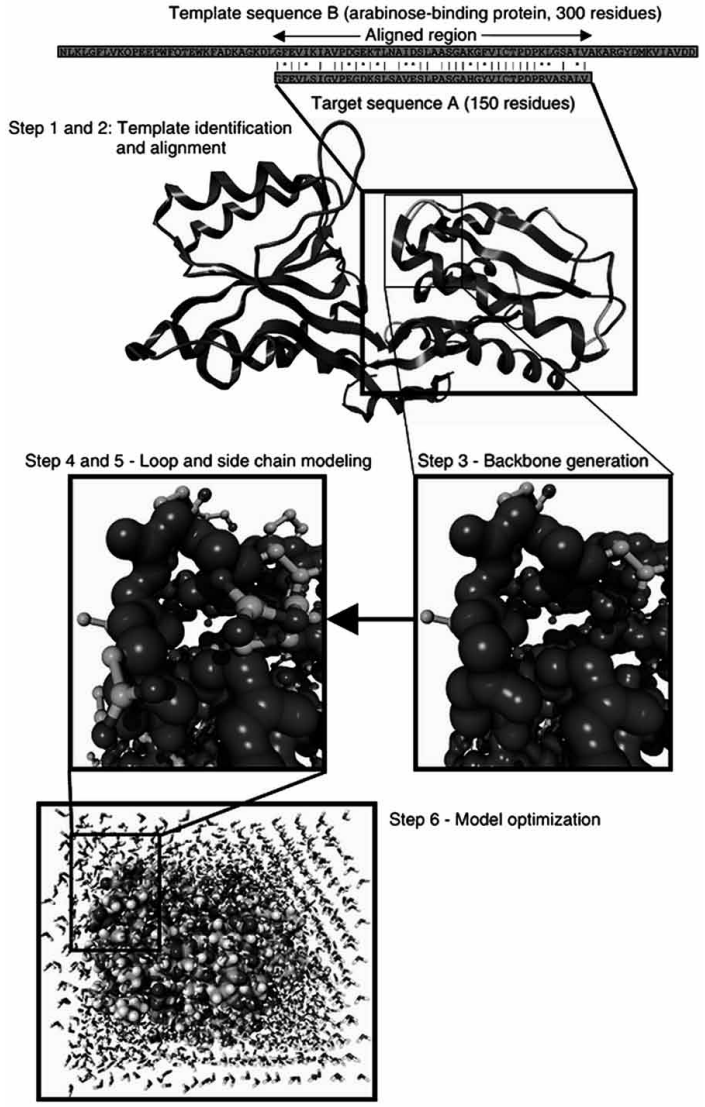
EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

based pharmacophore models example for the optimization and generation found in literature (Markt, Schuster, Kirchmair, Laggner, & Langer, 2007 and Barreca, 2007). Salam et al. (2009) defined a different procedure for creating structure based pharmacophore using active analysis. Software programs that allow for the manual construction of pharmacophores from protein-ligand complexes include Schrodinger's Phase, Accelrys Discovery Studio, MOE by the Chemical Computing Group and Inte:Ligand's LigandScout (Table 4).

Homology Modeling

The large scale different between the number of possible sequence and number of laboratory proof protein molecular sequence, which is limitation by time, product cost and laboratory objection built-in to the development of ligand structure determination could likely may be decide using homology modeling(Eswar, Eramian, Webb, Shen, & Sali, 2008). In non-attendance of laboratory proof structure homology modeling play important role of structure based drug development process.homology modeling is performed in seven phases (Krieger, Nabuurs, & Vriend, 2003).

1. Template recognition and initial alignment
2. Alignment correction
3. Backbone generation
4. Loop modeling
5. Side-chain modeling
6. Model optimization
7. Model validation



These phase may be continue until a good model is assembled (Cavasotto & Phatak, 2009). Although homology structure model are description of the known three dimension protein ligand structure, their property for virtual screening moment has been proved (Miguet, Zhang, Barbier, & Grigorov, 2006) (Figure 8).

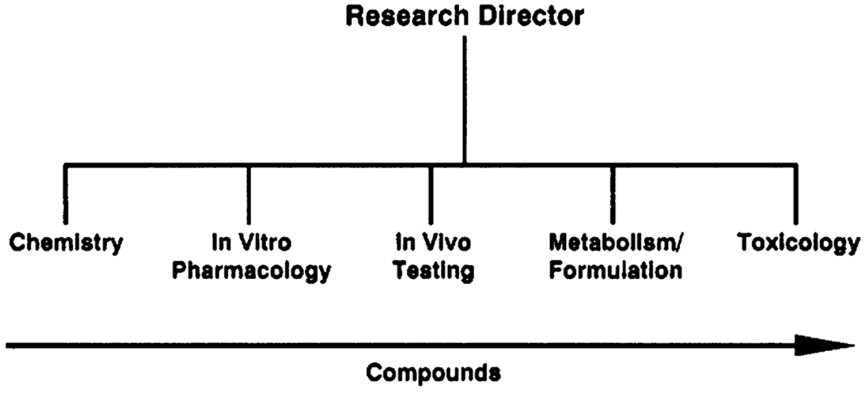
Drug Discovery Process (Drug Cycle)

Approach for computer aided drug design deployment depend on the molecular structure and other biologically data information helpful regarding the propose target (Receptor/Enzyme) and screen ligand. Present time used in drug design deployment process two approach modeling design of drug directly and indirect design. In the direct strategies drug design based on relative analysis of the stretcher based characteristic know active and passive molecular compound. In direct drug design the three dimensional characteristic by the propose target (inhibiter) are directly consider (Frenking et al., 1996).

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

The strategy of drug discovery process has remained evasive despite important analysis. Like the biological approach bioinformatics on which the drug designs discovery process is based (Cavagnaro & Lewis, 1987). Discovery process strategies for drug development depend on following factors-



- Corporate sector, research, and marketing department cultures
- Individual scientists working within a company
- Synergies among various research disciplines
- Good quality of research management R&D leadership
- Individual and corporate experience
- Extent to which the management of a company is accustomed to risk Serendipity
- A particular company's market franchise (the therapeutic areas in which it markets drugs)

These processes are completed in 12-15 years (Figure 9)

Transmembrane Ion Channels

Voltage gated ion channel are a class of transmembrane ion channels that are activated by changes in electric potential difference. Sodium channels are integral membrane proteins that form ion channels which conducting sodium ions (Na^+) through a cell's plasma membrane (Jessell & Sanes, 2000).Voltage Gated Sodium channels (VGSCs) are members of the ion channel protein superfamily consisting of a large core protein, the α-subunit (220–260 kDa, ≈2000 amino acids), associated with one or more smaller regulatory β-subunits (22–36 kDa). VGSCs are transmembrane complexes play an essential role in neuronal and non-neuronal function, being responsible for the initiation and propagation of action potentials in excitable cells by allowing the influx of sodium ions. The α-subunit is sufficient for functional expression, forming the pore, determining the biophysical properties of the channel, and containing the ion selectivity filter. B-Subunits can modify the kinetic and voltage dependence properties of the channel and are involved in channel localization and interaction with cell adhesion molecules, extracellular matrix, and intracellular cytoskeleton. Voltage-dependent calcium channels (VDCC) are a group of voltage-gated ion channels found in excitable cells (e.g., muscle, glial cell, neurons etc.) with a permeability to the ion Ca^{2+}(William, Goldin, & Stephen, 2005). These channels are slightly perme-

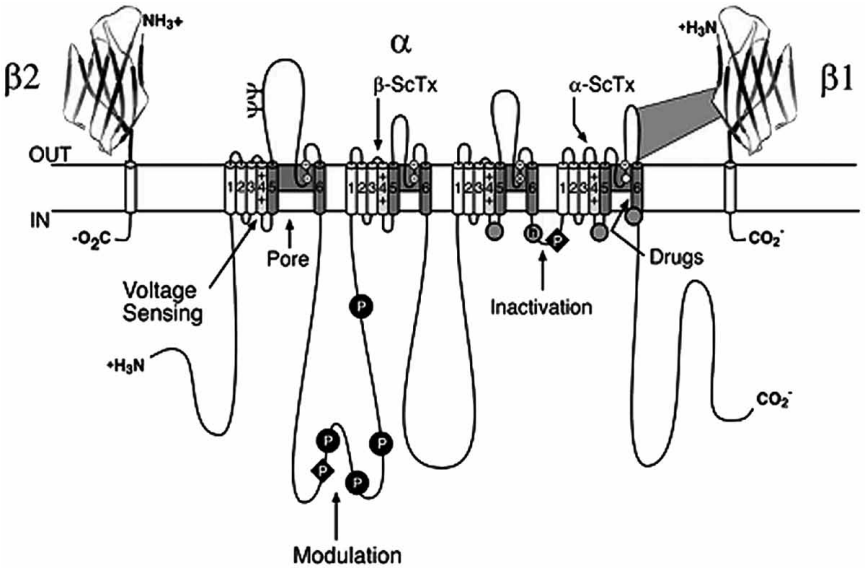
Figure 9. Functional organization graph

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

able to sodium ions so they are also called Ca^{2+}-Na^{+} channels, but their permeability to calcium is about 1000-fold greater than to sodium under normal physiological conditions(Yamakaqe & Namiki, 2002). A physiological or resting membrane potential VDCCs are normally closed. They are activated (i.e., opened) at depolarized membrane potentials and this is the source of the "voltage-dependent" epithet Activation of particular VDCCs allows Ca^{2+} entry into the cell, which, depending on the cell type, results in activation of calcium-sensitive potassium channels, muscular contraction (Michael & Walsh, 1982),excitation of neurons, up-regulation of gene expression or release hormones or neurotransmitters. On the other hand, K+ channels are membrane proteins that allow rapid and selective flow of K+ ions across the cell membrane, and thus generate electrical signals in cells. Voltage-gated K+ channels (Kv channels), present in all animal cells, open and close upon changes in the transmembrane potential. Kv channels are one of the key components in generation and propagation of electrical impulses in nervous system. Voltage-gated K^{+} channels are selective for K^{+} over other cations such as Na^{+}. Sodium channels are integral membrane protein that form ion channels which conducting sodium ions Na^{+}through a cell's plasma membrane. In excitable cells such as neurons, myocytes and certain types of glia, sodium channels are responsible for the rising phase of action potentials. Sodium channels can be of two types: voltage-gated called VGSCs and the other ones that respond upon binding by a ligand and thus are called as ligand-gated sodium channel. The sequence set of DNAs for VGSC, VGKc, VGCC and its Docking sites with various neurotoxins can help us to understand the structure and function of these ion channels. Further, neurotoxins that bind can be a potent Analgesics, Also this can be useful in knowing the molecular basis of the diseases which are the result of disfunctioning or the alteration in their normal rhythmicity of the ion channels.

Calcium Channel Sub Unit

Calcium channel biochemical properties are ligand protein complex composed of near about four or five separate encoded subunit by multiple genes (William, 2000) (Figure 10).



Sodium channel are tetrodotoxin resistant degree due to changes in amino acid protein sequence a indusial position of domain and more expressed in root ganglion neurons and heart pace maker(Fozzard & Hanck, 1996) (Table 5).

Table 5. Receptor site target on sodium channels.

Drug	Receptor Site	Domains
Tetrodotoxin, **Saxitoxin, μ-Conotoxin**	Neurotoxin receptor site-I	IS2–S6, IIS2–S6 IIIS2–S6, IVS2–S6
Veratridine, Batrachotoxin **Grayanotoxin**	Neurotoxin receptor site-II	IS6, IVS6
α-Scorpion toxins, Sea anemone toxins	Neurotoxin receptor site-III	IS5–IS6, IVS3–S4, IVS5–S6
β-Scorpion toxins	Neurotoxin receptor site-IV	IIS1–S2, IIS3–S4
Brevetoxins, Ciguatoxins	Neurotoxin receptor site-V	IS6, IVS5
δ-Conotoxins	Neurotoxin receptor site-VI	IVS3–S4
Local anesthetic drugs Antiarrhythmic drugs **Antiepileptic drugs**	Local anesthetic receptor site	IS6, IIIS6, IVS6

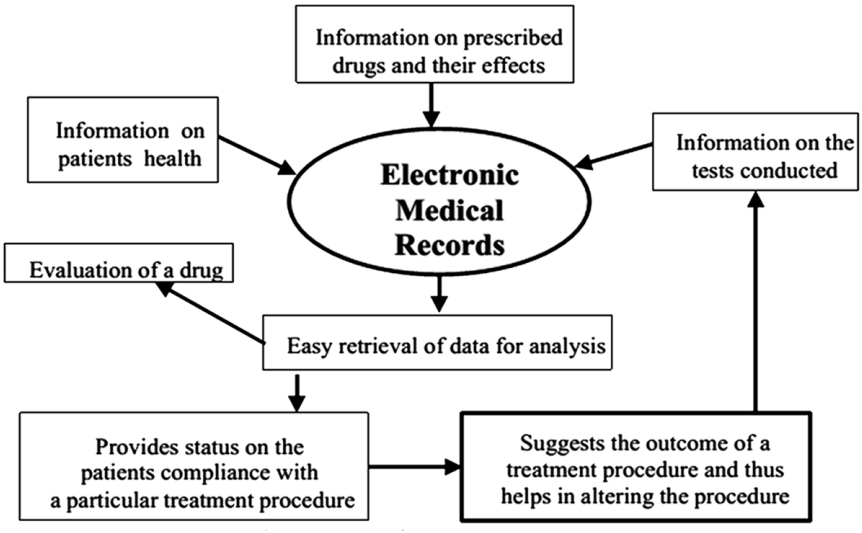
Figure 10. Transmembrane organization of sodium channel subunits. The primary structures of the subunits of the voltage-gated ion channels are illustrated as transmembrane-folding diagrams. Cylinders represent probable α-helical segments. Bold lines represent the polypeptide chains of each subunit, with length approximately proportional to the number of amino acid residues in the brain sodium channel subtypes. The extracellular domains of theβ1 and β2 subunits are shown as immunoglobulin-like folds. ψ, sites of probable N-linked glycosylation; P, sites of demonstrated protein phosphorylation by protein kinase A (circles) and protein kinase C (diamonds); shaded, pore-lining S5-P-S6 segments; white circles, the outer (EEDD) and inner (DEKA) rings of amino residues that form the ion selectivity filter and tetrodotoxin binding site;+ +, S4 voltage sensors; h in shaded circle, inactivation particle in the inactivation gate loop; open shaded circles, sites implicated in forming the inactivation gate receptor. Sites of binding of α- and β- scorpion toxins and a site of interaction between αand β1 subunits are also shown.

BIOINFORMATICS AND MEDICAL SCIENCES (CLINICAL SCIENCES)

Bioinformatics has a deep effect in Medical sciences (Clinical Application). The molecular biological data base is very helpful for physicians to diagnose the disease and research strategies for therapy. Consider a situation where a patient with a genetic disease meets physicians. The physicians is not classified symptom casing disease physicians go to web information resource available at http://www.ncbi.gov. in which available detail gens related information on symptom. The information on the protein crystal structure can be acquired by following the link to web-protein data bank given in swiss port database. Following the other link to the DNA molecule sequence in the molecular genetic database also called gene bank the nucleotide sequencing of the gene is accrued along with data of gene asymmetry. Thus the Doctor/Physicians used in the biological database to collection of biological information about the symptom which disease diagnose and device approach for therapy (Cote & Robboy, 1980; Slee, 1978 and Current procedural terminology, 1970).

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

The human genome project policy to complete the human gene sequencing process a gene database of all the dissimilarity in gene sequencing. And other bioinformatics tool is already acquired in certain clinical problem in diagnoses and treatment plan like PubMed etc (Markowitz & Ritter, 1995).



Most important of EMR (Electronic Medical Record) in medical science the information can be very easily acquired and shared in comparison to Conventional medical record. The EMR data expected for a study can be obtained directly from the electronic medical record thus producing research biological data collection for medical analysis a side effect of generally clinical data record keeping. The electronic medical record helpful for research protocol, point out to a physician when a eligible for a study, or when the protocol for a study calls for a specific management plan given the currently available data about that patient (Figure 11).

GENE THERAPY

Gene therapy is the therapeutic delivery of nucleic acid polymers into a patient's cells as a drug to treat disease. Gene therapy is a way to fix a genetic problem at its source level. The polymers are either expressed as proteins, interfere with protein expression, or correct genetic mutations. Biomedical helps to build up a therapeutic method to treat genetic diseases. The most common form uses DNA that encodes a functional, therapeutic gene to replace a mutated gene. The polymer molecule is caged within a carrier or vector, which carries the molecule inside affected cells.

Gene therapy was conceptualized in 1972, by authors who urged caution before commencing human gene therapy studies. The first gene therapy experiment approved by the US Food and Drug Administration (FDA) occurred in 1990, when Ashanti DeSilva was treated for ADA – SCID. (Sheridan, 2011), Bioinformatics has led to identification of several genes and development of databases where large data is stored which can be seen for conducting gene therapy.

MICROBIAL GENOME APPLICATION

Microbial genome is ubiquitous and microorganisms are found in every place and any time. They have been found living and growing in crown of heat, cold emaciation, mineral acid, basicity and pressure. They are present in atmosphere, in human body and water, air and food. Generally use has been built of a different of microbial characters in the fermentation, bakery and food Technology Company. The coming of the whole genome sequence and their atmosphere, energy, healthy and food technology application. Introduced in 1994 department of energy (DOE) US proposed the microbial genome project (MGP) to sequencing gene of bacteria produced in energy formation, clean atmosphere, company processed food and harmful waste material.

Disease Causing Microorganisms

- Bacillus anthracis
- Brodetella pertusis
- Chlamydia trachomatis
- Clostridium botulinum
- Clostridium perfringens
- Clostridium tetani
- Corynebacterium diphtheriae
- Escherichia coli
- Gardinerella vaginalis
- Helicobacter pylori
- Haemophilus influenzae
- Klebsiella pneumoniae
- Legionella spp.
- Listeria monocytogenes
- Borrelia burgdorferi
- Anthrax
- Lyme disease
- Trachomas (blindness), etc.
- Botulism
- Gas gangrene & food poisoning
- Tetanus
- Diphtheria
- Typhoid fever
- Vaginitis
- Stomach ulcer
- Lung, ear infection, meningitis
- Atypical pneumoniae
- Legionnaire's disease
- Damage to fetus
- Whooping cough (pertusis)

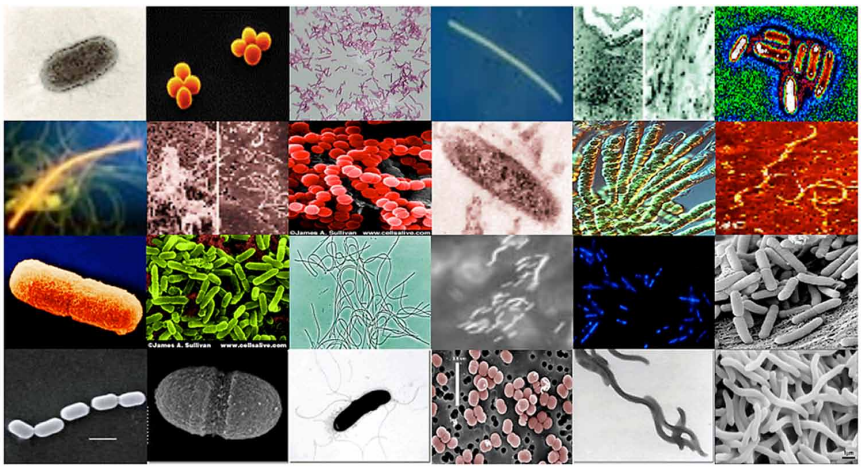
Understanding of specialized organism system used on microbial host to live in climate environment with other host. (http://microbialgenomics.energy.gov/) (Figure 12)

MOLECULAR MEDICINE



The human genome study has profound effect on the area of modern clinical research and bio medical science. This may be due to genetic response to environmental pressure which results in change in genome like-Diabetes, cancer, cardiac disease etc. The new knowledge of the molecular mechanism properties of causing disease will offer potentially best treatment and develop specific tool for disease diagnosis, treatment and prevention (Muniba, 2010) (Figure 13).

PERSONALIZED MEDICINE

Personalized medicine is a medical system which points out the systematic use in information technology about clinical medicine and patient information is collected and this has created a new area i.e. pharmacogenomics (Indiana University Division of Clinical Pharmacology, 2010). This field studies affected body genetic character response to medicine. Some medicine have been rejected in market (development phase) because of a less presence of the personalized medicine patient population, displays advance effect to a medicine due to gene sequencing variant in their DNA molecule. Personalized medicine can be defined by this field and nature of human physiology change that permit the targeting of medical medicine treatment which may include cell or tissue therapeutics (Muniba, 2010) (Figure 14).

To date, the labeling of more than 100 approved drugs contain information on genomic biomarkers (including gene variants, functional deficiencies, expression changes, chromosomal abnormalities, and others). Some, but not all, of the labeling include specific actions to be taken based on genetic information. Pharmacogenomic information can appear in different sections of the labeling (e.g., Therapeutic Indications, Warnings and Precautions) (Table 6).

Medical product (drug) characteristic must be arranged with adequate information about the drug molecule and its application. Food and drug administration (FDA) desire medical product arranged to be adequately (U.S. Food and Drug Administration., 2013). Scientifically accurate, tricky and finally information must be communicated to health care practitioner for drug prescription (Margaret & Hamburg, 2013).

BIOINFORMATICS IN AGRICULTURE

Application of bioinformatics in agriculture plays most important role in fast generation society, world economy and environment. Mainly crop is important part of agriculture. Today crop percentage yield has increased since last century. And will continue to increase as agronomy relies on new breeding technology and biotechnological approach (Xue, Zhao, Liang, Hou, and Wang, 2008).

FUTURE RESEARCH DIRECTIONS

Today large scale of commercial and academic enterprise such as pharmaceutical industry research & development and Quality control employ bioinformaticians to work, perform and analyse. There is large scale and complete bioinformatics demand from the academia and industry. Today increasing demand of Bioinformatics expert has arisen from most of the pharmaceutical laboratory and biomedical department. Bioinformatics growth has been global due to developed computer network allowed for easy access to molecular biological data and development of various type of software program for easy analysis.

CONCLUSION

Rapid advances in the field of computers coupled with increasing computer literacy among professionals favor the implementation of computer applications in medical practice. Further, the availability of numerous databases on the Internet has revolutionized the way by which a physician devices a strategy for treatment. Projects like the Human Proteomics Initiative is a classic example to show the necessity of integrating Bioinformatics to predict structures and functions of proteins, Medical Sciences - to identify proteins that are important in metabolic or other disorders and Pharmacology (drug discovery) - to identify novel drugs against the predicted targets. Thus it is apt to conclude that all the three areas must work in concert to achieve the ultimate goal of understanding the basis of life process and apply it for the betterment of human lives.

KEY TERMS AND DEFINITIONS

Bioinformatics: As an interdisciplinary field of science, bioinformatics combines computer science, statistics, mathematics, and engineering to analyze and interpret biological data.

Biomedical: Is the application of engineering principles and design concepts to medicine and biology for healthcare purposes (e.g. diagnostic or therapeutic).

Cheminformatics: Use of computer and informational techniques applied to a range of problems in the field of chemistry.

Database: A database is an organized collection of data.

Genomics: Is a discipline in genetics that applies recombinant DNA, DNA sequencing methods, and bioinformatics to sequence, assemble, and analyze the function and structure of genomes.

Pharmaceutical: Is a drug used to diagnose, cure, treat, or prevent disease.

Pharmacoinformatics: Drug discovery and development requires the integration of chemistry, biology, pharmacology, pharmaceutical technology and extensive use of information technology.

Proteomics: Is the large-scale study of proteins, particularly their structures and functions.

Chapter 17
A Perspective on the Phytopharmaceuticals Responsible for the Therapeutic Applications

Rajesh K. Joshi
Regional Medical Research Centre (Indian Council of Medical Research), India

ABSTRACT

The word phytopharmaceutical deals with a complex mixture of compounds derived from the plant source that is used as a medicine or drug. Primitive human societies have been depending on plants and plant products for various remedies. Several plants in the different forms have been reported in traditional medicine and to find a rational for the treatment of various diseases than to isolated single compounds. Many of the single compounds isolated from the plant origin are effectively used in the medicine. The search of natural products in drug discovery has been greatly enhanced in the last few years. The impetus to use phytopharmaceutical agents for the treatment of disease, most of the plant based drugs are quite safe and have lesser adverse effects and are claimed that it works as synergistic effects.

INTRODUCTION

Primitive human societies have been depending on plants and plant products for various remedies. In certain areas, these folk medicinal prescriptions are endemic and have survived through ages from one generation to next through word of mouth. They do not exist as written knowledge. Generally, these systems of medicines depend on old people's experiences. The person, prescribing these medicines has so-called scientific knowledge about the diseases. Indigenous systems of medicine are specially conditioned by cultural heritage and myths. In India, the reference to the curative properties of some herbs in the Rig Veda seems to be the earliest records of use of plants in medicine. The identity of several plants referred to in Suktas of the Rig Veda can be fixed with reasonable certainty, e.g. of *Semal, Pithvan, Palash,* and *Pipal.* A more detailed account is available in the Atharva Veda. The period of Rig Veda is

estimated to be between 3500 and 1800 B.C. After the Vedas, there is no information on the development of this science in India for a period of about 1,000 years. Then appeared the two most important works on Indian system of medicine, the works of Charak and Susruta, namely the Charak-Samhita and Susruta-Samhita. The latter deals with about 700 drugs, some of these are not indigenous to India. In the modern era, the medicinal plants are being replaced more and more by synthetic drugs. But of late it is being realized that synthetics, though useful as life saving drugs, are responsible for many hazardous side effects. This has led to the revival of interest in herbal medicine with the reawakening of efforts to promote indigenous system of medicine.

Since antiquity, man has used plants to treat common infectious diseases and some of these traditional medicines are still included as part of the habitual treatment of various maladies. For example, the use of bearberry (*Arctostaphylos uva-ursi*) and cranberry juice (*Vaccinium macrocarpon*) to treat urinary tract infections have been reported in different manuals of phytotherapy, while species such as lemon balm (*Melissa officinalis*), garlic (*Allium sativum*) and tee tree (*Melaleuca alternifolia*) are described as broad-spectrum antimicrobial agents (Rios& Recio, 2005).

Variety of plant extracts, such as an extract of the root of *Sophora flavescens*, an extract of stem bark of *Magnolia obovata*, and oil of *Melaleuca alternifolia*, have been used as traditional medicines for microbial infections, strongly suggests that natural products are the major source of important antimicrobial agents (Sohn et al., 2004). Several essential oils and their isolates have been found to exhibit strong antibacterial and antifungal activity. According to Wan et al. (1998), the majority of the essential oils assayed for their antibacterial properties showed a more pronounced effect against the Gram positive bacteria. The resistance of Gram negative bacteria to essential oil has been ascribed to their hydrophilic outer membrane, which can block the penetration of hydrophobic compounds into target cell membrane (Wan et al. 1998). The essential oils of the medicinal and aromatic plants rather than their extracts that have had the greatest use in the treatment of infectious pathologies in the respiratory system, urinary tract, gastrointestinal and biliary systems, as well as on the skin (Rios & Recio, 2005).Various essential oils viz., *Plectranthus mollis* (Joshi, 2014a), *Ocimum basilicum* (Joshi, 2014b), *Artemisia absinthium* (Joshi, 2013a), *Ocimum gratissimum*, *Ocimum sanctum* (Joshi, 2013b),*Cyathocline purpurea* (Joshi, 2013c), *Senecio belgaumensis* (Joshi, 2012a), *Lantana camara* (Joshi, 2012b), *Tridax procumbens* (Joshi& Badakar, 2012), *Phlomis bracteosa* (Joshi et al., 2011), *Feronia elephantum* (Joshi et al., 2011), *Erigeron floribundus* (Joshi et al., 2011), *Craniotome furcata* (Joshi, 2010) and *Anaphalis nubigena* var. *monocephala* (Joshi et al., 2009) have been reported promising *in vitro* antimicrobial activity.

The essential oils seem to have no specific cellular targets. As typical lipophiles, they pass through the cell wall and cytoplasmic membrane, disrupt the structure of their different layers of polysaccharides, fatty acids and phospholipids and permeabilize them. Cytotoxicity appears to include such membrane damage. The cytotoxic property is a great importance in the applications of essential oils not only against certain human or animal pathogens or parasites but also for the preservation of agricultural or marine products (Bakkali et al., 2008). Cytotoxic activities of essential oils or their major components, sometimes activated by light, have also been demonstrated in the mammalian cells *in vitro* by short-term viability assays using specific cell staining or fluorescent dyes including NRU (Neutral Red Uptake) test, MTT (3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl-tetrazolium bromide) test, Alamar Blue (resazurin) test, Trypan Blue exclusion test or Hoechst 33342 and propidium iodide test (Bakkali et al., 2008).

Essential oils have a calming, stimulating, pain alleviating and mood enhancing effect. They improve the functioning of internal organs like heart, lungs etc. Till now they were on the periphery of pharmacological preparations, inflammatory and flavouring agents. This is because they have multiple

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

beneficial effects than just being pain relievers (Shukla & Shukla, 1997). Aromatherapy by essential oils and their isolates have been studied as an emerging trend of treatment for some physiological disorder (Buchbauer & Jirovetz, 1994). Pharmacology, pharmaceutical botany, medical and clinical microbiology, phytopathology, and food preservation are some fields in which the essential oils can be applied (Daferera et al., 2000).

Terpenoids are also used as chemical messengers. In the communication between different parts of the same organism, the messenger is referred to as a hormone. Chemicals that carry signals from one organism to another are known as semiochemicals, and grouped into two main classes. If the signal is between two members of the same species, the messenger is called a pheromone. Chemicals which carry message between members of different species are known as allelochemicals (Devon& Scott, 1972).

The ancient medical literature reports that surgery was performed but that physicians also recommended the use of some natural, and especially plant products, which represent an interesting point of comparison with current knowledge (Nobili et al., 2009). Curcumin has been widely studied because of its antioxidant and anti-inflammatory properties. It inhibits growth and induces apoptosis in a range of different cell types. Curcumin has ability to inhibit signaling through NF-kB and reduce expression of COX-2, LOX, NOS, MMP-9, uPA, TNF-a, cyclin D1, downregulates growth factor receptors EGFR, HER2, inhibits Bcl-2, Bcl-XL, IAP, Inhibits activity of protein kinases (EGFR, HER2, ERK, JNK, PKB/Akt, PKC, CYPs, GSTP1-1 and Inhibits VEGF production (Manson et al., 2005). Epigallocatechin-3-gallate, a polyphenol found in green tea, also affects growth, inducing G0/G1 cell cycle arrest and apoptosis in many cell types, and appears to modulate a range of signalling pathways and target molecules. Epigallocatechin-3-gallate inhibits the activity of 5-cytosine-DNA methyltransferase, p38, TNF-α- release, urokinase, LOX, COX. angiogenesis and VEGFR phosphorylation and VEGF induction. It also downregulates signalling through Her2 neu, PDGFR, transcription factors AP-1 and NF-kB (Manson et al., 2005).

Podophyllotoxins have a long therapeutic history. Podophyllotoxins have been extracted from the root of the Indian podophyllum plant (*Podophyllum peltatum*). Podophyllotoxin was used as a remedy by the American Indians for its emetic, cathartic, and anthelmintic effects. From a wide program of chemical synthesis (about 600 derivatives from 1950s to 1960s), two active compounds, etoposide and teniposide, emerged. Unlike other podophyllotoxin derivatives, etoposide and teniposide have no effect on microtubular structure or function at concentrations used in the clinic (Nobili et al., 2009). Psoralen is a natural photodynamic compound belongs to the family of furocoumarins, whose chemical structure consists of a furan ring fused with coumarin. It is produced by a variety of plants as a natural defence against pest. It occurs in *Psoralea corylifolia*, from which the natural compound derives its name, as well as in the common fig, celery, parsley, and parsnips. Its extended π-electron system, psoralen displays UV light-induced photosensitizing activity, useful in photodynamic treatment of various diseases, including psoriasis, vitiligo and other skin conditions like cutaneous T-cell lymphoma (Nobili et al., 2009). Natural products play a relevant role in cancer therapy today with substantial numbers of anticancer agents used in the clinic being either natural or derived from natural products from various sources such as plants, animals and microorganisms (also of marine origin) (Nobili et al., 2009).

Use of plants as a source of medicine has been an ancient practice and is an important component of the health care system in India (Pandey et al., 2013). In India, about70 percent of rural population depends on the traditional Ayurvedic system of medicine. Most healers/practitioners of the traditional systems of medicine prepare formulations by their own recipes and dispense to the patients. In the Western countries, approximately 40 per cent of people are using the herbal medicine for the treatment of various

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

diseases (Pandey et al., 2013).The results of the herbal treatments led to their increased acceptance by the local people of Thailand. In a recent scientific studies that supported treatment with herbal preparations at the Kabchoeng Hospital of Thailand, where the efficacy and safety of *Cinnamon stomachic* mixture has been reported. The research suggested that this preparation was suitable for the treatment of patients with functional dyspepsia, in clinical randomized controlled trials, compared with simethicone (Chotchoungchatchai et al., 2012). The folk healers maintained knowledge regarding the proper use of indigenous plants for healing diseases specific to that area. Various preparations have been derived from folk medicine knowledge that consisted of medicinal plants that were available in the local area and were used for symptoms that related to diseases of the local people of Thailand (Chotchoungchatchai et al., 2012). For implementation of herbal medicine into hospitals, some uncertainty exists about the safety, effectiveness, and cost-effectiveness of complementary and alternative medicine methods, expanding their use, where reasonable evidence of their effectiveness and good evidence of their safety exists, might yield health, social, and economic benefits (Pandey et al., 2013).

Nature has gifted varieties of plant species occurring from different regions of world, whereas some species are found in particular zones. The alpine flora has their own properties to produce secondary metabolites compared to temperate region plants and vice versa. A plant can be considered as a system where many biochemical reactions occur. The secondary metabolites of plant or phytopharmaceutical are the product of biosynthesis where several factors alter the synthesis route. These factors are soil, climate, rainfall, altitude, grazing frequency, sunshine length etc, where plant produced different metabolites. As per the geoclimatic distribution of the flora, botanicals are consumed by the people as their own localities to cure the diseases. Some plants are frequently used in the food preparation almost as their daily recipes. A single plant is used in the treatment of various diseases or as a food supplement can varies phytochemicals as per the geoclimatic distribution. As the development of technologies more efforts are utilized to search of new chemical entities for treatment of the diseases which are safe from adverse effects. Now a day's various bioactive compounds are investigated from those where the plants are traditionally used for treatment of particular disease.

The isolated compounds which are found to be potent biological activities have been synthesized in laboratories as a modern medicine to fulfill the requirements of patients. A multidisciplinary approach to drug discovery, involving the generation of truly novel molecular diversity from natural product sources, combined with total and combinatorial synthetic methodologies, and including the manipulation of biosynthetic pathways (so-called combinatorial biosynthesis), provides the best solution to the current productivity crisis facing the scientific community engaged in drug discovery and development (Newman & Cragg, 2007). The exploration of Nature as a source of novel active agents that may serve as the leads and scaffolds for elaboration into desperately needed efficacious drugs for a multitude of disease indications (Newman & Cragg, 2007). For this purpose plant cell can be cultured as an alternative potential renewable source for sustainable production of phytopharmaceuticals. Though several studies on such aspects have been published in peer reviewed journals of national and international repute, the amount of research transferred from laboratory to published papers are more as compared to apply research findings to field or real ground is very less (Hurakadle et al., 2010; Pai et al., 2008). The greatest discovery in this field was made by Haberlandt (1902), where he showed un-natural successful growing of plant tissue and further use of plant growth regulators to control the organogenesis phenomenon. Since then it come across many successes stories in using this technique to grow, multiply and transfer number of plant species belonging to above mentioned categories. The only success being in agriculture industry wherein, varieties of banana, sugarcane have been widely used commercially apart from floriculture crops

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

frequently using this technique. Medicinal plant industry is a booming cell which has several branches such as nutraceuticals, cosmetics, health medicines and several others. Most of today's herbal industries rely on the natural plant population as it being easy and less cost bearing in comparison to the costlier technologies in biotechnology field.

The discovery of fungal endophytes that produce novel compound has significant biological and commercial implications. Commercially, the fungal culture can be scaled up to provide adequate production to satisfy new drug development and patient treatment needs. This production reduces the need to harvest wild populations of the source plants, preserving these species for the future (Eyberger et al., 2006). Endophytic fungi from herbs could the sources of new drugs for treatment of various diseases in humans, animals, and plants. Endophytes are microorganisms that live within plants for at least a part of their life cycle without causing any visible manifestation of disease (Bacon & White, 2000). The fungi in the plant appear to "peacefully coexist" with each other in the nutrient-rich tissues of the host plant. This coexistence may actually be more of a "chemical truce" (Rahman, 2000). Medicinal plants have been recognized as a repository of fungal endophytes with novel metabolites of pharmaceutical importance (Strobel et al., 2004). Distinctly from plants, endophytes can be cultured quickly and the biomass can be accumulated by large scale fermentation. Production of bioactive compounds can be increased by using biotechnology on endophytic fungi in order to meet demands while keeping biodiversity and sustainable ecosystem (Onifade, 2007).

A successful account of the necessity of other source like endophytes from *Taxus brevifolia* for production of taxol has been described by the Stierle and Strobel, (1995). According to Stierleand Strobel, (1995), the highly functionalized taxol a diterpene was isolated primarily from the inner bark of the relatively rare and slow growing Pacific yew tree, *Taxus brevifolia*, and a few related species, in extremely small quantities (<0.02% dry wt). The emergence of taxol as an effective anticancer agent created a difficulty viz., how to ensure an adequate supply of a natural compound of non-microbial origin. Although the pharmaceutical potential of taxol elevated the status of the yew from a nuisance weed to a precious commodity and natural resource, it did not alter the underlying problem; there were simply not enough trees to supply the growing demands for taxol. Advanced preclinical and phase I clinical development of taxol required several collections ranging in size from 5,000 to 15,000 pounds of dry bark. A mature Pacific yew (100 years old) yields approximately 10 pounds of dry bark, so each collection required the sacrifice of 500 to 1500 trees. As the efficacy of the compound became more apparent, the demand for additional taxol was increased. In 1987-1988 a 60,000-pound bark collection was undertaken with little controversy. The need for a second 60,000-pound bark collection in 1989, however, sparked concern about the impact such collection sizes may have on the continued existence of the species.

Even with this estimate, however, it was clear that additional sources of taxol would be necessary. In 1991-1993, a single course of clinical treatment was 125-300 mg of taxol, and typical treatments extended for ten or more courses. Treatment of the 12,000 women who die annually of ovarian cancer alone would consume as much as 36 kg of the drug. Isolation methods yielded 1 kg of taxol from 25,000 pounds of dried bark, or the bark of 2,500 yews. Simply treating ovarian cancer over a one-year period would consume 90,000 mature yews. The recent approval of taxol for the treatment of breast cancer will triple the projected demand. Should taxol prove as effective against other refractory cancers (head and neck and non-small cell lung cancers) as clinical trials have indicated, it is not unreasonable to assume that the demand for taxol may exceed 300 kg, or 750,000 trees per year. This represents an enormous demand on a limited resource. There are simply not enough yews growing in North America to satisfy projected needs of this drug over the next twenty years (Stierle & Strobel, 1995).

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Several research groups have addressed the supply problem in a variety of ways. Total syntheses from simple precursors were published virtually simultaneously by Holton et al., (1994) and Nicolaou, et al., (1994) and their co-workers. Although these syntheses are chemical masterpieces, they will probably not answer the supply question (Stierle & Strobel, 1995). To fulfill the requirement of the taxol, a novel endophytic fungus isolated from the inner bark of the Northwest Pacific yew tree was able to synthesize taxol in de novo fashion (Stierle & Stierle, 2000).

The clinically-active agents, topotecan (Hycamtin) and irinotecan® (Camptosar®; CPT-11), are semi-synthetically derived from camptothecin, isolated from the Chinese ornamental tree *Camptotheca acuminata* Decne (Cragg & Newman, 2009). Camptothecin has also been reported to be produced by an endophytic fungus of the family Phycomycetes, subsequently identified as *Entrophospora infrequens*, isolated from the inner bark of *Nothapodytes foetida* (Cragg & Newman, 2009). Despite being dropped from clinical trials by NCI in the 1970s due to severe bladder toxicity, extensive research on the structural modification of camptothecin led to the development of the more effective derivatives, topotecan (Hycamtin®) and irinotecan (CPT-11; Camptosar®). Topotecan is used for the treatment of ovarian and small cell lung cancers, while irinotecan is used for the treatment of colorectal cancers. This class of agents acts through inhibition of topoisomerase I, another important enzyme involved in the replication pathway of DNA during cell cycle progression and, to date, remains by far the most important class of topoisomerase I inhibitors (Cragg & Newman, 2004).

Many endophytes have the potential to synthesize various bioactive metabolites that may directly or indirectly be used as therapeutic agents against numerous diseases (Strobel et al., 2004; Staniek et al., 2008). In recent years, substantial efforts to discover effective inhibitors of α-glucosidases from natural sources have been made (Miller et al., 2012; Rivera-Chavez et al., 2013). Endophytic fungi are thus a rich source of novel organic compounds with interesting biological activities and a high level of biodiversity (Hussain et al., 2009). Novel antibiotics, antimycotics, immunosuppressants, anticancer, anti-diabetic compounds are few natural products have been obtained from endophytic fungi (Dompeipen et al., 2009). A non-peptidal fungal metabolite (L-783,281) was isolated froman endophytic fungus *Pseudomassaria* sp. collected from an African rainforest near Kinshasa in the Democratic Republic of the Congo (Zhang et al., 1999). This compound acts as an insulin mimetic and unlike insulin, is not destroyed in the digestive tract and may be given orally. Oral administration of L-783,281 to two mouse models of diabetes resulted in significant lowering of blood glucose levels. These results may lead to new therapies for diabetes (Zhang et al., 1999). The compounds thielavins A, J and K have been isolated from an endophytic fungus from *Hintonia latiflora*. All these compounds showed in vitro α-glucosidase inhibitory action which was higher than that of acarbose. The a-glucosidase inhibitory properties of thielavin K were corroborated in vivo since it induced a noted anti-hyperglycemic action during an oral sucrose tolerance test (3.1, 10.0 and 31.6 mg/kg) in normal and nicotinamide–streptozotocin diabetic mice. In addition, at a dose of 10 mg/kg, it provoked a moderate hypoglycemic activity in diabetic mice (Rivera-Chavez et al., 2013). Fungal endophytes have begun to be recognized as a rich and diverse source of natural products. Podophyllotoxin, an aryltetralin lignan, is a valuable natural product as a precursor to three anticancer drugs, etoposide, teniposide, and etoposide phosphate. Destruction of wild populations of the primary source plant (*Podophyllum emodi* Wall. Ex Royle) and difficulties of total synthesis of the compound have led many laboratories to search for alternative sources. Endophyte fungi are widespread and perhaps ubiquitous in their occurrence in higher plants (Eyberger et al., 2006).

BACKGROUND

The word phytopharmaceutical deals with a complex mixture of compounds derived from the plant source that is used as a medicine or drug. Plants are the "Sleeping Giants of Drugs Development" as they form a reservoir of potential useful untapped source of drugs that have been serving mankind since the dawn of civilization.

The plant chemicals used for these latter purposes are largely the secondary metabolites, which are derived biosynthetically from plant primary metabolites (e.g., carbohydrates, amino acids, and lipids) and are not directly involved in the growth, development, or reproduction of plants. These secondary metabolites can be classified into several groups according to their chemical classes, such alkaloids, terpenoids, and phenolics. The functions of secondary metabolites in the plants are not understood, but it is believed that these compounds are utilized by the plants for self-defense against microbes or by other external predators. Moreover, the quantitative and qualitative divergence of secondary metabolites may be due to the geographical, climatic, and soil conditions, which in turn may affect the composition and/or synthesize new secondary metabolites\chemotypes from the same plant species (Joshi, 2013d; 2014c). It was observed that *Ritu* or season influences secondary metabolite concentration in the plants or its parts. The ability to synthesize and accumulate the compounds in plants varied greatly throughout the seasons. Consequently, to obtain optimum utility of the plant as a source of medicine, the screening for presence of the secondary metabolites during different season is useful (Ketkar et al., 2015). Several plants in the different forms have been reported in traditional medicine and to find a rational for the treatment of various diseases than to isolated single compounds. The phytopharmaceuticals or extracts are under pipeline in clinical trials for treatment of diseases. The efficacy of phytopharmaceutical agents used in different forms by the people for centuries was validated in many cases by pre-clinical and clinical studies. The impetus to use phytopharmaceutical agents for the treatment of disease, most of the plant based drugs are quite safe and have lesser adverse effects and are claimed that it works as synergistic effects. Synergy effects of the mixture of phytopharmaceuticals and their byproducts contained in plants are claimed to be responsible for improved effectiveness. The multi-drug theory is already being practiced worldwide in the treatment of AIDS and other infectious diseases, hypertension, numerous types of cancer and rheumatic diseases. However, many of the single compounds isolated from the plant origin are effectively used in the medicine.

MAIN FOCUS OF THE CHAPTER

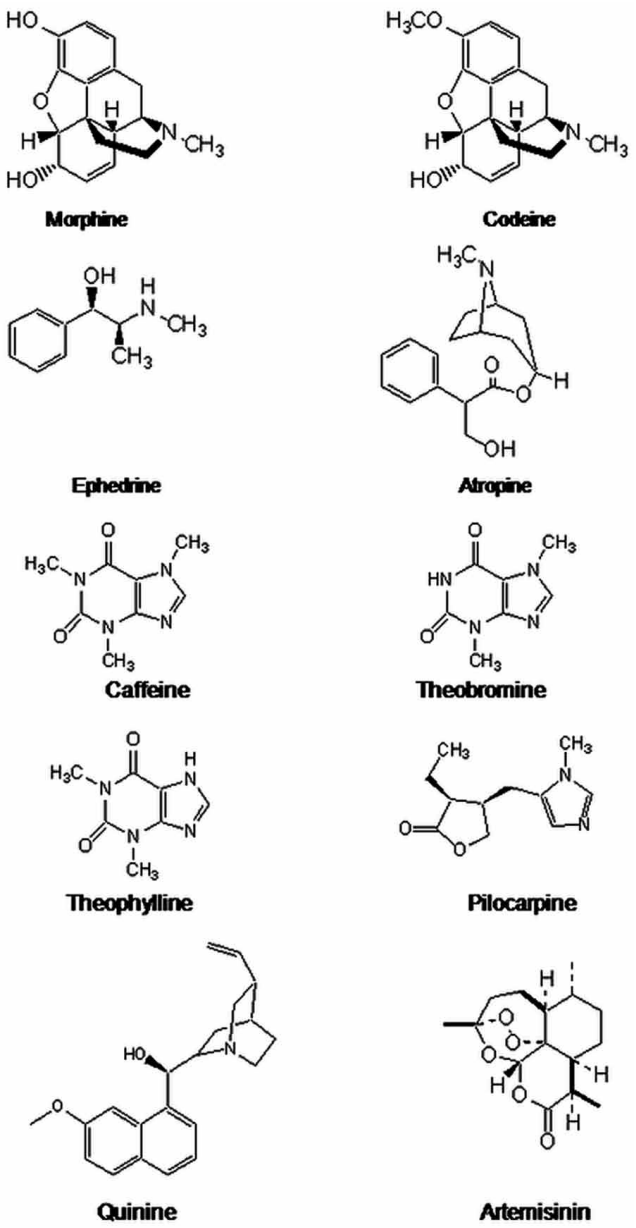
The search of natural products in drug discovery has been greatly enhanced in the last few years. In recent years many of the natural products of medicinal value are the source of drugs, which have been used effectively for centuries in traditional medicine. All the chemical structures are depicted in Figures 1, 2 and 3 wherein the compounds are numbered in parenthesis. In 1805, morphine (1) became the first pharmacologically active compound to be isolated in pure form from a plant. Morphine is profusely found in dried latex of unripe seedpods of *Papaver somniferum* commonly known opium poppy. Morphine is belongs as a narcotic analgesic drug which directly acts on the central nervous system of the body to relieve pain. Codeine (2) or 3-methylmorphine is also found in *Papaver somniferum* in low quantity but it can be derived from morphine. Codeine is used mainly as an antitussive agent, but also as a non-narcotic

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

analgesic. It has been said that it is useful in treating malaria patients. Its use in the treatment of diarrhoea, however, is out of date, because more effective substitutes are now available (Theuns et al., 1986).

Ephedrine (3) is a sympathomimetic alkaloid, isolated from traditional Chinese herb *má huáng*known as *Ephedra sinica.* The ephedrine is used for therapeutic purpose, primarily as a bronchodilator and decongestant. Its pharmacological applications are related to its sympathomimetic properties, which in turn occur due to its stimulating action on α-, β1-, and β2-adrenergic receptors through direct and indirect effects. Nowadays, there is a concern about the indiscriminate use of ephedrine, since it started to be used to weight loss and enhance athletic performance (Limberger et al., 2013).

The drug atropine (4) is a tropane alkaloid isolated from the plants *Atropa belladonna* of the family Solanaceae. In general, atropine counters the "rest and digest" activity of glands regulated by the parasympathetic nervous system. This occurs because atropine is a competitive antagonist of the muscarinic acetylcholine receptors (acetylcholine being the main neurotransmitter used by the parasympathetic nervous system). Atropine dilates the pupils, increases heart rate, and reduces salivation and other secretions (http://en.wikipedia.org/wiki/Atropine) (see Figure 1).



Caffeine (5) (1,3,7-trimethylpurine-2,6-dione), is a bitter white crystalline central nervous system stimulant psychoactive (Nehlig et al., 1992) alkaloid and has mild diuretic property (FDA, 2010). The chief source of caffeine is a plant *Coffea arabica* of the family Rubiaceae commonly known as coffee. The beans, leaves, and fruit of more than 60 plants contain varying quantities of caffeine (Kovacs, 2008; Andrews et al. 2006). In those plants caffeine serves as a pesticide, killing or paralyzing insects that feed on the plants. Coffee, tea, and cocoa are the major plants containing caffeine that are cultivated. Guarana, kola nuts, and yerba maté are also cultivated for use as sources of caffeine in energy drinks and snacks. The FDA says that caffeine is both a drug and a food additive. Caffeine is used in both prescription and over-the-counter medicines to treat tiredness or drowsiness and to improve the effect of some pain relievers. People with heart problems shouldn't use caffeine because it makes their hearts work too hard, and people with anxiety problems or panic attacks may find that caffeine makes them feel worse (http://www.fda.gov/downloads/UCM200805.pdf). Caffeine is used for prevention and treatment of bronchopulmonary dysplasia which is a chronic pulmonary condition that usually evolves after premature birth and respiratory distress syndrome (Kugelman & Durand, 2011; Schmidt, 2005). Caffeine therapy for apnea of prematurity improves weight gain (Schmidt et al., 2007), neurodevelopmental disability in infants, with very low birth weight. Caffeine is an adenosine-receptor blocker that inhibits adenosine induced vasodilatation by blocking these receptors used to treat orthostatic hypotension due to autonomic failure (Schmidt et al., 2006).

Theobromine (6) (3,7 dehydro3,7 dimethyl-IH-purine-2,6-dione) also known as 3,7-dimethylxanthine is a purine alkaloids. It is widely distributed in nature in a variety of plants such as *Commelia thea* (tea leaves), *Theobroma cacao* (cocoa), *Cola acuminata* (cola), *Paullinia cupana*, *Ilex aquifolium* and other *Ilex* species including Theaceae, Sterculiaceae, Sapindaceae (Eteng et al., 1997). Theobromine is used as a diuretic, central nervous system stimulants (Leonard et al., 1987), myocardial stimulants, vasodilators and smooth muscle relaxants (Windholz, 1983).

Theophylline (7) is the typical alkaloid in mate´ and green tea. Only the slightest of traces has been established in cacao (Matissek, 1997). Theophylline has been used in the treatment of asthma for over 70 years, but its use has recently declined, as inhaled corticosteroids have become the mainstay of asthma control and inhaled β_2-agonists are more effective bronchodilators (Ito et al., 2002).Asthma is a chronic inflammatory disease of the airways characterized by reduced airway patency, which is regulated by bronchodilators such as β-agonists, and by the infiltration of inflammatory and immune cells, which

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Chemical structures of: (1) Morphine; (2) Codeine; (3) Ephedrine; (4) Atropine; (5) Caffeine; (6) Theobromine; (7) Theophylline; (8) Pilocarpine; (9) Quinine; (10) Artemisinin.

is treated by corticosteroids (Ito et al., 2002). There is increasing evidence that theophylline has anti-inflammatory or immunomodulatory actions in asthma (Barnes & Pauwels, 1994).

Pilocarpine (8) is an imidazole alkaloid found large amount in the plant *Pilocarpus microphyllus* (Pinheiro, 1997). This plant is a shrub and found in the under storey of the pre-Amazonian rain forest and in the state of Maranhão (Sandhu et al., 2006). The pilocarpine is a cholinergic parasympathomimetic agent with predominantly muscarinic action, it may stimulate cholinergic receptors on the surfaces of

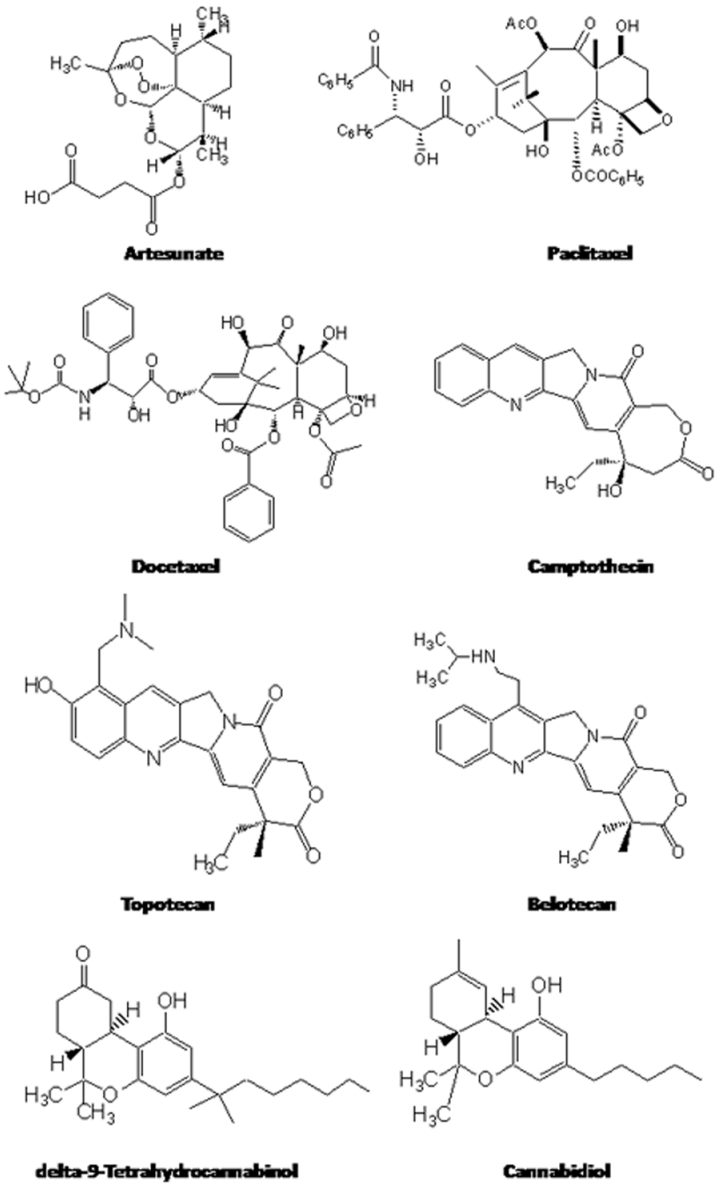
EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

the exocrine glands, causing a reduction of the symptoms of xerostomia, includes dry mouth, mucosal burning, and fissured lips and/or tongue, with difficulty in eating, swallowing, conversing, and wearing removable prosthetic devices such as dentures and even in patients with no measurable salivary flow at rest (Gornitsky et al., 2004). Xerostomia represents a frequent and significant radiation-induced side effect in the treatment of head and neck cancers. It leads to increased incidence of dental caries, oral mucositis, and impaired mastication (Gornitsky et al., 2004). Moreover, various studies reported that pilocarpine improves the overall condition of xerostomia when prescribed after radiotherapy (LeVeque et al., 1993; Johnson et al., 1993).

Quinine (9) is cinchona alkaloid isolated from the bark of several species of cinchonatrees. The high yield obtained from the plant *Cinchona ledgeriana* (Song, 2009). Quinine had a profound influence on modern colonial history and a number of historians have highlighted the importance of this single drug as one of the "tools of empire" (Meshnick & Dobson, 2001). Quinine was used as the antimalarial drug caused by *Plasmodium falciparum*. As per the recommendation of World Health Organization (WHO) quinine should be used when artemisinins are not available (WHO, 2006).

Artemisinin (10), having very strong potential as the non-conventional antimalarial drug, is a sesquiterpene lactone with endoperoxide bridge and has been isolated from *Artemisia annua*, a pervasive wormwood with a long history of use, known as 'Qinghao'. The Chinese scientist extracted a crystalline compound named "Qinghaosu" (QHS) from 'Qinghao', *Artemisia annua*(Kinghorn, 1987) and this stable peroxide emerged as a potent antimalarial (Luo & Shen, 1987).

Artesunate (11), a derivative of artemisinin isolated from *Artemisia annua* is recommended by the WHO in preference to quinidine for the treatment of severe malaria and has been used worldwide for many years (http://www.cdc.gov/malaria/diagnosis_treatment/artesunate.html). In laboratory models artesunate has demonstrated cytotoxic effects against a variety of cancer cells. However, there is little available information about the antitumor effects of artesunate on human gastric cancer cells (Zhang et al., 2015).



The taxane class agents (paclitaxel and docetaxel) are one of the most important cancer chemotherapeutics in the past several years. Both drugs are very similar in mechanism of action, preclinical and clinical activities. Paclitaxel (12) (Taxol), one of microtubule-stabilizing anticancer agent, was first obtained from the bark of Pacific yew (*Taxus brevifolia)* in 1971. The Pacific yew is a highly toxic plant but it was employed medicinally by several native of North American Indian tribes who used it to treat a variety of complaints (Moreman, 1988). Paclitaxel is used for the treatment of metastatic pancreatic cancer, non-small cell lung cancer and breast cancer (http://www.cancer.gov/about-cancer/treatment/drugs/fda-nanoparticle-paclitaxel) (see Figure 2).

Docetaxel (13) is semi-synthetically derived compound from 10-deacetylbaccatin III extracted from the needles of the European yew (*Taxus baccata)*. Docetaxel is used for treatment of various diseases viz., head and neck cancer, gastric cancer, breast cancer, prostate cancer, and non-small cell lung cancer (http://www.cancer.gov/about-cancer/treatment/drugs/fda-docetaxel). The laboratory studies showed that the paclitaxel a chemotherapy drug, can be used in the treatment of renal fibrotic diseases. Mechanistically, paclitaxel treatment blocks the STAT3 activity by disrupting the association of STAT3 with tubulin and STAT3 nucleus translocation (Zhang et al., 2015).

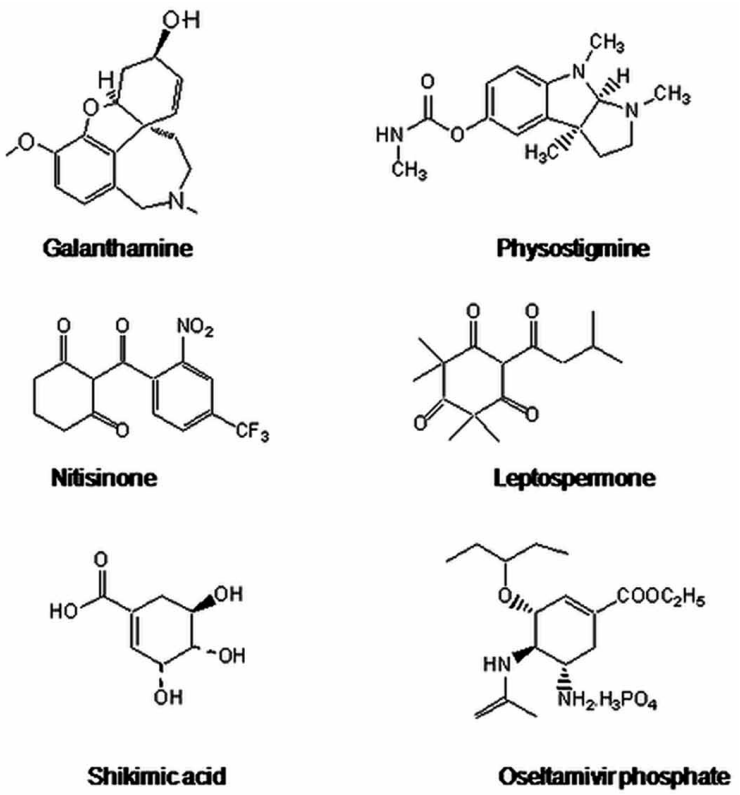
The compound camptothecin (14), a planar pentacyclic ring system containing a pyrrol (3,4-b) quinoline and α-hydroxy lactone was isolated from the plant *Camptotheca acuminata* Decne (Nyssaceae), a tree that is native to China, growing in relatively warm areas of southeastern provinces of Szechwan, Yunnan, and Kwangsi (Perdue et al., 1970). Topotecan(15) is a chemotherapeutic agent that is a topoisomerase

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Chemical structures of: (11) Artesunate; (12) Paclitaxel; (13) Docetaxel; (14) camptothecin; (15) Topotecan; (16) Belotecan; (17) delta-9-Tetrahydrocannabinol; (18) Cannabidiol.

inhibitor. It is a water-soluble derivative of camptothecin. It is used in form of the hydrochloride to treat ovarian cancer and lung cancer, as well as other cancer types (http://www.ebi.ac.uk/chebi/searchId.do?chebiId=CHEBI:63632. In addition, a semi-synthetic camptothecin derivative, belotecan (16), was launched in Korea for treatment of small-cell lung and cervical cancer (Butler, 2005).

Two FDA-approved drugs, dronabinol and nabilone, contain delta-9-tetrahydrocannabinol (THC) (17). They treat nausea caused by chemotherapy and increase appetite in patients with extreme weight loss caused by AIDS (NIDA, 2015). THC is the main ingredient of the plant marijuana, and is principally



EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

responsible for the psychoactive effects (Cooper & Haney, 2009). Marijuana is the crude drug derived from the plant *Cannabis sativa*, belongs to the family Cannabaceae that has only one genus *Cannabis* with only one species *sativa* that is highly variable (Elsohly & Slade, 2005). Cannabis has had a long history of use (over 5000 years) starting in Central and Northeast Asia with current use spreading worldwide as a recreational drug or as a medicine albeit unauthorized. The cannabis plant (*Cannabis sativa*) and products thereof (such as marijuana, hashish and hash oil) have a long history of use both as a medicinal agent and intoxicant. Over the last few years there have been an active debate regarding the medicinal aspects of cannabis. Currently cannabis products are classified as Schedule I drugs under the Drug Enforcement Administration (DEA) Controlled Substances act, which means that the drug is only available for human use as an investigational drug (Russo, 2001; 2002; Elsohly, 2002; Elsohly & Slade, 2005). Cannabidiol (18) (CBD) another compound of marijuana exhibited prominent anticancer activity (Scott et al., 2013).The United Kingdom, Canada, and several European countries have approved nabiximolssynthetic cannabinoids, a mouth spray containing THC and CBD. It treats muscle control problems. The United States is conducting clinical trials for its safe use in treating cancer pain (NIDA, 2015*).In vitro* studies of THC and CBD both alone and in combination with radiotherapy in a number of glioma cell lines (T98G, U87MG, and GL261) inhibit glioma growth as well as neutralize oncogenic processes such as angiogenesis. High-grade glioma is one of the most aggressive cancers in adult humans and long-term survival rates are very low as standard treatments for glioma remain largely unsuccessful. These studies suggested a potential clinical benefit for glioma patients by using these treatment modalities.

Alzheimer's disease (AD) was first described by the German psychiatrist, Alois Alzheimer, in 1907. Alzheimer's disease is a neurological disorder in which the death of brain cells causes memory loss and cognitive decline. It is a neurodegenerative disease, which means there is progressive brain cell death that happens over a course of time (National Institute of Neurological Disorders and Stroke (NINDS), 2013).The total brain size shrinks with Alzheimer's - the tissue has progressively fewer nerve cells and connections (NINDS 2013; Alzheimer's Association, 2013a). The most recent census has enabled researchers to give estimates that in 2010, 4.7 million people of 65 years of age and older were living with Alzheimer's disease in the US (Hebert et al., 2013). In 2013 statistical report from the Alzheimer's Association gives a proportion of the population affected - just over a tenth of people in the over-65 age group have the disease in the US. In the over-85s, the proportion goes up to about a third (Alzheimer's Association, 2013b). The development of galanthamine (galantamine) (19) a drug commonly used today in the treatment of AD. It is a natural product known from several members of the Amaryllidaceae and the idea for developing a natural product from these species seems to be based on ethnobotanical information. This alkaloid was first isolated from snowdrop (*Galanthus* spp., most notably *G. woronowii*), but today it is obtained from *Narcissus* spp. and *Leucojum* spp. (esp. *L. aestivum*) as well as synthetically (Heinrich & Teoh, 2004). Galantamine has a unique, dual mode of action. It is a reversible, competitive inhibitor of acetylcholinesterase, and proven activity as an allosteric modulator of nicotinic acetylcholine receptors (nAChRs). This latter activity is thought to be particularly important since decreases in the expression and activity of nAChRs make a large contribution to the reduction in central cholinergic neurotransmission in patients with AD (Lilienfeld, 2002). Physostigmine (20) or serine is a parasympathomimetic alkaloid, widely regarded as the antidote to anticholinergic toxicity, is a naturally occurring cholinesterase inhibitor found in the Calabar bean (Watkins et al., 2014) and short span of action has rendered it useless for treating Alzheimer's disease (Scheindlin, 2010).The Calabar bean or ordeal bean (*Physostigma venenosum* Balf. of the family Leguminosae) is the seed of a leguminous plant, a native of tropical Africa, poisonous to humans (Lloyd, 1897) (see Figure 3).

Figure 3. Chemical structures of: (19) Galanthamine; (20) Physostigmine; (21) Nitisinone; (22) Leptospermone; (23) Shikimic acid; (24) Oseltamivir phosphate

Tyrosinemia type 1 is a rare genetic metabolic disorder characterized by lack of the enzyme fumarylacetoacetate hydrolase (FAH), which is needed to break down the amino acid tyrosine. Failure to properly break down tyrosine leads to abnormal accumulation of tyrosine and its metabolites in the liver, resulting in severe liver disease. Tyrosine may also accumulate in the kidneys and central nervous system (McKiernan, 2006). Tyrosinemia type 1 affects males and females in equal numbers. It is estimated to occur in one of every 100,000-120,000 births in the United States. In one region of the Quebec province of Canada, the disorder is estimated to occur in approximately one in 1,850 births. The birth prevalence is also higher in Norway where it is estimated to be one in 60,000 (NORD, 2012). The triketones, an important new class of herbicides, are reported to be derivatives of the plant-produced phytotoxin leptospermone, derived from the bottlebrush plant (Callistemon spp.) (Duke et al., 2000). *Callistemon citrinus* commonly known as Bottlebrush belongs to a family Myrtaceae and comprises over 30 species that has a great medicinal importance (Mabberly, 1997). *Callistemon* spp. are also used as weed control (Wheeler, 2005) and as bioindicators for environmental management (Burchett et al., 2002). Nitisinone (21) is a derivative of leptospermone (22), a new class of herbicide isolated from the *Callistemon citrinus*. Both the compounds nitisinone and leptospermone inhibit 4-hydroxyphenyl pyruvate dioxygenase (HPPD), the enzyme involved in plastoquinone and tocopherol biosynthesis in plants (Duke et al., 2000). In humans, inhibition of HPPD prevents tyrosine catabolism, leading to the accumulation of tyrosine metabolites, 4-hydroxyphenyl pyruvic acid and 4-hydroxyphenyl lactic acid,

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

which can be excreted through the urine (Hall et al., 2001). The drug nitisinone was approved by the FDA for the treatment of hereditary tyrosinemia type 1 diseases.

Shikimic acid (23) was first isolated in 1885 by Eijkman from the fruit of the Japanese plant *Illicium religiosum* Sieb. The elucidation of its structure nearly 50 years later, and the discovery of shikimic acid, the starting material in the commercial synthesis of the antiviral agent oseltamivir under the trade name Tamiflu (Enrich et al., 2008). Oseltamivir phosphate (24) (Tamiflu) is an orally active neuraminidase inhibitor developed for the treatment and prophylaxis of influenza viruses A and B. The starting material for the oseltamivir synthesis is (−)-shikimic acid, an important biochemical intermediate in plants and microorganisms.

One of the compound fulyzaq (crofelemer), the first anti-diarrheal drug for HIV/AIDS patients has been recently approved by U.S. Food and Drug Administration (FDA). The compound crofelemer is a proanthocyanidin oligomer, isolated from red latex of the plant *Croton lechleri* (Euphorbiaceae) found in the western Amazonian regions of South America (Orozco-Topete et al., 1997). Native populations of South America have used the sap of the plant for self-treatment of secretory diarrhea for many years (Crutchley et al., 2010). Crofelemer is a first-in-class agent that may be useful for different types of secretory diarrhea, since it prevents chloride and fluid secretion into the bowel by directly inhibiting 2 distinct intestinal chloride channels (Crutchley et al., 2010). Crofelemer possesses a unique mechanism of action through inhibition of both cyclic adenosine monophosphate (cAMP)–stimulated cystic fibrosis transmembrane conductance regulator (CFTR) and calcium stimulated (CaCC) chloride intestinal Channels (Crutchley et al., 2010). The drugcrofelemer has been investigated for the treatment of several types of secretory diarrhea, including traveler's diarrhea (DiCesare et al., 2002), AIDS-associated diarrhea (Holodniy et al., 1999) and infectious diarrhea such as cholera (Bardhan et al., 1999).

Some of the botanical compounds, which have been demonstrated to have positive effects in cancer therapy, have a long history behind them. It was recently demonstrated that the green tea antioxidant epigallocatechin-3-gallate significantly slowed breast cancer growth in female mice: its use is attested in ancient Japanese texts (Nobili et al., 2009). The juice, peel and oil of *Punica granatum* has also been shown to possess anticancer activity, including interference with tumour cell proliferation, cell cycle, invasion and angiogenesis (Lansky & Newman, 2007). Promising and selective anti-cancer effects have been observed with Saffron (stigmata of *Crocus sativus* L.) *in vitro* and *in vivo*, but not yet in clinical trials (Nobili et al., 2009). Homoharringtonine was isolated from the Chinese tree *Cephalotaxus harringtonia* var. *drupacea* (Sieb and Zucc.), and a racemic mixture of harringtonine and homoharringtonine has been used successfully in China for the treatment of acute myelogenous leukemia and chronic myelogenous leukemia. Purified homoharringtonine has shown efficacy against various leukemias, including some resistant to standard treatment and has been reported to produce complete hematologic remission in patients with late chronic phase myelogenous leukemia (Cragg & Newman, 2009). Vinca alkaloids are isolated from the periwinkle plant *Catharanthus roseus*, also known as *Vinca rosea*. The extracts of *Vinca rosea* possess many therapeutic effects including anti-tumour activity. The compounds vincristine, vinblastine and vindesine are the first Vinca alkaloids with anti-tumour activity to be identified from the plant *Vinca rosea* (Nobili et al., 2009).

The compound vinflunine, a bis-fluorinated vinorelbine derivative, has been synthesized by superacid chemistry. Due to its favourable preclinical anti-tumour activities, including microtubule dynamics disruption, anti-angiogenesis and prolonged multidrug resistance development, vinflunine is now being widely studied in phase I–III clinical trials (Nobili et al., 2009).There are many flavonoids in the plant kingdom which may possess cancer chemopreventive efficacy. The isoflavone genistein from soya and

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

the flavone quercetin a constituent of onions, are examples of flavonoids which prevent cancer in rodent models of carcinogenesis. The compound genistein is currently in clinical trial for the prevention of recurrent localized prostate cancer subsequent to radical prostatectomy (Manson et al., 2005). Rohitukine, isolated as the constituent responsible for anti-inflammatory and immunomodulatory activity from *Dysoxylum binectariferum* Hook. f. (Meliaceae) which is phylogenetically related to the Ayurvedic plant *D. malabaricum* Bedd.used for rheumatoid arthritis. It is currently in phase I and phase II clinical trials, either alone or in combination with other anticancer agents, against a broad range of tumors, including leukemias, lymphomas and solid tumors (Cragg& Newman, 2009).

The plants have provided humans with many of their essential needs, including life-saving pharmaceutical agents from the antiquity. A number of terrestrial as well as marine flora are available and many of them have not yet been screened for biological activities and it need to explore the active constituents in the search for new medicines, particularly with the development of highly sensitive and versatile analytical methods are available.

ISSUES, CONTROVERSIES, PROBLEMS

Plants have been the mainstay of the oldest known systems of medicine in the world and have survived the ravages of time spanning thousands of years. Existing biological resources can be exploited in the search for new molecules, because while there are many compounds already under investigation for their chemopreventive properties, we have only begun to scratch the surface in terms of the number of possible efficacious agents in the plant kingdom (Manson et al., 2005).

The advent of next generation sequencing technology has led to the discovery of rare private mutations which has revolutionized our understanding of the genetics of complex diseases, with major focus on Cancer. The development of high-throughput platforms like Roche-454, Illumina Hiseq, Ion Torrent PGM etc., has provided the geneticists with large chunks of genomic data like never before, and its relevant bioinformatics pipelines contributing to uncover myriad cancer biological complexity and heterogeneity. Thus, there is a growing trend of studies undertaking whole genome and exome-sequencing from individuals affected with different subtypes of cancer thereby identifying and validating specific driver events and novel target genes by integrative approaches to understand their oncogenic potential and intratumoral diversity. The recent developments in diverse study designs and approaches in cancer genomics globally, viz., whole-genome, exome sequencing, transcriptome, methylome analysis, genome wide association studies, gene regulation analysis, cytogenetic analysis, DNA- Protein interaction analysis (CHIP-Seq), small RNA discovery to name a few have been inclusively studied. The focus on the future perspective of these genomic and epigenomic studies in developing important therapeutic targets and their subsequent validation by effective clinical trials that leads to cancer drug discovery, personalized medicines, painless and costless treatment, patients management and lifespan. Moreover, importance of dietary and natural resources as the medicine particularly phytochemicals for cancer prevention are required.

One of the major issue, more than 70% of all cancer patients are very interested in herbal drugs. However, many of them do not inform their oncologist about their use (Kelberet a., 2014). As 19 to 75% of all cancer patients suffer from sleep disturbances. The cancer patients often have difficulties to sleep and are restless, so that they can use herbal drugs such as valerian in order to avoid chemically defined

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

sedatives and hypnotics as they fear becoming addicted. However, they state that warnings that valerian (*Valeriana officinalis*) may stimulate CYP 3A4 (Kelberet a., 2014).

Nutraceuticals are emerged as potential cancer preventive natural sources from food (Baichwal, 1999). It was hypothesized that this observation is related to diet or more specifically to nutraceuticals present in fruits, vegetables, common beverages, grains, marine products, medicinal plants, and herbs (Jankun et al., 2006). The nutraceuticals are natural bioactive chemical compounds and have value in health promoting, disease preventing or semi-medicinal properties. The nutraceuticals are found as natural products from (a) the food industry (b) the herbal and dietary supplement (c) pharmaceutical industry and (d) the newly emerged bioengineered microorganisms, agro products or active biomolecules. It may range from isolated nutrients, herbal products, dietary supplements and diets to genetically engineered "custom" foods and processed products such as cereals, soups and beverages (Dureja et al., 2003). Many dietary agents have extremely promising modes of action when investigated in cultured cells, but *in vivo* are much less effective. One of the reasons is bioavailability. Many purified dietary compounds have limited solubility, making it difficult to attain plasma or tissue concentrations equivalent to those showing activity *in vitro*. On a cautionary note, there may be a very good reason why many of these compounds are poorly available to tissues, so any attempts to use them in humans at higher doses than are available from the diet should be assessed for possible toxic consequences (Manson et al.,2005). Chemically the nutraceuticals may be classified as isoprenoid derivatives (terpenoids, carotenoids, saponins, tocotrienols, tocopherols, terpenes), phenolic compounds (couramines, tannins, lignins, anthocyanins, isoflavones, flavanones, flavanoids), and carbohydrate derivatives (ascorbic acid, oligosaccharides, non-starch polysaccharides) etc. (Sharma, 2009). The validation of nutraceuticals against cancer is under progress. In recent reports on cancer protection by nutraceuticals were evidenced for lymphoma (Russell et al., 2007), skin cancer (Hercberg et al., 2007), pancreatic cancer (Larsson et al., 2006), while vitamins and minerals were validated in chemoprevention trial of different cancers (Sandler et al., 2001). Two prominent nutraceuticals (curcumin and EGCG from green tea) have been implicated in anti-cancer activity (Manson et al., 2005). Natural product based drug discovery is increasing based on new technologies, such as combinatorial synthesis and high-throughput screening and their associated approaches. The vincristine, irinotecan, etoposide and paclitaxel are classic examples of plant-derived compounds; actinomycin D, mitomycin C, bleomycin, doxorubicin and l-asparaginase are drugs coming from microbial sources, and cytarabine is the first drug originating from a marine source. To date, new generations of taxanes, anthracyclines, vinca alkaloids, camptothecins, as well as the novel class of epothilones have been developed. Some of these are in clinical use, others in clinical trials. Other agents originating from marine sources (both plants and animals) (e.g. trabectedin-ET-743, bryostatin-1, neovastat) have also entered clinical trials (Nobili et al., 2009). Most *in vitro* studies investigating a new dietary agent initially look for indications of growth inhibition, cell cycle arrest and induction of apoptosis in tumour cell lines (Manson et al., 2005).

There is concomitant increase in the prevalence of type1 diabetes, the major driver of the epidemic is the more common form of diabetes, namely type2 diabetes which accounts for more than 90% of all diabetes cases. Nowhere is the diabetes epidemic more pronounced than in India as estimated that 32 million people had diabetes in the year 2000 (Wild et al., 2004). The International Diabetes Federation (IDF) estimates the total number of diabetic subjects to be around 40.9 million in India and this is further set to rise to 69.9 million by the year 2025 (Sicree et al., 2006). The most disturbing trend is the shift in age of onset of diabetes to a younger age in the recent years. This could have long lasting adverse effects on nation's health and economy (Mohan et al., 2007). Several plants are used for the management of the diabetes. Some example of the plants viz.,*Acacia arabica or nilotica* (Singh, 2011), *Cap-*

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

paris sepiaria (*S*elvamani et al., 2008), *Catharanthus roseus* (Rasineni et al., 2010; Singh et al., 2001), *Barleria prionitis* (Geetha and Wahi, 2001), *Barleria lupulina* (Suba et al., 2004), *Balanites aegypticea* (Baragob et al., 2014), *Aegle marmelos* (Seema et al., 1996; Das et al, 1996), *Allium cepa*(Augusti, 1973; Mathew & Augusti, 1975; Gupta et al.,1977), *Artemisia pallens*(Subramonium et al., 1996); *Areca catechu* (Chempakam, 1993), *Beta vulgaris* (Yoshikawa et al., 1996), *Biophytum sensitivum* (Puri & Baral, 1998), *Brassica juncea* (Khan et al., 1995), *Caesalpinia bonducella*(Sharma et al., 1997), *Cajanus cajan*(Amalraj & Ignachimuthu, 1998), *Citrullus colocynthis* (Abdel-Hassan et al., 2000), *Eugenia jambolana, Tinospora cordifolia* (Grover et al., 2000), *Feronia elephantum* (Joshi et al., 2009a), *Coccinia indica* (Mukherjee et al., 1972), *Eugenia uniflora*(Arai et al., 1999), *Bambusa arundinacea* (Joshi et al., 2009b), *Andrographis paniculata*(Nugroho et al. 2012), *Gymnema sylvestre* (Thakur et al., 2012) and may more plant possessing anti-diabetic activity in *in vivo* models. Several compounds viz., S-methyl cysteine sulphoxide (sulphur containing amino acid) (Kumari et al., 1995), allicin (Mathew & Augusti, 1973), S-allyl cysteine sulphoxide (sulphur containing amino acid) (Sheela & Augusti, 1992), C-flavonol glucoside called as shamimin (Saleem et al., 1999), andrographolide (Nugroho et al., 2012), gymnemic acid, gymnemagenin (Persaud et al., 1999; Porchezhian & Dobriyal, 2003)and many more compounds have been isolated from various plants containing anti-diabetic activity.

Parthenin (a sesquiterpene pseudoguaianolide) isolated from *Parthenium hysterophorus* exhibits significant anti-malarial activity against a multidrug resistant strain of *Plasmodium falciparum*. Molecular matching of the oxygen atoms of parthenin and the new anti-malarial drug qinghaosu (Artemisinin) show that both molecules to be amphipathic with common areas for their oxygen atoms and hydrogen framework (Hooper et al., 1990). Parthenin also shows antiamoebic (Sharma & Bhutani, 1988) and allelopathic properties (Kanchan, 1975; Patil &Hegde, 1988). Forskolin (also called Coleonol) is a labdane diterpene that is produced by the Indian Coleus plant (*Coleus forskohlii*). Forskolin is commonly used to raise levels of cyclic AMP (cAMP) in the study and research of cell physiology. Forskolin activates the enzyme adenylyl cyclase and increases intracellular levels of cAMP. cAMP is an important second messenger necessary for the proper biological response of cells to hormones and other extracellular signals. It is required for cell communication in the hypothalamus/pituitary gland axis and for the feedback control of hormones (Mulhall et al., 1997). The flavonoids are known to exhibit several biological activities including anti-HIV activity (Vlietinck et al., 1998). The anti-HIV prenylated flavonoids as 6, 8-diprenylaromadendrin, 6, 8-diprenylkaempferol and lonchocarpol an isolated from the plant *Monotes africanus* exhibited HIV-inhibitory activity in the XTT-based, whole-cell screen. (Meragelman et al., 2001). *Ixeris chinensis* Nakai (Compositae) known as Siyekucai, is a perennial plant, and used as a folk medicine in China for the treatment of bronchitis, pneumonia, pharyngitis, dysentery and poisonous indigestion on the basis of its anti-febrile, antidotal and analgesic effects (Shiojima et al., 1996). Three new guaianolides, 10α-hydroxy-3-oxoguaia-4(15),11(13)-dieno-12,6α-lactone, 10α-hydroxy-3-oxo-4βH-guaia-11(13)-eno-12,6α-lactone, and 10α-hydroxy-3-oxoguaia-4,11(13)-dieno-12,6α-lactone have been isolated from the methanolic extract of the whole plant of *Ixeris chinensis* (Zhang et al., 2002). 3-Hydroxy-4-pyrone-3*α*-D-Glucopyranoside a novel glucoside has been isolated from aerial parts of *Erigeron karwinskyanus* DC (Mathela et al., 1984), and shows a strong biological activity against certain pathogens viz., *Aspergillus, Penicillium* and *Fusarium* species (Mathela et al., 1986).

The major issue for the plant based drug especially isolated compounds which are present in plant with low yield. It cannot execute the demand of pharmaceutical industries. For this reason biotechnology should be apply taking consideration into enhancement of the compound of interest. Plant tissue culture is an option to solve the purpose. Though this statement is controversial we must think over in

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

the way to en-cash the amount of manpower and cost involved in such research. Here in this section it is attempting to highlight such issues in plant biotechnology especially related to tissue culture. Manipulation of DNA to alter its expression in medicinal plants is an area that is widely expanding, provided that the character of interest is present shelled to small number of genes. Although the primary target of trait for manipulation in medicinal plants is the content of active compounds, to which other traits such as development as crops, basic agronomic characters related to uniformity, stability, growth and development, and resistance to biotic and abiotic stresses, can serve as secondary also to be improved (Bajaj, 1998; Dubey & Guerra, 2002). The application of biotechnological approaches to medicinal plants does not start from a low baseline. There is already considerable interest in manipulating plant biosynthetic pathways to produce drug precursors, food components or pesticides; for example, through trichomes, specialized surface organs that manufacture, store and exude secondary metabolites (Stevenson, 2004).

In *Mentha* spp. (mints), biosynthetic pathways have been engineered to modify essential oil production in the trichomes and to enhance the resistance of the plant to fungal infection and abiotic stresses (Veronese et al., 2001). There is a long history of experimental and commercial production of high-value phytochemicals by tissue culture, an *in vitro* system for growing plant organs, explants, tissues and cells or protoplasts. Genetic transformation of cultures using bacterial vectors to transfer genes into the cultured plant DNA has been widely employed to improve product output in such systems. For example, hairy root cultures, transformed by infecting cells with the bacterium *Agrobacterium rhizogenes*, often sustain stable and high productivity in hormone-free culture conditions (Sevon & Oksman-Caldentey, 2002). An efficient transgene delivery system is thus already in place for several important medicinal plants, including *Papaver somniferum* (Park & Facchini, 2000), *Artemisia* spp. (wormwoods) (Chen et al., 1999), members of the family Solanaceae (Moyano et al., 1999) and *Taraxacum platycarpum* (Lee et al., 2004).

Tissue culture often promotes genetic disturbances, which result in somaclonal variation, greatly extending the range of useful variation available to the breeder (Kukreja & Dhawan, 2000). Tissue culture can also contribute to the conservation of valuable biodiversity (Augustine & D'Souza, 1997) and somatic embryogenesis. The micro-propagation of whole plants from cultured cells, has a potentially significant part to play in establishing breeding material from wild populations (Kintzios & Michaelakis, 1999) and in mass-producing material for selection or engineering (Lakshmanan et al., 2002).

The other option could be the plant endophytic fungi, where not only the possibilities to get plethora ofcompound of interest but also can be obtain new biologically active compounds in mass production. In this issue several plant endophytic fungi have been reported in the literature with varieties of the compounds which exhibited prominent biological activities. It must be considerable that genuine endophytic fungus producing the secondary metabolites likes signature constituent(s) or other compound(s) that produced by the plant itself, though in small quantity. Several research groups now a day are working in this area.

Herbs are natural products and their chemical composition varies depending on several factors, such as botanical species, used chemotypes, the anatomical part of the plant used (seed, flower, root, leaf, and so on) and also storage, sun, humidity, type of ground, time of harvest, geographic area; and merchandized products containing on the label the same product varying in their content and concentrations of chemical constituents from batch to batch; and even the same manufacturer can merchandize in different periods and products containing different substances although standardized to achieve a high pharmaceutical quality. This variability can result in significant differences in pharmacological activity involving both pharmacodynamic and pharmacokinetic issues (Firenzuoli& Gori, 2007).

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Currently, the major pharmaceutical companies have demonstrated renewed interest in investigating higher plants as sources for new lead structures along with development of standardized phytotherapeutic agents with proven efficacy, safety, and quality. Herbal medicinal preparations are normally very popular in developing countries because of being economical, backed with a long history of traditional use and also in some developed countries such as Germany, France, Italy and United States where appropriate guidelines for registration of such medicines (Sharma et al., 2010).Chemicals known to have medicinal benefits are referred to as "active ingredients" or "active principles" and their presence depends on a number of factors including the plant species, the time and season of harvest, the type of soil, the way the herb is prepared.The impact of variability of the constituents in herbs or herbal preparations due to genetic, cultural and environmental factors is a major issue in herbal medicines.

Standardization of active chemical constituents of herbal drugs as a finished product must be carried out using standard available protocols. Now a day various sophisticated techniques viz., high performance thin layer chromatography (HPTLC), high performance liquid chromatography (HPLC),gas chromatography (GC), gas chromatography–mass spectrometry (GC-MS), liquid chromatography–mass spectrometry (LC-MS) are frequently used in identification of known phytochemicals. The qualitative and quantitative divergence of the compounds in herbal materials may be due to the climatic, which in turn may affect the composition and other secondary metabolites of the plants (Joshi, 2013d; 2014c) and can accumulate the compound at a particular period and environment. According to WHO (1996a and b, 1992), standardization and quality control of herbals is the process involved in the physicochemical evaluation of crude drug covering aspects, such as selection and handling of crude material, safety, efficacy and stability assessment of finished products, documentation of safety and risk based on experience, provision of product information to consumer and product promotion. Quality of herbal medicines indices such as: macro and microscopic examination, foreign organic matter, ash values, moisture content, extractive values, crude fibre, qualitative and quantitative chemical evaluation, chromatographic examination and toxicological studies. The name of marker constituent(s) along with percentage of each herb either single preparation or multidrug formulation should be mentioned in the final and market product and must be under the strict surveillance of drug regulatory authority.

Various problems appeared during the clinical trial of the crude raw herbmaterial viz., chemical variations as per geographicallocations, climatic conditions, environmental hazards, harvesting methods, collection protocols, etc. which makes it a difficult task to standardize the end product for are producible quality (Bauer& Tittel, 1996). Adverse and side effects is another open problem, because in citizens still prevail the respect for everything that is natural tout court, more as a cultural-fashion based choice than thinking that the patient is introducing in his/her body chemical substances of vegetal origin; not knowing that salicylic glucosides and lactonic sesquiterpenes of many Compositae are often responsible of allergic reactions. Some constituents of the plants are cancerogenic like safrole, bergapten and pyrrolizidines alkaloids. Not of minor importance especially for the old patient using contemporary more synthetic drugs is the problem of drug interferences. Some plants reduce or improve the bioavailability of some drugs due to induction or inhibition of cytochromes (Firenzuoli & Gori, 2007).

In the case of wild harvesting, continual selection of the largest wild-growing individuals or those with the traits considered desirable from a medicinal point of view, if it involves destruction of the whole plant or its reproductive organs, will inevitably lead to a degradation of the wild population. It cannot use medicinal plants on a large scale without modifying the characteristics of the plant populations available to us. If medicinal herbs are brought into cultivation, then we can at least attempt to do this in a controlled manner and at the same time can attempt to conserve wild populations. A particular challenge for me-

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

dicinal plants is the degree to which synergistic effects can be not only conclusively demonstrated but also realistically defined for biotechnological intervention. Otherwise, increasing understanding of what the active components in herbs are and how they work will simply lead to their isolation as plant-derived drugs, and biotechnological interest in the plants and whole extracts from them will not be justifiable.

NOTE

In 2004, the FDA created a pathway for drug makers to get approval of drugs derived from plants. While it has received about 500 applications, it approved only one prescription botanical drug in the 8 years since, until today. There are lots of opportunities for developments of phytopharmaceuticals. Undoubtedly a very few molecules from plant origin have been characterized in detail as a drug candidates. One of the question arises taking into consideration of the yield of compound in the plant, if the compound showing prominent biological activity. Can it supply the demand of the drug based on the plant itself? The plant origin drug can only utilized for the research purpose and may not complete the demand of plant based drugs for disease like diabetes or other life style diseases. Otherwise alternate sources viz., plant tissue culture and endophytes can be the option for potential renewal sources for sustainable production of phytopharmaceuticals.

Quality control using modern analytical tools for testing the various qualitative parameters of herbal medicine as a final market product must be emphasized as per the allopathic medicine norms adopted by the various government agencies of the globe and WHO guidelines must be strictly implemented universally.

Chapter 18
Resealed Erythrocytes as Drug Carriers and Its Therapeutic Applications

Prabhakar Singh
University of Allahabad, India

Sudhakar Singh
Kolkata Medical College, India

Rajesh Kumar Kesharwani
NIMS University, India

ABSTRACT

In this pharma innovative world, there are more than 30 drug delivery systems. Today's due to lacking the target specificity, the present scenario about drug delivery is emphasizing towards targeted drug delivery systems. Erythrocytes are the most common type of blood cells travel thousands of miles from wide to narrow pathways to deliver oxygen, drugs and nutrient during their lifetime. Red blood cells have strong and targeted potential carrier capabilities for varieties of drugs. Drug-loaded carrier erythrocytes or resealed erythrocytes are promising for various passive and active targeting. Resealed erythrocyte have advantage over several drug carrier models like biocompatibility, biodegradability without toxic products, inert intracellular environment, entrapping potential for a variety of chemicals, protection of the organism against toxic effects of the drug, able to circulate throughout the body, ideal zero-order drug-release kinetics, no undesired immune response against encapsulated drug etc. Resealed erythrocytes are rapidly taken up by macrophages of the Reticuloendothelial System (RES) of the liver, lung, and spleen of the body and hence drugs also. Resealed erythrocytes method of drugs delivery is secure and effective for drugs targeting specially for a longer period of time. This chapter will explain the different method of drug loading for resealed erythrocytes, their characterization, and applications in various therapies and associated health benefits.

INTRODUCTION

The emerging new drug delivery technologies are likely to have significant and lucrative impact on drug industries. Drugs delivery assembly suffers various limitation including the amount of molecule delivered and parallel adverse effects. To improve the targeting of drugs a number of attempts has been performed through engineering the properties of the drugs carrier system (Dinda, 2013). The present scenario about pharmaceutical research is aimed to develop drug delivery system with lower side effects and maximum therapeutic benefit. The major desirable properties of a drug carrier is being selective to a target tissue as well as to protect the drugs from premature bio-inactivation. New emerging drug targeting strategies through improving carrier towards tissue exhibit maximal therapeutic index with minimum adverse effects. In diverse drugs carrier, the cellular carriers fulfill maximum criteria desirable in clinical applications. Various carrier are being uses as drug targeting; however, cellular carriers like erythrocytes, platelets, leukocytes, fibroblasts, hepatocytes etc. evidenced themselves to have greater potential over other cellular carriers (Hamidi & Tajerzadeh, 2003, Rossi et al., 2005). Erythrocytes are most common type of blood cells travel thousands of miles from wide to narrow pathways to deliver oxygen, drugs and nutrient during their lifetime (Pandey & Rizvi, 2010). Erythrocytes have good potential carrier capabilities for varieties of drugs and could efficiently deliver various drugs to selected target cells (Gothoskar, 2004). Drug-loaded carrier erythrocytes or resealed erythrocytes are promising for precise drugs targeting.

Resealed erythrocytes as carrier for drugs provides secure and more effective drug targeting for longer period of time and have advantage over several drugs carrier models regarding the biocompatibility, biodegradability without toxic products, inert intracellular environment, entrapping potential for a variety of chemicals, protection of the organism against toxic effects of the drug, able to circulate throughout the body, ideal zero-order drug-release kinetics, no undesired immune response against encapsulated drug etc. (Gothoskar, 2004). Loading of drugs in erythrocytes are performed through process of collecting blood, isolating erythrocytes from blood, entrapping drug of interest in the erythrocytes then followed by resealing the resultant erythrocytes carriers (Green & Widder, 1987). Drug loading process in erythrocytes and sealing of them is based on the response of erythrocytes under osmotic condition (Jain & Jain, 1997). Drug loaded erythrocytes or resealed erythrocytes are biocompatible with large drug loading capacity, biodegradable, non-immunogenic which could circulate for long periods of time (months) through circulation of blood and can be easily targeted to macrophages. In clinical trial, use of resealed erythrocytes was extensively investigated *in vitro* and recently validated *in vivo* also.

BLOOD

Blood is mobile connective tissue composed of fluid called plasma and cells have been extensively uses in pathologies and research laboratory. Blood have several functions including transport of oxygen to cell for aerobic respiration, nutrients, drugs, and excretes toxic substances generated endogenously. Circulating nature of blood makes it universal and primary sample for assessing several organ functions test. Blood have two major components as cellular component (erythrocytes, white blood cells and platelets) and the solvent of cellular component called plasma. Cellular component are again fractionated major cell RBCs and WBCs and platelets (Guyton & Hall, 2006). Blood is a tissue of mesenchymal origin with liquid matrix. The matrix in which the cells are suspended is termed as plasma. This plasma holds the

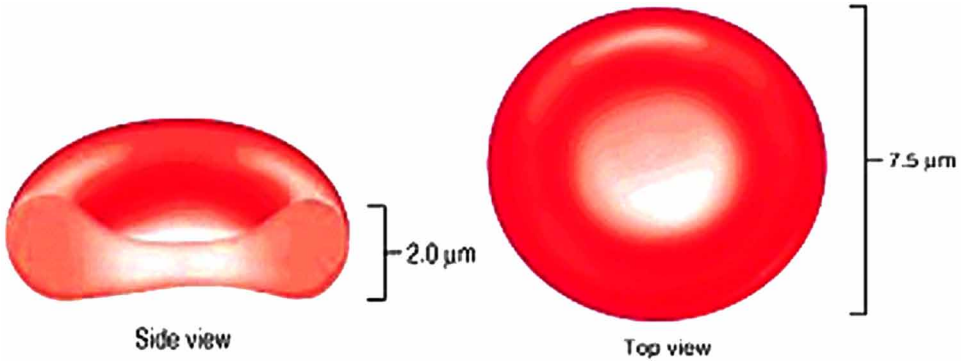
EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

blood cells in form of a suspension. As whole plasma consists of 55% of blood volume and rest 45% is made up of formed elements (blood cells). The cellular component of blood are categories as red blood cells (RBCs) or erythrocytes, white blood cells (WBCs) and platelets.

Plasma

Plasma, the non-living fluid portion of blood is slightly alkaline (pH 7.40) containing an immense number of ions, inorganic molecules and organic molecules. Plasma transits to various parts of the body with several substances. It consists up to 5% of body weight, or roughly 3500 mL in a 70-kg man (Guyton & Hall, 2006). Generally, plasma clot in the absence of anticoagulant, and after clotting the remaining fluid is called serum. Serum has essentially the same composition as plasma except fibrinogen and clotting factors II, V, and VIII, and has a higher serotonin level. Plasma consists of 90-92% water, 0.9% mineral salt, sodium bicarbonate, nutrients (glucose, fatty acid, amino acids, nucleosides, etc.), 7 -8% plasma proteins, defence compound immunoglobulin, anticoagulant, vitamins, enzymes, dissolved gasses and excretory substances (Guyton & Hall, 2006).

The plasma protein consist albumin, globulin, and a fraction of fibrinogen. The globulin fraction is subdivided into α1, α2, β1, β2, and γ globulins and fibrinogen. Circulating antibodies in the γ globulin fraction of the plasma proteins are manufactured in the plasma cells. Most of the other plasma proteins are synthesized in the liver. Plasma protein provides 15% buffering capacity of blood due to presence of weak ionization of their substituent COOH and NH_2 groups. Albumin serves as a carrier for metals, ions, fatty acids, amino acids, bilirubin, enzymes, and drugs despite antioxidant potential (Guyton & Hall, 2006). Plasma protein used as marker of oxidative stress via measuring protein hydroperoxides, protein carbonyl (PCO), and advance oxidative protein products (AOPP) (Rizvi & Pandey, 2011, Singh & Rizvi, 2015).



Plasma lipid includes cholesterol, low density lipoprotein (LDL)-cholesterol, high density lipoprotein (HDL)-cholesterol, very low density lipoprotein (VLDL) cholesterol, triglycerides, phospholipids and free fatty acids. Phospholipids, LDL cholesterol and triglycerides are generally found to in higher amount and repeatedly used in diagnosis of fatty liver, atherosclerosis, or susceptibility for cardiac attack. Plasma proteins and lipids are good marker of oxidative stress implicated in several diseases (Mehdi & Rizvi, 2013, Singh & Rizvi, 2015). Carbohydrates content in plasma are mainly arise from the ingested food and dissociated glycan moiety form the cellular membrane. Plasma carbohydrates are presently uses to diagnose and evaluate various pathological conditions due to increasing the oxidative stress or with ageing (Mehdi et al., 2012).

Erythrocytes

Erythrocytes (Greek *erythros* for "red" and *kytos* for "hollow vessel", with -cyte translated as "cell" in modern usage) are unique circulating cells in the mammalian cells travels thousands of miles from wide to narrow pathways to deliver oxygen, drugs and nutrient during their life time. In normal men, the average number of RBCs per cubic millimeter is 5,200,000 (±300,000); in normal women, it is 4,700,000 (±300,000). Persons living at high altitudes have greater numbers of RBCs. RBCs have the ability to concentrate hemoglobin in the cell fluid up to about 34 grams in each 100 milliliters of cells. Millions of erythrocytes are produced every second, they developed in bone marrow and circulate for about 100-120 days in the human body however the mean erythrocyte lifespan of Wistar rats is 59.8 ±

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Morphology of Erythrocytes: Side view & Top view

2.2 days and fixed during the modeling process, 60 days (Guyton & Hall, 1996). In most mammalian blood, mature RBCs are oval and flexible biconcave disks with lacking cell nucleus and most organelles to accommodate maximum space for hemoglobin. Normal erythrocytes are approximately 5.7 µm in diameter and a thick 2.5 µm at the thickest point and 1 µm or less in the center, discoid, and biconcave in cross (Figure 1) section (Guyton & J.E. Hall, 1996).

Erythrocyte Membrane

The erythrocyte membrane is composed of cholesterol and phospholipids, and secured an elastic network of skeletal proteins via trans-membrane proteins (Mohandas & Gallagher, 2008). Membrane is bilayer in nature and the composition of outer and inner layer is according to requirement. Glycolipids, phosphatidylcholine and sphingomyelin are located in the outer half of the bilayer; however, phosphatidylinositol, phosphatidylethanolamine and phosphatidylserine occur in the interior layer facing the cytoplasm (Mohandas & Gallagher, 2008). Due to membrane fluidity and flexibility erythrocytes can squeeze themself through much narrower than their diameter and can recover rapidly to their original shape. Phosphatidylcholine forms highly fluid lipid regions to induced fluidity, while sphingomyelin induces rigidity of membrane. Lipid domain controlling the fluidity is determined by the molar ratio of cholesterol to phospholipid, degree of unsaturation of phospholipid acyl chains and phosphatidylcholine sphingomyelin ratio (Mahmmoud, 2011).

An intact membrane skeleton is crucial for the mechanical and functional integrity of the RBCs because intact membrane skeleton determines RBCs viscoelastic properties to withstand the shear forces of the circulation and squeeze out through capillaries (Chassis et al., 1988). The membrane skeleton is constituted by a multi-protein network (ankyrin, anion exchanger (AE1 or band 3) and protein 4.1, 4.2 etc.) lying just beneath the plasma membrane (Lux & Palek, 1995). Band 3 and glycophorin A are most abundant glycated integral membrane protein whose concentration in the membrane varies according to the weather of living subject. Band 3 present as dimer, composed of two identical subunits in membrane and serves as a channel for the passive exchange of anions across the membrane like chloride shift. The tetrameric form of band 3 binds to ankyrin (Michaely & Bennett, 1995) and protein 4.2 (Rybicki et al., 1996) constituting the major attachment site of the RBCs membrane to the underlying cytoskeleton. A second site of attachment involves the glycophorin C complex with protein 4.1 and p55. Glycophorin

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

A is 1TMS consisting carbohydrate cover 16 oligosaccharide chains and make up of 60 percent of the molecule's weight. Glycophorin have negative charge due to presence of sialic acid the sugar residue at the end of carbohydrate chain due to which RBCs repel each other and prevent the RBCs from clumping during circulation through the tiny capillaries (Mehdi et al., 2012).

Functions of Erythrocytes

In the 19th century, Hope Seyler identified hemoglobin and its crucial role in oxygen delivery to various parts of the body (Telen, 1993). In some lower animals, hemoglobin circulates as free protein in the plasma not enclosed in RBCs. The tetrameric hemoglobin molecule in turn is designed to unload oxygen cooperatively within the range of physiological tissue pO_2 (Sivilotti, 2004). Carbonic anhydrase, an important enzyme of erythrocytes catalyzes the reversible reaction between carbon dioxide (CO_2) and water to form carbonic acid (H_2CO_3) regulates the acid base balance in the blood. Despite these gaseous exchange, hormones, enzymes and nutrients transport function, blood actively remove toxic excretes of different cells, drugs of chemical inhaled, injected or ingested (Table 1) (Sivilotti, 2004).

When RBCs undergo shear stress during the circulation in constricted vessels, RBC release ATP which in turn relax and dilate the blood vessel to promote normal circulation of blood flow (Ristenpart et al., 2008). After deoxygenation of hemoglobin erythrocytes release S-nitrosothiols, which also acts as vasodilator for directing more blood in areas having less oxygen of the body (Diesen et al., 2008). Erythrocytes has also been found to synthesize nitric oxide is another vasodilator via using L-arginine as substrate (Kleinbongard et al., 2006). Shear stress on erythrocytes induced the nitric oxide synthase for nitric oxide synthesis and exportation of them is thought to involve in the regulation of vascular tonus (Ulke et al., 2009). Erythrocytes is also reported to produce hydrogen sulfide, a signaling gas which have similar effects like vasodilator through relaxing the vessel walls. It is believed that the cardio protective effects of garlic are due to erythrocytes converting its sulfur compounds into hydrogen sulfide (Benavides et al., 2007). For all these functions to run well, efficient and regulated transport of these molecules (O_2, CO_2 HCO^{3-}, Cl^-, S-nitrosothiols, nitric oxide) is very essential.

Table 1. Important biochemical reaction occurs in erythrocytes

Process	Chemical Reaction
Production of superoxide (by-product of various reactions)	$O_2 + e^- \rightarrow O_2^{\bullet -}$
NADPH-oxidase	$2\ O_2 + NADPH \rightarrow 2\ O_2^{\bullet -} + NADP + H^+$
Superoxide dismutase	$O_2^{\bullet -} + O_2^{\bullet -} + 2\ H^+ \rightarrow H_2O_2 + O_2$
Catalase	$H_2O_2 \rightarrow 2\ H_2O + O_2$
Myeloperoxidase	$H_2O_2 + X^- + H^+ \rightarrow HOX + H_2O$ ($X^- = Cl^-, Br^-, SCN^-$)
Glutathione peroxidase (Se-dependent)	$2\ GSH + R\text{-}O\text{-}OH \rightarrow GSSG + H_2O + ROH$
Fenton reaction	$Fe^{2+} + H_2O_2 \rightarrow Fe^{3+} + OH^{\bullet} + OH^-$
Iron-catalyzed Haber-Weiss reaction	$O_2^{\bullet -} + H_2O_2 \rightarrow O_2 + OH^{\bullet} + OH^-$
Glucose-6-phosphate dehydrogenase (G6PD)	$G6P + NADP \rightarrow 6\ Phosphogluconate + NADPH + H^+$
Glutathione reductase	$G\text{-}S\text{-}S\text{-}G + NADPH + H^+ \rightarrow 2\ GSH + NADP$

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Life Span of Erythrocytes and Changes Associated with Erythrocyte Senescence

Worn-out erythrocytes are removed from circulation and destroyed in the spleen and liver, and the breakdown products are recycled. In human, erythrocytes are produced in red bone marrow under the regulation of a hemopoietic hormone erythropoietin by process called erythropoiesis (Torotra & Grabowski, 1993). RBCs are produced exclusively in the bone marrow until age of in younger age; however, most of cells continue to produce in marrow of vertebrae, sternum, ribs, and ilia. Blood cells are originated from pluripotential hematopoietic stem cells. Pluripotential cells differentiate in to committed stem cells which differentiate to form the other cells in the blood. Growth and differentiation of stem cells in to erythrocytes are controlled by multiple regulatory proteins as growth factor protein regulates the growth of stem cells and differentiation inducer induced the differentiation.

Erythropoiesis is process of production of erythrocytes from the committed stem cells through different process via different organs in about seven days. In healthy adult red bone marrow is the major site for the continuous synthesis of RBCs at a rate of 2 million per second. After the process of erythrocytes maturation steps, RBCs live in the blood for about 100-120 days (Guyton & Hall, 2006). Like animal aging erythrocytes passes through cellular aging as at the end of life erythrocytes become senescent and removed from the blood circulation. They become susceptible to selective recognition by macrophages and subsequent phagocytosis in the reticuloendothelial system (spleen, liver and bone marrow), thus removing old and defective cells and continually purging the blood. This process is termed eryptosis, or erythrocyte programmed cell death (Guyton & Hall, 2006).

Process of erythrocytes ageing induced changes in the membrane composition, fluidity and hence the activity of various enzymes and transport system (Rizvi et al., 2010). Progressive aging of erythrocytes increased the cellular density which could affect the properties of resealed erythrocytes. Aged cells shows a little decreases in the deformities index. Increases in the elastic modulus and surface viscosity in senescent erythrocytes has been observed as compare to young erythrocytes (Racca et al., 1999). There are studies which indicate a decrease in antigenic expression in the population of senescent erythrocytes of both blood group. One hypothesis that is related with erythrocytic senescence proposes that denatured/oxidized hemoglobin (hemichromes) arising late during an RBC's life span induces clustering of the integral membrane protein, band 3. In turn, band 3 clustering generates an epitope on the senescent cell surface leading to autologous IgG binding and consequent phagocytosis (Michael et al., 1999).

Oxidation of hemoglobin is caused by free radicals and ROS (reactive oxygen species) with progressive aging (Pandey & Rizvi, 2010). The progressive accumulation of oxidized hemoglobin covalently bound to the membrane skeleton not only disrupts membrane organization but also threatens eventual phospholipids oxidation via a calcium-promoted quasi-lipoxygenase activity. The emergence on the cell surface of a threshold concentration of oxidized phospholipids, principally phosphatidylserine, signals recognition by the CD36 macrophage receptor (Kiefer & Snyder, 2000).

Erythrocytes as Model Study

Erythrocytes have been extensively studied for their potential carrier capabilities for the delivery of nutrients, gasses, excretory products, toxic substances and drugs. Currently different types of mammalian erythrocytes have been used for research purpose, including erythrocytes of mice, cattle, pigs, dogs, sheep, goats, monkeys, chicken, rats and rabbits (Gothoskar, 2004). Erythrocytes are specialized cells

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

perform critical functions in wide range of cellular environments. Due to absence of protein synthesizing machinery in erythrocytes they have additional impact on carrier capabilities for varieties of drugs.

RESEALED ERYTHROCYTES

Erythrocytes have water content 65% and rest of 35% are solid. Isotonic nature of plasma for erythrocytes protects them against osmosis. However, if medium is hypotonic erythrocyte get swelled and simultaneously lose their hemoglobin content. Erythrocytes without hemoglobin content are termed as ghost. There are three types of ghost has been recognized as (a) ghosts which reseal immediately after haemolysis, (b) resealed ghost after reversal of haemolysis by addition of alkali ions and, (c) erythrocytes ghost with leaky nature under different experimental conditions (Deloach et al., 1980, Ihler, 1983, Ihler & Tsang, 1987, Jain & Jain, 1997). During hypotonic shock and on resealing of erythrocytes hemoglobin is lost but cellular constituents are retained and erythrocytes called "resealed erythrocytes".

Encapsulation of adenosine triphosphate (ATP) in erythrocytes with was tried in 1953, by Gardos (Gardos, 1953). Ihler et al. and Zimmermann (1973) reported to use erythrocytes as drugs carrier; however, the term carrier erythrocytes was came in existence in 1979 which describe drug-loaded erythrocytes (Ihler, 1983, Zimmermann, 1973, Jain & Jain, 1997). It was found that several molecules leak rapidly from erythrocytes via membrane due to simple diffusion. However, principally drugs having nature of peptides, nucleic acids etc. may potential be entrapped in to erythrocytes. Erythrocytes have its own enzymatic activities which can be conveniently utilized to convert an inactive pro-drug into an active drug. These behavior of erythrocytes leads to design a number of pro-drugs with charged chemical groups making them non-diffusible or non-toxic. Red cells enzymes hydrolyze these chemical groups and converted pro-drug in to an active drug which can diffuse through erythrocytes membrane and released them in circulation or at specific sites. Hemoglobin free resealed erythrocytes with drugs serves as slow circulating depots to reticuloendothelial system (RES) (Zimmermann, 1983, Lewis & Alpar, 1984, Ropars et al., 1987, Jain & Jain, 1997).

Morphology of Resealed Erythrocytes

The survival and existence of resealed erythrocytes in biological system is affected by the membrane fluidity and biological behavior of resealed erythrocytes. The *in vitro* characterization of resealed erythrocytes is an important process to predict the biological properties of resealed erythrocytes in *in vivo*. Erythrocytes are flexible and they squeeze out themselves in narrow capillaries hence morphology of erythrocytes after loading of drugs and resealing decides their life span after their administration in body.

Morphological evaluation are usually performed through the microscope. Light microscopy has been reported to reveals no observable change in resealed cells; however, some spherocytes (spherical erythrocytes) has been detected (Talwar & Jain, 1992a, Jain et al., 1995, Jain et al., 1997). Increasing the resolution power, i.e. scanning electron microscopic (SEM) have shown that maximum drug loaded resealed erythrocytes are in their biconcave discoid shapes (Jrade et al., 1987), some form spherocytes with invagination in one point (stomatocytes) after the drug loading procedure (Garin et al., 1996). Smaller cells (microcyte) were also reported in some cases (Teisseire et al., 1987).

Deformities of erythrocytes has also been reported to modulate the life span of erythrocytes. Viscoelasticity of erythrocytes membrane, viscosity of the cell contents, and cellular surface-to-volume ratio

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

are found to affects the rheological behavior of resealed erythrocytes in narrow capillaries and the RES (Jrade et al., 1987). Changes in the shape of resealed erythrocytes after drugs loading measured by the passage time of definite volume of resealed erythrocytes via a polycarbonate filter (pore size of 45 μm) or a capillary of 4 μm diameter (Jrade et al., 1987, Zanella et al., 1987). Turbidimetrically, chlorpromazine mediated shape changes is another approach to evaluate morphological changes (Hamidi et al., 2001).

PREPARATIVE METHODOLOGY

Source and Isolation of RBC

Erythrocytes isolated form mice, cattle, pigs, dogs, sheep, goats, monkeys, chicken, rats, and rabbits have been used for resealed erythrocytes or drugs encapsulated erythrocytes. Fresh erythrocytes isolated from whole blood has been found to have more encapsulation efficiency for the loading purposes of drugs. It has been also reported that young erythrocytes have higher capability then old erythrocytes. Fresh blood, collected from mammals chilled have to be store at 4 ºC and less than of two days. The erythrocytes are harvested and washed with phosphate buffer saline by centrifugation. Mammalian erythrocytes have advantage over the other species erythrocytes due to lacking the nucleus and various cellular organelles such as their mitochondria, golgi apparatus and endoplasmic reticulum in their mature state. Erythrocytes consist nucleus during the early phases of erythropoiesis but the gradually disappear during development in order to provide more space for hemoglobin. Due to absence of nucleus and cellular organelles erythrocytes they do not contain DNA, cannot synthesize any RNA and also used to depend on ATP by the glycolysis (Ihler & Tsang, 1987). These properties of erythrocytes ensures that no virus can target erythrocytes for growth and propagation (Vienken et al., 1978).

Carrier erythrocytes are prepared collecting blood samples, separating erythrocytes from plasma, entrapping desire drug in the erythrocytes, and finally resealing the carriers (Green & Widder, 1987). Venous blood from different healthy volunteers or subjects can obtained in heparin by venipuncture. The blood was centrifuged at 800 × g for 10 min at 4°C. After the removal of plasma, buffy coat and upper 15% of the packed erythrocytes, the packed erythrocytes were washed twice with cold phosphate buffer saline at 4°C (0.9% NaCl, 10 mM Na_2HPO_4, pH 7.4). The washed erythrocytes are diluted with phosphate buffer saline and stored at 4ºC until used (Singh et al., 2015, Singh & Rizvi, 2015).

Methodology of Drugs Loading

Various methods has been established to load drugs or other bioactive compounds in erythrocytes isolated from different mammals. Majorly includes physical method like electricalpulse method, osmosis-based systems, and chemical methods. Erythrocytes have capability to reverse the shape changes with or without accompanying volume change of erythrocytes and for reversible deformation under various stress.

Osmosis and Concept of Tonicity

Tonicity is a measure of the osmotic pressure of two solutions separated by a semi permeable membrane. Like osmotic pressure, tonicity is influenced only by solutes which cannot cross the semi permeable membrane. Higher the concentration of solute higher will be the tonocity of solution. Term is generally

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

used when describing the response of cells immersed in an external solution. The process by which water moves across the semi permeable membrane from the region of higher solute concentration to the region of lower solute concentration is termed as osmosis. The process of osmosis is depended on erythrocytes response under the osmotic conditions. These methods exchanged the extra cellular solute having desired drugs with the cellular solute (hemoglobin) of erythrocytes before resealing. Hypo-osmotic methods are again classified in to hypotonic dilution methods, dialysis methods, Presswell method, and isotonic osmotic lyses.

Hypotonic Dilution

A hypotonic solution is that which contains a lesser concentration of impermeable solutes than the solution on the other side of the membrane. When a cell's cytoplasm is hypotonic than surrounding then water will be drawn out of the cytoplasm. If water molecules continue to diffuse into the cell, it will cause the cell to swell, and finally lysis will occur. Hypotonic dilution was the first method investigated for the encapsulation of chemicals into erythrocytes (Iher, 1973). In this methods, erythrocytes are exposed to hypotonic solution of 0.4% NaCl to escape of cellular contents in the exchange of hypotonic solution having desired drugs. This method was used to entrap β-glucosidase, β–galactosidase (Iher, 1973), asparginase (Updike & Wakamiya, 1983), and arginase (Adriaenssens et al., 1976), as well as bronchodilators salbutamol (Bhaskaran & Dhir, 1995). Hypotonic dilution methods is simplest and fastest (exchange of cellular content and hypotonic solution equilibrium is achieved with in one minute), but having lower capsulation efficacy (1 – 8%).

Dialysis

This methods are performed by erythrocyte dialyzer through which initially a desired haematocrit is achieved through suspending the washed erythrocytes with phosphate buffer (pH 7.4) having desired drug solution. This method provide good entrapment efficiency yet have disadvantages of time consuming and size distribution of loaded ghosts were not found to be homogeneous.

Press Well Dilution Method or Hypotonic Preswelling

This method was developed by Rechsteiner (1975) and again was modified by Jenner et al. (1981). Method is based on swelling the erythrocytes without the lyses due to suspending them in to slightly hypotonic solution (0.6% NaCl) and recovered the swollen erythrocytes by centrifugation at low speed. Then, a little volumes of drug solution are added to the point of erythrocytes lyses. Now cells placed in isotonic medium to make resealed erythrocytes. Press well dilution method are simple and fast with higher survival rate *in vivo* as long as native RBCs.

Isotonic Osmotic Lyses or Osmotic Pulse Method

Isotonic solutions contain equal concentrations of impermeable solutes on either side of the membrane. When cell cytoplasm is isotonic to surrounding no such change occur because there is no net movement of water across the cell membrane. Red blood cells are bound by a membrane which allows water to pass through while generally restricting the solutes. This process, causes cells to shrink due to loss of water (called exosmosis) when placed in hypertonic solutions. On the other hand, red cells absorb water (called endosmosis) when in a hypotonic medium. This results in swelling and ultimately hemolysis as the cell

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

bursts. In isotonic osmotic lyses or osmotic pulse method erythrocytes are placed in high transerythrocytic membrane permeability solution which allow encapsulation of drugs through solution into erythrocytes via direct chemical potential gradient. Various chemical methods has adopted for isotonic hemolysis like ammonia chloride, urea solution, and polyethylene glycol (Davson & Danielli, 1970, Billah et al., 1977).

Electrical Breakdown/ Electro-Insertion/ Electroencapsulation

Zimmermann (1973) developed this method to encapsulate bioactive molecules. However, Kinosita & Tsong (1977a) suggested the use of transient electrolysis for required membrane permeability for drug loading. In this method optimum intensity of an electric field and optimal discharge time has been reported between 1–10 kW/cm and between 20–160 μs (Zimmermann et al., 1976, Kinosita & Tsong, 1977b, Zimmermann, 1983, Lewis & Alpar, 1984,, Tsong & Kinosita, 1985). Voltage (2kV/ cm for 20μ sec) mediated polarization induce electrical breakdown of erythrocytes membrane through formation of pore which helps in entrapment of drugs. Pore generation generally takes place at the lipid protein junction or lipoid regions in membrane and can be resealed by incubation in suitable solution at 37º C. In comparison with osmotic methods advantage of this method is the uniform distribution of loaded cells (Zimmermann, 1983). However, this process is very expensive.

Endocytosis

This method was reported by Schrier et al. (1975). In erythrocytes intracellular vesicles with desired drugs could be induce. This process can load virus (up to 1000 nm diameter), enzymes and small molecules. Intracellular vesicles derived from cytoplasm may release intracellular content in erythrocytes cytoplasm depending upon the nature of drugs. This method have been used to encapsulate primaquine and related 8-amino-quinolines, vinblastine, chlorpromazine and related phenothiazines, propranolol, tetracaine, hydrocortisone, and vitamin A (Tsong & Kinosita, 1977, DeLoach, 1983, Schrier, 1987).

Membrane Perturbation

This method is based on the ability of chemical to modulate membrane permeability of erythrocytes. Deuticke et al. (1973) has found that the erythrocytes membrane permeability increases when RBCs expose to polyene antibiotic such as amphotericin B. Antibiotics have ability to increase the permeability of erythrocytes membrane were exploited for loading of drugs in to erythrocytes e.g. Amphotericin-B interacts with the cholesterol in plasma membrane causing change in permeability for anti-leukemic drugs. Kitao et al., (1978) entrap the daunomycin (antineoplastic drug) in human and mouse erythrocytes. However, Lin et al. (1999) used halothane for the same purpose.

Lipid Fusion

Lipid vesicles are generally used to encapsulate the drugs and loaded to erythrocytes. Lipids vesicle tagged with specific phospholipids induced the drugs loading potential and functional properties of drugs loaded erythrocytes. This method was mainly used for entrapping inositol monophosphate which improve the oxygen carrying capacity of RBCs (Nicolau & Gersonde, 1997).

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Red Cell Loader

Red cell loader was developed by the Magnani and co-workers, a novel method for loading of non-diffusible drugs into erythrocytes (Magnani et al., 1998). The loading process takes place in two sequential steps of hypotonic dilutions of washed RBCs and then an isotonic process for resealing the erythrocytes. This process of drugs entrapment have 30% of drug loading efficiency with 35–50% cell recovery despite normal survival of erythrocytes *in vivo*.

IN VITRO CHARACTERIZATION OF RESEALED ERYTHROCYTES

Characterization of resealed erythrocytes with drugs provide the significances of methods used to prepare the drug encapsulated erythrocytes. The following process could be used to evaluate and characterized the resealed erythrocytes-

Measuring Erythrocyte Sedimentation Rate (ESR)

Erythrocyte sedimentation rate determine the sedimentation rate of blood cells in a standard tube. It measure the suspension stability, size and number of the RBC in plasma or relative concentration of plasma protein (fibrinogen and α, β globulins). ESR is standardized as 0 to 15 mm/hr. for normal blood, higher rate indicates active but obscure disease processes (Teisseire et al., 1987).

Measuring Drug Content

Drugs contents was evaluated in erythrocytes. Initially erythrocytes were depolarized with acetonitrile and then centrifuge the whole content at 2500 rpm for 10 mins. Now supernatant was used to evaluate the drug content (Gothoskar, 2004).

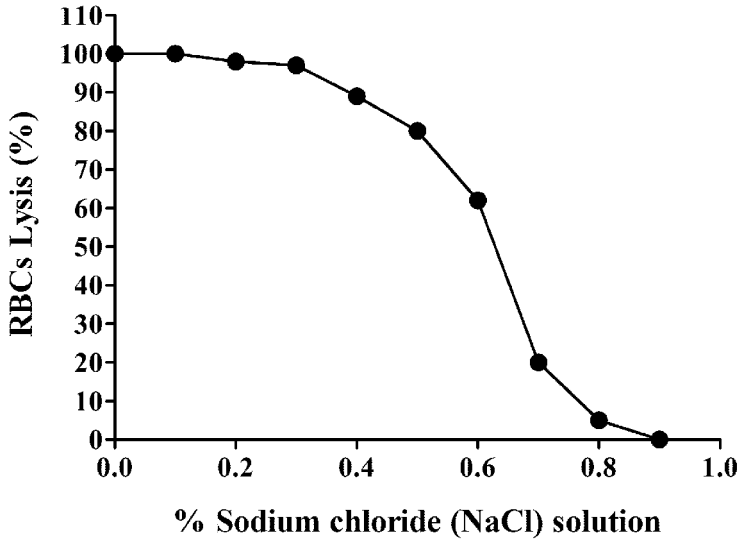
In Vitro Release of Drug and Hemoglobin

In this process normal and resealed erythrocytes are incubated at room temperature in PBS in metabolic rotating wheel incubator path. Now sample was depolarized to evaluate the drugs content and hemoglobin. Hemoglobin can be measured by correlating the hemolysate solution with standard hemoglobin graph (Gothoskar, 2004).

Drug Release Pattern

Drug release pattern is the most important parameters to evaluate the properties of resealed erythrocytes. Hemoglobin is also reported to invariably release with drug form erythrocytes due to loss of cell membrane integrity, but drug releasing potential of erythrocytes is considerably higher than hemoglobin, reflects readily diffuses of drug. Size and polarity of the drug molecule are two factors that determine the drug release pattern (Eichler et al., 1987). It was found that cell lysis is not essential for the release of lipophilic drugs like phenytoin, dexamethasone (Eichler et al., 1987), methotrexate (Lewis & Alpar, 1984), primpquin (Talwar & Jain, 1992), and vitamin B-12 (Eichler et al., 1985). However, cell lysis

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use



is essential for non-diffusible or polar drugs like heparin, gentamicin and enalaprilat, and enzymes asparginase, peptides urogasterone and l-lysine-l-phenylalanine (Gothoskar, 2004). Cross-linking cell membrane with gluteraldehyde is reported to reduce the drugs release rate (Jenner et al., 1981, Talwar & Jain, 1992). Complex formation of drug with dextran and albumin also reduced the release rate (Ihler, 1983). Entrapment of biodegradable prodrug (cortisol-21- phosphate, o-acetyl propranolol, o-pivaloyl propranolol, and cytosine arabinoside monophosphate) has similar effects on drugs release pattern (Gothoskar, 2004).

Osmotic Fragility

The osmotic fragility test is a measure of the resistance of erythrocytes to hemolysis by osmotic stress. Osmotic stress is produced by exposing cell to NaCl solution of tonicity lower than that of plasma. The test consists of exposing red cells to decreasing strengths of hypotonic saline solutions and measuring the degree of hemolysis calorimetrically at room temperature (Pandey & Rizvi, 2014a). The osmotic fragility test ultimately tries to determine the concentration of solute inside the cell subjecting it to the hemolytic effects of solutions of different concentrations. Erythrocytes were added to tubes containing increasing concentrations of phosphate-buffered sodium chloride (0%, 0.1%, 0.2%, 0.3%, 0.5%, 0.7%, 0.8%, and 0.9%) solution at pH 7.4 in a final volume of 10 ml and incubated for 30 min at 37 ºC. After centrifugation at 1500 x g for 10 min, absorbance of the supernatant was measured at 540 nm. Hemolysis in each tube was expressed as a percentage, using hemolysis in distilled water (0% NaCl) as 100% as shown below in Figure 2 (Pandey & Rizvi, 2014b).

In osmotic fragility test % hemolysis values are calculated and finally plotted against concentration to give and sigmoidal curve. This sigmoidal shape of curve indicates that normal RBC varies in their resistance to hypotonic solution. The osmotic fragility of resealed erythrocytes is affected by concentration, type and process of drugs loading. Osmotic fragility indicate the changes in cell membrane integrity and their resistance towards osmotic pressure of the suspension medium.

Figure 2. Osmotic fragility

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Based on integrity and resistance of cell membrane another method, turbulence fragility measure the resistance of drugs loaded erythrocytes against hemolysis from turbulent flow within circulation by vigorously shaking (Hamidi et al., 2001) or by passing them through needles with smaller internal diameter (e.g., 30 gauge) (Talwar & Jain, 1992a, Talwar & Jain, 1992b, Jain et al., 1995, Jain et al., 1997). In above both method released hemoglobin and drug were determined and found that turbulent fragility is higher than osmotic fragility of resealed cells (Talwar & Jain, 1992a, Talwar & Jain, 1992b, Jain et al., 1995, Jain et al., 1997, Hamidi et al., 2001).

Morphological Evaluation

The plasma membrane of RBC is closely associated with a proteinaceous skeleton. This cytoskeleton and other features like excess membrane for given volume of cell make RBC (Mehdi et al., 2012). Erythrocyte membrane consists of approximately equal amounts of lipids proteins. Phospholipids and unesterified cholesterol constitute major portion of membrane lipids. Phosphatidylcholine are more abundant in the outer leaflet whereas phosphatidylethanolamine are more concentrated on the inner leaflet of the lipid bilayer. Cholesterol molecules are intercalated between the phospholipid molecules. The relative amounts of cholesterol & phospholipids are responsible for the fluid properties of the RBC membrane (Ballas & Krasnow, 1980). The distribution of lipids in both leaflet is asymmetrical. This asymmetry is maintained by action of flippase proteins (Daleke & Lyles, 2003). Morphological evaluation including changes in shape due to changes in membrane biochemical composition or altering the proteinaceous skeleton modulates the cellular compatibility to survive in various solution or pressure of narrow capillaries.

ADVANTAGE OF RESEALED ERYTHROCYTES (GOTHOSKAR, 2004)

- Able to circulate throughout the body
- The biocompatibility of resealed erythrocytes and no immunological responses.
- It degraded biologically and do not release any toxic substances.
- Generally in produced uniform and drugs carriers.
- Intracellular environment are inert hence protection of encapsulated dugs by endogenous chemicals
- Have capability to entrap wide variety of chemicals.
- It also protects the organism against side-effects of drugs
- It check the immune response by organism against the loaded drug
- Ideal for deal zero-order drug-release kinetics (Eichler et al., 1986)
- Ensures the dose sufficiency as a large amount of drugs can be loaded in the resealed erythrocytes.
- Resealed erythrocytes have larger life span comparatively other synthetic drugs carriers
- Easily monitoring and control of resealed erythrocytes during life span ranging from minutes to months (Summers, 1983).

APPLICATIONS OF RESEALED ERYTHROCYTES

Erythrocytes as carrier for drugs cover pharmacological as well as therapeutic targets. Resealed erythrocytes with drugs has been reported to have slow releasing tendency of drugs when intravenously injected

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

(Gothoskar, 2004). Erythrocytes is used as circulating carriers to release drug for a long period of times as well as target specific for liver, spleen, and lymph nodes. Despite these the following are the major application of resealed erythrocytes as drugs carriers.

Slow Drug Release

Due to long life span or erythrocytes, resealed erythrocytes as drugs carrier could be used as circulating depots of various drugs including anti-tumor, anti-parasitic, antibiotics, cardiovascular drugs, vitamins and steroids (Jenner et al., 1981, Pitt et al., 1983, Eichler et al., 1985, Magnani et al., 1998). Slow drugs release propensity of resealed erythrocytes arise when drugs or selected methods for drugs loading do not changes the morphological and physiological properties of erythrocytes.

There are various mechanism which explain the drugs releasing properties-

- Passive diffusion
- Specialized carrier transporter at the membrane
- Macrophages of RES do phagocytosis of resealed erythrocytes with drugs and finally accumulated drugs into the macrophage interior fallowed by slow release pattern of drug (Talwar & Jain, 1992a, Jain & Jain, 1997).
- The subcutaneous injection resulted an accumulation of erythrocytes in lymph nodes followed by hemolysis to release the drug (Deloach et al., 1987).

Drug Targeting

Modification on the surface of erythrocytes has been used to target the organs of mononuclear phagocytic system or reticuloendothelial system (Alvarez et al., 1998). Site-specific and target-oriented drug delivery system exhibit maximal therapeutic index with minimum adverse effects.

Targeting RES Organs

Kupffer cells in liver and spleen has been found to rapidly clear the damaged erythrocytes from circulation. Modification in erythrocytes membrane induces the targeting specificity. In presence scenario, various approaches has been performed to modify the surface characteristics of erythrocytes membrane with the help of antibodies, gluteraldehyde, carbohydrates such as sialic acid, sulphydryl, chemical cross-linking (Alvarez et al., 1998). Sialic acids has been responsible to induced negative surface on erythrocytes reduce in erythrocytes membrane with aging (Mehdi et al., 2012).

Targeting the Liver

Enzyme Deficiency/Replacement Therapy

This methods is used to prevent the accumulation of glucocerebrosides in the liver and spleen by glucocerebrosidase-loaded erythrocytes (Deloach & Ihler, 1977). This methods used to overcome the allergic reactions, and toxic manifestations in exogenous enzyme therapy because resealed erythrocytes with enzymes can be treated as native cell.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Treatment of Hepatic Tumors

Antineoplastic drugs used in hepatic tumors like methotrexate (Zimmermann, 1983, Jaitely et al., 1996), bleomycin (Zimmermann, 1973), asparginase (Updike & Wakamiya, 1983, Jaitely et al., 1996), and Adriamycin have been found to delivered successfully by resealed erythrocytes (Benatti et al., 1987, Zocchi et al., 1988, Al-Achi & Boroujerdi, 1990, Jaitely et al., 1996).

Treatment of Parasitic Diseases

Parasitic infection involve the harboring of parasites in the RES organs which can be successfully treated by the drug loaded resealed erythrocytes due to selectively accumulation within RES organs. Results has been reported as favorable in animal models for anti-malarial (Summers, 1983), anti-leishmanial (Summers, 1983, Eichler et al., 1986, Berman, 1987), and anti-amoebic drugs (Talwar & Jain, 1992b, Jaitely et al., 1996).

Removal of RES Iron Overload

It was found that aged erythrocytes are destroyed in RES organs which in turn increased the accumulation of iron in these organs. Resealed erythrocytes with desferrioxamine induction has been found to reduce the excess iron accumulated in thalassemic patients (Berman, 1987, Jaitely et al., 1996,).

Removal of Toxic Agents

Resealed erythrocytes encapsulated with recombinant phosphodiestrase has been reported to reduce the organophosphorus intoxication (Pei et al., 1994). Cannon et al. (1994) also reported that carrier erythrocytes containing sodium thiosulfate and bovine rhodanase inhibited the cyanide intoxication.

Targeting Other Organs

Despite the RES targeting, resealed erythrocytes have been used to target other organs. Various method have been used for different organs like entrapment of paramagnetic particle with desired drugs, drugs with photosensitive material, attachment of antibody at erythrocytes membrane or use or ultrasound waves (Gothoskar, 2004).

Entrapment of paramagnetic particle in to erythrocytes could induced their localization under the influence of an external magnetic field to a particular location. Photosensitized erythrocytes are photo-triggered carrier use to deliver methotrexate in cancer treatment (Flynn et al., 1994). Targeted micro bubble destruction with ultrasound has also been used to deliver the colloidal particles and erythrocytes to tissue through rupturing of microvessel (Price et al., 1998).

Despite the above approaches following could also use for targeting different organs other than RES:

- Preparation of erythrocytes carrier having thermo responsive liposomes (localization could performed through an external thermal source)
- Intra-peritoneal injection for drug targeting to peritoneal macrophages

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Resealed cells pre-treated with lectin and loaded with antineoplastic drugs for improving target specificity to tumor cells.

Delivery of Antiviral Agents

Resealed erythrocytes have been used to deliver recombinant herpes simplex virus type 1 (HSV-1), deoxycytidine derivatives (Ihler, 1983), azidothymidine derivatives (Benatti et al., 1989), fludarabine phosphate (Fraternale et al., 1996), glycoprotein B (Chiarantini et al., 1995) and azathioprene, acyclovir (Magnani et al., 1998). Resealed erythrocytes has been used to deliver to anti-viral agents because most of them are either nucleotides or nucleoside analogs. Nucleosides have tendency to rapidly transported across the membrane; however, nucleotides have not, and hence exhibiting a prolonged release profiles.

Enzyme Therapy

Various biochemical derangement has been associated with the altered or deficient enzymes activity. Direct injection of enzymes into the body has been reported to induce the immunological response or deactivation due to other enzymes activity. Resealed erythrocytes overcome the above problem and act as a "circulating bioreactors" in which substrates enter, interact with enzymes, and generate products (Ihler et al., 1975, Adriaenssens et al., 1976, Zimmermann et al., 1976, Zimmermann, 1983, Alpar & Lewis, 1985, Fiorelli et al., 1987, Magnani et al., 1989, Jaitely et al., 1996) In addition, it can also accumulate enzymes in RES after hemolysis (Iher, 1973, Deloach & Ihler, 1977, Lewis & Alpar, 1984).

Following enzymes are being uses with resealed erythrocytes:

- β-glucoserebrosidase for the treatment of Gaucher's disease (Beutler et al., 1977)
- Aasparginase for the treatment of pediatric neoplasms.
- β -aminolevulinate dehydrogenase (ALA-D) against lead poisoning

Despite these, urease (Zimmermann et al., 1976), galactose-1-phosphate uridyl-transferase (Harris, 1977), uricase (Ihler et al., 1975), and acetaldehyde dehydrogenase (Tan, 1977) has also been reported to use in resealed erythrocytes.

Oxygen Delivery to Tissues

Hemoglobin is the red pigmented protein responsible for the oxygen transporting capacity of erythrocytes. Under normal condition the major fraction of oxygenated hemoglobin is recirculated with venous blood to the lungs. Use of this bound fraction has been reported in oxygen deficiency. 2,3-Diphosphoglycerate (2,3-DPG) a side glycolysis product through Rapoport-Luebering cycle has been reported to changes the binding affinity of hemoglobin for oxygen. Affinity of 2,3-DPG towards oxygen has been reported to much higher than that of hemoglobin (Guyton & Hall, 1996). Despite these 2,3-DPG, inositol hexophosphate (IHP) is also one of the modulator of binding affinity of hemoglobin for oxygen. IHP or 2,3-DPG loaded erythrocytes could beneficial under high altitude conditions, patient having reduced number of alveoli, reduction in oxygen carrying capacity, mutation or chemical modification associated

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

with decrease in oxygen affinity for hemoglobin, oxygen-delivery capacity of stored blood and ischemia of myocardium, brain, or other tissues (Zimmermann, 1983, Villareal et al., 1987, Teisseire et al., 1987, Baron et al., 1987).

CURRENT NOVEL APPROACHES

Microinjection

Macromolecules such as DNA, RNA, and proteins are currently exploited in every field of therapeutics and research. Various models are present today; however, erythrocytes lacking of complex cellular components (e.g., nucleus) with relatively simple structure make them good candidates for the entrapment of macromolecules (Furusawa et al., 1974). In this microinjection methods, erythrocytes are used as microsyringes for injection of biomolecule or drugs to the host cells (Zimmermann, 1983). Above process takes place *in vitro* as culturing host eukaryotic cells coated with fusogenic agent (Sendai virus, or its glycoproteins or polyethylene glycol) are suspended with biomolecule or drugs loaded erythrocytes in an isotonic medium (Furusawa et al., 1974, Zimmermann, 1983, Schlegel & McEvoy, 1987). The microinjection process has been performed for micoroinject of DNA fragments (Lewis & Alpar, 1984), ferritin, latex particles, arginase (Kruse et al., 1981, Kruse et al., 1987), bovine and human serum albumin, and thymidine kinase (Wille & Willecke, 1976) to various cultured eukaryotic cells.

Erythrosomes

It is engineered vesicular systems which are chemically cross-linked to erythrocytes by modified reverse-phase evaporation technique. Erythrosomes has been hypothesized for macromolecular drugs encapsulation in erythrocytes (Cuppoletti et al., 1981, Jung, 1987, Vyas &. Dixit, 1999).

Nanoerythrosomes

Extrusion of erythrocyte ghosts has been associated with the production of small vesicles (diameter 100 nm) known as nanoerythrosomes. Specially used for daunorubicin which was found to with covalently conjugated with the help of gluteraldehyde spacer to nanoerythrosomes. Covalently conjugated daunorubicin to nanoerythrosomes has been reported to more active than free daunorubicin alone in *in vtiro* model as well as *in vivo* model (Moorjani et al., 1996, Lejeune et al., 1997).

IN VITRO STORAGE OF RESEALED ERYTHROCYTES

Resealed erythrocytes activity also depends to a greater extent on the medium and duration of their *in vitro* storage. Drug encapsulated erythrocytes and maintaining their life with drug content can be regulated by using appropriate *in vitro* storage methods. Hank's balanced salt solution (Lewis & Alpar, 1984, Lewis, 1984, Lewis & Desai, 1987, Jaitely et al., 1996, Hamidi et al., 2001,) and acid–citrate–dextrose media are has been reported to frequently uses as storage media for resealed erythrocytes (Zimmermann, 1983). Erythrocytes with drug remain viable regarding the physiological and carrier properties when

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

stored in above media for at least 2 weeks at 4ºC (Lewis & Desai, 1987). Cells circulation life span was found to improve after addition of the purine nucleosides (Alpar & Irwin, 1987, Lewis & Desai, 1987) or calcium-chelating agents (Alpar & Irwin, 1987). Membrane stabilizing agents (dimethyl,3,3-di-thio-bispropionamide, dimethyl sulfoxide, toluene-2-4- diisocyanate, gluteraldehyde) exposure to drug loaded cells followed by sintered glass filtration and lyophilization has been reported to significantly increase the resealed erythrocytes stability upon storage (Jain & Jain, 1997, Talwar & Jain, 1992a, Talwar & Jain, 1992b, Bhaskaran & Dhir, 1995). Lyophilized powder has been found to stable without any detectable changes for at least one month. The major drawback of this method is the lower circulation life span of resealed erythrocytes. Despite this method encapsulation of a prodrug (Talwar & Jain, 1992a), high glycerol freezing technique (Zanella et al., 1987, Fiorelli et al., 1987), and reversible immobilization in alginate or gelatin gels (Zimmermann, 1983, Lewis & Alpar, 1984, Lewis, 1984) are other progressive methods use to perform for increasing storage stability of resealed erythrocytes.

CONCLUSION

Resealed erythrocytes are promising for precise and safe drugs delivery. In presence scenario methodologies applied for drugs encapsulation and preparation of resealed erythrocytes need some optimization for making it usual drugs carriers. The concept of resealed erythrocytes can be also extended to increase the bioavailable of various molecule including biopharmaceuticals. Above chapter prompt us to conclude that resealed erythrocytes is an effective carriers to deliver the various drugs and bioactive molecule, and much remains to be explored regarding the potential of resealed erythrocytes.

Chapter 19
Sedation and Analgesia

Jordan Brand
San Francisco VA Medical Center, USA & University of California – San Francisco, USA

ABSTRACT

Patients in the cardiothoracic intensive care unit (CTICU) are subject to numerous physical and mental stresses. While most of these cannot be completely eliminated, intensivists have many tools in their armamentarium to alleviate patients' pain and suffering. This chapter will consider the importance of analgesia and sedation in the CTICU and the relevant consequences of over- or under-treatment. We will examine the tools available for monitoring and titrating analgesia and sedation in critically ill patients. The major classes of medications available will be reviewed, with particular attention to their clinical effects, metabolism and excretion, and hemodynamic characteristics. Lastly, experimental evidence will be assessed regarding the best strategies for treatment of pain and agitation in the CTICU, including use of non-pharmacologic adjuvants.

INTRODUCTION AND BACKGROUND

The experience of being in the intensive care unit (ICU) can present many stresses, both physical and psychological. Up to 77% of patients in the ICU suffer pain (Van Gulik et al., 2010) and 15% may go on to develop posttraumatic stress disorder (PTSD) (Girard et al., 2007). Many of the daily necessities of critical care, such as endotracheal intubation, mechanical ventilation, placement and maintenance of lines, and use of restraints, cause pain and distress, to say nothing of the discomfort that can come from surgical wounds and interventions. Through the use of judicious analgesia and sedation, intensivists are able to attenuate these stresses.

Inadequate sedation and analgesia have been associated with elevated catabolism, immunosuppression, hypercoagulability, and sympathetic overactivity (Consales, Chelazzi, Rinaldi, & De Gaudio, 2006). These effects are deleterious for patients in the perioperative period, even more so for those with cardiovascular disease, in whom they may precipitate arrhythmias and myocardial ischemia. Conversely, heavy sedation can lead to more time spent undergoing mechanical ventilation, longer ICU stays, and increased needs for imaging and other studies to evaluate patients' neurologic status, all of which put patients at risk for complications (Kress, Pohlman, O'Connor, & Hall, 2000).

As a result, it is critical to maintain a balance between providing adequate analgesia and sedation and limiting side effects. Several principles seem to logically follow from this:

1) Selection of medications should be tailored to the individual patient and situation.
2) There is growing evidence that the medications used in the ICU may impact long-term outcomes, so current best evidence and guidelines should be followed.
3) Titration of medications should be based on reproducible, validated measurements, and frequent reassessment is mandatory.
4) Use of non-pharmacologic measures should be optimized to reduce the need for medication.

While analgesics and sedatives can produce adverse effects, they have the potential to relieve suffering and improve patients' outcomes and quality of life. This is as true in the cardiothoracic population as in any other group of critically ill individuals. The goals of this chapter will be to discuss the assessment of pain and mental state in the cardiothoracic ICU (CTICU), review various options for providing analgesia and sedation, and provide a framework for evaluating the evidence and selecting the most appropriate agents and strategies for individual patients.

ASSESSMENT OF LEVEL OF ANALGESIA/SEDATION

Regardless of the sedative used, it is critical to monitor level of analgesia and sedation closely so as to avoid over- or under-dosing. For pain intensity, the gold standard is the patient's subjective report; when this is not available, clinicians are forced to estimate pain levels via observation of behavior. One simple and well-validated tool for measuring self-reported pain intensity is the Visual Analog Scale (VAS), which plots relative pain intensity along a line. An alternative is the Numerical Reporting Scale (NRS), which adds numerical increments to the VAS (Hawker, Mian, Kendzerska, & French, 2011).

When patients cannot report their pain intensity due to altered mental status or inability to communicate, an observational scale may be used, such as the Behavioral Pain Scale (BPS). The BPS relies on visual indicators of discomfort, assessed by a healthcare practitioner, and ranks pain intensity on a scale of 3 to 12 (see Table 1). This scale has been shown to have good reliability and validity in a broad population of critically ill patients (Cade, 2008). However, the BPS relies partially on increases in patient movement to indicate greater pain intensity, and some studies suggest that increased pain intensity is correlated with *decreased* movement, calling its results into question (Blenkham, Faughnan, & Morgan,

Table 1. The behavioral pain scale

Item	1 Point	2 Points	3 Points	4 Points
Facial Expression	Relaxed	Partially tightened	Fully tightened	Grimacing
Upper Limb Movements	No movement	Partially bent	Fully bent with finger extension	Permanently retracted
Compliance with Mechanical Ventilation	Tolerating movement	Coughing but tolerating ventilation for most of time	Fighting ventilator	Unable to control ventilation

(Adapted from Payen et al., 2001)

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

2002). When the BPS has been compared to self-reported measurements, it indeed has been found to underestimate pain intensity, especially at higher levels of discomfort. Therefore, it is appropriate to utilize patients' self-report of pain intensity whenever feasible (Ahlers et al., 2007).

Similarly, quantitative tests of level of sedation provide for more uniform assessment and trending of data over time. One of the most commonly used sedation assessment tools is the Ramsay Sedation Scale, which uses a series of numbers to identify levels of arousal ranging from severe agitation to coma (See Table 2). It exhibits good inter-rater reliability and has been used for many years, making it familiar to clinicians (Sessler, Grap, & Ramsay, 2009). The Ramsay scale, however, has several problems, one of which being that patients may fall under more than one of its levels at the same time if, for example, they are suffering from a mixed form of delirium. Additionally, the scale only has one score corresponding to agitation.

Another tool to assess sedation is the Richmond Agitation-Sedation Scale, or RASS (See Table 3). The RASS has the advantage of having a full range of responses quantifying both sedation and agitation, and has been found to have excellent inter-rater reliability (Sessler et al., 2002).

Table 2. The Ramsay Sedation Scale

Score	Definition
1	Anxious and agitated or restless or both
2	Cooperative, oriented, and tranquil
3	Responds to commands only
4	Brisk response to a light glabellar tap or loud auditory stimulus
5	Sluggish response to a light glabellar tap or loud auditory stimulus
6	No response to a light glabellar tap or loud auditory stimulus

(Adapted from Sessler, Grap, & Ramsay, 2009)

Table 3. The Richmond Agitation-Sedation Scale

Score	Term	Description
+4	Combative	Violent, immediate danger to staff
+3	Very Agitated	Pulls on or removes tube(s) or catheter(s) or has aggressive behavior towards staff
+2	Agitated	Frequent nonpurposeful movement or patient-ventilator dyssynchrony
+1	Restless	Anxious or apprehensive but movements not aggressive or vigorous
0	Alert and Calm	
-1	Drowsy	Not fully alert, but has sustained (more than 10 s) awakening, with eye contact, to voice
-2	Light Sedation	Briefly (less than 10 s) awakens with eye contact to voice
-3	Moderate Sedation	Any movement (but no eye contact) to voice
-4	Deep Sedation	No response to voice, but any movement to physical stimulation
-5	Unarousable	No response to voice or physical stimulation

(Adapted from Sessler, Grap, & Ramsay, 2009)

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Since delirium is common in the ICU, it behooves clinicians to have an objective way of evaluating it and grading its severity. One of the most utilized tools for doing this is the Confusion Assessment Method for the Intensive Care Unit (CAM-ICU) (See Table 4). This instrument was the first developed to monitor for delirium in ICU patients receiving mechanical ventilation; it can also be used in patients who are not receiving ventilator support (Ely et al., 2001).

Unfortunately, visual observation and neurologic examination are not always adequate for evaluating a patient's level of sedation, especially if he or she is minimally responsive. An alternative method is to use physiologic variables, such as processed electroencephalography (EEG). The BIS monitor, a popular device used to assess depth of anesthesia in the operating room, analyzes the frequency spectrum of the EEG and produces an indexed value representing the patient's level of sedation. This device can assess states ranging from full alertness to deep anesthesia (Riker & Fraser, 2001). Unfortunately, the EEG signal can be degraded by artifact, especially in patients who are moving, but it can provide valuable information in those who appear to be deeply sedated or are receiving neuromuscular blockers.

ANALGESICS

Almost all patients in the CTICU will suffer from some degree of pain, whether it is due to surgical trauma or other sources. Risk factors for more severe postoperative pain include younger age, duration of surgery, and location of surgery; the thoracotomy incision is generally more painful than the median sternotomy

Table 4. Confusion assessment method for the intensive care unit (CAM-ICU)

Features and Descriptions	Absent	Present
1. Acute Onset or Fluctuating Course		
C. Is there evidence of an acute change in mental status from baseline? D. Did the abnormal behavior fluctuate during the past 24 hours as evidenced by fluctuations in the RASS or Glasgow Coma Scales?		
2. Inattention		
Did the patient have difficulty focusing attention (score of less than 8 on the visual or auditory components of the Attention Screening Examination)?		
3. Disorganized thinking		
Is there evidence of disorganized or incoherent thinking as evidenced by incorrect answers to 3 or more of the 4 questions and inability to follow commands? Questions: 5. Will a stone float on water? 6. Are there fish in the sea? 7. Does 1 pound weigh more than 2 pounds? 8. Can you use a hammer to pound a nail? Commands: 4. Are you having unclear thinking? 5. Hold up this many fingers. 6. Now do the same thing with the other hand.		
4. Altered level of consciousness		
Is the patient's level of consciousness anything other than alert, such as being vigilant or lethargic or in a stupor or coma?		
Overall CAM-ICU Assessment: Features 1 and 2 and either Feature 3 or 4		

(Adapted from Ely et al., 2001)

(Cogan, 2010). Analgesia is crucial for these patients for multiple reasons. Inadequate analgesia may result in hypertension, tachycardia, and other hemodynamic changes, increasing the risk of myocardial ischemia, arrhythmias, and bleeding (Rouby et al., 1981). It may also predispose patients to atelectasis and respiratory compromise. Likewise, while many analgesics have some sedative properties, it is difficult to achieve adequate sedation without sufficient analgesia. Therefore, it is prudent to ensure that a patient's pain is treated before adding additional sedatives to their regimen. It has also been suggested that inadequate analgesia may increase the risk of delirium, especially in the elderly (Morrison, 2003).

Numerous approaches to analgesia are available for CT surgery patients. Multiple approaches can be used simultaneously as "multimodal analgesia," potentially improving pain control and decreasing side effects. This strategy has been shown to be effective in both cardiac (Rafiq et al., 2014) and thoracic (Bottiger, Esper, & Stafford-Smith, 2014) surgical populations. The medications and techniques used to achieve pain control depend somewhat on the individual patient and surgery. In many cases, however, standardized perioperative analgesic algorithms can be developed to improve the efficacy and efficiency of perioperative analgesia.

OPIOIDS

Parenteral opioids are the mainstay of pain management for CT surgery patients. This approach offers flexibility, relative hemodynamic stability, and a manageable side effect profile. Some commonly used opioids include fentanyl, morphine, and hydromorphone (See Table 5). All opioids act through stimulation of opioid receptors in the central nervous system (CNS), which belong to the G-protein-coupled receptor family, causing multiple physiologic effects, including reliable dose-dependent analgesia. Other effects include miosis, pruritus, sedation, decreased gastrointestinal motility, and suppression of hypercarbic respiratory drive. Opioid analgesia appears to be mediated primarily by inhibition of pain signals via pathways involving the midbrain, medulla, and dorsal root ganglion of the spinal cord, as well as possibly at other sites (Basbaum & Fields, 2004). The most significant receptor subtype mediating analgesia for the majority of opioids is the μ-opioid receptor (Jordan & Devi, 1998).

The most severe toxicity of opioids is respiratory depression due to inhibition of the central response to hypercarbia. Up to 1% of patients receiving postoperative opioid analgesia may experience respiratory depression (Shapiro et al., 2005), and such events can result not just in morbidity and mortality, but also increased hospital length-of-stay and costs (Oderda et al., 2007). Patients receiving potent IV opioids

Table 5. Comparison of typical opioids used in the CTICU

Drug	Typical IV Bolus Dose	Onset	Duration of Action After Bolus	Metabolism	Active Metabolites?
Fentanyl	25-100 mcg	1-4 min	30-60 min	Hepatic	No
Morphine	2-5 mg	5-10 min	2-6 hrs	Hepatic	Yes
Hydromorphone	0.2-1 mg	5-10 min	3-5 hrs	Hepatic	No
Sufentanil	5-50 mcg	1-4 min	30-60 min	Hepatic	No
Remifentanil	0.5-1 mcg/kg	1 min	5-10 min	Plasma esterases	No

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

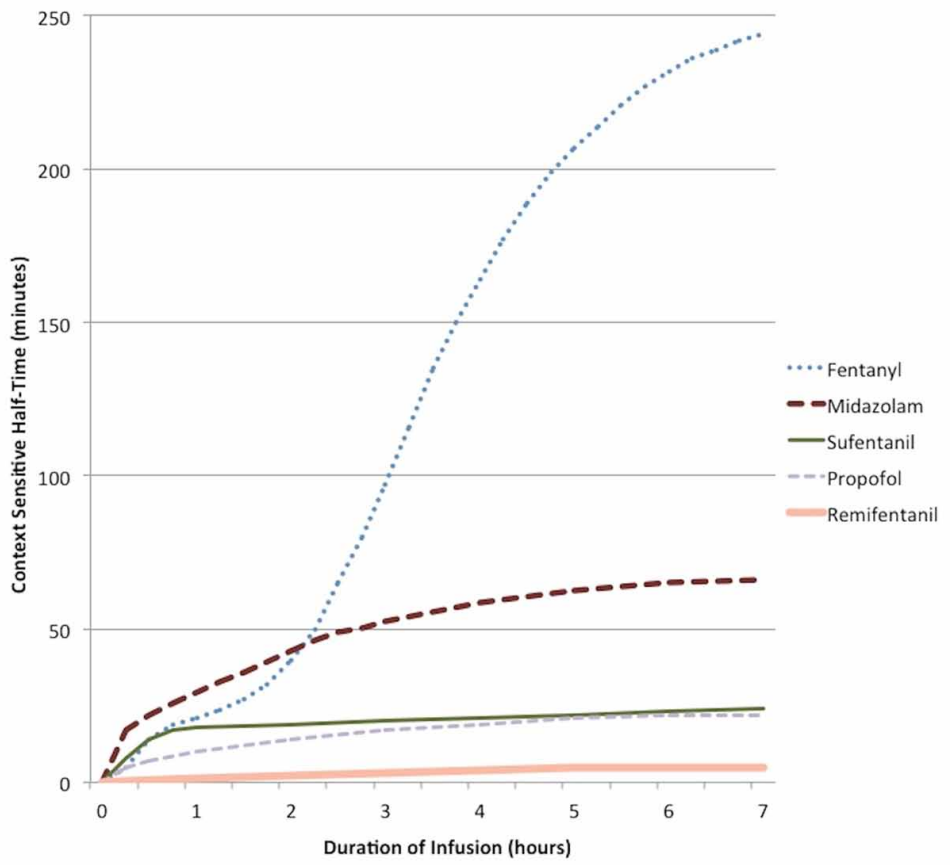
should be monitored closely for hypoxia and hypercarbia. The use of end-tidal CO2 (EtCO2) monitoring, "smart" infusion devices, and other interventions may mitigate such risks (Maddox, Oglesby, Williams, Fields, & Danello, 2006). Other opioid-related adverse effects include nausea, vomiting, pruritus, and constipation. Opioid administration is associated with development of tolerance and may necessitate dose escalation.

Some of these side effects can be treated with opioid antagonists. Naloxone, which is a non-selective opioid receptor antagonist, is useful in the management of respiratory depression. However, naloxone itself can induce rebound pain, tachycardia, and hypertension. It should therefore be administered in smaller, titrated doses (20-40 micrograms at a time) when the situation is less emergent. As an additional consideration, naloxone has an elimination half-life of roughly 30 minutes, so it may need to be redosed when used to counteract the effects of a long-acting opioid. Several new agents are being investigated to treat opioid-induced respiratory depression, such as serotonin agonists, ampakines, and minocycline, all of which help maintain respiratory drive via pathways that bypass opioid receptors (Dahan, Aarts, & Smith, 2010). While these agents are still being tested experimentally, they have the potential advantage of treating opioids' side effects without counteracting their analgesic effects. Nausea and vomiting may respond to 5HT-3 receptor antagonists and other antiemetics, and methylnaltrexone, a peripheral opioid antagonist, is useful in ameliorating adverse effects on gastrointestinal motility.

Hemodynamically, most opioids induce some degree of bradycardia and hypotension. This occurs due to a decrease in sympathetic and an increase in parasympathetic autonomic tone, mediated by the central nervous system (CNS). These changes can be potentiated by the use of other medications, like beta-blockers, that cause similar effects. Direct effects on cardiac contractility are variable between opioids but are probably relatively minor compared to other classes of sedative medications (Fukuda, 2010). Opioids may also exert protective effects against myocardial ischemia, although the clinical significance of this fact is unclear (Schultz, Hsu, & Gross, 1996).

Fentanyl

Fentanyl is a synthetic opioid that is highly lipophilic and has a relatively fast onset of action. It diffuses quickly in and out of the CNS. Fentanyl may be administered by bolus and can also be given via infusion at doses ranging from 25 to 200 mcg/hr. It is metabolized in the liver by CYP3A4 enzymes and has no active metabolites.



Although it has an elimination half-life of several hours, fentanyl's clinical effect is usually terminated via redistribution out of the CNS into other tissues, such as muscle and adipose tissue, rather than elimination. Therefore, it appears to have a shorter duration of action than would be expected based on its metabolism and elimination. However, fentanyl is notable in that its context-sensitive half-time increases substantially after 120-180 minutes of continuous infusion. At this point, non-CNS tissue compartments start to become saturated, and the drug's clinical effects will last much longer after discontinuing an infusion. Dosage may need to be adjusted accordingly (Hill, 2004). (See Figure 1)

Morphine

Morphine is the least lipophilic of the commonly used opioids. While morphine actually has a shorter elimination half-life than fentanyl, it diffuses more slowly out of the CNS once it has entered and thus appears to have a longer duration of action than fentanyl and other highly lipophilic opioids (Hug, Murphy,

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Context-sensitive half-times of common analgesics/sedatives
(Adapted From Hughes, Glass, & Jacobs, 1992, and Egan et al., 1993)

Rigel, & Olson, 1981). Morphine can cause prominent histamine release, particularly if given as a rapid bolus. Additionally, it is conjugated in the liver to morphine-3-glucuronide, which has neuroexcitatory properties, and morphine-6-glucuronide, which has properties similar to morphine itself (Christrup, 1997). Because these metabolites are partially excreted by the kidneys, repeated doses or prolonged infusion of morphine may have unpredictable effects in patients with renal insufficiency.

Hydromorphone

Hydromorphone, which has pharmacokinetic and dynamic properties similar to morphine, has a slightly more favorable side-effect profile. It appears to cause less histamine release and may have a more consistent duration of action; some pain specialists feel it may cause less nausea and constipation, although studies on this subject have produced mixed results (Felden et al., 2011; Wirz, Wartenberg, & Nadstawek, 2008). IV hydromorphone is roughly seven times as potent as IV morphine. Both morphine and hydromorphone are available in oral form although hydromorphone is less orally bioavailable than morphine.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Sufentanil

Sufentanil is a synthetic opioid that has similar properties to fentanyl but is 5-10 times more potent. It is commonly used intraoperatively during cardiac surgery and provides similar hemodynamic control to fentanyl (Thomson, Harding, & Hudson, 2000). However, sufentanil exhibits much less increase in context sensitive half-time than fentanyl with longer infusions (see Figure 2). Some studies have found that sufentanil consequently facilitates earlier emergence and more rapid extubation than other opioids, particularly when high doses of opioids are administered as adjuncts to general anesthesia (Sanford, Smith, Dec-Silver, & Harrison, 1986).

Remifentanil

Another potent and very short-acting synthetic opioid is remifentanil, which is particularly notable because it is metabolized by nonspecific plasma esterases instead of by hepatic enzymes. Therefore, remifentanil's duration of action is unaffected by hepatic or renal dysfunction. Its context sensitive half-time is the shortest of the opioids and is affected minimally by duration of infusion (see Figure 2). As a result, remifentanil is an ideal choice when patients may need frequent neurologic assessments or must undergo procedures that are short but painful (Ruggeri et al., 2011). Because remifentanil is so potent, it can cause pronounced bradycardia and hypotension, especially when bolused; it can instead be administered by infusion at doses of 0.05-2 mcg/kg/min. It can also easily induce apnea and should be dosed carefully when patients are breathing spontaneously.

While remifentanil has several practical advantages, it can also have adverse effects. When used intraoperatively, remifentanil can induce rapid opioid tolerance, which may result in higher postoperative narcotic requirements (Guignard et al., 2000) and even hyperalgesia (Angst, Koppert, Pahl, Clarke, & Schmelz, 2003). These effects may be particularly problematic in patients with chronic pain disorders and remifentanil should be used judiciously in this population.

KETAMINE

Ketamine is a phencyclidine derivative that can act as both an analgesic and a sedative/anesthetic. It acts primarily via antagonism of the *N*-methyl-D-aspartate (NMDA) receptor, but likely has numerous other targets, such as opioid receptors, monoaminergic receptors, muscarinic receptors, and ion channels (Hirota & Lambert, 1996). Higher doses of ketamine (1-2 mg/kg) will produce sedation and a "dissociative" state, which is characterized by an appearance of alertness although the patient will generally be amnestic and minimally responsive. Dense analgesia is also a prominent feature of this state. Ketamine has a fast onset (1-5 minutes after a bolus). It can also be administered by infusion as a sedative with doses in the range of 10-30 mcg/kg/min.

At lower, subanesthetic doses (4-5 mcg/kg/min), ketamine has relatively little sedative effect, but acts as an analgesic. A Cochrane review found that low-dose ketamine given postoperatively decreases opioid requirements and leads to less nausea and vomiting without substantial side effects (Bell, Dahl, Moore, & Kalso, 2006). It also seems to attenuate acute opioid tolerance (Kissin, Bright, & Bradley, 2000). This effect is particularly helpful in patients with high postoperative opioid requirements, either due to chronic opioid use or the magnitude of surgery itself.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Ketamine is metabolized in the liver, producing norketamine, a less potent active metabolite. Its clinical effect is terminated by redistribution, and it has an elimination half-life of 2 to 3 hours. Because of its active metabolite, the duration of action of ketamine may be prolonged in patients with liver or renal dysfunction or those who receive multiple doses.

Ketamine's major cardiovascular effect is stimulation of central sympathetic outflow. This results in increased heart rate, blood pressure, and cardiac output, as well as potentially increased pulmonary arterial pressures (Tweed, Minuck, & Mymin, 1972). These effects seem to be more prominent after bolus dosing than with infusions, and can be attenuated by premedication with benzodiazepines or other sedatives (Jackson, Dhadphale, & Callaghan, 1978). In some cases, this sympathetic stimulation may be beneficial, preserving hemodynamic stability. However, in critically ill patients, ketamine may occasionally cause hypotension, presumably due to its direct myocardial depressive effects, which are typically masked by increased sympathetic tone (Schwartz & Horwitz, 1975). Because of these diverse hemodynamic effects, use of ketamine in the CT surgery population requires careful monitoring.

An additional benefit of ketamine compared to opioids is its relatively benign respiratory profile. It has minimal effect on respiratory drive and airway reflexes, even with higher doses (Soliman, Brinale, & Kuster, 1975; Lanning & Harmel, 1975), and can act as a bronchodilator. However, ketamine can also cause an increase in salivation. Antisialogogues (such as glycopyrrolate) can be administered to avoid this effect.

Ketamine also has prominent neurologic effects. While it is sometimes cited as a proconvulsant and can induce epileptiform activity in deeper brain structures, it does not appear to induce generalized seizures (Myslobodsky, Golovchinsky, & Mintz, 1981). Likewise, while it was long thought to increase intracranial pressure (ICP), ketamine likely maintains or decreases ICP as long as ventilation is controlled and PaCO2 does not rise substantially (Mayberg, Lam, Matta, Domino, & Winn, 1995). Most prominently, ketamine can cause emergence delirium as its effect is wearing off. This state is characterized by hallucinations, vivid dreams, and confusion. Emergence delirium may occur in up to 30% of patients receiving higher-dose ketamine for anesthesia; risk factors include age > 15 years, female gender, total doses greater than 2 mg/kg, rapid administration, and a history of personality issues or frequent dreaming (White, Way, & Trevor, 1982). Premedication with GABA-ergic agents, particularly benzodiazepines, seems to lessen this effect, with midazolam being the preferred medication (Cartwright & Pingel, 2007). Interestingly, it seems that despite this effect, ketamine may not precipitate long-lasting delirium. In fact, low-dose ketamine administered intraoperatively may reduce delirium after cardiopulmonary bypass (CPB) via anti-inflammatory effects (Hudetz et al., 2009).

ADJUVANTS

Numerous other non-sedative medications may be used to augment the analgesic effect of opioids and ketamine. Ideally, this enables the reduction of a patient's analgesic dosage and thus reduces adverse effects. Multiple agents may be used together as part of a multimodal pain management strategy.

Non-Steroidal Anti-Inflammatory Drugs (NSAIDs)

NSAIDS act via inhibition of cyclooxygenase-1 (COX-1) and cyclooxygenase-2 (COX-2). These enzymes participate in the formation of mediators such as prostacyclin, prostaglandins, and thromboxane, causing fever, inflammation, and pain. While inflammation often serves an adaptive purpose, it can be

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

counterproductive if it increases post-surgical pain and impedes recovery. Numerous NSAIDs have been used in the management of postoperative pain, such as diclofenac and ketorolac. Ketorolac is available in intravenous form, facilitating perioperative use.

NSAIDs exert potent analgesic and anti-inflammatory effects. They improve pain control after sternotomy and allow for decreases in opioid dosage, resulting in decreased rates of prolonged intubation, desaturation, and gastrointestinal side effects when compared to therapy with opioids alone (Fayaz et al., 2004). As an additional (and perhaps unintentional) benefit, use of ketorolac has been suggested to improve graft patency after coronary bypass grafting and possibly improve postoperative survival (Engoren, Hadaway, Schwann, & Habib, 2011). Ketorolac has been shown to have similar efficacy in relieving post-thoracotomy pain, resulting in improved respiratory parameters (Carretta et al., 1996). Thoracic surgical patients frequently have limited pulmonary reserve and may thus be unable to tolerate the respiratory depression that can result from high doses of systemic opioids.

Unfortunately, NSAIDs do have adverse effects that must be taken into account. All NSAIDs can induce some decrease in renal function, potentially resulting in fluid retention, hyperkalemia, and other abnormalities. These effects are particularly likely in individuals whose renal function is already impaired and are dependent on prostaglandin production to maintain renal blood flow and glomerular filtration rate (GFR). Interstitial nephritis is also possible but rare. Most of the decrease in GFR due to NSAIDs is reversible when the medication is discontinued (Whelton & Hamilton, 1991).

Because they decrease production of prostaglandins, NSAIDs can induce systemic hypertension. They are also known to cause gastropathy and upper gastrointestinal bleeding, due to decreased levels of prostaglandin-induced mucus and bicarbonate production. Older patients, those with a history of gastritis or peptic ulcers, and those taking steroids or anticoagulants are at higher risk (Hawkey, 2000). NSAIDs inhibit platelet function and may exacerbate postoperative bleeding, especially when combined with other antiplatelet agents or anticoagulants.

COX-2-specific NSAIDs may have some theoretical advantages over agents that inhibit both COX-1 and COX-2. COX-2 inhibitors induce lower rates of bleeding and gastropathy, which would seem to make them advantageous for perioperative use. However, concerns have been raised about whether these medications predispose patients to adverse cardiovascular events. (Some similar concerns exist for nonspecific NSAIDs as well.) In a study evaluating the use of valdecoxib and parecoxib, two COX-2 inhibitors, after coronary artery bypass grafting (CABG), it was found that use of these drugs vs. placebo resulted in higher rates of adverse cardiovascular events, such as myocardial infarction, stroke, and pulmonary embolism (Nussmeier et al., 2005). Such concerns have resulted in valdecoxib being withdrawn from the market, although parecoxib, its prodrug, remains available in some countries. In the aggregate, it appears that NSAIDs have a useful role in perioperative pain control, but should be used carefully, with close monitoring for side effects.

Acetaminophen

Acetaminophen is one of the most widely used pain medications in the world due to its perceived efficacy and benign side effect profile. Acetaminophen is typically administered orally or rectally; an intravenous formation is also available for perioperative use. It produces analgesic and antipyretic effects. The mechanisms of acetaminophen's effects remain poorly understood. While it has some inhibitory effects on the COX enzymes and inhibits prostacyclin production, it does not seem to strongly affect thromboxane, and thus has minimal effect on platelets (Trettin et al., 2014). It has been proposed that acetaminophen

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

may act via activation of central serotonergic pathways and stimulation of the endocannabinoid system, as its effect seems more dependent on CNS concentration than systemic levels (Anderson, 2008).

While acetaminophen itself is a relatively weak analgesic, it exhibits synergistic effects with opioids and other analgesics. Administration of acetaminophen after major surgery reduces morphine consumption in a similar fashion as that found with NSAIDs. However, NSAIDs seem to have more benefit in reducing gastrointestinal side effects and may result in slightly less sedation (McDaid et al., 2010).

While acetaminophen confers minimal risk of postoperative bleeding or gastropathy, it does have notable adverse effects, the most significant of which is hepatotoxicity. Acetaminophen is metabolized by cytochrome enzymes in the liver to a reactive metabolite, *N*-acetyl-*p*-benzoquinone imine, which is usually bound and detoxified by glutathione. However, when large doses are given, glutathione is depleted and the metabolite binds to proteins. This results in oxidative stress, inflammation, and hepatic necrosis (Hinson, Roberts, & James, 2010). Certain patients, particularly those who habitually consume alcohol, are at higher risk, and total daily dosage may need to be limited. Theoretically, intravenous administration may be beneficial in these patients because it avoids first-pass metabolism in the liver.

REGIONAL ANALGESIA

While it requires some additional expertise, the use of regional techniques to provide analgesia after CT surgery has grown substantially. Use of regional analgesia can provide pain relief while avoiding some of the side effects of systemic medications.

Epidural Analgesia

Epidural analgesia involves the placement of a small flexible catheter in the space between the ligamentum flavum and the dura mater in the spinal canal. Medications, usually local anesthetics, opioids, or both in combination, are infused through the catheter. Pain is reduced via multiple mechanisms: local anesthetics block sodium channels on the spinal nerves in the paravertebral and intradural spaces, producing segmental analgesia that is proportional to the volume of medication administered (Bromage, 1975). Epidural opioids, in contrast, act on receptors both within the spinal cord and supraspinally. Supraspinal mechanisms seem to become more important when opioids are administered by infusion rather than bolus (George, 2006).

Thoracic epidural analgesia (TEA) has gained wide acceptance as the analgesic technique of choice for thoracotomy and, at some centers, video-assisted thoracic surgery (VATS). Typically, an epidural catheter is inserted in the mid-thoracic region, and a continuous infusion of medication is delivered, in some cases with additional bolus doses on demand via patient-controlled analgesia. When compared to systemic analgesics, TEA has been shown to reduce pain scores, time to extubation, ICU length of stay, consumption of rescue medication, and rates of postoperative arrhythmias, and seems to improve pulmonary measures such as functional residual capacity (FRC) (Guay, 2006). Other reviews have suggested that epidural analgesia reduces rates of pulmonary complications such as atelectasis and pneumonia (Ballantyne et al., 1998; Popping, Elia, Marret, Remy, & Tramer, 2008). On the other hand, these studies do not show an improvement in mortality with epidural analgesia. As an added benefit, some authors have concluded that use of TEA is associated with less chronic postthoracotomy pain, particularly if the epidural infusion is initiated preoperatively (Senturk et al., 2002). TEA can also be utilized in VATS, and

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

has been shown to provide better analgesia than systemic analgesics (Yoshioka et al., 2006). However, it is not clear that this leads to fewer pulmonary complications after thoracoscopic surgery.

TEA has also been shown to have a role after cardiac surgery. Many of the same benefits posited in thoracic and abdominal surgery have been found in post-cardiac surgical patients. Several meta-analyses have found lower rates of arrhythmias and respiratory complications in cardiac patients who received epidural analgesia, as well as faster time to tracheal extubation (Liu, Block, & Wu, 2004; Svircevic et al., 2013). Notably, as with thoracic surgery, these investigators did not find any significant effect of TEA on rates of myocardial ischemia or mortality. The use of TEA in cardiac surgery has been limited by concerns over the risk of epidural hematoma, particularly when CPB requiring full heparinization is utilized. The risk of TEA-associated epidural hematoma after cardiac surgery has recently been estimated at roughly one in 5500, which is similar to the risk in the non-cardiac surgical population of one in 6600 (Hemmerling, Cyr, & Terrasini, 2013).

Besides the risk of hematoma formation, epidural analgesia has some other notable side effects. Epidural opioids can potentially cause any of the side effects of systemic opioids, although this is theoretically ameliorated by the lower total doses required. In particular, pruritus and urinary retention can be particularly severe (Ladak et al., 2009). Use of epidural local anesthetics substantially improves pain relief compared to epidural opioids alone and causes some degree of sympathectomy; while this may be beneficial in decreasing arrhythmias and myocardial oxygen demand, it can also lead to hypotension (Joshi, 2008). Hypotension may require reduction or temporary discontinuation of the epidural infusion.

Intrathecal Opioids

In some cases, intrathecal administration of opioids may be preferable to the epidural route. Because intrathecal injection is performed with a smaller needle than that used to place an epidural, it is theorized that the rate of spinal hematoma is lower with this technique. Additionally, because no catheter is left in place, there is no concern for how to accomplish catheter removal in patients who become coagulopathic or thrombocytopenic postoperatively or those who require postop anticoagulation. The rate of hematoma formation does seem to be somewhat lower with intrathecal injection, but such complications are extremely rare and thus rates vary widely across studies and between patient populations (Moen, Dahlgren, & Irestedt, 2004; Emazabel-Yunta et al., 2008).

Intrathecal opioids provide postop analgesia that is at least equivalent to that provided by intravenous narcotics. In cardiac surgery, they seem to reduce postoperative opioid requirements although they may also delay time to tracheal extubation (Chaney, Furry, Fluder, & Slogoff, 1997; Alhashemi, Sharpe, Harris, Sherman, & Boyd, 2000). Other data suggests an improvement in postoperative spirometric parameters and no change in time to extubation (Jacobsohn et al., 2005), but this has not been shown to translate into a decrease in complications, morbidity, or mortality. Studies examining patients undergoing thoracotomy also show decreased postop opioid requirements and improved respiratory function versus parenteral narcotics (Askar et al., 2007), although direct comparisons between epidural and intrathecal techniques are lacking.

One of the shortcomings of intrathecal injection is that because a catheter is generally not left in place, repeat doses of medication cannot be given, limiting the duration of analgesia. Intrathecal opioids can cause any of the side effects of systemic opioids, such as respiratory depression, nausea, vomiting, and pruritus. While this technique may be useful, it has not truly been shown to be superior to intravenous opioids, and since it is more expensive and effort-intensive, its appeal is likely to remain limited.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Paravertebral Infusion

Another regional technique that can enhance postoperative analgesia is continuous paravertebral infusion (CPI). In this technique, a catheter is inserted into the paravertebral space on the surgical side and local anesthetic is infused, anesthetizing the spinal nerves as they exit the intervertebral foramina and producing unilateral pain relief (Richardson, Lonnqvist, & Naja, 2011). No opioids are included in the infusion, and the sympathectomy induced is unilateral, providing improved hemodynamic stability. Meta-analyses have shown that CPI seems to result in equivalent analgesia after thoracotomy when compared to TEA, and may induce less urinary retention, nausea, and hypotension (Ding et al., 2014). In an intriguing study in breast cancer patients, CPI was even found to reduce rates of cancer recurrence and distant metastasis when compared to systemic opioid analgesia (Exadaktylos, Buggy, Moriarty, Mascha, & Sessler, 2006). However, because the benefits in this study were suggested to be due to attenuation of the stress response and decreased use of opioids (which can be immunomodulatory), it is worth noting that TEA may result in similar benefits. This is still a question in the early stages of investigation.

While it appears to have a good side-effect profile compared to epidural analgesia, CPI does have its own risks. Because it is still an invasive procedure close to the spinal cord, its use is limited in coagulopathic patients. It also has limited utility in pain relief after sternotomy, when unilateral analgesia may be inadequate. However, this technique seems likely to grow in popularity in the future.

SEDATIVES

While analgesia forms the basis of patient comfort, additional sedatives are sometimes necessary to ensure anxiolysis and ventilator synchrony. Numerous agents are available which may act through different pathways and thus can have divergent effects. The choice of agent is largely dependent on a patient's individual medical condition and needs.

BENZODIAZEPINES

Benzodiazepines (BZDs) have a long history as ICU sedatives. They interact with the Gamma aminobutyric acid type A (GABA-A) receptor and enhance the action of GABA, the primary inhibitory neurotransmitter in the CNS. This produces numerous effects including sedation, anxiolysis, muscle relaxation, and anterograde amnesia. The BZD binding site on the receptor is distinct from the binding sites for other GABA-ergic sedatives, such as barbiturates and ethanol, and BZDs' effects can be synergistic with these agents (Olsen, 1981). BZDs are metabolized by CYP450 enzymes in the liver, then undergo glucuronidation, and are finally excreted renally. Some have active metabolites. Three of the most commonly used benzodiazepines in critical care practice are midazolam, lorazepam, and diazepam (See Table 6).

BZDs have several advantages: they provide reliable anxiolysis and have a high specificity for inducing amnesia, which can be very useful for procedural sedation. This anterograde amnesia appears to be strongly related to the lipid solubility of the drug (Fox, Liu, & Kaye, 2011). BZDs are also useful for treating alcohol withdrawal and delirium tremens.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 6. Comparison of benzodiazepines most commonly used in the CTICU

Drug	Typical IV Dose	Onset	Duration of Action After Bolus	Elimination Half-Life	Active Metabolites?
Midazolam	1-5 mg	1-5 min	20-60 min	2-6 hrs	No
Lorazepam	0.5-4 mg	2-5 min	1-4 hrs	12-18 hrs	No
Diazepam	2-10 mg	15-20 min	1-6 hrs	20-70 hrs	Yes

Another advantage to BZDs in patients with cardiovascular disease is their relatively benign hemodynamic profile. When given at clinically relevant doses, BZDs may cause mild vasodilation but only a slight drop in arterial blood pressure (Stoelting, 1981). They seem to have minimal effects on coronary blood flow (Marty, Nitenberg, Blanchet, Zouioueche, & Desmonts, 1986) and are generally well-tolerated even in patients that are hemodynamically unstable.

As with other sedatives, BZDs have several drawbacks. Because they are hepatically metabolized and renally cleared, they may have prolonged effects in patients with end-organ dysfunction. While BZDs modestly decrease respiratory drive and response to hypercapnea and hypoxia (Forster, Gardaz, Suter, & Gemperle, 1980), clinical experience indicates that they rarely cause respiratory failure when given in isolation (Gaudreault, 1991). Flumazenil, a competitive BZD receptor antagonist, is readily available to reverse BZD effects. However, it should be reserved for severe cases because of the relatively benign nature of BZD overdose and the risk of seizures and agitation with flumazenil administration, particularly if a patient has been taking BZDs chronically. When indicated, flumazenil is given in increments of 0.2 mg IV, up to 1 mg total.

More concerning for intensivists, BZDs have been implicated in increasing the risk of ICU delirium. Lorazepam, in particular, has been associated with the transition to delirium in critically ill patients. This relationship seems to be dose-dependent, with an increasing risk of delirium at doses from 0 to 20 mg/day and a plateau in risk after 20 mg/day (Pandharipande et al., 2006). Additionally, total lorazepam dose has been correlated with risk of post-traumatic stress disorder (PTSD) after intensive care (Girard et al., 2007). However, these relationships are strongest in cohort and case-control studies and thus may be affected by unmeasured biases. One possible mechanism by which BZDs may increase risk of PTSD is the very amnesia that leads many intensivists to use them: at least one study has indicated that patients who have delusional memories of their ICU stay, with no true memories, are actually at higher risk for PTSD than those with true memories of the ICU (Jones, Griffiths, Humphris, & Skirrow, 2001).

Midazolam

Midazolam is a fast-acting, water-soluble BZD that is very lipophilic. This results in a speedy onset of action and a high level of anterograde amnesia. It is available in IV, oral, and intranasal forms, although it has low oral bioavailability. Midazolam's clinical action is typically terminated by redistribution out of the CNS, and, like fentanyl, its context-sensitive half-time increases after a prolonged infusion (see Figure 2). When given as an infusion, doses for midazolam range from 1-10 mg/hr.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Lorazepam

Lorazepam has an onset of action that is similar to midazolam but has a longer duration of action. It also causes some anterograde amnesia. Because it undergoes direct glucuronidation without prior P450 metabolism and has no active metabolites, lorazepam's half-life is not substantially influenced by hepatic or renal dysfunction, making it an especially useful agent in critically ill patients (Olkkola & Ahonen, 2008). It can also be administered by continuous infusion at doses similar to midazolam. As previously mentioned, lorazepam has been associated with increased risk for delirium, but it is possible that this effect applies to all BZDs and lorazepam is simply the one most commonly used in the ICU setting.

Diazepam

Diazepam has a longer onset of action than midazolam or lorazepam. Because it has active metabolites (temazepam, oxazepam, and desmethyldiazepam), diazepam's apparent duration of action is much longer, and this effect is more pronounced in older patients or those with renal dysfunction. Indeed, it has been suggested that diazepam's half-life increases by 1 hour for every year of age after 40 (Griffin, Kaye, Bueno, & Kaye, 2013). Diazepam has prominent myorelaxant effects, especially at higher doses. Unlike midazolam and lorazepam, its IV formulation contains propylene glycol, which can cause injection pain and thrombophlebitis.

PROPOFOL

Propofol is a short-acting anesthetic that is chemically distinct from other sedatives. Because of its low solubility in aqueous solutions, it is prepared in a lipid emulsion containing soy and egg ingredients. Usual doses are 1-2.5 mg/kg for boluses and 1-5 mg/kg/hr for sedative infusions. Propofol has a very rapid onset (1-2 minutes) after bolus dosing and is cleared similarly quickly, with an initial redistribution half-life of 2-3 minutes and a longer elimination half-life of 34-56 minutes (Kanto & Gepts, 1989). Because the initial redistribution is what typically terminates the effect of propofol, its clinical effect usually dissipates in 5-10 minutes after a bolus. While propofol exhibits some increase in context-sensitive half-time with prolonged infusion, this effect is relatively mild compared to other sedatives (See Figure 2). In general, propofol induces a deeper state of unconsciousness than benzodiazepines or opioids, with more muscle relaxation (Dueck, Oberthuer, Wedekind, Paul, & Boerner, 2003). While this makes it useful for situations that demand heavy sedation, it also means that propofol must be given in a monitored environment and by clinicians experienced in its administration.

Propofol's metabolism is still a matter of some investigation. Very little propofol is excreted unchanged in the urine. While propofol undergoes hepatic metabolism, its rate of clearance seems to be greater than hepatic blood flow. The apparent explanation for this conundrum is that propofol is also metabolized in extrahepatic sites like the kidney and the lung. Experimental evidence suggests that 60% of propofol is metabolized in the liver and 33% in the kidney, with studies equivocal as to the lung's contribution (Hiraoka et al., 2005). Interestingly, propofol clearance does not seem to be affected significantly by cirrhosis or renal failure (Veroli et al., 1992; Morcos & Payne, 1985).

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Hemodynamically, propofol is known to cause hypotension after an IV bolus. This effect is more pronounced than that induced by BZDs or opioids. Much of this decrease appears to be related to decreased systemic vascular resistance (SVR), although propofol may also have some myocardial depressant effects, especially if PaCO2 is maintained at normal values rather than allowed to rise (Searle & Sahab, 1993). Propofol can depress the baroreceptor response to hypotension, which can exacerbate these effects. It is notable that much acute hypotension from propofol may be related to the fast rise and equally fast drop-off in blood levels that follows a propofol bolus. When an administration protocol was used that was specifically designed to avoid overshoot of desired blood levels, researchers found that hypotension was minimal (Roberts, Dixon, Lewis, Tackley, & Prys-Roberts, 1988). Propofol seems to cause some decrease in coronary blood flow (likely due to decreased blood pressure) but also decreases myocardial oxygen consumption by a similar magnitude; these changes seem to reverse with stimulation (Stephan, Sonntag, Schenk, Kettler, & Khambatta, 1986). Overall, propofol is likely safe to use in all but the most unstable cardiac patients, but should be administered with caution, especially when given as a rapid bolus.

As previously stated, propofol acts as a respiratory depressant. When used at anesthetic doses, propofol depresses minute ventilation and shifts the CO2 response curve to the right (Allsop, Taylor, Grounds, & Morgan, 1988). It can cause periods of apnea after bolus administration. However, lower doses of propofol used to induce conscious sedation have not been shown to have a significant effect on respiratory variables (Rosa et al., 1992). Higher doses of propofol can also cause a decrease in airway muscle tone, which may induce or exacerbate airway obstruction (Mathru et al., 1996).

One complication of propofol administration that has more recently come to light is propofol infusion syndrome (PRIS), a severe metabolic disorder. This syndrome is characterized by bradycardia, arrhythmias, rhabdomyolysis, lactic acidosis, fatty liver, renal failure, and cardiovascular collapse if unchecked. While this syndrome is rare enough that its prevalence is difficult to measure, its severity and high risk of mortality (estimated around 60%) make it significant (Kam & Cardone, 2007). Risk factors that have been proposed include higher doses of propofol (> 10 mg/kg/hr), prolonged infusion, impaired nutritional status, critical illness, and younger age. The most likely mechanism for PRIS is that propofol interferes with fatty-acid oxidation and may affect the electron transport chain (Wolf, Weir, Segar, Stone, & Shield, 2001). In those who are malnourished and dependent on fatty acids for energy, this may result in global metabolic failure.

DEXMEDETOMIDINE

One of the newest sedatives to gain popularity is dexmedetomidine, which acts as an α-2 adrenergic receptor agonist. Dexmedetomidine produces anxiolysis, mild analgesia, and a sedative state that has been termed "calm responsiveness." Patients receiving this agent will frequently remain asleep until stimulated, at which point they awaken and can follow commands, but will return to sleep when the level of stimulation drops. Dexmedetomidine has very little effect on respiratory drive and as such, is increasingly seen as an ideal choice for sedating patients who are extubated and breathing spontaneously or those who may benefit from early extubation (Venn, Hell, & Grounds, 2000). On the other hand, these characteristics may make dexmedetomidine unsuitable for situations requiring deep sedation. It is typically administered via a bolus of 1 mg/kg over 15 minutes, followed by an infusion of 0.2-1 mcg/kg/hr.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Dexmedetomidine causes hemodynamic effects similar to other α-2 agonists such as clonidine: infusion of dexmedetomidine is associated with a decrease in heart rate and blood pressure, which may be quite profound in susceptible patients. Decreased blood pressure is primarily a result of reduced SVR, although cardiac output may decrease as well (Bloor, Ward, Belleville, & Maze, 1992). Bolus dosing can cause hypertension and bradycardia, which is thought to result from the increased α-1 agonist activity of the drug at higher concentrations, resulting in a temporary rise in SVR. In cardiac surgical patients, dexmedetomidine seems to decrease SVR and BP without significant effects on cardiac output, although mixed venous oxygen concentration has been noted to decrease (Ishikawa et al., 2006). It can blunt sympathetic responses to stimuli effectively but does not seem to have as significant an effect on baroreceptor response (Hogue et al, 2002).

Another advantage of dexmedetomidine is its fast onset and offset. Dexmedetomidine is metabolized both by the cytochrome P450 system and by direct glucuronidation and has no active metabolites. Like many other sedatives, it is redistributed extensively with an initial half-life of 6 minutes; its terminal elimination half-life is closer to 2 hours. Because dexmedetomidine has a high margin of cardiovascular and respiratory safety, it is usable in patients with hepatic impairment, although some dose adjustment may be necessary.

ANTIPSYCHOTICS

Antipsychotics are used both as a sedative and to treat delirium, a common problem in the CTICU. They produce varying degrees of sedation but have minimal effects on respiratory drive and thus can be advantageous in patients with compromised respiratory function (Tjia & Gitlin, 2010).

The two major categories of antipsychotics are typicals, such as haloperidol and thorazine, and atypicals, like olanzapine and quetiapine. Typical antipsychotics act primarily via dopaminergic (D2 receptor) antagonism and have a greater risk of associated extrapyramidal symptoms (EPS), such as Parkinsonism and tardive dyskinesia. Atypical antipsychotics modulate both dopaminergic and serotonergic systems and carry a lower risk of EPS, but have been associated with metabolic side effects such as weight gain and diabetes mellitus (Meltzer, 2012). Antipsychotics also have variable anticholinergic and α-adrenergic-blocking effects, which can potentially cause dry mouth, blurry vision, and hypotension (Guzman & Farinde, 2014). Lastly, but of substantial importance in the CTICU, is the risk of QTc interval prolongation with antipsychotics, which seems to be most prominent for haloperidol, droperidol, thioridazine, clozapine, and olanzapine, and can result in Torsades de Pointes in susceptible patients. Interestingly, low-dose quetiapine seems to have minimal effects on the QTc, while aripiprazole may actually shorten it (Goodnick, Jerry, & Parra, 2002). Careful ECG monitoring is essential in patients receiving these medications in the CTICU. In some studies of elderly dementia patients, antipsychotics (especially typicals) have been associated with increased overall mortality, but the relevance of this association with regard to shorter-term ICU therapy is unclear (Gill et al., 2007).

Antipsychotics, particularly haloperidol, have been shown to be efficacious in the treatment of acute delirium in the hospital setting (Lacasse, Perreault, & Williamson, 2006). However, this evidence has not always translated to the ICU, as other studies focusing specifically on critically ill patients have suggested no difference between groups receiving antipsychotics versus placebo in terms of days alive without delirium or coma (Girard et al., 2010). In contrast, Devlin et al. (2010) found that scheduled quetiapine combined with as-needed haloperidol produced faster resolution of delirium, reduced dura-

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

tion of delirium, and less agitation than haloperidol alone, as well as possibly better functional status at discharge, although quetiapine had a higher incidence of somnolence. Studies evaluating whether scheduled haloperidol can prevent the onset of delirium in the ICU have similarly produced mixed results (Page et al., 2013; Wang et al., 2012). Overall, while it seems the efficacy of antipsychotics in treating ICU delirium is not well established, these drugs may be useful in patients with or without delirium whose conditions warrant a sedative with minimal respiratory effects. Further research is necessary to compare the efficacy of antipsychotics to other sedatives and better delineate their best role as part of an overall sedative regimen.

TRENDS IN ANALGESIA AND SEDATION

Before assessing what are the best agents and strategies to apply to CTICU patients, it is instructive to see what patterns are most common in current practice and what approaches are recommended by professional societies. A recent summary of international surveys by Mehta, McCullagh, and Burry (2009) showed that while there is much variation across countries, several trends are evident. Lighter sedation is becoming more common, and propofol is being used progressively more than benzodiazepines. Shorter-acting opioids are also gaining in popularity, with fentanyl and remifentanil taking the place of morphine. At the time of this review, notably, dexmedetomidine was not a commonly used agent.

The most recent guidelines from the Society of Critical Care Medicine suggest how to further refine practice to fit the best evidence (Barr et al., 2013). This set of recommendations emphasized pain control and frequent reassessment of pain as a primary objective. Other evidence-based suggestions were to titrate agents to achieve light rather than deep sedation, to monitor patients closely for delirium, and to use early mobilization as a tool to prevent delirium. Epidural analgesia was suggested for certain types of procedures, although some uncertainty about its benefits was noted. Few recommendations were made for the use of individual pharmacologic agents.

CHOICE OF MEDICATIONS: IS THERE A "BEST AGENT?"

Many factors need to be considered in choosing an analgesic and sedative strategy for a given patient. It is instructive to lay out goals for the patient on daily rounds: is deep sedation required, due to hemodynamic instability or severe hypoxia, or would the patient benefit from lighter sedation and a greater focus on weaning from the ventilator? And are there any measures that can be taken to reduce the need for sedation and analgesia, such as instituting physical therapy, environmental modifications, or an improved sleep regimen?

An additional question to consider is how to minimize the adverse effects of the sedative regimen on the patient. One population that warrants specific concern is patients at greater risk for delirium, such as those with advanced age, sensory impairment, alcohol abuse, or electrolyte abnormalities (Elie, Cole, Primeau, & Bellavance, 1998). This is of particular importance as delirium has been associated with increased mortality and length of stay in critically ill patients (Ely et al., 2004), as well as increased ICU and hospital costs (Milbrandt et al., 2004). In the cardiac surgery population, delirium may occur in more than 30% of patients. Risk factors include older age, medical comorbidities, decreased preoperative cognitive function, longer cardiopulmonary bypass time, and greater inflammatory response (Guenther

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

et al., 2013). CT surgical patients who experience delirium have greater drops in postoperative cognition and are less likely to return to their preoperative baseline (Saczynski et al., 2012).

Other characteristics of the CT surgical population may impact choice of analgesics and sedatives. Hemodynamic instability may necessitate regimens that have less cardiovascular depressant effects. Organ failure may preclude the use of medications with long elimination half-lives or active metabolites. Patients with impaired pulmonary function may be unable to tolerate agents with prominent respiratory depressant effects. Considering these issues can help to tailor a patient's analgesic and sedative regimen to their needs.

A separate question is whether any one sedative regimen is better than another in terms of overall outcomes, and various studies have been undertaken to answer this question. As has been touched on before in this chapter, an important question is whether BZDs are associated with worse outcomes or more adverse events, particularly delirium. A meta-analysis examining BZD-based sedation vs. non-BZD-based sedation found that use of non-BZD regimens resulted in shorter ICU length of stay and shorter duration of mechanical ventilation but no significant difference in rates of delirium or mortality (Fraser et al., 2013). In a similar vein, another meta-analysis found that use of dexmedetomidine for ICU sedation was associated with a reduction in ICU length-of-stay and time to extubation, although this result was limited by high heterogeneity between studies (Pasin et al., 2013).

Several randomized studies have also been undertaken comparing specific sedatives in terms of efficacy and side effects. When midazolam and propofol have been compared, propofol seems to result in more time spent at target levels of sedation and earlier extubation than midazolam, especially after more prolonged infusions (Hall et al., 2001). This is intuitively sensible, since propofol has a substantially shorter context-sensitive half-time than midazolam. Even when the higher cost of propofol has been factored in, earlier weaning from mechanical ventilation seems to make propofol a more economically viable choice (Barrientos-Vega et al., 1997).

More recently, dexmedetomidine has grown in popularity and this is reflected in the literature. Pandharipande et al. (2007) conducted a randomized controlled trial (RCT) using lorazepam vs. dexmedetomidine for sedation in 106 mechanically ventilated medical and surgical patients. In this trial, patients receiving dexmedetomidine spent more time at their targeted level of sedation and also spent more days alive without delirium or coma. However, this latter composite outcome was driven primarily by more coma in the lorazepam group. There was a trend towards fewer days with delirium in the dexmedetomidine group but it did not reach significance. This study found no difference in mortality between groups.

A similar study was conducted in by Riker et al. (2009) comparing dexmedetomidine to midazolam for the sedation of critically ill, ventilated patients. In this instance, patients treated with dexmedetomidine spent less time on the ventilator, experienced less delirium, and were less likely to exhibit tachycardia and hypertension. Dexmedetomidine was, unsurprisingly, associated with more bradycardia, but the proportion of patients experiencing bradycardia that required treatment was much smaller. Notably, in this study, neither medication resulted in more time spent at the desired level of sedation.

Jakob et al. (2012) synthesized two multi-center Phase 3 RCTs, one comparing dexmedetomidine to midazolam and another comparing dexmedetomidine to propofol for sedation of mechanically ventilated ICU patients. This study found that all three agents were equivalent at maintaining desired levels of light to moderate sedation. Using dexmedetomidine seemed to lead to shorter duration of mechanical ventilation than midazolam and more ability to communicate with patients than either midazolam or propofol. However, dexmedetomidine caused more hypotension and bradycardia than either of the other sedatives used.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Results of trials conducted specifically in CT surgical patients have found similar results. When comparing an analgesic regimen based on morphine vs. one based on dexmedetomidine, with open-label propofol administered as needed for additional sedation in both groups, Shehabi et al. (2009) found that the dexmedetomidine-based regimen resulted in shorter duration of delirium, earlier extubation, and less vasopressor use than the morphine-based regimen, although it also produced more episodes of bradycardia. In this study, there was also a trend towards a lower incidence of delirium in the dexmedetomidine group, but it did not reach significance. In an open-label study, Maldonado et al. (2009) found that dexmedetomidine administered after valvular cardiac surgery resulted in less opioid use and substantially lower rates of delirium than midazolam or propofol. Notably, this study had a number-needed-to-treat to prevent delirium of just over 2, implying a large clinical effect; however, it was limited by its smaller size, its open-label structure, and a high dropout rate. In the aggregate, while it seems dexmedetomidine may have some distinct advantages as a sedative in critically ill CT surgery patients, the choice of medication regimen still needs to be tailored to the individual patient.

CHOICE OF SEDATIVE STRATEGY

Several approaches towards analgesic/sedative administration seem to be useful regardless of the specific drugs chosen. One of these is the use of daily sedation interruption (DSI), sometimes referred to as a "sedation vacation." In this technique, a period each day is designated wherein sedatives are withheld and patients are allowed to awaken. This allows assessment of the depth of sedation, facilitates neurologic examination, and can be an ideal opportunity to conduct spontaneous breathing trials. The foundational study on interruption of sedation by Kress, Pohlman, O'Connor, and Hall (2000) revealed that this approach leads to shorter duration of ventilation and ICU length-of-stay, as well as fewer diagnostic studies, than usual care, with no increase in complications like self-extubation.

One concern with this strategy is that withholding sedation may lead to more stress for patients, greater impact of traumatic experiences, and even more PTSD. However, the evidence does not suggest this. In fact, examining retrospective data, it seems that DSI is associated with unchanged rates of adverse psychological outcomes, as well as fewer symptoms of PTSD, and possibly lower eventual rates of PTSD (Kress et al., 2003). Most of the studies examining DSI have been in mixed medical-surgical populations, with few CT surgical patients included, but there is no reason to think such an approach would not be equally effective in CT patients as long as severe hemodynamic instability is not present.

Not all studies on sedation interruption, however, have found the same results. A Cochrane review by Burry et al. (2014), which examined 9 trials of DSI, found that the intervention reduced rates of tracheostomy but did not change duration of mechanical ventilation or ICU stay. The studies analyzed had significant heterogeneity, which may have affected the results. In a randomized trial, Mehta et al. (2013) studied 430 critically ill, ventilated patients who were being treated using a protocol designed to target light sedation. In this case, again, DSI did not change length of stay or duration of ventilation. Notably, the DSI group in this study received higher daily doses of analgesics and sedatives than the group that was treated via sedation protocol alone. It seems that some of the benefit from DSI may be related to light sedation and not the daily interruption itself. This is consistent with the results of the original study by Kress et al. (2000), in which the DSI group received significantly less sedatives and analgesics than the control group.

Another approach that has been evaluated is the use of analgesics with minimal or no sedation, even when patients are intubated. A trial by Strøm, Martinussen, and Toft (2010) randomized critically ill, mechanically ventilated patients to receive morphine boluses for analgesia with or without a concurrent propofol infusion. The group receiving propofol underwent daily interruption of sedation. Patients received haloperidol if they were felt to be delirious. Those in the morphine-only (or "no-sedation") group were assigned a dedicated caregiver to comfort and calm them if they were anxious or uncomfortable despite analgesics. If these measures failed repeatedly, patients in the "no-sedation" group could receive rescue sedatives by infusion. 18% of the patients in the "no-sedation" group eventually had to cross over and receive continuous sedatives. In the intent-to-treat analysis, this study found that the "no-sedation" group spent more time free from mechanical ventilation and had shorter LOS in the ICU and hospital. There was a trend towards lower ICU mortality in the "no-sedation" group but it was not significant. Conversely, the "no-sedation" group experienced more agitated delirium and received more haloperidol.

While this study creates interesting food for thought, it is not always feasible to forego sedation entirely, especially in patients who are unable to tolerate episodes of coughing, movement, or delirium. Again, while it seems prudent to limit any extraneous use of sedatives, a certain level may be necessary to avoid counterproductive stress responses. Intensivists must balance long-term outcome goals with the medical (and human) imperative to limit pain and anxiety when possible.

Another common strategy utilized in the CTICU is "fast-track" management. This term does not have a concrete definition, but involves various components of care in the intraoperative and postoperative periods that are designed to facilitate earlier ventilator weaning and extubation, shorter ICU stay, and improved recovery after CT surgery in appropriate patients. A meta-analysis of 25 trials by Zhu, Lee, and Chee (2012) evaluated two of the most common components of fast-track cardiac care, low-dose intraoperative opioids and early extubation protocols. They found that these 2 inverventions were associated with significantly shorter times until extubation and ICU length of stay; the fast-track patients had no increase in complications as a result. Other components not evaluated in this study include use of short-acting sedatives like remifentanil and dexmedetomidine and use of epidural analgesia. While fast-track recovery protocols do not clearly lead to shorter hospital stays or lower rates of complications, they appear safe and are consistent with the recognized goals of minimizing sedation and avoiding unnecessary interventions.

NON-PHARMACOLOGIC APPROACHES

While medications continue to be the mainstay of analgesia and sedation in the CTICU, other non-pharmacologic techniques may also prove useful. Physical therapy may facilitate early mobilization and can avoid painful stiffness and contractures, as well as potentially improve function and mood. Alternative therapies, such as acupuncture, massage, meditation, and visualization, may help to alleviate pain, although their use in the CTICU has not been well evaluated. Guided music therapy has been shown to decrease heart rate and myocardial oxygen demand and to improve sleep quality (Jacobi et al., 2002). As little of 20 minutes of music after cardiac surgery has been shown to significantly reduce anxiety and pain (Sendelbach, Halm, Doran, Miller, & Gaillard, 2006). Lastly, attention to sleep- frequently a rare commodity in the ICU- can potentially prevent delirium and help the healing process (Kamdar et al., 2013). Keeping the ICU quiet, turning down lights, and avoiding procedures overnight can all aid in this objective.

CONCLUSION/DIRECTIONS FOR FURTHER RESEARCH

Patients in the CTICU are at risk for pain and anxiety from many sources, many of which are unavoidable in the perioperative period. Through judicious use of medications and non-pharmacologic interventions, intensivists and surgeons can alleviate much of their distress. However, it is of paramount importance to avoid adverse effects that can result from analgesics and sedatives, such as hypotension, bradycardia, delirium, and prolonged mechanical ventilation. There are many ways to achieve these goals, and more research is needed to better delineate whether certain agents may confer benefits in terms of mortality, neurocognitive dysfunction, or other long-term outcomes. It is also less clear whether certain populations may benefit from different agents more than others. While inferences can be made about this possibility, little empirical evidence exists. Dexmedetomidine seems to hold great promise both as a sedative and an analgesic adjuvant, and it may be informative to evaluate its efficacy when combined with other agents such as ketamine for postoperative analgesia. Unfortunately, dexmedetomidine's use is limited by its relatively high cost, although some studies imply that this is outweighed by the shorter duration of ventilation associated with dexmedetomidine (Lachaine, 2012). While antipsychotics are frequently used in the CTICU, there is little data as to their efficacy as sedatives and how best to use them as part of a sedative strategy.

Regardless of which agents are used, sedation interruption, sedation protocols, and other approaches that limit deep sedation seem to hold potential benefits for patients. More research may help to predict which patients are the best candidates for "fast-track" management and whether specific sedative and analgesic protocols may improve outcomes in subsets of the population.

The role of non-pharmacologic techniques in alleviating pain and agitation in the CT surgical population is a field that is ripe for study. These techniques are particularly attractive because they may help limit adverse drug effects, although their relative efficacy needs to be tested in a more formalized way. It may be useful in the future to combine multiple types of analgesics, sedatives, and alternative approaches to establish clinical pathways and protocols based on best evidence. This will help standardize care and make the perioperative process more efficient and less traumatic.

KEY TERMS AND DEFINITIONS

Analgesic: An agent or technique that provides relief from painful sensations.

Cardiothoracic: Of or pertaining to the heart, lungs, or other intrathoracic organs.

Cardiothoracic Intensive Care Unit: An ICU providing specialized preoperative and postoperative care for patients undergoing cardiothoracic surgery.

Context-Sensitive Half-Time: The time required for blood levels of a drug to drop by 50%, which may be due to redistribution, metabolism, or elimination, and which may vary after different durations of drug infusion.

Delirium: A multifactorial syndrome characterized by acute onset, a fluctuating course, as well as possible attentional deficits and an altered level of consciousness.

Elimination Half-Life: The time required for blood levels of a drug to drop by 50% due to elimination from the body.

Intensive Care Unit: Specialized hospital unit wherein patients are cared for who require support of vital organ functions, including those suffering from respiratory, circulatory, and renal failure.

Opioid: One of a class of analgesics related to naturally-derived opium.

Regional Analgesia: A technique by which analgesia is provided through blockade or modulation of afferent pain signals, not via systemic medications.

Sedative: A medication that induces a depressed level of consciousness.

Chapter 20
Phytonutrients of Nutraceutical Importance: Exploring Antimicrobial, Antiproliferative, and Antioxidant Activities

Marcus Vinícius Dias-Souza
Federal University of Minas Gerais, Brazil

Renan Martins dos Santos
Federal University of Minas Gerais, Brazil

ABSTRACT

Phytotherapy re-emerged in the latest years as a healing system accepted and spread worldwide, and different molecules have been investigated due to their benefits to health. Nutraceutical formulations, which allow the intake of phytonutrients (generally in low levels in plant food) in concentrations that are enough to achieve the desired outcomes, represent feasible alternatives to improve general health and to prevent and treat varied diseases. Notwithstanding the incompleteness of an evidence-based clinical use of nutraceuticals, many questions remain unanswered regarding their global effects in humans and animals. Thus, the aim of this chapter is to provide recent evidence on chemical and pharmacological features of the main phytonutrients explored in nutraceutical formulations, focusing antimicrobial, antioxidant and antiproliferative potentials. Also, some insights on drug-phytonutrients interactions will be discussed.

INTRODUCTION

The rapidly increasing knowledge on nutrition, pharmacology and plant biotechnology has changed some concepts about food and health. Epidemiologic studies from the latest 50 years have provided evidence of an inverse association between the dietary intake of fruit and vegetables and occurrence of varied illness such as diabetes, osteoporosis, cancers, cardiovascular and infectious diseases. This protective effect obtained in food intake has been assigned to plant secondary metabolites; specifically, phytomol-

ecules with nutritional properties, the phytonutrients. In a few words, phytonutrients can be defined as plant-derived compounds with nutritive properties that can have also curative or preventive effects over diseases (Michels et al., 2000). These phytomolecules are thought to be responsible for most of the health benefits observed in individuals that adopted long-time diets rich in fruits, vegetables, beans, cereals, and plant-based beverages such as tea and wine. The correlation between observed effects and the type or concentration of some phytomolecules has been described, such as Lycopene and Resveratrol, for instance, in cancer prevention. In plants, several phytomolecules of nutraceutical interest are part of defense mechanisms against environmental challenges such as damage due to ultraviolet light exposure and natural predators such as insects and other plagues (Hecht, 2000; Sharma et al., 2009).

The low bioavailability of phytomolecules is an important limitation on their use to prevent or treat diseases. The often low concentration found in plasma has led to some skepticism in this sense; however, in spite of their low bioavailability, varied studies in the latest years have provided evidence of their beneficial effects in humans and animals. To overcome the issue of low levels of phytonutrients in fruits and vegetables, pharmaceutical and nutritional companies have developed several pharmaceutical dosage forms of nutraceutical formulations and other dietary plant-based supplementary products. This becomes even more relevant considering that nutraceutical formulations provide adequate concentrations of phytomolecules and thus, different beneficial effects to health can be expected. Moreover, nutraceutical formulations make the use of phytonutrients feasible in a clinical perspective (McCullough et al., 2003; Key et al., 2004; Yang et al., 2010). Examples of Nutraceuticals are presented in Table 1.

The Dietary Supplement Health and Education Act, adopted by the American Association of Clinical Endocrinologists (Mechanick et al., 2003), provides adequate definitions of dietary supplements and nutraceuticals, which will be adopted and slightly adapted in this chapter for a better comprehension by non-specialist readers. According to Mechanick et al. (2003), dietary supplements comprise five main groups of ingredients/elements:

1. Vitamins or minerals;
2. General phytomolecules;
3. Amino acids;

Table 1. Examples of phytomolecules-based nutraceutical formulations

Formulation Brand	Phytomolecules	Manufacturer	Indications
Inneov Solar®	β-carotene, Lycopene, tocopherols and *Polypodium leucotomos* extract	Loreal and Nestlé	Oral photoprotection
Lauricidin®	Lauric acid	Med-Chem	Stimulation of the immune system
Extra-Strength Broccoli Extract with Glucosinolates®	Glucosinolates of broccoli extract	Green Foods	ROS/RNS scavenger, protection of the cardiovascular system
Flavonoid 1000®	Hisperidin, rutin, bromelin and citric bioflavonoids (200, 50, 50, 1000 mg, respectively)	DaVinci	Relief on varicose veins, reduction of inflammatory processes associated to pain, metabolism booster.

ROS: Reactive oxygen species; RNS: Reactive nitrogen species.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

4. Other substances that increase the total dietary intake such as enzymes;
5. Byproducts such as metabolites and constituents, or even extracts of any of the elements mentioned in topics 1 to 4.

Thus, dietary supplements are not foods in their natural form, but are not limited to common nutritional agents.

Nutraceuticals, on the other hand, are defined as sophisticated dietary supplements based in concentrated presentations of one or more pure bioactive substances, originally isolated from plant foods, although mineral and animal bioactive molecules are also included. These formulations are prepared in different pharmaceutical dosage forms and are used in dosages many times superior to those detectable in their original sources to improve health in varied aspects (Mechanick et al., 2003).

Most nutraceutical and dietary supplements formulations may be purchased without medical prescription in several countries, and in the latest years, pharmaceutical and health food companies have come up with new formulations claiming to have varied pharmacological effects of interest to prevent diseases (although some of them are still demanding more evidence from clinical studies, as will be discussed in this chapter). Different groups suggest that nutraceuticals present drug-like actions, and therefore, their formulations should be marketed, for instance, as over-the-counter medication. Considering this, a question arises: the rules of Lipinski et al. (1997), widely accepted to characterize a molecule or compound as not "drug-like", states that when a substance falls into one or more of the following properties:

1. More than five hydrogen-bond donors, considering OH and NH moieties;
2. More than ten hydrogen-bond acceptors, considering N and O atoms;
3. Molecular weight beyond 500 g/Mol;
4. Octanol/water partition coefficient log P higher than 5.

Therefore, as it is not reasonable to assume that the chemical properties of all nutraceuticals are within these reference levels, it becomes technically difficult to generalize that nutraceutical formulations could be regulated as over-the-counter drugs. Also, most of the phytomolecules used as nutraceuticals have not shown cytotoxic effects in several *in vivo* and *in vitro* models, being widely recognized as safe for human and animal use (Zhao et al., 2012).

Strong recommendations for consumption of nutraceuticals have become progressively popular to improve health, and to prevent and treat diseases. Nutraceuticals and dietary plant-based supplements, among other properties such as antioxidant and antiproliferative, can stimulate immune response and result in fewer infections or control of infectious diseases, particularly in the elderly and in malnourished, critically ill individuals (Pham-Huy et al., 2008; Lee et al., 2009).

Notwithstanding the incompleteness of an evidence-based use of nutraceuticals, many questions remain unanswered regarding their global effects in humans and animals. Therefore, the aim of this chapter is to provide recent evidence on chemical and pharmacological features of the main phytonutrients explored in nutraceutical formulations, focusing their antimicrobial, anti-oxidant and anti-inflammatory potentials. Also, some insights on drug-phytonutrients interactions will be discussed. With more direction on flavonoids, carotenoids, phytosterols, lauric acid and glucosinolates, we shall present recent evidence of the mentioned pharmacological activities and the possible benefits on the treatment of infectious diseases and cancers with important burden on human health worldwide. However, we do not intend here to exhaust the subject, but to propose discussions to open doors for more advances in this exciting research field.

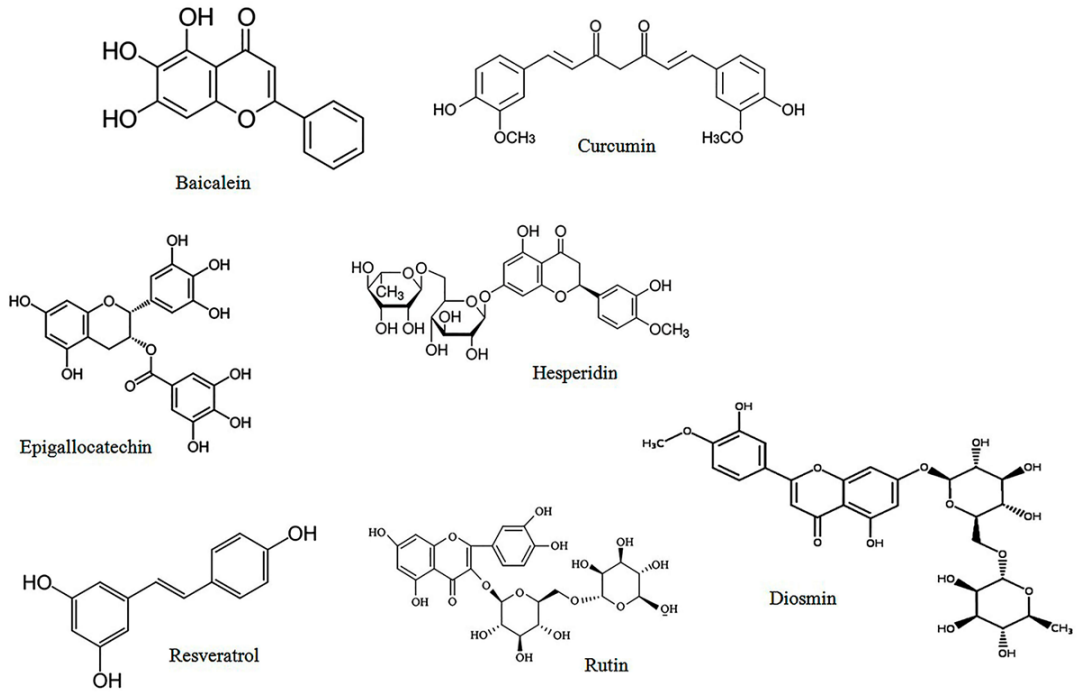
BACKGROUND

Flavonoids

Flavonoids are a diverse family of phytonutrients derived from phenylpropanoid and malonyl-coenzyme A pathways, characterized by two aromatic cycles (rings A and B) linked to a heterocycle (C ring) (Figure 1).



This phenylpropanoid core with 15 carbon atoms is usually modified by reactions such as alkylation, glycosylation, hydroxylation, methylation, methoxylation and oxidation, generating the major subgroups aurones, anthocyanins, chalcones, flavones, flavonols, flavanones, isoflavans, isoflavones, isoflavonols, stibenes, and proanthocyanidins. Currently, more than 10.000 flavonoid structures had been elucidated, and several pharmacological potentials have been assigned to them, such as antiproliferative, wound healing, anti-diabetic, cardioprotective, vasotonic, neuroprotective, antioxidant, antibacterial, antifungal, antiviral, and metabolism booster (Gutteridge, 1994; Haslam, 1996). Following, important flavonoids widely used as nutraceuticals will be discussed (Figure 2).

Authors' personal archive.

Baicalein

Baicalein ($C_{15}H_{10}O_5$) is found in citric fruits and mostly in *Scutellaria baicalensis*, a chinese herbal remedy known as skullcap or Huang Qin. Due to its good lipophilicity, baicalein can be transported into cells by passive diffusion. Most of the compound passes through glicuronization and and sulphation during absorption, and becomes too polar to pass through the lipid barriers. being transported in other ways inhibit CYP2C9 enzyme. Baicalein is able to (Stobiecki, 2000; Chen et al., 2006).

Chen et al. (2006) investigated the antimicrobial activity and the possible mechanism of action of baicalein on Methicillin-resistant *Staphylococcus aureus* (MRSA). Changes on membrane penetrability, protein synthesis, DNA topoisomerase activities and restriction map were assessed. The minimum inhibitory concentration reached 0.04 mg/mL, and after 16 h, the total soluble content of proteins decreased 44.62%. The flavonoid inhibited the activities of DNA topoisomerase I and II in a concentration of 0.025 mg/mL. Later, Moghaddam et al. (2014) examined the *in vitro* antiviral activity of baicalin, the main metabolite of baicalein, in different steps of dengue virus replication. Baicalin inhibited virus replication at IC50 = 13.5 ± 0.08 µg/mL with SI = 21.5 following virus internalization by Vero cells. Baicalin exhibited activity against DENV-2 extracellular particles and showed anti-adsorption effect.

Liu et al. (2015) assessed the protective effects of baicalein using an *in vivo* model of polymicrobial sepsis-induced liver injury. Polymicrobial sepsis was induced in C57BL/6 mice, which were treated with intraperitonial 100 mg/kg baicalein after 1, 6 and 12 h of the infection. Baicalein inhibited the mitogen-activated protein kinases (MAPKs) activation and suppressed the transcriptional activity of nuclear

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

factor-kappa B (NF-κB). Resulting effects comprised improved survival of septic mice, ameliorated liver injury, and reduced both neutrophil infiltration and hepatic inflammatory cytokines expression and release.

Li et al. (2013) synthesized baicalein-8 benzyl amino acid derivatives and evaluated their cytotoxicity *in vitro* against HepG2 cells. Substitutions on positions C6 and C8 were considered, and amino acids were subjected to methylation and aminoacylation reactions. Through carboxyl group protection and aminoacylation of amino acid and benzyl protection of baicalein, derivatives of baicalein-6-O-amino acid esters were obtained. A total of 13 novel derivatives were synthesized and chemically characterized. Four derivatives showed a significant increase in cytotoxicity when compared to baicalein. Some baicalein-5-O-amino acid derivatives were also synthesized, but they lost cytotoxic activity. This suggested that 5-OH is an important structural feature for the cytotoxic activity of baicalein and its derivatives.

Luo et al. (2014) studied the *in vitro* antiproliferative effect of 30 novel synthesized baicalein derivatives. Three human cancer cell lines were used: HepG2 (human liver carcinoma), A549 (human alveolar basal epithelial adenocarcinoma) and BCG-823 (gastric carcinoma), and baicalein was used as a comparative control. The compounds were tested over a range of concentrations from 0.1 to 100 M for 48 h, and IC50 values were estimated. Apoptosis mechanism was identified for 8 compounds, which moiety of 7-benzyloxy group exhibited more potent anti-proliferative activity against the tumor cell lines when compared to baicalein. One of the molecules was found to be 14-fold, 16-fold, and 6-fold more potent than baicalein against HepG2, A549 and BCG-823 cancer cell lines, respectively.

Zeng et al. (2015) assessed the anti-allergic and anti-inflammatory activities of baicalein and chrysin, by analysing the interactions between hyaluronidase using experimental methods and molecular docking. With the increase of baicalein or chrysin concentration, the activity of the enzyme decreased significantly and the 50% relative activity (IC50) of baicalein and chrysin were estimated to be 52 ± 7and 267 ± 33 mol/L, respectively. Considering thermodynamic parameters and molecular modeling, authors suggested that each molecule could bind to hyaluronidase spontaneously through electrostatic forces, hydrophobic interactions and hydrogen bonding.

Curcumin

Curcumin ($C_{21}H_{20}O_6$) was firstly isolated from turmeric. The flavonoid is usually a bright orange to yellow powder, with melting point at around 183 ºC, sensible to light and of low bioavailability in humans, but is rapidly metabolized in the liver. Low levels of this substance can be detected in plasma and tissues, and due to its low water solubility and poor absorption, it is quickly excreted. Curcumin inhibits epigenetic enzymes such as histone deacetilases, and has been associated with protection against cancer and cardiovascular diseases. Although the route of biosynthesis of Curcumin is not fully understood, there are two proposed mechanisms that may help to explain its synthesis: the first mentions the extension reaction of cinnamic acid with five malonil-CoA molecules, and the second involves two cinnamate molecules joined by malonil-CoA (Kuzuyama et al., 2005; Rocks et al., 2012).

Rudrappa and Bais (2008) analyzed the effects of curcumin on the virulence of a *Pseudomonas aeruginosa* strain through *in vitro* assays for virulence factors production and tests in pathogenicity models using *Arabidopsis thaliana* and *Caenorhabditis elegans*. Curcumin inhibited the expression of virulence factors such as biofilm, pyocyanin, elastase, protease, and acyl homoserine lactone production, resulting in reduced pathogenicity of the strain. Transcriptomic analysis of the treated strain showed downregulation of quorum sensing genes. Kaur et al. (2010) also described a mechanism for the antimicrobial activity of curcumin in *Bacillus subtilis* and *Escherichia coli*, which relies on growth inhibition by blocking the

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

assembly of the cytoskeletal FtsZ protein, involved in prokaryotic cell division and present in several bacterial species.

The possible synergism of mitomycin C and curcumin was studied by Zhou et al. (2011) in order to suppress human breast cancer *in vitro* and *in vivo.* Experiments were performed through assessing cell cycle phases of MCF-7 cells with flow cytometry. Tumor growth and cell cycle-associated protein expression were also monitored. It was seen that curcumin inhibited MCF-7 breast cancer cell viability in a concentration-dependent manner, and IC_{50} value was of 40 μmol/L.

Chhunchha et al. (2011) investigated the mechanisms involved in the antioxidant activity of curcumin, exploring peroxiredoxin 6 pathway, an anti-ROS pleiotropic oxidative stress-response protein, via specificity of protein 1 activity, against proapoptotic stimuli. Molecular analyses indicated that curcumin enhanced specificity protein 1 and peroxiredoxin 6 mRNA and protein expression in a concentration-dependent manner and downregulated ROS-mediated apoptosis by blunting ROS expression and lipid peroxidation. Curcumin could not activate peroxiredoxin 6 expression in the presence of specificity protein 1 inhibitors, suggesting that curcumin increased expression of peroxiredoxin 6 in a dependent way of specificity protein 1 activity.

Rocks et al. (2012) studied the effects of curcumin complexes with cyclodextrin alone or in combination with gemcitabine on the growth of orthotopically implanted lung tumors *in vivo*. Tumors were monitored on 7, 10, 14, 18 and 21 days after cell injection. Tumors development was almost completely abolished when mice were treated by the association with gemcitabine. The association of curcumin–cyclodextrin-gemcitabine resulted in a two-fold reduction of proliferation index in mouse lung tumours when compared to mice treated with the vehicle alone or non-soluble curcumin.

Diosmin

Diosmin ($C_{28}H_{32}O_{15}$) is a flavone originally isolated from *Teucrium gnaphalodes,* and is quite abundant in citric fruits, with concentrations ranging from 17.8 to 245 mg/100 g. This flavonoid is hydrophobic and has a melting point of around 274 ºC, being obtained via dehydrogenation of hesperidin,. Its half life is of around 11 hours, being mostly eliminated (80%) in stool. Diosmin has anti-inflammatory, venotonic vasoprotective effects, being the latest ones associated to the extension of norepinephrin activity in veins, increasing the venous tonus and the intensity and frequency of contractions in the lymphatic vessels (Bae et al., 2000).

Studies of antimicrobial activity of diosmin are, curiously, rare. Bae et al. (1999) described the anti-Helicobacter pylori activity of varied flavonoids, and in their study, the minimum inhibitory concentration of diosmin was higher than 100 μg/mL. Later, Bae et al (2000) assessed the antiviral activity of several flavonoids, and the inhibitory effects of diosmin in cell lines infected wih rotavirus was reached with 10 μg/mL.

Regarding its antioxidant activity, Akroum et al. (2010) described effective free radical scavenging activity of diosmin in the DPPH assay, reaching 50.35% activity at 10 μg/mL. Also, the effect of diosmin in oxidative stress in streptozotocin-nicotinamide induced diabetic rats was studied by Srinivasan and Pari (2012) through assessing lipid peroxidation and ameliorative properties. Diabetic animals had increased plasma glucose concentration with significant decrease in plasma insulin levels. The activity of superoxide dismutase, catalase, glutathione peroxidase and glutathione-S-transferase were reduced. The levels of vitamins C, E and reduced glutathione decreased while lipid peroxidation markers increased in

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

liver and kidney tissues of diabetic control rats, when compared to healthy control rats. The oral treatment with diosmin showed ameliorative effects on the analyzed biochemical parameters.

Barreca et al. (2013) demonstrated that diosmin binding to human serum albumine can contribute to protect it against degradation. Fluorescence experiments indicated that the binding site of the flavonoid involved modifications around Trp214 at the subdomain IIA. A decrease in α-helix structure following flavonoid binding was also detected. *In silico* analyzes suggested that the primary binding site of diosmin was located in a microenvironment able to stabilize the binding of the ligand in non-planar conformations, known as Sudlow's site I.

Using animal model of Wistar rats, Tahir et al. (2013) described the effect of diosmin on attenuation of hepatic toxicity induced by 2-acetylaminofluorene and, the chemopreventive efficacy of the flavonoid against hepatocarcinogenesis induced and increased by diethylnitrosamine and 2-acetylaminofluorene, respectively. The protective effect of diosmin was demonstrated by reductions of visible hepatic nodules, restoration of early tumor markers such as Ki67 and ODC, and reductions of serum cytotoxicity enzyme markers AST and ALT, oxidative stress biomarkers, cell necrosis markers like TNF-α and inflammatory enzymatic markers COX-2 and iNOS.

Epigallocatechin

This polyphenol of molecular formula $C_{22}H_{18}O_{11}$, is available at higher levels in the leaves of *Camelia sinensis* (around 7400mg/100 g as green tea, and around 4300 mg/100 g as white tea). It can also be found in lower concentrations in the skin of apples, plums, onions, walnuts and hazelnuts. This flavonoid is characterized as a white to pink powder, with melting point around 218 ºC. Different from other flavonoids, it is soluble in water, and also in ethanol and DMSO (Assis et al., 2015).

Lipson et al. (2015) recently used epigallocatechin against rotavirus. After 3 days in culture, pure epigallocatechin concentrations of 80, 160, and 320 μg/mL reduced the virus infectivity titer levels to 50, 20, and 15% of the control, respectively. No cytotoxicity was detected in the concentrations used.

To increase the antimicrobial activity and stability of epigallocatechin, Sun et al. (2011) complexed the flavonoid with Cu^{+2} into polyvinyl alcohol nanofibers. MICs of the complex against different bacteria and yeasts ranged from 8 to 600 ug/mL, and high values of MIC are related to *S. cerevisiae* and *C. albicans*. The bactericidal activity of the complex against *E. coli* and *P. nitroreducens* was not significantly weaker than that against Bacillus cereus and *B. subtilis.* The activity against *S. aureus* was lower than that against the other bacteria (including Gram-negative).

Nevertheless, epigallocatechin was not effective in eliminating *Streptococcus mutans* from dentin caries-like lesions. Assis et al. (2015) evaluated the efficacy of epigallocatechin at 0.5%, 1%, and 2% concentrations in an in vitro model of dentin caries-like lesions. When compared, chlorhexidine digluconate, an antimicrobial molecule widely used against caries, the antimicrobial efficacy of epigallocatechin was significantly lower against the tested *S. mutans* strain.

Harpole et al. (2015) investigated the effects of epigallocatechin against SK-OV-3 ovarian cancer cell line model, aiming to explore antioxidant exposure to slow the progression of the disease. A statistically significant increase in nitric oxide following the administration of epigallocatechin alone and in combination with thymoquinone was detected at 24, 48 and 72 hours, being approximately three times higher than the control.

Considering that high doses of epigallocatechin can induce toxicity in the liver, kidneys, and intestine, Cai et al. (2015) investigated the proliferation and apoptosis of H9C2 cardiomyocytes treated with

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

high doses of epigallocatechin. Using the CCK8 and TUNEL assays, and western blotting detection of alterations of Sirtuin 1 (SIRT1), it was seen that different from other organs, epigallocatechin inhibited H9C2 cardiomyocytes proliferation and induced apoptosis in a time-dependent and dose-dependent way. The downregulation of SIRT1 protein expression is possibly involved in this mechanism.

Hesperidin

The name "hesperidin" is derived from the term "hesperidium", which means "fruits produced in citric trees". Hesperidin ($C_{28}H_{34}O_{15}$) is able to inhibit LDL oxidation and thus, prevent atherosclerotic plaque growth. It is also able to inhibit the intestinal absorption of cholesterol and increase its hepatic catabolism. It is usually the most abundant molecule among the flavonoids present in lemon or orange. Hesperidin is hydrophobic, of pale yellow color and with melting point ranging from 262 to 258 ºC (Wilcox et al., 2001).

Abuelsaad et al. (2013) performed susceptibility tests through agar-diffusion against *Aeromonas hydrophila.* Hesperidin was tested in the concentrations of 100, 50, 25, and 12.5 mg/ml. The concentration of 100 mg/ml was the most effective in reducing bacterial growth. Using borth microdilution, authors investigated minimal inhibitory concentrations (MIC) and minimal bactericidal concentration (MBC). Hesperidin MBC was of 12.500 μg/mL and MIC was of 3.125 μg/mL. Similarly, Abass et al. (2014) assessed the antimicrobial activity of crude extracts of orange peels, rich in hesperidin, against *Bacillus subtilis, Staphylococcus aureus, Streptococcus pyogenes, Escherichia coli* and *Salmonella typhi* by agar diffusion. The extract was effective mostly against *B. subtilis* (45 μg/mL), and E. coli (75 μg/mL), and less effective against *S. typhy* and *S. aureus* (175 μg/mL)

In one of the first studies with commercial formulations of phytomolecules of nutraceutical importance, using animal (rats) model, Damon et al. (1987) administered hesperidine tablets (Daflon® 500 mg) by gastric intubation for a period of 26 weeks. There were no deaths, no alteration of weight and standard functional tests had no modifications.

Bigoniya & Singh (2014) investigated the anti-ulcer potential of hesperidin through evidences of histological analyzes of its antioxidant activity in mucosal tissue of the stomach. Ulcers were induced with indomethacin (oral doses of 150, 300 and 450 mg/kg) and hypothermic restrain stress. At the doses of 300 and 450 mg/kg, hesperidin induced pH increase, with histological evidences of cytoprotection. Glutathione, super oxide dismutase and catalase, important antioxidant enzyme systems, and mucin levels (for tissue protection) increased significantly at 450 mg/kg. Thus, the antioxidant, mucoprotective and cytoprotective effects of hesperidin are strongly associated to its anti-ulcer properties.

Using a murine model, Man et al. (2015) demonstrated that topical applications of hesperidin improved epidermal functions in aged skin. Hesperidin did not stimulate epidermal proliferation, but decreased the pH in aged skin. Slight increase in transepidermal water loss rates (however ranging within normal loss rates of a healthy skin) was detected in treated skin, and accelerated barrier recovery was detected at 2 and 4 hours after the treatment. The expression of filaggrin, involucrin, and loricrin genes, all trivial for skin integrity, was increased in adult keratinocytes cultures treated with hesperidin. Topical hesperidin increased the levels gene expression of HMG-CoA and FAS in aged skin.

Resveratrol

Resveratrol ($C_{14}H_{12}O_3$) is a stilbene (3,5,4′-trihydroxystilbene) produced by several unrelated plant species like blackberry, ginger, blueberries and grapes, in response to injury, ultraviolet irradiation, micro-

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

bial infections and other stressing conditions. Takaoka (1939) isolated this flavonoid for the first time from the roots of *Veratrum grandiflorum*. This flavonoid is also present in processed products based on grape and wine, appearing in other foods at lower concentrations. It is poorly soluble in water and is described as a yellowish-white powder, with melting point ranging from 261 to 263 ºC. The molecule exists as cis- (Z) and trans- (E) diastereomers. The (E) diastereomer is the form in which resveratrol is found in nature. When exposed to ultraviolet irradiation, resveratrol can undergo isomerisation to the (Z) form.When administered orally, less than 5% of the flavonoid can be found in blood plasma. Among its biological activities, important anti-inflammatory mechanisms comprise the modulation of NF-κB and inhibition of action and expression of cyclooxygenases (COX). It has been described that resveratrol can also induce apoptosis, indicating its antiproliferative potential (Chen et al., 2012; Kumar & Pandey, 2013; Fremont, 2014).

Hwang & Lim (2015) investigated the mechanisms of the antimicrobial potential of resveratrol over E. coli species. It was seen that the production of reactive oxygen species (ROS) increased in the strains, although cell growth was not recovered by ROS quenching. Thus, ROS formation and cell death were not directly correlated to resveratrol treatment. DNA fragmentation increased in cells, and cell elongation was also observed. FtsZ, an essential cell-division protein involved in cell elongation in prokaryotes, had its gene expression and its formation strongly inhibited in *E. coli* strains.

A recent mechanism of the antifungal activity of resveratrol against *C. albicans* yeasts was proposed by Lee & Lee (2015). Interestingly, resveratrol can induce apoptosis in clinical isolates of *C. albicans*, as shown by the loss of mitochondrial membrane potential, an important event in resveratrol-induced apoptosis. Resveratrol also activated metacaspase and promoted cytochrome c release, confirming the apoptosis-induced mechanism.

Resveratrol is effective in scavenging free radicals to prevent LDL oxidation (Chang et al., 2011), and as an effective *in vivo* inhibitor of cyclooxygenase activity, resveratrol can significantly reduce oedema, osteoarthritis, airway inflammation, and can also prevent allograft rejection (Elmali et al., 2005Wu et al., 2005 a and b). In this context, the elegant study of Park et al. (2012) provided data on a new pathway in which resveratrol directly inactivates phosphodiesterase enzymes, indicating that the metabolic effects of this flavonoid are result of competitive inhibition of cAMP-degrading phosphodiesterases, leading to elevated cAMP levels and to a signaling cascade that activates situin 1.

The antiproliferative activity of resveratrol is also widely recognized. Reis-Sobreiro et al. (2009) analyzed the antimyeloma and antileukemia potentials of resveratrol. The flavonoid induced apoptosis in multiple myeloma and leukemia T-cell through coclustering of Fas/ CD95 death receptor and lipid rafts. Resveratrol-induced disruption of mitochondrial transmembrane potential was inhibited by a FADD dominant negative mutant by downstream signaling of Fas/CD95 blockage. This mechanism also inhibited apoptosis induced by resveratrol. Cells deficient in Fas/CD95 did not undergo resveratrol-induced apoptosis.

Frampton et al. (2010) assessed the antiproliferative effects of resveratrol on cholangiocarcinoma cells, in combination to chemotherapeutic drugs. Cholangiocarcinoma cell lines were treated with resveratrol and following, with 5-fluorouracil, gemcitabine, or mitomycin C. The combined treatment with resveratrol decreased cell proliferation and increased apoptosis in all in vitro assays, and more extensively than any of the chemotherapeutic drugs alone.

Scherzberg et al. (2015) studied the antiproliferative effect of the a methylated resveratrol analog Z-TMS [(Z)-3,5,4'-Trimethoxystilbene] over varied cancer cell lines, and compared the analog molecule results to pure resveratrol. Flow cytometric analysis revealed a G2/M cell cycle phases arrest after Z-TMS

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

treatment, whereas resveratrol caused S phase arrest. Furthermore, Z-TMS impaired tubulin and microtubule polymerization, and no beneficial effects on lipid accumulation were observed for this molecule. The lacking beneficial metabolic effects of Z-TMS were assigned to a possible loss of activity on genes that may have the expression regulated by resveratrol.

Rutin

Rutin ($C_{27}H_{30}O_{16}$) has been described to be an effective angiogenesis inhibitor that is also able to block vascular endothelial growth factor (VEGF), what can potentially contribute to the control of some types of cancer. This flavonoid is present in fig, apples and wheat, and is usually presented as a solid yellow to white powder of melting point around 242 °C, being more soluble in methanol than in water. Other pharmacological properties described for rutin comprise anti-inflammatory activity and platelet aggregation inhibition, decreasing capillary permeability and improving microcirculation. These potentials contribute to prevent clots formation and thus, prevention of infarcts and strokes (Haslan, 1996; Ugusman et al., 2014).

Interestingly, the antimicrobial activity of rutin is still controversial somehow. Singh et al. (2008) identified rutin as the major flavonoid in *Pteris vittata* (Brake Fern). Hydromethanolic extracts of *P. vittata* (70, 80, and 90%) were tested against Gram-negative bacteria, and the 70% extract was the most effective against *Pseudomonas aeruginosa* and *Klebsiella pneumoniae*. Orhan et al. (2010) reported antimicrobial activity of rutin against MRSA, *E. coli, P. mirabilis, K. pneumoniae, P. aeruginosa* and *A. baumannii*. However, no activity was observed for rutin against Gram-negative bacteria in the study of Alves et al. (2013).

Ananth et al. (2015) developed thioglycolic acid-capped cadmium telluride quantum dots (TGA-CdTe QDs) and conjugated them to rutin, aiming to enahnce its antimicrobial activity. These complexes were tested against *E. coli*. Adsorption of conjugated QDs on cell wall and its penetration through porins were described as the main possible mechanisms of action of the antimicrobial activity of the complex. QDs also induced stable oxidative stress by ROS production, what contributes to increase the membrane permeability.

Rutin is mostly recognized for its potent antioxidant and anti-inflamatory activities, control of high blood pressure, protection of UV–radiation and mainly, its ability to decrease capillary fragility (Ugusman et al., 2014). Also, effects on bone resorption have been studied. Using a cell culture of bone marrow cells isolated from 4-5-week-old C57BL/6J mice, Kyung et al. (2008) described the effect of rutin on osteoclast formation. Rutin inhibited osteoclast formation induced by receptor activator of NF-κ B ligand (RANKL) at an early stage by reducing levels of ROS and TNF-α, which are elevated via RANKL. Rutin also lowers NF-κ B activation in response to RANKL.

Rutin contains disaccharide moieties and is generally better distributted on the body than other flavonoids. Choi et al. (2013) investigated the mechanisms of rutin and its direct targets involved in reduction of COX-2 expression in JB6 P+ cell lines by benzo[a]pyrene-7,8-diol-9,10-epoxide (B[a] PDE), its active metabolite. AP-1 and NF-kB activities (at DNA level) were mediated by the activation of MAPK-signaling pathways when induced by B[a]PDE, involving ERK, JNK, and p38 proteins. Thus, the transactivation of AP-1 and NF-kB was inhibited, an important mechanism of downregulation that affects the immune system. Rutin suppressed phosphorylation of ERK and upstream kinases such as MEK and Raf induced by B[a]PDE. Akt phosphorylation induced by B[a]PDE was suppressed in JB6

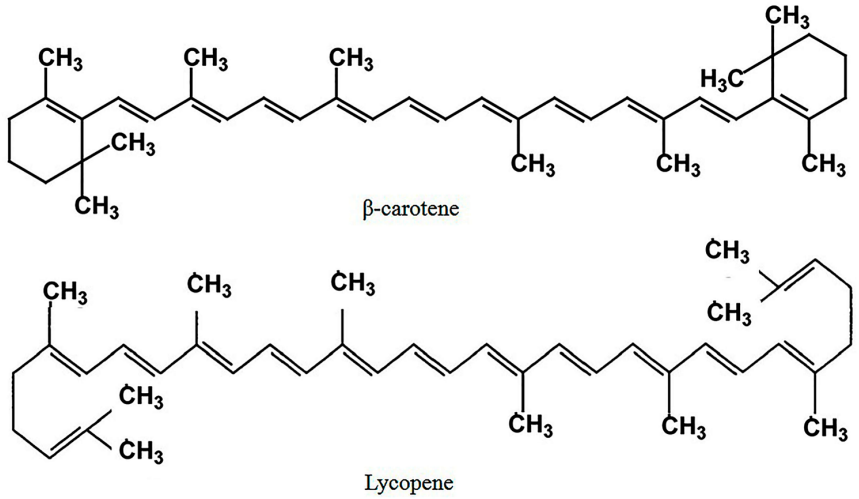
EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

P^+ cells as well. Although rutin reduced B[a]PDE-induced Raf/MEK/ERK and Akt activation, it had no effect on the phosphorylation of the epidermal growth factor receptor (EGFR). Even $EGFR^{-/-}$ mouse embryonic fibroblast cells had COX-2 expression diminished after exposed to B[a]PDE. EGFR appeared to be directly targeted by rutin, and the suppressive effect on COX-2 expression is likely to be mediated by Raf/MEK/ERK and Akt signaling.

Xu et al. (2014) studied the effects of rutin in the clinical evolution of Alzheimer's disease (AD) in a murine model, and proposed the use of this molecule in AD treatments. Orally administered rutin attenuated memory deficits in AD-induced mice, and decreased the levels of oligomeric extracellular β-amyloid (Aβ) plaques. Super oxide dismutase (SOD) activity and glutathione (GSH)/glutathione disulfide (GSSG) ratio were increased, demonstrating its antioxidant activity in the central nervous system. Rutin also reduced GSSG and malondialdehyde (MDA) levels, downregulated microgliosis and astrocytosis, and decreased interleukin (IL)-1β and IL-6 levels in the brain, indicating its anti-inflammatory neuroactivity. The pretreatment with rutin reduced the activity of hepatic transaminases and improved the histological signs of acute liver damage in intoxicated mice. Rutin was effective in the suppression of nitrotyrosine formation, but had weak effects in attenuation of the inflammation in the liver, as indicated by measurements of nuclear factor-kappa B (NF-κB), tumor necrosis factor-α (TNF-α) and cyclooxygenase (COX-2). The expression of inducible nitric oxide synthase (iNOS) was potently suppressed by rutin. Thus, protection against nitrosative stress and hepatocellular damage can be effectively achieved by rutin, in spite of the weak antioxidant and anti-inflammatory activities.

Carotenoids: Lycopene and β-Carotene

Carotenoids are widespread natural pigments (mostly yellow, orange, red, salmon and other variants), and almost all are from the family of terpenoids (tetraterpenes). They can be found in plants, bacteria, fungi, yeasts, algae, and non-mammalian animals. More than 700 different carotenoids have been isolated from natural sources, including some molecules with hydrophilic profile, and more than 600 molecules are fully characterized.



Carotenoids photoprotection and the antioxidant potential for preventing cancer, scavenging of reactive species and diseases of the eye remain important active fields of investigation. Also, carotenoids may boost the immune system by increasing the number of white blood cells. On the other hand, rare studies have demonstrated antimicrobial potentials for this chemical group. Until the time of preparation of this chapter, the exact mechanisms of these biological potentials of carotenoids remain unknown.

In humans, the role that carotenoids play in protecting those tissues that are most heavily exposed to light is the most explored. Oral photoprotection formulations, for instance, are already commercially available. β-carotene, α-carotene, lutein, zeaxanthin and β-cryptoxanthin are major carotenoids detected in human blood and tissues; nevertheless, β-carotene and lycopene are the most studied carotenoids, and the most used for nutraceutical purposes. Thus, certain aspects of these molecules will be more explored here (Figure 3).

Lycopene is a red pigment found in plant food like tomatoes, guava and watermelon. This molecule consists in a long acyclic chain of chemical formula $C_{40}H_{56}$. It is usually presented as a dark red hydrophobic solid with melting point ranging between 172 and 173 ºC. Lycopene can be found in foods such as tomatoes in an average of around 3.31 mg/100 g, and papaya, in an average of around 3.39 mg/100 g. (Hark & Deen, 2005).

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Structure of β-carotene and lycopene
Authors' personal archive.

Lycopene levels in vegetables are usually analyzed through spectrophotometric techniques, however, it can be measured indirectly through chromaticity values obtained via colorimetric analysis. This last technique, nevertheless, is recommended for plants with high production of Lycopene.

The synthesis of lycopene and its decomposition are quite pronounced during the ripening of fruit, and at temperatures above 30 °C, the synthesis is inhibited, but it can be reversed as the vegetable return of to lower temperatures. External factors such as pH, temperature and oxidation, can influence the stability of carotenoids.

β-carotene is commonly found in many vegetables, fruits and plants such as carrots. The molecule also has molecular formula $C_{40}H_{56}$. When the cyclisation of lycopene occurs at both ends of the molecule, β-carotene is then formed. It is presented as an orange or red-to-purple solid with a density ranging from 0.935 to 0.947 g/cm^3 and has melting point ranging from 180 to 182 ºC. The molecule is hydrophobic and very slightly soluble in methanol.

β-carotene is a precursor of liposoluble retinol. A significant part of the formation of retinol metabolism occurs in the gastrointestinal mucosa, being its absorption pH sensitive. β-carotene is also able to enhance the induction of CYP2E1, important in the metabolism of several drugs. Its average concentration in carrots usually reaches around 7 mg/100 g.

Because the bioavailability of β-carotene is very variable among people, Borel et al. (2015) investigated the possible effects of variations in genes involved in β-carotene absorption and postprandial metabolism on this variability on the bioavailability of the carotenoid. Single-nucleotide polymorphisms (SNPs) were genotyped with the use of whole-genome microarrays. A total of 33 healthy and nonobese adult men were enrolled. After an overnight fast, patients consumed a test meal containing 100 g tomato paste with 0.4 mg β-carotene. Postprandial plasma chylomicron β-carotene concentration was then measured at 8 h intervals, and 54 genes representing 2172 SNPs were investigated. The postprandial chylomicron β-carotene response was highly variable and positively correlated to the fasting plasma β-carotene concentration. A total of 25 SNPs in 12 genes affected the long-term blood β-carotene status and thus, explained (69%) of β-carotene bioavailability variance.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Horváth et al. (2015) proposed that carotenoids might modulate transient receptor potential ankyrin 1 and vanilloid 1 (TRPA1 and TRPV1) activation predominantly on peptidergic sensory nerves, considering that carotenoids are incorporated into membranes. β-carotene, lutein and lycopene were used in a murine model of cutaneous neurogenic inflammation, induced by mustard oil and capsaicin. Administration of 100 mg/kg subcutane lutein or β-carotene (three times during 24 h) resulted in significant swelling reduction, and Lutein decreased neutrophil accumulation induced by TRPA1 activation, although mustard oil-evoked intestinal contraction was not influenced. Curiuously, lycopene had no effect in none of the tested parameters. None of the three carotenoids could overcome capsaicin-evoked inflammation.

Woodside et al. (2015) investigated the possible benefits of anti-inflammatory and antioxidant properties on the risk of diseases that predominate in older people. Authors suggested that carotenoid intake and status are associated with reduced risks of cardiovascular diseases, although β-carotene supplementation increases the risk of lung cancer and does not reduce the risk of cardiovascular diseases. Increased lycopene intake may reduce prostate cancer progression.

Photoprotective effects of these carotenoids are still in debate. Stahl & Sies (2012) reviewed the topic and provided evidence that a carotenoid-rich diet or carotenoid supplementation might have photoprotective benefits through scavenging of ROS. Considering that carotenoids are part of a complex blend nutrients in food, other components can contribute to this effect. As expected, photoprotection through dietary intake of β-carotene or lycopene is lower than the achieved by topical sunscreens. the combination of both strategies, however, increases skin protection against UV irradiation and contributes to preserve skin health and appearance.

Ascenso et al. (2014) proposed that lycopene modulation of gap-junctional communications, involved in cell growth and molecular signalling of proliferation and apoptosis through proteic channels such as connexin 43, are important in cell cycle dynamics and for carotenoids behaviour as cellular anti-oxidants *in vivo*. Fernández-García (2014) assessed the antioxidant effect of lycopene alone or combined to α-tocopherol or naringenin on human dermal fibroblasts (hdf) exposed to ultraviolet-A light. UVA irradiation led to reduced cell viability in a dose dependent manner, and similar effects were observed when cells were exposed to lycopene. However, this reduction was suppressed in the presence of naringenin. α-tocopherol had no effect in this parameter. Lycopene combined to naringenin was able to inhibit ROS formation and increased the stability of the carotenoid. Thus, combinations of dietary antioxidants might be more effective than the sole use of lycopene.

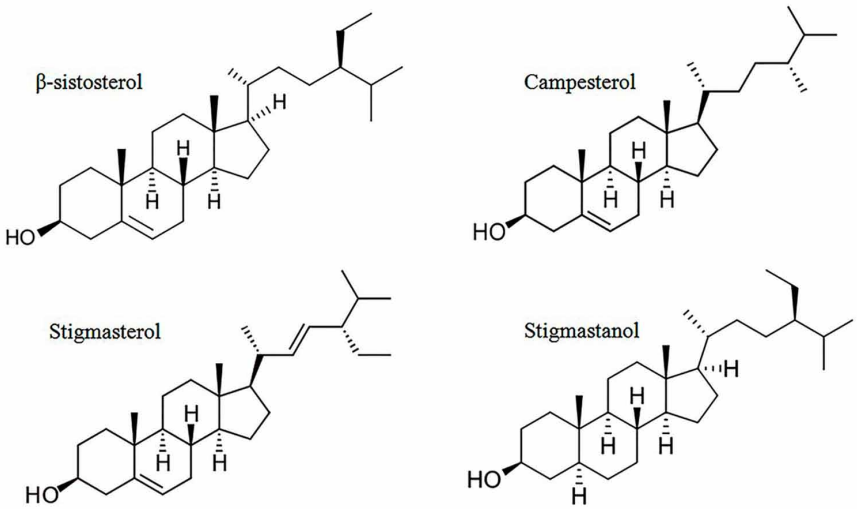
Nevertheless, the work of Sokoloski et al. (2015) reported that lycopene regular intake in pills or tomato paste, although safe and with no side effects, did not provide systemic photoprotection against ultraviolet-B light. A total of 20 subjects using lycopene pills or tomato paste received only ultraviolet B irradiation and the variation of color was compared to normal skin after 24 h. Evaluations were made at baseline and after 4, 8, and 10 weeks. Conversely, no difference was detected in the mean of minimal erythematous dose at baseline between groups.

Phytosterols

In the latest years, several pharmacological potentials of phytosterols have been described, including cardiovascular protection, antiproliferative and antimicrobial effects and lipid metabolism improvement. However, they still lack of evidence generated in clinical studies. Currently, most of their biological activities have been demonstrated *in vitro*, one of the reasons that explains the controversial status of most of the existing investigations. Also, nutraceutical formulations developed with these molecules are

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

scarce, but several types of food are enriched with these compounds, such as dairy products. Phytosterols are of abundant occurrence in plant and marine species, and are hydrophobic white crystalline solids. Phytosterols present from twenty-seven to twenty nine carbon atoms resembling the cholesterol molecule. These can be distinguished by the arrangement of the nucleus, the structure and composition of the side chain and by polar moieties of the molecule (Robbers et al., 1997; Brafau et al., 2008).



The biosynthesis of these compounds usually begins with Coenzyme A generating mevalonate. A set of similar reactions pathways is observed in phytosterols when compared to the synthesis of terpenes. Due to structural characteristics very similar to those of cholesterol, phytosterols are able to perform common cellular functions of cholesterol by interfering in membrane fluidity and water permeability. They can also act as phytormones precursors (Robbers et al., 1997; Thomas et al., 2006).

Phytosterols may be found in foods with high levels of lipids such as sesame seeds, walnuts and peanuts, as well as being present in some vegetables, grains and fruits. These compounds make up part of the unsaponifiable fraction of vegetable oils. In soy and corn, phytosterols might be detected in up to 330 and 970 mg/100g of total oils, respectively (Thomas et al., 2006) (Figure 4).

Monu et al. (2008) investigated the potential antimicrobial activity of a commercial formulation of phytosterols (ss-sitosterol, campesterol, sitostanol, and campestanol) in milk and their effect on yogurt starter cultures. No antimicrobial effect was detected on plate count or on psychrotroph population in pasteurized milk stored at 4 °C. A microbial challenge test of the formulation using *Pseudomonas spp*., *Saccaromyces cerevisiae* and *Aspergillus ochraceous*, in cold milk, confirmed that the blend of phytosterols had no antimicrobial activity. The formulation also had no effect on the growth of *Lactobacillus bulgaricus* and *Streptococcus thermophilus* during yogurt production. When combined to dispersing agents, the formulation presented some antimicrobial effects.

Mahmood et al. (2013) studied the effects antimicrobial activities of β-sitosterol complexed to Cu (II), Co (II), and Fe (III), important trace elements in the human organism. All the complexes presented antimicrobial potential against highly pathogenic bacterial and fungal species. More recently, a group headed by the same author described the complexation of β-sitosterol with Palladium (Pd) (Mahmood

Figure 4. Structures of major phytosterols
Authors' personal archive.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

et al., 2015). This complex showed significant antibacterial and antifungal activity, being superior to the previous ones.

Ramprasath & Awad (2015) recently reviewed the biological potentials of phytosterols. Although the mechanisms of action remain to be elucidated, improvements in blood lipid profile have been described as the main pathway to its cardioprotective effects. However, the levels of phytosterols in natural diets might range from less than 60 mg to more than 500 mg/2000 Kcal, and in an optmistic perspective, they might reduce only 3-14% LDL levels, what suggests the urgent need of phytosterols-based nutraceutical formulations (Racette et al., 2015). Reductions in growth of various cancer cells have been demonstrated, and mechanisms such as inbihition of cell growth and multiplication, reduction of angiogenesis and impairment of tissues invasion and metastasis, have been proposed to explain its antiproliferative activity (Ramprasath & Awad, 2015).

Ravikumar et al. (2009) isolated both α-spinasterol and spinasterol from a petroleum ether extract fraction of *Polyalthia cerasoides* seeds, and tested them against Caco-2 cell line. These molecules exhibited antiproliferative potential at different concentrations, and IC50 was of 57.7±6.81 nM/mL for spinasterol and 60.0±7.10 nM/mL for α-spinasterol. Carange et al. (2011) analyzed the protective potential of 24-epibrassinolide, a natural brassinosteroid (a type of phytosterol with potential of inducing stress tolerance of vegetables) in an *in vitro* model of Parkinson's disease. Neuronal PC12 cells were treated with 1-methyl-4-phenylpyridinium, which induced oxidative stress and consequent apoptosis in dopaminergic neurons. The treatment with the phytosterol reduced the levels of intracellular ROS and modulated the activity of antioxidant enzymes such as superoxide dismutase, catalase, and glutathione peroxidase. 24-epibrassinolide also inhibited apoptosis by reducing DNA fragmentation as well as the Bax/Bcl-2 protein ratio.

On the other hand, Cilla et al. (2015) tested the antiproliferative effect of β-cryptoxanthin and phytosterols (β-sitosterol, campesterol and stigmasterol) against human colon cancer Caco-2 cells. The molecules showed no antiproliferative activity against Caco-2 cells, nor alone nor in combination. Caco-2 cells were treated with β-cryptoxanthin and/or phytosterols alone or in combination, at concentrations commonly detectable in human serum levels. Decreased cell viability was detected due to apoptosis, which was followed by dephosphorylation of BAD enzyme, mitochondrial depolarization and caspase 3-dependent PARP receptor cleavage. Also, intracellular Ca^{+2} influx and increased ROS/RNS levels were detected.

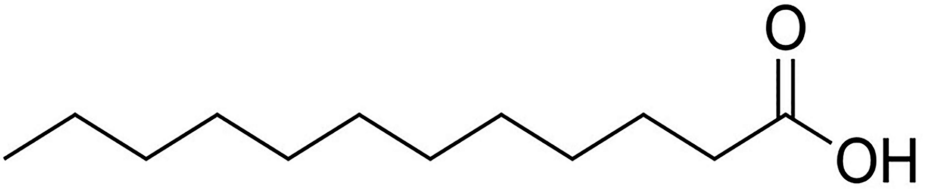
Lauric Acid

Lauric acid, also known as dodecanoic acid, is a fatty acid of structural formula $CH_3(CH_2)_{10}CO_2H$. Lauric acid is available mainly in coconut oil (from 43 to 53% of total fatty acids), palm kernel oil (40 to 52%) and in smaller fractions in other food, such as 5.8% of the total milk fat, 2.2% of total cow's milk and 4.5% of the fat present in goat's milk. The biosynthesis of this acid occurs through a reverse β-oxidation. Generally, it is presented as a hydrophobic white solid, with slight soap-like odor and lacking uniformity. It has an approximate density of 0.88 g/cm^3, and melting point ranging between 44 and 46 ºC.

Lauric acid can activate the release of interleukin 2 and stimulate the bone marrow to produce white blood cells. The anti-inflammatory potential of lauric acid is belived to be associated to local inhibition of prostaglandin E_2 (PGE_2) and Interleukin 6 synthesis, pro-inflammatory mediators in arthritis, rheumatism and muscle inflammation. Upon arriving in the intestine, it is metabolized by lipases to monolaurin, which is absorbed and has the ability to solubilize virus capsules, causing its destruction, what indicates

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

its antiviral properties. Lauric acid induces the opening of cell membranes allowing glucose and insulin levels to normalize. It is also able to balance HDL levels and to reduce LDL oxidation (Figure 5).



Rouse et al. (2005) combined lauric acid monoesters to lactic, mandelic, malic, or benzoic acid, and evaluated them against MRSA in a murine model of nasopharyngeal colonization. Administration of the molecules 128774-49E or 128774-53A was associated to reduction of MRSA carriage in 71% and 83% of animals, respectively. Administration of the compound 128774-53A resulted in 50% more reduction of MRSA carriage than mupirocin. Also, in vitro experiments were performed to assess the antimicrobial activity of 13 lauric acid monoester formulations and mupirocin against 30 methicillin-susceptible *S. aureus* (MSSA) isolates and 30 (MRSA) isolates. MSSA and MRSA MIC90 values were 0.25 µg/mL for mupirocin and ≤4 µl/ml for all LAM formulations tested.

Skrivanová et al. (2005) determined the susceptibility of *Clostridium perfringens* strains to C(2)-C(18) fatty acids. Among the tested molecules, lauric acid showed the highest antimicrobial activity, followed by myristic, capric, oleic and caprylic acid. Cultures of *C. perfringens* strains treated with capric and lauric acid at pH 5.0-5.3, the number of viable cells was very reduced; however, only lauric acid reduced the number of viable cells of the strains below 10(2) ml(-1) at pH > 6. The proposed mechanism of action for lauric acid was separation of inner and outer membranes, and cytoplasma disorganization, suggesting its use for controling of clostridial infections.

Nakatsuji et al. (2009) demonstrated that lauric acid can be used to treat acne. This compound showed antimicrobial activity against clinical isolates *of Propionibacterium acnes, Staphylococcus aureus* and *Staphylococcus epidermidis*, both *in vitro* and *in vivo* (using a murine model). Lauric acid yielded minimal inhibitory concentration (MIC) values against more than 15 times lower than those of benzoyl peroxide (a molecule highly used in topical formulations) in the tested species. *P. acnes* was the most sensitive bacteria to lauric acid among the tested species. No cytotoxicity was detected in human sebocytes exposed to lauric acid. *In vivo*, intradermal and epicutaneous applications of lauric acid decreased the count of *P. acnes* isolated from mouse ears.

The antinflammatory potential of lauric acid has been explored in the latest years. The classical study of Henry et al. (2002) described high inhibitory activity of lauric acid over cyclooxygenase enzymes COX-I and COX-II at 100 µg/mL. Further, Fauser et al. (2013) compared lauric acid (C12:0) and butyrate (C4:0) regarding their potentials to induce apoptosis, modify glutathione levels, generate ROS and modify phases of the cell cycle in Caco-2 and IEC-6 cancer cell lines. Lauric acid was more potent to induce apoptosis in Caco-2 and IEC-6 cells when compared to butyrate. In Caco-2 cells, lauric acid was more efficient to reduce GSH availability and in generation of ROS when compared to butyrate. Also, butyrate protected IEC-6 cells from ROS-induced damage, but lauric acid induced high levels of ROS when compared to butyrate.

Glucosinolates

Glucosinolates are generally found in plants with spicy flavor such as leaves and roots of the turnip and mustard seeds, and in vegetables like broccoli and cauliflower. This effect is mostly perceived when these plants are chewed. Most of glucosinlates are water soluble, and when plants suffer mechanical damage, 60 to 80% of total glucosinolates are converted into sulfurano-nitrile compounds. When cooking, the enzyme miriosinase is denatured and glucosinolates can be absorbed with no chemical alteration, being converted into sulforaphane only in the intestines after exposed to bacterial tioglucosidases. Most of the glucosinolates are excreted in the form of N-acetyl-cysteine. among others (Nastruzzi et al., 2000) (Figure 6).

Leoni et al. (1997) investigated the antiproliferative effects of glucosinolates and their isothiocyanate-derived products on K562 (erythroleukemic human) cells. Strong inhibitory activity on K562 cells growth was detected for sinigrin, progoitrin, epi-progoitrin, glucotropaeolin and glucocheirolin. Later, researches conducted by this group (Nastruzzi et al., 2000) described the effects of isothiocyanates and several glucosinolates-derived nitriles (epi-progoitrin, glucocheirolin, glucoraphenin, glucotropaeolin and sinalbin) in an *in vitro* model of colorectal cancer using K562 cells. Isothiocyanates were more potent to inhibit cancer cell growth than the glucosinolates-derived nitriles epi-progoitrin, glucotropaeolin, glucoraphenin, and glucocheirolin.

Lampe and Peterson (2002) reviewed the effects of genetic polymorphisms on the chemoprotective properties of cruciferous vegetables against different types of cancer. This pharmacological activity of cruciferous vegetables is generally assigned to the high content of glucosinolates and its metabolites detectable in them. They can modulate important biotransformation enzymatic systems such as the monooxygenases from cytochrome P450, influencing, for instance, scavenging and immune regulation. Beyond the (somehow) expected failure of chemoprotective activity due to genetic and biochemical alterations that influence receptors and transcription factors that interact with these compounds, functional variations due to genetic and biochemical instabilities in enzymes like glutathione S-transferase (mainly M1 and T1 isotypes), which metabolize isothiocyanates, can increase cancer risk due to the intake of cruciferous vegetables.

More recently, Calmes et al. (2015) investigated the mechanism by which glucosinolate-derived isothiocyanates could cause fungal cell death using *Alternaria brassicicola*, a *Brassica* species pathogens. Exposure of the strain to isothiocyanates led to a decreased rate of oxygen consumption, intracellular accumulation of ROS and depolarization of the mitochondrial-membrane, impairing its function in fungal cells. The expression of different oxidative-response genes was increased in the fungus when exposed to isothiocyanates-derived ROS, what may explain the protection of the fungus against isothiocyanates, as mutant strains deficient in the specific transcription factors were hypersensitive to the tested isothiocyanates.

Interactions of Phytomolecules of Nutraceutical Interest and Antimicrobial Drugs

As mentioned, most of the phytonutrients discussed present varied spectrum of antimicrobial activity. Varied practices of traditional medicine in countries such as, Brazil, China, India and several African countries include the use of plant extracts for several illnesses, including infectious diseases. In many cases, patients and health professionals employ a drug-therapy regimen in which the patient used natural products rich in phytonutrients and other phytomolecules of (generally) recognized biological activity combined to medication. However, these interactions are poorly investigated and represent a serious problem in drug therapy due to poorly predictable interactions (Saavedra et al., 2010; Dias-Souza et al., 2013). We will present here in brief some discussion in this topic.

When these combinations include antimicrobial drugs, the risk of favoring microbial resistance is high, given that the efficacy of synthetic antimicrobial drugs can be severely impaired, due to antagonistic interactions. However, it can also be enhanced, as a result of synergic interactions. Saavedra et al. (2010) evaluated the antimicrobial activity of several phytonutrients against *E. coli, P. aeruginosa, L. monocytogenes* and *S. aureus*, and the possible synergism of combinations of streptomycin and these molecules. Phenolic compounds (caffeic acid, chlorogenic acid, ferulic acid, gallic acid, tyrosol, chalcone - phloridzin; flavan-3-ol - (-) epicatechin; seco-iridoid -oleuropein glucoside) and glucosinolate hydrolysis products (allylisothiocyanate, benzylisothiocyanate and 2-phenylethylisothiocyanate) were tested in combination to ciprofloxacin, gentamicin and streptomycin in a disc diffusion assay. All of the tested isothiocyanates had superior antimicrobial activity when compared to phenolic molecules, being *P. aeruginosa* the most sensitive microorganism. Synergy was demonstrated between streptomycin and gallic acid, ferulic acid, chlorogenic acid, allylisothiocyanate and 2-phenylethylisothiocyanate against Gram-negative bacteria.

Sato et al. (2006) provided evidence of the synergic effect of the combination of vancomycin and isoflavones isolated from *Erythrina poeppigiana* against (MRSA). Isolupalbigenin and erythrinin B exhibited the highest anti-MRSA activity. Later, Gould et al. (2009) described the synergic effect of the combination of pomegranate rind extract and cupric sulphate against methicillin-sensitive and resistant *S. aureus,* and Panton-Valentine Leukocidin positive community acquired MSSA. The authors observed reduction in bacterial growth for 80% of the isolates.

Because of the strong resistance of bacteria to the currently available antimicrobial drugs, natural products and specific molecules have been investigated as alternatives to synthetic drugs, and our group has been exploring chemical, microbiological and pharmacological aspects of some natural products that might be interesting candidates for using in antimicrobial therapy (Dias-Souza et al., 2013; Marçal

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

et al., 2014; Figueiredo et al., 2015; Pereira et al., 2015). Concerning drug interactions with natural products, our group is currently investigating possible synergic or antagonist effects of the combination of antimicrobial and antioxidant natural products with synthetic antimicrobial drugs (Dias-Souza et al., 2013; Santos et al., 2015; Santos et al., 2016).

Annacardium occidentale (cashew) is a plant used in Brazil and India for treating infectious diseases and for wound healing, and the fruit is widely explored for juice pulp commercialization. The antimicrobial activity of *A. occidentale* stem bark hydroethanolic extract was demonstrated by our group by the first time against *S. aureus* and *S. epidermidis* by the first time (Dias-Souza et al., 2013), and using an adapted disc diffusion method, strong antagonism was detected when the extract was combined to antimicrobial drugs against *S. aureus* strains (Dias-Souza et al., 2013).

When analyzing specific phytomolecules, we demonstrated that some flavonoids and carotenoids can impair the antimicrobial activity of some drugs, but can also enhance this pharmacological activity. We developed an adaptation to the method used with *A. occidentale* extract and tested phytonutrients against clinical isolates of *S. aureus, E. coli* and *P. aeruginosa*. Interestingly, none of the phytonutrients presented antimicrobial activity against any of *S. aureus* and *E. coli* strains. Nevertheless, most of the tested combinations generated antagonistic effects for these species, being more pronounced for *S. aureus* strains. In investigating *E. coli* strains, the antimicrobial activity of cefalexin and amoxicillin was strongly reduced, whereas most of the drugs tested for *S. aureus* lost their pharmacological activity completely. Conversely, the antimicrobial activity of the drugs tested against *P. aeruginosa* strains was strongly favored, and synergism was evidenced (Santos et al., 2015; Santos et al., 2016).

Like most of the scarce studies on antimicrobials-phytomolecules interactions studies, the mechanisms by which these interactions work remain to be elucidated. We hypothesized that some sort of membrane injury might be involved, considering that, until the preparation of this chapter, the tested phytonutrients does not present any evidence that they may overcome the resistance mechanisms for the tested drugs. An important aspect of investigating such interactions is the necessity of exploration of isolated molecules with pharmacological activity, after the interference of a crude extract on specific drugs is well described.

The research performed by our group and others are being directed for, in a near future, begin investigations with animal models, such that the *in vitro* findings can be confirmed. With *in vivo* data from animal models, it will be possible to plan the use of some associations for clinical studies, in order to reach a combined formulation to be used as a medication.

CONCLUSION

The phytonutrients discussed have many chemical and pharmacological aspects concerning their antimicrobial, antiproliferative and antioxidant activities described, but several points remain to be elucidated, especially the ones related to mechanisms of action. The safety of these molecules for human consumption is largely recognized; however, the combined use with medications may induce unpredictable effects. The evidences of the wide spectrum of antimicrobial and antiproliferative activities of the discussed molecules open doors for more investigations in order to reach the point in which the development of pharmaceutical dosage forms will extrapolate nutraceutical purposes and will be no more a promising alternative to clinical treatments, but effective tools of large scale production against several diseases.

Chapter 21
Prediction of Structural and Functional Aspects of Protein: In-Silico Approach

Arun G. Ingale
North Maharashtra University, India

ABSTRACT

To predict the structure of protein from a primary amino acid sequence is computationally difficult. An investigation of the methods and algorithms used to predict protein structure and a thorough knowledge of the function and structure of proteins are critical for the advancement of biology and the life sciences as well as the development of better drugs, higher-yield crops, and even synthetic bio-fuels. To that end, this chapter sheds light on the methods used for protein structure prediction. This chapter covers the applications of modeled protein structures and unravels the relationship between pure sequence information and three-dimensional structure, which continues to be one of the greatest challenges in molecular biology. With this resource, it presents an all-encompassing examination of the problems, methods, tools, servers, databases, and applications of protein structure prediction, giving unique insight into the future applications of the modeled protein structures. In this chapter, current protein structure prediction methods are reviewed for a milieu on structure prediction, the prediction of structural fundamentals, tertiary structure prediction, and functional imminent. The basic ideas and advances of these directions are discussed in detail.

INTRODUCTION

A protein is a sequence produced by combination of 20 amino acids. Amino acids are characterized by polar (hydrophilic) and non polar (hydrophobic) based on its residue. These amino acids are associated to each other with peptide bond to form a protein sequence (Laskowski*et al.,* 2003). The fabrication of a protein sequence is much effortless than the determination of a protein structure. However, the structure of a protein gives much more impending in the function of the protein than its sequence. Consequently, a number of methods for the computational prediction of protein structure from its sequence have been

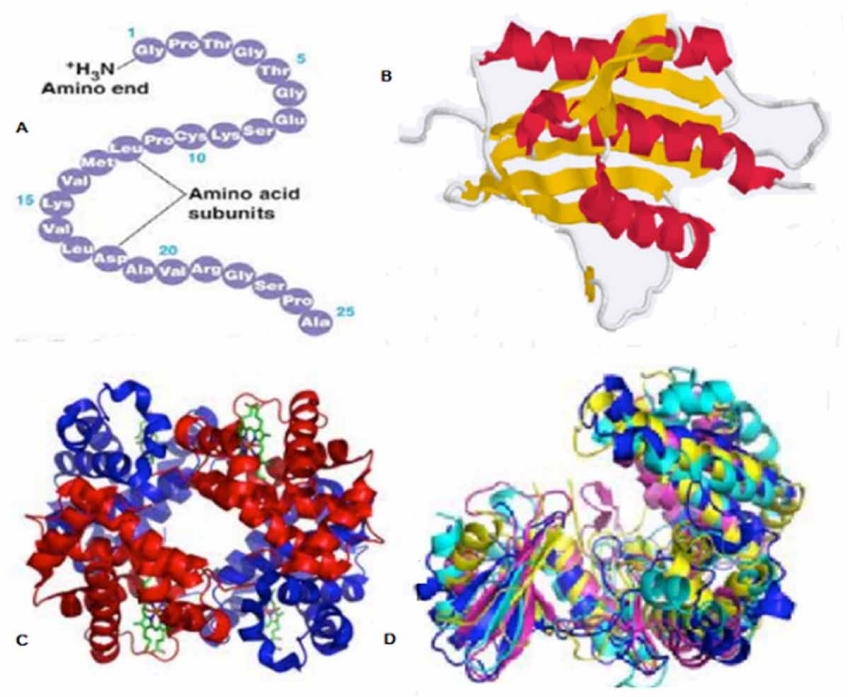
developed. Protein structure prediction is the prediction of the three-dimensional structure of a protein from its amino acid sequence that is, the prediction of its secondary, tertiary, and quaternary structure from its primary structure. The native structure is the 3D structure of the protein sequence. It necessitates knowing the native protein structure so that we can find out the function of that protein structure. There are numerous algorithms used to predict the native confirmation of a protein. Protein sequences are folded on lattice with non overlapping amino acid chain. These self circumventing conformations produced native structures which have smallest energy configuration. The protein sequence-structure gap is broadening speedily. The number of identified protein sequences (*Bairoch and Apweiler, 2000)* is blasting as a outcome of genome and other sequencing projects. The rising number of protein sequences is much bigger than the escalating number of known protein structures (Berman *et al*., 2000). Hence, computational predictive tools for protein structures are badly needed to narrow the widening gap. Prediction of 3D protein structure from the amino acid sequence is one of the most exigent tribulations in theoretical structural biology (Montelione *et al*., 1999; Skolnick *et al*., 2000).Three-dimensional protein structures still cannot be correctly predicted straight from sequences. A transitional but helpful step is to predict the protein secondary structure, which is a way to simplify the prediction problem by projecting the very complicated 3D structure onto one dimension, i.e. onto a string of secondary structural coursework for each residue.

Fortitude of the exclusive tertiary (three-dimensional) structure of a protein from its amino acid sequence alone is one of the most significant and exigent problems in modern biology. The information on the tertiary structure of a protein is pretty decisive in accepting the function and biological responsibility of the protein. At present, genome-sequencing projects are producing an extraordinary amount of linear amino-acid sequences. An exponential growth of protein sequence database in current years by far outpaces the experimental determination of protein tertiary structures. Structure prediction is vitally dissimilar from the inverse problem of protein design. Protein structure prediction is one of the most key targets accomplished by bioinformatics and theoretical chemistry; it is extremely important in medicine and biotechnology for designing of the drug and novel enzymes.

This chapter begins with a thorough introduction to the protein structure prediction problem and is divided into four themes: a background on structure prediction, the prediction of structural elements, tertiary structure prediction, and functional insights.

The Protein Structure

Proteins are building blocks of life. It reveals more sequence and chemical complexity than DNA or RNA. It is a polymeric macromolecule fictitious of amino acid building blocks set in a linear chain and coupled jointly by peptide bonds. A protein sequence is a linear hetero polymer made up of one of the 20 different amino acids. Protein structures range in size from tens to several thousand residues (Brocchieri and Karlin, 1987). Protein structure is the bimolecular structure of a protein molecule that is a sequence formed from various residues. To be able to perform their biological function, proteins fold into one or more specific spatial conformations, driven by a number of non-covalent interactions such as hydrogen bonding, ionic interaction, Van der waals forces, and hydrophobic packing. The primary structure is usually symbolized by a sequence of letters above a 20-letter alphabet linked with the 20 naturally arising amino acids. Proteins are the foremost building blocks and useful molecules of the cell, pleasing up roughly twenty percent of a eukaryotic cells weight, the biggest involvement after water. They execute ample range of functions in the living organism, playing diverse catalytic, structural, regulatory and sig-



EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

naling roles essential for the cellular development, differentiation, replication and survival. The secondary structure is precised by a sequence classifying each amino acid into the consequent secondary structure constituents (e.g., alpha, beta, or gamma). The 3D structure of proteins can be solved by 1) Experimental methods, or 2) Structure prediction. It is incredibly inflexible to solve the structures experimentally. Solving through X-ray crystallography produces awfully excellent results but we require to have a very pure protein sample which should form crystals that are fairly perfect. Solving through NMR is restricted to tiny soluble proteins. The acquaintance of the 3D structure is helpful for rational drug design, protein engineering, exhaustive study of protein bimolecular interactions, study of evolutionary relationship between proteins or protein families etc. Structural features of proteins are frequently described at four levels of complexity. The primary structure of a protein can voluntarily be deduced from the nucleotide sequence of the analogous messenger RNA. Based on primary structure, various features of secondary structure can be predicted with the assist of computer programs. Conversely, predicting protein tertiary structure relics a very rough problem, although some progress has been made in this important area.

Primary Structure

The primary structure refers to linear arrangement of amino acids in a protein and the location of covalent linkages such as disulfide bonds between amino acids. The primary structure of a protein is determined by the gene corresponding to the protein. This structure is held together by covalent or peptide bonds, which are made during the process of protein biosynthesis or translation. The sequence of a protein can be determined by methods such as Edman degradation or tandem mass spectroscopy. Figure 1 A. Depicted a linear chain of amino acids.

Figure 1. A) Primary Structure of protein, B) Secondary Structure C) Tertiary structure and D) Quaternary structure of Protein

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Secondary Structure

Secondary structure is a confined frequently occurring structure in proteins and is mainly formed through hydrogen bonds between backbone atoms called random coils, loops or turns. There are two types of stable secondary structures: Alpha helices and beta-sheets (Figure.1B). Alpha-helices and beta-sheets are preferably located at the core of the protein, whereas loops prefer to reside in outer regions. Secondary structure prediction is a set of techniques in bioinformatics that aim to predict the local secondary structures of proteins. For proteins, a prediction consists of assigning regions of the amino acid sequence as likely alpha helices, beta strands, or turns. These secondary structures are defined by patterns of hydrogen bond between the main-chain peptide groups. They have a regular geometry, being constrained to specific values of the dihedral angles ψ and φ on the ramchandran plot (Chiang *et al*., 2007). Specialized algorithms have been developed for the detection of specific well-defined patterns such as transmembrane helices and coiled coils in proteins, or canonical microRNA structures in RNA(Mount, 2004)

Tertiary Structure and Quaternary Structure

The three-dimensional structure of a protein thatresults from a large number of non-covalent interactions between amino acids (figure.1C). Quaternary structure is the 3D structure of a multi-subunit protein and how the subunits robust together. In this perspective, the quaternary structure is stabilized by the matching non-covalent connections and disulfide bonds as the tertiary structure. Complexes of two or more polypeptides are called multimers. Distinctively it would be called a dimer if it contains two subunits, a trimmer if it contains three subunits and a tetramer if it contains four subunits. The subunits are recurrently associated to one another by symmetry maneuver, such as a 2-fold axis in a dimer. The best example of quaternary structure is hemoglobin (Figure.1D).

Protein Structure Prediction and Modeling

Protein structure prediction is one of the largely imperative problems in modern computational biology. It is consequently becoming gradually more significant to predict protein structure from its amino acid sequence, using impending obtained from already known structures. Amino acid sequence analysis offers essential insight into the structure of proteins, which in turn deeply assisted the perceptive of its biochemical and cellular function. Endeavors to exploit computational techniques in predicting protein structure based only on sequence information started 40 years ago (Chou and Fasman, 1974). The tertiary structure of proteins involves the folding of the secondary structural elements. The physical properties that determine fold are the backbone rigidity, interaction between the amino acids which include the electrostatic interaction, the van der waals interaction, hydrogen and disulphide bonds and interaction with water. (Dunbrack *et al*., 2000). The structure of an organized protein is indispensable for the understanding of its function. Even though the number of experimental accessible proteins is exponentially rising over the last several years, there are a large number of proteins with unidentified fold and devoid of a noticeable homology with any protein, which has been determined. Experimentally, protein structures possibly will be gritty *via* the X-ray crystallography or protein NMR (Chance *et al.*, 2002). Other experimental methods are currently of a lesser practical consequence. In practice, *abinitio* and molecular dynamics (MD) techniques are too sluggish or too imprecise. Thus, the best *de novo* prediction methods use mainly statistical information from known structures (Rohl et al., 2004). The most

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

truthful prediction method so far is the template, or homology modeling approach, which predicts the structure by a comparison to a similar sequence. Understanding of a protein three-dimensional structure is aninput to understanding the protein biological function, to the rational drug design, protein engineering, etc. (Simons*et al.*, 2001).

Types of Protein Structure Predictions

There are assorted approaches and algorithms to predict the structure may be recapitulate as follows, 1) Prediction in 1D engross, Prediction of secondary structure, Prediction of solvent accessibility, Prediction of trans-membrane, helices. 2) Prediction in 2D engross, Prediction of the inter-residue and strand contacts. 3) Prediction in 3D engross, searching the database to locate a appropriate template for modeling. There are three methods for protein structure prediction namely, 1) homology modeling, 2) Fold recognition or threading, and 3) Ab-initio method. All these methods engage searching the database for a homologue to the target protein.

Homology Modeling

Homology modeling is sustained on the actuality that if two sequences have a high sequence similarity then they have similar 3D structure. But this is forever not the case. The free modeling technique has predicted some structures with very elevated precision; sometimes even exceeding the correctness of template/homology based approaches. The step in conventional homology modeling consists following possessions. Database search: Sequence similarity searching is a crucial step in analyzing newly determined protein sequences. A template for modeling desires to be recognized and sequence alignment between the template and target sequences has to be generated. Recurrently, template identification is executed by firm standard tools, such as PSI-BLAST, and the resulting alignment is consequently rectified by other tools and ultimately by physical professional corrections. The aligned fragments of templates are used to construct the corresponding fragments of the target structure. Multiple sequence alignment (MSA), main chain modeling, loop modeling, side chain modeling, energy refinement are the important parameters. The final, step of modeling is structure refinement which rivets repacking the side chains and energy minimization of the entire structure. The model obtained may be evaluated using PROVE, PROCHECK and what-if checks. There is some useful software routinely used for homology modeling like SwissPDB. TASSER, newer software also using the fragment approach, is very attractive because it is capable to predict the targets with similar precision while needing far less computing time (Zhou et al., 2007). Rosetta is also lucratively used for the homology modeling target as a refinement step.

Fold Recognition or Threading

Protein three-dimensional structure resolves protein function. But what resolves 3D structure is the question. The hypothesis that structure also referred to as ‘the fold’, is exclusively determined by the specificity of the sequence, has been confirm for many proteins (Kolinski and skolnick, 2004). Although it is now acknowledged that fussy proteins like chaperones frequently play a role in the folding pathway, and in correcting misfolds, it is still commonly implicit that the final structure is at the free-energy minimum (Sali, 1993,1995). The threading and sequence-structure alignment looms are stands on the observation that many protein structures in the PDB are incredibly analogous. The mainly exact prediction method

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

so far is the template, or homology modeling approach, which predicts the structure by a contrast to a similar sequence. In favor of two thirds of sequences, a similar sequence can be establish and consequently the structure can be predicted by homology modeling with good exactitude for those with fewer than 300 residues. Nevertheless, it is expected that most of the remaining third also has identified folds. Homology modeling does not work for sequence disparity larger than 20% and thus *de novo* methods are desirable for those (Zhou and Zhou, 2002). A cluster of methods, called "threading", were developed which used structural information from several less intimately related structures. Conversely, they are less truthful than modern fragment methods and are thus only used as a module in some software (Moult et al., 2005).The accomplishment of the prediction of protein three-dimensional structure from its amino acid sequence is inadequate by paucity in the conformational search procedures aimed at finding the global energy minimum and in the efficient impending used to evaluate the free energies of possible structures (Cymerman et al., 2004). The protein fold-recognition approach to structure prediction aims to recognize the known structural scaffold that accommodates the target protein sequence in the finest way. Classically, a fold-recognition plan encompasses four mechanism: (1) the illustration of the template structures (2) the evaluation of the compatibility between the target sequence and a template fold (3) the algorithm to compute the optimal alignment between the target sequence and the template structure, and (4) the way the ranking is computed and the statistical significance is estimated (Fischer and eisenberg, 1996). Homology modeling and fold recognition are the most steadfast structure-prediction practice is to identify its matching structural folds from offered known structures with or without significant sequence similarity. This approach is also referred as template based modeling. Template-based modeling becomes progressively more dominant because most popular structure folds are known (Daiet al., 2011). On the other hand, recognizing structurally similar folds in the absence of sequence similarity or fold recognition is exigent. New methods ORFeus (Observatories and Research Facilities for European Seismology) uses sequence profiles and ignore the experimental structural information from the template, and attempts to predict the structure de novo both for the target and the template families (Ginalskiand Rrychlewski, 2003). Protein fold recognition scheme endeavor to recognize the suitable template from a structure template library for a query protein and create an alignment between the query and the recognized template protein, from which the structure of query protein can be predicted. Protein fold recognition using the protein threading procedure has established enormous success (Moult et al., 2003).

Unusual techniques can be used in order to face the computational difficulty of protein fold recognition problem such as Molecular Dynamics, Monte Carlo, Genetic Algorithms and Neural Network. The GenTHREADER method uses a conventional sequence alignment algorithm to produce alignments which are then appraised by a method derived from threading techniques. All threaded model is evaluated by a neural network in order to produce a single gauge of assurance in the projected prediction (Jones, 1999).

Lin *et al(*2002) have developed a new program TUNE (Threading Using Neural network based on an artificial neural network model to predict compatibility of amino acid sequences with structural environment. Jiang *et al (*2005) anticipated a new fold recognition model with mixed environment-specific substitution mapping called MESSM.A support vector machine is engaged to measure the significance of the sequence-structure alignment. MESSM shows good performance on protein fold recognition. Support Vector Machine (SVM) regression approach to directly predict the alignment accuracy of a sequence template alignment has been implemented by (Xu, 2005). Threading or remote homologue

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

design is a protein structure prediction technique carried when there is not enough sequence similarity between the target and template. The recognition of the template is a problem by itself and hence it is also called fold recognition.

AB-Initio Prediction

Proteins are among the foremost significant groups of biomolecules, with their biological functions ranging from structural elements to signal transducers between cells. Independently from their biological role, incident related to protein behavior in solutions and at solid interfaces can find an extensive range of engineering applications such as in biomedical implants, scaffolds for artificial tissues, bioseparations, biomineralization and biosensors. The functionality of a protein is directly related to its three-dimensional structure (i.e. conformation) for both biological and engineering applications. Process such as homology and threading that depend on a large database of accessible experimental data are the most popular means of predicting the conformation of proteins in their native environment. Ab-initio prediction is conceded out when there is no appropriate homologue found in the database. Prediction is done completely from the sequence that may be based on An finsen's hypothesis that the native state of the protein represents the global free energy minimum. Ab-initio method tries to find these global minima of the protein. *Ab initio* protein folding has regularly been an area of entirely academic interest characterized by relatively slow progress.

The purpose of ab initio structure prediction is effortless: Given a protein's amino acid sequence predict the structure of its native state. It is normally understood that a protein sequence folds to a native conformation or ensemble of conformations that is at or near the global free-energy minimum. Thus, the problem of finding native like conformations for a given sequence can be decomposed into two sub problems: (a) developing an accurate potential and (b) developing an efficient protocol for searching the resultant energy landscape. There are two mechanisms to *ab initio* prediction: devising a scoring (i.e, energy) function that can distinguish between correct (native or native-like) structures from incorrect ones, and a search method to investigate the conformational space. In various techniques, the two apparatus are coupled together such that a search function drives, and is driven by, the scoring function to find native-like structures. Unlike computational approaches to the problem fluctuate as to which assumptions are made. A promising approach, based on the discretization of the conformational space, is that of deriving a protein-centric lattice, by allowing the backbone torsion angles, phi, psi, and omega, to take only a distinct set of values for each different residue type. Under biological circumstances, the bond lengths and bond angles are fairly rigid. Consequently, the internal torsion angles along the protein backbone determine the main features of the final geometric shape of the folded protein. To predict protein structure *de novo* for larger proteins will necessitate superior algorithms and larger computational resources like those afforded by either influential super computers e.g. Blue Gene or MDGRAPE-3) or distributed computing. Even though these computational barriers are vast, the potential benefits of structural genomics make *ab initio* structure prediction an active research field. *Ab initio* prediction methods use just the sequence of the protein. Threading and Homology Modeling methods can build a 3D model for a protein of unknown structure from experimental structures of evolutionary related proteins (Zhang,2008).There are two kinds of model.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

1. **Lattice Model:** This represents peptide chain as lattices. But fails to represent subtle geometric consideration like strand twist and its backbone prediction is not all that accurate.
2. **Discrete State off-Lattice Model:** It improves upon the lattice modelby applying restraints like allowing only certain side chain structure and limiting the peptide bond rotation. In order to reduce the complexity, local structure biases are used. But the strength and multiplicity of the local structure prediction is highly sequence dependent. There are two type of scoring functions namely knowledge based scoring function and force field based function which are used. Currently there does not exist a reliable scoring function or search method. There is a new fully automated ab-intio prediction method in which the Monte Carlo fragment insertion method (ROSETTA) of Baker and others has been merged with the Isite (library of sequences structure motifs) and the HMMSTR model for local structure in proteins.

Comparative Modeling

Comparative modeling predicts the 3D structure of a specified target protein sequence based principally on its alignment to one or more proteins of known structure i.e. templates. The prediction method consists of fold assignment, target–template alignment, model building, and model evaluation. The number of protein sequences that can be modeled and the accuracy of the predictions are growing progressively because of the growth in the number of known protein structures and because of the improvements in the modeling software. The aspire of comparative or homology protein structure modeling is to build a three-dimensional (3D) model for a protein of unknown structure on the basis of sequence similarity to proteins of known structure. Two situations must be met to build a useful model. First, the likeness between the target sequence and the template structure must be obvious. Second, a substantially correct alignment between the target sequence and the template structures must be calculated (Marti-Renom et al., 2002). Comparative modeling methods are useful for predicting the tertiary structure of the target protein if there is a template for a homologue with a comparatively high sequence similarity. During comparative modeling, the target sequence is aligned to templates, and then all atom structures of the target protein are formed ensuing to fulfilling in alignment gaps and correctly orienting side chains (Baker and Sali, 2001). Comparative modeling is presently the most habitually used approach to the theoretical prediction of protein structure (Holm and Sander, 1996).

Whereas a protein structure and function is evolutionary too much conserved than the protein sequence, similarity of sequence of a new protein to a protein of known structure entails their structural similarity (Clark, 1999).

A template protein probably will be identified by a sequence comparison method (Altschul*et al.*, 1997) or by a threading algorithm (Kiharaand Skolnick, 2004).

The almost all conservative approach to the comparative modeling occasionally called homology modeling, although meticulously speaking homology is not required for the sequence and structure similarity. Comparative modeling ruins the most dependable and routinely used method for protein structure prediction (Eswar*et al.*, 2008, Ginalski, 2006). The unusual term of homology modeling is regularly used. That is because the identification of a structural template is classically based on the homology relation between the target protein and the templates, which is usually reflected by a certain level of sequence similarity. All existing comparative modeling methods consist of four sequential steps: fold

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

assignment and template selection, template–target alignment, model building, and model evaluation. If the model is not satisfactory, template selection, alignment, and model building can be repeated until a satisfactory model is obtained.

Applications

Comparative modeling is an increasingly efficient way to obtain useful information about the proteins of interest. Comparative models can be helpful in designing mutants to test hypotheses about a protein's function

- Identifying active and binding sites,
- Identifying, designing and improving ligands for a given binding site,
- Modeling substrate specificity,
- Predicting antigenic epitopes,
- Simulating protein–protein docking,
- Inferring function from a calculated electrostatic potential around the protein,
- Facilitating molecular replacement in X-ray structure determination,
- Refining models based on NMR constraints,
- Testing and improving a sequence–structure alignment,
- Confirming a remote structural relationship and rationalizing known experimental observations.

Transmembrane Topology

Transmembrane protein topology prediction methods play significant roles in structural biology, since the structure determination of these types of proteins is enormously tricky by the common biophysical, biochemical and molecular biological methods. The need for accurate prediction methods is high, as the amount of known membrane protein structures plunge extreme behind the estimated number of these proteins in various genomes. The precision of these prediction methods emerges to be higher than most prediction methods applied on globular proteins, however it reduces vaguely with the increasing number of structures. A transmembrane protein is a protein that spans an entire biological membrane. These proteins go from one side of a membrane through to the other side of the membrane. Transmembrane proteins are aggregate and precipitate in water. They need nonpolar solvents for extraction, while some of beta-barrels can be also extracted using denaturing agents. Transmembrane proteins control the flow of information and substances into and out of the cell and are involved in a broad range of biological processes. All transmembrane proteins are integral membrane proteins, but not all integral membrane proteins are transmembrane proteins.

There are two fundamental types of transmembrane proteins: 1) Alpha-helix- This is the major category of transmembrane proteins present in the inner membranes of bacterial cells or the plasma membrane of eukaryotes. In humans, 27% of all proteins encompasses predictable to be alpha-helical membrane proteins. 2) Beta-plated sheets-These proteins are found only in outer membranes. Membrane proteins are crucial for survival. They constitute key components for cell–cell signaling, mediate the transport of ions and solutes across the membrane, and are crucial for recognition of self (Chen *et al.*, 2002). Most

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

TM proteins are helical (TMH) proteins. Helices in membrane spanning regions are more tightly packed than the helices in soluble proteins. The topology of TMH proteins, includes, the membrane spanning regions and the amino-terminal orientations. The determination of the topology of a TMH protein is useful for the annotation of its biological function (Zhou, 2003). Many different methods have been developed to predict the topology of transmembrane protein TMH proteins. Transmembrane helices can be predicted based on the distinctive patterns of hydrophobic and polar regions within the sequence. Kyte and Doolittle developed one of the first methods that evaluated the hydrophilicity and hydrophobicity of a protein along the amino acid sequence (Kyte and Doolittle, 1982). The first HMM-based transmembrane protein topology predictors were introduced ten years ago: TMHMM and HMMTOP (Tusnady, 1998). TMpred is one of the methods using such statistical preferences to predict membrane helices taken from an expert-compiled data set of membrane proteins. The HMM Phobius was designed to combine the signal peptide model of Signal P-HMM [Nielsen and krogh, 1998] with the transmembrane topology model of TMHMM (Sonnhammer et al., 1998). Reynolds et al, 2008 described Philius, a DBN-based approach to transmembrane protein topology prediction. Hidden Markov models (HMMs) have been successfully applied to the tasks of transmembrane protein topology prediction and signal peptide prediction. Consensus methods based on multiple prediction algorithms were also developed (Drew et al., 2002).

Ligand-Binding Residue Prediction

In this section, we explore means for predicting protein residues that interact with small molecules. The accurate prediction of ligand binding residues from amino acid sequences is imperative for the programmed functional annotation of new proteins. The rationale of the ligand binding site residues in a protein is also vital, because substrate specificity of an enzyme is determined by the well information of the binding site residues, such as side chain orientation and physiochemical properties (Schwede, et al. 2009).

The conquering identification of ligand-binding sites on protein surfaces is usually the opening point for the annotation of protein function and drug discovery. The identification of ligand-binding sites is frequently the starting point for protein function annotation and structure based drug design. Many computational methods for the prediction of ligand-binding sites have been developed in latest decades. The protein surface can form pockets that are binding sites of small molecule ligands. Therefore, the identification of pocket sites on the protein surface is often the starting point for protein function annotation and structure-based drug design. The prediction of protein-ligand binding sites has great significance for protein function annotation and computer-aided drug design. Besides the binding site identification, the binding sites' ranking according to their likeliness to accept a molecule is also an important and challenging issue (Gao et al., 2012**).** Identifying ligand-binding residues reliably aids the overall understanding of the role and function of a protein by using them to subsequently predict the types of ligands to which they bind and, in the case of enzymes, the types of reactions that are catalyzed. Moreover, knowledge of the residues involved in protein-ligand interactions has broad applications in drug discovery and chemical genetics, as it may be used to better virtually screen large chemical compound libraries and to aid the process of lead optimization. In addition, the ligand-binding residues of a protein can be used to influence target-template sequence alignment in comparative protein modeling which has been shown to improve the quality of the 3D models produced for the target's binding site. These quality improvements in the binding site's 3D model are critical to docking-based approaches for virtual screening (Kauffman and Karypis, 2009).

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

The number of predictors that submitted new methods in this category was highly encouraging and suggests that current technology is at the level that experimental biochemists and structural biologists could benefit from what is clearly a growing field. Several different protein ligand binding site prediction methods have been developed, which mostly fall into two major categories: sequence-based methods and structure based methods. The sequence-based methods rely on identifying conserved residues that may be structurally or functionally important and include methods such as firestar, WSsas, FRcons, ConFunc, ConSurf, FPSD, Pand INTERPID. The structure based methods can be further subdivided into the geometric methods utilized by FINDSITE and Site Hunter; energetic methods utilized by SITEHOUND and Q-Site Finder. The FunFOLD software implements a competitive method for the prediction of protein binding site residues, which can also be used to determine the putative ligands interacting with a protein. The FunFOLD software is freely available as both a standalone package and a prediction server, providing competitive ligand binding site residue predictions for expert and non-expert users alike. The software provides a new fully automated approach for structure based function prediction using 3D models of proteins. Nevertheless, for the 3D models the LigandSite and Phyre server are frequently used. Similarly MAMMOTH used for structural superposition of similar templates with bound ligands (Roche et al., 2011).

To predict the potential binding site, several computational methods have been developed. In brief, these algorithms can be divided into three categories (1) purely geometry-based methods, which follow the assumption that the protein-ligand binding sites are generally located at crevices on the protein surface or cavities in the protein. Methods falling in this category include POCKET, LIGSITE, PASS, SURFNET, and Pocket Picker. (2) energetic-based methods, which coat the protein surface with a layer of probes to calculate van der Waals interaction energies between the protein and probes. As an example, Q-Site Finder is a classical tool falling in this category (3) knowledge based methods, which includes various statistical methods, machine learning methods and similarity comparison methods. Besides, a part of them predict protein-ligand binding sites by searching for clusters or patterns of the conserved residues.These methods include POCKET, LIGSITE, LIGSITEcs, SURFNET,CAST, PASS and Pocket Picker all of which use pure geometric characteristics and do not require any knowledge of the ligands (Roche et al.,2010). Identification of binding sites is of fundamental importance in SBDD and virtual ligand screening. Identifying sequence and structural similarity with proteins with known functional sites is an emerging area for identifying ligand binding sites. Energy- based methods of pocket detection include those of Meta Pocket and Q-Site Finder is online.

Loop Modeling

Loop modeling is conceivably the hardest step in comparative modeling process along with alignment. When target and template share above 35% sequence identity, errors in loops are the dominant problem in comparative modeling. *Loop modeling* is a crisis in protein structure predictions necessitating the prediction of the conformations of loop regions in protein with or without the use of a structural template. Computer programs that resolve these troubles have been used to research a extensive sort of scientific issues from ADP to breast cancer (Baloria et al., 2012). Since protein function is gritty by its shape and the physiochemical properties of its exposed surface, it is essential to build an accurate model for protein or ligand interaction studies (Fiser and Sali, 2003). The process for modeling a loop in a given situation is illustrated here by specifying its three main mechanisms: The depiction of a protein; the manacles that define the objective or energy function; and the scheme for optimizing the energy function. The

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

modeling method is completely automated and is implemented in the program MODELLER-5. Whilst the mostly recurrent application of the technique is to predict single loops, it is also technically suitable for modeling any set of contiguous or noncontiguous residues or atoms e.g., several loops, a loop with a ligand, a huddle of side chains in the preset environment created by the respite of the protein. Consequently, ingenuous modeling of loops is indispensable for structure-based prediction of function from sequence. For example, a comparative model can occasionally be used with computational ligand docking to locate a putative ligand or determine preferences within a limited set of ligands (Xu et al., 1996). A somber complication is that the ligand may persuade conformational changes in loops with which it interacts. Loop modeling methods can be classified in two approaches: *Ab initio* methods and database searching or knowledge-based methods.

Ab Initio Methods

Ab initio loop prediction is based on a conformational search guided by a scoring or energy function -the later describing the physico-chemical properties of a protein and its environment. It is also called as non-template based technique. The non-template based looms employ a statistical model to seal in the gaps created by the unknown loop structure known as an *ab initio* method. Several of these programs include MODELLER, Loopy, and RAPPER; but each of these programs approaches the problem in a dissimilar way. Further programs exploit a de novo approach that samples sterically feasible loop conformations and selects the best one. The determining a best model means that a scoring method must be fashioned to compare the diverse conformations (Adhikariet al., 2012)

Knowledge-Based Methods

Knowledge-based approaches, which are the most widely used also called as template based technique. It utilizes libraries of regular rotamers extracted from high resolution X-ray structures. This approach is executed in most automatic homology modeling events. The CORALL module of WHATIF and the SCWRL program important software using such approach. Sections of a structural model that are predicted by non-template-based loop modeling tend to be greatly less perfect than regions that are predicted using template-based techniques. Conversely, loops are commonly too short to present sufficient information about their local fold. Fragment of up to nine residues occasionally have totally unrelated conformations in different proteins (Cohen and Pressnell, 1993).It is furthermore referred as database searching approach. This is more precise and resourceful if it is precedent by a structural classification of the loops here in the database. This approach to loop prediction initiated by finding segments of main chain that fit the two stems of a loop. The stems are defined as the main chain atoms that herald and follow the loop but are not part of it. The search is carrying out through a database of many known protein structures, not only homologues of the modeled protein. The preferred segments are then superposed and annealed onto the stem regions. These initial crude models are often refined by optimization of some energy function. The database search ensue to loop modeling is truthful and proficient when a specific set of loops is created to tackle the modeling of that group of loops like b-hairpins and the hyper variable regions in immunoglobulins (Sibanda et al.,1989). There are many such methods, exploiting different protein representations, energy function terms, and optimization or enumeration algorithms. ModLoop is a web server for automated modeling of loops in protein structures. The server relies on the loop modeling usual in MODELLER that predicts the loop conformations by satisfaction of spatial restraints, without relying

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

on a database of known protein structures (Fisher, 2009). FREAD is a database search loop modeling algorithm. Its principal use is to fill in the gaps in imperfect 3D models of protein structures. The input is a 3D model of a protein structure as well as the location and amino acid sequence of the loop region to be modeled (Choi et al.,2009). FALC-Loop is an internet server for protein loop modeling. The FALC-Loop server uses the protein loop modeling method that utilizes fragment assembly and analytical loop end developed in the Reference. The method shows a brilliant presentation when compared to earlier loop sampling methods (Lee et al., 2011).YASARA Structure features a loop modeler, that can swiftly retrieve loop conformations that overpass two sets of anchor residues from the Protein Data Bank. This knowledge-based approach profits extremely from the increasingly growing PDB, and has been shown to be a strong competition for ab-initio loop prediction (Michalsky et al., 2003).

CONCLUSION

The 3D structures of proteins are preset by a linear sequence of amino acid residues. To predict structure from sequence is an intricate job enough to have occupied a generation of researchers. Remarkable looms to predict the structure obtain into account unlike chemical and physical properties. Nonetheless these are not appreciably perfect or trust worthy adequate to predict all kinds of proteins. Ab-initio prediction methods even with their very low accuracy can give a reliable functional annotation.

KEY TERMS AND DEFINITIONS

Ab Initio Prediction: The ab initio structure prediction of proteins is to correctly characterize the 3D structure of a protein using only the amino acid sequence as input.

Insilico Analysis: The term 'in silico' is a modern word usually used to mean experimentation performed by computer and is related to the more commonly known biological terms in vivo and in vitro. These in silico methods include databases, quantitative structure-activity relationships, pharmacophores, homology models and other molecular modeling approaches, machine learning, data mining, network analysis tools and data analysis tools that use a computer.

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Molecular Modeling: Molecular modeling is an application of computers to generate, manipulate, calculate and predict realistic molecular structures and associated properties. The techniques are mainly used in the fields of computational chemistry, drug design, computational biology and materials science for studying molecular systems.

Protein Structure: Proteins are single, unbranched chains of amino acid monomers. Protein structure is biological polymers composed of amino acids. Amino acids, linked together by peptide bonds, form a polypeptide chain. One or more polypeptide chains twisted into a 3-D shape form a protein. Proteins have complex shapes that include various folds, loops, and curves. Folding in proteins happens spontaneously.

Visualization Software: Visualization software is required to view the structure that is encoded by atomic coordinate PDB files and to be able to manipulate the images to view the molecule from various perspectives. Visualization typically takes the form of two dimensional displays, where interactive controls allow the user to explore and experience the three-dimensional structure of the protein under study.

Chapter 22
Flavonoids: Prospective Strategy for the Management of Diabetes and Its Associated Complications

Vineet Mehta
Jaypee University of Information Technology, India

Udayabanu Malairaman
Jaypee University of Information Technology, India

ABSTRACT

Diabetes Mellitus is one of the major healthcare problems faced by the society today and has become alarmingly epidemic in many parts of the world. Despite enormous knowledge and technology advancement, available diabetes therapeutics only provide symptomatic relief by reducing blood glucose level, thereby, just slows down development and progression of diabetes and its associated complications. Thus, the need of the day is to develop alternate strategies that can not only prevent the progression but also reverse already "set-in" diabetic complications. Many flavonoids are reported, traditionally as well as experimentally, to be beneficial in averting diabetes and lowering risk of its accompanying complications. In the present chapter we have convened different flavonoids beneficial in diabetes and comorbid complications and discussed their mechanisms of action. Further, we conclude that coupling current therapeutics with flavonoids might provide exceptional advantage in the management of diabetes and its complications.

INTRODUCTION

Diabetes mellitus (DM) is a complex metabolic disorder arising from variety of factors, genetic or environmental, resulting in hyperglycemia. Hyperglycemia leads to acute and chronic metabolic abnormalities, amongst which neuropathy, nephropathy, retinopathy, learning and memory impairment and cardiovascular complications are the major causes of morbidity (Goodman, 2011). Hyperglycemia is a consequence of either pancreatic β-cells destruction, thereby decreasing the level of insulin secretion

(Type-1 Diabetes Mellitus; T1DM) or due to decreased responsiveness of target cells towards insulin with or without insulin secretory defects (Type-2 Diabetes Mellitus; T2DM) (American Diabetes Association, 2013). In 2013, 382 million people across the globe were reported to be diabetic amongst which 5.1 million lost their lives and therapeutic management of diabetes costs $548 billion. By the year 2035, diabetic population of the world is projected to increase by 55% and its management cost is expected to reach $627 billion. Major concern is that 46% cases of DM remain undiagnosed for longtime (International Diabetes Federation, 2013) and by the time clinical symptoms appear, damage has already been done. Majority of current diabetic research is focused on identifying various therapeutic targets with protective as well as restorative ability to reverse the diabetic damage. Currently available antidiabetic medications controls hyperglycemia by reducing dietary glucose absorption, disposing blood glucose into muscles, liver or adipose tissue and by increasing its excretion form the body thereby providing only symptomatic relief. None of the available treatments are capable of reversing the damage inflicted by diabetes and ceasing its progression (Tripathi, 2013; Verma, Itankar, & Arora, 2013). Hyperglycemia in diabetes generates excessive reactive oxygen/nitrogen species (ROS/RNS) by oxidation of glucose. These highly reactive ROS/RNS binds and disturb normal functioning of biomolecules such as proteins, ribonucleic acid (RNA), deoxy-ribonucleic acid (DNA), etc. and thus, directly or indirectly aids in the development of various diabetic complications (Rochette, Zeller, Cottin, & Vergely, 2014).Thus the use of flavonoids, which are natural antioxidants, may provide additional advantage over current antidiabetic therapy. Present chapter discusses various targets that are currently used for the management of DM and potential of various flavonoids to exploit them. It also provides the list of flavonoids that were reported to be effective in managing diabetes or diabetic complications with their possible mechanisms, which needs further exploration to fully understand their antidiabetic potential.

All the therapeutic interventions currently used clinically for the management of DM exploit primarily following biochemical processes of human body.

1. **Glucose Absorption:** Dietary polysaccharides are converted to glucose prior to their absorption in gastrointestinal tract by α-glucosidase and α-amylase. Therefore, inhibition of these enzymes reduces glucose absorption and ultimately lowers blood glucose level (Etxeberria, de la Garza, Campión, Martínez, & Milagro, 2012; Kim, Kwon, & Son, 2000; Kim, Nguyen, Kurihara, & Kim, 2010; Sales, Souza, Simeoni, Magalhães, & Silveira, 2012). Reduction in blood glucose level results in enhanced glycogenolysis and lipolysis for generating glucose to fulfill the energy requirements of body and thus provide beneficial outcomes in obesity and associated insulin resistance (InR). Both of these enzymes are important targets for antidiabetic therapy and compounds such as acarbose andglucsidase inhibitors are clinically used for the management of diabetes (Goodman, 2011).
2. **Glucose Disposal from Blood:** Insulin is a peptide hormone responsible for maintaining glucose homeostasis by disposing blood glucose into skeletal muscles (for energy), adipose tissue (lipogenesis) and liver (glycogenesis). Mechanistically, this is achieved through interaction of insulin with heterotetrameric insulin receptor (IR) which ultimately leads to the transcription and translation of glucose transporter-4 (GLUT4), responsible for glucose disposal. Insulin potentiators (sulfonylureas etc.), insulin analogues (beef and pork insulin preparations etc.) and insulin signaling modulators (peroxisome proliferator activated receptors-γ (PPAR-γ)) are extensively used clinically for the management of diabetes (Goodman, 2011; Tripathi, 2013). Further, glucagon like peptide-1 (GLP1) is responsible for disposing glucose from the blood by lowering glucagon and increasing insulin blood levels. GLP1 is degraded by enzyme dipeptidyl peptidase-4 (DPP4), inhibition of DPP4

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

results in GLP1 mediated lowering of blood glucose. DPP4 inhibition is a newly discovered and promising antidiabetic target for the clinical management of hyperglycemia (Janardhan & Sastry, 2014).

3. **Glucose Metabolism:** Glucose is the primary energy source of our body and is oxidized by a series of enzymatic reactions to produce energy in the form of adenosine triphosphate (ATP). In one such reaction, aldose reductase (AR) converts glucose into sorbitol by utilizing nicotinamide adenine dinucleotide (NAD) and reduced nicotinamide adenine dinucleotide phosphate (NADPH) during the process. During hyperglycemic state, excessive sorbitol generation inflicts osmotic stress and thereby damages microvasculature, especially in the eyes causing retinopathy. Enormous depletion of NADPH (antioxidant) further augments oxidative stress within the body which is responsible for the initiation and constant progression of diabetic complications. Inhibition of AR and other glucose metabolizing enzymes is very effective in reducing the progression of diabetic complications by lowering osmotic and oxidative stress. But AR inhibitors do not have any significant effect on blood glucose level and hence are not able to halt the progression of DM (Sharma & Sharma, 2008).
4. **Glucose Excretion:** Kidneys filter about 180g of glucose per day which is entirely reabsorbed from proximal tubule by transporters such as sodium glucose co-transporter-2 (SGLT2). Drugs which inhibit SGLT2, such as canagliflozin, results in the excretion of glucose in urine and thereby reduces blood glucose level. This transporter has recently gained attention as a potential target for lowering blood glucose level (Tahrani, Barnett, & Bailey, 2013). Although it slows down the progression of diabetes associated complications, but like other targets, it is also ineffective in halting or reversing these complications.
5. **Oxidative Stress Induced Damage:** High blood glucose level inflicts excessive oxidative stress by generating advanced glycation end-products (AGE), ROS, RNS and depleting natural antioxidant defense of the body (viz. catalase, superoxide dismutase (SOD), glutathione reductase (GSH), NADPH etc.) through activation of stress sensitive signaling, hexoseamine, polyol and AGE pathways. All these factors sum up to induce neuropathy, nephropathy, vascular and other diabetic complications (Fisher, Zhang, Geoffrey, & Steven, 2006; Johansen, Harris, Rychly, & Ergul, 2005). Compounds that lower oxidative stress may not be able to reduce blood glucose levels but can be very effective in reducing diabetic complications. These agents can be given along with hypoglycemic agents for the effective management of diabetes and its complications.

FLAVONOIDS AND DIABETES

From the above discussion, role of oxidative stress in development and progression of diabetic complications becomes evident. Thus, the use of flavonoids, which possesses natural antioxidant properties, may provide additional advantage over traditional therapeutic strategies. Flavonoids are the 15 carbon polyphenolic compounds in which two aromatic rings are linked by a 3 carbon bridge i.e. C6-C3-C6 linkage (Jaganath & Crozier, 2010). Todate, more than 6000 different flavonoid molecules have been characterized, which are produced by plants as secondary metabolites in fruits, vegetables, nut, seeds, flowers, stem etc. (Harborne & Williams, 2000; Jaganath & Crozier, 2010). Rapid rise in the metabolic and neurodegenerative diseases worldwide has necessitated to speed-up the search of effective alternatives to the available therapeutics. According to a World Health Organization (WHO) report, about 90%

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

of T2DM, 80% of cardio vascular disorders and 33% of cancers can be avoided just by adopting necessary lifestyle and dietary changes (World Health Organization, 2003). A number of studies conducted in recent past have established the inverse relationship between enhanced intake of dietary flavonoid and epidemiology of neurodegenerative disorders. These studies demonstrated that occurrence of DM and neurodegenerative disorders can be reduced by consuming diets rich in polyphenols and flavonoids (Anderson, Anthony, Cline, Washburn, & Garner, 1999; Law & Morris, 1998; Steinmetz & Potter, 1996). Meta-analysis study involving 2,84,806 subjects revealed that the risk of T2DM is reduced significantly by enhanced consumption of dietary flavonoids (Liu et al., 2014). Further, evidence suggests that flavonoids can control DM and its associated complications by reducing hyperglycemia, hyperlipidemia (Bansal et al., 2012; Chen et al., 2013; Nisha & Mini, 2013; Zheng et al., 2011), inflammation stress (Lin, Wu, Fang, & Yen, 2012; Nisha & Mini, 2013; Zheng et al., 2011), oxidative stress (Bansal et al., 2012; Chen et al., 2013; Nisha & Mini, 2013), improving insulin release and its signaling(Jin, Shi, Tang, Qiao, & Duan, 2013; Zheng et al., 2011), glucose tolerance (Bansal et al., 2012), diabetic profile of pancreas and liver (Bansal et al., 2012; Bansal et al., 2011; Dias, Bronze, Houghton, Mota-Filipe, & Paulo, 2010) and by regulating PPAR-γ activity (Zheng et al., 2011). Apart from these, few other studies depicts that flavonoids control diabetes by inhibiting α-amylase and α-glucosidase(Yao, Zhu, Chen, Tian, & Wang, 2013), AMP-activated protein kinase (AMPK) signaling (Jin, Shi, Tang, Qiao, & Duan, 2013;Kim, Kim, & Kim, 2011)andprotein-tyrosine phosphatase 1B(PTP1B)(Li et al., 2013). All these reports provide us with the strong justification regarding the antidiabetic potential of the dietary flavonoids. However, only few flavonoid molecules have been studied extensively for their antidiabetic activity, but the mechanisms through which they act remains unclear to large extent till date. In this chapter flavonoids that had been reported to possess antidiabetic activity are categorizes according to their possible mechanism of action.

TARGETS OF FLAVONOIDS FOR ANTI-DIABETIC POTENTIAL

1. Aldose Reductase (AR)

AR is a monomeric reduced NAD/NADPH-dependent enzyme which belongs to aldo-keto reductase superfamily of enzymes. In 1956, Hers reported that AR inhibition results in lowering of blood glucose level (Hers, 1956) and later on, in 1959, its elevated level during diabetes was confirmed (Van Heyningen, 1959). Counting on this information, Kinoshita *et al.* and Varma and Kinoshita demonstrated that AR inhibitors prevented cataractogenesis in diabetic rats and rabbits (Kinoshita, Dvornik, Kramil, & Gabbay, 1968; Varma & Kinoshita, 1976). Since then it has been looked upon as a potential target for the management of diabetic complications, especially retinopathy.

AR acts on a variety of substrates in the body and is responsible for glucose metabolism through polyol pathway, catecholamine metabolism, steroid metabolism and detoxification of aldehydes(Yabe-Nishimura, 1998).Under normoglycemic condition, majority of body's glucose is converted to glucose-6-phosphate (G6P) by hexokinase and about 3% of total glucose enters polyol pathway, where it is metabolized by AR. However during hyperglycemia, AR work load shoots up by 10 fold and more than 30% of the total glucose enters polyolpathway (González, Barnett, Aguayo, Cheng, & Chylack, 1984; Morrison, Clements Jr, Travis, Oski, & Winegrad, 1970). AR initially catalyzes theNADPH-dependent reduction of glucose into sorbitol, which is then converted to fructose by sorbitol dehydrogenase through NAD utilization (Hers, 1956). Sorbitol accumulates in the body, especially in ocular lens, and inflicts osmotic stress

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

which disrupts cell membranes, leading to various diabetic complications amongst which retinopathy is the best known (Nagata et al., 1989). Further during hyperglycemia, NADPH is depleted and reduced NAD is accumulated which consequently give rise to abnormalities in body's antioxidant enzymes, GSH and nitric oxide synthase (NOS), thereby inflicting oxidative stress. Endothelial cells cultured in high glucose media showed lower level of GSH and were more liable to the damage inflicted by hydrogen peroxide (H_2O_2)(Kashiwagi et al., 1994). Likewise, NOS production from L-arginine was reduced due to non-availability of NADPH cofactor and thus elicits microvasculature damage coupled with sluggish nerve conduction (Cameron, Cotter, Dines, & Maxfield, 1993; Stevens et al., 1994).

Elevated NADH/NAD^+ ratio favor the synthesis of diacylglycerol (DAG) by increasing dihydroxyacetone phosphate availability and enhancing the reduction of *sn*-glycerol-3-phosphate, which is intermediate in DAG synthesis (Pugliese, Tilton, & Williamson, 1991). DAG in turn activates protein kinase C (PKC) which increases sodium-proton antiport activity, responsible for regulating intracellular pH, cellular growth and differentiation (Williams, 1995). All these biochemical changes associated with high glucose induced vascular complications were demonstrated experimentally in various tissues including retina, aorta, and renal glomeruli and were ameliorated by using β isoform of PKC (Ishii et al., 1996).

AR metabolizes toxic aldehydes, such as 4-hydroxynonenal (HNE) and glutathione-HNE (GS-HNE), generated by lipid peroxidation during hyperglycemia. AR efficiently reduces HNE and GS-HNE to non-toxic 1,4-dihydroxy-2-nonene (DHN) and GS-DHN. However in doing so, AR, phospholipase-C (PL-C) and PKC activates mitogen activated protein kinase (MAPK) and nuclear factor kappa B (NFκB) which enters nucleus and initiates transcription of their target genes (Pladzyk, Ramana, Ansari, & Srivastava, 2006; Zeng et al., 2013). Tumor necrosis factor-α (TNF-α), inter leukin-6 (IL-6), IL-1 and other cytokines and cytokines like substances, thus generated, induces InR and adds up in the development of diabetic complications (Goldberg, 2009).

To date numerous flavonoids have been shown repeatedly in literature to havethe potential to inhibit AR enzymatic activity *in-vitro* (Table 1; Figure 1) (Matsuda, Morikawa, Toguchida, &Yoshikawa, 2002; Shimizu et al., 1984; Varma and Kinoshita, 1976). Mok and Lee (2013) isolated quercetin, kaempferol, afzelin, myricitrin, quercitrin and myricetin from the flowers of *Rhododendron mucronulatum*(Ericaceae) and reported them to be a potent inhibitor of AR activity, quercitrin being most potent showing IC_{50} value 0.13 μg/ml (Mok & Lee, 2013). Similarly, 2'.4-dihydroxy-4'-methoxydihydro chalcone and davidigenin(Govorko et al., 2007; Logendra et al., 2006), erigeroflavanone(Yoo et al., 2008), butein, sulfuretin(Lee et al., 2008), engeletin and astilbin(Wirasathien et al., 2007) are also known to inhibit AR activity. From these, apigenin, guaijaverin, desmanthin-1 and luteolin inhibited AR with IC_{50} value in the range of 0.082-7.67 μM (Yoo et al., 2008; Matsuda, Morikawa, Toguchida, & Yoshikawa, 2002). In a separate study, cosmosiin and lonicerin were reported to be potent AR inhibitors with 99 and 91.5% inhibition of enzyme activity respectively (Shimizu et al., 1984).All these reports are based on *in-vitro* screening of these compounds against AR enzyme and further animal experimentation is needed to gain better understanding of their antidiabetic potential.

2. α-Glucosidase and α-Amylase

α-glucosidase (EC 3.2.1.20) is an exo-type α-glucosidic*O*-linkage-hydrolase enzyme located in the surface of intestinal villi and micro-villi. It catalyzes the final step in digestion of carbohydrates where it breaks oligosaccharides and α-glucans through hydrolytic reaction, which splits α-1,4 glycosidic bond between glucosyl residue and glucosidic oxygen followed by proton exchange reaction between water

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

and glucosyl residue, thus giving absorbable D-glucose as the final product (Kim et al., 2010). α-amylase (EC 3.2.1.1.) is a calcium metalloenzyme present in saliva and pancreatic juice. It is responsible for the hydrolysis of α-D-(1,4)-glycosidic bond of starch, amylose, amylopectin, maltodextrins and glycogen, converting them to shorter oligosaccharides so that they can be absorbed into the body (Etxeberria, de la Garza, Campión, Martínez, & Milagro, 2012; Sales, Souza, Simeoni, Magalhães, & Silveira, 2012). Inhibition of these enzymes aids diabetes management by suppressing the absorption of glucose from the ingested meals and thus keeping the blood glucose level low.

Many flavonoids are capable of inhibiting α-glucosidase and α-amylase *in-vitro* which makes them an appropriate moiety for antidiabetic research (Table 2; Figure 2). Daidzein (Park, Ju, Park, & Han, 2013), trilobatin (Dong, Li, Zhu, Liu, & Huang, 2012), baohuoside I (Phan, Wang, Tang, Lee, & Ng, 2013) and luteolin (Kim, Kwon, & Son, 2000), inhibited both enzymes whereas saponarin (Sengupta, Mukherjee, Goswami, & Basu, 2009), pelargonidin-3-α-O-rhamnoside and cyanidin-3-α-O-rhamnoside (Cherian, Kumar, Augusti, & Kidwai, 1992; Hanamura, Hagiwara, & Kawagishi, 2005) are effective in inhibiting α-glucosidase only. Antidiabetic potential of majority of these findings needs to be further justified through *in-vivo* experimentation.

3. Antioxidant Pathway

Oxidative stress is characterized by excessive amount of ROS/RNS in the body either because of excessive production or insufficient removal from the body. ROS and RNS are highly reactive molecules which react with biomolecules such as proteins, lipids and DNA and consequently inflict enormous oxidative damage. Diabetes associated complications are attributed mainly to the involvement of superoxide ($^{\bullet}O_2^-$), nitric oxide ($^{\bullet}NO$), and peroxynitrite ($ONOO^-$) free radicals which are produced either through nitric oxide synthase pathway ($^{\bullet}NO$ and $ONOO^-$) or by NADPH oxidases and mitochondrial electron transport chain (Johansen, Harris, Rychly, & Ergul, 2005). Human body has its own defense mechanism against these free radicals in the form of SOD, GSH, glutathione peroxidase (GSH-Px) and catalase enzymes which convert them to non-toxic forms. SOD is present nearly in all cells and is the first line of defense against $^{\bullet}O_2^-$ converting it to H_2O_2, which is further, degraded by GSH-Px or catalase to non-reactive forms. GSH-Px and catalase are located in mitochondria and peroxisomes respectively and are responsible for detoxifying H_2O_2 (Fisher et al., 2006; Johansen, Harris, Rychly, & Ergul, 2005). During hyperglycemia ROS/RNS are produced excessively, thereby, antioxidant capacity of these defense enzymes gets saturated. This renders biological system open to the damaging effect of these free radicles and activates oxidative stress pathway. Generally five oxidative stress pathways are involved in diabetes and its complications (Figure 1).

3.1 The Polyol Pathway

In polyol pathway, NADPH is a co-factor which is responsible for regenerating antioxidant molecule, GSH. GSH is an important scavenger of ROS. During hyperglycemia, NADPH level is reduced markedly through polyol pathway because of which reduced glutathione fails to regenerate. This in turn exacerbate intracellular oxidative stress (Giacco & Brownlee, 2010). Further sorbitol dehydrogenase oxidizes sorbitol to fructose which activates PKC through elevated $NADH/NAD^+$ ratio causing redox imbalance mediated oxidative stress (Brownlee, 2001).

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

3.2 Hexosamine Pathway

Fructose-6-phosphate (F6P) is the substrate for hexosamine oxidative stress pathway. Under normoglycemic condition almost entire F6P is involved in glycolysis and very little amount is available for hexoseamine pathway. However, hyperglycemic condition produces excessive F6P which ultimately becomes available for hexosamine pathway where glutamine-fructose-6-phosphate amidotransferase (GFAT) converts it to UDP-N-acetylglucosamine, an essential metabolite for producing glycosyl chains in proteins and lipids. O-glucosamine-N-acetyl transferases enzyme utilizes UDP-N-acetylglucosamine for making post-translational changes at serine and threonine residues of cytoplasmic and nuclear proteins involved in diabetes such as insulin receptor substrate(IRS), pancreatic duodenal homeobox 1 (PDX1), endothelial nitric oxide synthase (eNOS) and sp1, rendering them non-functional, leading to InR and other related complications (Buse, 2006; Dias & Hart, 2007; Giacco & Brownlee, 2010).

3.3 Diacylglycerol (DAG) and Protein Kinase C (PKC)

During diabetes, dihydroxyacetone phosphate level is elevated in body via glycolysis. It is then reduced to glycerol-3-phosphate which conjugates with fatty acids to chronically enhance the de novo synthesis of DAG. DAG activates the signaling cascade mediated through the activation of PKC, which is a serine/threonine kinase (Geraldes & King, 2010).PKC is also activated as a consequence of inhibition of glycolytic enzyme, glyceraldehide-3-phosphate dehydrogenase, (Brownlee, 2001; Giacco & Brownlee, 2010) and through interaction between AGEs and their extracellular receptors (Scivittaro, Ganz, & Weiss, 2000). PKC subsequently activates MAPK, NADPH oxidase and NF-κB, which upsurges oxidative and inflammatory stress induced diabetic complications (Ceriello, 2006).

3.4 Advanced Glycation End-Products (AGEs)

AGEs are associated with both T1DM (Chiarelli et al., 1999; Hwang, Shin, & Yang, 2005) and T2DM (Aso, Inukai, Tayama, & Takemura, 2000; Tan et al., 2002; Tan, Chow, Tam, Bucala, & Betteridge, 2004). Degree of association is related to the severity of diabetic complication which includes microvascular complications (Aso, Inukai, Tayama, & Takemura, 2000;Chiarelli et al., 1999; Wautier et al., 2003), macrovascular complications (Aso, Inukai, Tayama, & Takemura, 2000; Kilhovd et al., 2007; Kilhovd, Berg, Birkeland, Thorsby, & Hanssen, 1999), insulin resistance (Tan, Shiu, Wong, & Tam, 2011) and enhanced marker of inflammation and endothelial dysfunctioning (Tan, Chow, Tam, Bucala, & Betteridge,2004). AGE production is initiated by nucleophilic addition reaction between amino group of protein and carbonyl group of a reducing sugar, forming a Schiff base, which rearranges itself to more stable ketoamine or amadori product. Initial part of reaction is reversible as the concentration of reactants is low and thus under normoglycemic condition Schiff base breaks into its reactants in reversible manner. However during hyperglycemia, excessive reactant concentration leads to the formation of more stable amadori product, which is non-reversible reaction. Further, glycated proteins undergo a series of dehydration, oxidation-reduction and other rearrangements reactions to produce AGEs. Interaction of AGE and its receptor depends upon the load of the AGE available. Under normoglycemic conditions, when AGEs are low, the expression of receptor for advanced glycationendproducts (RAGE) is downregulated and expression of advanced glycationendproduct receptor-1 (AGER1) is upregulated. AGER1 activation has inhibitory effect on the RAGE mediated activation of transcription factors nuclear NFκB, activator

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

protein 1 (AP-1) and forkhead box protein-O-subclass (FOXO) and consequently transcription of the genes initiated by them. Besides inhibiting RAGE activity, AGER1 also initiate degradation process of AGE itself. The entire scenario changes during hyperglycemic state when AGE are produced excessively, causing upregulation of RAGE and downregulation of AGER1, leading to the activation of inhibited transcription factors and subsequent transcription of genes related to oxidative and inflammatory stress (Bansal et al., 2013; Morita, Yano, Yamaguchi, & Sugimoto, 2013; Nass & Simm, 2009).

3.5 Stress-Sensitive Signaling Pathways

Apart from inflicting damage on biomolecules, oxidative stress is known to be involved in the activation of various stress sensitive signaling cascade which ultimately result in the enhanced cytokine release, inflammation and apoptosis. These signaling mechanisms mainly involve MAPK, stress-activated protein kinase (SAPK) and Janus kinase (JAK)/signal transducer and activator of transcription (STAT) pathway during diabetes. p. 38 MAPK is a regulatory protein activated through chemokines, neurotransmitters, radiation, physical, and chemical stresses including oxidative stress. Hyperglycemia enhance the activity of p38 MAPK in vascular smooth muscle cells, retinal pericytes (Igarashi et al., 1999), and mesangial cells where it regulates inflammation, differentiation and cellular proliferation through transcription of its specific genes. Further, inhibition of p38 MAPK reduces apoptosis (Liu et al., 2003),arachidonic acid release (Igarashi et al., 1999) and improves sensory nerve conduction (Agthong & Tomlinson, 2002) in diabetes along with enhancing translocation of the insulin-responsive GLUT4 to the cell membrane (Carlson, Koterski, Sciotti, Poccard, & Rondinone, 2003). Furthermore, oxidative stress activates SAPK and JAK/STAT signaling cascade which inflicts inflammatory stress induced damage by enhancing cellular proliferation, apoptosis and inflammatory response along with sensitizing cellular response to interferons and interleukins (Gomperts, Kramer, & Tatham, 2009).

Flavonoids possess antioxidant property and many of them are also known to possess significant anti-diabetic potential (Table 3; Figure 3). Quercetin improved blood glucose profile, body weight, macrophage count and biochemical profile in alloxan induced diabetic rats. Though its exact antidiabetic mechanism still remains unclear but prevention of DNA damage, antioxidant and anti-inflammatory property suggest that it probably act by reducing oxidative stress (Bhutada et al., 2010; Maciel et al., 2013; Oršolić et al., 2011). Bucolo et al., (2012) evaluated effect of eriodictyol on streptozotocin (STZ) induced diabetic rats and reported it to attenuate inflammation, lipid peroxidation and reduce production of inflammatory mediator viz. TNF-α, intercellular adhesion molecule-1 (ICAM-1), vascular endothelial growth factor (VEGF), and eNOS level in retina (Bucolo, Leggio, Drago, & Salomone, 2012). Diosmin normalized oxidative status by elevating plasma level of SOD, catalase, GSH-Px, glutathione-S-transferase (GST) and non-enzymatic antioxidants such as vitamin C and vitamin E. Further, it was reported to reduce plasma glucose and glycosylated haemoglobin (Hb1Ac) levels and elevate insulin and hemoglobin level (Pari & Srinivasan, 2010; Srinivasan & Pari, 2012). Epigallocatechin-3-O-gallate eliminated oxidative stress by enhancing SOD and GSH-Px enzyme activity and by reducing malondialdehyde (MDA) and 8-isoprostaglandin plasma levels in Wistar rats. It also reduced free fatty acid (FFA) level thereby abolishing InR, probably through inhibiting lipolysis (Li et al., 2011). Fisetin and luteolin reduced the levels of blood glucose and HbA1c and increased plasma insulin level. They further reduced the circulating levels of lipid peroxides and hydroperoxides in hepatic tissues and normalizing altered alanine transaminase (ALT), aspartate transaminase (AST), alkaline phosphatase (ALP), SOD, catalase, ROS, GSH-Px, GST and GSH activity. Thus, they seems to alleviate diabetes induced oxidative stress to

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

counteract its complications (Kim, Kwon, & Son, 2000; Liu et al., 2013; Prasath & Subramanian, 2013; Qian et al., 2010; Wang, Lu, Li, Zhao, & Zhang, 2011). Treating STZ-diabetic rats with hesperidin, naringin, epicatechin and rutin showed reduction in blood glucose, HbA1c, thiobarbituric acid reactive substances (TBARS), MDA, nitric oxide (NO), TNF-α, IL-6 level and lipid peroxides in serum and hepatic tissue with enhanced GSH, catalase, GSH-Px, and SOD enzymatic activity. Though not clear, but their antidiabetic potential also seems to be mediated by eliminating oxidative stress (Kamalakkannan & Prince, 2006; Mahmoud, Ashour, Abdel-Moneim, & Ahmed, 2012; Quine & Raghu, 2005). *In-vitro* studies conducted on puerariafuran, coumestrol, sulfuretin, astilbin, pelargonidin-3-α-O-rhamnoside and cyanidin-3-α-O-rhamnoside reports significant inhibition of AGE, which is a key mediator of diabetic complications (Hanamura, Hagiwara, & Kawagishi, 2005; Jang et al., 2006; Lee et al., 2008; Wirasathien et al., 2007). 4,2',4'-trihydroxy-3'-[6-hydroxy-3,7-dimethyl-2(E),7-octadienyl] chalcone, 3,4,2',4'-tetrahydroxy-3'-geranyldihydrochalcone and 4,2',4'-trihydroxy-5'-geranyldihydrochalcone inhibited mRNA expression of RAGE, IL-6, TNF-α and cyclooxygenase-2 (COX-2) and reduced ROS generation along with improving mitochondrial morphology and functioning in diabetic animals (Lin, Wu, Fang, & Yen, 2012). Pelargonidin and glabridin facilitated oxidative defense of body by increasing SOD activity and lowering MDA levels in different tissues of diabetic animals (Mirshekar, Roghani, Khalili, Baluchnejadmojarad, & Moazzen, 2010; Wu, Jin, & Jin, 2013). Similar elevation of antioxidant status in diabetic animals after apigenin and puerain treatments had been reported previously (Rauter et al., 2010; Yoo et al., 2008; Zhu et al., 2010).

4. Insulin Signaling

As discussed earlier, Insulin is responsible for maintaining normal glucose homeostasis in the body, which is achieved through binding of insulin to α-subunit of IR and subsequent auto-phosphorylation of its tyrosine residue on β-subunit. This triggers phosphorylation and activation of insulin receptor substrates proteins 1-4 (IRS1-4), Shc, Gab-1, Cbl, and APS (Saltiel & Pessin, 2002), and switches "on" downstream signaling cascade by activating numerous intermediate effectors, which ultimately leads to the activation of protein kinase B (PKB)/Akt.Akt, a serine-threonine kinase, enters nucleus to induce transcription and translocation of GLUT4 to the membrane. Akt independent pathway are also known to be involved in the translocation of GLUT4 via phosphorylation of proto-oncogene Cbl, thereby aiding in the disposal of glucose (Cole, Astell, Green, & Sutherland, 2007; Plum, Schubert, & Brüning, 2005; Saltiel & Kahn, 2001). PKB is known to promote fatty acid synthesis, protein synthesis, glycogen synthesis, PIP3-dependent kinase (PDK) mediated inhibition of lipolysis through cyclic adenosine monophosphate(Camp)/protein kinase A(PKA) pathway and thus aids in establishing glucose homeostasis (Proud, 2006).

Since insulin/insulin signaling is directly involved in regulating blood glucose level, it is thus the most important target for the management of diabetes. Many flavonoids have been reported to effectively counter diabetes by their direct action on insulin receptor and by modulating insulin signaling (Table 4; Figure 4). Apigenin-6-C-β-fucopyranoside enhances insulin signaling and produces subsequent dose dependent disposal of blood glucose into liver and muscles of diabetic animals (Cazarolli et al., 2012). Karanjin enhances GLUT4 translocation and AMP-activated protein activity to produce antidiabetic effect inL6-GLUT4 mycmyotubes (Jaiswal, Yadav, Maurya, Srivastava, & Tamrakar, 2011). Myricetin was reported to enhance phosphorylation of IRS1 and Akt. It further elevated protein level of IRS1, GLUT4 and phosphatidylinositol-3 kinase (PI3K) with subsequent reduction in blood glucose and

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

HbA1c levels (Liu, Tzeng, Liou, & Lan, 2007). Puerarin upregulated IRS-1 and insulin-like growth factor-1 (IGF-1) expression and thus reduce circulating blood glucose level in STZ challenged rats (Wu et al., 2013). Baicalein was reported to enhance phosphorylation and activation of the IRS1/PI3K/Akt pathway thereby improving insulin signaling. Further, it abolished InR and improved glucose intolerance (Pu et al., 2012). Morin activate and potentiate insulin signaling on HepG2 cells (Paoli et al., 2013) and thus can be a molecule of interest for future anti-diabetic research. Two flavonol glycosides isolated from *Cinnamomumosmophloeum* leaves showed promising result in an *in-vitro* model for mimicking insulin action. They enhanced GLUT4 translocation and phosphorylation of IRβ-subunit (Lee, Rao, Chen, Lee, & Tzeng, 2009). Rutin showed antidiabetic potential by increasing glucose uptake into soleus muscle through activation of PI3K and MAPK pathway (Kappel, Zanatta, Postal, & Silva, 2013). Epigallocatechin-3-O-gallate improved insulin signaling and InR by enhancing AMPK level, Akt level and GLUT4 translocation in skeletal muscle and adipose tissue in diabetic animals (Li et al., 2011). *In-vitro* and *in-vivo* studies conducted on tangeretin reported its ability to improve insulin signaling and translocation of GLUT4 to cellular membrane. This action may be a result of enhanced phosphorylation of AMPK, which itself is a key component of insulin signaling cascade (Kim, Hur, Kwon, & Hwang, 2012). Antidiabetic reports of all these molecules are just preliminary and needs to be explored further so as to understand the detailed mechanism through which they control diabetes.

5. Peroxisome Proliferator-Activated Receptors (PPAR) Receptor

PPARs belong to the nuclear receptor superfamily of transcription factors which have been extensively exploited as therapeutic targets for T2DM and dyslipidemia in resent past. PPARs consist of three different subtype of receptors i.e. PPAR-α, PPAR-γ and PPAR-α/γ amongst which PPAR-γ plays an important role in T2DM because of its influential effect on fatty acid flux from adipose tissue which alleviates InR and reduces blood glucose levels. PPAR-α on the other hand has lipid modifying properties. Upon activation, PPAR-γ conjugates with retinoid-X receptors (RXRs) forming a heterodimer (PPAR-RXR). This heterodimer migrates to nucleus and binds to specific DNA sequence, peroxisome proliferator–response elements, and initiate the transcription of GLUT4 genes. PPAR-α has regulatory effect on genes controlling the fatty acid uptake, oxidation process, inflammation, and vascular function whereas PPAR-γ regulates genes for fatty acid uptake and storage, inflammation and glucose homeostasis in the body (Mello, Polvani, & Galli, 2009; Plutzky, 2011).

Non-responsiveness of fat cells to insulin results in chronic elevation in plasma level of FFA, which in turn induces resistance towards insulin in liver and skeletal muscles. This further induces hyperglycemic state by increasing gluconeogenesis and reducing glucose disposal into these organs. Resistant fat cells produces excessive amount of cytokines (TNF-α, IL-6 and restin) which further adds up to InR and inflammatory stress. It has been observed that about 70% T2DM patients have some degree of dyslipidemia (Fagot-Campagna et al., 2000) which is characterized by increased triglycerides (TGs) and reduced high density lipoprotein (HDL) cholesterol levels (Malmberg et al., 2000). PPAR-γ has direct effect on lipid and glucose metabolism in adipose tissue, liver and skeletal muscles. PPAR-γ promotes differentiation of adipocyte, FFA uptake and facilitates its storage in subcutaneous adipose tissue rather than visceral adipose tissue. This lowers FFA level in blood and restores insulin sensitivity. It further enhances glucose disposal into liver and skeletal muscle by increasing expression and translocation of glucose transporters (GLUT1/GLUT4) thereby reducing the level of blood glucose (Kramer, Shapiro, Adler, Bush, & Rondinone, 2001).

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

In recent past, few flavonoids have shown good potential to upregulate PPAR-γ receptor and thus they alleviated InR and reduced hyperglycemia and associated complications (Table 5; Figure 5). Isoginkgetin(Liu et al., 2007), luteolin(Ding, Jin, & Chen, 2010; Puhl et al., 2012) and other flavonoids isolated from *G. glabra*(Kuroda et al., 2010) are reported to upregulate PPAR-γ receptor in various *in-vitro* and *in-vivo* studies, developed for the management of InR in T2DM and its associated complications.

6. Glucose Metabolic Pathway

Glucose is the primary energy source of our body. After entering cells, it is oxidized to generate ATPs through glycolysis. Glucose is first converted to G6P by the reaction catalyzed by hexokinase which is further converted to F6P by phosphoglucoisomerase enzyme. F6P, thus formed, either enters pentose phosphate pathway leading to the generation of NADPH or is converted into glyceraldehyde-3-phosphate by glyceraldehyde-3-phosphate dehydrogenase (GAPDH) to yield pyruvate as an end product of glycolysis through series of reactions. Pyruvate now enters Kreb's cycle and mitochondrial metabolism to further enhance energy production in the form of ATP (Nelson, Lehninger, & Cox, 2008).

During hyperglycemia, ROS generated by mitochondria inhibits GAPDH and activates poly-ADP-ribose polymerase-1 (PARP-1) enzyme which is involved in DNA repair and apoptotic pathways (Brownlee, 2001; Brownlee, 2005; Giacco & Brownlee, 2010). DNA damage inflicted by ROS activates PARP-1 which consumes NADPH excessively thereby elevating oxidative stress as discussed above. GAPDH inhibition (Brownlee, 2005) results in accumulation of glyceraldehyde-3-phosphate which in turn activates two major pathways of diabetic complications, AGE and DAG pathway. In AGE pathway, excess of glyceraldehyde-3-phosphate is converted to methylglyoxal through non enzymatic process. DAG activates PKC pathway and inflicts subsequent damage as discussed previously. GAPDH inhibition further leads to the accumulation of F6P upstream which enter hexosamine pathway and is converted to UDP–N-Acetylglucosamine by GFAT resulting in various diabetic complications. Lastly, GAPDH inhibition results in accumulation of glucose which becomes available to polyol pathway in excess and initiate diabetes induced damage (Giacco & Brownlee, 2010).

Interfering with the enzymes of the glucose metabolic cycles so as to reduce the blood glucose level is another mechanism through which antidiabetic activity of many flavonoids has been observed (Table 6; Figure 3). Diosmin (Pari & Srinivasan, 2010), eupatilin (Kang et al., 2008)and biochanin A (Harini, Ezhumalai, & Pugalendi, 2012) reduced the activity of glucose-6-phosphatase, fructose 1,6-bisphosphatase, phosphoenol-pyruvate carboxykinase and increased activity of glucokinase, glucose-6-phosphate dehydrogenase in diabetic animals, and thereby controlling hyperglycemia.

7. Other Targets

7.1 Protein-Tyrosine Phosphatase 1B (PTP1B)

PTP1B is a member of protein tyrosine phosphatases family of enzymes and is reported to be linked to InR and T2DM by several experimental studies. These studies demonstrated that PTP1B dephosphorylates the IR and IRS-1 and thus acts as a negative regulator of insulin signaling (Bandyopadhyay et al., 1997; Goldstein, Bittner-Kowalczyk, White, & Harbeck, 2000). Overexpression of PTP1B in cell cultures lowered insulin mediated phosphorylation of IR and IRS-1whereas reduction in PTP1B level enhanced insulin signaling (Byon, Kusari, & Kusari, 1998; Kenner, Anyanwu, Olefsky, & Kusari, 1996;

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Sreejayan, Lin, & Hassid, 2002; Tagami et al., 2002). Recently, studies conducted on PTP1B knockout mice clarified its involvement in insulin signaling, T2DM, inflammation and obesity (Grant et al., 2014) thus making it as a promising target for antidiabetic therapy. Secondly, PTP1B is known to down regulate leptin, which is an adipocyte-secreted hormone responsible for reducing food intake and enhancing energy expenditure through its action on hypothalamus. PTP1B binds and dephosphorylates JAK2, which is required for downstream signaling of leptin pathway (Lund, Hansen, Andersen, Møller, & Billestrup, 2005; Zabolotny et al., 2002). Further, neuronal PTP1B regulates leptin production in adipocytes and leads to the development of leptin resistance (Bence et al., 2006). Thus, impairment of leptin signaling by PTP1B over activity also adds on to the progression of diabetes and its associated complications.

Flavonoids capable of inhibiting PTP1B are listed in Table 7. 2',4-dihydroxy-4'-methoxydihydro chalcone and 2',4'-dihydroxy-4'-methoxydihydro chalcone, isolated from *A. dracunculus*, lowered PTB1B activity by 36% and 26% respectively with previous one having IC_{50} value of 61 μM (Wang et al., 2006). Morin was also reported to possess PTP1B inhibitory activity through *in-vitro* assay (Paoli et al., 2013). PTP1B signaling, as indicated, plays effective role in progression of diabetes and thus these compounds can be looked upon as potential agents to explore this target for controlling diabetic complications.

7.2 Sodium Glucose Co-Transporter 2 (SGLT2)

In healthy human being, kidney filters approximately 180g glucose/day which is completely reabsorbed by the highly selective sodium coupled glucose transporters, SGLT2 and SGLT1, located in the proximal tubule of the kidney. Out of these two, 90% of the glucose is reabsorbed by SGLT2 and remaining by SGLT1 (Gerich & Bastien, 2011). Therefore, inhibition of SGLT2 increases urinary glucose excretion and reduces blood glucose level in hyperglycemic condition in insulin independent manner. Recent clinical studies conducted on canagliflozin, a SGLT2 inhibitor, demonstrated its exceptional therapeutic efficacy and safety in diabetic patients in comparison to placebo and other established antidiabetic drugs (Cefalu et al., 2013; Lavalle-Gonzalez et al., 2013; Wilding et al., 2013).

SGLT2 inhibiting potential of flavonoids is yet to be demonstrated experimentally, either *in-vivo* or *iv-vitro*, though luteolin had shown potential to inhibit SGLT2 through *in-silico* docking study using 2QX2 PDB (Table 7) (Annapurna et al., 2013). However, *in-silico* studies cannot be considered conclusive and experimental justification needs to be established.

7.3 Nuclear Factor Kappa B (NFκB)

As discussed earlier, NF-κB is a cytoplasmic transcription factor which on activation migrates to nucleus and regulates the expression of genes for TNF-α, tissue factor, cell adhesion molecules and chemotactic proteins. Along with PARP, it activates inducible-NOS (iNOS), intercellular Adhesion Molecule-1 (ICAM-1) and histocompatibility complex class II, and thereby enhancing inflammatory damage. Activation of NFκB in endothelial cells induces apoptosis (Du, Stocklauser-Farber, & Rosen, 1999; Gomperts, Kramer, & Tatham, 2009). A study conducted by Kim et al. (2007) demonstrated that inhibition of NFκB signaling through activation of PPAR-γ protects pancreatic β-cells from cytokines induced cytotoxicity/cell death. In animal experiments, NFκB inhibition is known to provide protection against chemical induced diabetes (Ho, Chen, & Bray, 2000; Park & Park, 2001). Recently, NFκB was reported to play crucial

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

role in diabetic cardio-vascular complication and its suppression by various agents provided beneficial outcomes in these complications (Parra et al., 2014; Xiang, Wang, Zhang, Ling, & Xu, 2012). Further, inhibition of NFκB protected apoptosis of cardiomyocytes via reduction in ROS generation (Kuo et al., 2013). These reports thus make NFκB an auspicious target for management of diabetes.

Two flavonoids (Table 7), baicalein (Pu et al., 2012)and scutellarin (Luo et al., 2008), were reported to counteract hyperglycemia elicited metabolic abnormalities and vascular inflammation directly by interfering with the expression and signaling mechanism of NFκB. Thereby, they can be useful in impeding the progression of diabetic complications, especially cardio-vascular.

7.4 Jun N-Terminal Kinase (JNK) Signaling

JNK signaling is activated by cytokines, endoplasmatic reticulum stress and hyperlipidemia, all of which are elevated in DM (Hotamisligil, 2010). Insulin gene expression is markedly reduced by the activation of JNK signaling pathway through oxidative stress and JNK inhibition protected pancreatic cells from oxidative damage (Kaneto et al., 2002; Kim et al., 2010). Recently, Norseen et al. (2012) demonstrated that retinol binding protein-4 play an important role in insulin signaling and development of InR. This action was attributed to the involvement of JNK signaling pathway via its effect on pro-inflammatory cytokines Evidence suggest that, elevated JNK level reduces insulin sensitivity (Ye, Xue, Sha, Li, & Zhen, 2009) whereas lower levels enhance the utilization of fatty acids thereby improving insulin sensitivity. Further, it diverts glucose from oxidative pathway towards glycogenesis, and thus, lowered blood glucose level and subsequent oxidative stress (Vijayvargia, Mann, Weiss, Pownall, & Ruan, 2010).

Pu et al., (2012) reported that baicalein alleviated diabetes and counteracted its complications through insulin and NFκB signaling. Same study also depicted that along with insulin and NFκB signaling, JNK signaling cascade may also play crucial role in the development of diabetic complications (Table 7) (Pu et al., 2012). Thus inhibition of JNK signaling may also prove useful in countering diabetic complications.

8. Unknown Mechanisms

Many flavonoids have been screened for their antidiabetic activity through preliminary *in-vitro* and *in-vivo* studies but the exact mechanism through which they benefit diabetic complications is still not clear (Table 8). Chrysoeriol reduced circulating glucose level, improved glucose tolerance, ALT and AST level of kidney and liver (Rauter et al., 2010). Naringenin prevented DNA damage in the alloxan treated animals through unknown mechanism (Oršolić et al., 2011). Quercetin-3'-methoxy-3-O-(4''-acetylrhamnoside)-7-O-α-rhamnoside, kaempferol-4'-methoxy-3.7-dirhamnoside and isorhamnetin-3-O-β-D-glucoside enhanced *in-vitro* glucose disposal into myotubes and thus can be assumed to show same effectiveness in animal models as well (Motaal, Ezzat, & Haddad, 2011). Silymarin improved body weight and hepatic glycogen level along with reducing daily urinary output volume in STZ treated rats. It further normalized MDA, NO, total thiol, AST and ALT level, improved histopathological profile of liver, downregulated cytochrome P450-3A2 (CYP 3A2) and upregulated GSH-Px expression. Though their effect can be attributed to the alleviation of oxidative stress but still no clear-cut observation is there (Malekinejad, Rezabakhsh, Rahmani, & Hobbenaghi, 2012). Kaempferol 3-*O*-α-(2''-galloyl) rhamnoside, quercetin-3-*O*-α-rhamnoside, kaempferol 3-*O*-α-rhamnoside, quercetin 3-*O*-α-arabinoside

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

and quercetin 3-*O*-α-(2″-galloyl) rhamnoside were reported to inhibit rat liver microsomal glucose-6-phosphatase enzyme. Glucose-6-phosphatase is a key enzyme involved in the glucose metabolic cycle and its regulation affects the accumulation or disposal of glucose from the circulation. Thus these molecules can be further subjected to *in-vivo* antidiabetic study to test their activity in living system (Estrada et al., 2005). 4-hydroxyderricin and xanthoangelol were reported to enhance differentiation of 3T3-L1 cells to adipocytes and increase glucose disposal into these cells. They also reduced blood glucose level and alleviated polydipsia in diabetic KK-A^y mice through unknown mechanism (Enoki et al., 2007). Likewise delphinidin had shown effectiveness in controlling hemoglobin and albumin glycosylation in *in-vitro* and *in-vivo* study and may be considered as a good candidate for future diabetic research (Gharib, Faezizadeh, & Godarzee, 2013). Genistein improved glucose tolerance, reduced circulating glucose and modified the levels of ALT, AST, SOD and MDA in STZ induced diabetic rats (Baluchnejadmojarad & Roghani, 2008; Rauter et al., 2010). Kaempferitrin reduced blood glucose level in alloxan induced diabetic rats by enhancing glucose disposal into soleus muscle (Jorge, Horst, de Sousa, Pizzolatti, & Silva, 2004). Only preliminary studies have been conducted on these molecules and majority of them are reported to normalize altered biochemistry and hematological parameters, which are generally seen in diabetes. These results cannot be considered conclusive and cannot be attributed to any single mechanism and require further investigation.

CONCLUSION

Current chapter discusses the impact of diabetes on global health and current strategies that are being used to counter diabetes and its associated complications. It is well known that the currently available diabetic therapeutics is not capable of preventing or reversing the complications associated with DM. In this regard, current focus of diabetic research is to identify and counter mechanisms responsible for the development of these complications. Oxidative stress, in form of ROS/RNS that are generated excessively during hyperglycemia, is one of the major reasons for development and progression of diabetic complications. Evidence suggests that antioxidants are capable of preventing and reversing these secondary complications in early stages in diabetic animals (Abiko et al., 2003, Koya, Lee, Ishii, Kanoh, & King, 1997) and also prevent the hyperglycemia induced biological changes within the body (Greene, Nelson, Robinson,& Buse, 2001;Montero et al., 2000;Studer, Craven,&DeRubertis, 1997).

Flavonoids are natural antioxidants and are well known for their antioxidant potentials. Many of them, such as quercetin, rutin, etc., had been reported to counter diabetes and its complications through enhancing oxidative defense and other mechanisms. Flavonoids may benefit in diabetes by abolishing oxidative stress induced damage by eliminating free radicals and by potentiating oxidative defense of the body. Exceptional beneficial effect of flavonoids become evident from findings that suggests that enhanced intake of diets rich in polyphenols lowers risk of diabetes and development of its complications by 80% (Steinmetz & Potter, 1996; Law & Morris, 1998; Anderson, Anthony, Cline, Washburn, & Garner, 1999; WHO, 2003). Thus, it can be concluded that effective and efficient diabetic therapeutics can be achieved by coupling traditional diabetic treatment strategies together with flavonoids. Flavonoids can be used as dietary supplements and may prove to be efficient in eliminating development and progression of diabetes and its associated complications.

KEY TERMS AND DEFINITIONS

Aldose Reductase: Aldose reductase is an oxidoreductase enzyme responsible for catalyzing biochemical reaction that leads to detoxification of aldehydes and carbohydrates, especially glucose.

Antioxidant: Substance that inhibits oxidation is referred to as antioxidant. In biological system, any substance which either directly inhibits oxidative stress or indirectly facilitates regeneration or formation of antioxidant enzymes is referred to as antioxidant.

Diabetic Complications: Complications in the biological system that arise secondary to long standing diabetes are known as diabetic complications. They include neuropathy, nephropathy, retinopathy, etc.

Flavonoids: Flavonoids are 15 carbon polyphenolic secondary metabolites of plants having two aromatic rings linked by a 3 carbon bridge i.e. C6-C3-C6 linkage. Flavonoids are mainly responsible for antioxidant property of the plants.

Herbal Therapy: Whole plant or its any part or extract or other such preparations or isolated compound or mixture of these when used for preventing or curing any disease or disease condition, such therapy is referred to as herbal therapy.

Insulin: Insulin is a 51 amino acid peptide hormone produced in the β-cells of pancreas. It is responsible for maintaining normal blood glucose level in the body.

Type 2 Diabetes Mellitus: The most common type of diabetes, characterized by insulin resistance leading to hyperglycemia. Thus it is also known as non-insulin-dependent diabetes.

This work was previously published in the Handbook of Research on Advancing Health Education through Technology edited by Victor C.X. Wang, pages 286-328, copyright year 2016 by Medical Information Science Reference (an imprint of IGI Global).

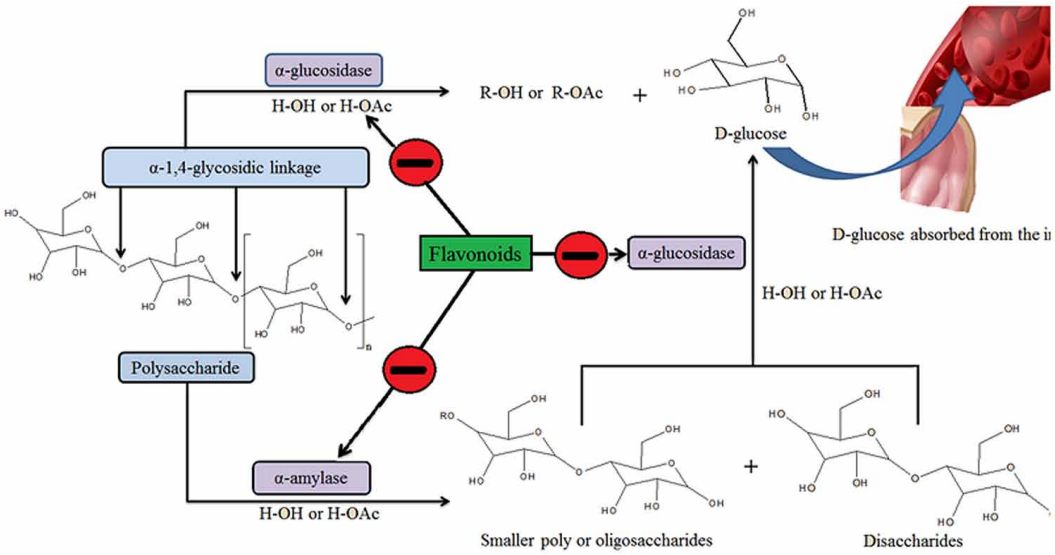
APPENDIX: FIGURES AND TABLES

In Figure 1, (A) AR converts glucose into sorbitol which directly leads to retinopathy by inflicting osmotic stress. This process consumes and depletes antioxidant NADPH, leading to excessive oxidative stress induced damage at cellular and molecular levels. (B) AR is also responsible for the detoxification of aldehydes from the body. This process leads to the transcription of excessive inflammatory stress markers, causing cytotoxicity through DAG-PKC-NFκB-MAPK pathway. Flavonoids are known to inhibit AR activity thereby prevents the development of subsequent damage inflicted by hyperglycemia.

Dietary polysaccharides are broken down into absorbable monomers (D-glucose) by α-glucosidase and α-amylase in small intestine. Flavonoids inhibit these enzymes and thus polysaccharides remain in non-absorbable form which automatically reduces the dietary glucose uptake and hyperglycemia as shown in Figure 2.



Glucose is the primary energy source for every cell of our body. Glucose is oxidized to produce ATP, through various biochemical processes (glycolysis, Kreb's cycle and polyol pathway). During hyperglycemia, oxidation of excess glucose generates enormous ROS and AGE through various metabolic pathways. These highly reactive molecules reacts with biomolecules (proteins, RNA, DNA etc.) thereby compromising their biological functions leading to various diabetic complications. Flavonoids are natural antioxidants and help to reduce oxidative stress by direct free radical scavenging ability, directing excess glucose to glycolysis and Kreb's cycle for energy production and by blocking various pathways that leads to generation of ROS and AGE (Figure 3).

Figure 1. Role of AR and its inhibition by flavonoids in the development of diabetic complications

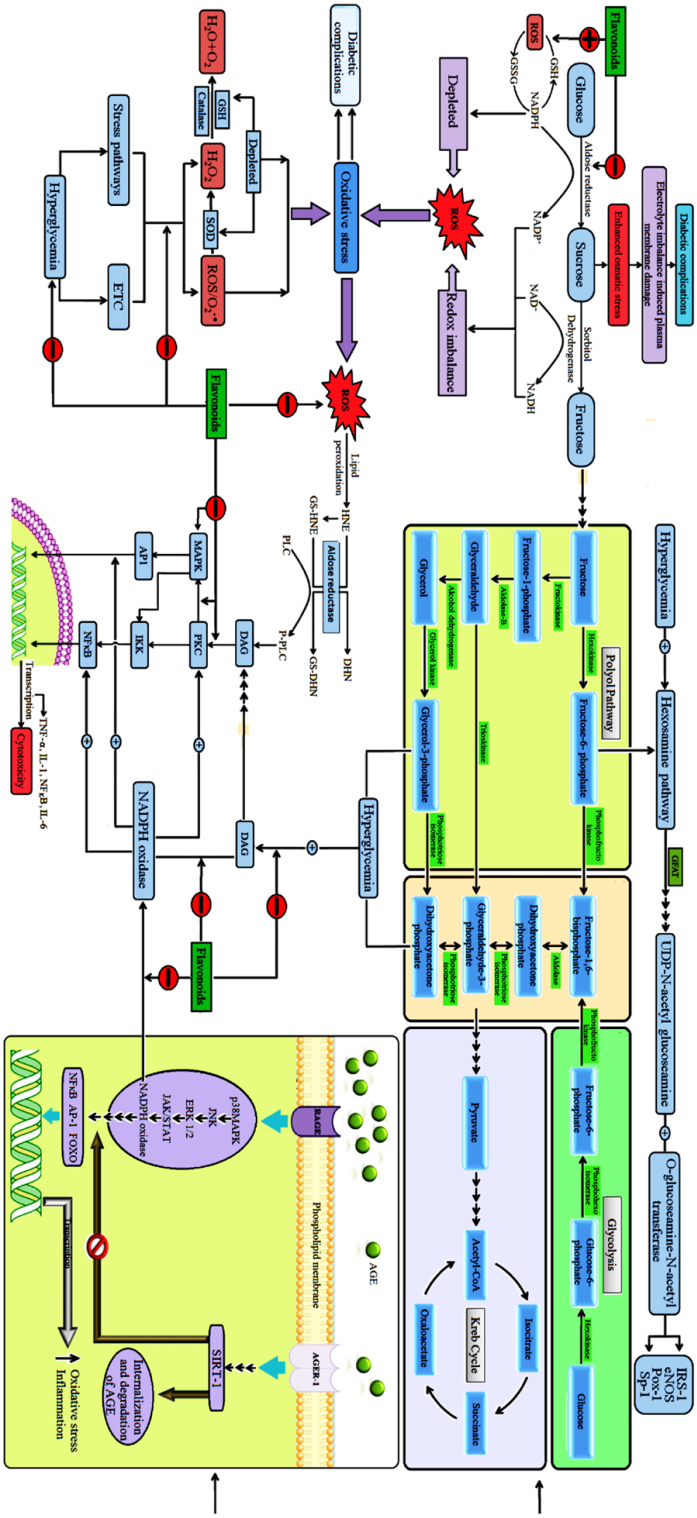
Figure 2. Role of α-glucosidase and α-amylase and their inhibition by flavonoids in diabetes



Insulin is responsible for maintaining glucose homeostasis by potentiating transcription and translocation of GLUT4 to cell membrane via multistep signaling cascade and thereby disposing blood glucose into skeletal muscle (energy production), adipose tissue (stored as fat) and liver (converted to glycogen). Flavonoids potentiate insulin signaling and GLUT4 translocation thereby enables disposal of glucose from the blood and reduces hyperglycemia (Figure 4).

PPAR-γ on activation binds to RXR forming an activated dimer which binds to specific target genes and initiates transcription of insulin receptor protein. IR is then translocated to cell membrane where it binds to insulin and result in insulin mediated disposal of glucose into skeletal muscle, adipose tissue and liver. Flavonoids binds to PPAR-γ and initiates dimerization with RXR and initiate further downstream signaling to ultimately dispose excess glucose from the blood (Figure 5).

Table 1. List of flavonoids having AR inhibitory activity

S. No.	Flavonoid (Source)	Dose	Model/Assay	Major Findings	Reference
1.	Quercetin; Fruits, vegetables etc.	*In-vitro* 01, 0.5 and 1 µg/mL	Inhibition of AGE formation and rat lens AR assay	2. IC_{50} = 0.48 µg/mL and 7.21 µM)	Mok & Lee, 2013; Yoo et al., 2008
2.	Kaempferol; *Rhododendron mucronulatum* (Ericaceae)*; Erigeron annuus* (Asteraceae)	*In-vitro* 0.5, 1 and 5 µg/mL	Inhibition of rat lens AR assay	2. IC_{50} = 0.79 µg/ml and 1.33 µM	Mok & Lee, 2013; Yoo et al., 2008
3.	Afzelin; *R. mucronulatum* (Ericaceae)	*In-vitro* 01, 0.5 and 1 µg/mL	Inhibition ofrat lens AR assay	2. IC_{50} = 0.31 µg/mL	Mok & Lee, 2013
4.	Myricitrin; *R. mucronulatum* (Ericaceae)	*In-vitro* 0.5, 1 and 5 µg/mL	Inhibition of rat lens AR assay	2. IC_{50} = 2.67 µg/mL	Mok & Lee, 2013
5.	Quercitrin; *R. mucronulatum* (Ericaceae)	*In-vitro* 0.05, 0.01 and 1 µg/ mL	Inhibition of rat lens AR assay	2. IC_{50} = 0.13 µg/mL, 0.16 µM and 50.15 µM	Mok & Lee, 2013; Yoo et al., 2008; Matsuda et al. 2002
6.	Myricetin; *R. mucronulatum* (Ericaceae)	*In-vitro* 1, 5 and 10 µg/mL	Inhibition of rat lens AR assay	2. IC_{50} = 11.92 µg/mL	Mok & Lee, 2013
7.	2',4-dihydroxy-4'-methoxydihydro chalcone; *Artemisiadracunculus* (Asteraceae)	*In-vitro* 3.75 µg/ml	Human recombinant AR2 enzyme inhibition assay	2. Inhibited AR activity (58.2% inhibition)	Logendra et al., 2006
8.	Davidigenin; *A. dracunculus* (Asteraceae)	*In-vitro* 3.75 µg/ml	In-vitro human recombinant AR2 enzyme assay	2. IC_{50} = 10 - 12.70 µM	Logendra et al., 2006
9.	Erigeroflavanone; *E. annuus* (Asteraceae)	*In-vitro* Multiple concentrations	Rat lens AR inhibition assay	2. IC_{50} = 6.67 µM	Yoo et al., 2008
10.	Butein; *Rhusverniciflua*(Anacardiaceae)	*In-vitro* 0.5, 1 and 2 µM	Recombinant human AR inhibition assay	2. IC_{50} = 0.7 µM	Lee et al., 2008
11.	Sulfuretin; *R. verniciflua* (Anacardiaceae)	*In-vitro* 0.5, 1 and 2 µM	Recombinant human AR inhibition assay	2. IC_{50} = 1.3 µM	Lee et al., 2008
12.	Engeletin; *Stelechocarpuscauliflorus* (Annonaceae)	*In-vitro* 2.5 and 5 µg/ml	Recombinant human AR inhibition assay	2. IC_{50} = 1.16 µM	Wirasathien et al., 2007
13.	Astilbin; *S. cauliflorus* (Annonaceae)	*In-vitro* 2.5 and 5 µg/ml	Recombinant human ARinhibition assay	2. IC_{50} = 26.7 µM	Wirasathien et al., 2007
14.	Apigenin; *Genistatenera* (*Fabaceae*)	*In-vitro* multiple concentrations	Rat lens AR inhibition assay	2. IC_{50} = 6.67 µM	Yoo et al., 2008
15.	Guaijaverin; *Myrciamultiflora* (Myrtacea)	*In-vitro* 25 µL sample solution in 0.5 ml volume	Rat lens AR inhibition assay	2. IC_{50} = 0.18 µM	Matsuda et al. 2002

Table 1. Continued

S. No.	Flavonoid (Source)	Dose	Model/Assay	Major Findings	Reference
16.	Desmanthin-1; *M. multiflora* (Myrtacea)	*In-vitro* 25 µL sample solution in 0.5 ml volume	Rat lens AR inhibition assay	2. IC_{50} = 0.082 µM	Matsuda et al. 2002
17.	Cosmosiin; *Various plants* (Myrtacea)	*In-vitro* 25 µL sample solution in 1.5 ml volume	Rat lens AR inhibition assay	2. 99% inhibition at 10^{-5} M	Shimizu et al., 1984
18.	Lonicerin; *Various plants* (Myrtaceae)	*In-vitro* 25 µL sample solution in 1.5 ml volume	Rat lens AR inhibition assay	2. 91.5% inhibition at 10^{-5} M	Shimizu et al., 1984
19.	Luteolin; *E. annuus* (Asteraceae)	*In-vitro* Multiple concentrations	Rat lens AR inhibition assay	2. IC_{50} = 1.54 µM	Yoo et al., 2008
20.	Apigenin-7-O-β-D-glucuronide; *E. annuus*(Asteraceae)	*In-vitro* Multiple concentrations	Rat lens AR inhibition assay	2. IC_{50} = 1.28 µM	Yoo et al., 2008

Table 2. List of flavonoids having α-glucosidase and α-amylase inhibitory activity

S. No.	Flavonoid (Source)	Dose	Model/Assay	Major Findings	Reference
1.	Daidzein; fruits, nuts, soybeans, legumes etc.	*In-vitro* 0.04-0.4 mM	α-glucosidase and α-amylase inhibition assay	2. Inhibited α-glucosidase (45.64-88.37%) and α-amylase (22.53-60.87%) enzymatic activity	Park et al., 2013
2.	Trilobatin; *Lithocarpuspolystachyus* (Fagaceae)	*In-vitro* 0.2. 0.4, 0.8, 1.2, 1.6 and 2 mg/ml	α-glucosidase and α- amylase inhibitory assay	3. α-glucosidase IC_{50} = 0.37 mg/ml 4. Week inhibitor of α-amylase activity (21.2 ± 3.2%)	Dong et al., 2012
3.	Baohuoside I; *Epimediumbrevicornum* (Berberidaceae)	*In-vitro* 1, 10 and 100 µM	α-glucosidase and α-amylase inhibitory assay	3. α-glucosidase IC_{50} = 28.9 µM/L 4. Week inhibitor of α-amylase activity	Phan et al., 2013
4.	Luteolin; *Lonicerajaponicum* (Caprifoliaceae)	*In-vitro* various concentrations	α-glucosidase and α- amylase inhibitory assay	3. α-glucosidase IC_{50} = 0.5-1 mg/ml 4. α-amylase IC_{50} =50-500 µg/ml	Kim et al., 2000
5.	Saponarin; *Tinosporacordifolia* (Menispermacea)	*In-vitro* multiple doses; *In-vivo* 20-80 mg/kg/ day/p.o. (maltose fed rats)	α-glucosidase inhibition assay	2. Competitive inhibited α-glucosidase IC_{50} = 48 µM (intestinal maltase) and 35µM (intestinal sucrose)	Sengupta et al., 2009
6.	Pelargonidin-3-α-O-rhamnoside; *Malpighiaemarginata*(Malpighiaceae)	*In-vitro* 4.79 mM	α-glucosidase inhibition assay	2. Inhibited α-glucosidase enzymatic activity (approx. 9-23%)	Hanamura et al., 2005
7.	Cyanidin-3-α-O-rhamnoside; *M. emarginata* (Malpighiaceae)	*In-vitro* 4.62 mM	α-glucosidase inhibition assay	2. Inhibited α-glucosidase enzymatic activity (approx. 12-20%)	Hanamura et al., 2005

EBSCOhost - printed on 2/11/2023 5:31 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 3. List of flavonoids having oxidative stress protective effect during hyperglycemia

S. No.	Flavonoid (Source)	Dose	Model/Assay	Major Findings	Reference
1.	Quercetin; Fruits, vegetables etc.	*In-vitro* Various concentrations *In-vivo* 5, 25 and 50 mg/kg/p.o. weekly; (male wistar rats)	Inhibition of AGE formation assay; STZ induced diabetes in rats	4. Normalized TBARS level in serum 5. Improved catalase and SOD activity in liver and kidney 6. Inhibited formation of AGE (IC_{50} = 23.9 μM)	Maciel et al., 2013; Yoo et al., 2008
2.	Sulfuretin; *R. verniciflua* (Anacardiaceae)	*In-vitro* 0.5, 1 and 2 μM	AGE inhibition assay	2. IC_{50} = 124 μM	Lee et al, 2008
3.	Astilbin; *S. cauliflorus* (Annonaceae)	*In-vitro* 2.5 μg/ml μ	AGE inhibition assay	3. 64.9% inhibition of AGE formation 4. IC_{50}= 0.76 μM	Wirasathie-n et al., 2007
4.	Luteolin; (commercial)	*In-vivo* 50, 100, 200 mg/kg/day/p.o(male SD rats)	STZ induced diabetes	6. Reduced MDA levels in cerebral cortex 7. Elevated GSH, SOD and catalase levels in diabetic brain 8. Inhibited ROS levels in aorta 9. Elevated NO level, NOS and SOD activity in aorta 10. AGE formation IC_{50} = 22.7 μM,	Liu et al., 2013; Qian et al., 2010; Wang et al., 2011; Yoo et al., 2008
5.	Pelargonidin-3-α-O-rhamnoside; *M. emarginata* (Malpighiaceae)	*In-vitro* 0.125, 0.25, 0.3, 0.5 and 2 mg/ml	Inhibition of AGE formation	2. Strongly inhibited AGE formation (approx. 78-82%; 0.3 mg/ml)	Hanamura et al., 2005
6.	Cyanidin-3-α-O-rhamnoside; *M. emarginata* (Malpighiaceae)	*In-vitro* 0.125, 0.25, 0.3, 0.5 and 2 mg/ml	Inhibition of AGE formation	4. Strongly inhibited AGE formation (approx. 70-79%; 0.3 mg/ml)	Hanamura et al., 2005
7.	Eriodictyol; *Eriodictyoncalifornicum*(Hydrophyllaceae)	*In-vivo* 0.1, 1, 10 mg/kg/day/p.o(male SD rats)	STZ induced diabetes	4. Reduced blood glucose, retinal TNF-α, ICAM-1 and eNOS levels 5. Preserved blood-retinal barrier by attenuating retinal inflammation and lipid peroxidation 6. Prevented early retinal abnormalities linked to diabetes	Bucolo et al., 2012
8.	Diosmin; Citrus fruits	*In-vivo* 100 mg/kg/day/p.o(male wistar rats)	STZ-nicotinamide induced diabetes	4. Potentiated SOD, catalase, GPx, GSH and GST antioxidant activity in liver and kidney 5. Elevated vitamin C and vitamin E level in liver and kidney homogenate 6. Lowered lipid peroxidation in tissue homogenate	Srinivasan & Pari, 2012

Table 3. Continued

S. No.	Flavonoid (Source)	Dose	Model/Assay	Major Findings	Reference
9.	Epigallocatechin-3-O-gallate; *Camellia sinensis* (Theaceae)	*In-vivo* 5 and 10 mg/kg/i.p. every 8 h; (male wistar rats)	Free fatty acid induced InR	3. Reduced MDA and 8-isoprostaglandin plasma level 4. Enhanced antioxidative enzymes level (SOD and GPx) in serum	Li et al., 2011
10.	Fisetin; strawberries, onion, persimmon etc	*In-vivo* 10 mg/kg/day/p.o (male wistar rats)	STZ-induced diabetes	3. Reduced TBARS, lipid peroxides and hydroperoxides levels in hepatic tissue 4. Normalized SOD, catalase, GPx, GST and GR activity in liver	Prasath & Subramani-an, 2013
11.	Hesperidin; Citrus sp. (Rutaceae)	*In-vivo* 50 mg/kg/day/p.o (male albino rats)	High fat fed/ STZ-induced diabetes	4. Reduced lipid peroxidation, MDA and NO levels in serum 5. Elevated serum GSH, vitamin C and E levels 6. Elevated GSH, catalase, GPx, GR and SOD activity in hepatic tissue	Mahmoud et al., 2012
12.	Naringin; Citrus sp. (Rutaceae)	*In-vivo* 50 mg/kg/day/p.o (male albino rats)	High fat fed/ STZ-induced diabetes	4. Reduced lipid peroxidation, MDA and NO levels in serum 5. Elevated serum GSH, vitamin C and E levels 6. Elevated GSH, catalase, GPx, GR and SOD activity in hepatic tissue	Mahmoud et al., 2012
13.	Epicatechin; tea, grapes, red wine, coca etc.	*In-vivo* 15 and 30 mg/kg/day/i.p. (male wistar rats)	STZ-induced diabetes	3. Reduced TBARS and hydroperoxides level in liver, kidney and heart 4. Elevated GSH, catalase, SOD and GSH-Px activity in liver, kidney and heart tissues	Quine &Raghu, 2005
14.	Rutin; Fruits and vegetables	*Iv-vivo* 100 mg/kg/day/p.o(male wistar rats)	STZ-induced diabetes	3. Reduced TBARS and hydroperoxides level in brain, kidney and liver 4. Improved GSH, GSH-Px, SOD, catalase, vitamin C and vitamin E antioxidant activity in liver, kidney and brain	Kamalakkannan & Prince, 2006
15.	Puerariafuran; *Puerarialobata* (Fabaceae)	*In-vitro* Multiple dose	AGE inhibition assay	2. Inhibited AGE formation (IC_{50}= 0.53 μM)	Jang et al., 2006
16.	Coumestrol; *P. lobata* (Fabaceae)	*In-vitro* Multiple dose	AGE inhibition assay	2. Inhibited AGE formation (IC_{50}= 0.19 μM)	Jang et al., 2006
