List of Contributors

Abdulganiy, Olatunji / *University of Ilorin, Nigeria* 1476
Abereijo, Isaac Oluwajoba / *Obafemi Awolowo University – Ile-Ife, Nigeria* 657
Agrawal, Rajat / *Indian Institute of Technology, India* 1428
Akan, Mahmure Övül Arıoğlu / *Marmara University, Turkey* 537
Akar, Sevda / *Bandırma Onyedi Eylul University, Turkey* 1187
Akdoğan, Dilek Akbaş / *Marmara University, Turkey* 1187
Almeida, Manuela / *Universidade do Minho, Portugal* 1371
Altun, Tülin / *Cumhuriyet University, Turkey* 893
Amorim, Filipa / *MIT Portugal, Portugal* 1371
Anđić, Dunja / *University of Rijeka, Croatia* 1212
Anjinappa, Gopala / *Bangalore University, India* 1262
Antonova, Albena / *Sofia University, Bulgaria* 1570
Anurag, Varma / *TERI University, India* 132
Appana, Subhash / *University of the South Pacific, Fiji* 402
Avdic, Anders / *Örebro University, Sweden & Dalarna University, Sweden* 467
Balanlı, Zeynep / *Boğaziçi University, Turkey* 1133
Barron, Elise / *Kingston University, London, UK* 486
Beachcroft-Shaw, Harry / *University of KwaZulu-Natal, South Africa* 936
Beken, Hikmet Gülçin / *Gümüşhane University, Turkey* 771
Belgrado, Elisa / *University of Perugia, Italy* 1500
Bozkurt, Filiz / *Doğuş University, Turkey* 1152
Braga Jr, Sergio Silva / *UNESP – Univ Estadual Paulista, Brazil* 433
Brown, Mike / *La Trobe University, Australia* 1167
Buyya, Rajkumar / *The University of Melbourne, Australia* 1456
Cai, Tianxing / *Lamar University, USA* 156
Candelise, Chiara / *Bocconi University, Italy* 1680
Capelo, Ana / *University of Aveiro, Portugal* 868
Carvalho, Miguel / *MIT Portugal, Portugal* 1371
Ciani, Adriano / *University of Perugia, Italy* 1500
Cicea, Claudiu / *Bucharest University of Economic Studies, Romania* 1031
Ciocoiu, Carmen Nadia / *Bucharest University of Economic Studies, Romania* 1031
Coduti, Cinzia / *Coldiretti, Italy* 1500
Cotgrave, Alison J. / *Liverpool John Moores University, UK* 1278
Dao, Hang / *University of Lisbon, Portugal & Aalto University, Finland* 1371
Dhakal, Subas P. / *Curtin University, Australia* 516

Diotallevi, Francesco / *University of Perugia, Italy* 1500
Diviacco, Paolo / *Istituto Nazionale di Oceanografia e di Geofisica Sperimentale - OGS, Italy* 618
Djeflat, Abdelkader / *Université de Lille 1, France* 234
Doğru, Bülent / *Gümüşhane University, Turkey* 771
Dolatkhah, Mahdi / *University of Tehran, Iran* 252
Dolunay, Ozge / *OZ Solar Energy Irrigation Systems, Turkey* 882
Dulle, Mira / *Institute of Instructional and School Development, Alpen-Adria University, Austria* 60
Eames, Katherine A.T. / *Kingston University, London, UK* 486
Ellis, Debbie / *University of KwaZulu-Natal, South Africa* 936
Enachescu, Daniela / *Petroleum-Gas University, Romania* 1109
Ergen, Ahu / *Bahçeşehir University, Turkey* 1152
Escalante, Gino de Jesús Roa / *Technical University of Cartagena, Spain* 590
Faxas, Juan-Gabriel / *Technical University of Cartagena, Spain* 590
Ferrão, Paulo / *MIT Portugal, Portugal* 1371
Fikiin, Kostadin / *Technical University of Sofia, Bulgaria* 721
Fırat, Seniye Ümit Oktay / *Marmara University, Turkey* 537
Gantumur, Amarbayasgalan / *University of the Humanities, Mongolia* 271
García-Cascales, M. Socorro / *Technical University of Cartagena, Spain* 590
Gedikli, Ayfer / *Istanbul Medeniyet University, Turkey* 1605
Getsel, Uranchimeg / *Mongolian State University of Education, Mongolia* 271
Ghazali, Zulkipli / *Universiti Teknologi PETRONAS, Malaysia* 843
Ghosh, Nilanjan / *Multi Commodity Exchange of India Limited, India* 41,94
Ghraizi, Rachid / *Indra, Spain* 284
Gogonea, Rodica-Manuela / *Academy of Economic Studies, Romania* 1109
Gomes, Ricardo / *MIT Portugal, Portugal* 1371
Görkem, Hilal / *Çanakkale Onsekiz Mart University, Turkey* 893
Goswami, Anandajit / *The Energy and Resources Institute, India* 41,94
Goundar, Sam / *United Nations University, Macau, China* 402
Grigore, Anna Maria / *University of Bucharest, Romania* 1500
Grunewald, Nicole / *University of Goettingen, Germany* 201
Guedes, Manuel Correia / *Instituto Superior Técnico, Portugal* 1371
Harrington, Robert J. / *University of Arkansas, USA* 1526
Hassaan, Marwa / *Mansoura University, Egypt* 673
Herciu, Mihaela / *"Lucian Blaga" University of Sibiu, Romania* 1702
Hesapçı, Özlem / *Boğaziçi University, Turkey* 1133
Hübner, Renate / *Institute of Intervention Research and Cultural Sustainability, Alpen-Adria University, Austria* 60
Husnain, Ali / *Örebro University, Sweden & COMSATS Institute of Information Technology Virtual Campus, Pakistan* 467
Ivolga, Anna / *Stavropol State Agrarian University, Russia* 1330
Jackson, Liz / *University of Hong Kong, Hong Kong* 1
Kavitha T.N / *Government Polytechnic, India* 1428
Kefelew, Gebrye / *Addis Ababa University, Ethiopia* 1351
Khosravi, Atefeh / *The University of Melbourne, Australia* 1456
Kifor, Stefania / *Lucian Blaga University of Sibiu, Romania* 311

Table of Contents

Preface xviii

Volume I

Section 1
Fundamental Concepts and Theories

Chapter 1
Education for Sustainable Development: From Environmental Education to Broader Views 1
Liz Jackson, University of Hong Kong, Hong Kong

Chapter 2
Sustainability Evaluation of IT/IS Projects 26
Gilbert Silvius, LOI University of Applied Sciences, The Netherlands & University of Johannesburg, South Africa

Chapter 3
Economic Growth, Sustainable Development, and the Role of Markets 41
Nilanjan Ghosh, Multi Commodity Exchange of India Limited, India
Anandajit Goswami, The Energy and Resources Institute, India

Chapter 4
Implementing an Interfaculty Elective "Sustainable Development": An Intervention into a University's Culture Between Organized Scientific Rationality and Normative Claim 60
Renate Hübner, Institute of Intervention Research and Cultural Sustainability, Alpen-Adria University, Austria
Franz Rauch, Institute of Instructional and School Development, Alpen-Adria University, Austria
Mira Dulle, Institute of Instructional and School Development, Alpen-Adria University, Austria

Chapter 5
Interdisciplinarity in Sustainability Science: Challenge or Opportunity? 74
Rosario Adapon Turvey, Lakehead University, Canada

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 6
Economics, Environmental Policy, Trade and Sustainability 94
Nilanjan Ghosh, Multi Commodity Exchange of India Limited, India
Anandajit Goswami, The Energy and Resources Institute, India

Section 2
Development and Design Methodologies

Chapter 7
Role of HRM in Sustainable Organisational Development 115
Fawzy Soliman, University of Technology Sydney, Australia

Chapter 8
Significance of Cultural Dimensions in Urban Planning Process for Sustainability of Pilgrimage Towns in India..... 132
Varma Anurag, TERI University, India
Shaleen Singhal, TERI University, India

Chapter 9
Application of Soft Computing Techniques for Renewable Energy Network Design and Optimization 156
Tianxing Cai, Lamar University, USA

Chapter 10
The Sustainable Development Approach in the Economy-Ecology Dilemma..... 176
Gökhan Tenikler, Dokuz Eylül University, Turkey
Gamze Yıldız Şeren, Namık Kemal University, Turkey

Chapter 11
Green Growth in Mexico, Brazil, and Chile: Policy Strategies and Future Prospects..... 201
Inmaculada Martinez-Zarzoso, University of Goettingen, Germany
Nicole Grunewald, University of Goettingen, Germany

Chapter 12
Harnessing Knowledge for Sustainable Development: Challenges and Opportunities for Arab Countries..... 234
Abdelkader Djeflat, Université de Lille 1, France

Chapter 13
Integration of Demand-Side Management Programs and Supply-Side Alternatives for Decentralized Energy Planning: An Analysis of Energy Import and Export Effects 252
Masoud Rabbani, University of Tehran, Iran
Mahdi Dolatkhah, University of Tehran, Iran

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 14
Policy Provisions and Teachers' Needs on Climate Change Education for Sustainable Development in Mongolia 271
Navchaa Tugjamba, University of the Humanities, Mongolia
Batchuluun Yembuu, Mongolian State University of Education, Mongolia
Amarbayasgalan Gantumur, University of the Humanities, Mongolia
Uranchimeg Getsel, Mongolian State University of Education, Mongolia

Chapter 15
Smart Energy and Cost Optimization for Hybrid Micro-Grids: PV/ Wind/ Battery/ Diesel Generator Control 284
Imene Yahyaoui, Federal University of Espírito Santo, Brazil
Rachid Ghraizi, Indra, Spain
Fernando Tadeo, University of Valladolid, Spain
Marcelo Eduardo Vieira Segatto, Federal University of Espírito Santo, Brazil

Chapter 16
Developing Sustainable Processes Through Knowledge Management 311
Thanh-Dat Nguyen, Quy Nhon University, Vietnam & Lucian Blaga University of Sibiu, Romania
Stefania Kifor, Lucian Blaga University of Sibiu, Romania

Chapter 17
Making Sustainable Energy Communities a Reality: The "MPC+" Decision Support Framework 324
Vangelis Marinakis, National Technical University of Athens, Greece

Chapter 18
Enablers of Sustainable Manufacturing Overview, Framework and Further Research Directions 363
Shibin K. T., Symbiosis International University, India

Chapter 19
Green Energy in Data Centers 386
Kanahavalli Mardamutu, Quest International University Perak, Malaysia
Vasaki Ponnusamy, Universiti Tunku Abdul Rahman, Malaysia
Noor Zaman, King Faisal University, Saudi Arabia

Chapter 20
Mainstreaming Development Policies for Climate Change in Fiji: A Policy Gap Analysis and the Role of ICTs 402
Sam Goundar, United Nations University, Macau, China
Subhash Appana, University of the South Pacific, Fiji

Chapter 21
Sustainable Development and the Integration of Normative Standards 433
Eduardo Guilherme Satolo, UNESP - Univ Estadual Paulista, Brazil
Alexandre Tadeu Simon, UNIMEP - Universidade Metodista de Piracicaba, Brazil
Sergio Silva Braga Jr, UNESP – Univ Estadual Paulista, Brazil

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 22
Identifying the Contemporary Status of E-Service Sustainability Research 467
Ali Husnain, Örebro University, Sweden & COMSATS Institute of Information Technology Virtual Campus, Pakistan
Anders Avdic, Örebro University, Sweden & Dalarna University, Sweden

Chapter 23
Embedding Sustainability Learning: Robustness in Changing Circumstances - Perspectives From a United Kingdom (UK) Higher Education Institution (HEI) 486
Ros Taylor, Kingston University, London, UK
Elise Barron, Kingston University, London, UK
Katherine A.T. Eames, Kingston University, London, UK

Chapter 24
'*Net*' Social Change: Grassroots Empowerment for Sustainable Development 516
Subas P. Dhakal, Curtin University, Australia

Section 3
Tools and Technologies

Chapter 25
Renewable Energy Sources: Comparison of Their Use and Respective Policies on a Global Scale 537
Mahmure Övül Arıoğlu Akan, Marmara University, Turkey
Ayşe Ayçim Selam, Marmara University, Turkey
Seniye Ümit Oktay Fırat, Marmara University, Turkey

Volume II

Chapter 26
How to Manage Sustainability: A Framework for Corporate Sustainability Tools 568
Yasemin Sen, Istanbul University, Turkey

Chapter 27
Grid Stabilization Effect of Combined Electricity Generation From Wind and Photovoltaic Systems in Murcia, Spain 590
Gino de Jesús Roa Escalante, Technical University of Cartagena, Spain
J. Miguel Sánchez-Lozano, University Centre of Defence at the Spanish Air Force Academy, Technical University of Cartagena, Spain
Juan-Gabriel Faxas, Technical University of Cartagena, Spain
M. Socorro García-Cascales, Technical University of Cartagena, Spain
Antonio Urbina, Technical University of Cartagena, Spain

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 28
Balancing Formalization and Representation in Cross-Domain Data Management for Sustainable Development 618
Paolo Diviacco, Istituto Nazionale di Oceanografia e di Geofisica Sperimentale - OGS, Italy
Adam Leadbetter, Marine Institute, Ireland

Chapter 29
The Economics of Renewable Energy Promotion Policies: A Case of Wind Power in Brazil 642
Govinda Timilsina, The World Bank, USA

Chapter 30
Ensuring Environmental Sustainability Through Sustainable Entrepreneurship 657
Isaac Oluwajoba Abereijo, Obafemi Awolowo University – Ile-Ife, Nigeria

Chapter 31
Sustainability Reporting in Transitional Economies 673
Marwa Hassaan, Mansoura University, Egypt

Chapter 32
The Strategic Association Between Information and Communication Technologies and Sustainability: A Country-Level Study 694
Sarah Jinhui Wu, Fordham University, USA
Wullianallur Raghupathi, Fordham University, USA

Section 4
Utilization and Applications

Chapter 33
Integration of Renewable Energy in Refrigerated Warehouses 721
Kostadin Fikiin, Technical University of Sofia, Bulgaria
Borislav Stankov, Technical University of Sofia, Bulgaria

Chapter 34
Green Development: Case of Turkey, Norway, and China 771
Bülent Doğru, Gümüşhane University, Turkey
Hikmet Gülçin Beken, Gümüşhane University, Turkey

Chapter 35
Transforming University Curricula Towards Sustainability: A Euro-Mediterranean Initiative 805
Vassilios Makrakis, University of Crete, Greece

Chapter 36
Transdisciplinary Methodology of an Architectural and Urban Discourse in Higher Education 828
Svetlana Perović, University of Montenegro, Montenegro

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 37
Sustainable Education: A Buzzword of Universiti Teknologi PETRONAS, Malaysia 843
Muhammad Zahid, Universiti Teknologi PETRONAS, Malaysia
Zulkipli Ghazali, Universiti Teknologi PETRONAS, Malaysia
Haseeb Ur Rahman, Universiti Teknologi PETRONAS, Malaysia

Chapter 38
Integration of Education for Sustainable Development Into Formal Secondary Curricula of East Timor 868
Ana Capelo, University of Aveiro, Portugal

Chapter 39
A Paradigm Shift: Empowering Farmers to Eliminate the Waste in the Form of Fresh Water and Energy Through the Implementation of 4R+T 882
Ozge Dolunay, OZ Solar Energy Irrigation Systems, Turkey

Chapter 40
Employment Aspect of Energy Performance Practices in Buildings and Fiscal Policy Proposals for Turkey 893
Tülin Altun, Cumhuriyet University, Turkey
Hilal Görkem, Çanakkale Onsekiz Mart University, Turkey

Chapter 41
Different Resources Consumption of Renewable Energy 919
Soobia Saeed, Institute of Business and Technology, Pakistan

Chapter 42
Using Successful Cases to Promote Environmental Sustainability: A Social Marketing Approach 936
Harry Beachcroft-Shaw, University of KwaZulu-Natal, South Africa
Debbie Ellis, University of KwaZulu-Natal, South Africa

Chapter 43
Sustainable Development and the Sustainability of Socioeconomic Systems: Some Reflections on Crises and Corporate Systemogenesis 954
Tikhomirova Olga, Saint Petersburg National Research University of Information Technologies, Mechanics and Optics, Russia

Chapter 44
Renewable Energy Technologies, Sustainable Development, and Environment 971
Abdeen Mustafa Omer, Energy Research Institute (ERI), UK

Chapter 45
Environmental Accounting for Industrial Growth and Sustainable Development in India: An Overview and Theoretical Framework 1009
Archana Singh, Symbiosis International University, India
Nehajoan Panackal, Symbiosis International University, India
Bhama Venkataramani, Symbiosis International University, India

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 46
Development of the Green Economy in Romania: Dimensions, Strengths and Weaknesses 1031
Carmen Nadia Ciocoiu, Bucharest University of Economic Studies, Romania
Claudiu Cicea, Bucharest University of Economic Studies, Romania

Chapter 47
Exploring Landscapes in Regional Convergence: Environment and Sustainable Development in South Asia 1051
Srinivasan Rajamanickam, Pondicherry University, India

Chapter 48
Citizen Science and Its Role in Sustainable Development: Status, Trends, Issues, and Opportunities 1088
Hai-Ying Liu, Norwegian Institute for Air Research, Norway
Mike Kobernus, Norwegian Institute for Air Research, Norway

Chapter 49
Romanian Rural Tourism in the Context of Sustainable Development 1109
Marian Zaharia, Petroleum-Gas University, Romania
Rodica-Manuela Gogonea, Academy of Economic Studies, Romania
Daniela Enachescu, Petroleum-Gas University, Romania

Volume III

Chapter 50
Sustainability Campaigns and Consumer Involvement: Effects of Altruism, Locus of Control, and Long-Term Orientation 1133
Zeynep Balanlı, Boğaziçi University, Turkey
Özlem Hesapçı, Boğaziçi University, Turkey

Section 5
Organizational and Social Implications

Chapter 51
Promoting Healthy Lifestyle for Sustainable Development 1152
Filiz Bozkurt, Doğuş University, Turkey
Ahu Ergen, Bahçeşehir University, Turkey

Chapter 52
A Fourth Wave of Education for Sustainability (EfS) in Higher Education 1167
Mike Brown, La Trobe University, Australia

Chapter 53
Environmental and Economic Impacts of Wave Energy: Some Public Policy Recommendations for Implementation in Turkey 1187
Sevda Akar, Bandırma Onyedi Eylul University, Turkey
Dilek Akbaş Akdoğan, Marmara University, Turkey

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 54
Interdisciplinary Approaches to Sustainable Development in Higher Education: A Case Study From Croatia 1212
Dunja Anđić, University of Rijeka, Croatia
Sanja Tatalović Vorkapić, University of Rijeka, Croatia

Chapter 55
Rule of Law: A Fundamental Pillar Enabling Sustainable Development and Reduction of Poverty in India 1262
Gopala Anjinappa, Bangalore University, India

Chapter 56
Are University Lecturers Literate in Sustainability? 1278
Noora Kokkarinen, Liverpool John Moores University, UK
Alison J. Cotgrave, Liverpool John Moores University, UK

Chapter 57
Energy Cost Saving Tips in Distributed Power Networks 1292
Alain Tcheukam Siwe, New York University, USA
Hamidou Tembine, New York University, USA

Chapter 58
Ecological Influences on the Evolving Planning System in Turkey 1315
Ufuk Fatih Küçükali, Istanbul Aydin University, Turkey

Chapter 59
Rural Tourism in Transitional Russia's Economics: Fake or Real Alternative to Traditional Agricultural Production? 1330
Anna Ivolga, Stavropol State Agrarian University, Russia

Chapter 60
Challenges and Opportunities for the Development and Management of Urban Green Areas in Addis Ababa: The Case of Cooperative Housing Green Areas and Street Trees in Nifas Silk Lafto Sub-City 1351
Gebrye Kefelew, Addis Ababa University, Ethiopia
Tebarek Lika, Addis Ababa University, Ethiopia

Chapter 61
The Drive Towards NEAR Zero Energy Buildings Through Professional Training in Southern Europe: The SouthZEB Project 1371
Filipa Amorim, MIT Portugal, Portugal
Ricardo Gomes, MIT Portugal, Portugal
Hang Dao, University of Lisbon, Portugal & Aalto University, Finland
Miguel Carvalho, MIT Portugal, Portugal
Carlos Silva, MIT Portugal, Portugal
Paulo Ferrão, MIT Portugal, Portugal
Manuel Correia Guedes, Instituto Superior Técnico, Portugal
Manuela Almeida, Universidade do Minho, Portugal

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 62
Conditions for Development of Renewable Energy in Poland..... 1398
Katarzyna Osiecka-Brzeska, University of Gdansk, Poland

Chapter 63
Supply Chain Social Sustainability and Manufacturing 1428
Mani V, Indian Institute of Technology, India
Rajat Agrawal, Indian Institute of Technology, India

Preface

The constantly changing landscape of Sustainable Development makes it challenging for experts and practitioners to stay informed of the field's most up-to-date research. That is why Information Science Reference is pleased to offer this three-volume reference collection that will empower students, researchers, and academicians with a strong understanding of critical issues within Sustainable Development by providing both broad and detailed perspectives on cutting-edge theories and developments. This reference is designed to act as a single reference source on conceptual, methodological, technical, and managerial issues, as well as to provide insight into emerging trends and future opportunities within the discipline.

Sustainable Development: Concepts, Methodologies, Tools, and Applications is organized into seven distinct sections that provide comprehensive coverage of important topics. The sections are:

1. Fundamental Concepts and Theories;
2. Development and Design Methodologies;
3. Tools and Technologies;
4. Utilization and Applications;
5. Organizational and Social Implications;
6. Critical Issues and Challenges; and
7. Emerging Trends.

The following paragraphs provide a summary of what to expect from this invaluable reference tool.

Section 1, "Fundamental Concepts and Theories," serves as a foundation for this extensive reference tool by addressing crucial theories essential to the understanding of Sustainable Development. Introducing the book is "Education for Sustainable Development: From Environmental Education to Broader Views" by Liz Jackson, a great foundation laying the groundwork for the basic concepts and theories that will be discussed throughout the rest of the book. Section 1 concludes, and leads into the following portion of the book, with a nice segue chapter, "Economics, Environmental Policy, Trade, and Sustainability" by N. Ghosh and A. Goswami.

Section 2, "Development and Design Methodologies," presents in-depth coverage of the conceptual design and architecture of Sustainable Development. Opening the section is "Role of HRM in Sustainable Organisational Development" by Fawzy Soliman. Through case studies, this section lays excellent groundwork for later sections that will get into present and future applications for Sustainable Development. The section concludes with an excellent work by P. Dhakal, "'Net' Social Change: Grassroots Empowerment for Sustainable Development."

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Section 3, "Tools and Technologies," presents extensive coverage of the various tools and technologies used in the implementation of Sustainable Development. The first chapter, "Renewable Energy Sources: Comparison of Their Use and Respective Policies on a Global Scale" by Mahmure Övül Arıoğlu Akan, Ayşe Ayçim Selam, and Seniye Ümit Oktay, lays a framework for the types of works that can be found in this section. The section concludes with "The Strategic Association Between Information and Communication Technologies and Sustainability: A Country-Level Study" by Sarah Jinhui Wu and Wullianallur Raghupathi. Where Section 3 described specific tools and technologies at the disposal of practitioners, Section 4 describes the use and applications of the tools and frameworks discussed in previous sections.

Section 4, "Utilization and Applications," describes how the broad range of Sustainable Development efforts has been utilized and offers insight on and important lessons for their applications and impact. The first chapter in the section is "Integration of Renewable Energy in Refrigerated Warehouses" written by Kostadin Fikiin and Borislav Stankov. This section includes the widest range of topics because it describes case studies, research, methodologies, frameworks, architectures, theory, analysis, and guides for implementation. The breadth of topics covered in the chapter is also reflected in the diversity of its authors, from countries all over the globe. The section concludes with "Sustainability Campaigns and Consumer Involvement: Effects of Altruism, Locus of Control, and Long-Term Orientation" by Zeynep Balanlı and Özlem Hesapçı, a great transition chapter into the next section.

Section 5, "Organizational and Social Implications," includes chapters discussing the organizational and social impact of Sustainable Development. The section opens with "Promoting Healthy Lifestyle for Sustainable Development" by Filiz Bozkurt and Ahu Ergen. This section focuses exclusively on how these technologies affect human lives, either through the way they interact with each other or through how they affect behavioral/workplace situations. The section concludes with "Supply Chain Social Sustainability and Manufacturing" by Mani V, Rajat Agrawal, Vinay Sharma, and Kavitha T.N.

Section 6, "Critical Issues and Challenges," presents coverage of academic and research perspectives on Sustainable Development tools and applications. The section begins with "Energy and Carbon Footprint-Aware Management of Geo-Distributed Cloud Data Centers: A Taxonomy, State of the Art, and Future Directions" by Atefeh Khosravi and Rajkumar Buyya. Chapters in this section will look into theoretical approaches and offer alternatives to crucial questions on the subject of Sustainable Development. The section concludes with "A New Barrier for the Future of Energy Market in Turkey: Internal Capital Adequacy Assessment Process (ICAAP)" by Esin Okay.

Section 7, "Emerging Trends," highlights areas for future research within the field of Sustainable Development, opening with "Sustainable Consumption Trends in the World in the Context of Green Economy and Sustainability" by Seda Yıldırım, Durmuş Çağrı Yıldırım, and Ayfer Gedikli. This section contains chapters that look at what might happen in the coming years that can extend the already staggering amount of applications for Sustainable Development. The final chapter of the book looks at an emerging field within Sustainable Development, in the excellent contribution, "CSR Strategies in Emerging Markets: Socially Responsible Decision Making Processes and Business Practices for Sustainability" by Claudia Ogrean and Mihaela Herciu.

Although the primary organization of the contents in this multi-volume work is based on its seven sections, offering a progression of coverage of the important concepts, methodologies, technologies, applications, social issues, and emerging trends, the reader can also identify specific contents by utilizing the extensive indexing system listed at the end of each volume. As a comprehensive collection of

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

research on the latest findings related to using technology to providing various services, *Sustainable Development: Concepts, Methodologies, Tools, and Applications* provides researchers, administrators, and all audiences with a complete understanding of the development of applications and concepts in Sustainable Development. Given the vast number of issues concerning usage, failure, success, policies, strategies, and applications of Sustainable Development in countries around the world, *Sustainable Development: Concepts, Methodologies, Tools, and Applications* addresses the demand for a resource that encompasses the most pertinent research in technologies being employed to globally bolster the knowledge and applications of Sustainable Development.

Chapter 1
Education for Sustainable Development:
From Environmental Education to Broader Views

Liz Jackson
University of Hong Kong, Hong Kong

ABSTRACT

Education for Sustainable Development (ESD) is an important educational agenda at the international level, with significant implications for both formal and nonformal education. Though a relatively new topic in modern education, ESD frameworks have evolved and grown in number over the last few decades, from an early concern with education for development and environmental education, to more critical orientations that focus on the relationship between individual and social factors and between environmental and political factors contributing to challenges today for ecological sustainability and global development and flourishing. In this dynamic field, priorities may vary with social context, as a critical interrogation of the importance of place in education is considered fundamental to modern ESD frameworks. This chapter explores and assesses the development of ESD over the past few decades as a formal and nonformal educational policy and practice across world regions, before considering future directions for research and practice.

INTRODUCTION

In the last decade, Education for Sustainable Development (ESD) has become an important educational agenda internationally, with significant implications for both formal and nonformal education. However, as noted by the United Nations Educational, Scientific and Cultural Organization (UNESCO) at the conclusion of its declared Decade of Education for Sustainable Development (2005-2015), at this time ESD faces many challenges to effective implementation across a wide variety of societies, both developing and developed, while there remains much uncertainty in the public and in educational communities about its aims, means, and significance. One of the main causes of the challenges for researchers and educators in

this field is no doubt related to the wide variety of educational missions associated with the phrase, not all of which are mutually compatible, that have come to coexist across and within societies over time.

Part of this diversity of aims and meanings is related to the history of ESD. Originally, and still in some sense today, ESD has been a top-down approach to reform, wherein education is regarded as a tool for development in modernizing countries, as according to its use by global developmental and governance organizations, particularly UNESCO and United Nations Environmental Programme (UNEP). Yet as societies face different developmental challenges and opportunities, diversity rather than uniformity at the level of practice has been a natural result. On the other hand, ESD has also unfolded in everyday educational use in industrialized countries as a form of environmental education that focuses on the environment as an eco-system and the role of humans to conserve resources and decrease negative impacts on the natural world. Again, diversity in ecological contexts, risks, and possibilities create different grounds for such environmentally-based ESD, facilitating additional forms of diversity within environmental education (EE). From these beginnings, the term has further evolved and developed, to include critical political and educational orientations that focus on the relationships between individual, social, environmental, and political factors contributing to contemporary challenges for sustainability and local and global development and flourishing. Today, some eschew the terms "ESD" and "sustainability" as "empty signifiers" (Bengtsson & Ostman, 2013) in light of this plethora of educational meanings and practices attached to these terms. Among such critics include those who argue that social justice should be foregrounded in a holistic approach to EE, "ecopedagogy," and in related postmodern views.

This chapter explores and assesses the development of ESD over the past few decades as a formal and nonformal educational policy and practice across world regions. After giving a historical overview and survey of the field across contexts, it considers future directions for research and practice in ESD and related fields. Though the purpose of this chapter is not to take sides in debates traced out and explored, it does aim to give readers a clear view of potentially beneficial ways forward for effectively conceiving of and implementing ESD, through analyzing the challenges ESD faces at the practical level from a global view.

BACKGROUND

Some argue that the diversity of definitions and understandings of ESD across research and education contexts can be attributed to its early definition being given not by educational (or research) communities but actually by people within the policymaking field. Indeed, education for social development and environmental sustainability has its roots not in the educational community, but in larger social debates over environmental ethics which emerged in developed Western contexts in the 1960s and 1970s. Before this time, environmentalism consisted largely of land conservation, such as in the formal establishing and protecting of lands as modern public parks in western societies in the nineteenth and twentieth centuries. Yet as Light and Rolston note (2003), Rachel Carson's *Silent Spring*, published in 1962, heralded a new ecological consciousness in western societies, which rejected the liberal Enlightenment view of the natural environment as infinitely exploitable for human purposes. With the book notably increasing public awareness of the toll of pesticides on animals, plants, and human health, a critical and postmodern environmental movement emerged alongside peace and civil rights movements that argued for reorganizing of human life with greater consideration of the natural world.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

This consciousness of the social and biological worlds as component parts of a more holistically understood ecosystem thereafter emerged in the first place in educational imperatives of nonbinding international governance organization recommendations. The 1977 UNESCO conference on environmental education, organized in cooperation with UNEP in Tbilisi, Georgia, laid first groundwork for the educational concept of ESD (Sarabhai, Ravindranath, Schwarz, & Vyas, 2012). Known as the Tbilisi Declaration, the conference recommended the development of standards to guide EE at local, national, and global levels that was interdisciplinary in nature. Viewing EE as "the reorientation and dovetailing of different disciplines and educational experiences which facilitate an integrated perception of the problems of the environment," the declaration argued that EE must enable understanding of the "biological, physical, social, economic, and cultural aspects" contributing to our physical, "natural and built" environment (UNESCO, 1978, p. 25). It further specified that EE must equip people with "knowledge, values, attitudes, and practical skills" to resolve environmental problems, bridging divides between formal academic schooling and real-world action and behavior. It articulated "economic, political, and ecological interdependence of the modern world," and recommended that such EE was not only a responsibility of schools but also of the media and nonformal education, to cater to all ages and social groups within society.

This view of ESD, as an education focused on understanding the intertwining of social and natural worlds through formal and nonformal educational means remained influential since this foundational recommendation. The concept of sustainable development as requiring integrated thinking about economic and environmental domains was affirmed again by the United Nations (UN) General Assembly in 1987, which established the World Commission on Environment and Development (WCED; also known as the Brundtland Commission) in 1983. The Brundtland Commission defined sustainable development more succinctly as "development that meets the needs of the present without compromising the ability of future generations to meet their own needs," and appealed to the educational community in a general rather than specified manner, to increase social awareness of the need for sustainable development for the future (WCED, 1987).

In 1992, the United Nations Conference on Environment and Development at Rio de Janeiro, Brazil, aimed to operationalize ESD at a more practical level for the first time. Its Agenda 21, Chapter 36, argued for a program to systematically reorient education toward sustainable development, and it appointed UNESCO and UNEP to facilitate global revision of education for sustainable development across all societies and all levels of formal education (United Nations, 1992). However, even in this document, ESD was not envisioned exclusively or even primarily as a curricular or pedagogical program (Hopkins & McKeown, 2002). Rather, it framed ESD as a wide-ranging perspective on how to improve the world through education, recognizing education as a catalyst for more (and less) sustainable economic and political development in poor regions, for improvement of human rights as actualized capabilities for empowerment of previously disadvantaged groups (Sen, 1999), and more. In this broad view, developing wider basic educational access was regarded by UNESCO as a primary step in this global ESD project, as limited access to quality education is recognized by the UN and its subunits to hinder development (economic and political) in much of the world.

The next step, as discussed in Chapter 36 of the Rio Agenda 21, was to reform education across diverse contexts to align with social and environmental sustainable development (Hopkins & McKeown, 2002). Yet even here, definitions of ESD were given in a general rather than particular way in developing local curriculua, as in the 1977 and 1987 documents before it. This reforming and reorienting of diverse society's educational systems toward ESD implied in part a focus on *local* community needs

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

and contextual considerations, rather than a borrowing of curricula, for example, from UNESCO. The document additionally emphasized an important shift from content knowledge to skills development in all types of education (formal and nonformal), to meet practical challenges effectively. Broader public awareness and training was also recommended.

Since 1992, UNESCO has thus led practices of defining, designing, and implementing ESD as a variety of formal and nonformal, locally appropriate and contextually specific programs of education, that focus on knowledge, skills, and/or values and perspectives seen to (or hoped to) that promote and enable sustainable development. Knowledge of ESD is understood as effectively trans- or inter-disciplinary, cutting across social, cultural, technical, political, economic, and ecological domains, while noteworthy skills include capabilities to deliberate and critically think alongside others to make effective action. A perspective oriented toward global peace, equality, and social justice is encouraged that is intergenerational, while human and biological diversity are held as intrinsically valuable, in line with the UN's larger ends. (Hopkins & McKeown, 2002).

In 2002 the UN again emphasized the significance of ESD as a global policy agenda, by tasking UNESCO with the 2005 launch of the 2005-2015 Decade of Education for Sustainable Development (DESD). Accepting this charge, UNESCO thereafter developed an International Implementation Scheme, with four thrusts and seven strategies for ESD that echoed the statements from the conference in Rio in 1992. The four thrusts include (1) improving basic education, (2) reorienting education toward sustainability, (3) increasing public awareness, and (4) providing training across sectors about sustainability (UNESCO, 2014, pp. 15-16). Rather than top-down implementation of a specific model program at the local level, the scheme's strategies included advocacy, consultation and ownership, partnership, capacity building, research and innovation, technology development and promotion, and (limited—in line with its authority) monitoring and evaluation.

In late 2014, as the UNESCO DESD came to its conclusion, UNESCO reported positively on the DESD, noting that a shift in public knowledge from ESD as formal curriculum to a broader understanding has resulted (2014). UNESCO has also reported (2012, pp. 28-31) that:

- Educational systems are responding more effectively to sustainability needs,
- Sustainable development and education agendas are converging,
- Political leadership with stakeholder and local involvement has productively grown,
- Holistic, comprehensive institutional approaches are increasing,
- Interactive, student-centered pedagogies are increasing,
- Nonformal and informal ESD is increasing, and
- Training that advanced sustainable development is increasing.

However, UNESCO has not described the DESD as an unqualified success. It goes on to note that significant challenges remain. In many countries, ESD is poorly implemented, due to the need for a holistic approach despite a lack of interdepartmental cooperation across different national and local government sectors (such as agriculture, economy, education, and so on). ESD is still not being effectively evaluated in many areas even as formal education, as formal education (schools) is as yet largely undergoing the reorientation process in most societies (UNESCO, 2014, p. 32).

Indeed, it becomes difficult to discuss practices of ESD generally at the global level, with a wide variety of contexts enabling diverse interpretations and priorities. Furthermore, despite UNESCO's observation that different contexts require different methods of reorientation and implementation, others argue that

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

UNESCO tacitly supports a globalist, neoliberal view of education and sustainable development that undermines impactful ESD that truly encourages values of global diversity and social justice (Bengtsson & Ostman, 2013; Gonzalez-Gaudiano, 2005). When one breaks down ESD approaches by society and sector, no single essential type of ESD can be readily identified, leading to the claim that ESD is an "empty signifier…ridden with internal contradictions" (Bengtsson & Ostman, 2013, p. 481). Less provocatively, it is clear in surveying the field that wide discrepancies in interpretation and implementation are the norm, with differences being decipherable across societies based on the levels of educational development generally. In developing countries, nonformal education is more typical due to a common lack of high levels of formal education, while in developed societies strides are being taken toward a systematic curriculum, though again divergence rather than commonality can be seen. The rest of this chapter considers different approaches to ESD, focusing on teaching and/or learning related to sustainable development, rather than increasing educational quality and access for sustainable development. The next sections survey the extent of ESD geographically in formal and nonformal education, before considering matters of contemporary debate over meanings, values, and goals.

THE EXTENT OF ESD AROUND THE WORLD

Formal Education

According to UNESCO's DESD final report (2014, p. 83), 40% of the 70 countries that participated in the final assessment questionnaire describe their key reorientation of education towards ESD in terms of formal curricula, in primary and/or secondary education. Generally, most countries have some national/public education curricula dedicated to discussing environmental and/or sustainability issues, either with an integrated (interdisciplinary) approach, or within subjects such as social studies, science, and related areas. However, UNESCO goes on to report that most countries describe their efforts toward increasing attention to ESD as "in progress" rather than as implemented or achieved.

As a top-down approach initiated at the political level rather than educational level, substantive reorientation toward ESD in most countries is no doubt hindered by competing national-level goals for educational reform. In this context, as Hopkins and McKeown note (2002), interested individuals and non-governmental organizations (NGOs) may often "undertake the reorientation effort with either little or no government assistance" (p. 23). Relatedly, given the diverse national orientations toward centralization and regulation of the educational curriculum worldwide, a plethora of approaches, rather than one common method of reorientation, is the norm in many societies (Feinstein, Jacobi, & Lotz-Sistika, 2013).

In Europe, formal education in many countries has significant content on ESD today, owing to greater relative public commitments that have been observed there related to sustainability principles (UNESCO, 2014; Tilbury, 2002; Jucker & Mathar, 2015). Environmental education was called "an integral and essential part of every European citizen's upbringing" by the Ministers of the European Union in 1988, who focused on education as significant within their Fifth Action Plan for the Environment in 1995. Various organizations within Europe have thus helped reorient education formally toward ESD rather than those associated with the UN or global NGOs. In particular, the Organisation for Economic Cooperation and Development Environment and Schools Initiative Group (ENSI) has supported environmental education and related ESD programs with various aims in a wide variety of countries, including Austria, Belgium, Denmark, Finland, France, Germany, Hungary, Italy, The Netherlands, Norway, Portugal, Scotland, Spain,

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Sweden, and Switzerland (Tilbury, 2002). Many European nations include ESD as a significant formal component of their national education policies and plans, with impacts felt widely regardless of whether their educational systems are centralized or decentralized. Challenges remain in Europe for ESD, related to effective implementation within societies system-wide given competing reform agendas (Jucker & Mathar, 2015); nonetheless, many countries in Europe provide instances of exemplary programs at the international level for ESD.

For instance, in Austria a strategy for ESD was developed in 2005 and 2006 that involved 400 stakeholders from formal, nonformal, and informal education (Rauch & Pfaffenwimmer, 2015). Central and regional support for ESD in formal education is supported by seminars for educational leaders and awards for school's ESD performance (Lechner & Rauch, 2014). Special programs to increase attention to ESD in higher education and technical and vocational education also exist and are being evaluated and reformed in an ongoing process. Such programs are common throughout Europe, for instance in the automotive sector in Sweden and in engineering in Poland (Leal Filho, 2010), to interrelate labor and sustainability practices. EE and ESD are also understood as separate and complementary tasks for education in Austria, to ensure both have a significant place in curriculum (Rauch & Pfaffenwimmer, 2015; see also Reti, Horvath, Czippan, & Varga, 2015).

Student-centered learning approaches are common in much of Europe and also reflected in ESD there at the classroom level. For instance, in classrooms in Italy teachers rely mostly on discussion and collaborative learning, wherein students are asked questions (such as what causes global warming or what is the greenhouse effect) and encouraged to reflect on their background knowledge in developing further understanding additionally informed by scientific views (Mason & Santi, 2006). Group discussion that facilitates argumentative practice wherein students "transform their personal beliefs into reasoned views" is also found to be more effective in such contexts than teaching to the tests in middle age groups, while the aim of ESD is conceptualized by many teachers in Italy as enabling students to develop empowered views (see also Andresen, Hogmo, & Sandas, 2015).

In Asia, formal integration of sustainable development topics into teaching of traditional subjects is not uncommon (UNESCO, 2014). However, given the highly academic orientation toward curricula in much of Asia and the related tendency toward teacher-centered and test-centered rather than student-centered education, emphasizing content over skills, it is likely that such curriculum appears as add-ons in many cases (Fien, 2002). Without ESD knowledge and skills integrated into assessments, the latter of which are often focused on knowledge in key disciplinary areas, it is likely students are not systematically or substantively focusing on ESD in formal education in many Asian countries.

As UNESCO notes (2014), where ESD is most successful in Asian formal education contexts is mostly likely in subjects that focus on student-centered and/or experiential learning, and interdisciplinary coursework. For instance, in Japan, Korea, Hong Kong, and elsewhere, experiential learning has increased in popularity. In these contexts, ESD projects focused on local sustainability issues may be easily and effectively implemented. As social sciences are frequently integrated across disciplinary areas in curriculum—for instance, in Hong Kong a recently required (2009) Liberal Studies subject includes environmental studies, global studies, and other social studies (Curriculum Development Council, 2007)—within such general studies subjects, ESD can easily be included.

However, as Asia in contrast with Europe does not yet place a major societal value on sustainability and environmentalism, without related teacher education via reformed pre-service and in-service teacher training, curriculum guidelines promoting ESD in formal education are unlikely to lead to effective classroom implementation there (Hopkins & McKeown, 2002). And indeed, across Asian countries

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

(and elsewhere) such revision of teacher education is often piecemeal. UNESCO (2014, p. 92) reports that most countries described their integration of ESD into teacher education in 2013 as "in progress," in contrast to in 2005, when most only had an emerging interest. As Kwo (2011) notes, because most teacher education is normally provided through institutions of higher education, curricula for teacher education for sustainable development may be slow to change as this requires restructuring of programs overall, including their length and structure. Furthermore, as teacher education training (particularly in Asia) often focuses on teacher development of skills and techniques rather than content knowledge, there may be a hidden curriculum in such contexts which deemphasizes and devalues ESD. This hidden curriculum is further shaped by the ideally integrated, interdisciplinary nature of ESD curricula, as "something which officially is everybody's responsibility can in practice be nobody's responsibility" (Kwo, 2011, p. 47). Without explicit changes, ESD may not be effectively promoted in Asian contexts where top-down reform and monitoring for teacher accreditation is also increasingly the norm (Law, 2003).

Teacher buy-in is also necessary for implementation to take place, and such buy-in will depend upon teachers' current attitudes toward sustainability (Kwo, 2011). No generalizations about a region as large as Asia can be made with regard to teachers' attitudes. Rapid industrialization is seen alternatively across individuals in Asian societies as inherently positive or as problematic, with regard to sustainability. In highly developed and quickly developing Asian contexts anti-environmental attitudes among the general public have been clearly observed. Small-scale surveys of the public (Wong, 2011), stakeholders (Chan 2008; Hills, 2005) and educators in Hong Kong (Lee, 1997; Lee, Lam & Williams, 2009; Stimpson, 1997) reveal developing interest in sustainability education; yet they also indicate that many people tend to distinguish in their attitudes between political-economic and environmental concerns. Environmental problems are thus framed as apolitical, or not worth critically considering in light of political-economic needs. Whole-school approaches, as well as a focus on nonformal education, such as media campaigns and outside training, are therefore increasingly recommended (UNESCO, 2014).

African and Arab states have been the slowest to implement ESD reorientation in formal curricula generally (UNESCO, 2014). In many countries in these regions reorientation remains under review at the formal educational level by educational policy makers, while more progress is being made at the informal level. Given development challenges in many parts of these regions, ESD policies and programs are generally aimed more at the level of increasing access and quality of education, including primary education and early childhood education, rather than at the level of curriculum reform.

Across North and South America ESD incorporation in formal education is sporadic, with countries indicating different levels of commitment and progress toward reorientation. In Canada and the United States, ESD is not widely embraced socially or politically as compared with Europe, and within the two countries' their decentralized educational systems diversity of approaches and orientations is one result (Stevenson, 2002). In Latin America, environmental education and related developmental pedagogies have a long history within and outside of formal education. Many countries in the region, although not all, have what can be regarded as either substantive or implicit ESD curriculum at the formal level, in addition to much nonformal ESD activity (UNESCO, 2014).

In Australia and New Zealand environmental awareness is generally high and a variety of formal educational approaches are taken. Australia implemented a national action plan for EE and ESD in 2000 (Tilbury, 2004). Across states in Australia there is varying levels of curricular integration at this time. Notably, schools in Victoria have long had ESD as EE and developing appreciation for the natural environment, bird watching, and so on. This homegrown tradition provides fertile ground for implementation of more recent national ESD initiatives there (Gough, 2006). Similarly New Zealand's natural environment

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

lends itself to outdoor "study abroad" education, wherein students visit the South Island for 15 days to meet leaders of conservation movements across the island (Cusick, 2008). Such field experiences as part of formal curricula are recognized there as enabling transformative education that promotes wellbeing of people and environments.

Nonformal Education

In some contexts ESD is more visible outside of formal education, in the spheres of nonformal education and training. In such cases it is led typically by NGOs rather than government departments or ministries. In UNESCO's final report on the DESD, it was found that most countries had made progress in the domains of adult education, public awareness campaigns and media, and other nonformal education programs. In many nations much of schoolchildren's ESD is provided by NGOs and related community groups, who may sponsor in-school or extracurricular activities or have their services used by the schools to learn about community and environmental issues in the local context. Adult community education that aims to be sustainable and develop local capacities is common in developing countries, and includes literacy programs, community business support, health education, and more. Public awareness campaigns by NGOs are found around the globe, such as Earth Day (UNESCO, 2014). Local groups may also spread awareness through performances and celebrations, websites, and television productions, depending on the context and the cultural and social appropriateness of various means.

In Asian developing contexts, nonformal community-based education for all members of society which is focused on sustainability and development is common. Community theatre and related artistic and dramatic groups often spread awareness while entertaining people in society, in countries including Vanuatu (Passingham, 2002) and Indonesia (Fuhker, 2002). These and related programs can be seen to help sustain cultural traditional understandings of the relationship between people and the environment against a modern, western exploitative view. In Africa, sustainability knowledge is increased by local groups who focus on the natural world through field trips and public education campaigns for living sustainably. Campaigns may focus on clean drinking water, waste management, disease prevention, alternative energy sourcing (such as solar power) and related local development challenges (UNESCO, 2014; Schreuder, 2002). The Peace Corps is highly active across much of Africa and Asia, where volunteers coming from the United States may work on projects in one or more of these fields to aid development, building wells, supporting health clinics, enabling and assisting with sustainable gardening, and more.

In contexts where formal schooling is well developed and standards of living are higher, such as in much of Europe, Australia, North America, and East Asia, nonformal education for ESD is typically related to formal schooling. In these regions, NGO activities may revolve around working with schools in partnerships to take young people out of classrooms and interact in communities and learn more about local environments. As mentioned above (in the case of New Zealand), field trips (or field days), organized camping, and volunteerism in disadvantaged areas are all common approaches. Experiential learning and service learning may be incorporated into ESD nonformal curriculum in these cases. In Canada and the United States, conservation of natural resources may be examined in particular (see Jickling, 2002).

In Latin and South America nonformal education has been viewed as key to development, and popular education movements there have been influenced by the Brazilian educational thinker Paulo Freire, who argued that all education should be community based, and involve praxis as a blend of learning for empowerment and social action (Freire, 1989; Misiazek, 2014). In postcolonial contexts in this region this framework has been taken up against academic schooling to involve local community members of all

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

ages to take part in social development and reconstruction. Such education has had developmental as well as political connotations, and has also been connected to liberationist theology with a related emphasis on social justice. The pedagogical approaches associated with this form of ESD originating from Latin and South America have been to seen to impact educational approaches to ESD worldwide with regard to envisioning aims and methods, within or outside of formal education (Gadotti, 2009; Gadotti & Torres, 2009). These focus on critical thinking and critical empowerment of young and indigenous people, through dialogue, value sharing, and community problem solving activities. I now turn to the different models and approaches to ESD, and debates over values, meanings, and goals, in the next section.

CONCEPTUALIZING ESD: CONTEMPORARY APPROACHES

In terms of curriculum choices regarding aims, content, and teaching and learning practices, a wide variety of approaches is used today that go beyond a traditional academic model that focuses on environmental education. Varying emphases across approaches reflect different understandings of the causes and solutions to global sustainable development challenges. This section focuses on different pedagogies and curriculum for the formal sector, particularly for older students, in secondary and higher education.

The Traditional Model

The traditional approach to ESD focuses on knowledge accumulation, citing as the cause of sustainability challenges lack of awareness across populations (Scott & Gough, 2003). Knowledge is understood within such models as objective, factual, and scientific. The facts can straightforwardly tell us what to do in a variety of cases, as learning can directly lead to behavioral change (Vare & Scott, 2007). Scott and Gough (2003) describe this as a Type 1 approach, while Vare and Scott (2007) similarly describe this as ESD1 and as learning *for* sustainable development.

ESD1

As Vare and Scott elaborate (2007), in Type 1 or ESD1, behavioral change related to sustainability is caused directly by increased knowledge and understanding of the relationship between one's actions and behavior and sustainability challenges. Indirect impacts can also be made in the public's behavior through economic management of behavior based on social scientific understanding. In either case, the approach is centered on expert knowledge and the use of such knowledge.

Many people have assumptions about ESD underpinning Type 1 or ESD1. In a survey of higher education students in Canada (Wolf, Brown, & Conway, 2014), they found that most identified as communitarian or economist types. Communitarians, in their framing, view acting on knowledge of sustainability issues as every individual's responsibility, and the causes of contemporary challenges as adequately understood for individuals to take action. Economists in their research likewise think that data supports action, and that environmental scientists and economic and political researchers can determine what needs to be done and ensure that required changes are implemented across public and private sectors, respectively (Wolf, Brown, & Conway, 2014, p. 510).

Others describe the traditional ESD model of ESD1 as a *liberal* orientation, connecting commonplace ESD attitudes and understandings to the western Enlightenment view of human liberty, wherein

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

humans attain freedom via the use of technology over the material world. This traditional model clearly has strengths. As Wapner writes (1996), "liberal environmentalism has been enormously important in identifying and containing many harmful activities. The Clean Air Act, the National Forest Management Act, and the Clean Water Act [in the United States] represent liberal victories." Additionally, as an orientation toward managing challenges, it is positive and optimistic about the potential of knowledge to create a better world and guide action, often at the individual level. For example, green consumption, the actions of individuals purchasing "green," more sustainable goods, can be seen to lead to personal empowerment of individuals to make a difference by acting on ESD knowledge against a backdrop of increasing uncertainty and risk in the environmental and political domains (Connolly & Prothero, 2008). Many specific examples can readily come to mind here, such as in the case of the production and use of energy-conserving lightbulbs, where knowledge and research can easily guide behavior that can clearly be seen to be more environmentally sustainable (see also Laessoe, Feinstein, & Blum, 2013).

Additionally, this traditional model, with its focus on content knowledge that students can learn, can be taught and assessed in straightforward ways. Knowledge can be imparted through books, lectures, discussions, or even films, online courses and websites, among other ways. Thus, in countries where teacher-centered pedagogies are commonly used (such as many Asian and African societies), reorienting curricula while using a traditional model of ESD does not imply such a comprehensive reform of teaching and learning to be successful. Content can simply be added to (or replaced within) the curriculum, with no major pedagogical changes required in such cases. Similarly, assessment of knowledge-based ESD can be simply designed to evaluate the impact of knowledge sharing on students as individuals and for other assessment purposes, such as for evaluating teacher effectiveness or program effectiveness. Quizzes, short answer questions, and the like can be used, as preferred in many contexts where more innovative alternative assessment modes are not as yet commonly appreciated today.

One particular program of assessment that has emerged to test sustainability knowledge at a global level in higher education is the UN Sustainability Literacy Test. This test was initiated by Jean-Christophe Carteron with funding and technical support from the Foundation for Sustainable Leadership of the Kedge Business School and DEGETEL, both based in France (Sustainability Literacy Test, 2013). Its senior advisory board includes the UNEP, the UN Department of Economic and Social Affairs, and UNESCO. As part of the Higher Education Sustainability Initiative, it aims to enable measurement of sustainability knowledge among diverse students of higher education, and measurement of higher education institutions' improvement and performance in teaching students for sustainable development (Sustainability Literacy Test, 2013). The test aims to measure students' knowledge using objective questions, in environmental, social, and economic realms. It therefore aspires to develop and test students on an international foundation of "minimal level knowledge" seen as valuable to students in higher education around the world. Questions are focused on "challenges facing society and the planet," and "organization's responsibility in general and on corporate responsibility in particular."

The promotion and use of such a test gives visibility to the importance of ESD and the role of higher education institutions in promoting sustainability at a global level, ambitiously aiming to become akin to other well-known and respected international standardized tests, such as the Programme for International Student Assessment (PISA), the Trends in International Mathematics and Science Study (TIMMS), the SAT U.S. College Admission Exam, and more. In societies where environmentalism is less common, the promotion and use of this test as a global indicator could develop a greater sense of urgency around educational reforms toward ESD, motivating people to learn more about sustainability concepts.

Challenges to the Traditional Model

Despite the popularity and commonplace use of the traditional or ESD1 model today, many researchers and educators object to the exclusive use of this model, given several notable shortcomings. First, researchers contest availability of clear existing data to easily guide sustainable action in many areas of life. As Vare and Scott (2007, p. 195) note, ESD1 is inadequate by itself because "we can't measure success in terms of environmental impacts because this is an open-ended process; outcomes will depend on people's unforeseen decisions in future, unforeseeable circumstances." What constitutes the most useful knowledge depends on circumstances which are dynamic rather than static, across the world today and in the future.

Indeed, uncertainty about how knowledge can or should guide action can often be seen to reign in educational and public debates about sustainability today, against traditional ESD1 model ideals. In relation, whether humans should be seen as rational actors is essentially contested, as many argue that the evidence suggests that people often act against their own ultimate interests rather than toward them (Vare & Scott, 2007). Much research on green consumption suggests that people readily change some behaviors in more straight-forward areas, while not making changes in more complicated domains, where more impact can nonetheless be made (Wolf, Brown, & Conway, 2014; Connolly & Prothero, 2008).

Relatedly, the complicated nature of current sustainability challenges requires that people put trust in experts. These experts' views may be disseminated through mass media in better or worse ways, and may be presented in a provocative and exaggerated way, or as controversial, for media purposes. When it comes to individual decision making, there is no best practice for how to utilize such varying expert opinions. Uncertainty can thus reign over certainty. For green consumers, knowing whether it acceptable to purchase genetically modified produce, or how to weigh different options can be a nerve-racking, not straightforward, process. How to compare environmental risks to personal health risks, or weigh long-term versus short-term impacts of various personal decisions, is not easy for any individual to navigate (Connolly & Prothero, 2008).

Finally, critics of the traditional ESD model view it as significantly limited in its understanding of the relationship between individuals, political and economic forces, and the environment. As Maniates (2001) argues, American environmentalism over the last few decades has been limited to a focus on individual responsibility, over private or state responsibility, due to a lack of national NGO financing and the need for American NGOs to avoid confrontations with corporations and national entities that truly deserve responsibility for most significant and large-scale environmental and developmental challenges. As neoliberal models of private individual economic choice became popular which cast federal government as inferior and inadequate by comparison with corporations, "almost overnight, the responsibility for fundamental change in American consumption and production landed squarely on the backs of individual consumers" who are seen to more effectively "vote" through their consumer choices (Maniates, 2001, p. 40). In this ideological context, young people may be skeptical of social, non-corporate solutions, viewing them as idealistic within a framework that precludes an account of democracy and social responsibility of corporations (Maniates, 2001). Relatedly, American students have been found to suspect that people cannot learn or be persuaded of what they may believe they know themselves about sustainability challenges and the way to alleviate them, viewing others' lack of idealism thus as an intractable challenge (Wolf, Brown, & Conway, 2014). In the United States, young people perceive

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

skepticism about human abilities to face sustainability challenges as the mainstream view (Wolf, Brown, & Conway, 2014), leading to a pessimistic view about collaboration for social change.

However, responsibility for sustainability challenges cannot rationally be put only upon individuals as private citizens, according to critics of the ESD1 model. Maniates (2001, p. 44) thus fears a downward spiral where cynicism will grow as knowledge increases given levels of public skepticism:

In the end, individualizing responsibility does not work—you can't plant a tree to save the world—and as citizens and consumers slowly come to discover this fact their cynicism about social change will only grow: "you mean after fifteen years of washing out these crummy jars and recycling them, environmental problems are still getting worse—geesh, what's the use?"

Wapner (1996) similarly writes,

Liberal environmentalism is so compatible with contemporary material and cultural currents that it implicitly supports the very things that it should be criticizing. Its technocratic, scientistic, and even economistic character give credence to a society that measures the quality of life fundamentally in terms of economic growth, control over nature, and the maximization of sheer efficiency in everything we do…Liberal environmentalism is unconcerned with reflecting upon who we are, our place in the global ecosystem, and our relationship with other species who also inhabit the earth.

In summary, the traditional ESD approach of ESD1 focuses on imparting knowledge to individuals, with the understanding that such knowledge, effectively disseminated, can lead people to change their behaviors and actions to align with what future sustainable development apparently can be seen to demand. While this has clearly been an effective approach in many instances and enables straightforward pedagogical practices and assessments of ESD teaching and learning, it is not without its limitations. People argue that a traditional academic model where knowledge is seen as politically impartial and unproblematically related to positive change through its dissemination at the individual level as inadequate given (1) the limitations of current knowledge, (2) factual and conceptual lack of clarity as individuals struggle to understand and act on expert views, and (3) the intertwined way that individuals alongside state and corporate actors actually bare responsibility for sustainability challenges. Others contend that ESD must focus not only on technical knowledge but also on skills, attitudes, and values and/or dispositions, if it is to have a positive impact.

Alternative Models

In contrast to the traditional ESD model of teaching and learning aligned with traditional, academic, teacher-centered views of education, many educators argue that ESD must relate to development of skills and changes in values, attitudes, and dispositions in order to have a truly positive impact. Various skills, values, and attitudes have been identified by such scholars and elaborated as educational aims.

Skills: ESD2

As mentioned previously, Vare and Scott (2007) argue that, while it is clearly essential as one part of ESD, ESD1 as a focus on content knowledge accumulation is unsufficient without attention to the fact that sustainable knowledge practices require a focus as well on student development of cognitive and interpersonal skills. In contrast to Type 1 ESD, which assumes the world's problems are basically

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

environmental and can be solved through application of knowledge, Vare and Scott emphasize two additional types. They note that Type 2 identifies our problems as social rather than environmental. Type 3 "approaches assume that what is (and can be) known in the present is not adequate; desired 'end-states' cannot be specified. This means that any learning must be open-ended" (2007, p. 193). Arguing that Type 3 is also a useful way to understand the current situation that ESD responds to, they argue that ESD1 must be complemented by *ESD2*. ESD2 focuses on how learning itself can be sustainable, by building capacities of critical thinking that extend beyond current coin of expert knowledge. As Vare and Scott (2007, p. 194) write, "our long-term future will depend less on our compliance in being trained to do the 'right' thing now, and more on our capability to analyse, question alternatives and negotiate our decisions." Furthermore, they frame ESD1 and ESD2 not as linear learning models (with ESD1 occurring before ESD2), but argue that they should be viewed as a yin-yang (2007, p. 196).

The ESD 2 approach is often presented as a case for more liberal education (which it may well be) in opposition to ESD 1, which reflects a more limiting 'instrumental' view of education. Viewed from the Yin-Yang perspective, ESD 1 and 2 are complementary because people need to hear with the sustainability lobby and governments are telling us to do (through ESD 1) in order to have relevant subject matter to debate and test in our own contexts. ESD 2, although open-ended, cannot exist in a vacuum devoid of content.

Maniates (2001) similarly focuses on skills to ameliorate the harmful impact of consumeristic and individualistic thinking in the ESD realm, emphasizing particularly the need for a focus on imagination. He distinguishes his sense of the meaning and importance of imagination, from a "soft," emotional sense of new age earth-mother enlightenment, to instead emphasize the need to think more critically about what possibilities for social change are viewed as realistic versus idealistic within contemporary material and political contexts.

Political Perspectives

More radical alternative approaches to ESD highlight educational aims that are political and related to fundamental changes in values and perspectives of young people. Gruenewald's (2003) elaboration of a *critical pedagogy of place* aims to join educational movements he labels as "critical pedagogy" and "place-based education." Critical pedagogy, Gruenwald notes, has its roots in Freire's (1989) pedagogy of the oppressed framework, which places student empowerment, in light of students' local community needs, at the heart of educational invention. Education should not be dictated by educators or policymakers according to Freire's influential approach, but should be developed dialogically by students and teachers, working together as democratic equals. Educational labor should help improve students' worlds and lives; to do this, teachers must release some of their traditional power to students, in developing curriculum and teaching methods. This is an inherently critical and political kind of education, as it is presumed in this approach that the world needs changing, and that education therefore has a function of social and material reconstruction.

Ecological place-based education similarly intends to engage students in their physical and social worlds in a direct way, taking the student outside the traditional formal classroom, and enabling students to take part in their worlds and interact within them productively (Gruenwald, 2002). As in critical pedagogy, the context of education thus plays a role in developing teaching and learning activities. While critical pedagogy invites student action to transform students' world, ecological education has

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

traditionally encouraged conservation. By joining the two approaches, Gruenwald argues, students can develop a critical orientation toward sustainability, realizing that informed, democratically developed changes are needed, while students must simultaneously work to sustain that which supports flourishing in the future (2002).

Gruenwald's critical pedagogy of place represents a kind of locally oriented eco-pedagogy project, that gives less attention to the notion of students as potential actors on a global stage. However, other educators have developed related conceptions of eco-citizenship, as a form of global citizenship oriented toward grappling with complex global challenges with environmental and social (often economic) implications. Wolf, Brown, and Conway (2009) argue explicitly for what they describe as *ecological citizenship*. As they note, such a view of citizenship is distinct from how citizenship is normally conceived, in that there is no legal status of the eco-citizenship concept, or rights associated with it, and therefore no objective determination of what makes one such a citizen. However, as citizenship is also understood in political theory to have moral and social responsibilities, it is apt for highlighting our interconnection and interdependence with one another at a global level regardless of nationality, and our duty to act to decrease harm and increase good internationally.

Bengtsson and Ostman (2013) that ESD should be seen as practices of meaning making in the context of politics and global inequality. Rather than accept dominant, popular and hegemonic meanings of development, sustainability, and globalization which complement neoliberal, market-driven, globalist approaches, Bengtsson and Ostman (2013) note that ESD should be involved with deconstructing meanings at different levels and developing alternative articulations based on location, perspective, and subjectivity. By implication, refinement and reclaiming of these terms in ways that may be more locally empowering is an educational aim.

Wapner (1996) similarly argues that educational values must be dramatically reoriented toward a global environmental level, within an "ecological politics." Wapner cites Aldo Leopold in describing an ethic of environmentalism wherein all humans are fellow citizens, "which included plants and animals as well as other people, and the community as a whole" (1996). In terms of practices of teaching and learning, similar to Gruenwald's critical pedagogy of place, Wapner argues that teachers can build bio-regional awareness by involving students in understanding local ecosystems through visits, making needed connections between their everyday lives and those of diverse others (human and animal) in their community. As caring should be extended beyond the nation-state to help improve life more holistically, Wapner goes further however to recommend teachers highlight holistic senses of community over nationalistic ones in ESD education. Finally, Wapner encourages participatory ecological practice, embracing citizenship within an ecological politics as requiring personal efforts, connecting the personal to the political, to develop better understanding of how one's own actions can make a difference (1995).

ESD as Developing Global Civic Values

Relatedly, others emphasize ESD as a new way of understanding the world and one's relationship and responsibilities to it. Within such framings, ESD is about developing globally sustainable values and caring understandings of the relationships between self and other living creatures in the world. Gadotti (2008) argues for education for sustainable *life* rather than sustainable development. Gadotti (2008, pp. 23-24) summarizes such a movement towards education for sustainable life as having the following goals:

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

1. **Global Thinking:** In an era of information…there is no need to accumulate information. But it is vital to know how to think….We must educate so that people understand that we have only one home.
2. **Feelings:** Human beings are the only creatures who ask about the sense of life. We must educate to feel, to care, to take care and to live every moment of our lives making sense. We are humans because we feel, not only because we think.
3. Our identity on the Earth as a vital human condition. Our common destiny is to share life on the planet with others…
4. **Planetary Awareness:** Understanding that we are interdependent. The Earth is a single nation and we, the people on Earth, are its citizens. We don't need passports. Nowhere on the Earth should we be considered foreigners. Separating the world into the First World and Third World means dividing it so it can be ruled by the most powerful…
5. **Understanding:** We must educate for human ethics rather than for market ethics…
6. **Voluntary Simplicity and Quietness:** Our lives need to be guided by new values: simplicity, austerity, quietness, peace, serenity, listing, living together, sharing, discovering and building together…

Gadotti points here to radical reorientation of values and perspectives through education in this approach to ESD as education for sustainable life. Other global citizenship educations similarly focus on developing values and understandings of a global community for global sustainable development and well-being. Amartya Sen (1999) and Martha Nussbaum (2001) have advanced capabilities approaches to education, which hold that societies have responsibilities to educate the world for living together with greater equality and collaboration. Such capabilities can inform ESD, as the basic goal of increasing meaningful educational access around the world, as well as for revising pedagogies for global citizenship needs in developed societies. Nussbaum's capabilities in particular can be seen to interrelate with Gadotti's (2008) conceptualization of education for sustainable life. They include (2001, p. 416-417):

1. **Life:** Being able to life to the end of a human life…
2. **Bodily Health:** Being able to have good health…
3. **Bodily Integrity:** Being able to move freely from place to place…having opportunities for sexual satisfaction…
4. **Senses, Imagination, and Thought:** Being able to use the senses, to imagine, think and reason—and to do these things in a "truly human" way…
5. **Emotions:** Being able to have attachments to things and people outside ourselves; to love those who love and care for us…
6. **Practical Reason:** Being able to form a conception of the good and to engage in critical reflection about planning of one's life…
7. **Affiliation:** Being able to live with and toward others, to recognize and show concern for other human beings…
8. **Other Species:** Being able to live with concern for and in relation to animals, plans, and the world of nature…

Nussbaum argues that global citizenship must be prioritized by countries because the problems faced are global. She further argues that such citizenship must be fundamentally compassionate. Hytten (2009) likewise argues that education must help people to develop compassion, care and empathy toward others

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

globally, by focusing on the root causes of global problems rather than on symptoms of social problems. Thus Nussbaum and Hytten see it as a political project within civic education to develop concern for others at the global level, with development of requisite cognitive skills, alternative understandings of the world, and different values and emotional dispositions. Caring is also the focus of much work in global citizenship education. Though focusing primarily on her work on interpersonal caring in educative relations, lead caring theorist Noddings (1999) has described concern for more-distant others' sufferings as the "foundation of justice."

Return from Feelings to Skills in Alternative Approaches to ESD

Although feelings are emphasized in many of the approaches to ESD highlighted here, some argue that such emotional education has grave risks. Zembylas (2008) notes that students experiencing empathy and compassion regarding others' trauma or suffering in such critical political or related educational projects can unfortunately also lead to an inappropriately sentimental reaction by students, who want to do and be good people despite of (and in relation to) their experiencing unfair advantage and privilege over others. In this response, students are prone, particularly in observing cases of global underdevelopment and poverty, to orient themselves to suffering using a 'deficiency imaginary of development' (Jackson, 2014a). According to the deficiency imaginary, people are missing something which other people—student volunteers, for instance—can provide. This sentimentality can thus create a naive assumption that once an empathy gap is bridged, problems of a structural nature can easily be solved (Zembylas, 2008). Compassionate models of citizenship realized as international volunteerism, seemingly celebrated in some of Noddings's work (2003), can thus lead to ideologically fueled development work, whose outcomes are actually more indeterminate for the so-called subjects of aid (Cook, 2012). The response is doubtlessly one of emotional concern and care, but the result is far from appropriate and effective.

With regard to ESD more generally, Maniates notes how the focus on personal change in such civic education models inappropriately presumes individual responsibility. People may feel morally committed to the earth through such education, but can hardly heal the planet by changing personal consumption (Jackson, 2015). In ESD it has also been observed that students across diverse countries feel gloomy, pessimistic, and guilty, but not sure how to respond appropriately to these feelings, or to environmental challenges (Morris, 1996; Fein, Sykes, & Yencken, 2002; Gruenewald, 2004). As Fein, Sykes, and Yencken (2004) notes, "it is not so much a question of creating anxiety during environmental education. The problem is more [one of] how to handle the anxiety and worry which students already feel." Though care and emotions toward others nearby and distant is emphasized in models of global citizenship for living together and sustaining the planet, ESD research suggests that students need problem-solving skills to understand sustainability challenges and realize the need to work effectively with others, given the scale of challenges. Developing right emotions, about others or the planet, is not crucial. Cognitive skills are required to empower people to help others (today and in the future). Thus some theorists have extended this work into more cognitive and rational directions.

Engster (2005) has incorporated care theory into explorations of how to consider and treat people across the world. He echoes Noddings' original theory of care by characterizing it as attentive, responsive, and respectful. Attentiveness is a kind of active-listening orientation toward others, which entails considering needs or causes of dilemmas below the surface in seeking to understand others' situations, in line with views such as Hytten's, that compassionate global citizens should address causes, not symptoms, of social injustice. Responsiveness relates to the appropriateness of a reaction. Engster takes an example

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

from Noddings (2002) of the flood of donations of food and clothing to Afghanistan after an earthquake, when what was needed were building materials (see also Gallwey & Wilgus, 2013). Respect is recognition that one is an end in their own right, with their own worldview, and not an extension of oneself.

For Engster, human interdependency justifies a duty to care. As he (2004) writes, "since all human beings need care and claim the right to be cared for when in need, and more generally depend upon the caring of others to sustain not only our own lives but also human life and society, we must logically recognize the rights of others to make claims upon us for care when they need it, and should endeavor to provide it when we are able to do so without significant danger to ourselves." Sigal Ben-Porath (2008) argues in parallel that the fact of global interdependency justifies a global ethics of care as a practice of interacting with international others with attentiveness, responsiveness, and respect. Although Ben-Porath concedes it may seem strange to discuss caring of social entities such as nation-states, she elaborates that "caring relations among groups refer broadly to the common understandings they have about possible ways to perform caring acts. The way the other is portrayed…and the self-understanding of each group as related to its role with the other…generates the basis for the relationship among the groups" (2008, p. 5).

To incorporate emotional learning into education that aids development, Chouliaraki (2010) argues for a "post-humanitarian communication" style that enables more meaningful interrelations of people globally across divisions of power. Understanding emotions not just sociologically but economically, "this style acknowledges that compassion fatigue lies not so much in the excess of human suffering that transcends individual capacity to feel for or act on it, but rather in the excesses of discourses of morality around which we are called to organize our feelings and action towards suffering" (Chouliaraki, 2010, p. 120). Similarly Leighton describes empathy as "a limited resource that we need to use wisely" (2011, p. 226; cited in Jackson, 2014b). These ideas are empirically grounded, in media theory, in Chouliaraki's (2008) observation that emergency news discourse—unlike other types of news stories about development and aid—can produce a moral demand for action, based on fragile and incidental, rather than systemic, historical, connectivity to distant others. Such discourse can potentially bolster one's sense of cosmopolitan spirit in responding to distant others' needs, without begging painful questions of historical-causal intergroup relations, or drifting into sappy and patronizing sentimentality. Developing a better objective future is a desire binding social groups in disparate conditions, while in emergency conditions, there are fewer emotionally or psychologically pesky problems of power, politics, and resistance to the status quo.

Summary

In sum, a variety of different perspectives exist on ESD as teaching and learning, with some focused on a traditional curriculum which is teacher-centered and focused on knowledge dissemination and accumulation, while others focus more on skills, feelings, dispositions, and civic and moral values and responsibilities. Within this latter group, diversity of orientations is evident, as well as different prioritization of the importance of emotional versus cognitive and rational education for sustainable living and development at local and global levels.

What emerges most clearly in examining the kinds of contemporary ESD approaches taken today from a global and comprehensive view is the diversity of aims, values, and methods used. Such diversity can be seen to follow from the understanding that ESD must fundamentally be contextualized within concrete settings rather than accepted as recommended from the top-down. Local reorientation of ESD, which is encouraged by UNESCO in the implicit acceptance of a student-centered view of education (see also UNESCO, 2007), implies that ESD education should unfold with consideration of the options

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

and one's own educational context, as what works best will depend not only on expert knowledge but on the background knowledge of learners, community context, and more. The claim can be made that ESD teaching and learning should not only be knowledge-based, but should also meaningful engage and enhance students' skills, deeper level understandings, dispositions, moral attitudes, and more. However beyond this general statement, research is ongoing in this area about what approaches work best based on context, as not all students, communities, and environments around the world are alike.

CONCLUSION

ESD as a trend in conceptualizing and enhancing environmental and sustainable knowledge and know-how has changed dramatically over the years. Originally, it was seen not as a teaching and learning trend or area of content knowledge. In contrast to today's understanding, in its first few decades of emergence, in the 1970s and 1980s, it was viewed instead as a means toward using education for development generally. At that time, it was also understood by advocating political bodies that ESD could unfold as curriculum, based on sustainability principles and environmental knowledge. However, the original aim was merely to use education to drive development, thus implying a focus mostly on developing countries where capacity building was needed in aid of modernization and industrialization.

A global perspective on the current state of ESD which stems from this historical background reflects that a variety of activities are still held as appropriate for ESD across diverse world regions and contexts, beyond traditional classroom teaching and learning. In Africa and parts of Asia and the Middle East, educational access and quality enhancement is still a primary goal. Adult literacy training and other community services to increase capacities of local people in the same regions are thus typically included under the basic umbrella of ESD in these same parts of the world. Media and public awareness campaigns are often also common in these areas, and around the globe more universally, signaling that ESD is not just about classroom disciplinary development, but about all members of society becoming encouraged to take part in positive global change.

At the level of curriculum, a similar diversity of approaches and impacts can be seen from a global survey of the extent of ESD in formal education. In formal education, ESD is most prevalent in secondary education, where it may be part of general studies curriculum, social studies education, or science and environmental education. It may be a standalone topic or integrated in other areas; additionally, it can be part of a whole-school reorientation to ESD, which includes consideration of a hidden curriculum. In this domain, recycling campaigns, the values of educators the use of school resources (as examples) may all be considered part of ESD in the formal education system. Indeed, research shows that without awareness of this hidden curriculum, ESD may be less effective however it is to be formally included, particularly as educator interest, commitment, and "buy-in" to ESD, ideally formed through pre-service and in-service teacher training, is seen as critical to successful integration.

Comparing countries, one can see major discrepancies in terms of integration and/or orientation of curriculum toward ESD. Some of this can be seen to relate to different stages of development of different societies, as typically those countries that are more focused on ESD as basic educational access will have a less systematic inclusion of ESD principles in their curriculum. However, even in Europe, Asia, and the Americas the methods and significance of inclusion of ESD in curriculum vary from country to country. Indeed, some scholars have argued a national-level analysis of ESD is unhelpful due to the vastly different structures of education across different countries, enabling a wide variety of practices

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

across societies based on difference in regulation, accountability, curriculum development practices, and other matters (Feinstein, Jacobi, & Lotz-Sisitka, 2013).

ESD as educational practices can be further broken down in relation to various aims and objectives that educators and researchers argue for as components of ESD. Traditional models of ESD focus on content knowledge, which can be easily assessed, and lead in many cases to educational practices seen as culturally sustainable today, as many countries still prefer teacher-centered, academic education in formal education. Such knowledge is seen as productive for instructing people about what they should do, as well as developing societal structures that encourage and discourage particular behaviors and actions among the public based on social science principles.

As discussed here, such a traditional approach to ESD as knowledge, as in Type 1 and ESD1 approaches, can clearly be seen as having a direct impact on people's behaviors, particularly in areas where individuals can make clear positive changes in their behavior toward sustainability, such as in consumption of resources. However, others critique this model for focusing on knowledge at the neglect of skills development, when ESD knowledge must itself change over time in relation to dynamic circumstances. Additionally, not all knowledge is clear in its implications for individuals' actions, in a complex, expert-driven domain where personal and environmental risk often appears alarmingly close at hand. Furthermore, critics argue that such a depoliticized view of knowledge emphasizes individual consumer choice at the cost of understanding how large-scale environmental destruction is not actually conducted by individuals, but by states and corporations. Political and social change should be enacted according to this view of ESD knowledge; such change requires that ESD develop people's skills to think, act, and work together interpersonally in an interdependent global setting, rather than just act as individuals.

Therefore, others argue that ESD in formal education must not focus only on knowledge accumulation, but also on skills, attitudes, understandings, dispositions, moral and civic responsibilities, and emotions. ESD2 is thus seen as a complement to ESD1, as we must apply skills to interpret knowledge which does not by itself tell us how to proceed in concrete circumstances. Imaginative, creative, and critical thinking are also emphasized by thinkers who believe environmental problems require radical changes in perspective and awareness that current views of ESD, sustainability, development, and globalization, are politically framed, rather than neutral. ESD should thus deconstruct views critically in classroom settings.

More radical views include a critical pedagogy of place, dedicated to changing the world around the classroom, and various views of global ecological citizenship. A wide variety of these latter views can be readily identified, which focus holistically on changing student understandings of themselves in the world, emphasizing connections and interdependence with others species and life around the world regardless of political borders. These approaches emphasize relationships and the production of positive feelings toward others worldwide, such as caring, compassion, empathy, and related feelings. They also call on people to develop a moral sense of civic duty toward the planet and all other living creatures, developing a critical, deeply felt commitment to helping the world develop more sustainable living patterns.

These latter views also have their limitations and challenges for implementation. Emotional education can be challenging and can also risk developing cynicism, guilt, and despair among students, given the complex relationship between individual actions and global challenges. When one realizes the critical systematic features of global sustainable development challenges, one may develop many feelings, but not necessarily a sense of empowerment. In this context, researchers have reoriented such emotional education toward a rational sense of global duty connected to civic responsibility. Post-humanitarian views also encourage an understanding of relationality that may be less deeply felt at an emotional level,

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

but more promising when it comes to the impact of understanding on behavior, recognizing that emotions in ESD are also scarce resources that should be enhanced sustainably.

Today no single path among these options is held by researchers or UNESCO as the single best practice for ESD. After all, ESD that is aligned with best educational practice will interrelate with communities at hand to be sustainable, and the local environments they live in. In some cases, increasing basic education so as to enhance local capabilities and capacities for development will be most urgent, while in other cases increasing ESD more systematically in the formal curriculum will be an important goal. For others, developing an appropriate curriculum in terms of aims and objectives that reflect local interpretations and perspectives as intertwined with global sustainability challenges is a worthwhile agenda. For this latter group, further developing the field of research knowledge on best practices for ESD as teaching and learning can additionally fuel future ESD, as practices must be grounded in particular contexts with an eye to making an impact on change, in order to be effective. As ESD becomes more firmly integrated into curriculum worldwide in the future in relation to countries' professed mutual aspirations, how to better integrate ESD formally at policy and pedagogical levels will remain important questions to ask while our understanding of the heart of sustainable development issues also continues to unfold.

KEY TERMS AND DEFINITIONS

Decade of Education for Sustainable Development: An initiative of the United Nations, led by UNESCO practically, for promoting Education for Sustainable Development around the world in formal and nonformal education from 2005-2015.

Education for Sustainable Development: An umbrella term that captures formal and nonformal education initiatives that aim to provide people with knowledge, skills, attitudes, and/or training for sustainable development.

Education for Sustainable Development 1: A traditional model of Education for Sustainable Development, that prioritizes disseminating and using knowledge from various disciplines in order to enhance sustainable development.

Education for Sustainable Development 2: An alternative orientation to Education for Sustainable Development, that prioritizes skills and attitudes people need to continually gather, analyze and make decisions collaboratively based on values and new information and situations of the unforeseen future.

Environmental Education: Education about learning about place, ecology, and the natural environment. Often has a place-based component and explores local forests, rivers, and other natural features.

Nonformal Education: Education that takes place outside of formal schooling.

Sustainable Development: Economic, political, and/or cultural development that meets the needs of the current generation without risking the needs of future generation.

Chapter 2
Sustainability Evaluation of IT/IS Projects

Gilbert Silvius
LOI University of Applied Sciences, The Netherlands & University of Johannesburg, South Africa

ABSTRACT

Sustainability is without doubt one of the most important challenges of our time. How can one develop prosperity without compromising the life of future generations? Companies are integrating concepts of sustainability in their marketing, corporate communications, annual reports and in their actions. Information technology (IT) and information systems (IS) provide organizations with the ability to change and improve business processes to better support sustainable practices. IT/IS evaluation methods should therefore reflect this ability and include criteria for the assessment of sustainability aspects of IT/IS projects. However, IT/IS evaluation methods are today still dominated by the economical perspective that resulted from the infamous IT productivity paradox. This paper aims to broaden the perspective on IT/IS evaluation, by exploring the integration of indicators that reflect the concepts of sustainability into IT/IS evaluation methods. Based on an identification IT/IS evaluation methods and an overview of frameworks for sustainability indicators, an analysis is made of the inclusion of the indicators and principles of sustainability assessment in IT/IS evaluation methods. The analysis will conclude that integrating sustainability considerations in IT/IS evaluation requires far more than a set of additional criteria to be considered.

INTRODUCTION

Sustainability is recognized by the United Nations as one of the most important challenges of our time (Glenn and Gordon, 1998). How can we develop prosperity without compromising the life of future generations? The pressure on companies to broaden its reporting and accountability from economic performance for shareholders, to sustainability performance for all stakeholders has increased substantially (Visser, 2002). Proactively or reactively, companies are looking for ways to integrate ideas of sustainability in their marketing, corporate communications, annual reports and in their actions (Hedstrom et al., 1998; Holliday, 2001).

The growing concern about sustainability and the preservation of our planet is increasingly being recognized by the information technology (IT) and information systems (IS) disciplines. CIOs identify 'Green IT' as an important strategic technology (Thibodeau 2007), but the 'green' aspects of IT go beyond the technology. Given IT's functional ability to improve, change and reinvent business processes, it can also be an important contributor to more sustainable business practices (Kazlauskas and Hasan, 2009). However, this 'Greening by IT' perspective, is not reflected in IT/IS evaluation methods, as these methods tend to focus predominantly on an economic perspective. Probably fuelled by the much quoted 'IT productivity paradox' (Brynjolfsson, 1993), researchers and practitioners have been challenged to proof that IT/IS brings economic value to the organization. And although many evaluation models have been developed that also include other variables than Return on Investment (Renkema and Berghout, 1996), the debate on the contribution of IS seems to be dominated by the economic perspective (Silvius, 2010).

This paper explores the integration of indicators that reflect the concepts of sustainability into IT/IS evaluation methods. The paper will present a brief overview if IT/IS evaluation methods and an exploration of frameworks for sustainability reporting and evaluation. The paper will then analyze how these two concepts, IT/IS evaluation and sustainability, fit, and make a number of observations on the similarities and differences of the concepts.

IT/IS EVALUATION

Through research and in practice, a substantial number of evaluation methods to assess the contribution of IS/IT to business performance was developed. After considering over 50 evaluation methods Renkema and Berghout (1996) grouped these methods into four categories: Financial methods, Multi-criteria methods, Ratio methods and Portfolio methods.

Financial Methods

The financial methods consider the valuation of an IT/IS investments as an economic issue for which it is irrelevant whether the investment is in IT or in any other resource. As long as the effects of the investment are understood, calculating the value of it is merely a financial technicality (Silvius, 2010). However, in reality capturing value is not quite that straightforward. Financial valuation methods all have assumptions and limitations. Table 1 provides an overview of these valuation methods.

The limitations of these financial methods to capture the more qualitative aspects of IT/IS value and impact led to the development of other methods.

Multi-Criteria Methods

Multi-criteria methods are a reaction to the problems of capturing the full value of IT/IS investments in just financial metrics. These methods aim to identify different relevant aspects of value and risk in order to enable a thorough discussion and an informed discussion (Frisk, 2007). The most influential method using multiple criteria is Information Economics (Parker et al., 1988). This method is suited for evaluating a single project as well as a portfolio of projects.

Table 1. Overview of Financial valuation methods (based on Silvius, 2010)

Valuation Method	Qualities	Limitations
Return on investment	Easy to calculate Easy to interpret (a simple percentage) In line with the financial administration	Outcome sensitive to amortization method Ignores the time-value of money Ignores risk
Pay-back period	Quite easy Intuitively coping with risk	Ignores part of the revenues Simplistic, does not determine value
Internal Rate of Return	Includes the time-value of money Easy to interpret (a simple percentage) Based on cash-flows	Complex Not in line with the financial administration Ignores risk Multiple outcomes, or none, possible
Discounted Cash Flow / Net Present Value	Includes the time-value of money Based on cash-flows Copes with risk	Complex Complex to interpret Not in line with the financial administration Not conclusive in case of projects with different durations
Economic Value Added	Includes the opportunity value of money In line with 'shareholder value'	Value calculation based upon one of the other methods Not in line with the financial administration
Real Options Valuation	Includes optimality and managerial flexibility in investments	Complex Complex to interpret Data often not available Not in line with the financial administration
Game theory	Includes market developments Adds a strategic perspective	Data often not available Not in line with the financial administration

Information Economics identifies assessment criteria in two domains: business (IT/IS demand) and IT (IT/IS supply). Criteria in the business domain are: Return in Investment, Strategic Match, Competitive Advantage, Management Information, Competitive Response and Organizational Risk. Criteria in the IT domain are: Strategic Information Systems Architecture, Definitional Uncertainty, Technical Uncertainty and Infrastructure Risk. The importance or 'weight' of the different criteria may not be equal. Management therefore has to decide upon a weight factor for each criterion.

Based upon the set of criteria and weight factors each project or investment is given a score on all of the criteria. It is crucially important that the scores are underpinned in this more objective way in order to create acceptation for the results of the evaluation process.

The results of the evaluation process can be presented in a graphically attractive way. The scores on the criteria Return in Investment, Strategic Match, Competitive Advantage, Management Information, Competitive Response and Strategic Information Systems Architecture, are totaled to a score representing the 'value' of the investment. The scores on the criteria Organizational Risk, Definitional Uncertainty, Technical Uncertainty and Infrastructure Risk, add up to a total 'risk' score. Combining the two scores in a two-dimensional graph provides management with a concise overview of the investment portfolio.

An important quality of multi-criteria methods is that they allow for the evaluation of value and risks that are hard to quantify in monetary terms, such as Strategic Match, Competitive Advantage, Management Information, Competitive Response, Organizational Risk, etc. A critique on the methods is that they lack objective measurement of these criteria in the projects that are evaluated.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Ratio Methods

Different from the financial and multi-criteria methods are ratio methods not aimed at evaluating a specific investment or project, but at finding the 'right' level of total IT/IS costs in an organization. This level is expressed as a ratio, e.g. IT costs / total revenue or IT costs / employee. The outcome of these ratios should be considered relative to the same ratios at competitors or for one organization in time. Lower or higher scores on these ratios than comparable organizations are not per-se right or wrong, but should give reason for investigation and discussion.

The most prominent author on ratio methods is Paul Strassmann. He developed sophisticated ratios for specific industries. Based on his research he remains sceptical about the value of IT investments. Strassmann states that "For 55% of U.S. firms the computer budget exceeds their economic value-added." and "The "right" level of spending for computers reflects the bureaucratic characteristics of a firm, not revenue or profits." (Strassmann, 1997). A limitation to the applicability of the ratio methods, however, is the availability of data required for the ratios.

Portfolio Methods

In 1981 F. Warren McFarlan suggested to analyze and manage IT/IS investments and projects in terms of revenues and risks using portfolio theory, as was done in the financial world (Warren McFarlan, 1981). 'Portfolio theory' referred to the 'modern portfolio theory' as developed by Markowitz (Markowitz, 1952). Although appealing, the use of this insight did not really take off until the Clinger-Cohen Act. This Act states that the management of IT in US government institutions 'must reflect a Portfolio Management approach … and decisions to terminate or make additional investments are based on performance much like an investment broker is measured and rewarded based on managing risk and achieving results'.

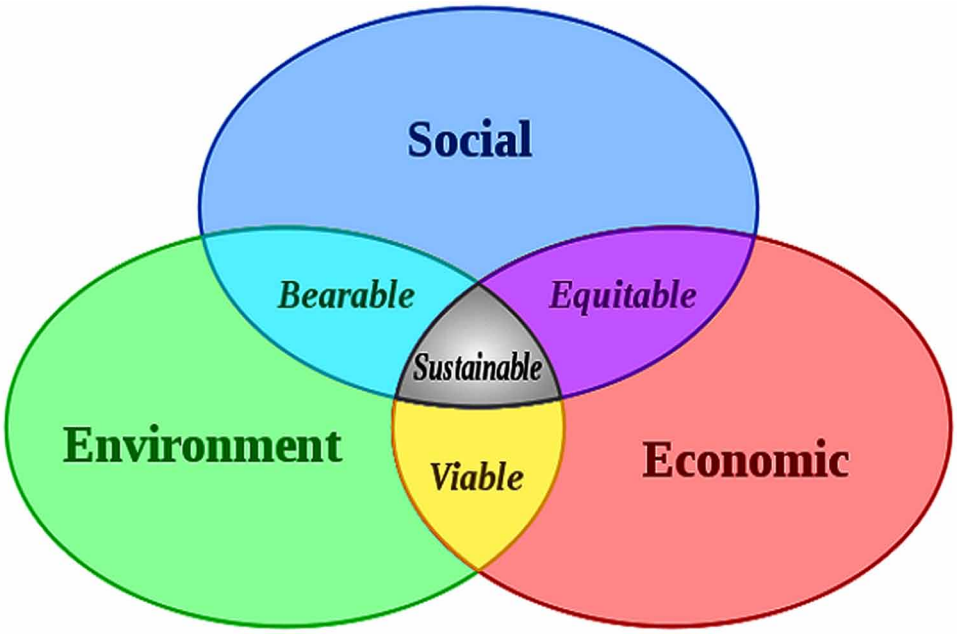
With its appeal on portfolio theory, the Clinger-Cohen Act aimed to bring transparency to IT/IS costs and benefits. When applying portfolio theory to IT projects however, some issues may occur regarding the scalability of the investments, the tradability of the investments, the unique character of some investments, the exchangeability of benefits, the unfamiliarity of project risks, etc. Although the difference in characteristics between financial investments and IT investments does imply limitations to the applicability of portfolio theory, some useful insights could be derived (Van Rossum and Silvius, 2006).

An important insight in portfolio theory is the understanding that the value of an investment will be influenced by other investments or assets in the portfolio. In other words, investment decisions are not taken in isolation. Whereas all other evaluation methods study the value of an investment as an autonomous value, portfolio methods study value of investments in conjunction to other investments and assets. An insight that appeals to the common sense when considering architectural aspects. Portfolio theory also points out the importance of having a structured process in place for the continuous evaluation of the total portfolio of IT/IS investments and projects.

THE ROLE OF IT/IS IN SUSTAINABILITY

Societal concerns about the balance between economic growth and social wellbeing has been around as a political and managerial challenge for over 150 years (Dyllick and Hockerts, 2002). Propelled by the World Commission on Environment and Development (1987) and the 1992 Rio Earth Summit, the

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use



opinion that none of these three goals, economic growth, social wellbeing and a wise use of natural resources, can be reached, without considering and effecting the other two, got widely accepted (Keating, 1993). With this widespread acceptance, sustainable development became one of the most important challenges of our time.

Sustainability in the context of sustainable development is defined by the World Commission on Environment and Development (1987) as "forms of progress that meet the needs of the present without compromising the ability of future generations to meet their needs". This broad definition emphasizes the aspect of future orientation as a basic element of sustainability. This care for the future implies a wise use of natural resources and other aspects regarding the environmental footprint. However, sustainability requires not just an environmental "green" perspective, but also a social one. Elkington (1997), recognizes this in his 'triple bottom line' or 'Triple-P (People, Planet, Profit)' concept (Figure 1): Sustainability is about the balance or harmony between economic sustainability, social sustainability and environmental sustainability (Elkington, 1997).

In the debate on sustainability and IT/IS, a commonly used term is 'Green IT'. As was stated in the introduction, however, a distinction can be made between 'Green IT' and 'Greening by IT', more commonly referred to as 'Green IS' (Kazlauskas and Hasan, 2009; Watson et al., 2010). In this distinction, Green IT refers to the energy efficient utilization of IT equipment and Green IS to the use of IS to enable more sustainable business processes (Boudreau et al., 2008).

The environmental impact of IT/IS has been subject to discussion. The promise of a decreased environmental footprint because of paperless offices and tele-working has been opposed by claims of increased power consumption and hazardous waste because of the use of IT needed to operate the systems. Because of this diversity of direct and indirect indicators, the overall effect of IS/IT on environmental sustainability is not easy to determine. Plepys (2002) concludes "The discussion on what the role is of IT and,

Figure 1. The Triple-P concept of sustainability

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

particularly, Internet for sustainability is still going on and will hardly reach any definite conclusion, as the environmental impacts of the new technologies will depend on how they are used".

The concepts of sustainability mentioned above suggest that in the debate on the sustainability aspects of IS/IT, not just the environmental effects should be considered, but also the social effects of IS use. The United Nations (UN) concluded that IS has the ability to be a powerful enabler of social sustainability and contributor to development goals, because of its unique characteristics to dramatically improve communication and the exchange of information to strengthen and create new economic and social networks (United Nations Development Program, 2001).

In some parts of the world, IT/IS is contributing to revolutionary changes in business and everyday life. In other parts of the world, the lives of people have hardly been touched by these innovations. If people in developing countries are unable to acquire the capabilities for using IS, they will be increasingly disadvantaged or excluded from participating in the global information society. The social and economic potential of these new technologies for development is enormous, but so too are the risks of exclusion (Mansell, 1999). Economic research suggests a positive correlation between the spread of IS and economic growth (Siegel, 2003). IS can contribute to income generation and poverty reduction. It enables people and enterprises to capture economic opportunities by increasing process efficiency, promoting participation in expanded economic networks, and creating opportunities for employment.

SUSTAINABILITY INDICATORS

Crucial for developing more sustainable business practices is the ability to evaluate the sustainability aspects of different policies and projects, as well as to monitor progress. Or, as Jain (2005) argues: "The ability to analyze different alternatives or to assess progress towards sustainability will then depend on establishing measurable entities or metrics used for sustainability". The most frequently used instruments in this context are frameworks or sets of sustainable development indicators (SDIs), both as a way of measuring and evaluating (proposed) actions, and as a way of communicating this information (Bell and Morse, 2003).

Many organizations have developed frameworks of indicators for this goal. In fact, the literature on these models is a veritable jungle of different approaches and numerous case studies (Olsson et al, 2004). The International Institute for Sustainable Development (IISD) maintains an online directory of SDI initiatives. This directory includes more than 600 initiatives at national and international levels by governments, non-governmental organizations (NGOs) and individuals. It can therefore be concluded that the use of SDI as an evaluative tool is still very much in its infancy (MacGillivray, 1995, Bell and Morse, 2003) resulting in more questions than answers. What should be measured and what could be excluded? What are the most effective indicators? How should they be organised? And how can the indicators be communicated?

The following section gives an overview of some of the most influential frameworks for SDIs.

Natural Step Framework

One of the first initiatives to bring scientific principles to the assessment of sustainability was by Swedish scientist Karl-Henrik Robèrt. Robèrt coordinated a consensus process to define and operationalize sustainability. At the core of the process lies a consensus on what is called 'the Natural Step framework'.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

The Natural Step Framework is a holistic framework which helps organizations to integrate sustainability principles into their business strategies. It provides a tool for developing a shared vision, shared identity and shared goals among departments and along supply chains. Foundation of the Natural Step Framework is the principle that a company should try to reduce its negative impacts on the biosphere while enabling humans to fulfil their needs. It stimulates companies to re-think production processes and product design and to find innovative alternatives for achieving their business goals. The framework provides a good basis for both awareness raising as well as strategy development.

IISD Dashboard of Sustainability

The IISD is a Canadian-based, public policy research institute, dedicated to advancing sustainable development. The IISD developed a sustainability 'dashboard' that "illustrates the complex relationships among economic, social and environmental issues" (International Institute for Sustainable Development, 2012). This Dashboard of Sustainability is intended for decision-makers and others interested in sustainable development. It is based on the Millennium Development Goals indicators for developing countries. These indicators help define Poverty Reduction Strategies and monitor the achievement of the Millennium Development Goals.

WBCSD Measuring Impact Framework

The World Business Council for Sustainable Development (WBCSD) is an organization of companies that joined forces in order to create a sustainable future for business, society and the environment. The WBCSD argues that "sustainable development is good for business and business is good for sustainable development". This view is supported by some economists that state that, contrary to the popular belief that sustainability requires a trade-off of economical and environmental/social benefits, it is possible for the concepts of sustainable development and competitiveness to merge if enacted wisely (Esty and Porter, 1998).

The WBCSD developed a framework, the Measuring Impact Framework, to assess the contribution of business to the economic and broader development goals in the societies where business operates. It is designed to help companies understand their contribution to society and use this understanding to inform their operational and long-term investment decisions, and have better-informed conversations with stakeholders.

The Measuring Impact Framework includes a 4-step methodology to help companies in any industry operating in any part of the world to measure, assess and manage their impacts on society. In the application of the methodology, an organization should adapt it to the specific company strategy and development context in which the business operates;

UN Global Compact Framework

The United Nations (UN) Global Compact (2010) is a framework of ten universally accepted principles, developed by the UN and a number of large corporations. It covers the areas of human rights, labour, environment and anti-corruption. Participating companies agree to comply with these principles. They can use the framework as a platform for disclosure. This initiative has been created because the UN realized that businesses are primary drivers for globalization and can help ensure long-term value creation

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

that can bring benefit to economies and societies all over the globe. In the absence of global regulations, this voluntary code of conduct has been developed, hoping to stimulate companies to more sustainable business practices.

UNCSD Indicators of Sustainable Development

Following the 1992 Rio Earth Summit, the UN Commission on Sustainable Development (UNCSD) started the development of the 'Indicators of Sustainable Development'. This resulted in a set of 134 indicators of sustainable development. Country case studies and further discussion in the UNCSD led to the rejection of a framework in lieu of "themes" and a more comprehensive set of 'core' indicators.

The third, revised set of the UNCSD indicators was finalized in 2006 by a group of experts from developing and developed countries and international organizations. This third edition of the indicator set is based on the previous two (1996 and 2001) editions, which have been developed, improved and extensively tested. It contains 96 indicators, including a subset of 50 core indicators. The guidelines on indicators and their detailed methodology sheets are available as a reference for all countries to develop national indicators of sustainable development.

ISO 26000 Core Subjects and Issues

As a response to businesses' growing interest and the increasing number of sustainability-related institutions and frameworks, the International Organization for Standardization (ISO) launched ISO 26000, a comprehensive guideline on social responsibility, to help companies introduce more sustainable practices. ISO 26000 is a guideline on social responsibility that is designed for all types of organizations. ISO 26000 summarizes seven social responsibility 'core subjects': Organizational governance, Human rights, Labour practices, The environment, Fair operating practices, Consumer issues and Community involvement and development. These core subjects are further broken down into 'issues', specific themes or activities a company should work on in order to contribute to sustainable development.

GRI Sustainability Reporting Guidelines

The Global Reporting Initiative (GRI) is a non-profit organization that pioneered the world's most widely used sustainability reporting framework, the Sustainability Reporting Guidelines (SRG). Companies can use the SRG to indicate to shareholders and consumers their economic, social and environmental performance. GRI's objective is to facilitate sustainability reporting for companies and thereby stimulate them to operate more sustainably. The SRG framework consists of an extensive set of indicators, from which companies can select a set that is relevant to their operations or industry.

Dow Jones Sustainability Indexes

The Dow Jones Sustainability Indexes (DJSI) are not a reporting tool, but a family of indexes evaluating the sustainability performance of the largest 2,500 companies listed on the Dow Jones. They are the longest-running global sustainability benchmarks worldwide. The DJSI is based on an analysis of cor-

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

porate economic, environmental and social performance, assessing issues such as corporate governance, risk management, branding, climate change mitigation, supply chain standards and labor practices. It includes general as well as industry specific sustainability criteria.

From the above overviews of SDI frameworks, it should be concluded that, although many organizations have offered meaningful lists of indicators, consensus on how to measure and assess sustainability has not emerged yet. A recurring structure in many frameworks is the Triple-P concept mentioned in section 3. However, some frameworks, for example ISO 26000, adopt a completely different structure and also different perspectives. Many specialists actually question whether or not a common list is even possible, given the wide variety of conditions and the differences in values in different contexts.

In the so called Bellagio principles, a set of overarching principles for the assessment of sustainability are formulated, thereby suggesting that a truly 'universal' framework to measure sustainability may be illusive. The Bellagio principles are (International Institute for Sustainable Development, 1997):

Principle 1: Guiding Vision and Goals

Assessment of progress toward sustainable development should:

- Be guided by a clear vision of sustainable development and goals that define that vision.

Principle 2: Holistic Perspective

Assessment of progress toward sustainable development should:

- Include review of the whole system as well as its parts.
- Consider the well-being of social, ecological, and economic sub-systems, their state as well as the direction and rate of change of that state, of their component parts, and the interaction between parts.
- Consider both positive and negative consequences of human activity, in a way that reflects the costs and benefits for human and ecological systems, in monetary and non-monetary terms.

Principle 3: Essential Elements

Assessment of progress toward sustainable development should:

- Consider equity and disparity within the current population and between present and future generations, dealing with such concerns as resource use, over-consumption and poverty, human rights, and access to services, as appropriate.
- Consider the ecological conditions on which life depends.
- Consider economic development and other, non-market activities that contribute to human/social well-being.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Principle 4: Adequate Scope

Assessment of progress toward sustainable development should:

- Adopt a time horizon long enough to capture both human and ecosystem time scales thus responding to needs of future generations as well as those current to short term decision-making.
- Define the space of study large enough to include not only local but also long distance impacts on people and ecosystems.
- Build on historic and current conditions to anticipate future conditions.

Principle 5: Practical Focus

Assessment of progress toward sustainable development should be based on:

- An explicit set of categories or an organizing framework that links vision and goals to indicators and assessment criteria.
- A limited number of key issues for analysis.
- A limited number of indicators or indicator combinations to provide a clearer signal of progress.
- Standardizing measurement wherever possible to permit comparison.
- Comparing indicator values to targets, reference values, ranges, thresholds, or direction of trends, as appropriate.

Principle 6: Openness

Assessment of progress toward sustainable development should:

- Make the methods and data that are used accessible to all.
- Make explicit all judgments, assumptions, and uncertainties in data and interpretations.

Principle 7: Effective Communication

Assessment of progress toward sustainable development should:

- Be designed to address the needs of the audience and set of users.
- Draw from indicators and other tools that are stimulating and serve to engage decision-makers.
- Aim, from the outset, for simplicity in structure and use of clear and plain language.

Principle 8: Broad Participation

Assessment of progress toward sustainable development should:

- Obtain broad representation of key grass-roots, professional, technical and social groups, including youth, women, and indigenous people - to ensure recognition of diverse and changing values.
- Ensure the participation of decision-makers to secure a firm link to adopted policies and resulting action.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Principle 9: Ongoing Assessment

Assessment of progress toward sustainable development should:

- Develop a capacity for repeated measurement to determine trends.
- Be iterative, adaptive, and responsive to change and uncertainty because systems are complex and change frequently.
- Adjust goals, frameworks, and indicators as new insights are gained.
- Promote development of collective learning and feedback to decision-making.

Principle 10: Institutional Capacity

Continuity of assessing progress toward sustainable development should be assured by:

- Clearly assigning responsibility and providing ongoing support in the decision-making process.
- Providing institutional capacity for data collection, maintenance, and documentation.
- Supporting development of local assessment capacity.

These principles provide guidance in the analysis of the impact of integrating sustainability indicators in IT/IS evaluation, as reported in the next section.

ANALYSIS

When confronting the methods of IT/IS evaluation identified in section 2 with the overarching Bellagio principles derived from frameworks of sustainability indicators, a number of observations can be made.

Integrating Sustainability Indicators Suggests a Multi-Criteria Approach

The principles Holistic Perspective and Essential Elements, prescribe for sustainability evaluation the use of more perspectives than just the economic perspective. Most frameworks of sustainability indicators adopt the triple-P concept and some frameworks take an even more holistic view. This suggests that by definition an IT/IS evaluation approach based solely on the economic perspective is inadequate for capturing the sustainability aspects of IT/IS.

From the four groups of methods identified by Renkema and Berghout (1996), the multi-criteria group of methods seems most appropriate to include the multiple perspectives that the concepts of sustainability imply.

Inclusion of Sustainability Indicators Makes Good Sense

Multi-criteria methods for IT/IS evaluation, like Information Economics, typically include an indicator for the contribution of IT/IS to the strategy of the organization. IT/IS evaluation therefore links to strategy (Silvius, 2010). And as more and more companies are integrating statements about sustainability in their strategy (Hedstrom et al., 1998; Holliday, 2001), inclusion of sustainability indicators in IT/IS

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

evaluation makes sense. In the Bellagio perspectives this link is captured in the principle Guiding Vision and Goals, that prescribes that assessment of sustainability aspects should be guided by a clear vision of sustainable development and goals that define that vision.

A Universal Model for Evaluating (Sustainable) IT/IS is Illusive

The recognition in the Bellagio principles that a sensible and meaningful set of sustainability indicators is context specific, and that consensus should be sought on the level of principles rather than specific indicators, suggests that a 'one size fits all' approach to IT/IS evaluation may not be viable. This is also recognized by principle Practical Focus that stated that standardizing of measurement should be sought wherever possible, thereby suggesting that this is not always possible. For organizations this would imply that working with a universal 'business case' model, which most organizations do in order to be able to compare IT/IS investments and projects, actually does not lead to optimal decision making.

Including Sustainability Assessment Expands Scope

The logical 'unit of analysis' of IT/IS evaluation is the organization that uses the technology or systems or invests in them. This scope is based on economical reasoning and the concept of ownership. IT/IS should bring benefits to the economical unit that invests in, pays for or owns the technology or systems being assessed. In sustainability assessments, however, the sphere of influence is not limited to economical units or ownership. This is covered in the Bellagio principles Holistic Perspective and Adequate Scope. The principle Holistic Perspective mentions that assessment of sustainability should include a review of the whole system as well as its parts. The principle Adequate Scope prescribes that assessment of sustainability aspects should define the space of study large enough to include not only local but also long distance impacts on people and ecosystems.

Including Sustainability Assessment Implies Equality of Time

The economic perspective, that is so dominant in all IT/IS evaluation methods, values short term effects more than long term effects. This principle is most visible in the discounting of future cash flows. In economic theory an immediately cash flow holds more value than a future cash flow, thereby emphasizing the value of short-term benefits. However, social impacts or environmental degradation because of business decisions, may not occur before the long-term. Also this aspect is mentioned in the principle Adequate Scope, that states that assessing sustainability should adopt a time horizon long enough to capture both human and ecosystem time scales thus responding to needs of future generations as well as those current to short term decision-making.

Sustainability Assessment Implies Continuous Assessment and Institutional Capacity

The Bellagio principles Ongoing Assessment and Institutional Capacity prescribe an institutionalized, repetitive and iterative process to assess sustainability aspects. In IT/IS evaluation, this aspect is covered in some of the IT/IS evaluation methods, most explicitly in the concept of portfolio management. Portfolio management suggests a continuous process of monitoring, measuring, evaluating and selecting

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

investments or assets. In fact, also project management methodologies like Prince2 include a continuous re-assessment of the business case of the project. Assessing sustainability, however, goes even further than this and suggests that the technology or system at hand is also continuously assessed during its exploitation. This could be compared with the 'business case management' in the post-implementation phase of a project.

Sustainability Assessment Implies Openness and Broad Participation

The Bellagio principles Openness, Effective Communication and Broad Participation prescribe how stakeholders are informed and engaged in the assessment of sustainability aspects. These principles touch upon the way assessments are performed. And although these aspects are not explicitly covered in the IT/IS evaluation methods, the graphical representations that are included in the Information economics methodology do facilitate participation of and communication with key stakeholders and decision makers. It is, however, debatable whether these formats and techniques are an adequate operationalization of the principle Openness.

CONCLUSION

Sustainability is one of the most important challenges of our time. How can we develop prosperity, without compromising our wellbeing or that of future generations? More and more companies recognize this and take responsibility for their role in this challenge. IT/IS can make a contribution to the sustainable development of organizations. It therefore makes sense to include an assessment of sustainability aspects in the evaluation of IT/IS. And although some considerations of sustainability can be found in the various methods of IT/IS evaluation, it has to be concluded that the integration of sustainability indicators in IT/IS evaluation is just in its infancy.

In a contribution to the understanding of sustainability considerations in IT/IS evaluation, this paper confronted the principles of sustainability assessment with the different methods of IT/IS evaluation. This analysis did not result in a set of additional criteria to be considered, but in a set of observations that form a foundation to reconsider IT/IS evaluation methods. These observations are:

- Integrating sustainability indicators suggests a multi-criteria approach.
- Inclusion of sustainability indicators make good sense.
- A universal model for evaluating (sustainable) IT/IS is illusive.
- Including sustainability assessment expands scope.
- Including sustainability assessment implies equality of time.
- Sustainability assessment implies continuous assessment and institutional capacity.
- Sustainability assessment implies openness and broad participation.

The implications of these observations may be far fetching, as their impact suggests a far more holistic and elaborated perspective on IT/IS evaluation than the infamous IT productivity paradox. The operationalization of this holistic and elaborated evaluation perspective, however, is still subject to further research.

Chapter 3
Economic Growth, Sustainable Development, and the Role of Markets

Nilanjan Ghosh
Multi Commodity Exchange of India Limited, India

Anandajit Goswami
The Energy and Resources Institute, India

ABSTRACT

This chapter tracks the long path that Development Theory has traversed over the last century. Its origin traces back to the notions of economic growth and development and eventually reached a stage where governments and academics are more concerned with more holistic notions of development than merely growth. Sustainable development has become the most important notion of the day and provides a more comprehensive definition of development, linking ecological services and quality of life with economic growth. Such a paradigm shift in less than a century is no less than a revolution. Expectedly, this shift has been marked by cognitive dissonance, bitter debates, and scholastic antagonism. This chapter traces the story of how the road has been traversed and the shift achieved. It highlights the various theories of economic growth and development and focuses on the debates among economists that have helped the discipline traverse this long way. Finally, this chapter talks of markets. While it has often been understood that markets can promote economic growth, this chapter further emphasizes how markets, under enabling conditions, might be the right catalysts to promote sustainable development.

THE DAYS OF CLASSICAL POLITICAL ECONOMY…

With political economy evolving out of the writings of Adam Smith and David Ricardo, the scope of economics as a discipline got defined in the confinements to find and explain the "nature and causes" of economic development. The scenario is neither so simple nor so comfortable for modern economists; it has always been considered a maverick field; lurking somewhere in the background but not really thought of as "real economics"—rather an amalgam of sociology, anthropology, history, politics, and all-too-often, ideology.

Though it has often been claimed that economic development as a branch of economic science emerged only in the '50s, there is no doubt that the notion of development existed even in the classical economic thought processes. The recognition of development economics as a discipline over the past 50 years earmarked the changes in our understanding of development. The wealth of experiments so far has revealed that there are clearly no sure-fire formulas for success; if there were, there would have been many more success than what there are today. Economic theory has, in fact, evolved to account for both successes and failures.

Nonetheless, few of the greatest economists actually ignored it outright. The Classical School, starting with Adam Smith, was concerned with "economic development." However, their notion of economic development was quite different from what is defined as development today by development theorists. This difference gets reinforced in Smith's *Wealth of Nations*, and Ricardo's *Principles of Taxation*, and goes on *till* Schumpeter's classic *Theory of Economic Development* (1911). The German Historical School—and its English and American counterparts—could very well be deemed as part of development economics. It was thoroughly geared towards the theory of economic growth.

However, the primary focus of economic research remained confined to developed nations till the 1930s. It was Colin Clark's quantitative study in 1939 that made economists realize that most of humankind did not live in an advanced capitalist economic system. Yet, the early concern was still Europe; namely, post-war European reconstruction and the industrialization of its eastern fringes as exemplified by the pioneering article of Paul Rosenstein-Rodan in 1943 and Kurt Mandelbaum's book in 1947. It was only some time after the war that economists really began to show their concerns for Asia, Africa, and Latin America.

To this end, decolonization was an important catalyst. Faced with a plethora of new nations whose standards of living and institutions were so different from the European way of life, modern development theory—by which we mean the analysis of not only growth but also of institutions that could induce, sustain, and accelerate growth—began in earnest to change its focus and rearrange its referential. After the Second World War, academes began to think of ways and means of effectively dealing with poverty and destitution that heavily weighed upon two-thirds of the human race (Pakdaman 1994).

The post-war formation of the United Nations and its attendant agencies, such as the World Bank, the IMF, the ILO, and various regional commissions, provided an impetus to the shift in focus and perceptions. The commissioning of numerous studies by these institutions led to the emergence of a non-academic strand of development theory.

POST-WAR PERIOD: STAGE THEORY OF GROWTH AND CAPITAL FORMATION

Post-war development was primarily looked at from the viewpoint of growth and capital formation. Even before that, developing nations looked at development primarily as a process of industrialization. This resulted in the concept of a Third World consisting of Latin American, Asian, and African countries, which were to be mostly viewed as "underdeveloped" countries. It was believed that they were in the early stages of development; and with time, they would be able to transcend the various stages. This was contingent upon the way the in which capital was being formed, industrialization was taking place, and GDP growth occurred.

This thought culminated in the "stage" theory of development, made famous by Gerschenkron (1962) and Rostow (1960). The stage theory assumes certain "linearity" in the development patterns of

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

economies, and argues that "underdevelopment" in some of the economies will be converted to "development" over time. A few Asian, African, and Latin American countries lagged behind the developed nations as for time. Interestingly, to view development, capital formation, and technological change as linear functions of time is an assumption that is reductionist, and which does not incorporate social and political variables that might result in differential and varying growth trajectories.

However, the role of capital formation as a crucial component that accelerates development was not only recognized by Gerschenkron and Rostow, but also by Nurkse (1953) and Lewis (1955). Early Keynesians, such as Kaldor and Robinson, attempted to call attention to income distribution as a determinant of savings and growth. Even modern Marxists like Maurice Dobb (1951and 1960) focused on the formation of savings. And even orthodox Marxists have had no conflict on this issue. Lewis and even Keynesians have argued that savings can be manipulated through government intervention (Singer 1950, Myrdal (1957)]. Thus, government involvement—whether by planning, socio-economic engineering, or effective demand management—was regarded as a critical tool of economic development.

POST-WAR MARXIST THINKING

A number of emigrant economists in Britain, influenced by their personal experience of late industrialization in Central and Eastern Europe, developed plans for the post-war transformation of underdeveloped regions. The contributions of Michael Kalecki, Kurt Mandelbaum, Joseph Steindl of Oxford University, and Paul Rosenstein-Rodan of the Royal Institute of International Affairs laid the basis of development economics as a formal sub-discipline. These Central European economists were more familiar with Marx than with Keynes, and the success of the Soviet five-year plans played a significant role in their approaches to developmental planning. It is well known that Kalecki's (1955 and 1956) model of an economy with under-utilized resources of labour and capital was similar to Keynes', but presented in Marxist rather than the more familiar Anglo-Saxon analytical categories. In fact, Kalecki's contribution to planning for economic development deserves to be widely acknowledged.

Newly formed economies like India also followed the planning processes, as was done by the USSR, and their growth models were based on the Soviet experience. It was generally accepted that the state must play a central role in economic transformation because the private sector was either dominated by landed and commercial oligarchies with vested interest in the status quo or was simply too weak and disorganized. The degree of state involvement in the economy varied across countries, but basic public infrastructure and its financing was universally undertaken by the state, which was accompanied by some form of long-term economic planning. In the first three post-war decades, countries were able to privilege domestic agriculture and industry by discretionary access to credit and foreign exchange, subsidies, and a variety of protective commercial policies. The principal of sovereignty regarding natural resources, and more generally the sovereign right of nations to formulate fiscal, monetary, commercial and all other aspects of government policy, was not questioned, although in practice it was often violated.

This was the time (first three post-war decades) when the new orthodoxy emerged around the notion of balanced growth with the works of Lewis and Nurkse. However, it never took much time for an antithesis to emerge in the notions of "unbalanced growth" with the works of Hirschman (1963, 1981) and Streeten (1959). They are of the view that balanced growth is not possible as the theory assumes that a modern sector should be superimposed on an old and traditional one. In the process, the "balanced

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

growth" theory loses its focus from the processes of change, which, in fact, should have been the real focus of development theory.

NEOCLASSICAL GROWTH THEORY

Neoclassical development theorists have emphasized the important role that international trade plays as a substitute for low domestic aggregate demand. They argue that governments should act as facilitators to promote international trade between economies. In the process of positioning the economy on an autonomous, sustained-growth path, the government has to remove barriers to international trade in commodities. Comparative advantage, combined with the Hecksher-Ohlin theorem, can then take care of the rest. Subsequent amendments to this position require the removal of price distortions in domestic factor and commodity markets ("getting prices right"); this is in addition to the list of government actions that is required to induce suitable movements of factors among sectors, encourage the adoption of appropriate technology, and increase capital accumulation. In this view, domestic and international liberalization programmes suffice to bring about sustained economic growth and structural change.

Many economies have revealed considerable faith in this framework and have relied extensively on export-oriented growth. This has been the main characteristic of Southeast Asian economies and present-day China. To a certain extent, even developing economies like India and Brazil have also subscribed to this thought process. Interestingly, export facilitation in many of the Southeast Asian economies resulted in pegged exchange rate regimes and free international mobility of capital. Although phenomenal economic growth has been achieved, yet there have often been problems of capital flight caused by the lowering of interest rates as currencies were devalued to promote exports. Hence, in developing economies like India, which proposes to go for full capital account convertibility in recent years, words of cautions have always been forwarded to "go slow" on this front—whether it is right or wrong remains the concern of a broader debate.

FROM ECONOMIC GROWTH TO ECONOMIC DEVELOPMENT

Capital formation remained an important component of growth for centuries, and even today, its importance remains undiminished. However, over time, its connotation has changed. T.W. Schultz (1963 and 1971), and was the first to recognize the need for "human capital" formation, as an important appendage to physical capital formation. This led to an emphasis on education and training as pre-requisites of growth and the identification of the problem of "brain drain" from the Third World to the First.

Lewis (1965) and Singer (1965) also subscribed to Schultz's thesis. Their argument was focused toward social development as a whole, which could be brought about by education, health, fertility, etc. Improvement in human capital thus began to be considered as a necessary pre-requisite for economic growth. In this view, industrialization, if it came at the cost of social development, could never be self-sustaining.

According to Singer (1965), "…Development is growth plus change," and "…change is not only economic but also social and cultural" (Singer 1965: 5). He pointed out that growth had not resolved the problem of poverty, and suggested "poverty-biased" policies to affect the lives of the poorest. Till this time, all arguments, even those in favour of development, were growth-centric.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

The growth-obsession of development theory received a huge jolt when Seers (1969) published a seminal essay where development was construed as a social phenomenon rather than merely being defined in the reductionist mode of per capita income growth. Development, in Seers' opinion, involved the movement toward the social goals of poverty reduction, employment, and equality.

Myrdal (1968) also supported Seers' views. In his presidential address at the 11th Conference of Society for International Development at New Delhi, Seers (1969) presented a more succinct statement of development with distinction: "…It is very slipshod for us to confuse development with economic development, and economic development with economic growth" Seers (1969:2). Haq (1971: 6) was galvanized by Seers' call to redefine economic development, when he stated, "…We were taught to take care of our GNP as this…[would] take care of poverty. Let us reverse this and take care of poverty as this will take care of GNP".

Thus, structural issues, such as dualism, population growth, inequality, urbanization, agricultural transformation, education, health, and unemployment, began to be reviewed on their own merits, and not merely as appendages to an underlying growth thesis. Eventually, there was an emerging debate on the very desirability of growth, which was led by the extremely provocative publication by Schumacher (1973) where he argued against the desirability of industrialization and inscribed the merits of handicrafts economies.

The social positions of development became even more prominent with the adoption of Human Development Index (HDI) as a somewhat rough measure of development by academics and multilaterals in the 1990s. The HDI measures life expectancy, literacy, education, and standard of living for countries worldwide. This provides an indicative measure of the impact of economic policies on the quality of life. The index was developed in 1990 by Amartya Sen, and Mahbub ul Haq with help from Gustav Ranis of Yale University and Meghnad Desai of the London School of Economics. Ever since its development, the United Nations Development Programme uses it as a standard measure for categorizing development of a nation in its annual *Human Development Report*. Though a "vulgar measure", as described by Sen because of its limitations, it nonetheless brings forth the broader aspects of development than the per capita income measure it supplanted, and provides a pathway for researchers to delve into the wide variety of detailed measures contained in the Human Development Reports. Even other multilaterals like the World Bank have started focusing their attention on social attributes like poverty. As a result, whether in policy making or in academic research, social variables began to be factored in and became an integral part of development economics.

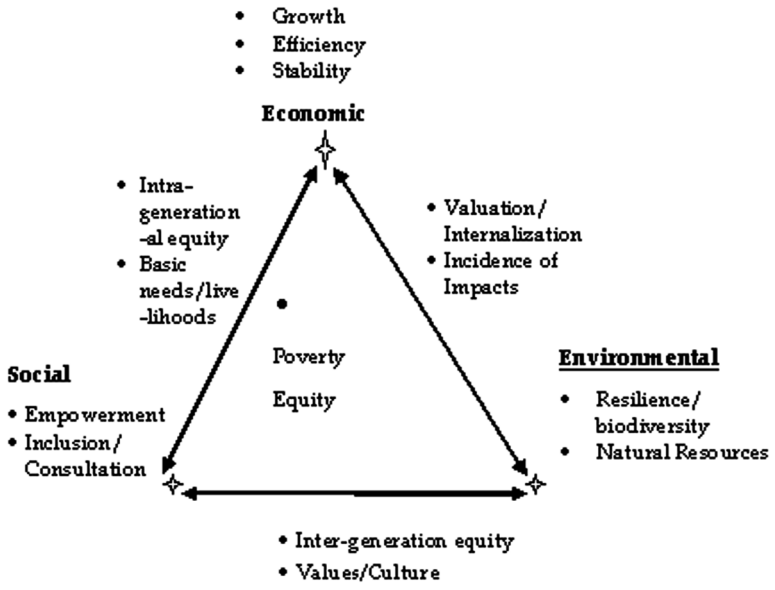
Yet, the debate between growth and development continued and took a new twist in the late 1980s and became more prominent in the 1990s when the very sustainability of economic development was being questioned by environmentalists because of grave concerns about the growing environmental crisis. Environmental pollution was seen as an externality of "mindless" developmental policies. The question that loomed large was: Growth? At what cost?

SUSTAINABLE DEVELOPMENT

Around three and a half decades ago, a group of academics known as the Club of Rome put forth the "limits to growth" theory, predicting disaster for humankind unless natural resource–depleting economic and technological progress were abandoned. Such pessimistic calls were, indeed, extreme in nature. However, the global recognition of the linkage between environment and development came as late as

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

1980 when the International Union for the Conservation of Nature (IUCN) published the *World Conservation Strategy* and used the term "sustainable development."



The concept came into general use following the publication of the 1987 report of the Brundtland Commission—formally the World Commission on Environment and Development (WCED). Set up by the United Nations General Assembly, the Brundtland Commission coined what was to become the oft-quoted definition of sustainable development: Development that "meets the needs of the present generation without compromising the ability of future generations to meet their own needs" [WCED (1987)]. This definition, despite being lauded as the first formal attempt to delineate sustainable development, has met with a lot of resistance and cognitive dissonance.

However, there is a misconception that sustainable development is all about environment and ecology. There cannot be anything more disastrous than conceiving such a reductionist scope of this notion. Rather than focusing solely on environmental issues, sustainable development policies broadly encompass three areas: economic, environment, and social. In support of this, several United Nations texts, most recently the 2005 World Summit Outcome Document, refer to the "interdependent and mutually reinforcing pillars" of sustainable development as economic development, social development, and environmental protection.

Among many subsequent definitions, the sustainable development triangle in Figure 1 shows one of the widely accepted explanations proposed by Munasinghe (1992) at the 1992 Earth Summit in Rio de Janeiro.

All the available documents of sustainable development acknowledge the interlinkages between the three domains, and have argued that environmental changes (e.g. in ecosystem services like food production and water purification) influence economic growth in the short and the long run, institutions, and culture (Munasinghe 1992, Munasinghe and Reid 2005). Changes in social values and behaviour

Figure 1. Elements of sustainable development
Source: Munasinghe and Reid, 2005

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

influence economic development and environmental management. And critically, economic growth and distribution of wealth and welfare influence both social and ecological attributes.

Sustainable development, eventually, led to the recognition that life support systems that are crucial to human development are given by nature and can be finite, diminishing, yet replenishable at times. In the context of non-replenishability, there is an utmost need to look for alternative sources so that the exploitation of such resources is diminished. It also gave recognition to the fact that a given stock, composition, and productivity of society's capital—natural, man-made, and human—can contribute toward meeting basic human needs in a sustained manner over time, but only up to a maximum limit (Sengupta and Sinha 2003).

Yet, the debate still rages. Despite various attempts to define "sustainable development", in terms of pathways, values, indicators, goals, practice, etc., yet a clear, fixed, and immutable definition remains elusive [Kates et al (2005)]. It has also led some to infer that sustainable development is an oxymoron: "development" and "sustainability" cannot be reconciled. Verily, Kates et al (2005: 20) state, "… Sustainable development draws much of its resonance, power, and creativity from its very ambiguity…its malleability allows it to remain an open, dynamic, and evolving idea that can be adopted to fit these very different situations and contexts across space and time. Likewise, its openness to interpretation enables participants at multiple levels, from local to global, within and across activity sectors, and in institutions of governance, business, and civil society to redefine and reinterpret its meaning to fit their own situation… Despite this creative ambiguity and openness to interpretation, sustainable development has evolved a core set of guiding principles and values, based on Brundtland Commission's standard definition to meet the needs, now and in the future, for human, economic, and social development within the restraints of life-support systems of the planet."

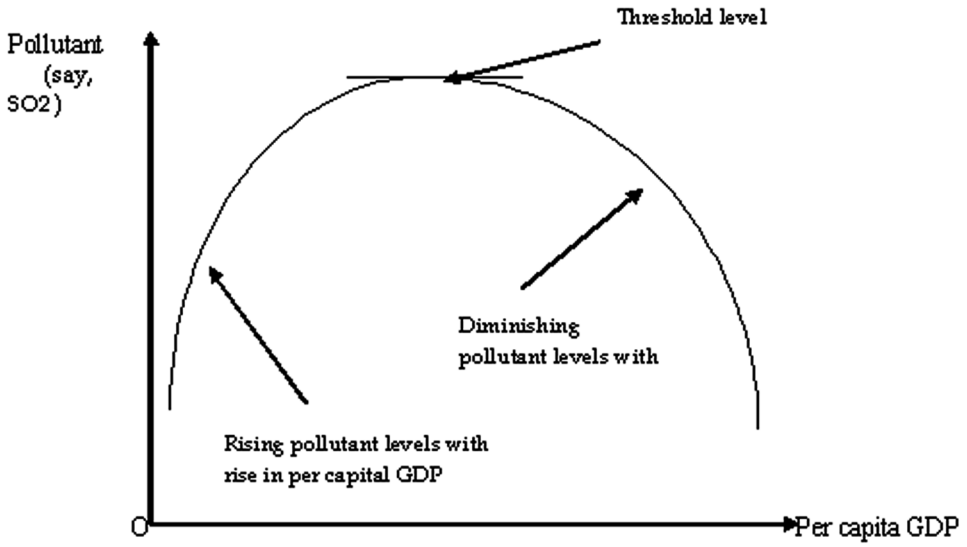
Hence, no ambiguity can deter one from concluding that sustainable development is probably one of the most powerful and holistic thought process that has enriched the development discourse, by challenging the reconciliation of what apparently seems to be the "irreconcilable trinity" of economic growth, social development, and environmental sustenance, thereby providing opportunities for a healthier and sustainable future.

IS SUSTAINABLE DEVELOPMENT OPPOSED TO ECONOMIC GROWTH?

Sustainable development has sometimes been treated as a notion emerging from the communistic thought processes, and sometimes as a tool used by antagonistic ecological activists. Both of these are widespread misconceptions about the notion. Rather, the notion is much more objective than being treated as inclined toward a particular tradition. The concrete challenges of sustainable development are at least as heterogeneous and complex as the diversity of human societies and natural ecosystems around the world. Unfortunately, both socialistic thought processes and ecological antagonism have used the notion as a powerful tool to talk against economic growth, and this has even deterred many market-oriented thinkers to adopt this notion. It needs to be remembered that sustainable development is not opposed to economic growth or development; rather, it talks of sustaining the process of growth and development over generations.

On the contrary, the relationship between economic growth and indicators of air and water quality indicates that growth does not always contribute to environmental degradation. The connection is highly

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use



dependent on income levels: there seems to be a U-shaped relationship between income and environmental quality.

This statement in favour of reconciliation of growth and ecological sustainability is best reflected in the Environmental Kuznets' Curve (EKC). EKC presents a relation between various indicators of environmental degradation and income per capita. In the early stages of economic growth, degradation and pollution increase, but beyond a threshold level of per capita income the trend reverses, so that at high-income levels economic growth leads to environmental improvement. The turning point varies according to the pollutant. This implies that the environmental impact indicator is an inverted U-shaped function of per capita income, as presented in Figure 2. EKC is named after Simon Kuznets (1955), who hypothesized that income inequality initially rises with per capita GDP and then falls as economic development proceeds beyond a threshold level.

The EKC concept emerged in the early 1990s with Grossman and Krueger's (1993) path-breaking study of the potential impacts of NAFTA and Shafik and Bandyopadhyay's (1992) background study for the 1992 World Development Report. However, the idea that economic growth is necessary for environmental quality to be maintained or improved is an essential part of the sustainable development argument promulgated by the WCED (1987). However, EKC is an empirical phenomenon, despite research papers on the topic being inflicted by weak econometrics.

In the context of the EKC, it is easy to interpret that the levels of suspended solids and toxic metals in air and water increase rapidly as incomes approach middle income levels but then decrease. The link between income and pollution arises because the composition of output changes with growth in favour of newer, cleaner technologies. EKC also presents a powerful statement on the political dimension of the economy-ecology linkage. Because of better education and awareness, citizens in higher income economies articulate their demands for a cleaner environment, in a more effective manner than those

Figure 2. The environmental Kuznets curve

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

in lower income nations. Hence, it is the concern of "environment" as a "good" being featured in the "utility bundle" of the consumer that acts as a prime driver in the scheme of things.

On the other hand, the convincing statements made by Munasinghe (1992 and 2005) and the recently published Millennium Ecosystem Assessment (2005 a) on ecosystem services affecting economic behaviour reveal that ecological services and economic development cannot be dissociated or disintegrated, and that the causality flows from both directions.

Developing countries have often perceived pollution abatement as being opposed to their development aspirations. An implausibly high level of technical progress in energy use would be needed if these were to result in the stabilization of emissions. Incidentally, in consonance with the EKC phenomenon, most developing countries are still well below the peaks of their pollution so that global environmental damage is likely to increase substantially before it declines. Does that imply that growth needs to be sacrificed for that? Rather sacrificing on growth would aggravate the problem, accelerating population growth, slowing the adoption of cleaner technologies and frustrating the development of democratic institutions. Pollution tends to be related to population, and population growth is inversely related to income growth. Higher average income and output levels are only good for the environment when associated with policies that lessen demographic pressures by reducing personal risk and the need for large families. Improvements in the security of employment, education and training, pension policies, social security and the employment of women are especially important.

Measurement of environmental costs and benefits is a key first step to the development of appropriate policies. The failure of current estimates of net national product to account for the depreciation of environmental resources amounts to imputing this depreciation to be zero, biasing investments and technological choices. If full account were taken of environmental depreciation, profits and national output would be lower. In Costa Rica, for example, it is estimated that the depreciation of forests amount to around 10 percent of GDP and over a third of gross capital accumulation. Biases like this have severe consequences everywhere, but are particularly pernicious in poor countries where small fluctuations in income or growth levels can spell the difference between famine or survival. Small changes in techniques of measurement, production and lifestyle are likely to prove sufficient to preserve the options for future generations. Investments in environmental maintenance are likely to lead to barely significant declines in income growth (under 1 per cent) in the short-term; longer term, they should facilitate more rapid and globally equitable development. Policies which facilitate growth and lead to the appropriate pricing of natural resources provide the basis for enhanced environmental management. The establishment of a pricing structure for natural resources which reflects their true value will also be invaluable. The failure to price natural resources, such as water, at their economic cost means that degradation of natural resources by present generations may undermine the basis for future economic growth.

Trade liberalization offers a particularly powerful impetus to growth and is entirely compatible with sustainable development. Indeed, trade distortions are a primary explanation for environmental degradation, as shown by the the high dependence on subsidised dirty fuels in China and Eastern Europe. To the extent that trade policies may have an adverse effect on the environment, it is up to governments to initiate policy changes. Improved minimum standards and global cooperation for environmental management are a vital step to ensuring that the benefits of economic growth may more quickly and effectively be reflected in an enhanced environment. Not only is growth sustainable, but it is a necessary condition for improved environmental management.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

THE ROLE OF MARKETS

From the discussion so far, it is clear that from the viewpoint of policymaking, a development path that is "sustainable" should also take into consideration institutions that will be conducive for greater participation of citizens at various levels. One of the critical elements that have been implicitly pointed out in this debate is the crucial role of market mechanism. Unfortunately, the role of market in sustainable development has not received much attention, and rather, in many cases, the same has been criticized by communist groups. Therefore, it is only pertinent here to talk of a few market phenomena that have emerged and might prove conducive for sustainable development.

Trading in Ecosystem Services: A Market for Nature

It has often been argued that ecosystems services should be viewed as natural capital; investment in which can prove more effective than that of the built capital to deliver key services. "As an example, consider the case of flood control. One can address floodwaters through built capital, such as engineered works (e.g. construction and maintenance of dikes and levees) or through natural capital, such as landscape management (e.g. restoration of wetlands in flood plains). In some instances, perhaps many, landscape management may prove a better public and private investment strategy for providing flood control, once one accounts for the positive externalities of improved water quality, wildlife habitat, and recreational amenities." (Salzman 2005) Many solutions have been proposed to halt environmental degradation and reverse the downward trend in ecosystem services. Some have been successful, while others have failed. An assessment of response strategies undertaken by the Millennium Ecosystem Assessment (2005b) highlighted the potential of market-based strategies to mitigate the degradation of ecosystem services.

At one point in time, it was thought that nature is endowed with resources in abundance. Anything that is supplied in abundance eventually has no value, and no market. However, over time, with human intervention in the working of the environment, there has been degradation and depletion of the resources. With the decline in their *supply*, a traditional response has been to turn to governments for continued supply of ecosystem services, through regulations, cost sharing, and other related mechanisms. This is what has been done for public goods and utilities so far. The status of the ecosystem is really a cause for more serious concern than that of public goods and utilities. The Hardin-initiated parable of "Tragedy of Commons" demonstrates how free access and unrestricted demand for a common, natural resource dooms the resource through overexploitation. This happens, as none of the beneficiaries from the resource are willing to take up the responsibility of restoration and maintenance, because the individual cost of doing so is perceived to be much higher than the benefits that accrue. According to the Millennium Ecosystem Assessment (2005a) "If current trends continue, ecosystem services that are freely available today will cease to be available or become more costly in the near future. The higher costs that primary users may face will be passed downstream to secondary and tertiary industries and will transform the operating environment of all businesses."

Since monitoring and regulation of the ecosystem services is difficult and expensive for the government, the need for creating markets and market values assumes importance. Ecosystem services affect the well being of individuals and the performance of firms. Yet, this is rarely reflected in the financial incentives that ecosystem participants get. Typically, those who reduce ecosystem services do not bear all the costs they impose on others, nor those who supply such services are rewarded for the benefits they

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

provide to others. In the absence of non-existent markets, allowing participants to act in their own private interest can result in fewer ecosystem services than is optimal for the society as a whole. Markets work well at providing rewards, and hence, markets are a way of encouraging resource managers to properly manage natural resources by offering them incentives.

When one looks at the value chain of any marketed commodity, one realizes that goods extracted from ecosystems have long been traded in markets (i.e. can be bought and sold at established prices). The services provided by ecosystems have been used for just as long, but have remained beyond markets and largely unpriced. The open access problem, whereby resources with poorly defined or undefined property rights (including forests, water, or grasslands), if not regulated in their use, can be accessed by all and used until exhaustion. But just as in any market, an emerging scarcity can make them tradable.

There have been establishments of markets for ecosystem services, and as argued by many, payments for ecosystem services can help in rural poverty alleviation and the process of conservation simultaneously (Uddhammar and Ghosh 2006, Ghosh 2007). Economists have also been instrumental in devising tools like environmental valuation to assess the value of the benefits accrued to human civilization by the environment (e.g. Costanza *et al* 1997, Chopra and Adhikari 2004)]. This has often helped in devising rules of compensation for environmental damages that cause economic losses to backward communities (e.g., Ghosh and Shylajan 2005).

Some of these ecosystem market-based initiatives include the establishment of carbon sequestration offsets, tradable development rights, tradable quota systems, eco-labeling and environment certification, and bio-prospecting. A brief synopsis of these processes is given below.

Market-Based Mechanisms for Ecosystem Services

- *Carbon sequestration offsets* encourage landowners to conserve natural vegetation and to reforest land by providing a market that allows them to be compensated for their costs and the profits they forgo.
- *Tradable development rights* are marketable rights awarded to landowners in areas reserved for conservation. These rights can be sold to owners of land in development areas to satisfy requirements that they hold a certain number of credits before gaining permission to develop the land.
- *Tradable quota systems* have been applied to a number of areas including fisheries management. Quota systems are a means of dealing with over exploitation by allocating quotas to individual fishers so that the sum of the individual quotas does not exceed the carrying capacity of the fishery. These quotas can be traded between groups of producers, or individually.
- *Eco-labelling and environmental certification* have gained significance particularly in natural resource extraction and management. These schemes are often voluntary, and are often created by private agents in the market. They seek to increase incentives for environmentally sound production by enabling consumers to differentiate between production techniques, product qualities, or producing organizations.

The recent expansions of markets for other environmental services suggest that they may rapidly become a central point of sustainable development financing, representing tens of billions of dollars annually within the next 10 to 15 years. All these moves toward markets have been triggered by two major drivers that include conscious national environmental policy movements towards market-based instruments, and rising demand for environmental goods and services from public authorities, private entities, and

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

consumers. On the one hand, there are new public regulations along with the establishment of market-based instruments, and on the other, it has become quite lucrative and fashionable for private players to show initiatives toward efforts of biodiversity protection. Consumer demand for derivatives of healthy ecosystems in the form of organic foods, fair trade products, and eco-tourism has also increased over time. Its positive incidence on human health and overall welfare is also being steadily documented.

Water Markets

Rosegrant and Binswanger (1994) suggest that water markets provide a flexible and efficient way to allocate water while at the same time providing incentives that are beneficial for water users. When water savings can be traded, they provide extra income to farmers, while pricing leads to a reduction in income. They also suggest that markets lead to the highest value use of water. As shown by Holland and Moore (2003) in the context of the Central Arizona Project, a restrictive market mechanism on groundwater resources could result in inefficient solutions. According to Hearne and Easter (1995), markets should be recognized as providing a means of allocating water according to its real value, thereby leading to efficiency gains and conservation. Gardner and Fullerton (1968), and Marino and Kemper (1999) suggest that markets can provide a means to allocate water according to its opportunity cost, resulting in efficiency gains.

Holden and Thobani (1996) talked of tradable water rights as an approach to resolve water shortages and promote investment. They expressed that a system of tradable water rights combined with effective institutional arrangements can solve many of the problems related to allocation that administered solutions fail to deal with. In another instance, Chile's National Water Code of 1981 established a system of water rights that were transferable and independent of land use and ownership. The most frequent transaction in Chile's water markets is the ——renting of water between neighbouring farmers with different water requirements (Gazmuri 1992).

Cases and analyses have widely been documented on physical market transactions of water all over the world or transactions of tradable water rights. Markets range from being formal to informal. Informal water markets are found in India (Saleth 1997), Pakistan (Bandaragoda 1998, Meinzen-Dick 1997), Chile (Hearne and Easter 1997), and Mexico (Thobani 1997). Transactions are typically small-scale and local, selling surplus water to neighbouring farmers or towns (Johansson 2000, Bosworth *et al* 2002). Formal markets involve buyable and sellable water rights, permanent and seasonal transfers or transactions between sectors and jurisdictions. Examples exist for the western US (Colby 1998), California (Howitt 1998), Texas (Griffin 1998), and Spain (Garrido 1998). It is claimed that the most advanced form of tradable water rights exist in the Murray-Darling Basin in Australia, with seasonal and permanent states of diversion entitlements (Bosworth *et al* 2002).

Virtual Water Imports

A recent concept that has emerged in literature on water resource policy is virtual water (Allan 1993, 1994, 1996, 1997, 2003;, Jobson 1999); Hakimian (2003); Hoekstra and Hung (2002); Wickelns (2001)]. The water "embedded" in agricultural commodities is called "*virtual water*". It requires about 1,000 tonnes [cubic metres] of water to produce a tonne of wheat; about 16 times this volume to produce a tonne of beef. This water is sourced from freshwater or from soil water. In other words, virtual water is the volume of water needed to produce a commodity or service (Jobson 1999). The concept is particu-

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

larly impressive in the way it ameliorates water scarcity over vast distances (Merrett 2003). It enables non-water self-sufficient economies and river basins to meet their strategic food needs (Allan 1997). This is, thus, a classic example of Ricardo's generic concept of comparative advantage. Products with extensive consumptive use of water, if imported, entail import of *virtual water*. Economies like Israel have tried to balance their water budget in that manner. Japan is the world's biggest importer of virtual water (Oki et al. 2003)]. Japan's needs are provided by the U.S. and Australasia by providing grain for consumption by humans and livestock. Apart from food grains, virtual water is present in commodities whose productions require water, e.g. hydropower, etc. (Jobson 1999).

Virtual water stands as one of the demand-side management options for water resources, which has often been argued as the crux of the new paradigm of water resources management. It has often been thought that the primary reason for water conflict is scarcity of the resource, thereby making the issue of scarcity the fundamental concern worldwide by creating the rationale for managing water demand.

Some Comments on These Emerging Markets and Sustainability

Market institutions make the common man understand the value of the services that the ecosystem provides to the economy as a whole, the incidence of economic activity on the ecosystem, and finally, its possible repercussions on the quality of life. This dictates the supply-side phenomenon of an economy, including human health, welfare, and eventually, labour markets. At the same time, trade in ecosystem services has the potential to become the new growth industry. Areas and projects where such trade is possible are likely to generate significant secondary benefits, such as eco-tourism, with multiplier effect on incomes and employment. The potential for synergies among various initiatives therefore are plenty. Not only can an economy fulfill its obligations under the various environmental conventions to combat desertification, biodiversity degradation, and global climate change, but the possibility also exists to engage various rural communities in formal market transactions, reducing thereby the extent and magnitude of poverty.

CONCLUDING REMARKS

Development theories have transcended various disciplinary barriers for finally arriving at the concept of sustainable development from the notion of economic growth. Sustainable development, by all means, is an all-encompassing notion involving parameters of human health, labour, education, industrialisation, and demand-side factors along with the recognition of the contribution of nature to the economy. Such a paradigmatic shift to a holistic concept of development from a reductionist notion in less than a century is no less than a revolution.

The "quality of life" indicators (see Oswald 1997), rather than simply growth, have increasingly become important for governments and academics, as disciplines are being transcended. As the biophysical constraints of land, soil, and water put an upper limit on the carrying capacity of nature, there is the utmost need to develop institutions like markets to manage the limited resources efficiently, ensure equity in the distribution of these resources, and allow substantial time for replenishment of the resources, and find alternatives to guarantee sustainability. This would simultaneously require a trans-disciplinary knowledge base[1], public action, and design of appropriate macro and sectoral policies. More critically,

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

the entire discourse of public policy needs to be viewed in the wider context of inclusive development, including those of future generations.

There is no doubt that one of the biggest catalysts in this phenomenon is the market. Ghosh (2011) has talked of how markets can help in cooperative behaviours and therefore bridge the "ingenuity gap"[2] between the developed and the developing nations. With the emergence of more and more markets and therefore cooperation over natural resources, scholars have increasingly recognized that increasingly cooperation over natural resource use and management is on. Even governments have been including local communities to offer eco-tourism benefits, which is another form of market creation leading to cooperative behaviour and mutual benefits. Cooperative behaviours have emerged in the use and management of forest resources. Local communities have been increasingly involved in forest management through institutions of joint forest management in India, Bangladesh, Nepal and Bhutan.

Worldwide, ecosystems markets are being developed with this notion. While carbon trading and clean development mechanisms (CDMs) are important interventions to bridge the chasm between the rich and the developing world, it seems that these institutions will only be enhanced over time, with more sophisticated instruments for trading. These initiatives have been helping the poor, as also the cause of species conservation, thereby reducing the frequencies of community–government conflicts in the developing world. Water markets at informal levels have helped in resolving water conflicts to a large extent, and have been conducive to promote local level developments. Unfortunately, while we note a lot of cases of cooperation at international levels over transboundary waters, international water markets are not yet in vogue. Cooperation over water at international and within national boundaries are exemplified by the cooperation of the seven states of Western US over the Colorado River, and the treaty over the Indus waters between India and Pakistan. However, the potential for international water markets to promote sustainable development at broader regional levels is immense. The last chapter in this volume talks of how a South Asian water futures exchange can help in resolving water conflicts at an international as well as at national levels in South Asia. There is therefore little doubt that a policy toward sustainable development can substantially reduce the inequalities in the economic, environmental, and social sectors, and one can never ignore markets and market-based instruments as important forces in helping attain that goal.

Chapter 4
Implementing an Interfaculty Elective "Sustainable Development":
An Intervention into a University's Culture Between Organized Scientific Rationality and Normative Claim

Renate Hübner
Institute of Intervention Research and Cultural Sustainability, Alpen-Adria University, Austria

Franz Rauch
Institute of Instructional and School Development, Alpen-Adria University, Austria

Mira Dulle
Institute of Instructional and School Development, Alpen-Adria University, Austria

ABSTRACT

A university is a place of organized scientific rationality, but as a social institution it is also committed to future generations. Therefore, it can be argued that universities should act as "models for sustainability". It is thus not sufficient to spend public funds efficiently in achieving their educational mission. Beyond that, the social and the environmental effects of their actions also have to be considered. Having this in mind, the status quo of sustainability in research, teaching, and administration at the Alpen-Adria University Klagenfurt in Austria was examined in 2010. Results showed that although important approaches and several internationally acknowledged contributions in research and teaching do exist, at the same time a concise and focused strategy for these actions is missing. However, there was some commitment that a coherent strategy would strengthen our University. The major challenge is that a system based on individual freedom in research and teaching needs to intervene in order to create, implement and live such a strategy. The conception and implementation of an interdisciplinary elective open for all Master and PhD students seemed to be a first appropriate step to implement sustainability

at the University across disciplinary and structural borders. To increase general acceptance of such an intervention and to cause impacts towards sustainability at the university as a whole an interfaculty approach was chosen. The corresponding processes and challenges are described in this chapter.

ORGANIZATION BACKGROUND

This chapter describes the developments of the Alpen-Adria-University Klagenfurt, and milestones in the field of Sustainable Development (SD). The University founded in 1970 for "Educational Sciences" evolved into an institution with five different disciplinary approaches: three conventional faculties (Cultural Studies, Economics and Business Administration, Informatics), one inter- and transdisciplinary Faculty and a School of Education. The rather young university - compared to other universities in Austria (the University of Vienna was founded in 1365) - focused from its very beginning on linking research and teaching to its relevance in societal practice. The IFF-Faculty for interdisciplinary studies (founded 1979 by six Austrian universities as an inter-university institute for interdisciplinary approaches in research and education) has always played a very specific role. It became a faculty at Klagenfurt University in 2004. This faculty bundles scientists from different disciplines around a societal problem together with the parties involved. Their work is based on intervention oriented approaches in research and teaching such as group dynamics, action research, intervention research and others. From very early in the 1990ies ecological problems have been seen as a huge social and cultural challenge, leading to specific approaches to the concept of sustainability internationally as accepted in science and politics, such as *social metabolism* and *social ecology* or the *cultural sustainability* approach and the concept of *intervention research* as well as approaches of *Education for Sustainable Development* (ESD).

Therefore it was no surprise that the Alpen-Adria University Klagenfurt earned the *Sustainability Award* commissioned by the Austrian Federal Ministries of Sciences and Environment for its IFF-Faculty for Interdisciplinary Studies in 2008[1]. As a consequence Renate Hübner and Franz Rauch, the initiators of the submission, were authorized to research the status quo of sustainability throughout the whole university in research, teaching and organization. An investigation based on the approach of Intervention Research (Heintel, 2005; Hübner, 2012; Krainer & Lerchster, 2012) of the status quo of sustainability at the University (Hübner, Hadatsch & Rauch, 2010) made many initiatives and approaches[2] also in other faculties and administrative areas visible. At the same time it showed that these initiatives were not linked with each other and existed without a unifying or at least joint strategy. This, even though the development plans of the Alpen-Adria University Klagenfurt since 2006 have included sustainability as highly relevant from a social and cultural science perspective, as the following milestones prove:

2005: Implementation of a Master's program in social and human ecology;
2006: Implementation of an In-Service University Course and a network "ESD – Innovation in Teacher Education";
2007: Implementation of a professorship for environmental history;
2007: Implementation of an Institute of Intervention Research and Cultural Sustainability;
2008: Winner of the Sustainability Award (category "communication and decision processes") of the Federal Ministry of Science and Research as well as the Federal Ministry of Agriculture, Environment and Water management for IFF-Faculty of Interdisciplinary Studies;

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

2009: Examination of the status quo of sustainability in research, teaching, and administration at the University of Klagenfurt;
2011: Implementation of sustainability within the strategy process of the University of Klagenfurt as one of the future inter-faculty core research areas and assignment to design and implement an inter-faculty elective "Sustainable Development";
2012: Again winner of the Sustainability Award of the Federal Ministry of Science and Research as well as the Federal Ministry of Agriculture, Environment and Water management (category "regional cooperation");
2014: Again winner of Sustainability Award (category "students initiatives").

The corresponding processes while implementing the milestones are characterized by an attitude of partnership and open discourse about different conceptions of sustainability, this also holds for the case described in this chapter, the conception and implementation of the Interfaculty Elective "Sustainable Development," initiated and financed by the IFF-deanship and led by the authors of this case study.

SETTING THE STAGE

The Underlying Understanding of Sustainable Development as an Attitude

This chapter describes the understanding of Sustainable Development which was and is the basis of our work, especially with regard to sustainable development at and by the Alpen-Adria University Klagenfurt. As with human rights, sustainable development (SD) may be regarded as a regulative idea (Kant, 1787). Such ideas do not indicate what an object consists of but serve as heuristic structures for reflection. They give direction to research and learning processes. In terms of sustainability this implies that inherent contradictions, dilemmas and conflicting targets need to be constantly re-negotiated in a process of discourse between participants in each and every concrete situation (Minsch, 2004). This means a great challenge but also offers considerable potential for enhancing innovative developments in education (Tschapka, 2012).

Education for Sustainable Development (ESD) originated in the context of worldwide discussions concerning the complex correlations between environmental change and people's living conditions. The idea of ESD has been implemented as the UN decade of "Education for Sustainable Development" (2005-2014) and aims at fostering education and learning processes as driving forces for change to create a broad basis for sustainable development (United Nations Educational, Scientific and Cultural Organization [UNESCO], 2006).

Based on the understanding of education in the tradition of enlightenment, the link between sustainable development and education can be described as follows: Sustainable development is integral to the general mandate of education: its humanistic aim emphasizes the self-development and self-determination of human beings as they interact with the world, their fellow humans, and themselves (Rauch, 2004). Ideally, ESD thus enables the next generation to establish a reflective and responsible society that respects natural and ecological constraints. ESD fosters the capability of individuals as well as of society to rethink and develop the values, principles and practices necessary to respond effectively to current and future challenges (Stoltenberg, 2010).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Over the last few years the ESD concept has been extended to higher education. In conclusion of their analysis of sustainable university research and development Beringer and Adomßent (2008) conclude that Sustainability in Higher Education – conceived as institutional, systems-level sustainable university research and development – remains an emerging field involving philosophical reflections, theoretical-conceptual analysis, empirical research, theorizing as well as knowledge mobilization and capacity building. Transdisciplinary research projects promise rich opportunities to grow higher education as the catalyst for a sustainable global society. Although the question as to whether this signals a fundamental shift of policy and practice remains still unresolved (Sterling & Scott, 2008).

In its new research framework program, Horizon 2020, the European Union identified six major current and future challenges (European Commission, 2011, p. 5):

- Health, demographic change and wellbeing;
- Bio-economy (food security, sustainable agriculture, marine and maritime research);
- Energy (secure, clean and efficient);
- Transport (smart, green and integrated);
- Environment (Climate action, resource efficiency and raw materials);
- Inclusive, innovative and secure societies.

These challenges are directing current and future research and sustainable development will be an overarching objective of Horizon 2020. Thus, thinking and acting in a sustainable way requires not only disciplinary knowledge and openness for approaches within other disciplines, but also a specific political and moral attitude as a citizen of planet earth. From this requirement two main questions arise regarding education in general as well as learning and teaching Sustainable Development:

- Which methods of teaching and studying are adequate to fulfil these requirements at university level?
- How can the teaching of sustainable attitudes and approaches be implemented into the university system?

To sum up with regard to implementing SD in the university's culture one has to see clearly that ESD lies between the contradictory contexts of being a concept of organized scientific rationality on the one hand, and of being a social and normative concept, committed to future generations, on the other. This turned out to be the challenge of our project on an SD elective.

CASE DESCRIPTION

Starting Processes: Sensitive Moments in a University's Culture

Starting a project which shall intervene in a social system, means starting a social process that needs broad acceptance of the people involved or concerned. Therefore intervention research pays close attention to the initial phase of such projects (Heintel, 2005; Hübner, 2012). The most important steps are related to composing the team and to enabling the individuals who hardly know each other to grow together. However, there is little experience of interventions in the own systems. Therefore, we had to be

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

even more sensitive about how to start this process. Personal contacts in all faculties and on a very open draft of how the elective could look like with different alternatives built the initial situation. Interested scientists of all faculties were identified and invited to develop the elective.

In the end the teaching team included eight representatives of the four faculties (Cultural Sciences, Business Administration & Economics, Technical Sciences, and Interdisciplinary Research and Education). The idea was to guarantee interdisciplinarity across faculty borders. This cooperation between the participating departments is a new approach for the Alpen-Adria University Klagenfurt which is expected to result in a wider scope and understanding of the facets of sustainability for both students and researchers/teachers. Furthermore, the development of a learning community as the core element of a new learning culture among students and among the core teaching team, can also be seen as an innovation: students and researcher/teachers work out relations and options for actions jointly and reflect on these actions as well as on the learning process, thus following Bateson's concept of first and second order learning (Bateson, 1972) or ESD following Vare and Scott (2007).

In comparison to 'traditional' university classes, additional competences have to be taught, such as the competence to critically question our modern information society, and/or social competences such as self-esteem, self-determination, individual initiative, and general participation capability. Furthermore, the capability of handling different concepts and contradictions and managing conflicts are seen to be important competences when it comes to Sustainable Development (Rauch, 2008). These concepts are not only part of the content of the elective, but can also be seen as learning opportunities for the teaching team at the University as a whole.

Finally and crucially, the elective takes into account an aspect which is all too often neglected in the SD-discourse: the cultural dimension (Heintel, 2007). SD concerns not only educational processes and processes of research and technological innovations, but also includes cultural reorientation and changes in consumption and production patterns (Der Rat von Sachverständigen für Umweltfragen [SRU], 1994). However, the cultural dimension needs practical and thematic contextualization to identify the differences between sustainable and non-sustainable patterns, for which "mobility and modern nomadism" had been selected as overarching subject for 2012/13.

An Interfaculty Approach and a Leading Faculty

The working hypothesis is that the idea of Sustainable Development benefits from interdisciplinary education through including the discussion of different theories, competences and methods. The implementation of the SD elective is a first trial to involve all faculties at the University in a single course. The interfaculty team should have at least one person from each faculty who is interested in such a new cooperation. This team should work on the concept and implementation as well as be part of the staff of the elective. Co-operation between faculties is still not usual, but at the same time it is crucial for the success of such a heuristic educational approach. Furthermore, it can be regarded as a new approach in Education for Sustainable Development (ESD) and thus also means an intervention in the teaching and studying culture of the university.

The development of the course is based on the assumption that – in order to practice and 'live' sustainable approaches – sustainability requires a (collective) process of (re)searching and developing (Rauch & Steiner, 2013). As such it needs a basic understanding of the social system. The teaching format aims at fostering the willingness for fundamental rethinking as well as at enhancing competence for reflective and sustainable actions. This interfaculty co-operation between the participating departments (mathemat-

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

ics, jurisprudence, economics, geography, sociology, intervention research and cultural sustainability, as well as instructional and school development) is seen as both a challenge and an innovative approach: it results in a wider scope and understanding of the facets of sustainability for both students and teacher (Dawe, Jucker & Martin, 2005), whereby the teaching team does not understand sustainability only or simply as a rational issue to be lectured and understood, but rather as an attitude towards life.

Thus, the course also serves as a model in which scientists from different disciplines and different faculties have to converge. Consequently, sustainability is approached from manifold perspectives (which possibly or even probably results in different outcomes for individual research progress). This may and hopefully will open up new pathways for the development of the university, especially within its learning and research culture. This is seen as a prerequisite for sustainability in teaching and research. To recap, we understand the project of developing an interfaculty elective on sustainable development as an intervention into the university system. This is taking place on different levels: interdisciplinary teaching, research, administration, and transdisciplinary cooperation.

Basic Contents of the Elective on Sustainable Development

Due to the wide diversity of topics it is important to have a clear listing of issues which are considered as necessary basics for sustainability. To have sustainable impacts, these fundamental basics have to be more than factual knowledge of a specific topic. The basics can be understood as the theoretical concept or matrix of the elective, the foundation for any further thematic differentiation drawn on and profiting from the manifold disciplines represented by the teachers and students participating. The basic contents of the "Sustainable Development" elective are:

- What does SD mean? Multiple facets and history of the term.
- SD and time: understanding time processes.
- Sustainable systems and growth.
- SD as coping with antagonisms (contradictions).
- SD and system-compatible thinking and acting.
- Philosophical and epistemological basics.
- SD, self-organization and non-linear dynamics.
- SD in different social conditions.
- Communication, reflection and learning (as an/the overarching theme).

These contents require inter- and trans-disciplinary approaches and consequently a mix of teaching methods: lectures, literature review, and joint investigation of practical examples (inquiry-based learning). Further teaching designs can be used (lecture courses, book presentations, project reflections, faculty research days).

Structural Principles and the Character of the Intervention

The notion of intervention can be distilled into one fundamental effect, namely the introduction or making accessible of a different point of view (Grossmann, 2007; Willke, 2005). An intervention is, in this sense, not a direct command to take action, but a process for the generation of awareness, which arises from the gaining of reflective distance to exactly those relationships in which one is a participant (Paul-

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Horn & Krainz, 2009). The development of this course is thus based on the assumption that – in order to practice and 'live' sustainable approaches – sustainability requires a collective process of re-searching and developing. As such, it depends on the respective cultural setting for which a basic understanding of the social system is needed.

Sustainable teaching stimulates orientation knowledge and systems knowledge (the former offers orientation in a modern world undergoing an increasing differentiation), providing inspiration for innovation and exploration (Schneidewind, 2009). Additionally it fosters discussion in interdisciplinary teams and offers fertile ground for a reflexive, participative and activating method of teaching.

The teaching format aims at enhancing the willingness to reconsider according to the metanoia principle: systems' thinking requires the willingness to change one's mind fundamentally (Ossimitz & Lapp, 2006; Senge, 1996), while simultaneously increasing the competence for reflection and sustainable actions. Sustainability thus has to be approached from different angles, which in turn fosters different outcomes for the individual and gives impulses to work in specific disciplines, too. This might open up new pathways for the development of the university, and particularly its learning and research culture. Corresponding innovations in the overall university culture need specific interventions in the system of teaching and studying within any given discipline. But there are also questions that go beyond disciplinary knowledge. Here lies the advantage of the elective SD, it offers a learning environment where disciplinary, as well as interdisciplinary questions can be discussed. Therefore, the elective is structured according to the principles of inquiry- based learning (Anderson, 2007) and problem-based learning (Schneider, 2006; Wildenburg, 2006). It is crucial that teaching is guided by research. The following basic decisions result from these considerations and build the framework for the elective:

- SD encompasses thinking and acting by identifying and reflecting contradictions.
- Projects gain practical and social relevance by focusing on one general topic per year, for which research topics and research questions are to be defined and studied. The results are discussed with representatives of non-academic practice (Topic for the first year: Mobility and modern nomadism).
- Self-organization of students.
- Reflection on everyday theories as well as disciplinary approaches and paradigms.
- Establishment of a learning community (both students and lecturer(s) are learners).
- The content, structure and effects of the course themselves follow the principle of resource-oriented thinking and acting.

Students have to fulfill different tasks that support the mutual learning process. Students attending the elective already hold a Bachelor degree in a certain academic subject, which builds the disciplinary basis for further inquiry. Orientation in a discipline supports learning and understanding in the interdisciplinary discourses on sustainable development in the elective.

By discussing their ideas with the teachers as well as with partners from working practice (industrial and public management, NGOs etc.) the students define research questions and methodology, write and discuss text reflections, organize and conduct small research projects in groups, followed by public presentations. In addition, students work on selected topics in small groups to discuss sustainability from ecological, economical, geographical, juridical, psychological, sociological and educational points of view with the aim of working out contradictions and consistent aspects that are important for all students of the course. The results of these group works have to be documented and prepared to inform other

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

students about the essential outcomes and to support the contribution of further scientific or didactic discourses on the subject.

In terms of a sustainable use of intellectual results, future students that attend the elective can build on the existing work of previous generations of students. The form of presenting the results will be chosen regarding perceivability (presenting the results in a comprehensible form for outsiders), economy (limit economic effort for the creation of the end products) and sustainability (practicability for science and teaching). The goal is to find a balance between the individual experience-based learning and the production of durable "products" that communicate the main results. Evaluations are made on the basis of feedback-comments that help students to identify their strengths and weaknesses and give them the chance to improve within the course.

The elective was intended to be implemented in several Master's and Doctoral programs across faculties and disciplines. It is seen as crucial that teaching in that elective should be guided by research. Therefore the teaching team decided to construct the elective as a research workshop ("Forschungswerkstatt"), that being the learning environment most adequate for the formation of a learning community. This idea cannot be realized in a single semester, therefore the course was held over two semesters. This turned out to be an additional challenge for the university's culture: one course has to be within one semester, something which goes beyond is called "curriculum" and immediately has a different status. This was a inhibiting for the accreditation of the course for the students' study programs.

CURRENT CHALLENGES FACING THE ORGANIZATION

The multiple organization-related challenges were caused by unforeseen simultaneous processes within the university as well as by structural and other cultural circumstances, like the value of team work, interdisciplinarity or skeptical positions which consider the sustainability concept to be not scientific enough.

1. **Context of New Curricula – Reduction of Free Electives:** Currently the University is going through a process of re-structuring its curricula and study plans. On the one hand, this is paving the way for the implementation of the elective. On the other hand, this process brings unforeseen changes: The amount of free electives of all Master's Programs has been reduced from 10% to 5% (6 ECTS[3]). Due to this the elective (with 12 ECTS) is now too large for these study programs. Nevertheless, due to the complexity of SD the core team decided not to change the concept in the expectation that there will be sufficient students interested in attending the elective.
2. **Potential Competition – Pleasant and Irritating at the Same Time:** Overlapping with our project the Faculty of Management and Economics planned for the same time a disciplinary module on "Environment and Energy" within their curricula, in which cooperation beyond the faculty was not on the agenda. For our elective this might have led to fewer students from economics-oriented studies and inhibited the interdisciplinary approach as well. On the other hand, such a progress in offers of sustainability-relevant courses is overall to be welcomed and could enrich the whole process of implementing SD at the University.
3. **Sustainability – A Plastic Word with Normative Touch Disturbs in a Culture of Rationality:** The concept of sustainability is viewed and understood in different, often controversial ways. This is due to the fact that sustainability has many facets, each of which cannot easily be claimed to be wrong or right, as this is a question of perspective. Whilst such a multi-perspective approach towards

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

sustainability is a major challenge for teaching as well as for learning, it offers huge potential for self-referential studying: sustainability builds on curiosity and a strong interest in interdisciplinary exchange – both of which at the same time have to be taught. However, critics claim that – instead of being multi-faceted – the term sustainability is merely vague and obscure, and hence without scientific value.

4. **Work in Teams and Across Disciplines - Not as Highly Valued as Individual Work in the Current University's Culture:** Personal commitment, bottom-up initiatives and memberships of the Alpen-Adria University Klagenfurt in university networks are a necessary, but not a sufficient condition for the successful implementation of an elective on sustainable development. Structural obstacles are evident which cannot be easily overcome, while strong individual dedication is not sufficient. At the University Klagenfurt co-operation between faculties is still not usual. As stated above, the teaching team assumes that sustainability requires constant rethinking and the willingness to question existing paradigms, concepts, methods and last but not least scientific 'beliefs'.
5. **The Practice – First Experiences:** The first course started in October 2012 with almost 30 students from studies across all faculties. Five interdisciplinary groups could be formed; most of the students had little experience with team work in courses and which turned out as a key burden. Almost all eight teachers have been present during all blocks, many of them experiencing team-teaching for the first time which in some mirrored the students' situation. More of two thirds of the students were lost after the first semester. Challenges are located on many levels, e.g. on the level of emotions, theoretical approaches, self-organization and assignments between the presence phases. All in all the tasks seemed to overburden a majority of the students. Those who finished the course learned a lot as they reported.

SOLUTIONS AND RECOMMENDATIONS

Lessons Learned

Pedagogical innovations are always unique, depending on the institutions involved, the region, historical paths and the educational culture in which it is embedded and last but not least on the acting personalities. Therefore we prefer to describe our experiences that the project was an intervention in our university's culture during the three years from the initial idea for the SD elective up to the finalization of the first course at the university. In gradually opening up the dominant university culture with regard to SD we have so far learnt the following lessons:

- **The Teaching Team as Multipliers:** By building an interfaculty teaching team we aimed at initiating a broad process at the university. Thereby, the elective should itself become self-referential, i.e. Sustainable Development is applied to itself. This, in turn, might establish a learning process that goes beyond disciplines. Inter-disciplinarity is known as key issue in researching and teaching sustainability. However, one should be aware that finding an approach for transcending faculty borders in order to organize a collective process is an invidious, wicked problem. It appears to be the norm that a basic contradiction exists between an organization and creative individuals. On the other hand we know from organization theory that the organization is sensitive to creative networking (Grossmann, Lobnig & Scala, 2007). Every educational organization, and above all a

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

university, has to find its own solutions to address this issue. Hierarchies at universities have to be seriously considered and the support of top-level staff is crucial. However, awareness can be raised by effective publicity (media presentations etc.)

- **Attractiveness Through Experiments in Teaching:** Such an interfaculty concept can also be attractive for those university teachers who are not primarily oriented towards sustainability but interested in innovative teaching and learning methods, and new settings.
- **Societal Requirements Placed on Universities:** The process of implementing SD (at least in part) at the Alpen-Adria University Klagenfurt started in 2005 when it was mentioned in the development plan, thus it has been running now for more than eight years. However, the question still remains: How can SD be brought into existence at the university as a place of organized rationality? Closely related to this question is the one of how the collective process of decision-making takes place within the university. After all, due to its systemic characteristics like freedom of research and teaching, a university cannot be led and managed like a business enterprise. This directly contradicts the new policy of introducing full economic autonomy into the university system. However, at the same time society's requirements and expectations are growing – that can help to implement SD in a university.
- **A Certificate to Overcome the ECTS-Corset:** The teaching team implemented a "Sustainable Development" certificate which requires 20 ECTs, 12 ECTs coming from the elective described in this article and 8 ECTs from a pool of seminars which deal with sustainability from interested colleagues across all faculties. With this certificate sustainability should be more visible and attractive for students.
- **Joint Writing of a Scientific Paper:** The joint writing of a paper for the conference "Leuphana Sustainability Summit 2012" in Germany has been a very interesting and valuable process of communication which has strengthened the teaching team through its common reflection on the process and its barriers in the conception phase. During the discussions of the paper relevant issues have been identified which had to be resolved for the implementation of the elective.
- **Financial and Mental Support:** Due to its long tradition with research-led teaching and problem-based learning, the IFF had got the lead for developing sustainability as an interfaculty core research field. Therefore the process was financially supported by the IFF-Faculty of Interdisciplinary Studies (one should not underestimate for instance the improving effect of financing accommodation and beverages for meetings in order to support team-building processes). Furthermore, the personal backing of its deanship strengthened the work and the project team and in cases of organizational difficulties solved the irritations caused by the project intervening in the university's culture and structures.
- **Self-Evaluation:** The internal evaluation of the pilot course by a colleague interviewing most of the participating students and the teaching staff helped a lot in going beyond a superficial understanding of the course's successes and weaknesses. It became a very useful basis for revising the second course which will start in the academic year 2013-14.

Answering Our Questions

Thus the process of implementing SD has been running now for more than 9 years. However, the question still remains: How can SD as a normative and holistic idea further be brought into existence into university's reality despite of its character of organized scientific disciplinized rationality?

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

In reflecting the first sub-question about teaching methods in the light of some current empirical literature (Bray, 2008; Ellis & Weekes, 2008) we decided that the teaching and learning methods to be chosen within the elective SD have to be based on the following principles: inquiry-based learning, problem- and research-based learning, building of learning communities, SD seen from different disciplines. Through that the elective contributes to fulfilling the requirements of ESD in higher education, while helping students to gain important theories, competences and methods to meet the demands of the present time and to ensure a future that is worth living.

To answer the second initial question - how can the teaching of sustainable attitudes be implemented into the university system? - it can be stated that the implementation process of an interfaculty SD elective needs strong support by top-level staff. Understood it as a regulative idea, the concept of SD contains both arbitrariness and a normative demand. Due to these features a permanent reflection process is necessary. This is why the implementation process of the elective is being scientifically supported and evaluated.

The development and implementation of the elective SD at the Alpen-Adria University Klagenfurt can be seen as another attempt to use the innovative potential of the SD-discourse. This potential concerns not only the conceptual and theoretical dimension, but also organizational challenges of development in accordance with new governance and the advancement of teaching and research cultures at the university.

The implementation process of this elective, based on a new type of cooperation among research and teaching team from all four faculties, turned out to be a challenging intervention not simply an innovation at course level. In order to implement Sustainable Development as a regulative idea across the university as a whole, faculty boundaries must be transcended on both management and structural levels. Its acceptance in all master programs of the university represents a serious challenge for the coming years.

ACKNOWLEDGMENT

We owe considerable thanks to Kirsten von Elverfeldt for reviewing an earlier draft of the paper. Günther Ossimitz, Gunhild Sagmeister, Larissa Krainer and Doris Hattenberger provided valuable comments that improved this paper significantly. We would like to dedicate the paper to Günther who left us too early in 2013.

ENDNOTES

1 In 2012 the Alpen-Adria University Klagenfurt got the Sustainability Award again; this time for the development of networks in education all over Austria (Rauch 2013).

2 Obviously, there exists a multitude of implicit concepts of sustainability. These concepts were deduced from twelve qualitative interviews with researchers from all four faculties and representatives of management and administration. We regard it as one of the key strengths of our elective to make these (and other) implicit concepts explicit and to include these – partly controversial – understandings of Sustainable Development in our teaching (please also refer to the section 'lessons learned').

3 European Credit Transfer System is a standard for comparing the study attainment and performance of students of higher education across the European Union and other collaborating European countries.

This research was previously published in the Handbook of Research on Pedagogical Innovations for Sustainable Development edited by Ken D. Thomas and Helen E. Muga, pages 510-522, copyright year 2014 by Information Science Reference (an imprint of IGI Global).

Chapter 5
Interdisciplinarity in Sustainability Science: Challenge or Opportunity?

Rosario Adapon Turvey
Lakehead University, Canada

ABSTRACT

Over the last few decades, Sustainability Science (SS) has gained momentum and emerged in the academy with an extraordinary performance in knowledge production and contributions to the research and publications enterprise, growth in academic programs at the undergraduate and graduate levels, creation of centers/laboratories, and formation of scientific communities, networks and associations. Increasingly, terms like integration, collaboration and bridging of fields and disciplinary boundaries are in the forefront of conversations and/or debates. The key question addressed by this review essay is this: Is interdisciplinarity in Sustainability Science a challenge or opportunity for educational institutions and local communities in the 21st century? Considering the recent momentum in educational advancements and institutional progress, the study outlines relevant literature on interdisciplinarity in SS; synthesizes recent thinking and developments in SS and attempts to address what challenges and opportunities people across the globe face in sustainability education and research and in the development of academic programs and sustainable communities. When scientists, policy makers, academics get together as teams, partners and collaborators they are likely to be engaged in interdisciplinary work and possibly doing sustainability research, policy development and problem-solving to deal with the pressing demands and challenges of the 21st century society. In this context, it is urgent in science and society to seek solutions to major sustainability problems such as climate change and one way to address that is by doing interdisciplinary work in Sustainability Science.

INTRODUCTION

This paper focuses on interdisciplinarity in Sustainability Science (SS) and explores the phenomenal rise of academic programs on SS and their likely influence in sustainable community development. As Frodeman (2011) once wrote: '…the age of disciplinary knowledge may be ending, but the true shape

of interdisciplinarity, and the essential characteristics of sustainability are as yet unknown (p. 111). With the topical currency of interdisciplinarity and SS, the key question addressed here is this: Is interdisciplinarity in Sustainability Science a challenge or opportunity for developing educational institutions and local communities in the 21st century? By contending a parallel narrative through an interpretative lens, as informed by the literature germane to interdisciplinarity and SS, this article is centered on three key aspects. *First*, it examines key perspectives on interdisciplinary thinking in current knowledge production beyond the traditional single disciplinary approach to systematic inquiry. Here, "systematic inquiry" means careful examination or investigation of a problem from a scientific, scholarly, professional or technical way to build new knowledge in a field or discipline (Wylls, 2003). *Second*, it discusses the trends in the growth of Sustainability Science in terms of academic program development in educational institutions (i.e., universities and research centers). The evolution of Sustainability Science (SS) is examined as an international science, an emerging field and vibrant forum linking disciplines across natural, physical and social sciences through the lens of academic program development in educational institutions across the globe. *Third* is to explore how interdisciplinarity in SS in a comparative context, relates to efforts toward building community sustainability. Broadly, the prospects for 'interdisciplinarity' are promising. As Frodeman (2011) claims, the term has become an idea embraced by almost every university's strategic plan and seen as a boom industry with a growing academic community. It crosses and bridges disciplinary boundaries (interdisciplinarity) and makes knowledge more pertinent to non-academic actors (transdisciplinarity). Increasingly, the growing interest is on the "how" rather than the "why" of interdisciplinarity in knowledge production, not only in creating new and additional knowledge but also in finding solutions to pressing societal and environmental issues (Lele & Norgaard, 2005). When scientists get together as teams, partners and collaborators, they are engaged in interdisciplinary work and possibly doing sustainability research to deal with the changing demands and challenges faced by society in the 21st century. But first, what do we mean by 'interdisciplinarity'?

WHAT IS 'INTERDISCIPLINARITY?'

Interdisciplinarity has, over the years, attracted scientists from the social and natural sciences to other areas of research practice. In early times, great minds during the scientific revolutions in 17th Century Europe like Isaac Newton and Robert Boyle made discoveries that dealt with every kind of interdisciplinary challenge (Merton, 1938). The principle of interdisciplinarity means an integration of theories, concepts, techniques and data from diverse bodies of knowledge (Porter et al., 2006; Rafols & Meyer, 2010). Since the 1970s, there has been an exponential growth of publications, a variety of networks and wide discussions of the concept (Klein, 1990). As Klein noted, the interdisciplinarians have yet to establish a common identity because they were still in a state of social and intellectual marginality. Interdisciplinarity is seen to challenge the academic status quo as it 'represents an innovation in knowledge production- making knowledge more relevant, balancing incommensurable claims and perspectives, and raising questions concerning the nature and viability of expertise (Frodeman, 2010, xxix). By the 1990s, a majority of people from various fields and disciplines were immersed with interdisciplinary research. By "interdisciplinary research" means "... a mode of research by teams or individuals that integrates information, data, techniques, tools, perspectives, concepts, and/or theories from two or more disciplines or bodies of specialized knowledge… to solve problems whose solutions are beyond the scope of a single discipline" (NAS, 2004 p. 2).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

As Klein (2010) identified, there are three widely cited labels in the typology, namely: multidisciplinary, interdisciplinary and transdisciplinary. Invariably, terms associated with 'interdisciplinarity' are integrating, interacting, linking, blending and intermeshing within the typology of the interdisciplinary spectrum (Klein, 2010). In terms of intellectual capital, increased borrowing across disciplines, unified/ holistic perspectives and mixing of genres in epistemological sense have put pressures on conventional disciplinary anchoring. In the 21st century, interdisciplinarity is one of the most inspiring of human pursuits- making connections to build new knowledge (NAS, 2004). However in the literature, a lack of agreement on its meanings indicates there is no universal definition of the terminology. This has been a recurring issue in the discourse where both terms of interdisciplinarity and integration have been used interchangeably when considering different viewpoints to problem solving, producing knowledge or finding new knowledge. Earlier, Kockelmans (1979) pointed out that we used the term loosely for describing all types of crossings between or among disciplines, glossing over the subtle differences between multi-, inter- and transdisciplinarity. It is different from other concepts because "multidisciplinarity" has been argued to have little or no effect to analyzing data sets, applying approaches to knowledge production in the environment and other fields (Frodeman, 2011 p. 106). We think collectively about complex problems and often it needs crossing boundaries both horizontally (across disciplines) and vertically (across experts, policymakers, practitioners, and the public (Klein 2004; Lele & Norgaard, 2005).

In the real world, there are at least two major categories or disciplinary blocks, one is the natural sciences and the other is social sciences. When interdisciplinarity is used to include scholars from both blocks, it is taken that all sorts of crossings between and among disciplines are possible and it is likely that scholars use multi-, trans- and interdisciplinarity in one way or the other (Lele & Norgaard, 2005). More recent research landscape show prospects of interdisciplinarity in problem solving, partnership building and use of novel methods and new technologies. However, researchers face disincentives and barriers in a world dominated if not highly influenced by traditionally discipline-based academic institutions that range from funding challenges to new modes of research organization (NAS, 2004). Indeed, there is a need for meaningful interaction given an array of interdisciplinary texts through bodies

of speeches, conference papers, institutional reports and working papers, reviews, articles and a number of books (Klein, 1990). In this age of knowledge society in the 21st century, there is a growing community producing knowledge that crosses and bridges disciplinary boundaries (Frodeman, 2011). It calls for a holistic view of theories, concepts, techniques and methods from a wide variety of disciplines (Rafols & Meyer, 2010). If knowledge production is an engine of the 21st century society, it is essential to look beyond current disciplinary anchoring by tapping potential opportunities offered by interdisciplinarity as an inherently inclusive, integrative and fundamental approach to current thinking. More importantly is the assertion that the academy needs theoretical and institutional changes which Frodeman (2011) calls beyond a disciplinary social epistemology. After all, there are world problems that need not be confined to a single discipline for finding solutions since collaborations are required to bring together experts from different disciplines to address major problems that cut across any discipline and field.

Today, the proliferation of studies from medicine to engineering indicates the power of combining disciplinary knowledge in interdisciplinary ways. It is employed in research marked by an integration of different approaches or methodologies whether narrow (chemists and chemical engineers or wide (natural scientists working with social scientists or humanities) (Frodeman & Mitchum, 2007; Klein, 2010). Recent "hot topics" in the current research landscape are interdisciplinary: from nanotechnology, genomics, neuroscience to bioinformatics and terrorism. Many innovative research triumphs are results of interdisciplinary inquiry and collaboration such as the discovery of the structure of DNA and laser

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

eye surgery (Beckman, 2005). If we are to meet the present day challenges and the changing place of knowledge in society, it is critical to recognize the limitations of disciplinary structures and then explore the promise of interdisciplinarity especially in dealing with pressing societal and environmental problems. Accordingly, the 20th century knowledge production has been under pressure from information technologies to demands for greater accountability, hence the attention given to interdisciplinarity to address this crisis in the current century. Despite a variation in 'texts' and publications, the problem-focused research have made scholars and actors increasingly engaged with interdisciplinary research. As Lele and Norgaard (2005) put it, researchers from different disciplines could study the same phenomenon but vary with their explanatory models as well as underlying assumptions. Often interdisciplinary work operates as teams whose membership is premised on shared interests, relevant expertise and knowledge and willingness to collaborate with, between and among other disciplines. Shared interests are seen to translate into a research plan with predetermined bridges between the disciplines. What best describes situations like these lie on the differences in methodological orientations, variation in problem definition, or broad range of solutions to a phenomenon. Yet, what is interesting for a group of scholars and actors is to work in an integrative way of thinking and working while recognizing differences in disciplinary backgrounds.

Emphasis has been placed on 'thinking collectively about complex problems by crossing boundaries both horizontally (across disciplines) and vertically (across experts, policymakers, practitioners and the public)' (Klein, 2004; Lele & Norgaard, 2005). While it may not be a panacea to challenges of knowledge production, the idea of interdisciplinarity has a place in the 21st century culture of knowledge society (Frodeman, 2011). In recent times, the growth of scientific and technical knowledge has prompted scholars to join teams and groups from varied disciplinary backgrounds for addressing the world's major problems that require broad, if not deep knowledge from different perspectives and disciplines. In current scholarship, interdisciplinarity has invariably been linked with problem-solving (Frodeman, 2011; Klein, 2004; Lele & Norgaard, 2005). There are problems of global importance with practical and major consequences such as global climate change and poverty that can be addressed through interdisciplinarity in sustainability research- possibly through creative integration, exchange and sharing of knowledge. The sustainability landscape indicates the need for combining knowledge from diverse expertise and practice of interdisciplinary inquiry. Despite the explosive growth of databases and information networks in our present day knowledge society, the recurring question of methods and methodology for operating concepts in the real world, remains.

Concerns for attaining sustainability are commonly debated within a broad range of possible solutions relating to interdisciplinarity in the academia. SS is seen at best, to be instrumental in finding solutions to real-world and place-based problems in efforts towards sustainability transition (Kates 2010). A focus on interdisciplinarity is relevant to sustainability science as a step in the right direction since it involves solving problems from a variety of disciplinary lens. As Frodeman (2011) puts it, "interdisciplinarity needs to be placed within an environmental context linking future knowledge production to the concept of sustainability" (p. 106). Establishing the relationship between interdisciplinarity with sustainability requires that some application of current methods and techniques particularly in second generation environmental issues such as climate change be considered and applied. Current environmental research are concerned with global debates on climate change deemed to provide useful insights in problem analysis and better understanding of associated issues from sea-level rise to significant atmospheric impacts. The next section discusses sustainable development and the sustainability idea before a discussion of Sustainability Science.

SUSTAINABLE DEVELOPMENT AND THE SUSTAINABILITY IDEA

In hindsight, since appearing in the United Nations Brundtland Report 'Our Common Future', the concept of sustainable development (SD) has gained much attention from various disciplines with many adopting its definition from the World Commission on the Environment and Development (WCED) (1987). The roots of the word 'sustainable' is said to go back to the ancient Romans when it meant to be capable of being maintained in existence without interruption or diminution (Engleman, 2013). Many authors recognize SD's extraordinary rise as it pervades agendas of governments, corporations, civil society, educational and research programs across the globe (Bettencourt & Kaur, 2011; Redclift, 2006; Komiyama & Takeuchi, 2006). As a concept, it is associated with economic and ecological sustainability, resource conservation, protection of biological diversity and sustainability of cultural and community life. SD concepts remain unclear if it has progressed into a scientific discipline with its agenda of integrative theory and applied science or generate a new interdisciplinary synthesis across fields (Bettencourt & Kaur, 2011). The central thesis of WCED is deemed to have brought new quality to the environmental discourse and continues to shape sustainability discussions today. In policy and academic circles, the WCED definition below of 'sustainable development' is the most widely cited and more exhaustive (Shao Li & Tang, 2011; Zhao, 2011; Redclift, 2006).

…development that meets the needs of the present without compromising the ability of future generations to meet their own needs. (WCED, 1987, p.8)

This canonical definition from the 1987 Brundtland Commission cites three elements: the environment, futurity and social equity for present and future generations (Pearce, 1993; Brand, 2010). By interpretation, its meanings have been subject to academic debate from how needs are met by generational differences (present and future) and how they are defined by varied cultures and societies. Though there are several debates on definitions in the environment and development literature, the SD concept has been deemed a term of contradiction, imprecise, blurred and vague (Glavic & Lukman, 2007; Shao et al., 2011; Quental, Lourenco & Nunes da Silva, 2011). As a normative term, it is useful as an approach to development as it can be an orienting vision to foster broader participation, consensus and appropriate to human inhabitants of this planet. As a concept, SD has referred to with extraordinary rise and success and central to the mission of research laboratories and universities worldwide (Bettencourt & Kaur, 2011). Why? As a moral imperative, it is a call to build healthy economies, influence planning policy and environments, and to improve the quality of life now, and in the future (Hopkins, 2013; Turvey, 2007). It has become a popular paradigm and subject of a series of debates but widely adopted as a goal by several countries and supported by almost everyone (Goodland, 1995; UNDP, 1996). The idea of sustainability is rooted in human cultures, more importantly the North American indigenous cultures (Engelman, 2013). In modern times, Engelman writes that sustainability took root in the work of George Parkin Marsh in the 1860s and 1870s with anthropogenic forces competing with natural forces to alter the Earth itself. From Marsh to later writers, it is asserted that human actions and decisions will affect the sustainability of present and future generations with respect to natural resources, the economy and the environment. Although publications of all sorts on sustainability have mushroomed, some claim its inherent ambiguity, others refer to it as an oxymoron that has 'come of age' but with questions about its future (Kajikawa, 2007; Redclift, 2006; Parris & Kates, 2003; Daly, 1996). Still others stressed how it could be applied for decision-making and management, advocacy, consensus building and research,

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

and analysis (Parris & Kates, 2003). Another definition of SD concerns the improvement of the quality of human life while living within the carrying capacity of supporting ecosystems (Daly & Cobb, 1989). What has been postulated in the academy is the parallel analysis of economic and social development being compatible with the preservation of the essential condition of human existence (Haberl et al., 2011). As a concept, it was deemed an intellectual answer to reconcile the conflicts and interests on the environment and economic growth (Quental et al., 2011). While the application of SD is argued to be embryonic (e.g., Kates & Parris, 2003; WRI, 2003 p. 145), attention to the environment has become central to national and international laws and institutions with regard to sustainability for more than 40 years (Quental et al. 2011). SD is an intellectual answer for reconciling conflicting goals between environmental protection and economic growth (Quental et al., 2011; Scheor, Wolfgang & Jurgen-Friedrich, 2012). In the environment and development lexicon, it has become a popular expression if not agreed to, and accepted by almost everyone worldwide.

The concepts, methods and approaches associated with the sustainability idea are undoubtedly useful that demand a diverse range of academic disciplines to carry out sustainable development work. Since the 1970s, the sustainability narrative has been called with urgency as a global problematique in the 21st century (Adams, 2006; Uskokovic, 2008). This is not surprising because academic discussions have raised the world's attention to a couple of fundamental issues, the first on environmental degradation and the second on the need for economic growth to alleviate poverty and these two issues are often intertwined when ranking global issues. Goodland (1995) outlined sustainability in three streams from social, economic to environmental sustainability where the latter is about maintaining environmental assets and not depleting natural resources. As well, SD and sustainability are taken as ethical concepts that seek desirable outcomes, given social and economic decisions to be made (Adams, 2006). Yet, in some cases, the rhetoric of SD is sometimes ignored in practical decisions and the term 'sustainable' is loosely applied that it can be taken as 'development as usual'. At the UN Millennium Summit in 2000, sustainability was among the eight Millennium Development Goals and one of the many examples where it can be used for divergent ideas with its worldwide popularity. Though some could argue about its lack of clarity and precision, one thing is sure, it brings people together (from various disciplines and sectors of society) for the sake of development and environmental concerns; so the debates and arguments on SD and sustainability will undoubtedly remain. Next is a brief discussion of the origins and definitions of 'Sustainability Science.'

ORIGINS AND MEANINGS OF SUSTAINABILITY SCIENCE

With a phenomenal interest in the sustainability idea to address the complex anthropogenic challenges on development and the environment, Sustainability Science has gained momentum as evidenced by progress in institutional developments and academic publications as mirrored in new journals, conferences, research projects and educational advancements (Bettencourt & Kaur, 2011; Wiek et al., 2011). The discussion in this section briefly tracks the origins and definitions of SS that bridges the knowledge gap between science and society to address the socio-cultural gaps on 'sustainable policy development and implementation' (Sanusi et al., 2013; Jerneck et al., 2011). From practical lens, SS is not entirely new; it is considered very much a part of ancient history within traditional wisdoms and/or indigenous knowledge and has long been part of human civilization (Sanusi et al., 2013). Since the 1980s, publications in the field has produced an unusual geographic footprint worldwide and characterized by scientific collaboration generating new interdisciplinary synthesis across fields (Bettencourt & Kaur, 2011). Ini-

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

tially, SS was highlighted at the World Congress "Challenges of a Changing Earth 2001" in Amsterdam by the International Council for Science (ICSU). Perceived as an international science policy project, it was said to be consolidated in the World Summit on Sustainable Development in Johannesburg in 2002 (Jerneck et al., 2011). The question is this: Is Sustainability Science a concept, an emerging field or new discipline that integrates arts and science or simply 'science' in its own terms?

The concept of SS was floated by Simonelli (1994), Hirch and Ghiderella (1994). In advancing SS as a concept, Hirsch and Ghiradella's (1994) work on Sustainability Science has been influential to feminist scholars like Londa Schiebinger (1997) supporting the idea of a socially responsible science such as ones responsibility toward nature and culture (Broadhead & Howard, 2011). As a concept, sustainability science is applied by those who are engaged in addressing (and correcting) environmentally destructive ways- scientifically and in practice (Broadhead & Howard, 2011). What is reflected in the literature is a changing relationship between science and society (for instance, in terms of well-being of society) (Lubchenco, 1998; Cortner, 2000; Blackstock & Carter, 2007). Indeed, SS has, over the last few decades, emerged as a vibrant field of research and innovation (Clark, 2006). As a research field, it makes scholars rethink the interactions of domains and scales such as nature and society (Jerneck et al., 2011; Hornborg & Crumley, 2006; Schellnhuber, 1999).

SS is recognized as a new science since the 1990s when the International Council for Science (ICSU) studied science and technology links for sustainable development (Komiyama & Takeuchi, 2006). It has been envisaged to harness 'science' toward sustainability and strengthening dialogue between science and society (Clark & Dickson, 2003; Jerneck et al., 2011). The literature suggests that what comes to light when redefining the functions, mandate and scope of scientific inquiry is this: Sustainability Science focuses on the needs and values in society while preserving the planet Earth's life-support systems (Kates et al., 2001; Backstrand, 2003). With this new momentum of SS from a science perspective, it has become part of the global discourse on SD closely linked across a range of disciplines and has reached out to, and from a world of problem-solving streams (Sanusi et al., 2013; Clark, 2006). The word 'science' in SS is somehow caught in a 'cross-fire' of two opposing camps in terms of how the word 'science' is interpreted. One is to look at 'science' as a major tool of the ideology driving industrialization, modernisation and the modern economy. The other looks at 'science' toward knowledge production and technology development as well as long-term management of resources. In exploring the nature and place of 'science' in Sustainability Science, some authors argue it is a 'set of principles by which sustainability knowledge is built' (Sanusi et al., 2013). The science of sustainability is deemed to require collaboration between perspectives and integration of theory, methods and approaches toward scientific rigour without which SS begs the question whether it has indeed become a field of science? Several scholars have advanced the idea of science towards sustainability; adopting convergence of multiple sciences and a holistic approach that advocates cooperation and integration of the social and natural sciences (Jager, 2009 a, b; Weaver & Jansen, 2004; Clark & Dickson, 2003). The argument is to promote a convergence, not a fragmentation of the sciences, of humanities and social sciences approaches values and perspectives together with natural sciences. As an ancient wisdom in practice from a long time in terms of the history of knowledge generation, some scholars may prefer the use of sustainability studies instead as the use of 'science' in SS could invite a debate in the compartmentalization of knowledge (Sanusi et al., 2013).

'What is sustainability science?' To Sanusi et al. (2013), the question may not be answered easily and with the sheer lack of a universal and precise definition, they argue is not actually a weakness in conceptual terms. Sustainability Science is defined in several ways after its introduction in the academy but it should be reiterated that specific academic fields, sub-fields and disciplines have their own standards for validity, vocabulary, principles and modus operandi that make it difficult for 'those outside the

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

discipline' to give a thumbs up to interdisciplinarity in sustainability science. According to Schoolman et al. (2011) some authors argue that SS is a distinct field where there is collaboration among researchers, policy makers and stakeholders with the purpose of learning from each other without worrying about the traditional disciplinary boundaries (Kates et al., 2001; Komiyama & Takeuchi, 2006; Ostrom, 2009; Characklis et al., 2011). As Kates et al. (2001) put it, 'It seeks to understand the character and interactions between nature and society, and to provide the knowledge needed to pursue paths that can meet human needs while preserving life-support systems of the planet' (p. 394). As the field matured, it was accorded a 'room of its own' in the Proceedings of the National Academy of Sciences (PNAS) in early 2005 (Clark, 2007). With the surge in SS publications and programs being developed, it has received increased academic attention but not to the extent of its interdisciplinarity as a subject of inquiry, and this is indeed an intellectual challenge in theory and practice. As Schoolman et al. (2011) indicated, '…the extent to which SS has lived up to its interdisciplinary ideas has, so far, not been the object of systematic inquiry.' Referred to as 'something 'intellectually exciting and practically compelling', Clark and Dickson (2003) viewed it as: "… not yet an autonomous field or discipline, but rather a vibrant arena that is bringing together scholarship and practice, global and local perspectives from north and south, and disciplines across the natural and social sciences, engineering and medicine." Most commonly, SS is described to be interdisciplinary; a field concerned with the relationship between nature-society system, the scope of work for which is 'ambitious' (Frodeman, 2011). Schoolman et al. argue that the '…principle of interdisciplinarity with respect to integration of theories, concepts, techniques and data from diverse bodies …is equally crucial to the study of sustainability.' The place of interdisciplinarity in SS is critical to understanding the conceptual foundations and practical underpinnings of sustainability as a whole. An important dimension of SS is the breadth and scope of publications in geographical and thematic sense. Based on the work of Bettencourt and Kaur (2011), a large corpus of publications in SS during the period 1974-2010 were analyzed which consisted of about 37,000 distinct authors of more than 20,000 papers from 174 countries and territories and 2, 206 cities worldwide. From that study, SS is noted to have grown exponentially with the first rate of growth seen in the late 1980s and continued to accelerate in recent times. An unusual feature of SS literature is the broad (geographic) distribution of contributions internationally, not only from countries with traditional strength in science but elsewhere from the developing world (Bettencourt & Kaur, 2011). In summary, Bettencourt and Kaur concluded that:

- As a field, SS has evolved as a collaboration network unified with a giant cluster of 'co-authorship' around 2000;
- The field is growing exponentially after the late 1980s-1990s when it accelerated its pace of growth to present levels and widely distributed internationally with a strong presence not only in the US, Europe and Japan but also elsewhere;
- With the substantial rise in publications, principal national centers and many smaller universities and laboratories contribute and have a presence in the field, given author affiliations and geographic distribution of publications, both in developed and developing countries;
- The spatial distribution of publications is a regionally diverse field with different contributors by type and form both from the social sciences and the natural sciences, including biology and engineering;
- The existence of a young and fast-growing unified scientific practice of sustainability science bodes well for dealing with humanity's greatest scientific and societal challenges.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Though others defined SS as a 'new discipline without a discipline', if structured along the lines of disciplinary- based categories of knowledge (Sanusi et al., 2013), SS is however claimed as a 'new academic discipline' with over a decade of collaborative research, publications and educational advancements are evident through the Alliance for Global Sustainability with the Massachusetts Institute of Technology, the Swish Federal Institute of Technology in Sweden (Komiyama and Takeuchi 2006). In Asia, Japan's University of Tokyo formed the Integrated Research System for Sustainability Science (IR3S) with a nationwide research network. As Komiyama and Takeuchi (2006) claim, there is great opportunity to advance SS as a new discipline as welcomed by scientific and academic circles worldwide.

SUSTAINABILITY SCIENCE: CHALLENGE OR OPPORTUNITY?

Is 'interdisciplinarity in sustainability science' a challenge or opportunity? Today, SS has posed some challenges as well as opportunities as it evolved as a concept to a vibrant field, then emerged as a 'new discipline'; but still others see it as a 'new discipline without a discipline' while some consider it a scientific discipline (Komiyama & Takeuchi, 2006; Clark, 2007; Sanusi et al., 2013). As the debate continues, there are challenges and opportunities that deserve attention to understand the progress of SS from the perspectives of interdisciplinary thinking and pervasiveness in the agendas of various institutions including governments, higher education and research programs worldwide as discussed in this section.

Challenge # 1: Interdisciplinarity and Researching Sustainability Challenges

First, interdisciplinarity is deemed crucial to researching sustainability, given a sense of urgency for its practice to deal with global economic, social and environmental issues. Scholars have already explored this concept in systematic inquiry for doing sustainability research (Schoolman et al. 2011). Though insights of one discipline is valuable to a government agency or stakeholder group, Frodeman (2011) argues that creating interdisciplinary knowledge for transdisciplinary reasons could be valuable in improving the production and use of knowledge itself. There are sustainability challenges that Sustainability Science itself faces. One of the sustainability challenges concerns the *modus operandi* of natural science which operates 'under paradigms that strive for scientific objectivity, reduced uncertainty, and scientific agreement as epitomized by the bottom line consensus on climate change' (Oreskes, 2004). To Jerneck et al. (2011), advocates of SS who are firmly grounded in the natural sciences are seen to be less theoretically or methodologically versed in justice, politics, power and critical research in the social sciences. If the aim in sustainability science is to foster a 'coherent interdisciplinary system of research planning and practice' there must be equal, not less room for research rooted in the social sciences and humanities that calls for the basic assumptions of modern society in question' (Jerneck et al., 2011). If we aim to address global sustainability challenges, Jerneck et al. argued it is unlikely it could be understood or solved solely from one side (the natural sciences, medical or engineering sciences) so equal efforts must be exerted toward addressing the challenges from other ontologies and epistemologies.

Challenge # 2: Knowledge Integration and Interdisciplinarity in SS

The next challenge involves knowledge integration and interdisciplinarity in SS. Achieving knowledge integration from across disciplines is a challenge in sustainability science due to institutional and organizational impediments in the conduct of interdisciplinary research (Fujikaki et al., 2000; Bercher &

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Trowler, 2011). Based on a growing literature, SS is a clear 'object of interest' (Kajikawa et al., 2007) considering that less than a decade ago, it was not yet an autonomous field or discipline but a dynamic arena that brought together scholarship and practice from north and south and disciplines across the natural and social sciences and others such as engineering and medicine (Clark & Dickson, 2003). Is SS integrative of knowledge across disciplines? Already, there are studies and investigations of the empirical validity of interdisciplinarity within sustainability research (Schoolman et al., 2011; Kajikawa, 2008; Adams, 2006; Kastenhofer & Rammel, 2005).

In his account of the state of knowledge production in the early 21st century, Frodeman (2011) stressed the limitations of single disciplinary structures; pointed out the 'promise of interdisciplinarity' from the standpoint of the university that must adapt to changing social demands and conditions and called for the need to take a broad perspective to a wide range of solutions the society faces, not through one discipline. Interdisciplinary approaches to knowledge need to be based in a fundamental way through single disciplinary knowledge and should be placed within an environmental context, linking future knowledge production to the concept of sustainability (Frodeman, 2011). As Frodeman clarified in linking interdisciplinarity to sustainability, it will need a reformulation of the underlying assumptions in the 21st century university- that is, make knowledge production sustainable, not just aim for more or additional knowledge and examine the question of what counts as academic rigor. In brief, interdisciplinary approaches to research and education will mean an integration of different disciplinary approaches to methodologies, not narrow ones (e.g., chemists and chemical engineers); or wide (natural scientists working with social scientists or humanists) interdisciplinarity (Frodeman & Mitcham, 2007; Klein, 2010). What this knowledge integration requires is a synthesis of theory and practice for finding solutions to complex problems or major sustainability challenges. In much of the literature, SS is articulated as a field concerned with problem-solving and overcoming challenges, not by single disciplines it employs (Clark, 2007; Jerneck et al., 2011, Wiek et al., 2011). New ways of integrating knowledge across the natural and social sciences and the two cross-cutting approaches of critical and problem solving research could be achieved by studying major sustainability challenges such as climate change, biodiversity loss; depletion of marine fish stocks, land degradation, water scarcity and global ill- health (Hotez et al., 2007; Broadhead & Howard, 2000; Cox, 1981). Next are opportunities posed by interdisciplinarity in SS.

Opportunity # 1: Interdisciplinary Knowledge Production

Knowledge production is seen as a driving engine of the current century society or knowledge society in general. As Frodeman (2011) puts it, 'the 20th century research university combined a Kantian belief in disciplinarity, a Humboldian commitment to linking research and education and academic autonomy; and a Cartesian allegiance to infinite knowledge production.' Blackstock and Carter (2007) viewed SS to be integrative for bridging disciplinary perspectives toward new understandings based on the creative interaction of multiple perspectives (p. 344). As an opportunity, SS gains from multiple forms of knowledge production and it is not simply interdisciplinary but engaged in conceptualizing why, how and by whom science is practised (Blackstock & Carter, 2007). While there are pressures upon traditional divisions of knowledge, increasingly what is sought is more crossing of disciplinary boundaries, collaboration and working in a variety of holistic and unified perspectives commonly labeled to be 'interdisciplinary' (Klein, 1990; Lele & Norgaard, 2005; Frodeman, 2011). With the limitations already identified in existing disciplinary structures and the potential of interdisciplinarity to enhance university research to adjust to changing demands and challenges, the need to examine SS and how it is linked

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

with interdisciplinarity is compelling. Of utmost significance is to place SS within the context not only of environmental sustainability but within sustainability science in future knowledge production. Over the last few decades, scholars have tried to address the question of interdisciplinarity as an 'object' of systematic inquiry', particularly in sustainability research (Schoolman et al., 2011). Linking interdisciplinarity to sustainability science requires a review of the nature of sustainability research and the academic programs being developed in the 21st century (Sanusi et al., 2013; Clark et al., 2011; Frodeman, 2011).

Opportunity # 2: Problem Solving of Sustainability Challenges

In past efforts to address complex questions, we turn to interdisciplinarity to tackle broad issues, solve problems beyond the scope of a single discipline and attain unity of knowledge, whether of limited or grand scale (Klein, 1990). A wide range of actors and sectors are attracted to interdisciplinarity with a goal for achieving key sustainability objectives and answering complex issues concerning the environment and development. Since anthropogenic influences in the world's life support systems are critically unprecedented in human history, it is recognized to address sustainability in 'interdisciplinary rather than disciplinary ways' (Jenerck et al., 2011). As Jerneck et al. (2011) asserts, an integrated approach (to research) involves different disciplinary perspectives and grounded in problem-solving and critical approaches where epistemological reflexivity is essential for successful interdisciplinary dialogue. As an important opportunity for problem-solving of major sustainability issues, this approach is critical to sustainability science in terms of research because the Earth's major problems from the perspectives of both the environment and development could not be solved by just one sector or discipline alone (Dale, 2004). Researchers like Kajikawa (2008) considered the triple aspects of economic growth, social well-being and natural systems for promoting interdisciplinarity in sustainability research which demands active interdisciplinary participation. Multi-stakeholder decision- making and pressing solutions to global issues like climate change and world poverty are inherently interdisciplinary and transdisciplinary in approach- the latter for making knowledge accessible to non-academic actors. As a problem-solving activity, it needs novel methods and techniques and expertise from people across disciplines and sectors from both the natural and social sciences. To move beyond a disciplinary social epistemology, academics and practitioners in interdisciplinary and sustainability work must recognize the inadequacies of the existing regime of knowledge because there is an unprecedented level of knowledge integration required to deal with pressing issues today. With traditional disciplinary boundaries, scholars argue that the academy without interdisciplinarity is too specialized, lacking societal relevance and lost the larger purpose of things (Frodeman, 2011).

Interdisciplinarity in sustainability science is relevant to the conduct of results evaluation in programs and projects concerned with sustainability- the evaluation of outputs, outcomes and impacts (OOI) called singly as results demand holistic, integrative and complex coordination of databases, methods of assessment and synthesis to arrive at a particular level of sustainability. The idea of interconnectedness and interrelationships is vital when doing sustainability research and sustainable development in the same way that interdisciplinarity is seen as an integration of theories, concepts and techniques from various bodies of knowledge (Schoolman et al., 2011; Rafols & Meyer, 2010). Even more important is the idea of applying approaches that are integrative of knowledge in terms of outputs, outcomes and impacts from sustainable development work. Analyzing their complex systems of phenomena requires an interdisciplinary inquiry and exchanges between and among fields as it has been demonstrated in academic publishing and record of collaborations across disciplines over time (Schoolman et al., 2011).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Opportunity # 3: Academic Program Development in Sustainability Science

The opportunity to develop Sustainability Science as an emerging new discipline is evident in academic and scientific circles worldwide (Komiyama & Takeuchi, 2006). The significant institutional momentum over the past few years in educational (scientific and academic) advancements in the US, Europe and Japan has been recognized and the interdisciplinary research style in SS has been examined (Clark, 2003; Kajikawa, 2008; Khagram et al., 2010; Clark et al., 2011; Wiek et al., 2011; Sanusi et al., 2013). With the growing number of academic programs in sustainability, especially Sustainability Science, there is a proliferation of international events, sustainability courses, growth in research and publications and academic societies on sustainability (Wiek, 2011; Bettencourt & Kaur, 2011; Sanusi et al., 2013). Primarily, the emergence of academic programs on sustainability is associated directly with the urgency of solving complex environmental issues and anthropogenic challenges (Kates et al., 2001; Komiyama & Takeuchi, 2006; Sarewitz & Kriebel, 2010). At the local level of cities, the contributions to publications is a key dimension of SS growth with evidence of collaboration networks, strong productivity and well-connected research centers with a global reach from Washington D.C to London, Tokyo, Canberra to Cape Town, South Africa (Bettencourt & Kaur, 2011). A few years ago, progress in SS is mirrored in the rise of undergraduate and graduate academic programs in sustainability and being a 'new discipline', this clearly indicates the promotion of SS at the university platform. Examples of such programs around the world can be found in the US from Arizona University to Harvard University; Lund University in Sweden; Maastricht University, The Netherlands; Technical University of Catalonia, Barcelona, Birmingham Initiative on Sustainability Sciences, UK; University of Tokyo and the United Nations University in Japan, and the Lakehead University in Orillia, Canada. In the US, the Sustainability Science Program at Harvard University's Kennedy School is the hub for teaching, research and interventions on sustainable Development (Sanusi et al., 2013). In Japan, there are several teaching and research centers on SS including:

- Center for Sustainability Science (Census), Hokkaido University,
- Ritsumeikan Research Center for Sustainability Science,
- Institute of Sustainability Science, Kyoto University,
- Institute for Sustainability Science, Osaka University,
- Graduate Program in Sustainability Science, University of Tokyo,
- Graduate Program on Sustainability Science, Ibaraki University,
- Institute of Advanced Study on Sustainability, United Nations University.

Apart from university-based initiatives in sustainability education and research at both national and smaller universities and laboratories, there are activities and programs carried out internationally by the UN agencies and non-governmental organizations level such as the United Nations mega-conferences, Decade for Education for Sustainable Development, UNESCO's science and sustainability activities and alliances (e.g., Alliance for Global Sustainability) and Academic Leadership for Sustainability by the Salzburg Academy (Sanusi et al., 2013). Already, scholars have noted efforts to provide useful knowledge for solving the very practical but highly complex problems such as climate change and often required fundamental advances in our conceptualization and understanding of coupled human-environment systems (Clark, 2006). At Harvard University's Center for International Development, their Sustainability Science Program has set out goals for advancing the 'basic understanding of the dynamics of human-environment

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

systems, to facilitate the design, implementation and evaluation of practical interventions that promote sustainability in particular places and contexts' (CID, 2010). There are other global initiatives in terms of policies, multi-party agreements, research networks from the Tailloires Declaration of Presidents for a Sustainable Future, to the Sustainable Development Solutions Network to the global-meta network led by the United Nations University concerning SS (Sanusi et al., 2013).

Opportunity # 4: Sustainability Science in Building Sustainable Communities

The exponential and extraordinary rise of SS in sustainability education, research and teaching brings more meaning at the community level since attention to sustainability in many places is about meeting the urgent human needs, improving quality of life and doing research on the complex dynamics of human-environment systems. In understanding the relationship between the environment and development for shaping nature-society interactions and applied problem-solving at the bottom level of governance, i.e., the community, the benefits gained from education, research, policy development and publications permeates different levels of development-national, regional and area and community. Regardless whether SS is a field, a 'new discipline' or scientific discipline, it is fast growing, and diverse that recently turned into a 'unified scientific practice' (Bettencourt & Kaur, 2011). At this point, an important opportunity is how SS can contribute toward shaping communities into 'sustainable communities' to ensure solutions to complex environmental issues such as water crises, land degradation and biodiversity loss. If one is to view SS from its role to promote applied problem-solving and education, the ultimate gains could be generated by such communities, whether in the developed or developing world.

The literature indicates there is no universal definition of 'sustainable communities' (Rogerson et al., 2011). From a local perspective, the dilemma is not the lack of, or absence of a definition but the variation in context and how a community is viewed. In the 1990s, an international social movement on community sustainability has emerged (Innes & Booher, 2000). The concept of 'sustainable communities' was used in Agenda 21 following the sustainable development model in the UK and elsewhere (UN (a), 1996; UN (b), 1998; ODPM, 2003). The tendency has been to move from its narrow focus of environmental sustainability in the 1960s towards a more holistic recognition of the environmental, social and economic principles of sustainability and the roles communities play (Agyeman, 2005; Marsden & Hines, 2008). Hempel (1998) defined it as a 'community with economic vitality, ecological integrity, civic democracy and social well-being to foster a high quality of life' (p. 48). In the past, sustainable communities are labeled in various ways- as green cities, eco-cities, sustainable cities, eco-communities and livable cities. They can be any type of neighbourhood, town, city or region. Past studies referred to the garden city movement (Howard, 1898); bio-regional planning and design (Geddes, 1915); spaceship Earth idea (Fuller, 1969); resilient ecological communities (Holling, 1973); and architectural visions of neoliberal towns and healthy cities (Van der Ryn & Cathorpe, 1993). From the nineteenth century to the present, progress in creating 'sustainable communities' has been deemed patchy and challenging even with the objective to transform a community into a place desirable to its residents with better (if not the highest) quality of life. The idea of 'sustainable communities' can be grouped into different types, including communities defined from the perspective of policy and planning, resource management, quality of life, integration of social, economic and environmental dimensions and local governance. Or, it could mean a community that is continually adjusting to meet the social and economic needs of its residents while preserving the local environment (Bridger & Luloff, 2001). The goal towards a better quality of life, maintenance of nature's ability to function overtime and revitalizing natural resources

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

are commonly applied and such communities represent the successful integration of four key objectives, namely: ecological integrity, economic security, high levels of quality of life and citizen empowerment. Roseland (1998) stressed the potential and economic dimensions of community sustainability relative to growth management, urban ecology and environmental planning. What a 'sustainable community' needs is an integrative approach to transforming communities through an interdisciplinary process of incorporating the goals and principles of environmental sustainability and a holistic planning system that considers the environment, the economy and society. These communities develop economically, socially and environmentally, respecting the needs of future generations succeeding now. The key is to find lasting, rather than temporary, solutions to major problems. Broadly, sustainability draws from three popularly cited 'pillars' of the environmental, economic and social sciences to articulate three positions. It can be argued that engaging in sustainability research must be more interdisciplinary than disciplinary and that the three pillars of interdisciplinarity require the active involvement of various disciplines to achieve sustainability in local areas, country, or region. As we experience an extraordinary growth of SS over the last few decades with an agenda of integration, scientific collaboration and a scenario beyond single disciplinary anchoring to connect knowledge and practice, the promise of sustainability from an interdisciplinary and community context is here.

CONCLUSION

Obtaining impetus from progress in current literature, this article placed interdisciplinarity in Sustainability Science through a parallel narrative and interpretative lens and considered the challenges and opportunities in SS facing the 21st century society. Having reached its momentum that could pave the way toward a sustainable society, the juxtaposition of interdisciplinarity with sustainability science is not simply an academic exercise that explores 'what interdisciplinarity is but adds to the conversation on what can be derived from the founding of SS whether it influences the creation of academic programs, build an intellectual enterprise on sustainability through research and publications, form professional associations, networks and so on. Arguably, interdisciplinarity is crucial to researching and teaching sustainability, whether in the developed or developing countries. With a revisit of interdisciplinarity and the roots of SS, the review essay found the profound gains from collaborative networks, scholarship exchanges, publications and research in efforts to find creative solutions to major environmental, economic, and social development issues- all valuable to enhance sustainability in our home planet called Earth. Overall, interdisciplinarity in Sustainability Science reflects a dynamic conjunction that may help to determine the direction, content and shape of local communities; provide a balanced and bright future concerning the economy, the environment and society. In the 21st century, the value of interdisciplinarity is not limited to the classroom and the substantive and substantial growth of Sustainability Science will stay as an intellectual phenomenon confronting some challenges yet offering more opportunities. Although the future of SS may not be contingent upon a generation who will live up to its interdisciplinary ideals in its entirety, the key is to push for collaboration, networking and building skills and research competencies to shape sustainable communities for tomorrow, today.

Chapter 6
Economics, Environmental Policy, Trade and Sustainability

Nilanjan Ghosh
Multi Commodity Exchange of India Limited, India

Anandajit Goswami
The Energy and Resources Institute, India

ABSTRACT

Sustainability has to be measured by different tools of valuation. Furthermore, the philosophy behind environmental policy making also decides the way sustainability is perceived and measured in a society. Moreover, in a growing globalized world, trade regimes and routes also impact the social, economic and environmental segments of sustainability of trade partners. This chapter makes an attempt to outline these notions to bring a larger clarity on the subject of sustainability.

Sustainability is a concept which is quite broad ended. It is because of this researchers working on the domain of sustainability can link it with economic, environment, governance and social aspects. Researchers from the discipline of economics trained particularly by the mode of neoclassical thinking often relate sustainability concept to the framework of valuation. According to this school, an essential tenet of sustainability has to deal with how to value the resources all around us. Valuation is done mostly through monetary accounting of these resources which gives the people a sense that any resource poses a certain value which is incommensurable. However this view can be contested. In a ways the origin of this kind of thinking can be traced back to a quote by Hicks (1946) when he said that:

The purpose of income calculations in practical affairs is to give people an indication of the amount which they can consume without impoverishing themselves.

But the world today has moved far forward than this and the principles of these income calculations from resources are widely contested now. But the objective of this chapter is not to elaborate on those debates: it will instead aim through to take the readers through some of these income accounting practices that are largely applied in measuring resources and in its further association to the concept of sustainability.

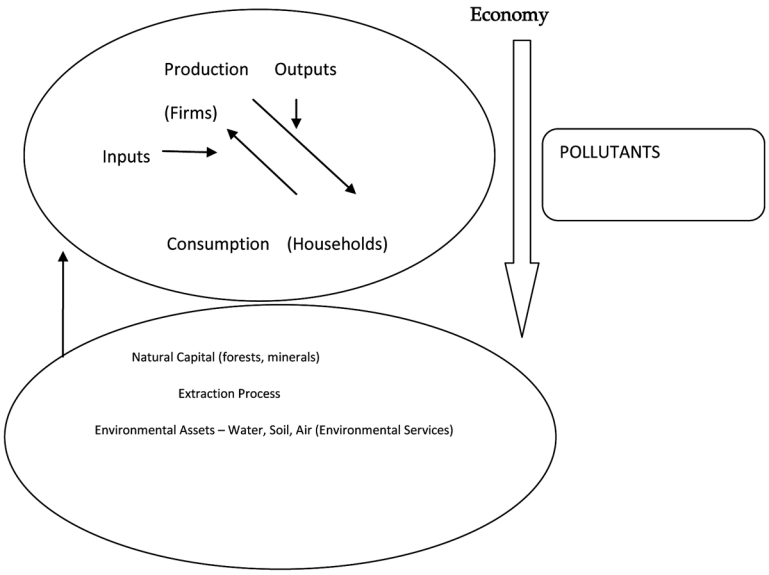
Therefore, the chapter first starts with some of the natural resource accounting practices and thereafter moves towards the broader context of international trade and sustainable development which also forms the essential blocks of sustainability. Trade and sustainability connections are observed because today the world has become integrated. Income streams of countries are coming through exports of goods and services. With the growing dependence of countries on each other and south south cooperation measures between developing countries, dependence of these countries (for whom sustainability concerns are extremely important in comparison to developed countries), it is essential to explore some of the facets of trade and sustainable development interlinkages to understand the future of these developing countries. The next sections of this chapter make an effort to take the reader through these facets.



NATURAL RESOURCE ACCOUNTING

Conventional SNRA (Systemic Natural Resource Accounting)

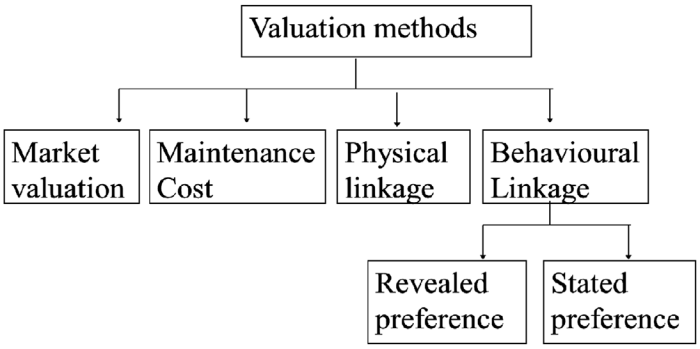
This system of accounting creates a statistical framework by which the total value of the final output produced across sectors of the economy is estimated and maintained. Further, in this framework, the details of distribution of the factor incomes producing such a value of an output is also provided along with the final expenditure made within the economy on a particular year. Thus within this framework an attempt is made to understand the effects of economic policy measures on different sectors, institutions and the factors involved in those sectors. Hence within this framework, households, firms will be interacting with each other in Figure 1.

But to understand this flow between each element of the economy, it is essential to value resources which flow across the firms and households. Thus, at this juncture it is essential to ask the fundamental question of why there is a need to value and account for natural resources (Hardin, 1968)?

Figure 1. Economy-environment interactions

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

There is a need to value resources because there is a need to understand the impact of economic growth on degradation of natural capital. In order to understand such a degradation it is essential to know the value of the natural capital. Developing countries which have started to grow late might not have the adjustment factors to understand the depreciation of natural capital. Moreover, value of natural resources are often not included within the national wealth. Neither are they assessed by indicators of environmental quality. Thus there is a major need to create and put in place proper frameworks to initiate valuation of resources within an economy. Such a valuation framework will have to imbibe the following measures:



VALUATION TECHNIQUES

The first step of the framework will have to deal with the preparation of physical accounts. Such a preparation will have to measure the extent of natural resource depletion and enhancement within the economy of the country. As a part of this, a value of the stock of minerals, forests, air, and water has to be assessed. Further, the extent of degradation of the value of such resources has to be measured. In order to do that a series of measures have to be implemented. Those measures will include – collection of data related to physical account of all natural and environmental resources. This has to be followed by a valuation of all these resources and further interlinkages between the economic, human development and the degradation of the value of these resources has to be done. Once this is done, the degradation of the value of these resources has to be reflected within the national income of the country. Such an adjustment has to come by reducing or adding the value of the natural resource degradation/upgradation to the national income of the country that has been generated owing to economic growth. Essential aspect of all these calculations is the creation of a physical account of the stock of natural and environmental resources. Changes in the stock will indicate the level of resource depletion and enhancement. In order to do that the following equation structure is followed which is:

Opening stock + Quantity changes (economic use/other reasons) = Closing stock

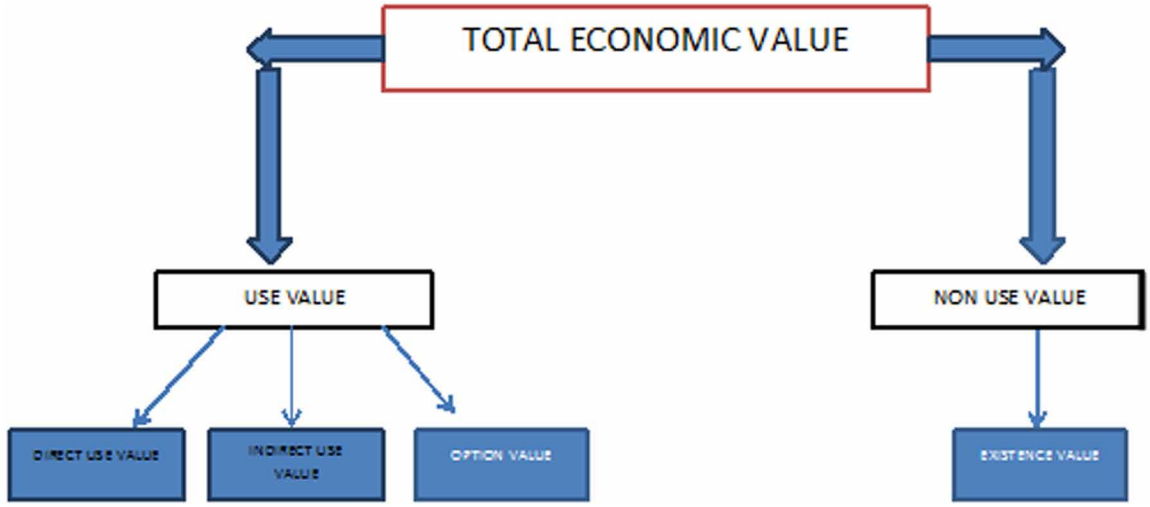
After the physical accounts are estimated, the value of such resources are estimated. Values of resources are estimated through the following techniques which are represented by the schematic structure in Figure 2.

Figure 2. Monetary valuation

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

While calculating the value of resources, the following overarching framework is kept in mind. Pictorial representation of the framework is given in Figure 3.

Hence the total economic value is a sum total of use and nonuse value. This use and non - use value are measured by using the following techniques:



Market Valuation

In the market valuation technique, all resources are visualized as non produced fixed assets. For valuing these non produced fixed assets, market prices used in the market transactions of non produced fixed assets are used as surrogate conversion factor to estimate the corresponding monetary value of such a non produced fixed asset. However, if market prices are not available then market price of similar assets which can be comparable to these assets are used. In monetary valuation exercise of these assets, the rental or lease value of assets play an important role. In order to value the resource, the prices of the extracted goods, service generated by these natural assets are estimated. Once such an estimation is done, the value is reduced by the cost or expense incurred to extract such an amount of resource. Then the total stream of value of the resource over its entire life time is calculated and a present discounted value of the resource is found out. These kinds of techniques are applied in the case of net price methods of estimating the value of resource which principally follows the below mentioned equation structure:

Net Price Method (Vt) = (pt – Ct) Rt (where Rt – Volume of proven reserve, pt – average market value per unit of the resource, Ct – per unit cost of extraction, development, exploration)

However, a net price method operates within a neoclassical framework and in many cases are far away from the complexities of resource degradation challenges faced by developing countries with abundant resources. This is because a net price method assumes that the price of natural resource in a perfectly competitive market rises at the rate of interest of alternative investment offsetting the discount

Figure 3. Definition of economic value Adapted from D. Pearce, et.al., Introduction to Environmental Economics, 1996

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

rate. Therefore it assumes that the price of natural resource is equivalent to the rate of return earned by the money put in to extract the resource when that money is put into a bank (Hotelling, 1931). The framework is reductionist as it assumes that the return given by a bank within a perfect competitive set up is the value of resources without internalizing the vast range of future impacts on the economy, ecology, society that are created by such a resource extraction process. Hence the value of the resource is explained by a rental value which is called as *Hotelling Rent and explained as – (pt – Ct) (where pt – average market value per unit of the resource, Ct – per unit cost of extraction)*

Another way of valuing the resources is through replacement cost based methods. In the replacement cost methods, value of the resource is based on the incremental annual unit cost of adding and replacing reserves into the reserve base. The other method of valuation of the resource is through depreciation method. In this depreciation method, difference in the value of the resource stock at the beginning and end period is taken as the value of the resource. The revenue from the sale of resources is also taken as the value of the resource. In this method, the revenue calculated is based on the present value of annual net revenues from the sale of resources considering the lifespan of the resource. One essential aspect of this discounting technique is the calculation of the discount factor which is generally based on the banking rate of return on any financial resources invested or kept in bank. Once the discount factor is calculated it is used in coming up with the discounted value of the income generated from the sale of resources after considering the life span of the resource. A similar approach is taken in user cost valuation method, where the net income from the revenues of the sale of an exhaustible resource is taken as the value of the resource (Devarajan & Fisher, 1981). In calculating the net income, investments made from the revenue arising from sale of resources is deducted. Discount rates after considering the life span of the resource is used to arrive at the net income. The income measures of resource valuation is based on realized income data and doesnot internalize the preference pattern of the people of society who depends or might depend on the resources.

In order to internalize the preference pattern within the valuation techniques, contingent valuation measures are used. Some aspects of such a valuation measures is highlighted below:

CONTINGENT VALUATION

In a contingent valuation technique, the people are asked specific questions on how they value a certain resource. As a part of these questions, the people are asked about their goals, aspirations, political causalities and how they impact the value of the resource. Many times, the people are also asked about how much they are willing to pay for consuming a certain amount of resource. Essentially, the users of the resource or who can be impacted from the degradation of the resource are given an alternative situation of the resource provision and thereafter they are asked to state a value that they are ready to pay for such an amount of resource. Sometimes the question that they are asked is as follows:

what is the most you are willing to pay for a certain amount of clean water? Or are you ready to incur a cost Rs. X for getting one bottle of clean water?

Within the questions a certain amount of monetary value is embedded and stated which is being asked to the respondents. The value comes from various relevant market prices. In case the value and cost number is not given and open ended question is asked, it can then result in an overvaluation and

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

undervaluation of the resource if the respondent is not well aware of the real tangible benefits of the existence of the resource. So it is always better to use closed questionnaire. Another technique that is used for valuing resources is called – "Hedonic Estimation Technique".

HEDONIC ESTIMATION TECHNIQUES

In hedonic estimation technique, questions are asked about how property prices can increase if a clean natural resource is provided. Thus using increase in property prices as a proxy, the incremental value of any resource (say trees, clean air) is calculated. Generally, these estimations are done through questionnaire based techniques.

Strong sustainability is determined by the preservation of today's resources without compromising the needs of future generation. In order to do that, it is critical to measure and value today's resources so that the importance of preserving it future is established. From that background principle, all these above valuation measures are carried out. Once they are valued they should be also reflected within the national income of the country. This therefore means that the net value of the resources owing to the economic growth path of a country should be reflected into the accounting exercise of the gross domestic product of a country. Once that is done it will give rise to green GDP. Thus by this way the natural accounting techniques will be integrated with the national income accounting and a recognition will be given to a sustainable growth i.e. a growth which not only takes into account of GDP but also reconciles the impact of such a growth process within the mainstream GDP oriented economic growth thinking.

Thus the integration process will involve the following measures:

Estimation of the value of gross domestic product (GDP), environmental service, environmental damage and defense expenditure. Once it is done the following measurement of a GDP should be worked out that takes into account of the environmental services and damages in the following manner:

gGDP = GDP + Environmental services - Environmental damages - Defensive expenditure

Once the gross domestic product is estimated, it should be followed by an estimation of the net domestic product in which the gross value of the domestic product will be reduced by consumption of fixed and natural capital. Thus from this estimation, net wealth generated from the economy of the country can be estimated. Net wealth of the economy will be a summation of

Net financial assets + Net man-made tangible assets + Net natural tangible assets

One aspect that has to be kept in mind is each of these elements that contribute to the net wealth can only be estimated if extensive data is available. All man made tangible assets, natural assets have to be valued using certain types of valuation techniques. Some of the challenges that can be faced with respect to the estimation are as follows:

- Availability of data,
- Disagreement over the appropriate unit of measurement,
- Disagreement on the rate of discount,

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Problems of aggregation,
- Treatment of defensive expenditure,
- Choice of method and comparability of results.

Measures coming out of the green GDP (g GDP) can guide the policy makers on how the country has performed in her growth path. Further that will indicate what value of environmental and natural resources are left for the future generation of a country. Essentially, valuation of the environmental and natural resources will indicate the need to take measures to create a sustainable growth path. Once these measures are provided by the planning commission or statisticians working with the central planner of a country, then specific measures and policy framework has to be laid out by the policy makers to address the sustainability concerns (that will be indicated by the numbers provided by statisticians).

However, the question is once these numbers are obtained by the planners, on what basis an environmental policy should be made.

Primarily, within the literature of environmental policy making two kind of theoretical principles are embedded. The principles follow either – a) Coasian or b) Pigovian stream or a c) mix of both.

Under the Coasian framework (Coase, 1960), an environmental pollution or a natural resource degradation happens at a decentralized level. So many times a centralized policy making and its implementation to tackle a decentralized environmental or natural resource degradation problem might not be feasible. Therefore, it is feasible and pragmatic to create property rights on natural and environmental resources. Once the rights are well developed, the negotiation to demand the environmental rights and tackling of the environmental challenges should be done through decentralized negotiation between the polluters and the people, communities who are or can be affected from such pollution. This will therefore help in reducing the transaction costs of implementing measures to address the environmental and natural resource degradation challenges in a big developing country with a lot of variations within the communities at the decentralized level (Ostrom, 1990).

The other framework is the Pigouvian school of thought in which the markets through direct, indirect taxes sends the signal to the polluters that they have to pay if they pollute. And their payment will be further distributed to the affected communities. In this framework, subsidies can also be given to clean technologies of production to create a sustainable production that can create a better a pollution free environment for future will less pollution and wastes.

In countries which have democracy with a wide diversity of culture amongst the local population and communities which are or can be affected by the challenges of environmental degradation and pollution, often determination and implementation of strong property rights can become a challenge (Baumol & Oates, 1960). When people within the community are also not well aware of their rights and future implications of any pollution on the community, then the Coasian stream of implementation might not be the right approach. Further, when the markets are distorted by fragmentation and information asymmetries are existing within the market, a Pigovian regime might not work in such a case.

It is with this background for certain specific situations and in certain context, a command and control regime through enforcement of law can be an alternative. Within India too, a command and control regime has been operational to address the challenges of environmental and natural resource degradation. A quick glimpse of the history in India suggests that within India, way back in 1972 a national committee of environmental planning and coordination was established. The 42nd constitution amendment act of 1976 had an article 48A which declared that the states have the right to protect and save environ-

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

ment. This in a way was a kind of Coasian framework, where the law was used to establish the right of protecting environment by the communities. *As a follow up to this, several legislations were passed which were - Clean Air Act 1970, Wild Life Act 1972, Water Act 1974, Forest Act 1981, Environment Act 1986*. Water Act of 1974 led to the formation of state and central pollution control boards. The duty of the state pollution control boards have been to regulate and oversee that the standards of pollutant concentrations in any production processes are maintained. Further audits of any production process is done by the Ministry of Environment and Forest. The view point was that public health should not be affected from any production process. Further a continuous reporting of these activities has to be done by the state pollution control boards to the central pollution control boards.

All these measures have a contribution in maintaining the environmental aspect of sustainability for a country like India. However, a larger review of the global literature shows that various instruments have been used across the world to maintain the environmental domain of sustainability. A tabular representation of the findings is stated in Figure 4.

Some of the tenets of the command and control measures with respect to emissions in India are mentioned below:

1. Source specific effluent and emission standards are valid for point sources of pollution,
2. Ambient concentration standards are developed for non point sources.

CPCB, SPCB are supposed to implement these standards as set by the legislations within India. Most of the times, the emission standards are of the following types:

Figure 4. Country specific measures

Country	Type of Measure	Facets	Implications
China	Preferential grid price for desulphurized power generation	Monitoring mechanisms in place	savings for the power industry due to lower pollution levy payments reduction in environmental damage from power generation
South Africa	a levy on water effluent as part of its evolving water pricing strategy largest emitters are taxed highly to create strong incentives to reduce effluent loads	Has cost recovery and revenue raising component tax/levy on effluent discharged to the environment	Reduction of effluent loads over a certain concentration
Thailand	retail (pump) price of unleaded gasoline 0.3 (USD 0.012) per litre less than that of leaded gasoline	government agencies, representatives of oil companies, and automobile manufacturers were involved in making this pricing strategy target dates for implementing key actions, and continual monitoring and follow-up evaluation	Reduction in use of leaded gasoline
Brazil, Chile, Ecuador, Venezuela, Netherlands, Thailand and Singapore	landfill tax, waste generation tax, waste treatment and disposal tax	waste management by urban bodies	Reduction in waste generation
OECD Countries			

Source - T E R I. 2011, Environmental Fiscal Reforms in India: Where and How? New Delhi: The Energy and Resources Institute. 184 pp. [Project Report No. 2009RD03]

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

1. Concentration based (suspended particulate matter not to exceed permissible limit),
2. Equipment based standard (for control of sulphur dioxide emission),
3. Load/ mass based standard (for industries like urea).

Thus in order to maintain sustainability, the legislations and acts have given power to CPCB, SPCB to examine the process. In case an industry is polluting, it has to obtain certificates from boards for production. Further, in case of non compliance, penalties will be imposed on the industry. Both the command control and market based instruments have certain advantages and challenges. Those advantages and challenges are outlined below:

Limitations of the Existing CAC Measures

- *Source specific standards dependent on technology or performance,*
- *No incentives to opt for cleaner abatement technologies,*
- *Penalties for noncompliance are unrelated to the compliance costs,*
- *Fines are not linked to quantity, quality of emissions,*
- *Problems in enforcing laws.*

MARKET BASED (ECONOMIC INSTRUMENTS)

Demerits

- Allow little flexibility: Tend to be high cost, ruling out variation in technology deployed.
- Freeze on development of technology; no incentives to exceed target pollution levels.
- Leakages due to bargaining between parties.

Merits

- Wide application across countries and sectors leading to substantial experience.
- Effective in implementation or attaining goals.
- Useful when environmental concern is highly damaging or irreversible.

ADVANTAGES OF ECONOMIC INSTRUMENTS

- Flexibility, market driven, Cost effectiveness.
- Revenue raising.
- Incentive for environmentally friendly behavior.
- Resource conservation.

Having laid to the advantages, challenges of the various environmental policies, an interconnection between such policies is attempted. The framework shown in Figure 5 is adapted from Sterner (2003).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 5. Types of environmental policies Source: Adapted from Sterner 2003

Using markets	Creating markets	Direct provision	Environmental regulations	Engaging the public
Environmental taxes and charges	Property rights and decentralization	NRM or waste management programmes managed by the government	Standards	Education/ awareness
User charges	Tradable permits and rights		Bans	Information disclosure
Subsidy reduction	International offset systems		Permits and quotas	
Deposit refund schemes			Zoning	
Targeted subsidies				

In the above sections, therefore an attempt is made on how valuation of resources contributes to environmental policy planning of a country which is a key to ensure the environmental domain of sustainability without compromising the needs of the future generation of a country. The implementation of the plan needs to have a strong basis of environmental policy. Further, the policy has to be implemented through legislations and market based instruments to address the environmental domain of sustainability. However, sustainability also has the domain of income. Emphasis and focus on the sustainability of any country has to ensure that enough income is generated for future generations and further they are distributed properly so that people at the marginal segments of a country earns income and gets money to live a healthy and happy life. One way, in which all countries in today's globalizing world earns income for herself is through the trade in goods and services. Merchandise trade in goods and trade in services gives a country net export revenue if the export revenue income is greater than the import outflows of the country. Thus a picture of sustainability will not be complete if the connections between "Trade and Sustainability" is shown for the developing and other countries which are following a path of growing income and development. Next few sections aim to bring forth such a connection between "Trade" and "Sustainability".

TRADE AND SUSTAINABILITY

The discussion on "Trade and Sustainability" often centres around the terms "Trade and Sustainable Development" It is because, sustainable development entails a development of a country that emphasizes on the need of balancing the economic, environment and social aspects, needs of a country. Sustainability

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

also highlights the same importance. Therefore, essentially a discussion on "Trade and Sustainability" is actually a debate on how "Trade" of a country can balance the environment, economic and societal needs which are critical in the development path of a country. Next sections, will subsequently attempt to explore these connections.

Within today's global perspective, trade and sustainable development discourse is put forward through the following focus lenses – a) how trade can be a catalyst to the economic growth of countries, b) how can trade lead to higher demand for better environmental amenities and services in the society which thereafter can affect the environmental policies and social welfare and finally c) how can trade impact social indicators like – employment, gender empowerment.

These intuitive relationships cater to environment, economy and social dimensions of sustainable development. All the subsequent sections aim to expand these interlinkages.

Section 1 starts with trade and environment aspects followed by trade and growth, trade and its effect on society in the subsequent sections 2 and 3.

Section 1: Trade and Environment

Debates on trade and environment came to forefront in 1971 and in the entire debate the ideology which was highlighted was trade between countries should not suffer owing to environmental concerns.

Discussions on trade and environment issues came to the forefront in 1971 (Industrial Pollution Control and International Trade by GATT). During this time, main concern was that trade should not suffer because of environmental concerns. However over time that discourse has got reversed and use of non tariff barriers for getting market access through environmental and health protection instrument has become common in many countries. Context of sustainable development entered into the trade regime through the exceptions article XX embedded within the GATT principles. These principles were mentioned in the original GATT text which mentioned the importance to be sensitive to the fact that trade should not happen between countries by impacting human, animal and plant health. Notion of sustainability and protection of human, plant life got introduced to the principles of trade negotiations. In order to substantiate and consolidate the principles by which trade should happen, a plurilateral standards code was developed in 1979. The standards code brought out the principle that no country can be prevented from taking measures to safeguard and protect plant, animal and human health. Though in the trade context, sustainability principles came in this way, the word sustainable development was coined during 1992 United Nations Conference on Environment and Development (UNCED) at the summit of Rio De Janeiro. Agenda 21 of the Rio Summit mentioned of an action programme for promotion of sustainable development. Parallely, there were ongoing discussions of Uruguay Round during 1986 – 1994 which overlapped with debates on sustainable development raised by UNCED. While all these were happening, subcommittee on Trade and Environment of the WTO preparatory committee picked up the view points on sustainable development. This was manifested in the preamble of WTO after the Uruguay round was concluded.

Thus, sustainability was legitimized within WTO through the paragraph 1 of WTO in 1994. It stated that expansion of trade in goods and services will balance the needs of sustainable development through carrying a global trade regime which will be sensitive to environmental protection. Paragraph 31 III legitimised that by suggesting the essence of reducing the tariff and non tariff barriers on environmental goods and services: though the definition of environmental goods and services has not still become clear even now. The definition of environmental goods and services has remained vague, open and it

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

has entailed a wide range of equipment and services that can "measure, prevent, limit and bring in corrective action to reduce environmental damage to water, soil, air and ecosystem. Therefore majority of these goods have spread across a wide range of sectors that include – architecture and design, consulting and management, chemicals. Owing to this large definitional ambit of these goods and services, it has been seen by developing countries as a ploy of developed countries to create market access of a wide range of their products. Many times, instead of sustainability being the main focus of concern, the trade negotiations in environmental goods and services have been loomed by market access interests of companies of developed countries which has been vehemently protested by the developing country groups.

Growing interest of the developed countries for environmental goods market can be buttressed by Figure 6.

Figure 6 highlights that most of the largest environmental corporations who are operating in the environmental goods market are from Germany, France, UK, US and Japan. U.S controls 33% of the global market of environmental goods and services which grew by more than 15% during 1996-2002, and was estimated at US $652 billion in 2005. Major part of the production of these goods are happening in the developed countries. In the last five years or so a saturation has started showing in the environmental goods market of developed countries whereas the market size and demand for these goods and services in the developing countries is gradually growing. The companies from developed countries have shown competitive edge in the production of environmental goods and services as they started innovation, production of these goods and services in mid 70s which finally matured by 90s. Developed countries were higher on the development ladder in comparison to the developing countries and therefore a conciousness, awareness and demand for these goods and services matured earlier in these countries in comparison to the developing countries. Formulation of stringent environmental standards and regulation and their

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

implementation within developed countries also led to the formation of a strong environmental goods and services industry within the developed countries. Countries of South, South East Asia and Asia Pacific started later and now since they are catching up the developed countries the market and demand for these environmental goods and services has started expanding. Role of environmental regulation and policies are also playing a key role in this market expansion of environmental goods and services within the developing countries. Some more analysis will be required over time to find out how the growing expansion of the market of environmental goods and services and the trade in such goods, services have contributed to the sustainability, sustainable development of the developing countries where signs of such expansions are being shown.

Historical trend and data shows that trade has created both mpositive and negative effects on the environmental aspect of sustainability. These impacts of trade on environment has been channelled through a) Scale effect, b) Structural effect (risk of pollution havens), c) Product and Technology effect and d) Regulatory effect.

Within the parlance of scale effect, as trade between two countries have expanded and grown, the size of the GDP of countries has increased leading to a rise in environmental pollution. In Structural Effects as trade has expanded between countries, polluting industries have been shifted to developing countries where the goods have been produced by generating pollution and wastes. The finished product has been further sent back to the developed countries. This has been evident for the leather and textile industry of India where the goods have been produced by environmentally polluting wet blue process and the product has been exported back to the developed countries for final value addition to convert it to a high value added good for consumption within the developed country market. Strutural effects have also been observed in large amount of FDI that has gone into energy intensive pollution generating industries (mining, quarrying, petroleum, coke, chemicals, chemical products, rubber, non metallic mineral products, metals and metal products) of developing countries. Table 1 shows that though FDI stock in the mining, quarrying, petroleum, coke, petroleum and nuclear fuel industries of developing countries has grown to a larger extent: the stock for chemicals, rubber, plastics, non metallic mineral, metal and metal products has grown to a larger extent in developed countries in comparison to the developing ones.

Table 1 indicates that FDI from developed countries have gone to energy intensive and pollution generating industries of mining, quarrying and petroleum industries of developing countries where resources are available and the cost of production and extraction of these resources are low. But in effect, these FDI s' have created local wastes and environmental externalities for local communities. The production and extraction process has not happened by means of a clean technology though trade theorists for a long time have been saying that trade in goods and services can create clean technology transfers from developed to developing countries and can help in the reduction of environmental pollution in developing countries. Regulations can be created guiding and protecting environmental and ecosystem resources that can be dampened from production of certain goods that are traded. Trade can help in protecting environment unlike the structural effect of trade where it has a negative effect on environment owing to trade between two countries. Moreover, trade is largely being done through shipping routes. Merchandise trade through shipping generates global bads like carbon emissions that can impinge upon the environmental domain of sustainability. Discussions all around are targeting the ways of reducing these emissions which are going to increase in the near future. The European Commission estimates suggests that by 2020, emissions from the shipping will be the highest contributor to the global carbon emissions within the category of transportation. Hence, trade expansion through the shipping route

can hurt the environment and global commons like a clean air and can hinder strong sustainability by creating adverse effects on future generation owing to today's actions. So the critical question which the world faces today is - 'it is possible to restrict trade without restricting development and balancing the needs of the environment, climate'?. This question is becoming more pertinent day by day as the global trade regime has moved more towards an – 'intra industry trade' regime in which countries are importing (leading to emission through shipping while the import happens) same type of goods with different varieties to cater to preference of a section of population though another variety of the same product is produced within the importing country itself. Hence even if India produces a particular type of apple, it will still import certain type of apple from New Zealand to cater to the needs, preferences of Indian consumers. Consumer demand and larger heterogeneity of preferences of consumers within a market are leading to the flourishing of the intra industry trade leading to emissions and hurting the environmental aspect of strong sustainability by effecting the future generations. Thus, consumption and variety preference of an individual and environmental implications of importing goods to meet those preferences are contradicting to each other viz. objective of trade promotion on one hand and the saving of emissions from trade promotion. Our future generation which are moving towards a consumerist lifestyle can create a larger demand for intra industry trade leading to an enhancement of these contradictions posing larger challenges to sustainability. To counter this, countries have to take a consensual decision on how they balance the lifestyle needs of the vast consumer segments with the fallouts that those demands can create on global commons like availability of a clean air. One way can be through taxing imports that create larger emissions and for which domestic substitutable goods are available by also creating safeguard mechanism so that such bans do not have any impact on the economy and society of the countries engaged in the trade relationship.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Next sections highlight the interlinkages between trade and growth, society that can have implications on the economic, social aspects of sustainability owing to trade.

Section 2: Trade and Growth

Trade can create income, growth and if that income can be distributed to the communities for their development then it can lead sustainable development (Dollar & Kraay, 2001). The classical theories suggest that comparative and absolute advantage acts as an incentive for countries to trade which thereafter can generate income for them and lead to development. Neoclassical trade theorists also pose similar views. But in today's world, trade is rather efficiency, scale economy driven and it has a strategic element into it. Any decision of trade is driven by a countries larger political and strategic framework of building up foreign relations. Factors like efficiency, scale economies, strategic aspects of foreign relations change over time and economic gains from trade can also vary over different points of the way a country moves along. It also depends on how the country positioned in the growing discourse of globalization and openness to trade. However, econometric studies have not been able to prove this hypothesis empirically. Studies by Dollar and Kray (2001)[1] shows that post 1980 globalizers and are developing countries have grown faster than non globalizers. In this study, globalizers have been defined as the top 30% of the countries in terms of their trade to GDP ratio between 1975 – 1995.

With respect to this definition, the non globalizers are actually more globalized with respect to trade to GDP ratio and tariff barriers. This perplexes us then what is the actual definition of a globalizer. Global history of trade shows that manufacturers from United States of America have enhanced tariff protection in goods produced by competitors from Europe though U.S never had any comparative advantage. This is quite in contrast to the theory of comparative advantage and the established theory of comparative advantage driven trade. Natural resources, consumer goods were always allowed in the United States market whereas in high tech technological goods like computers, aircraft United States maintained a monopoly and sustained their trade in these products. Thus, technology played a pivotal role in generating income through trade for United States and its final distribution to the people for their sustainable development. Thus many developed countries as early globalizers have not played a responsible role in instrumenting trade as a potential tool to create sustainable development of countries which are down in the ladder. This kind of action becomes more evident when one comes to know of the fact that today United States which is an early globalizer collects larger tariff revenue from Cambodia than Singapore which is higher in income ladder than Cambodia. United States buys more value of goods from United Kingdom than from Indonesia but Indonesian exporters pay more tariff revenue to United States than what Britain does. Similarly Bangladesh pays more to United States than Spain in terms of tariff revenue. These anomalies within the global trade regimes hint that anomalies exists and the trade regime is not in reality generating income and leading to its distribution in a fair way as ideally it should be as mentioned by the WTO principles. Moreover, the trade regime between developed and developing countries is not therefore leading to a larger generation and distribution of income to the developing countries to create equity between countries and promote future strong sustainability of these countries. Thus a lot needs to be done to create income, eradicate inequality and foster the development of society of developing countries which are engaged in trade with developed countries. However, before some concrete conclusions are made, it is a prerequisite to see what trade has done to the social elements of sustainability of some of the developing countries who are and will grapple with the challenges of strong sustainability

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

in future. The following section precisely attempts to do that by exploring the interlinkages of trade on society, inequality and trade in services and its effects on sustainable development.

Section 3: Trade and Its Effect on Society

Trade can impact on gender empowerment, livelihoods, inequality and employment which can contribute to its effect on the social aspect of sustainability. This is elucidated by Ghosh (2003)[2] who points out that in export-oriented manufacturing and semi-industrialized sectors of developing countries, trade liberalization and global outsourcing has led to a jump in women's share of paid employment[3]. Some of the South Asian countries have witnessed this phenomenon. In these countries, though owing to trade a restructuring of work force has happened leading to demand for labour from a woman, financial status and bargaining power of women for wage revisions has not improved. The bargaining power has not improved and women are expected to work in inferior conditions earning lower wages than male counterparts and more vulnerable to the risk of job losses[4]. Trade liberalization and increased commercialization of the agriculture sector has had an increased negative effect on women employment (Cagatay, 2001)[5]. One of the reasons behind this is particularly in South Asian countries, many women act as unpaid family workers, landless labourers or marginal farmers engaged in subsistence land farming (Joekes,1999). Another area through which trade has been aimed to address the social aspect of sustainability is through the Geographic Indications which comes under the WTO Agreement on Trade Related Aspects of Intellectual Property Rights (TRIPS).[6] Geographical Indication (GI) for a good is linked to the climate, geography of a particular region that gives it a special character leading it to earn a premium on such goods. Thus it is believed that if communities in such geographical locations are associated with production of such goods, they will also benefit from such a premium and it will contribute to their livelihood and development. Thus the first issued GI was for wines and spirits which was linked to the soil and geographical factors of a particular place in France. But since then the concept of GI has got diluted and now GI has been claimed for items like rice, tea, coffee, honey, handicrafts and even muga silk. Many of these products have no exact relation with the geographical route of the product but rather associated with a specific skill. If the premium earning is more linked to a particular skill then training and capacity building of the people might be required. In absence of that, even with traditional cultures, practices, some of the communities might not be able to earn the premium from these goods. Thus the possibility of communities earning a premium from these goods is conditional on in certain cases whether the communities have adequate skill to produce a good. This has no connection with the geographical specificity of a good. Therefore one could not say with surety that a geographical indication will always bring in a premium and larger earning for communities leading to their development. One essential facet to attain such a development is through reduction of inequality. The next section aims to explore the association between "Trade and Inequality" which can cater to the economic and social domain of sustainability.

TRADE AND INEQUALITY

In order to explore this association, the first question to ask is whether trade between two countries can bring a change in income distribution and can impact inequality. However, whether it will increase or decrease inequality is not substantially proven as there are views on both sides. Papers by Paul Krugman

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

throw some light on this fact. It suggests that way back in 1980s, there was a rise in inequality within the U.S. economy. This was because owing to a rise in trade, there was a high growth of import of labour intensive goods from low wage countries. There was a demand for exporting large skill intensive high end technological goods which created demand for high skilled labour. Wages of educated, skilled labour went up and a rise in inequality was observed between high and low skilled workers. The labour intensive goods were imported from developing countries and high end technological goods were exported which demanded high skills.

Thus there was a change in the relative price of the skilled and unskilled labour leading to a rise in inequality within the U.S. economy. But this is a story of a developed country. One has to ask what was the effect of such a trade on developing countries of South. Data[7] of North South trade during 1990s show that effect of such trade on inequality levels of trade partners was modest. Soon the shift of analysis switched to how trade created outsourcing of services in the developing countries and raised the levels of inequality in the developed countries with rise in income of educated skilled workers with a subsequent fall in the income of the less educated workers.

Therefore it is important to analyse whether trade in goods and services contributes to the social goals of inequality reduction, enhancement of quality of life and generates sustainable development for the trade partners. The next segment looks on how trade in certain important services like health and tourism can promote and generate sustainable development.

TRADE IN SERVICES AND SUSTAINABLE DEVELOPMENT

Sustainable development of a country can be affected through trade in services (e.g., health and tourism services) by bringing a change on employment and livelihoods of local community through trade.

Growth in tourism trade which is very common in many developing countries could have an impact on the sustainable development of local people by generating more income. For example, post 2003 tourist arrivals have gone up to a large extent in India owing to the incredible India campaign and driven by many proactive state policies. In this regard, Kerala, Rajasthan have played an active role in promoting tourism in their state.

Local communities have been tapped and engaged in promotion of local cultural heritages. They have been exposed to global tourists and revenue from tourists has trickled down to the communities leading to income earning of communities through state driven policies.

Similarly, trade in health service is important in Indian context. Many south-east Asian developing countries and some developed countries are engaged in this trade with a developing country like India. However does this mean that an enhanced trade in tourism sector, health services sector has led to an overall development of the people of India by improving their quality of living, life.

The picture is not so clear in many regards because one cannot say that trade in health services in India has improved the basic quality of life indicators of the people of India. It gets validated when we observe that though Kerala performs well in terms of Infant Mortality Rate (14), many large states of India like U.P, Madhya Pradesh, performs ridiculously in IMR (Infant Mortality Rates) indicators.

U.P in 2000 accounted for 20% of the infant deaths. This picture is true although India's trade in tourism and health services have gone up. In 2002, India earned more than US $ 60 million exporting IT enabled services for the health sectors in developed countries. Most of the trade gains have occurred in medical billing and transcription. During 1998 – 2006, India was amongst the highest recipients of

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

H1A and H1B visas in U.S. Large outflow of health professionals from India has taken place due to pull factors of wage differentials, infrastructural conditions and push factors like lack of recognition.

But at the backdrop of all this, basic needs of access of common people of India to doctors is an unresolved issue although trade in health services has increased. According to Adkoli[8] (2006) there has been one Indian doctor for every 1325 Americans in U.S whereas it has been one Indian doctor for every 2400 Indians in India. So although trade has improved in health and tourism services, it still questionable that how far such trade gains have resulted in improvement of sustainable development of people of India by bring better quality of life for them.

CONCLUSION

Thus this chapter leaves us with a question of whether at the backdrop of globalization, trade can bring in better quality of life for future generation. However, it brings out clearly the role of an environmental policy in ensuring better quality of life. A sound environmental policy can address myriad of environmental challenges that can be faced at a decentralized local level in a vast country with large cultural differences. In order to come up with a sound environmental policy, there is a need to find out and assess the value of the natural resources as much as possible as not all values like the biodiversity, cultural and aesthetics value associated with certain natural resources might not be assessed. These valuation can be done through the means of various techniques that were mentioned in this chapter. In a way, all these techniques should show how the country is creating a footprint on natural resources. Once this is done it can indicate how the country is performing in terms of its impact on sustainability. Further, another channel through which this impact can happen is by means of trade.

Trade can impact the social, environment and economic domains of sustainability within the developing countries though in today's context negotiations on trade has seen a conflict between the developed and developing countries. While, the developed countries are pushing the trade agenda in specific products and sectors mostly with a market access philosophy, often their interests have gone against and have been pushed in a way which hamper the social, economic and environmental aspects of these developing countries. The more the world becomes integrated, globalized these concerns will increase. It is therefore, important for the developing countries to have strong domestic environmental policies and governance regimes which protect the sustainability needs of these countries even when the countries open up in terms of trade. In order to address the future needs of these developing countries it will be imperative to take these measures. Only then, the vision of strong sustainability will be attained and realized by these countries in the long run.

Chapter 7
Role of HRM in Sustainable Organisational Development

Fawzy Soliman
University of Technology Sydney, Australia

ABSTRACT

This chapter explores the role Human Resource Management plays to support sustainable organisation development by controlling and managing valuable resources including employees of the organisation. The chapter presents the concept of sustainable organisation development as vital and important requirement to survive the competition in the current financial era. This chapter explains that sustainable development could enable organisations to overcome current market problems as well as achieve their goals. The chapter proposes that HRM can play a crucial role in developing strategic leadership and management capabilities and thus promote economic, social and environmental forms of sustainable development.

INTRODUCTION

Sustainability from the environmental point of view is seen as activities that are friendly to the environments (BusinessDictionary.com 2014). Sustainable development means that organisations have to capable to create a development and able to keep it as on-going or continues process. Sustainable organisations have to be able to create development that will meet the current demands, without diminishing future opportunities to fulfil their needs (Vollenbroek, 2002).

Recent, high economic growth and fluctuating market conditions may lead to a complex working situation. This means the role of human resource management HRM need to find solutions to the questions of: How to deal with relationships between and with employees? and how to manage the firm's sustainable development?

This chapter explains the key responsibilities of HRM and in particular the critical role of HRM in organizational sustainable development. Organisations could formulate their creative strategies in order to act more effectively and efficiently in their operations (Zandee, 2011).

Sustainable organisational development definitions appear to be associated with the relationship between organisation, society and environment. Spooner and Kaine (2010) describe sustainability in businesses as the 'triple bottom line (TBL)', where economic, social and environmental issues are integrated.

Sustainability of an organisation has traditionally been viewed as the three E's being Economic, Environment and Equity. New definitions include the three P's being people, profit, and planet. According to Bowersox, et al (2013) "organisational sustainability can ultimately be refined into the following four dimensions being environmental, social, education, and economic."

1. Environmental Sustainability

Environmental sustainability includes conservation, usage reduction, and efficient business practices (Bowersox, et al 2013). It is noted that public's awareness of environmental issues has been recognized earlier by Drumwright (1994) who proposed that "The deterioration of the environment over recent decades has drastically increased the public's awareness of environmental issues". This type of awareness can either help or hinder a firm's position in the market depending on the firm's ability to manage potential environmental impacts within their functions. This view was also supported by Elkington (1998), who argued that "If we fail to address the wider political, social and ethical issues, the backlash will inevitably undermine progress in the environmental area". In addition, Porter and Linde (1995) also noted "Greening the supply chain can save resources, eliminate or reduce waste, and improve productivity and competitive advantage at the same time". Other scholars such as Bowersox et al. (2013 pp. 403) argue "There is growing belief that under specific circumstances, firms can increase their profits by adopting environmentally sustainable practices".

2. Social Sustainability

Traditionally social sustainability has received less corporate attention compared to environmental issues. In recent times Corporate Social Responsibility (CSR) has emerged as a tool for addressing ethical sustainability include employee relations, community involvement, and ethical business practices (Bowersox, et al 2013). Social sustainability is the economic, legal, ethical, and other expectations that society has of organisations at a given point in time. According to Elkington (1998 pp. 85), "the degree of trust between a corporation or industry and their external stakeholders is likely to be a key factor determining their long-term sustainability". This is particularly pertinent to a firm's ability to operate in a socially sustainable manner, however, following global headline-grabbing events such as the 2012 Bangladesh garment factory tragedy that drew major attention to well-known brands and the extent to which they were, or were not, managing their business in a socially sustainable way. Elkington (1998) highlights that social issues are so relevant to the firm's survival regardless of its position within the value stream (either from a customer or supplier perspective).

3. Economic Sustainability

There are two elements relevant to economic sustainability; namely internal management and external management. However, economic sustainability can be viewed as "The ability of desired performance to be maintained over time" (Bowersox et al. 2013 pp. 48). According to Min and Galle 2001 (p 1222-1238) "Cost concerns are the most serious obstacle for taking environmental factors into account in

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

the purchasing process". This demonstrates that firms may prioritise economic performance over environmental performance if the cost of sustainability is prohibitive to pursue. Therefore firms can't be considered truly sustainable in according with the triple bottom line theory if such trade-offs amongst sustainability measures creates an imbalance.

4. Educational Sustainability

Educational sustainability aims at ensuring the workforce is properly trained. Educational sustainability could prepare staff for an effective succession plans by ensuring the workforce is able to replace departing employees in the future. Approaches to addressing educational sustainability include employee relations, talent development, and collaboration with the supply chain (Bowersox, et al 2013).

BENEFITS OF ORGANISATIONAL SUSTAINABILITY

According to Perrot (2014), the key benefits as a result of being involved in sustainability actions may be:

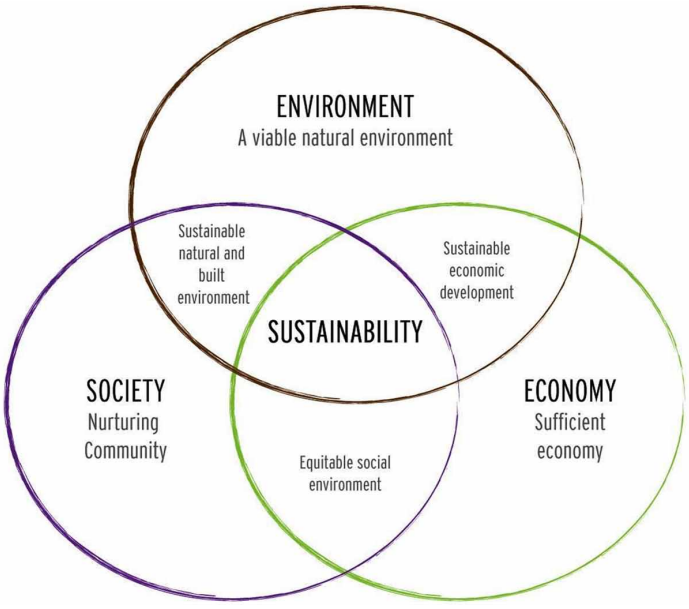
- Improved organisational reputation and image;
- Cost savings;
- Competitive advantage;
- Employee satisfaction, morale and retention;
- Innovation;
- New sources of revenue or cash flow;
- Effective risk management; and
- Enhanced stakeholder relations.

Additional benefits lies in performance improvement under sustainability programs. To address the extent to which firm performance improvement could be affected by sustainability, it is important to view the firm's sustainability from one single dimension, i.e. either economic or environmental perspectives. This approach is supported by Elkington (1998) who noted, "*Companies aiming for sustainability need to perform not against a single, financial bottom line but against all the triple bottom line*". Therefore, argument is provided that interdependence exists amongst the triple-bottom-line dimensions of economic, social and environmental sustainability, and that one-dimensional approaches to sustainability, i.e. an approach that focuses on environmental parameters disconnected from other social concerns, can be counterproductive to overall sustainability goals. (Matos and Hall 2007, p. 1087).

Further work by Zandee (2011) suggests that the organisational development in the context of sustainability could be divided into three main segments:

1. The first segment integrates the shared value of business and society.
2. The second segment looks at the application of organisational internal continuous improvement.
3. The third segment deals with organisational sensitivity in terms of sustainability of the organisation and its environment.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use



The earlier work by Gladwin et al. (1995) focused more on human development by introducing the term 'sustaincentrism' as an effort to attain human progress in an inclusive, affiliated, equitable, prudent, and secure manner. Therefore, human resource management may be considered as an organisational driver with a special role to achieve sustainable organisational development.

The significance of sustainable developments has growing rapidly in response to growing national and international concern about protecting the environment (Avery, 2005; Elkington, 2004). Since the Kyoto Protocol, environmental sustainability has gained worldwide attention. However the society and business community are now more concerned with the impact of environmental issues. Even the investment community interest in tracking sustainability related performance of firms has increased. That is why many global organisations are now re-strategizing for sustainability against the *Triple Bottom Line* (TBL) standards (Spooner and Kaine, 2010). As such, multi-national organisations have increasingly started to shift focus from economic and organisational growth to sustainable and balanced practices (Ardichvili, 2012).The following diagram (Figure 1) illustrates the relationship between environmental protection, social fairness and cohesion and economic prosperity.

Building a Sustainable Organisation

Building a sustainable organisation involves overcoming a number of challenges. Some of these challenges are due to the complexity in applying social sustainability in global organisations. In such case the organisational development need to address issues of social, environmental and sustainability reporting, as an extension of the financial reporting model as prospective source of "value creation" is the challenge faced by global and local organisations (Gray 2007). The building of sustainable organisation requires developing a number of appropriate strategies that embed sustainability in all or most of its processes.

Figure 1. Relationship between environmental protection, social fairness and cohesion and economic prosperity (Torugsa et al, 2012)

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

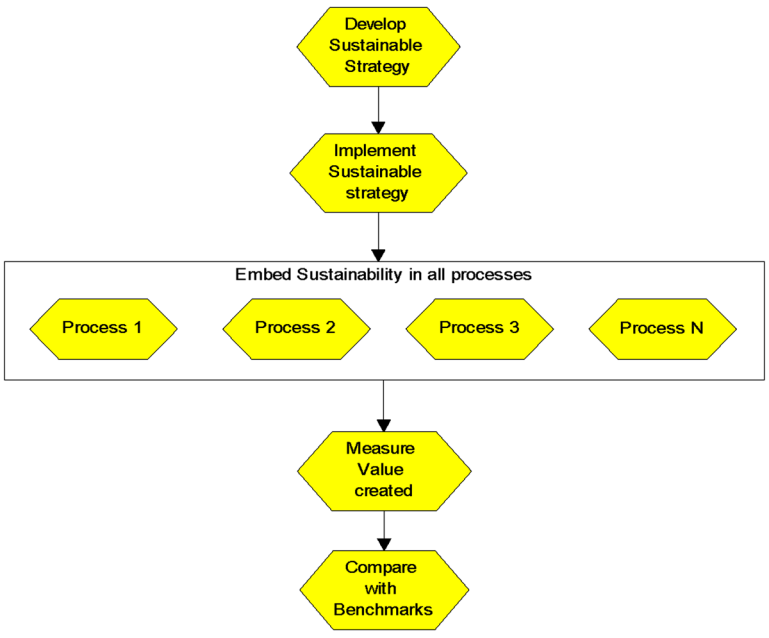


Figure 2, developed after Klettner, Clarke, and Boersma (2014), clearly illustrates that the process incorporates social responsibility and organisational development into the core business processes

Strategic Role of HRM in Sustainable Organisational Development

Corporate and environment sustainability can be attained through sustainability of human resources in current competitive environment. HRM has a prime role to play in adopting organisational development sustainability. This approach require strategically investing in employees who can offer the potential to develop a competitive advantage which eventually leads to long term sustainability of the organisation. Hence a strong focus is needed to build human resources and capabilities by implementing strategies to develop skills in them for long term.

HRM could face complex task in making sure that there will be appropriate staff within the firm to drive the sustainable development. Therefore, one of the HRM main responsibilities is to make sure that the organisation employs the right candidates to run the business. A number of scholars such as Mabey *et al.* (1998), Ellinger *et al.* (2002), and Soliman and Spooner (2000) emphasised the HRM role in their stamen "*employees are the organisation's internal sources that could create a sustainable competitive advantage for the organisation*". In other words, failure to recognise the value of human resource could lead the business into an unfortunate situation. To avoid being in this situation, HRM may have to fully understand the current employees' ability to drive the sustainable development. Therefore the organisation should conduct thorough evaluation regularly. Evaluation managers could also learn reasons behind any decline in the employee's ability to drive the sustainable development. Soliman (2011a) emphasized the critical role of the leader to drive the innovation. Similarly leadership to drive the sustainable development need to be effective leadership for transformation into a truly sustainable organisation.

Figure 2. Building a sustainable business

Leadership for Strategic Transformation into Sustainable Organisational Development

Strong and effective leadership is required when undertaking transformation to sustainable organisation. Change is usually associated with some form of resistance. The degree and strength of this resistance will be dependent on the leaders driving the change, and managing the implementation of sustainable programs.

Graetz (2000) describes instrumental and charismatic leaders are those that can inspire a shared vision and personally communicate the future with clear and honest answers to the what, why and how questions. Not only must the goals be emotionally compelling to all employees but they must know how they will contribute to achieving those goals (Soliman, 2011b).

Identifying sustainability issues is usually the first step to undertake by the leadership. This may require consulting widely across the organisation and investigating how these limiting factors are effecting each business function will enable leaders tailor and implement changes that have the greatest value to all those involved. The transformational leadership also has the task of ensuring that the goals related to sustainability can be accommodated into the HRM strategies (Barton et al 2000). The infrastructure should support learning, sharing, and knowledge management. HRM can contribute towards this by focussing on four key areas:

1. **Policy and Procedures:** HRM need to execute a new set of roles as knowledge facilitator, human capital steward, and a builder of sustainable development (Lengnick-Hall and Lengnick-Hall, 2003). This role facilitates learning and development, creating environment which supports knowledge creation, sharing and dissemination. These roles should complement an organisations sustainable development process by enhancing their ability to work across different organisational, national and international boundaries; helping employees to demonstrate their skills in problem solving across environmental, socio-political, technical and economic factors and enable staff and employees to demonstrate and replicate self-renewing behaviour.
2. **Employees-Management Relationships:** HRM can contribute towards creating a better environment by building relationships with managers, employees, customers, suppliers and distributors and linking them more directly towards the organisation's value creating process (Ulrich and Smallwood, 2003). A positive relationship building role by HRM should empower employees by helping them to think across boundaries, work across expanded markets and value chains, form and establish new relationships, demonstrate outstanding communication skills, become adaptive and flexible to restructuring and dynamic changes and sustainable development.
3. **Competence Development:** HRM should recognise and direct intellectual employees towards developing a compact set of key strengths, capabilities and competencies (MacDonald, 2003). Along with long range planning and long term strategy development, HRM should also develop a short term strategic approach to address the dynamic environmental problems. In addition to this short term strategy, firms also need to think about constant renewal and revitalisation for long-term sustainability. Thus HRM can create and develop capabilities that can generate wealth by investing in this intellectual capital and maintain an allegiance to sustainable imperatives.
4. **Learning:** HRM can significantly contribute towards sustainability by strongly emphasising on developing employees to achieve organisational sustainable development change. Employees' collective knowledge provides a useful tool for the HRM function to sustain organisational development

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

by directing towards capturing, using and re-using employees knowledge (Soliman and Spooner, 2000). HRM can serve in building quality, creativity, problem solving skills and employee development (Yahya and Goh, 2002) and thus play a pivotal role in nurturing and sustaining learning focus by identifying sources of employee knowledge, facilitate continuous learning, and by developing an understanding of the mediators who facilitate sharing of knowledge and make the information available to employees (Soliman, 2011c).

THE SUSTAINABLE DEVELOPMENT LEADERSHIP FACTOR

Leadership has always been the key factor for any firm in its success and competitive advantage as different attributes of leadership help in increasing the firm performance (Soliman, 2011a). The perspective of leadership has been changed and the new theories emphasize the relationship-oriented view which reflects both the leader and the follower. It also acknowledges that followers may influence leader decision making (Kouzes & Posner, 2004). There are different theories which describe the leadership characteristics but actually it's a process through which individuals or groups should get influenced and achieve goals in their respective work domain. Moreover, leader is the person who shows a vision of future and the path to achieve that vision when targeting a set of shared goals (Hogg et al., 2003). The theories related to leadership are generally describe the role of leader as an individual which is helping the society or organization in leading in different areas such as sustainable organisational development (Bowersox & Closs, 1996; Lambert et al., 1998a, b).

Transformation Leadership and Sustainable Organisational Development

Transformational leadership is the form of leadership in which leader transform the follower's moral and gives motivation through various mechanisms (Soliman, 2014). Doing this the performance of the followers is increased to the level which was not expected if there would not have been the influence of transformational leadership. Transformational and transactional leadership styles are contrary to each other. Transactional leaders doesn't aspire for changes in the system and also do not develop long term relationship rather they try to control their followers behaviour by giving rewards against performance for which the goals have been set by the leader. There are three behaviour patterns which is always visible with the transformational leadership (Avolio et al., 1999; Hater & Bass, 1988; Howell & Avolio, 1993):

1. Inspiration in which leader articulate a clear vision that shows a path of attaining that vision and set sustainable development measures assist in achieving a desired future.
2. Intellectual stimulation in which leader motivates his followers in creating something innovative and creative which should solve complex sustainable organisational development and various business problems.
3. Individualized consideration in which leader see what kind of training is require for the followers to increase their skill and show how to utilize the skills of followers in the correct way.

Transformational sustainable development leader tend to have clear purpose and mission. The followers and the leader have a shared set of values which is established between them which fives a sense of purpose. Leaders articulate a vision which gives a clear indication of improved sustainable organisational

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

development in the future also depicts as an inspirational behaviour. The new ideas needed for the sustainable organisational development are usually created and implemented by the staff of the firm. Sustainable organisational development leaders usually know that the followers are having different skill set and that not every follower in the organization is skilled and that some may need training to upgrade their skill.

According to Chaleff (2003) and Kelley (2004), there are four key behaviours that describe the domain of transformational followership. These key behaviours are:

1. Critical Thinking,
2. Assuming Responsibility,
3. Collaboration, and
4. Commitment to Organizational Success.

The above key behaviours could make followers to behave in a transformational style. Transformational sustainable organisational development followers use their skills to think critically in bringing better changes in the inter-organizational process. They could be pro-active in taking responsibilities to make the sustainable development process successful.

They are usually highly commitment to creating strong relationships with sustainable organisational development leaders and also with other members of the organization. Once the leader set the goal, the followers follow the directions and aligned their goals with it.

Strategies for Implementing Sustainable Organisational Development

HRM needs to address and facilitate the strategy for sustainable organisational development from three Perspectives:

1. **Rationale Perspective:** HRM needs to address and facilitate the human component of through:
   a. Gaining employee commitment by clarifying corporate motivation and sustainability involvement.
   b. Educating Top management on the business implications of sustainability. HR team can be instrumental by creating commitment and developing awareness in the top management team.
   c. Establishing roles sustainability champions (Lee Scott at Wal-Mart).
   d. Accommodating regulatory changes (Kyoto Protocol);
   e. Supporting these sustainability causes in their role as supervisors.
2. **Conceptual Framework Perspectives:** A conceptual framework helps organisations set up a sustainable model which fits its strategy by focusing and limiting perception and actions. HR professional by working with top management can simplify their scheme on sustainability which eradicates any ideological views and preconceived notions. HR can also create sustainable teams by developing a mental model which can increase the effectiveness (Rentsch and Klimoski, 2001). The values ingrained in this guiding model should be in sync with the values of the firm's culture. For example, a new CEO would face roadblock if he attempts to promote TBL strategy in an established organisation which focus exclusively on increasing stakeholder's value. HRM can contribute here by building a culture which not only fits but also nurtures the sustainability efforts of an organisation.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

3. **Directional Perspective:** The HR team can contribute by leading, coaching and advising. The advisory roles should help the top managers to decide the best employee who fits to lead the role of sustainability and where this function should be housed in the organisation's structure. The next role would be to serve as advisors to the selected leader and allow him to frame his own team from the respective functionalities and thus promote collaboration (Osland, 1994).They also need to ensure that leaders and cross-functional teams have the desired set of skills, change management techniques and global leadership training programs if they are needed to deal with cross-country efforts.

According to Ulrich cited in Brewster et al. (2011), "To create a sustainable organisational development, the role of HRM should be able to reflect the following five points in its strategy":

1. HRM needs to be able to travel with constant speed and dexterity into the market in order to control and foresee the changes. This can be achieved by eliminating bureaucratic processes of governance to enable rapid decision making and removing unnecessary processes.
2. HRM needs to create a brand for the organisation firm in order to attract consumer and other associated brand. The reputation and identity of the firm is depends on employees' actions and organisation human resource policies, experienced by two dimensions of reputation such as customers and investors."
3. HRM should serve as a customer interface to analyse data on consumer behaviour, needs and business processes as a feedback of performance management.
4. The company must have talented staff with superior competence and commitment. This not only makes the company an attractive workplace to the current staff but also helps other employees or prospective staff to dedicate energy into the company's performance.
5. Empowering innovation and learning. Companies should create and support a culture of inquisitiveness and innovation. Staff should be encouraged to be innovative.

Other areas that need attention include resource allocations and assigning accountability. Employees need to be well equipped, information required needs to be made available the network should be connected. Employees need to be empowered by means of assigning accountability. This helps create environment where employees feel they own the company and hence perform to their best capacity and ability. It should be noted that the process of sustainable organisational development also leads to enchaining the corporate memory in relation to sustainability (Soliman, 2014). This in turn should support the ability of the organisation to be a *Learning Organisation*.

Role of "Learning Organisation" in the Sustainable Development

The transition into a sustainable organisation could change the role that learning and knowledge management play within an organisation and between organisations comprising the supply chain. An increasing number of organisations are transforming from traditional knowledge monopolies to networks characterised by an increasing degree of interdependency and knowledge sharing and learning organisation. In addition the transformation into sustainable organisation may add further complexity in managing the sustainability knowledge and in turn the may lead difficulties in pursing the learning organisation concept.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Given that the ability to continuously adapt to a changing business environment and remain competitive depends on the willingness of all partners, it becomes a requirement that firms should be committed to implement holistic knowledge management and learning concepts across the entire firm.

The "Sustainable Learning Organisation" Concept

The concept of a learning organisation has been the subject of extensive research and debate since early 1990s and has its roots in the studies related to organisational learning in the 1960-1970s (Yeo, 2005). The "learning organisation" represents an entity that continuously learns and transforms, while "organisational learning" refers to a process of developing learning in organisations (Yeo 2005).

There have been numerous attempts to define a learning organisation (Peterson, 2002). Senge (2000) describes learning organisations as organisations that have developed knowledge management systems enabling them to constantly adapt to the changing environment based on learning particularly about sustainability. Seemann et al. (2000, p. 92) propose that learning organisations are characterised by "explicit management efforts to build intellectual capital in support of the firm's strategy". The implementation of the learning organisation concept is considered as enhancing the intellectual capital of the firm that contains both tacit and explicit knowledge of employees about sustainability.

As knowledge acquired by individuals often stays with them, the individuals are the learning entities (Örtenblad, 2001). Thus, the success of organisational learning is contingent upon the collective cognitive processes of individuals and requires personal capability and a supportive organisational culture that is characterised by commitment, trust and co-operation. What is expected of effective organisational learning is an observable shift in the extent to which individual behaviour, attitudes, knowledge base and specific skills change to meet organisational sustainability goals.

Effective knowledge management and organisational learning are considered crucial for developing a sustainable competitive advantage for an organisation (Skyrme, 2000). Organisations that have control over their knowledge or intellectual capital are widely considered to be more capable of responding to market threats and opportunities effectively and efficiently (Peterson, 2002).

Integration of Knowledge Management and Sustainability

The effectiveness of integration with sustainability in the organisation is dependent on the degree and the timeliness of information sharing between the sustainability participants (Soliman, 2013). It is therefore critical that sustainability participants extend their internal knowledge management systems and processes to include external entities and customers. This task requires an organisation to consider all knowledge-based systems that exist and to comprehensively map their knowledge management chain and its critical elements to ensure the required knowledge can be created, captured, organised, accessed and used in an effective and efficient manner (Soliman & Spooner, 2000).

Maqsood et al. (2007) argue that embedding the principles of knowledge management throughout the entire firm could facilitate sustainability and provide substantial competitive advantage. This requires the organisation to work collaboratively to develop a combined knowledge strategy that supports the idea of acting as an integrated entity rather than acting as separate participant. Such a knowledge strategy should aim at reducing fragmentation and adversarial relationships that may exist between participants in order to improve the overall productivity of the firm. Implementation of cloud system has shown to

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

be a factor assisting this strategy (Soliman, 2014). Thus integrating the cloud system with the process of developing the sustainable organisation may lead to benefits as discussed below.

According to Bowersox, et al (2008, p. 7), information, product, services, financial and knowledge these are the five critical flow of sustainable organisational development where value result come from. Such values are economic value, market value and relevance value. According to Baily, et al. (2008, p 18), value needs to be expressed in terms of total lifetime costs not "sticker" price, should consider possible business productivity and performance improvement and take into account potential value from areas such as:

- Innovation & Preferential Access to New Technology.
- Service, Responsiveness and Delivery.
- Quality.
- OH & S Related Improvements.
- Risk Reduction / Management / Avoidance.

Benefits of Integrating Sustainability with Other Functions

The benefits of integrating sustainability with other functions, such as increased responsiveness, inventory reduction, shorter product development cycles and lower transactional costs, could enhance the concept of the learning organisation with integrated sustainability practices (Peterson, 2002). A firm that exhibits high levels of trust and commitment between its participants in terms of sustainability knowledge creation and sustainability knowledge sharing can be seen as a "sustainable learning firm". Peterson (2002, p. 1331) defines a sustainable learning firm as an "integrated firm that has an added dynamic, agile ability to learn from and respond to changing market environments". Similarly, Mason-Jones & Towill (1999) argued the key distinction of sustainable learning firm is the capacity to simultaneously feed the end-user or market information to all participants through highly effective knowledge transfer mechanisms and tight co-ordination of information flows.

One of the key pre-requisites and benefits of sustainable learning firm is the fair distribution of returns among participants underpinned by reciprocal relationships and well-designed incentive structures (Peterson 2002). A fair distribution of returns from knowledge co-creation and sharing activities must be supported by an appropriate incentive scheme. Such an incentive scheme should take into account risks faced by each supply chain participant and provide each with an adequate and competitive reward for contribution to collective knowledge management.

Organisations aiming at embedding learning culture in their integrated sustainable learning firm may also benefit from practicing knowledge sharing networks comprising partner organisations, with a focus on developing common goals, holding joint planning sessions and performance reviews, and initiating employee rotations and secondments between entities. Such initiatives may generate enhanced levels of trust, commitment and interdependence between member entities, thereby contributing positively to the overall functioning of a sustainable learning firm.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

INFORMATION SHARING IN THE SUSTAINABLE ORGANISATIONAL DEVELOPMENT

Information is the most important aspect in the integration mechanism. Due to availability of information in the system all the members attached to the sustainable organisational development like internal and external members can exchange information in a timely, responsive and useable format. There is always an encouragement from leaders for the followers to innovate new processes so as to benefit the entire supply chain, this happens when there is a sharing of information across all members. Continuous improvement is usually a practice among the sustainable organisational development followers by using their critical thinking skills in creating a profitable sustainable organisational development which benefits every member attached to that chain. In holding all the things together in a sustainable organisational development communication plays a pivotal role. Through consistent communication between different partners in the sustainable organisational development trust and relationship is maintained and the satisfaction increases with the increase in the quality of communication. Transformational sustainable organisational development leaders always try to maintain a healthy environment of informal communication for better alignment of thoughts and they also seek feedback from time to time so as to keep the process streamlined without any error resulting in better effectiveness and efficiency in the sustainable organisational development.

The effectiveness of a sustainable organisational development is measured by the achievement of the goals that the leaders have set for the followers. There has to be some kind of structure which should be formed by the sustainable organisational development leaders and followers in measuring the performance of the sustainable organisational development i.e. how effective and efficient is the sustainable organisational development. Greater availability of information results in more efficient operations, better customer service and cater to changing customer demand patters. The leader and the followers should develop an informal communication in the sustainable organisational development as this will create a better relationship among the members and also strengthen the bond as inter-organizational integration. The big ambitious goals and rewards always keep the transformational sustainable organisational development leaders and followers to work in an environment where there is lot of emphasis on innovation in the current system and also it increases the collaboration between the members of the sustainable organisational development. This is usually achieved through integration.

CONCLUSION

This chapter examined the importance of trust and commitment between supply chain participants as a pre-requisite for successful implementation of knowledge management systems that span entire firm. The chapter also combined the concept of a learning organisation with integrated sustainability to analyse and describe key added capacities and characteristics inherent in sustainable learning firm.

HRM should tailor its functions to incorporate sustainable developments. This chapter argues that HRM play a crucial role in managing employees to help the organisation creating a sustainable development. The main role of HR management is not only to manage the recruitment process to find the right people to join the company, but also to provide training, controlling and monitoring the employees to achieve sustainable development. Therefore apart from the processes and practices in the organisation that drive vision, management approach also needs to be restructured especially when multiple perspec-

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

tives and stakeholders are concerned. Thus HR can play a crucial role in developing strategic leadership and management capabilities and thus promote economic, social and environmental forms of sustainable development.

Leaders of sustainable development must consult widely or run the risk of negative out comes and undermining from subordinates as well as other leaders within the organisation. The introduction of Information Technology and Cloud Systems require a driver that has a full understanding of the overall requirements of the organisation and can deliver alignment with cross functional areas. Groves (2006) has found that theoretical and empirical studies have linked the relationship between a leaders emotional competencies, including self-awareness, emotional expressivity, self-monitoring, and empathy, and a range of important leadership outcomes.

There is a distinct interdependence exists amongst economic, social and environmental sustainability, but as Hahn (2009) argued "A tri-dimensional approach can prove to be difficult in cases where trade-offs exist between any of the three dimensions". A multi-dimensional approach such as triple bottom line is in itself a challenge of sustainability. The challenge for firms is to embed policies that focus on the triple bottom line that will stand the test of time, supporting long term objectives, and preventing any of the three pillars of sustainability being abandoned at the expense of another, i.e. economic priorities outweighing others, thus plunging the firm into a single or double bottom line focus.

KEY TERMS AND DEFINITIONS

Economic Sustainability: Can be viewed as the ability of desired performance to be maintained over time.

Educational Sustainability: Includes activities used to prepare staff for an effective succession plans by ensuring the workforce is able to replace departing employees in the future.

Environmental Sustainability: Includes conservation, usage reduction, and efficient business practices.

Ethical Sustainability: Includes employee relations, community involvement, and ethical business practices.

Social Sustainability: Includes Corporate Social Responsibility (CSR) and other issues of social concern resulting for the activities of the firm.

This research was previously published in Business Transformation and Sustainability through Cloud System Implementation edited by Fawzy Soliman, pages 302-317, copyright year 2015 by Business Science Reference (an imprint of IGI Global).

Chapter 8
Significance of Cultural Dimensions in Urban Planning Process for Sustainability of Pilgrimage Towns in India

Varma Anurag
TERI University, India

Shaleen Singhal
TERI University, India

ABSTRACT

This chapter raises the significance of integration of cultural attributes in the urban planning process for sustainability of pilgrimage towns. It identifies the spatial connotations of cultural practices, processes and events to review synergies between culture and urban planning. Two Indian pilgrimage towns of Vrindavan and Haridwar with congruent cultural context but diverse urban setting have been examined. Eight significant diverse attributes of both case studies are discussed for examining linkages of cultural dimensions with urban planning, and sustainability of indigenous urbanism of Indian pilgrimage towns. Recent policy initiatives in India envision an increasing inclusion of cultural and heritage aspects in urban development, but are constrained by paucity of empirical spatial research on Indian pilgrimage towns.

INTRODUCTION

The sustainability debate increasingly focuses on urban development and sustainability is being considered unattainable without achieving sustainable urban development (UN-HABITAT, 2002). Further, Sustainable Development Goals (SDG's) adopted in the 2030 Agenda for Sustainable Development at the United Nations Sustainable Development Summit includes making "cities inclusive, safe, resilient and sustainable" as a goal (UN, 2015). At global scale, UN-Habitat summarizes climate change, gaps in energy supply, food security, changing demographics, size of cities and towns, income inequality and managing the cultural diversity as critical issues facing urbanism. In context of developing countries,

additional challenges of urban growth, urban informality, growth in peri-urban areas, linking of green and brown agendas and institutional and professional capacity building are identified issues to be addressed (UN-HABITAT, 2009). Emergence of alternative paradigms of urban development with greater inclusivity is envisaged in response to homogenizing influence of globalization in the developing countries.

With a shift in goals and emergent challenges, urban planning praxis and theory explore alternative urban and spatial planning paradigms. The attributes of sustainability imperative are variously interpreted in urban planning domain, and diverse approaches to achieve urban sustainability include conceptualization of eco-villages, eco-cities (Register, 1987) and eco^2 cities (Suzuki, Dastur, & Moffat, 2010); new urbanism (Talen, 2013) and sustainable urbanism (Farr, 2008); compact cities, green cities and resilient cities amongst others. Simultaneously, in response to globalization the place-based factors of local contexts are assuming significance in urban and spatial planning paradigms (WHO, 1999) (UN-DESA). Embedded in the local discourse, culture has emerged as a significant local, place-based determinant in urban planning process necessary for achieving sustainable urban development. UNESCO has initiated preparation of a 'Global Report on Culture and Sustainable Urban Development' for negotiations in the post 2015 Agenda which aims to provide guidelines and recommendations aimed to foster culture-based urban sustainable development initiatives at the international, national, regional and local levels (UNESCO, 2015). Significantly, the SDG's have adopted 'inclusive and sustainable urbanization' and to 'protect and safeguard the world's cultural and natural heritage' for making cities resilient and sustainable (UN, 2015) amongst other adopted goals. However, presently the linkage between cultural heritage and sustainable urbanization to make cities resilient and sustainable is tenuous and its progress is confounded by abstractions in definitions of both culture and sustainability, insufficient empirical evidence and a near absence of integrated conceptual framework (Parr, 2000). This chapter examines this gap through an exploratory study situated in context of pilgrimage towns in India.

Pilgrimage towns in India are characterized by high visitations of pilgrims, which stress the prevailing environmental services and result in degradation of built environment. The need for pilgrimage infrastructure results in urban growth; which, in absence of appropriate planning regulations, threatens cultural and environmental sustainability of the pilgrimage town (Shinde, 2012). Culture-led and event based urban regeneration strategies have been identified as a key theme for urban regeneration (Singhal, McGreal, & Berry, 2013) A recent Government of India scheme - Heritage City Development and Augmentation Yojana (HRIDAY) - recognizes the need to undertake strategic and planned development for sustainable development of heritage cities in India. Most of the cities shortlisted for the scheme involve an element of sacrality and attract pilgrims at varying scales. The scheme envisages to "preserve and revitalize soul of the heritage city to reflect the city's unique character….and facilitate inclusive heritage linked urban development" (Ministry of Urban Development, Government of India, 2015).

This chapter explores the relevance of identifying place-specific cultural characteristics and establish the need for its embedding in urban planning process at pilgrimage towns in India; fundamentally premised on significance of culture for sustainable urban development. The links between cultural characteristics - values, aspirations, activities, processes and patterns of a place, and urban planning are examined at two Hindu pilgrimage towns – Vrindavan and Haridwar - to predicate the relevance of culture to sustainable urban planning at pilgrimage towns in India. The case study towns exhibit congruence in terms of their religious significance, well-regarded sacredness, riverine geography and primacy of pilgrimage - and divergence in terms of presiding deity and associated rituals, cultural vitality, demographic patterns, urbanization trends and urban scale of the town. Briefly, the two selected case-study towns have convergent cultural backgrounds but divergent urban context.

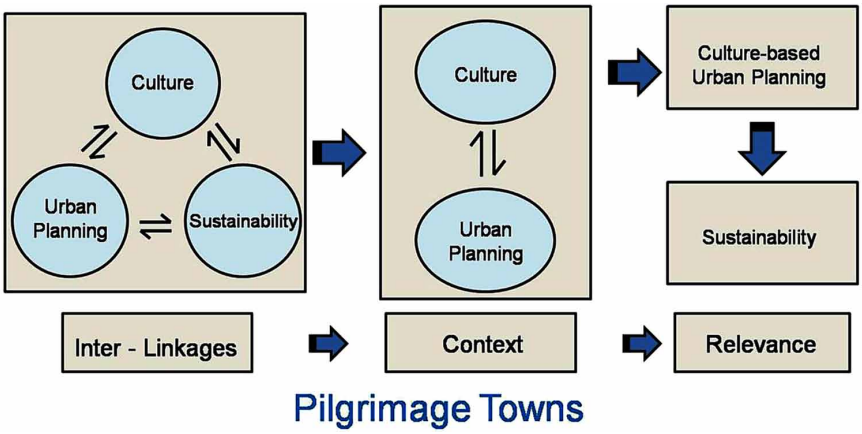
EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

The inter-linkages between culture, urban planning and sustainable urban development are gleaned from a review of available literature and inquiries during personal visits to the case-study towns. Synthesis of the information contributes towards emergence of a conceptual approach towards theoretically establishing the role of culture in urban planning process for sustainable urban development. The conceptual approach requires additional empirical data for its affirmation, and may have methodological synergies with investigations at similar Hindu pilgrimage towns in India, viz. Varanasi, Mathura, Rishikesh, Chitrakoot etc.

The chapter is organized in four sections wherein Section 1 provides a context to the theme being investigated. Section 2 reviews the inter-relationship between culture, sustainability and urban planning which provides a theoretical narrative supporting inclusion of culture as a major determinant of sustainable urban development. Section 3 briefly reviews distinctive characteristics of Indian urban conditions and pilgrimage towns to contextualize the case studies in a place-specific milieu. It also presents a review of two case study pilgrimage towns in India focussing on their cultural characteristics and synergy with urban planning. Section 4 includes discussions and conclusions, wherein an analysis and interpretation of two case studies lead to identification of attributes for examination of the inter-linkages between culture, urban planning and sustainability.

THEMATIC INTER-LINKAGES BETWEEN CULTURE, URBAN PLANNING AND SUSTAINABILITY

Development divorced from its human or cultural context is growth without a soul. – (Our Creative diversity, UNESCO 1995)



Multiple interpretations of culture necessitate a broad conceptualization of the embodied meaning in context of this study. Accordingly, culture is perceived as a 'way of life' and a way of living together (UNU-IAS and IICRC, 2002), as a generic nomenclature for 'diverse set of activities and pursuits' (Sen, Culture, freedom and independence, 1998) that embodies the following aspects:

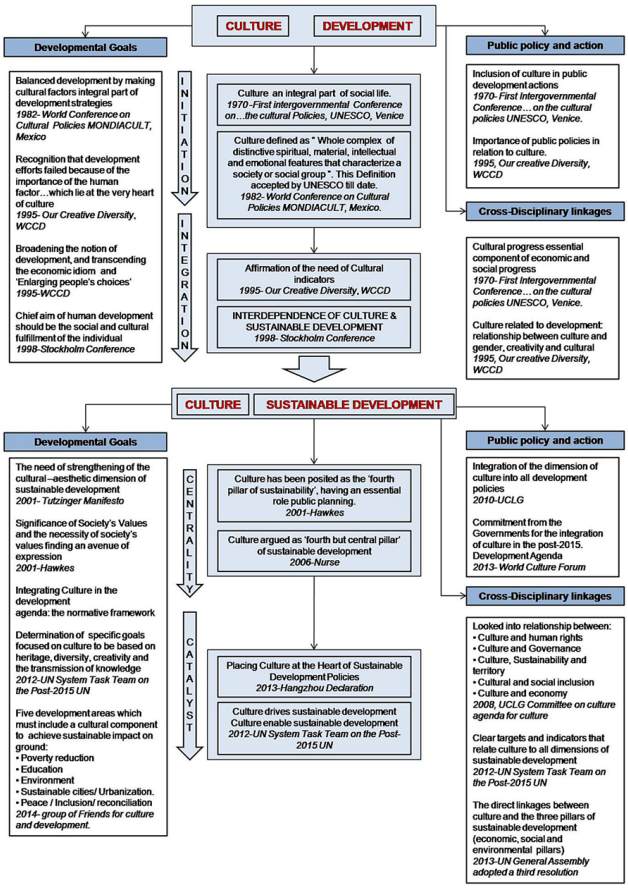
- Values and aspirations of the community, or linked to the place;
- The processes and mediums through which the values and aspirations are received and transmitted;
- The tangible and intangible manifestations of these values (Hawkes, 2001);
- Uniqueness of each culture, sensitivity towards the differentiation and respect for it also encourages cultural diversity and heterogeneity (Sen, 1998) (Nadarajah, 2007).

These following sub-sections explore the inter-linkages between the three concepts of 'culture', 'urban development' and 'sustainability', to deduce its implications for urban planning at Hindu pilgrimage towns in India. The theoretical linkages between the three concepts are established by a review of cross-sectorial development literature (Figure 1). Sustainability as conceptualized in the Brundtland Commission Report focuses on the environment and ecological strategies to ensure inter-generational parity. The three recognized pillars of sustainable development include economic development, social justice and ecological responsibility; though their weightages vary and are largely determined by the local context and philosophy driving development. The three pillars are in dialectical tension, and in praxis, sustainable development appears as a shifting adjustment among them (Hawkes, 2001). Earlier,

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Thematic linkages between culture, urban planning and sustainability

the prime determinants were the economic development and its environmental implications, with little consideration of cultural aspects, which was considered as included in the social criteria. The linkage of culture with either sustainability or urban planning and development is still an emerging area of research; with nebulous and meagre structured information available from either global research or praxis (Duxbury & Jeannotte, 2010) (Nadarajah, 2007).



Culture, Development, and Sustainable Development

The inclusion of culture in development is examined from existing literature and structured under three broad themes of development goals, public policy and action and cross-disciplinary linkages (Figure 2). Evidently, the role of culture first gained recognition in the development realm (Bandarin, Hosagrahar, & Albernaz, 2011), and later progressively gathered increasing acceptability in sustainable development domain. Increasing emphasis on human-centric development paradigms led to initiation and progressive integration of culture in sustainable development discourse, and latter sustainable development frameworks. As evidence of increasing theoretical significance, culture is advanced as the 'fourth pillar of sustainability', and its centrality as a catalyst, driver and enabler (UNESCO, 2013) for sustainable development is being acknowledged. The inclusion of culture for sustainable development is supported based on its relevance for:

- "Human capacity expansion" (Sen, 1990), and increasing emphasis of development towards 'enlarging people's choices' (World Commission on Culture and Development, 1996);
- Social and cultural fulfilment of an individual (UNESCO, 1998) perceived as objectives of human development
- Strengthening the cultural-aesthetic dimension of sustainable development (Tutzinger Manifesto, 2001);
- Emphasis on the significance of society's values, and the necessity of its finding an avenue for expression (Hawkes, 2001) and
- Cross-sectorial linkages with disaster resilience and climate change, social development, economic development, peace & reconciliation, environmental sustainability, sustainable urban development (UNESCO, 2013) (UN, 2014), poverty reduction and education (UN, 2014).

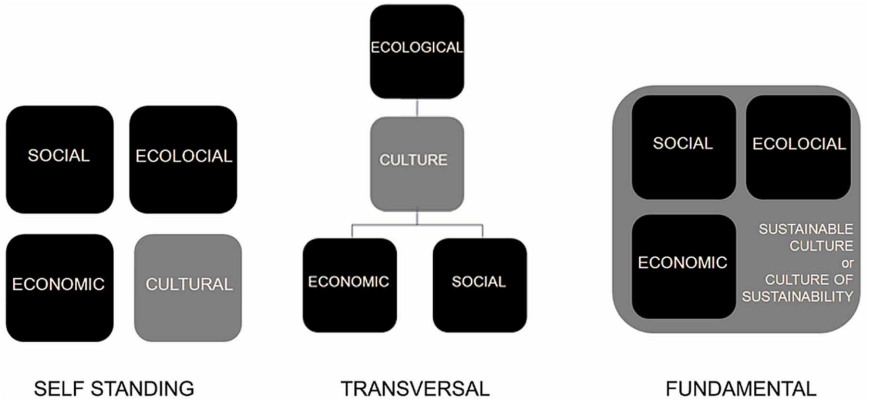
Figure 2. Increasing inclusion of 'Culture' in 'Development' and 'Sustainable Development' discourse

This research envisages culture as a repository of knowledge that helps a society to mediate challenges and positions culture as a resource, capital and capacity inherent in a local situation (Mercer, 2002).



The proposal for inclusion of culture as the fourth pillar of sustainability has led to a theoretical conceptualization of its critical relevance to the prevailing paradigm of sustainable development. This has included positioning of culture as a fourth pillar vis a vis other three pillars in the sustainable development paradigm. Accordingly, three conceptual possibilities of engaging culture with the existing sustainable development framework are conceptualized (Soini, 2013) as below:

- **Self-Standing:** Culture as the fourth pillar of sustainability
- **Transversal:** Culture as a catalyst in sustainable development
- **Fundamental:** Culture as a new paradigm of sustainability (Figure 3).

Concurrently, a wider role of culture in sustainability is also being advanced in the urban development discipline, wherein culture is seen as an invaluable tool for sustainable urban development (UNESCO, 2015).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Three approaches on role of culture in global sustainable development (Roders, 2013).

Urban Planning and Sustainable Development

Brundtland Commission's report – Our Common Future –places the issue of sustainable development at the core of urban policy and planning concerns (World Commission on Environment and Development, 1987). Complementary assertions of centrality of sustainability to the urban development processes (Berke, 2002) and sustainability initiatives centring on building sustainable cities (Yanarella & Levine, 1992) are indicative of conceptual connect of sustainability with the urban. Yet concentration of urban population and its quest for economic growth has substantial adverse implications of environmental degradation, resource depletion, deteriorating ecosystems and climate change (Dixon, 2011) and the urban planning process grapples for appropriate sustainable responses. In this context, Global Report on Human Settlements focuses on need of a new perspective for urban planning, and begun differently by setting the goal of sustainable urbanization as liveable, productive and inclusive cities, towns and villages (UN-HABITAT, 2009).

Inquiry into antecedents of contemporary urban planning paradigms reinforces need for emergence of new perspectives to deal with contemporary sustainability challenges. The concept of sustainability is historically considered intrinsic to the process of urban planning with implicit theoretical linkages. It has been established that urban settlements were perceived holistically as constituents of a larger eco-system by Alberti, Marsh 1865, Olmstead and Vaux 1887, Patrick Geddes 1915, Mumford 1968, Lynch 1981, McHarg 1969, Jacobs 1961 etc., an aspect that has well been documented by Spirn (2012) for the Anglo-American context (Spirn, 2012). Evolution of contemporary urban planning practices traces its roots in the concepts of modern urban planning in Western Europe in latter 19th century, primarily as a response to the Industrial Revolution. Urban development was perceived as an exercise in design and physical planning of human settlement with complex social, economic or political matters eluding it. At earlier stages, urban planning focussed on improvement of liveability criteria in its spatial territory, and harboured a fixation for the visual. The urban planning concepts of the industrial towns gradually spread the globe through processes of colonialism, market expansion and intellectual exchange; and embedded itself into local planning practices at dispersed location and diverse contexts (UN-HABITAT, 2009). Progressively, urban planning focussed on automobile-centric transportation, landuse and zoning based on spatial segregation of usages, and design standardization. Cities and settlements conforming to

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

these urban planning principles were devoid of cultural diversity in response to the local place, values, and context; and alienated the people from their habitat. Tracing these antecedents in the Indian urban experience, Menon strongly advocates professional engagement with specific complexities of traditional Indian urbanism as both a socio-cultural construct and technical entity (Menon, 1999).

In response to this context, "New Urbanism" gained prominence as an alternative to traditional US suburban design in the 1980's. It was presented as a model for sustainable urban development to address wider concerns as placeless sprawl, environmental deterioration, loss of agricultural lands and wilderness and erosion of society's built heritage. Offering spatial planning solutions, it strongly advocated the principles of: i) compact development for preservation of environmentally sensitive areas; ii) infill development to revitalize city centres; interconnected streets friendly to pedestrians and cyclists; iii) mixed land uses rather than single-use pods; iv) discreet placement of garages and parking spaces to avoid auto-dominated landscapes; v) transit-oriented development (TOD); vi) well-designed and sited civic buildings and public gathering places; vii) the use of building and street and building typologies to create coherent urban form; viii) high-quality parks and conservation lands used to define and connect neighbourhoods and districts; and ix) architectural design that shows respect for local history and regional character (Ellis, 2002). Though the sustainability criteria attracted professionals in addressing wider urban planning concerns, evidently the solutions continued to focus on issues concerning the visual urban form. The social, cultural and economic dimensions of sustainable development were either relegated or simply considered beyond the scope of the movement (White & Ellis, 2007).

It becomes important to explore the nature of urbanization and contextualize its wider inter-linkages at varying scales - metropolitan, small urban centre, town, and their surrounding rural area. Mostafavi expands the context of the urban in 'Ecological Urbanism' - a framework that deals with these complex economic, political, social and cultural perspectives through conjoining of ecology and urbanism (Mostafavi, 2010). Sustainable urban development and management is identified as a critical aspect influencing sustainability and crucial to quality of life of people (UN, 2015). As urban development focuses on sustainability, the planning process is required to meet not only the challenges of urban design but also many other social, environmental, economic, health and climate issues.

Culture, Urban Development, and Sustainability

In recognition of cities as active players for promotion of sustainable development and the significance of the urban context therein, culture is increasingly imagined as a key tool for sustainable urban development (UNESCO, 2015). In beginning of 2000, the Kanazawa Initiative examined the role of culture in building sustainable cities at four different Asian countries. The research involved empirical exploration into the nature of urbanization and its linkages with sustainability from a local culture perspective in different cities. Recognition of the varying urban contexts, and sensitivity to the diversity led to evolution of four culture-centric approaches for sustainable urban development (Nadarajah, 2007) that focussed on:

- Internal cultural transformation approach;
- The multiculturalism and enlightened localism approach;
- The urban cultural identity approach;
- The cultural mode of production approach.

The inter-linkages between culture and sustainable urban development are nebulous in contemporary urban context ((Rana & Piracha, 2007) (White & Ellis, 2007), and requires additional evidence and empirical data for its affirmation. The conceptualization has been recently enunciated and theoretical frameworks or methodologies for conducting research are emergent only. Further empirical research supported by evidence-based case studies in diverse contexts will significantly contribute to establish culture as a tool for sustainable urban development. Examination of the role of culture in urban planning and its relation to sustainable development is emerging as a key area of investigation. In this background, cultural mapping is emerging as a mode of enquiry and methodological tool for diagnosing potential role of culture in the urban planning processes (Evans, 2015). In practice though, culture is seldom used as a key urban development variable, and is characteristically referred in its intersections with other key (economic, environmental, social) development variables.

CHARACTERISTIC INDIAN URBANISM AND PILGRIMAGE TOWNS

Indian urban conditions are characterized by abundant diversity that results from a combination of multiple planning processes and spatial overlapping - vernacular, indigenous urbanism, formal planned and extra-legal 'pirate modernities' (Sundaram, 2010). They distinctly exhibit spatial juxtaposition of the planned and the un-planned (extra-legal) activities in, as theorized - 'static city' and 'kinetic city' respectively (Mehrotra, 2008) (Gupte, Mehrotra, & Shetty, 2010). The static city is usually permanent whereas kinetic city is impermanent, in a realm outside the planning framework, and usually extra-legal. Un-planned activities are a formidable presence in Indian urban conditions and are normally ignored or not included in the formal planning process (Roy, 2009). Largely manifested in the interstitial spaces of a city – road edges, slums and informal settlements the un-planned is constantly in a state of adversarial relationship with the planning process. The need of urban planning to negotiate contrasting urban conditions of neat suburban developments and heterogeneous traditional settlements, city of 'haves' and 'have-nots', automobile and the bicycle etc. has been emphasized (Menon). It is essential to closely assess the nature of Indian urbanism situated in the larger Indian background characterized by heterogeneity, plurality and multiculturalism.

These generic conditions appropriately describe the urban conditions for Indian pilgrimage towns. Both the case studies are constituted of the traditional core of the city, which is culturally vibrant, dense with high numbers of pilgrim visitations and inadequate hygiene and infrastructure. Pilgrimage related activities related to rituals, practices, and ritual offerings like flowers and prasad, accommodation, fooding and transportation, function largely at the periphery of the mainstream planning, informally and extra-legally. However, an inquiry into the indigenous urbanism as manifested in these sacred spaces offers an opportunity of its use as catalysts to revitalize the civic environment. A relevant approach for study of Indian heritage (traditional pilgrimage) towns from a cultural perspective has been postulated in the 'Architectural Knowledge Systems' (Thakur, 2002) that approaches study of Indian historic towns in a people-time-place continuum framework; thus implying an assimilative and holistic enquiry into the anthropological, historical and the geographical narrative of the city. The emergent Indian Cultural Landscape (ICL) is termed as the 'intellectual landscape' - a repository of knowledge, where collective memory, information and imagination shape the landscape (Thakur, 2011). Accordingly, the place may be conceived as an overlay of cultural layers in a temporal perspective, which may be unpeeled distinctively for each settlement.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Pilgrimage has had a long tradition and continuity as large civil society movement for religious/ spiritual experiences in the Hindu tradition of India (Singh, 2013). The number of pilgrims has increased manifold due to improvement in the communications and transportation system over time. Massive influx of pilgrims coupled with poor environmental infrastructure, lack of hygiene, weak governance apparatus, inadequate awareness, capacities and capabilities of the citizens or governance authorities creates problems related to health, safety and experiential aspects at the pilgrimage town. The resulting transformations are socially and environmentally detrimental for the pilgrimage town and diminish the quality of experience of the pilgrims (Shinde, 2012). Unless timely planned sensitively, the pilgrimage towns fail to offer any significant experience to pilgrims or a liveable quality of life to the residents; the town loses meaning for people and ceases to be sustainable. Aware that religious beliefs and traditions are the raison d'etre of pilgrimage towns; the following section investigates the potential role of culture in urban planning process for sustainable urban development through case studies of two Hindu pilgrimage towns. The methodology includes literature review, observations and unstructured interviews conducted at case study towns to identify cultural characteristics in its intersections with the urban planning, and inter alia sustainability of the urban development process.

Case Study of Vrindavan

Vrindavan is a small town in District Mathura within the administrative division of Agra - a city situated in Western Uttar Pradesh. Administered locally by a municipality, Vrindavan has a population of around 63,000 people distributed in 25 wards. A proposal to include seventeen more villages within the jurisdiction of Vrindavan municipality and its potential upgrade to a level of Municipal Corporation also emerges from information gathered locally during a field visit.

Notionally at centre of the sacred geography of Braj Kshetra (region) circumscribed by 84kos (252kms), Vrindavan is believed to be the place where Lord Krishna spent his early childhood. The cultural identity of Vrindavan is embodied in its religious values being a *dham* – abode of God (Brahmachari, 2011), and an eternal home to the divine Radha-Krishna who are perceived as a living presence in Vrindavan. Lost to the world as a Vrinda (Tulsi) vana (forest) on banks of River Yamuna until Sixteenth century, Vrindavan re-emerged when visited in by Chaitanya Mahaprabhu and Vallabhacharya, famous Vaishnava gurus and proponent of Bhakti movement (Entwistle, 1987). Mahaprabhu and later his disciples – the Chhat (six) Goswamis (priests), physically construed the entire town driven by divine inspiration, vision, consciousness and memory of its association with events in life of Lord Krishna. Largely because of its associative sacredness, Vrindavan soon became a leading centre of pilgrimage, Vaishnavism and Vaishnava learning. Intrinsically steeped in the metaphor of Radha-Krishna, the spiritual culture is the wellspring of many performing art forms like painting, sculpture, theatre, music, braj bhasha (language) poetry and dance. 'Raas Lila', the divine dance signifies unison of God with his devotees and related allegories are favourite themes of prominent classical dance forms all over India. Over six million pilgrims visit the sacred town of Vrindavan annually (Shinde, 2012) which acts as a testimony to the universal significance of the intrinsic cultural values associated with the place.

Vrindavan's spatial growth was predominantly guided by the Goswamis, who as religious heads exercised considerable influence over happenings in the town and region. Contemporary Mughal, Rajput and Jat patrons generously extended donation of land parcels and funding for establishment of Vrindavan as a spatio-cultural-religious town from neighbouring territories. The growth expanded outwards from banks of river Yamuna. Temples, temple precincts, ashrams, dharamshalas (charitable rest houses),

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

ghats (stepped bathing places along rivers) and princely estates were constructed with considerable architectural elegance, skill and craftsmanship. In accordance to the traditional and scriptural knowledge, considerable significance and reverence was attached to natural elements such as vanas (sacred groves), kunds (man-made water tanks), river Yamuna and sacred hills.

Architectural appurtenances were evidently employed to enhance beauty and utility of kunds, riverfront, and community-protected groves, forests and hills. The built fabric comprised of considerable architectural heritage (Figure 4) and ritual symbols are largely encompassed within a 10km pradakshina path (circumambulatory route), and part of the inscribed area is declared as a heritage area. The traditional ecological beliefs, sanctity of river Yamuna, and recognition of value and conservation of architectural heritage have been intrinsic to the way of life of the residents'. These values can be potentially leveraged to direct urban planning initiatives for addressing challenges posed by ecological imbalance, environmental degradation, obsolescence of built fabric and deterioration of quality of life of residents.

Collective memory, community values and beliefs underpin the temporal activities of the town, leading to distinct activity patterns and urban morphologies. Faith-driven residents or pilgrims converge at specific temples or river ghats for darshan of deities and/or ritual performances at varying periodicity. Extremely populated during the festivals, events and auspicious cycles of visitation, movement between the significant activity nodes and landmarks usually follow a pattern. Tradition of daily parikrama (circumambulation) along the pradakshina path is also a regular activity with many residents and pilgrims visiting Vrindavan. Pilgrimage movements along these networks present a livelihood option to the residents who develop trade and services' establishments. A mixed landuse pattern emerges with a rich mosaic of activities that impart vibrancy to the place, and simultaneously congests meagre spatial capacity available. Awareness of the temporal spatial patterns of human ritualistic activities and movements at a local area level becomes a significant consideration for urban planning interventions.

Lord Krishna is believed to permanently reside at Vrindavan, and the people reinforce His Grace and living presence by organizing community events and activities regularly. Colloquially Braj is known for celebrating more festivals than days in a year. The festivals, fairs and events are organized at varying scales ranging from a local to global scale and attract participation accordingly. The major congregation amongst others are the annual festivals of Janamashtmi and Holi with a national catchment, recitation of

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Srimad Bhagavatam katha (scriptural discourse) with a regional catchment, and sankirtan (congregational singing of devotional songs with music accompaniment) at local level that occurs daily. The community activities – participants include local populace and visiting pilgrims - are of profound cultural significance for perpetuation of traditions known to contribute positively to the well-being of the community. Temporal patterns of participatory community activities and the imperative to provide accessibility, sufficiency, safety and hygiene for continued enactment of these activities are key considerations for evolving urban planning strategies (Figure 5 & 6). Urban planning in accordance to the existing patterns

Figure 6. Congregational activities at temples

Figure 5. Temporal spatial patterns of pilgrimage activity as at streets leading to temples with prasad shops

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

of the community and the pilgrims activities reduces conflicts, and enables not only an enhanced quality of life for the residents but improves the pilgrim experience as well.

Vrindavan has a population of sixty three thousand people in the 2011 census, and a thriving pilgrimage-based cultural economy with about six lac visitors annually. Though most of the earnings accrue to religious actors and institutions, the pilgrimage activity also supports several allied activities, some rooted in traditional cultural economy. The allied activities include carving of stone statues, mukuts (crowns) and decorative clothes for deities, sanjhi and local cuisine amongst others (Figure 7 & 8). Presently, the production is undertaken usually in households informally at disjointed locations. Aggregation of the production activities through spatial planning may foster innovation by peer learning, economies of scale and better connect with the demand side. Thus, mapping of the processes and practices of cultural economy and assessment of its potential to generate sustainable livelihoods is an important component of urban planning initiative.

Numerous NGO's and community-based organizations related to tradition-based cultural domains have emerged to address divergent issues in Vrindavan. These issues primarily include revitalization of the holy river Yamuna and its ghats, conservation and restoration of built heritage, facilitating and promoting pilgrimage and community activities, propagation of traditionally community activities like sankirtan, Srimad Bhagavatam katha, revitalization of pradakshina path (circumambulation route), innovation and promotion of local arts and crafts, veneration and protection of cow and promoting traditional cow-based economy. A few of these organizations are crucibles of local practices and repositories of traditional knowledge; and are immense resource for cultural mapping and interpretative efforts. Local spiritual leaders and influential citizens, with urban development concerns usually place-based and local, patronize numerous significant organizations. A few enjoy easy access to the decision makers and exercise considerable influence on the residents and non-residents from across the globe. The significant

Figure 8. Mukut (crown) making for deities

numbers and outreach of these organizations presents a medium with a high capacity for mediation of local issues with official urban planning process. The participation of these organizations in urban planning framework can impart considerable insights in arriving at development objectives of local community in response to the needs and aspirations of their communities. There is a serious disquiet over the sporadic urban development in response to endogenous triggers and an inclusion of all stakeholders in the development process can potentially render the framework sustainable.

To sustain and enhance the rich cultural and historical significance through urban and spatial planning process, Uttar Pradesh Urban Planning and Development Act, 1973 mandates the Development Authorities for preparation and implementation of the master and the zonal plans. Vrindavan is regulated by the Master Plan 2021 that recommends the conservation of ancient religious, cultural and archaeological buildings, areas and precincts. The master plan delineates a heritage zone that includes built heritage and the cultural precincts in view of specific cultural considerations (MVDA, 2009). The heritage zone falls in the municipal area, and under the administrative jurisdiction of the municipality. Special development controls and guidelines are recommended in the building byelaws for physical development in the heritage zone. Zonal plans are mandated to include specific spatial recommendations for development of site plans and use/activity plans for achieving objectives envisaged in the master plan. The zonal plans for Vrindavan are not yet formulated, and thus the objectives envisaged in the master plan are under achieved.

The Vrindavan Eco-city project highlighted the people's concern about protection of cultural and traditional values (Kulshrestha, 2007); and field interactions reveal a real desire for engagement with the cultural aspects by the authorities as well. However, the role of the state witnesses a multitude of implementation agencies (Shinde, 2012), wherein overlapping responsibilities and jurisdictions are barriers in holistic fulfilment of objectives envisaged in master plan. Coherent action is also constrained by a lack of capacity and expertise in the prevailing planning system to evolve context specific urban

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

planning strategies. Vrindavan Eco-city project concluded that a participatory approach to planning and development appeared replicable.

It is thus gleaned that richness of traditions and cultural practices finding expression through the urban planning process is circumvented due to disregard of the cultural dimension in implementation tools viz. master/zonal plan, urban planning laws, planning regulations and conflicting institutional responsibilities. It is also implicit that culturally aware state, institutions and citizenry, conscious of traditional values accorded to the river Yamuna, hills forests, sacred groves, water bodies, temples etc.; are better positioned to imagine potential contribution of indigenous urbanism towards contemporary urban development. A cultural orientation is required for capacity building of individuals and institutions to understand and sustain the embedded patterns of urbanism as cultural expressions, and leverage them as catalysts to advance a sustainable urban development trajectory.

Case Study of Haridwar

Haridwar is an ancient tirtha, a sacred geography and one of the seven sacred cities that offer moksha (salvation) according to the Skandpurana. The region is known as Kedarkhand – the abode of Kedar (Lord Shiva); and the legendary association is reinforced by the presence of Daksha Mahadeo's temple at Kankhal (near Haridwar), earlier known in legends as Prajapati Daksha's capital. As suggested by the Puranas, Haridwar is the site for Bhagirathi's penance, which led to the descent of (river) Ganga. An event of immense cultural significance in the national consciousness, a sketch depicting the descent of river Ganga was enshrined in the Indian Constitution reinforcing its significance. Earlier known variously as Mayapur, Kapilasthana, it is called Har-dwar (gateway to Shiva) by the Saivites and Hari-dwar (gateway to Vishnu) by the Vaishnavites. Puranas and Mahabharata confirm the sanctity of Haridwar, and as a paramount pilgrim destination, its appeal has been non-sectarian and supra regional.

The importance of Haridwar centres on sacrality and reverence accorded to river Ganga that finds frequent mention in the scriptures. Devotees address the river as Ganga Maa (mother) and venerate her. The river is identified as an embodiment of sacredness, and its holy water is known to offer moksha – freedom from the cycles of birth and death. River Ganga descends to the plains at Haridwar flowing between two hills – 'neel' and 'bilwa', and is also known as the 'Gangadwar' - dwar (gateway) to a network of sacred pilgrimage spots in the Himalayas – Kedarnath, Badrinath, Gangotri and Yamunotri. Natural scenic beauty, enchanting ghats, picturesque sites, Sivalik forests, mandirs, ashrams and akharas have long been a primary attraction for pilgrims and travellers. Haridwar is a centre for traditional learning and ayurvedic knowledge, is home to erudite scholars and sanyasis of many orders. It also hosts Kumbh mela (fair) - a religious event of utmost national significance - every twelve years, with an approximate 30-50 million pilgrims visiting Haridwar during Kumbh mela in 2010. Kumbh mela is organized in an area equivalent to 130sq.kms extending much beyond Haridwar.

Situated at the right bank of river Ganga, Haridwar was earlier an area of wilderness that attracted pilgrims primarily for religious activities. It was known as 'Tapovan' - a meditational retreat - and scarce physical growth or development maintained its serenity. The sanctity attracted many seekers and devotees to the place, and livelihoods were organized strictly on basis of Vedic tenets. Mayapur – earlier prevalent name of Haridwar - was known as a riparian settlement and River Ganga was considered sacrosanct and worshipped. The physical location of earliest Mayapur is uncertain and is conjectured by findings from archaeological remnants, interpretation of texts and descriptions left by travellers. Rituals were conducted in 'purnyashalas' (charitable establishments) at Haridwar constructed by the wealthy patrons or kings

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

and resided at ashrams or dharamshalas at Kankhal or Jwalapur located close to Haridwar. Core of the traditional town at its present location is believed to have developed over ruins of an earlier settlement, though scarce evidences are available of the antiquity and architectural heritage.

Morphologically, Haridwar has evolved along the river Ganga on the land at its right bank and the adjacent 'Neel' parbat (hill). The growth of the town is guided by constraints in the availability of land, being bound by presence of river Ganga and 'Neel' on opposite sides. The spatial patterns in the traditional core area evolved linearly in response to its geography (Figure 9), and ritual and pilgrimage cycles; with the riverfront comprised of ghats assuming significance as hub of the town. Importantly, main worship and ritual areas developed along the riverbank and supporting livelihoods emerged within this area. Dharamshalas (charitable rest houses) were built along the river, and provided independent ghats and ritual bathing areas for the residents. Consequently, a mixed land use emerged at the traditional pilgrimage core that supported residential, commercial and religious activities. The number of pilgrims and their ritual and non-ritual activities exhibit variations in magnitude based on three temporal cycles i) The daily performance, ii) Performances during the auspicious occasions and festivals and iii) Every six years during the Kumbh/Ardh-Kumbh festival.

The cultural identity of Haridwar as a traditional centre of ritual-pilgrimage converges around river Ganga (Figures 10 and 11), and now mutated to a populous, physically dense, amorphous urban settlement with juxtaposition of varied activities – ritual, pilgrimage, livelihoods and trading in same urban space. The core pilgrimage area is proportionately insignificant to the spatial expanse of the town, and experiential aspects of the pilgrims' are qualitatively diminished. The unplanned transformations of built fabric, change in usages and activities, and lack of environmental services in the core ritual-pilgrimage area results in an unsustainable physical environment leading to gentrification from the traditional core.

Figure 9. Linear morphological spatial growth along the river visible at riverfront of River Ganga at Haridwar

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Contemporary urban development subsumes the indigenous patterns of urbanism, and traditional identity of Haridwar as a pilgrim town is being progressively obliterated.

Presently, Haridwar town is headquarter of Haridwar district and is comprised of three tehsils. The current population of Haridwar urban agglomeration exceeds three lacs in 2011 census and continues to exhibit significant growth rates. Current developments include housing and commercial development at the periphery of the core area, and an industrial estate in proximity; resulting in heterogeneity of activities compounded with diluted emphasis on traditional ritual-pilgrimage based activities.

Pilgrimage is prime cultural activity that contributes to the local economy. Religious actors and organizations benefit directly by the economic support and donations by the pilgrims, whereas immense indirect benefits accrue to other stakeholders in catering to pilgrims' requirements of accommodation, travel etc. Religious tourism and other tourism activities have also proliferated. Other heterogeneous economic activities like manufacturing have also developed; hence, direct benefits of cultural economy are relegated to relative insignificance. It is significant however, that cultural products are symbols to link memories to a place; and its high associative value be favourably considered to promote spatial provisions in urban planning.

Prominent NGOs, community based organizations active in the cultural domains focus on varying issues of making the Ganga clean, facilitating performance of traditional rituals, promotion of afforestation and conservation of forests, protection of natural heritage – flora and fauna, and protection of built heritage. Few large social and quasi-religious organizations are involved in research and synthesis of aspects related to traditional knowledge and local practices, and are potential resources for cultural mapping. Most organizations view the contemporary urban development as driven more by concerns of economic development that is evidently at crossroads with the cultural values of society. They stress on

Figure 10. Cultural identity of Haridwar as a pilgrimage town centred on River Ganga exemplified by ritual bathing in River Ganga

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

the critical need for mechanisms to integrate the embodied knowledge of the community, and mediation of cultural and traditional practices in the urban planning paradigm.

The urban and spatial planning processes to sustain the rich cultural and historical heritage of Haridwar are mandated through formulation of Master Plan. Additionally, 'A City Development Plan (CDP)' focussing on the municipal area in Haridwar was prepared under the ambitious Jawaharlal Nehru National Urban Renewal Mission (JNNURM) in 2007. The Haridwar Master Plan 2025 recommends cognisance of cultural aspects related to the historic-religious aspects of Haridwar in framing objectives for its future urban development. The vision statement of CDP Haridwar envisages it as a 'city of Hope, faith and Spirituality…an international destination of pilgrimage and tourism, in keeping with its rich cultural heritage' (GHK International, UK, 2007). Concurrently, Haridwar is identified as a potential site for urbanization and industrial growth due to availability of flat terrain in the hilly state of Uttarakhand. The urban planning and development strategies and policies are more reactive to existing urban situation with negligible evident efforts to centre-stage cultural aspects despite recognition of their primacy for urban growth.

To reinforce traditional identity in this transformed scenario, potential contribution of indigenous spatial patterns evolved through traditional spiritual-pilgrimage based cultural activities needs understanding as an important consideration in urban planning domain. Identification of activity patterns corresponding to the local activities and events and its inter-linkage with activity nodes emergent spatial patterns and the temporal variations are imperative for facilitation of traditional ritual-pilgrimage activities that are critical for reiteration of cultural identity of people. In view of the identified development objectives and context of accelerated urban growth, it is critical for urban planning initiatives at Haridwar to recognize the significance of the cultural values inherent in the city, spatial patterns of cultural activities, architectural heritage and ecological aspects of physical growth.

DISCUSSIONS AND CONCLUSION

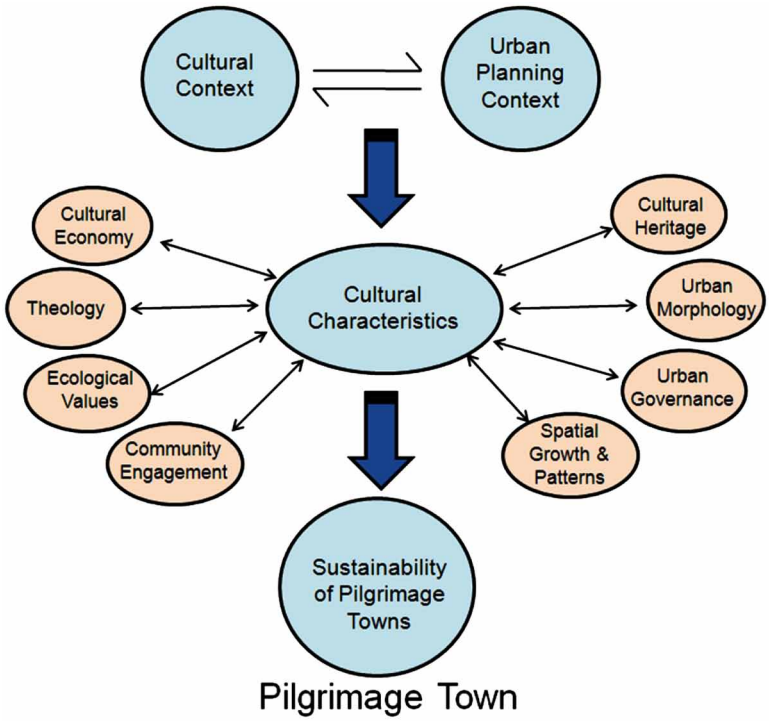
This chapter explores potential of cultural characteristics of a place to inform urban planning domain for evolving sustainable trajectories of urban development for pilgrimage towns in India. Theoretical linkages between the three variables gleaned from literature advocates inclusion of cultural aspects in urban planning considerations as critical for sustainable urban development – a learning well advised for sensitization of planning professionals. Integrative frameworks to empirically evaluate potential contribution of culture to urban planning may be theoretically situated in existing frameworks for examining contribution of culture to a wider development processes.

UNESCO has developed an analytical framework to explain and quantify how culture contributes to development processes, wherein direct references to urban planning processes are absent. It identifies twenty-two indicators from seven dimensions to elucidate on linkages between culture and development; and data is being generated in seventeen countries (UNESCO, 2011). Spain has developed a strategy for culture and development cooperation, which identifies a theoretical framework to include principles, approaches and concepts guiding the cooperation. It also envisages regulatory, institutional, methodological, instrumental and implementation frameworks within the scope of its strategy (AECID, 2007). Information from similar such interventions need to be cumulated to deduct its potential linkage to the urban planning and potential impact on sustainability issues. Paucity of empirical studies focussing on potential contribution of culture to the urban planning and sustainability domains renders formulation of integrated cooperation strategies elusive. Conducting empirical field studies and gathering evidence of inclusion of cultural dimensions in urban planning process to produce a sustainable development trajectory offers substantial research opportunities in varying urban and cultural contexts.

In contemporary Indian urban scenario, Jawaharlal Nehru National Urban Renewal Mission (JNNURM) initiated by the Government of India in 2005 conveys the intent to engage with Indian urbanism, and included urban planning interventions within its scope indirectly. Significantly, the criteria for selection of the towns eligible for funding under JNNURM scheme included cities/urban agglomeration of religious, historic or tourist importance. It is noticeable that a supplement Heritage toolkit (JNNURM, 2006) was prepared as an afterthought in cognisance of the specific cultural requirements for preparation of the City Development Plan (CDP) envisaged in the scheme. Similarly, a recent Government of India scheme - Heritage City Development and Augmentation Yojana (HRIDAY) - recognizes the need to undertake strategic and planned development for sustainable development of heritage cities in India. Two above schemes convey implicit priority accorded by the Government of India to engage with indigenous urbanism at heritage cities.

This chapter attempts to bridge theoretical gaps in examining potential contribution of culture to urban planning processes for achieving a trajectory of sustainable development by initiating a conceptual approach to advance the intent. Timely in the context of recent Government of India schemes (HRIDAY), a study of these linkages is confounded by challenges faced in engagement with indigenous Indian urbanism characterized by hybridity, plurality and informality. Empirical studies exploring the linkages between three variables viz. culture, urban planning and sustainable urban development in Indian cities are extremely rare, and sketchy where available.

This study examines the linkages to assess conceptually the potential role of culture in urban planning process at two existing pilgrimage towns in India – Vrindavan and Haridwar - and its influence on sustainability. Prime cultural characteristics of both the case studies are closely linked to their homogenous Hindu identity, and in being significant pilgrimage destinations. The primacy of deities - Krishna in Vr-



EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

indavan and Ganga in Haridwar – result in diversity of beliefs, rituals and activities. Religious and ritual activities are raison d'etre of pilgrim towns - hinging on Parikrama (circumambulation) and visitations to temples in Vrindavan, and on a holy dip in river Ganga at Haridwar. The legends of Lord Krishna's life have found expression in various cultural forms viz. dance, drama etc. which are performed and participated en-masse by the community and visitors in Vrindavan whereas Haridwar was predominantly known for being a taposthali steeped in asceticism.

The diversity of the belief system and concomitant activities, varying geographical settings, activity nodes and their inter-linkages resulted in evolution of varying spatial and morphological patterns at the two towns. Keeping in perspective the diversity in the manifest natural, urban and cultural contexts and variance in their interface with the urban planning and sustainability domains, the study evolves a conceptual approach for inclusion of culture characteristics leading to sustainable urban development of pilgrim towns.

The case studies identify eight diverse attributes significant for examination of the linkage between the cultural dimension of pilgrimage towns with urban planning and sustainable urban development. The identified attributes are urban morphology, spatial growth, theological values, ecological values, urban governance, community engagement, cultural heritage and cultural economy (Figure 12). Prima facie, the case studies also reveal that the inter-relation between the three variables is itself not static; and temporal, positional and structural transformations therein can be analysed through careful analysis of the eight attributes. Similarly, in spite of broad similarities in cultural attributes of the case studies, the inter-relationship varies in its causality at the two towns. Accordingly, inclusion of culture in urban

Figure 12. Attributes reflecting linkages between culture, urban planning and sustainable development

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

planning domain anticipates advancing a flexible framework for sustainable development, wherein the dynamic inter-relationships between variables continue on the sustainable trajectory.

Case studies at Vrindavan and Haridwar reiterate the need of additional research and empirical evidence to examine the ingenious urban linkages with other Hindu pilgrimage towns like Varanasi, Rishikesh, and Mathura etc. to establish a spectrum of indigenous urbanisms and establish conclusively inter-linkages between culture, urban planning and sustainable development.

Chapter 9
Application of Soft Computing Techniques for Renewable Energy Network Design and Optimization

Tianxing Cai
Lamar University, USA

ABSTRACT

Energy operation can be characterized by its complex network system composed of energy generation, energy transformation, energy transportation, and energy consumption. The network has provided the great flexibility for energy transformation and transportation; meanwhile, it presents a complex task for conducting agile energy dispatching when extreme events have caused local energy shortages that need to timely be restored. One of the useful methodologies to solve such a problem is soft computing, which conducts collaboration, association, and complementariness of the different techniques that integrates them. The applications and developments of soft computing have amazingly evolved in the last two decades. Many of these applications can be found in the field of renewable energy and energy efficiency where soft computing techniques are showing a great potential to solve the problems that arise in this area. In this chapter, several soft computing techniques are briefly introduced. Then the methodology framework and implementation procedures are presented to demonstrate the application of artificial neural networks and curve fitting for renewable energy network design and optimization, which has the capability to handle restoration during extreme and emergency situations with uncertain parameters.

INTRODUCTION

Nowadays energy supply is characterized by its diversity, including traditional energy such as fossil fuels, nuclear power, as well as renewable energy such as solar, hydroelectric, geothermal, biomass, and wind energy. It involves a complex network system composed of energy generation, energy transformation, energy transportation, and energy consumption. The network does provide the great flexibility for

energy transformation and transportation; meanwhile, it presents a complex task for conducting agile energy dispatching when extreme events have caused local energy shortages that need to be restored timely. The design and optimization of energy network needs to investigate the environment impact of current power plants in order to replace the fuel combustion method with renewable energy facility and integrate the consideration of the energy restoration during the emergency situation of regional shortage.

The energy network optimization actually involve a lot of factors such as climate change trend, regional energy demand forecast and regional environment impact assessment of traditional power plant operation with fuel combustion. The modeling and optimization to reversely determine the dynamic emission rate and search for the optimal energy restoration is always a high nonlinear multi-objective MINLP (Mixed Integer Nonlinear Programming) problem, which is difficult to solve with current deterministic MINLP solvers. Thus, the solving algorithm of multi-objective genetic algorithm (MGA) will be a good choice. MGA can directly obtain Pareto frontier of the raised two objectives from all possible patterns under different optimal scenarios. Furthermore, since the entire local area might be investigated, the whole region needs to be partitioned into a large number of grid cells and energy condition and its impact of each cell will be calculated. Thus, the optimization will involve lots of simulations, causing the simulation duty during the optimization is very heavy. All these operations are full of uncertain situations.

Facing these challenges, decision makers often encounters various uncertainties that inevitably influence the performance of a being designated energy dispatch plan. The uncertainties can upset the optimality and even the feasibility of the dispatch plan. Thus, quantitative analysis on the impact of uncertainties is of great significance for the study of energy network optimization. Technically, a viable approach is to conduct a full evaluation of the effects of uncertainties based on all their possibilities. This will provide decision makers a complete roadmap of the space of uncertainty parameters. Through this way, the objective function and the optimization parameters are represented as functions of uncertainty parameters (i.e., parametric programming); meanwhile, the regions in the space of the uncertainties characterized by these functions can be obtained. Therefore it is very useful for the stake holders to apply spatial and temporal predictive analysis techniques during the optimization of energy network operation. Among them, the soft computing techniques and artificial neural networks can be adopted to achieve the above purpose.

SOFT COMPUTING TECHNIQUES

Soft computing is a term applied to a field within computer science which is characterized by the use of inexact solutions to computationally hard tasks such as the solution of NP-complete problems, for which there is no known algorithm that can compute an exact solution in polynomial time. Soft computing differs from conventional (hard) computing in that, unlike hard computing, it is tolerant of imprecision, uncertainty, partial truth, and approximation. In effect, the role model for soft computing is the human mind. In computer science and related fields, artificial neural networks (ANNs) are computational models inspired by animals' central nervous systems (in particular the brain) that are capable of machine learning and pattern recognition. They are usually presented as systems of interconnected "neurons" that can compute values from inputs by feeding information through the network. These techniques have a very wide application (Ganesan, Elamvazuthi, Shaari, & Vasant, 2013; Elamvazuthi, Vasant & Ganesan, 2013; Vasant, 2013; Ganesan, Vasant, & Elamvazuthi, 2013; Ganesan, Elamvazuthi, Ku Shaari, & Vasant, 2013)

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

With the help of information technology, the spatial and temporal data are more than ever before. The environment monitoring for weather forecasting are typical spatial and temporal data. They have brought bring new challenges and opportunities to the research area of data analysis and intelligence solution. More predictive patterns should be identified from the integration of space and time dimensions in order to solve real-world problems. In real world, massive data volume are always available with uncertainty, complex relationship, and system dynamics. Spatial and temporal analysis has become one section of data mining (Fayyad, Piatetsky-Shapiro & Smyth, 1996). It has become interdisciplinary research field of computer science (ACM SIGKDD, 2006; Clifton, 2010; Hastie, Tibshirani & Friedman, 2009). which apply computation to identify and predict patterns from available large data sets. The applied methodologies or techniques include artificial intelligence, statistics, predictive analysis, information technologies, machine learning, and database systems (ACM SIGKDD, 2006). It aims to extract information from a data set and transform it into an understandable structure for further use (ACM SIGKDD, 2006). Besides data analysis, spatial and temporal analysis system also needs to integrate database, data management, data pre-processing, modeling and interpretation, complexity assessment, post-processing, visualization, and real time updating (ACM SIGKDD, 2006). All these are combined together computer decision support system. The tremendous information in the present age requires more accurate and comprehensive awareness in real time to enhance decision making. The critical part is to identify the particular points of area where critical decisions may be made, where the future may be predicted, and where the decision makers' abilities to manage their organizations may be enhanced.

The fast progress in the research has made the advanced techniques available for predictive analysis integrated with forecasting, modeling, and time series characterization, presenting identified patterns interactively, and finally, validating analytical models using real-world historical data which can be used for a range of applications ranging from intelligent alarms to monitoring and interpretation of trends in marketing systems. This convergence of interdisciplinary techniques for attuning adaptive models to specific application domains has brought the state of practice closer to the goal of developing models that are both predictive and explanatory. In order to support the prediction and analysis, a lot of techniques for regression analysis has been developed, such as the linear regression and ordinary least squares regression. The performance of regression analysis depends on the data generating process. The assumptions are made about this regression process. Regression models for prediction are often useful even when there are a lot of available data information. During the baby period of regression, it was called only "least squares"(Legendre, 1805; Gauss, 1809;Guass, 1821 & 1823; Mogull, 2004) Legendre The method is applied to solve the problem of determining from astronomical observations, the orbits of bodies about the Sun (mostly comets, but also later the then newly discovered minor planets).Afterwards, the regression techniques have been developed by multiple persons (Mogull, 2004; Galton, 1989; Galton, 1877; Galton, 1885; Yule, 1897; Pearson, Yule, Blanchard & Lee, 1993; Fisher, 1922; Fisher, 1954; Aldrich, 2005; Rodney, 2006). Due to their effort, regression methods are still at the status of active research. In recent decades, there appears new methods to handle robust regression, correlated responses, time series and growth curves, curve regression, image regression, graph regression, complex data objects, missing data, nonparametric regression, the predictor variables with error, more predictor variables than observations, and causal inference. On the other hand, the development of modeling with uncertainty is also very fast. It is very useful to make a full-scale evaluation of the effects of uncertainties based on all their possibilities. This will provide decision makers a complete investigation of the space of uncertainty parameters. Through this way, the objective function and the optimization parameters are represented as

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

functions of uncertainty parameters (i.e., parametric programming); meanwhile, the regions in the space of the uncertainties characterized by these functions can be obtained. In the field of parametric programming for handling uncertainties, Gal and Nedoma (Gal & Nedoma, 1972) developed an algorithm to solve multi-parametric linear programming problems based upon the Simplex algorithm. Acevedo and Pistikopoulos (Acevedo & Pistikopoulos, 1999) extended the field of parametric programming to address multi-parametric mixed-integer linear programs, and Dua, Bozinis and Pistikopoulos (Dua, Bozinis & Pistikopoulos, 2002) made significant contributions in the area of multi-parametric mixed-integer quadratic problems. Acevedo and Salgueiro (Acevedo & Salgueiro, 2003) presented a novel algorithm for the solution of convex multi-parametric nonlinear programming problems. More studies have also been reported in this area from Acevedo and Pistikopoulos (Acevedo & Pistikopoulos, 1997a; Acevedo & Pistikopoulos, 1997b); Ryu, Dua, and Pistikopoulos (Ryu, Dua & Pistikopoulos,2004); Jia and Ierapetritou (Jia & Ierapetritou, 2006a & 2006b); Verderame and Floudas (Verderame & Floudas, 2009). Therefore the combination of temporal and spatial analysis techniques with modeling under uncertainty will definitely extend the capability and capacity of energy network optimization.

APPLICATION OF SPATIAL AND TEMPORAL ANALYSIS FOR RISK ASSESSMENT, OPTIMIZATION AND DECISION MAKING ON ENERGY NETWORK OPERATION

The design and optimization of energy network operation needs to predict the potential demand trend, integrate the consideration of the energy restoration during the emergency situation of regional shortage and investigate the environment impact of current power plants in order to replace the fuel combustion method with renewable energy facility and. These will always involve large scale data and information systems. The application of spatial and temporal analysis for energy network operation will definitely helps to achieve these targets. The detailed description of their potential application will be provided as below.

Prediction of Energy Demand

Right now the techniques of modeling to predict or forecast energy demand has been available. According to Energy Demand Forecast Methods Report provided by California Energy Commission(California Energy Commission, 2005), in order to develop energy policies that conserve resources, protect the environment, ensure energy reliability, enhance the state's economy, and protect public health and safety, the Energy Commission is directed by Public Resources Code (PRC) Section 25301 to conduct regular assessments of all aspects of energy demand and supply. These assessments serve as the foundation for analysis and policy recommendations to the Governor, Legislature, and other agencies in the *Integrated Energy Policy Report (Energy Report)*. The Energy Commission's demand forecasting methodology features a variety of different models that follow into three large groupings: annual electric and natural gas consumption models and an electric hourly load model by sectors (or types of consumers). In most sectors, the Energy Commission's methodology attempts to simulate individual energy use decisions as they pertain to end use energy services. Examples of energy services are the comfort derived from a heated home, the clean dishes from a dishwasher, the illumination from a light fixture, and the evaporation of water from pulp in a paper making machine. Energy in the form of natural gas, electricity (or

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

other fuels) operates machinery to produce the service derived. Therefore, energy demand is a derived demand, not a direct one. End use energy consumption estimates can be developed from the application of analytical engineering techniques and econometric techniques for extracting information from customer use data. Early generation end use models were developed using largely engineering methods. As better data became available, disaggregate econometric techniques were incorporated. The advantage of end use modeling over other forecasting techniques is the ability to explain more fully how energy is actually used and factors affecting change in energy use. For example, the Energy Commission staff uses models involving different levels of end use detail to characterize the manner in which efficiency programs affect both energy requirements and peak demand.

Besides each state's development of its specific forecast model based on its own situation, United States Energy Information Administration (United States Energy Information Administration, 2009) also provides national wide standard modeling system, the National Energy Modeling System(NEMS). According to United States Energy Information Administration (United States Energy Information Administration,2009), the National Energy Modeling System (NEMS) is a computer-based, energy-economy modeling system of U.S. through 2030. NEMS projects the production, imports, conversion, consumption, and prices of energy, subject to assumptions on macroeconomic and financial factors, world energy markets, resource availability and costs, behavioral and technological choice criteria, cost and performance characteristics of energy technologies, and demographics. NEMS was designed and implemented by the Energy Information Administration (EIA) of the U.S. Department of Energy (DOE).

NEMS is used by EIA to project the energy, economic, environmental, and security impacts on the United States of alternative energy policies and different assumptions about energy markets. The projection horizon is approximately 25 years into the future. The projections in Annual Energy Outlook 2009 (AEO2009) are from the present through 2030. This time period is one in which technology, demographics, and economic conditions are sufficiently understood in order to represent energy markets with a reasonable degree of confidence. NEMS provides a consistent framework for representing the complex interactions of the U.S. energy system and its response to a wide variety of alternative assumptions and policies or policy initiatives. As an annual model, NEMS can also be used to examine the impact of new energy programs and policies.

Energy resources and prices, the demand for specific energy services, and other characteristics of energy markets vary widely across the United States. To address these differences, NEMS is a regional model. The regional disaggregation for each module reflects the availability of data, the regional format typically used to analyze trends in the specific area, geology, and other factors, as well as the regions determined to be the most useful for policy analysis. For example, the demand modules (e.g., residential, commercial, industrial and transportation) use the nine Census divisions, the Electricity Market Module uses 15 supply regions based on the North American Electric Reliability Council (NERC) regions, the Oil and Gas Supply Modules use 12 supply regions, including 3 offshore and 3 Alaskan regions, and the Petroleum Market Module uses 5 regions based on the Petroleum Administration for Defense Districts.

Baseline projections are developed with NEMS and published annually in the Annual Energy Outlook (AEO)(United States Energy Information Administration, 2009). In accordance with the requirement that EIA remain policy-neutral, the AEO projections are generally based on Federal, State, and local laws and regulations in affect at the time of the projection. The potential impacts of pending or proposed legislation, regulations, and standards¾or of sections of legislation that have been enacted but that require implementing regulations or appropriations of funds that have not been provided or specified in

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

the legislation itself¾are not reflected in NEMS. The first version of NEMS, completed in December 1993, was used to develop the projections presented in the Annual Energy Outlook 1994. This report describes the version of NEMS used for the AEO2009.1 The projections produced by NEMS are not considered to be statements of what will happen but of what might happen, given the assumptions and methodologies used. Assumptions include, for example, the estimated size of the economically recoverable resource base of fossil fuels, and changes in world energy supply and demand. The projections are business-as-usual trend estimates, given known technological and demographic trends (United States Energy Information Administration, 2009).

NEMS can be used to analyze the effects of existing and proposed government laws and regulations related to energy production and use; the potential impact of new and advanced energy production, conversion, and consumption technologies; the impact and cost of greenhouse gas control; the impact of increased use of renewable energy sources; and the potential savings from increased efficiency of energy use; and the impact of regulations on the use of alternative or reformulated fuels(United States Energy Information Administration, 2009).

In addition to producing the analyses in the AEO, NEMS is used for one-time analytical reports and papers, such as An Updated Annual Energy Outlook 2009 Reference Case Reflecting Provisions of the American Recovery and Reinvestment Act and Recent Changes in the Economic Outlook,2 which updates the AEO2009 reference case to reflect the enactment of the American Recovery and Reinvestment Act in February 2009 and to adopt a revised macroeconomic outlook for the U.S. and global economies. The revised AEO2009 reference case will be used as the starting point for pending and future analyses of proposed energy and environmental legislation. Other analytical papers, which either describe the assumptions and methodology of the NEMS or look at current energy markets issues, are prepared using the NEMS. Many of these papers are published in the Issues In Focus section of the AEO. Past and current analyses are available at http://www.eia.gov/oiaf/aeo/otheranalysis/aeo_analyes.html.

NEMS has also been used for a number of special analyses at the request of the Administration, U.S. Congress, other offices of DOE and other government agencies, who specify the scenarios and assumptions for the analysis(United States Energy Information Administration, 2009). Some recent examples include:

- *Energy Market and Economic Impacts of H.R. 2454, the American Clean Energy and Security Act of 2009*,[3] requested by Chairman Henry Waxman and Chairman Edward Markey to analyze the impacts of H.R. 2454, the American Clean Energy and Security Act of 2009 (ACESA), which was passed by the House of Representatives on June 26, 2009. ACESA is a complex bill that regulates emissions of greenhouse gases through market-based mechanisms, efficiency programs, and economic incentives.
- *Impacts of a 25-Percent Renewable Electricity Standard as Proposed in the American Clean Energy and Security Act*,[4] requested by Senator Markey to analyze the effects of a 25-percent Federal renewable electricity standard (RES) as included in the discussion draft of broader legislation, the American Clean Energy and Security Act.
- *Light-Duty Diesel Vehicles: Efficiency and Emissions Attributes and Market Issues*,[5] requested by Senator Sessions *to* analyze the environmental and energy efficiency attributes of diesel-fueled light-duty vehicles (LDV's), including comparison of the characteristics of the vehicles with those of similar gasoline-fueled, E85-fueled, and hybrid vehicles, as well as a discussion of any technical, economic, regulatory, or other obstacles to increasing the use of diesel-fueled vehicles in the United States.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

- *The Impact of Increased Use of Hydrogen on Petroleum Consumption and Carbon Dioxide Emissions*,[6] requested by Senator Dorgan to analyze the impacts on U.S. energy import dependence and emissions reductions resulting from the commercialization of advanced hydrogen and fuel cell technologies in the transportation and distributed generation markets.
- *Analysis of Crude Oil Production in the Arctic National Wildlife Refuge*,[7] requested by Senator Stevens to access the impact of Federal oil and natural gas leasing in the coastal plain of the Arctic National Wildlife Refuge in Alaska.
- *Energy Market and Economic Impacts of S.2191, the Lieberman-Warner Climate Security Act of 2007*,[8] requested by Senators Lieberman, Warner, Inhofe, Voinovich, and Barrasso to analyze the impacts of the greenhouse gas cap-and-trade program that would be established under Title I of S.2191.
- *Energy Market and Economic Impact*s of S.1766, the Low Carbon Economy Act of 2007,[9] requested by Senators Bingaman and Specter to analyze the impact of the mandatory greenhouse gas allowance program under S.1766 designed to maintain covered emissions at approximately 2006 levels in 2020, 1990 levels in 2030, and at least 60 percent below 1990 levels by 2050.

Therefore, it can be seen that the spatial and temporal analysis techniques have already been widely used to develop regional wide or even national wide energy modeling system. They really help to predict the potential demand under different scenarios of uncertain situations.

Energy Network Restoration Under Emergency Situation (Cai, Zhao, & Xu, 2012)

In recent years, the increasingly frequent occurrences of extreme events, such as U.S. southern storm and tornado (2011), Japan earthquake and tsunami (2011), and India power shortage (2010), have rang the world an alarm on reexamining whether current rescue policies are effective or efficient enough for a speedy recovery of the suffered areas. These disasters have caused tremendous damages to local areas in terms of economy, people's health and safety, transportation, as well as the energy and the living infrastructures. To restore the functionality and capability of these damaged systems, the recovery of energy system is one of the most important because all the other recovery operations have to be supported by enough available energy. On the other hand, if the local energy shortage caused by a disaster cannot be effectively restored, the local areas will be at risks of rescue delay, widespread power outages, economic losses, and even public safety threats. Therefore, the recovery time minimization of a suffered energy network system should be a top priority of an emergency rescue plan. On the other hand the climate change, population increasing and demand forecast have presented an increasing trend of energy demand. However, the high energy demand will always cause regional energy shortage.

From the literature survey, the reported work on local energy shortage and management problems has been studied. The contribution includes policy making of normal management (Bellarmine & Arokiaswamv, 1996), energy operation in buildings (Meier, 2006), economic impact from energy shortage (Sanghvi, 1991), energy shortage solution by economic lever function (Heffner, Maurer, Sarkar & Wang, 2010), typical technology proposal of renewable energy utility (Kainkwa, 1999), and energy system optimization for reduction of environmental impact (Berredo, Ekel, Martini, Palhares, Parreiras & Pereira, 2011). However, there is still lack of study on decision marking support for energy dispatch optimization under emergency situations. Conceivably, this is not a trivial task, because it involves multiple types of energy

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

(traditional energy and renewable energy), different energy shortage modes (e.g., short of energy source materials or incapable of energy transformation or transportation), and various energy dispatch scenarios (e.g., energy dispatch from one place to another place, 1→1for short; or possibly 1→n, n→1, and n→n) based on the available infrastructure of local energy dispatch network.

Nowadays energy supply is characterized by its diversity, including traditional energy such as fossil fuels, nuclear power, as well as renewable energy such as solar, hydroelectric, geothermal, biomass, and wind energy(United States Energy Information Administration, 2013). It also involves a complex network system composed of energy generation, energy transformation, energy transportation, and energy consumption. The network does provide the great flexibility for energy transformation and transportation; meanwhile, it presents a complex task for conducting agile energy dispatching when extreme events have caused local energy shortages that need to be restored timely. Conceivably, any type of dispatched energy under certain emergency condition has its own characteristics in terms of availability, quantity, transportation speed, and conversion rate and efficiency to other types of energy. Thus, different types of energy should be dispatched through a superior plan. For instance, energy sources such as petroleum or coal can be directly transported to a suffered area; meanwhile, they can also be converted to electricity in a source region and then sent to the suffered area through an available electricity network. Sometimes, even the transportation of the same type of energy may have different alternative routes for selection, which needs to be optimally determined from the view point of the entire energy dispatch system.

Environment Impact Assessment for Power Plant Emission (Cai, Wang, & Xu, 2013)

According to the Environmental Protection Agency's (EPA) 40 Code of Federal Regulation, malfunctions refer to any "sudden, infrequent, and not reasonably preventable failure of air pollution control equipment, process equipment, or a process to operate in a normal or usual manner"(United States Environment Protection Agency, 1982). "Gaussian Plume Model" is an approximate analytical method for point-source emissions for calculation of air pollutant concentration in the downwind area (Bowman, 1996;Turner, Bender, Pierce & Petersen, 1982;Griffiths, 1994; Halitsky, 1989;Slade, 1986; Seinfeld, 1986; Hanna, Briggs & Kosker, 1982; Turner, 1979;Turner, 1994; Pasquill, 1961; Pasquill, 1974; Church, 1949;Goldsmith & Friberg, 1976). Even though inverse modeling methods based on Gaussian plume models have been reported (Hogan, Cooper, Wagner & Wallstrom, 2005; Jeong, Kim, Suh, Hwang, Han & Lee, 2005; MacKay, McKee & Mulholland, 2006), they are generally used to estimate emission rates of point sources in an average long-time period based on measurements from multiple monitoring stations. In practice, the dynamic emission profiles can be very useful. For example, it can help schedule multiple plants' activity to minimize regional air quality impacts (Cai, Wang & Xu, 2013).

APPLICATION DEMONSTRATION

For the purpose of vivid illustration of the potential application of spatial and temporal predictive analysis in energy network operation research, two virtual cases have been included here. However, the attention should be paid that the handling of the real world problem of energy network will definitely involve regional or national wide scale of data system, which is much more larger than the provided virtual cases. Furthermore, the latest Annual Energy Outlook(United States Energy Information Administration, 2013)

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

can be referred to as the application result of the spatial and temporal predictive analysis technique to predict energy demand. Therefore the virtual case illustration has been omitted in this part.

Energy Network Restoration Under Emergency Situation (Cai, Zhao, & Xu, 2012)

An energy network is composed of three cities (A, B, and C). The infrastructure of city A is currently experiencing energy shortage. The other two cities (B and C) are not affected by the event and thus are able to provide energy and source materials to support city A. By following the first two stages of the proposed methodology, the energy initial conditions of this case study are summarized in Table 1, which gives all the parameters used in the energy dispatch model.

Beside the listed parameters, the efficiency of electricity transportation is approximated as 0.95, suggesting 5% loss during electricity network transmission; the hourly energy consuming index is 0.05, suggesting 5% of the available inventory energy will be consumed from the network. Meanwhile, there

Table 1. Given data of the case study

Description	Parameter	Energy Source	Unit	*i* / *j*		
				A/B or C	B/A or C	C/A or B
Electricity Conversion Efficiency from Other Energy Sources (*k*: electricity)		*l*: Petroleum Oil	MWh/Barrel	0.55	0.51	0.62
		l: Natural Gas	MWh/Million ft^3	0.12	0.125	0.11

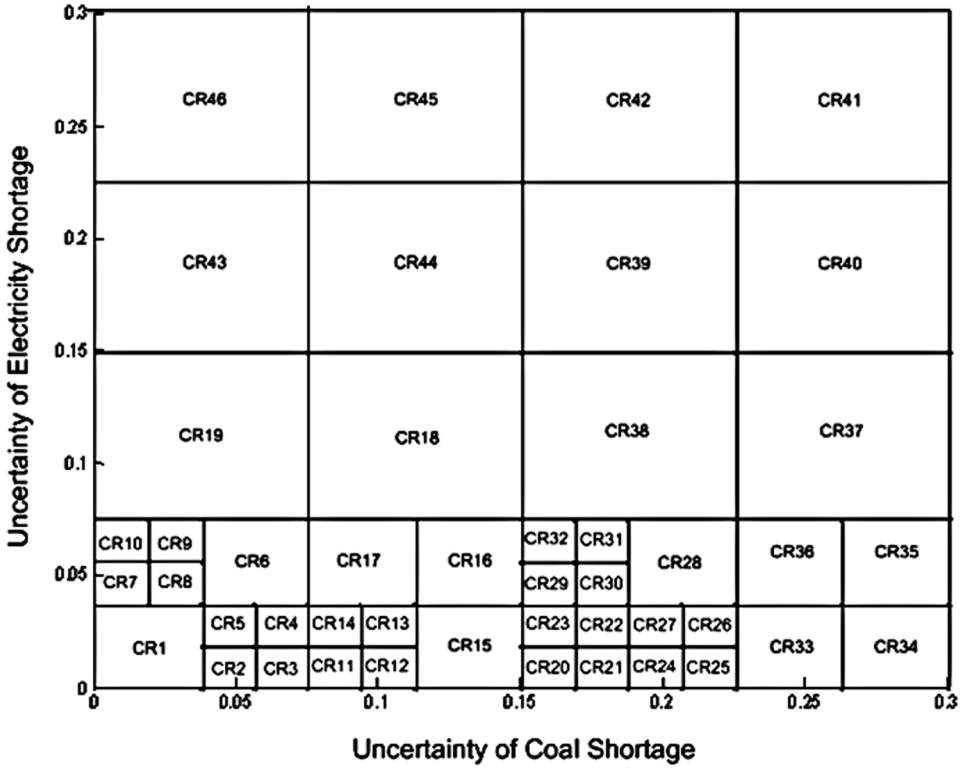
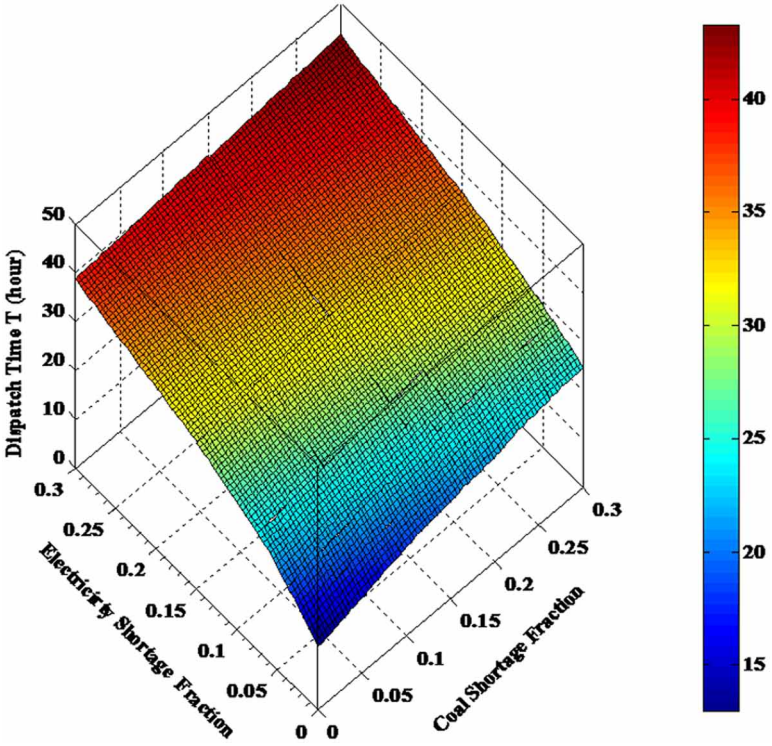
		k: Coal	Short Ton/hr	27	22.5	27
		k: Electricity	MWh/hr	0	0	0



EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

is no time retention for electricity transmission between cities while the transportation time for source material is two hours between two different cities.

During the emergency situation, assume all types of energy suffer 10% loss in city A, meanwhile there is no energy loss damage to the other cities. Based on the developed energy dispatch model with GAMS(Cai, Zhao & Xu, 2012), the optimization result shows that the minimum dispatch time for this energy restoration of city A is 26 hours. Two parameters, the energy loss for coal and electricity in city A, are estimated before the energy dispatch optimization. They are actually typical uncertainties that should be investigated to disclose their impact to the final energy dispatch optimization results. Assume they can vary within the range from 0 (no energy loss) to 0.3 (30% energy loss). Then based on the proposed algorithm of uncertainty space partition, a two-dimensional uncertainty space has been constructed, where uncertainties θ_1 represents the energy loss fraction of coal ($0 \le \theta_1 \le 0.3$) and θ_2 represents the energy loss fraction of electricity ($0 \le \theta_1 \le 0.3$). Figures 1 and 2 show the partitioning result with the total of 46 critical regions (CR1~CR46). The standard criteria (SC) of derivative percentage is set as 1.5% to identify the approximation performance of function regression.



Note that the 3D profile in Figure 2 is not a smooth surface although it looks like. They characterize the relation between the optimal energy dispatch time and the studied two uncertain parameters. They provide decision makers a reference manual for the easy lookup of the possible impact from uncertainties and thus help conduct right decisions. For example, the 3D surface generally shows the less coal and electricity shortages will result in less energy recovery time. As its 2D projection on the uncertainty

Figure 1. Uncertainty space partitioning for the case study

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Minimum energy dispatch time with respect to uncertainties

space as shown in Figure 5, any emergency case specified by coal and electricity shortage for City A corresponds to a point (say point S) in the plane. The energy dispatch behaviors among the network are actually moving the point S to finally reach the left-bottom corner point. It should be known that any movement in a short time period can be decomposed into two directions: one is toward the iso-time direction that does not reduce energy recovery time at all; the other is gradient direction perpendicular to the iso-time direction, which represents the shortest energy recovery time and smart move direction. For illustration, the iso-time and gradient directions at a point S (with 20% electricity and 15% coal shortages respectively) are demonstrated in Figure 3. Based on such information, the dynamic impact of different energy dispatch strategies can be evaluated, which will help decision makings under uncertainties.

Environment Impact Assessment for Power Plant Emission (Cai, Wang, & Xu, 2013)

The studied case study involves a sunny spring day with the strong radiation of 20 K/km lapse rate and the surface wind speed of 1.8m/s at 10 meter height and the ambient temperature of 20 °C. Firstly, the potential risk analysis has been conducted to examine the current power plant emission, which assume all the plants initiate their capacity enhancement at the same time (08:00). Since the potential risk analysis has identified the potential air quality problem according to the original plant start-up plan, the optimal rescheduling for the multi-plant start-ups must be perform in the second stage. The objectives of the developed MOO model are set to minimize the overall air quality impacts to all AQCRs and total

start-up time mismatch for all the plants by manipulating the start-up beginning time of each plant. The MOO modeling is implemented in MATLAB with the help of Global Optimization Toolbox. The optimal solution is shown in Table 2.

CONCLUDING REMARKS

This chapter has provided the brief introduction of spatial and temporal predictive analysis techniques, especially for their application in energy network optimization. The application scope will cover the energy demand forecasting and prediction, energy network optimization to meet the demand requirement and environment impact for the emission from the current power plants during capacity enhancement. The design and optimization of energy network operation needs to predict the potential demand trend, integrate the consideration of the energy restoration during the emergency situation of regional shortage

Table 2. Summary of optimal solutions under different scenarios

Category	**Case 1**	**Case 2**	**Case 3**		
Scenarios	**No Air Quality Risk**	**Manipulating E1, E2, E3**	**Manipulating E1 Only**	**Manipulating E2 Only**	**Manipulating E3 Only**
E1 Mismatch Time (hr)	--	0	3	0	0
E2 Mismatch Time (hr)	--	1	0	2	0
E3 Mismatch Time (hr)	--	3	0	0	1
Total Mismatch Time (hr)	--	4	3	2	1
Maximal Concentration in AQCRs (ppb)	45	55	75	105	77

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

and investigate the environment impact of current power plants in order to replace the fuel combustion method with renewable energy facility and. These will always involve large scale data and information systems. The application of spatial and temporal analysis for energy network operation will definitely helps to achieve these targets. It has shown a great potential to solve the problems that arise in the field of energy network operation. The technique significance and application demonstration have been presented to attract more engineers, scientists, researchers and the other related stake holders to dedicate to its development in the future.

DISCUSSION

This chapter provides valuable information for accidental investigations and root cause analysis for an emission event; meanwhile, it helps evaluate the regional energy network operation and air-quality impact as well. It lays out a solid foundation for multiple stake holders on diagnostic and prognostic decisions in face of an industrial air-pollution event, including government environmental agencies, regional chemical plants, and local communities.

FUTURE RESEARCH DIRECTIONS

It is necessary to further extend the current research to be integrated into the website service of environmental protection and energy management agency. Similar case studies and applications in using technologies and fundamental theory can be applied and demonstrated in the representative service domains with the combination of e-business services, mobile services, social networking services, cloud services, legal services, healthcare services, logistics services and educational services taking into account demands from government, organization, enterprise, community, individual, customer, and citizen.

KEY TERMS AND DEFINITIONS

Artificial Intelligence: Artificial intelligence (AI) is the human-like intelligence exhibited by machines or software.

Artificial Neural Networks: They are computational models inspired by animals' central nervous systems (in particular the brain) that are capable of machine learning and pattern recognition.

Energy: In physics, energy is a property of objects, transferable among them via fundamental interactions, which can be converted in form but not created or destroyed.

Fuzzy Logic: It is a form of many-valued logic which deals with reasoning that is approximate rather than fixed and exact.

Optimization: In mathematics, computer science, or management science, mathematical optimization (alternatively, optimization or mathematical programming) is the selection of a best element (with regard to some criteria) from some set of available alternatives.

Renewable Energy: Renewable energy is generally defined as energy that comes from resources which are naturally replenished on a human timescale such as sunlight, wind, rain, tides, waves and geothermal heat.

Soft Computing: It is a term applied to a field within computer science which is characterized by the use of inexact solutions to computationally hard tasks such as the solution of NP-complete problems, for which there is no known algorithm that can compute an exact solution in polynomial time.

This research was previously published in the Handbook of Research on Artificial Intelligence Techniques and Algorithms edited by Pandian Vasant, pages 204-225, copyright year 2015 by Information Science Reference (an imprint of IGI Global).

Chapter 10
The Sustainable Development Approach in the Economy–Ecology Dilemma

Gökhan Tenikler
Dokuz Eylül University, Turkey

Gamze Yıldız Şeren
Namık Kemal University, Turkey

ABSTRACT

The managerial model of cooperation and dialogue-driven, international, and supranational efforts during the past half-century form one of the most important topics within the "sustainable development" concept. Rapidly growing human population, together with the unsustainable pattern of consumption of renewable natural resources for future generations, also leads to the transfer of resources. The concept of development in keeping with ecological concerns about the impact of the dynamic approach should be reformulated. Faced with such dilemmas, these debates illustrate the need for a rational approach. Without jeopardizing the needs of future generations, to meet the demands of today's resource usage, the authors envision a sustainable development approach that seeks to balance protection and use. This approach should be addressed in the context of an understanding.

INTRODUCTION

The world we live in entered into a recent flurry of ends which can be estimated even today. However, this haste is not likely to be fulfilled only by those living in the present time, but needs to reach into future time.

So what's all the fuss about; what is the reason for this concern? Actually it is not too difficult to answer this question; the answer is very clear: Unsustainability. This concept corresponds to the expression: END OF LIFE.

It is mandatory to ensure continuity of natural resources, the living and non-living environment that constitutes the environmental components. So it is possible to separate these resources into two categories: living and nonliving resources (Keleş, Hamamcı & Çoban, 2012).

Live natural resources are biologically diverse and are composed of plants, animals and microorganisms. Humans are also a part of biodiversity and the life chain. Extinction of one of these species endangers other species which complement all the types generating the chain. If the Protection-usage balance cannot be established in a healthy way, the shortened chain may eliminate humans in the future. Commissioned by the United Nations Environment Program (UNEP), in 1995 the "Global Biodiversity Assessment" scientific report disclosed that about 1000 generations of species could rapidly become extinct (Türkman, 1998). Again, in 2010, declared the Year of Biodiversity by the United Nations, the International Union for Conservation of Nature (IUCN) reported that 44% face this danger, while 2% were also completely accounted for as extinct, of a total of 47,677 species on the IUCN's Red List (United Nations Environment Program [UNEP], 2010).

Essential and gradually decreasing living resources for food and agriculture are among the important advantages a country can have these days. The world's arable lands and water resources are rapidly becoming polluted and destroyed. Scientists agree that people will face a serious food and water problem in the near future. In the light of these developments, a country's biological diversity, particularly in terms of genetic resources, confers the status of a great power, because wild living resources are utilized to develop varieties with high production potential and resistance to environmental pressures (Convention on Biological Diversity [CBD], http://www.bcs.gov.tr/biodiversity/biodiversity.php).

Nonliving natural resources needed to sustain biological diversity are air, water, soil habitats and the subterranean base. The relative importance of these resources has an economic rather than ecological basis. As a result of unlimited economic growth, resource depletion has accelerated, creating the danger that the resources will fail to perform their functions due to global warming, soil erosion, and atmospheric pollution.

The exit point of the problems of living and non-living natural resources is related to conservation vs use, or "ecology" vs "economy", and reconciliation of these conflicting values.

The term "ecology" was first used by the German biologist Ernst Haeckel in 1866 (Keleş et al., 2012). He combined the Ancient Greek "Oikos", meaning "house, home, dwelling place, habitation" with the word "Logia", which means "speaking, discourse, treatise, doctrine, theory, science" (Okologie). In this respect, the word "ecology", derived from a discipline that identifies the subject areas of creatures' lives, encompasses the meaning "home science".

The etymological root of the word "economy" is similar to that of ecology. It (oikonomia) is derived from a combination of the Ancient Greek word for "home" (oikos) with the word for "law, management" (nomos). Economy might thus denote "thrifty household management", because in this context it incorporates the meanings "household management" and "being frugal, being thrifty".

However, the word "economy" has moved away from this meaning nowadays. Modern economics has lost its roots in the Greek word oikonomia (household management). It has instead absorbed chrematistics, or the maximization of short-run gain (Pearce, 1998, from Hayward, 1995).

SUSTAINABILITY OF RESOURCES

The famous Greek philosopher Plato is remarkable for his unconscious insight into the use of natural resources. In his work "Kritias" he wrote that, as a result of cutting trees, fertile soil is lost to excessive erosion, so that water resources are depleted. The slogan of today's environmentalists, "Let's protect biological diversity", has its source in the "abundance, productivity, diversity" principle put forward by Plato. The ancient Roman Tacitus is one of the most important environmental thinkers. Today he can be regarded as the pioneer of green values and of natural areas, as well as the person who first came up with the idea of leaving natural areas as they are. Tacitus particularly opposed dam construction and the modification of river channels (Tont, 1997).

A pessimistic approach to this aspect of the world, of course, depends on many factors which might arise. Two of these factors are located at the heart of the problem.

The first factor is "non-sustainable" consumption (Keating, 1993). Largely because of this problem, continuity can only be assured by the balanced use of resources. The second factor is the tremendous increase of the human population worldwide. In particular, the rapid population growth in the least developed and developing countries raises the prospect of impoverishment and degradation. In this sense the unplanned consumption of resources by the population has increased.

Unsustainable consumption patterns in a world with a growing population continues to put increasing pressure on natural resources. Former United States Vice President Al Gore declared in the documentary film "An Inconvenient Truth" (Isaacs, 2009):

We are witnessing a collision between our civilization and the Earth. And there are three factors that are causing this collision, and the first is population. When my generation, the baby boom generation, was born after World War II, the (world) population had just crossed the two billion mark. Now, I'm in my 50's, and it's already gone to almost six and a half billion. And if I reach the demographic expectation for the baby boomers, it'll go over nine billion.So, if it takes 10.000 generations to reach two billion and then in one human lifetime, ours, it goes from two billion to nine billion, something profoundly different is going on right now. We're putting pressure on the Earth. Most of it's in the poorer nations of the world. This puts pressure on food demand. It puts pressure on water demand. It puts pressure on vulnerable natural resources, and this pressure is one of the reasons why we have seen all the devastation of the forest, not only tropical, but elsewhere.

United Nations population projections in 2012 confirm Al Gore's statement. According to calculations made in 2013, the world population of 7,162,119 will reach 9,550,945 in 2050, and 10,853,849 in the year 2100 (United Nations [UN], 2013a).

Physical and biological properties of natural resources around the world in countries with existing assets are not unlimited. Renewable natural resources face the danger of misuse as a result of disruptive activities. Rapidly growing human populations are placing ecological and social pressure on these natural resources, leading to concern about a livable environment, especially for future generations, and even about the end of available resources, let alone their sustainability.

At Stanford University, biologist Petr Vitousek and his team stated that 40% of the annual net primary production on the earth's land is used directly to meet people's requirements, or used and destroyed indirectly by human activities. According to a simple calculation based on this statement, for the human species to survive on earth only 60% will remain of the millions of species. However, the speed of population growth threatens to increase the current rate of net primary production to 80% in 2030. In addition, the increase in per capita consumption may shorten this period. The earth's people, increasingly usurping the

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

dynamics of ongoing life, will further accelerate the collapse of natural systems. However, as indicated by Vitousek and his team, "it seems that the limits of growth today will be of interest to decision-makers who think it is so far away, unaware of this biological reality" (Brown, Flavin, & Postel, 1998).

Nowadays, the system of consumption of water, air and soil that we regard as "renewable" leads to the pollution of natural resources, the alternative being to reduce utilization. It should be noted that the resources of world are not compliant with this outlook; they are not enough.

All societies, especially in the developed countries, have a tendency to more and more consumption. In short, these societies have built their future scenarios on a world in which "they consume more than they produce", without being aware of the problems they may encounter as a result.

At this point, in the context of unsustainability, an imbalance emerges between the consumption of developing or less developed societies, and that of developed societies. First of all, continuity of supply represents a balance. Sustainability, ensuring a balance between the long-term integrated and systematic economic, environmental and cultural resources, is necessary and inevitable.

United States President Thomas Jefferson, on September 6, 1789, asked in a letter to the next president James Madison, "whether a generation, have the right to bind provisions of the next generation", and answered in the negative that the world belonged to the living not the dead and that therefore those currently living should not leave a debt to future generations (Boyd (ed.), 1950):

Would the present generation be obliged to apply the produce of the earth and of their labor to replace their dissipations? Not at all.

Former United States Vice President Al Gore, again, expressed the imbalance in consumption in the following way (Karaca, 1995): that every American child consumes and produces waste up to the equivalent of every 30 Indian children born.

The World Bank Development Indicators report for 2008 showed that, according to 2005 data, 20% of the richest countries in the world are consuming about 76.6% more than the rest of the world. However, constituting 20% of the world's population, the poor countries, despite being equally proportional in size to the rich countries, consumed just 1.5% (World Bank, 2008).

In the early 1990s, Mathis Wackernagel developed the methodology for the "Ecological Footprint" along with his doctoral advisor Professor William E: Rees at the University of British Colombia in Canada. This is a natural resource accounting tool that measures how much of nature we have, how much we use and who uses what (Amend et al. (eds), 2010).

It is a measure of how much area of biologically productive land and water an individual, a population or an activity requires to produce all the resources it consumes and to absorb the corresponding waste (such as carbon dioxide emissions from fossil fuel use), using prevailing technology and resource management practices. The Ecological Footprint is usually measured in global hectares (gha), and includes the area of built-up land (Wackernagel et al., 2012).

According to ecological footprint calculations in 2008, our planet's biocapacity was 12.0 billion gha, or 1.8 gha per person, while humanity's ecological footprint was 18.2 billion gha, or 2.7 gha per person. This indicates a biocapacity deficit of 0.9 gha per person. Biocapacity per capita continuously declines as population increases (World Wildlife Fund [WWF], 2012).

Every country of the world has a different ecological footprint. For example, if all humanity lived like an average Indonesian, only two-thirds of the planet's biocapacity would be used; if everyone lived like an average Argentinean, humanity would demand more than half an additional planet, and if everyone

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

lived like an average American, a total of four Earths would be required to regenerate humanity's annual demand on nature (WWF, 2012).

Advanced societies not only consume their own natural resources quickly but also consume those natural resources of less-developed societies which are not used or operated due to lack of money.

Thus has emerged an imbalance of natural resources, on the one hand those developed by cultures grown better able to achieve their targets, and on the other hand those in cultures of developed societies that have reached a level of rapid rationalization leading to destruction.

While this disparity lasts, people living in poverty-ridden societies will find it difficult to wait for the protection of natural resources. However, one of the most important steps is to establish a balance between the positive and the moderate in seeking sustainability of natural resources and human resources.

Hence, all countries are obliged to create sustainable consumption patterns, the goal being pursued by a sincere effort under the leadership of developed countries. So, arising from unsustainable consumption of natural resources, we are required to review and limit the addiction that minimizes the world's resources and carrying capacity, in line with a more accurate understanding of consumption (Keating, 1993).

After a general statement about the elements of sustainability that should be seen as a threat, there is the question of what the concept of "sustainability" means and what its scope is.

PROTECTION AND USAGE BALANCE: SUSTAINABLE POLICY

The purpose of economic development since the 1950s, over 10-year periods, has been defined by a variety of changing catchwords. For example, in the 1950s it was "Industrial Development", and shortly afterwards, "Agricultural Development" (Agricultural Development); the 1970s brought in the concepts of "Poverty" and then "Basic Needs", when determining economic purposes; finally, "Sustainability" is added to the list in the middle of the 1980s (Bennett, 2002).

Along with the concept of sustainability as based in ecology, development-based approaches are also seen. Naturally, the question "Sustainability of what?" arises.

Scope of Sustainability

Sustainability embodies issues of environmental values as well as the question of the scope of democracy (International Council for Local Environmental Initiatives [ICLEI], 1997).

The environmental management principle and the democratic decision-making principle are the indispensable conditions of sustainability. The environmental management principle is applied within the time available and as long as each generation continues to achieve sustainability. However, sustainability cannot be realized independently of the principle of democratic decision-making. In an environment conducted independently of this principle it can only be managed to a certain level.

Likewise, when adopting the concepts of democracy and equality within the idea of sustainability, namely environmental values in the geographic and spatial sense, rejecting democracy and equality is unthinkable.

Sustainability, in the context of a rational use of resources, is also intended to address issues of intergenerational democracy and social equality. Over time, the understanding of democracy and equality presents a case extending well into future generations. In not separating future needs from those of today, sustainability represents a democratic element in terms of time. Likewise, when adopting the concept

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

of democracy and equality within the idea of environmental sustainability in the geographic and spatial sense, it would be out of the question to reject democracy and equality.

Sustainability as a concept does not target a single point within the community. The aim of creating a sustainable life requires a joint effort by all institutions of the society. For example, an improvement to be made in consumption patterns cannot be separated from the population. Again, the selection of technology appropriate to the idea of sustainability cannot be independent of the social and cultural structure of the society. Hence, in forming a global community of interdependent parts, sustainability alone is unthinkable.

Sustainability is a broad concept in scope. The proposal entails provisions affecting many elements of society: population is kept under control by reducing poverty, alternative technology is introduced, consumption patterns are improved, hunger/famine issues affect biodiversity, the adequate apportionment of resources is established.

So the concept of sustainability involves not only the outlook of the ecological movement which aims to prevent environmental pollution, but also has much wider societal implications. However, the application of this insight is not possible solely within the concept of sustainability. The success of its implementation and realization of its purposes depends on management of the social and political struggle.

Transformation of Development Approach

The history of mankind's struggle with nature offers many examples. Some authors have asserted that societies must struggle with Nature in order to create civilization.

The famous historian Arnold Toynbee described the struggle of humanity with nature in his "Challenge and Response Theory", according to which, in the emergence and development of civilizations, the available geographical environment determines the status of the constant human "challenge". But it should be noted that the struggle against nature undoubtedly involves taking advantages of the resources given by nature. As early as 3000 BC, the oldest written epic, the Sumerian Gilgamesh Epic, relates how the King of Gilgamesh fought to kill the monster Huwawa, a protector of a forest containing cedar trees, which provide timber, an important raw material in meeting his country's development needs (George, 2003).

The human–nature struggle that went on through the historical process has been reshaped as further growth in the developed countries today, and the further development, as reflexes, of the developing countries.

The 18th century classical economist Adam Smith promoted economic growth on the assumption that natural resources are unlimited. Especially in the 19th century, marked by the Industrial Revolution, natural resources were under pressure, as they provided the input to intensive production.

The effect of imperialist values on the use and allocation of resources should not be underestimated. For example, in 1855, the Indian Chief Seattle, whose natural resources the white man wished to purchase, made a speech which is impossible not to heed. This letter may be considered among the "first civilian protests against imperialism bearing the ecological label" (Toprak, 2012).

Although the ideas of the Industrial Revolution and the Enlightenment are the main source of the increase in prominent ecological problems, they also played a major role in the increase in environmental and ecological sensitivity. Awareness of nature began with the problems of industrial society. In the United Kingdom the Alpine Club (founded 1857), the Open Spaces Society (1865) and the Royal

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Society for the Protection of Birds (1889), were among the organizations that displayed such sensitivity (Görmez, 2010).

In the second half of the 20th century, intense debate over intergenerational obligations became the subject of the period, though in the first half of this century, highlights from the work and comments of the economist Pigou on "Wealth and Welfare" (1912) are noteworthy. Indeed, Pigou was one of the earliest economists to robustly defend the interests of future generations, who are likely suffer harm due to the indulgence of present generations (Kula, 1998).

Especially in the period after the Second World War, states and governments revived moves to continue within the framework of the their intense development efforts up to 1960, so that, to ensure the legitimacy of these efforts, natural resources were neglected.

Problems related to the rational use of natural resources began to be noticed by 1960. However, this awareness had not yet spread throughout the world.

In 1962, the ideas of Rachel Carson's "Silent Spring" and Garrett Hardin's "The Tragedy of the Commons" were among the first examples of effective efforts towards sustainable development. Paradigm-breaking books and articles such as these galvanized individual countries and the international community into action (UNEP, http://www.unep.org/geo/GEO3/english/pdfs/chapter1.pdf).

Carson's work, discussing the impact of the use of the chemicals, especially DDT, and the nature of jamming, saw the beginning of the modern environmentalist movement, while Garrett Hardin's discussion of the pressure on natural resources created by population growth in public areas is considered an important contribution to environmental understanding in the 1970s.

The "Environmentalist years", as the 1970s were called, along with development of the "green management" approach, were building the tendency towards non-rational use of resources based on this awareness.

The concept of development has become one that needs to be reformulated, after evaluating the managerial approach within the framework of economic perceptions, along with the impact of the approach based on ecological concerns.

Looking Both Responsive to Development and Sensitive to the Environment

In the 70s, Western scientists and industrialists, observing the process of environmental problems arising and necessary measures not being taken, resulting in greater risks to vibrant life, began to offer responses having universal dimensions.

In 1971, MIT (Massachusetts Institute of Technology) professionals were commissioned by the Rome Club and in 1972, as a suggestion offered by developed countries to less developed countries in "The Limits to Growth" report, originated the "Zero Growth" model (Meadows, Meadows, Randers, Behrens, 1972).

The model's basic logic rested on the view that a stage of developed countries' economies and a certain level of welfare had to be reached before the environment was destroyed. Starting from that idea, developing countries could be prevented from making similar mistakes, so that at least in other parts of the world the environment would remain intact.

At that time the model seemed Utopian and exaggerated, containing elements contrary to equality in developing countries, and rightly evoked strong reactions. It was suggested that the Rome Club report was a "trap" for the development efforts of less developed or developing countries. Developed countries following such a model encouraged the establishment of polluting industries in less developed countries,

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

thus indirectly threatening the latter while allowing their own capital in these countries to increase, but without the risk of contamination.

The reaction created by this concept, in a sense has led to the countries' search for a more realistic use of resources.

In 1972, the world experienced a development that would be recognized as a turning point in environmental policy: the Stockholm Conference on the Human Environment.

Recognizing the environment as a right for the first time, this conference took an important step towards sustainable development. Maurice Strong, secretary-general of the conference, who first used the maxim "environment does not exclude development" (Eco development), intended to adopt a development strategy from local sources, expressing the concept of equitable benefit (Keleş et al., 2012).

At the end of the conference, the Stockholm Declaration was issued, highlighting the relationship between the two principles for present and future generations, as the basis for recognition of sustainable development in the near future (UN, 1972):

- "Man has the fundamental right to freedom, equality and adequate conditions of life, in an environment of a quality that permits a life of dignity and well-being, and he bears a solemn responsibility to protect and improve the environment for present and future generations." (Principle 1)
- "The non-renewable resources of the earth must be employed in such a way as to guard against the danger of their future exhaustion and to ensure that benefits from such employment are shared by all mankind." (Principle 5)

In 1973, in Ernst Friedrich Schumacher's book "Small is Beautiful", underlining scarce resources in terms of production and consumption relations and the reorganization of necessity, criticized the capitalist perspective which defends growth and increases consumption (Schumacher, 1973).

In 1973, establishment of the United Nations Environment Program (UNEP) was among the first steps formulated in the corporate sense of environment–development relationships.

The most important of these concrete steps was the World Conservation Strategy (WCS) certificate, prepared and published in 1980 by UNEP, in partnership with the International Union for the Conservation of Nature and Natural Resources (IUCN) and the World Wildlife Fund (WWF).

The document was entitled "World Conservation Strategy – Living Resource Conservation for Sustainable Development". As can be seen, the "sustainable development" concept, first used in this strategy document with its current meaning, meant that the handling of its present meaning would take place in subsequent years.

WCS emphasizes the need for conservation and development to be dealt with so as to achieve a sustainable society. The document's definitions of development and conservation are as follows (International Union for Conservation of Nature [IUCN], UNEP, WWF, 1980):

Development is defined here as: the modification of the biosphere and the application of human, financial, living and non-living resources to satisfy human needs and improve the quality of human life. For development to be sustainable it must take account of social and ecological factors, as well as economic ones; of the living and non-living resource base; and of the long term as well as the short term advantages and disadvantages of alternative actions.

Conservation is defined here as: the management of human use of the biosphere so that it may yield the greatest sustainable benefit to present generations while maintaining its potential to meet the needs and aspirations of future generations. Thus conservation is positive, embracing preservation, maintenance,

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

sustainable utilization, restoration, and enhancement of the natural environment. Living resource conservation is specifically concerned with plants, animals and microorganisms, and with those non-living elements of the environment on which they depend. Living resources have two important properties the combination of which distinguishes them from non-living resources: they are renewable if conserved; and they are destructible if not.

The issue highlighted in this strategy document is the conservation of living resources. Accordingly, living resource conservation has three specific objectives:

- To maintain essential ecological processes and life-support systems (such as soil regeneration and protection, the recycling of nutrients, and the cleansing of waters), on which human survival and development depend;
- To preserve genetic diversity (the range of genetic material found in the world's organisms), on which depend the breeding programs necessary for the protection and improvement of cultivated plants and domesticated animals, as well as much scientific advance, technical innovation, and the security of the many industries that use living resources;
- To ensure the sustainable utilization of species and ecosystems (notably fish and other wildlife, forests and grazing lands), which support millions of rural communities as well as major industries.

"Sustainable utilization" is introduced to international literature in this document along with other concepts.

This first formulation of the sustainable development approach, foregrounding the more ecological approach and conservation of living resources, will consider reasons such as opposition to perceived improvement and the criticism that each activity will adversely affect the environment. The narrow perspective brought forward in WCS on the relationship between economy and ecology has created the need for reformulation of the concept of sustainable development. Development in a sustainable manner, without destroying natural resources and realizing the principles and decisions concerning the infrastructure, was outlined in the Brundtland Report of 1987 and has become effective.

1987 Brundtland Report (Our Common Future)

Unconscious and unplanned results of the use of natural resources, furthering the process of destruction, was an issue to be addressed once again, gaining importance in the international arena. By 1983 the United Nations created the UN World Environment and Development Commission (UN World Commission on Environment and Development); by 1987, it organized a meeting at the Kenyan capital Nairobi, where the principles for a sustainable future were applied and decisions were made. Here, the concept of sustainability, which today is used literally, was expressed by the Commission at the "Our Common Future" meeting, chaired by the UN Secretary General, former Norwegian Prime Minister Gro Harlem Brundtland. Hence the name "Brundtland report" entered the world agenda.

The most valid approach to the concept of sustainable development is found in the official definition of its scope provided by UNWCED (United Nations World Commission on Environment and Development) in 1987, in the Brundtland Report (Our Common Future):

According to the report, Sustainable development is development that meets the needs of the present without compromising the ability of future generations to meet their own needs (United Nations World Commission on Environment and Development [UNWCED], 1987). Development, thus, includes not

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

only rising aggregate consumption or output, but also environmental quality, social factors, and the distribution of income (Bretschger & Egli, 2001).

It contains within it two key concepts:

- The concept of "needs", in particular the essential needs of the world's poor, to which overriding priority should be given; and
- The idea of limitations imposed by the state of technology and social organization on the environment's ability to meet present and future needs.

Critical objectives for environmental and developmental policies that follow from the concept of sustainable development include:

- Reviving growth;
- Changing the quality of growth;
- Meeting essential needs for jobs, food, energy, water, and sanitation;
- Ensuring a sustainable level of population;
- Conserving and enhancing the resource base:
- Reorienting technology and managing risk; and
- Merging environment and economics in decision making.

Sustainable development requires:

- A political system that secures effective citizen participation in decision making;
- An economic system that is able to generate surpluses and technical knowledge on a self-reliant and sustained basis;
- A social system that provides solutions to the tensions arising from disharmonious development;
- A production system that respects the obligation to preserve the ecological base for development;
- A technological system that can search continuously for new solutions;
- An international system that fosters sustainable patterns of trade and finance; and
- An administrative system that is flexible and has the capacity for self-correction.

This report counted as priority issues population, food, agriculture, energy, industry, health, human settlements, and environmental cooperation in international relations.

The concept of sustainability has been introduced to the world's agenda in a way that has not been top-down. This concept in the international sense of addressing, on the basis of "development carried out for every legitimate action and development for the sake of resources consumed in an unconsciously destructive process" was unquestioned in the 1960s, when a developmentalist ideology appeared, and the environmental movement, emerging as a response in the 1970s, had its effects. Here the Brundtland Report, in the 1980s, served the purpose of the 1960s developmentalist ideology, reconciling it with the environmental understanding of the 1970s.

The report does not offer policy recommendations, but instead focuses on current problems and preventative challenges. The report indicates the need for an integrated planning approach that no country's sustainable development can perform while abstracting itself from other countries. Thus the report

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

reveals the necessity of change in international relations, mentioning the importance of the World Bank's leadership role in sustainable development.

The principles in the report were turned into a declaration by the UN General Assembly. Such a transformation in the form of recommendations is an important step in the creation of binding international environmental policy.

Despite the ideas it presented, the report has been subject to various criticisms (Erdoğan & Ejder, 1997). For example, some developed countries, especially in Germany, where the environmental groups were combined under the name "Alliance for Sustainable Development", presented their own reports. One such report, while praising the Brundtland Report, which drew attention to useful information and created an international debate about the environment, stated that the report would not bring fundamental change. The idea of showing environmental degradation as poverty and offering expansion as a remedy was rejected. The concept of Western-type growth and development from outside was a fallacy, since they should come from within the country. As an example, in answer to a question about the chances of India reaching Britain's living standards, Gandhi asserted: "this wealth of England was required to reach half of the world's resources. How many planets does a country like India want?"

The United Nations Conference on Environment and Development – Earth Summit

The Brundtland report provides a wealth of information on the concept of sustainable development, as well as paving the way to a global action plan for its implementation. However, the report has fallen far short of the expected "participation" that increasingly began to gain importance in the world (Emrealp, 2005).

Hence, the sustainable development approach adopted in 1987 must seek concrete implementation in terms of action-oriented policy, through arrangement of a global meeting to discuss need.

Indeed, in 1972, in Stockholm the world's first environmental conference was held, known as the "Human Environment Conference"; and on its 20th anniversary, the second largest world conference was held, on 3-14 June 1992 in Rio de Janeiro, the capital of Brazil.

For the development of environmentally compatible development policy, the summit aims at "a collective association", including representatives of the heads of state and governments as well as of non-governmental organizations (NGOs), considered as partners.

Meetings were carried out in two stages: the "Conference on Environment and Development (UNCED; 3 to 11 June 1992)" and "Earth Summit (12 to 14 June 1992)". Over 30,000 people from 172 countries participated in the well-attended conference, which brought together heads of state and government representatives at the global level for the first time to consider issues of environment and development.

As a result of UNCED, the Rio Declaration was published without a binding clause specifying the rights and obligations of countries in regard to environment–development issues.

The United Nations Conference on Environment and Development released, as one of the conference's five[1] documents, a declaration of principles containing 27 points.

The decisions taken and principles identified at the 1972 Stockholm Conference on Human Environment were reaffirmed; global environment and development systems would be studied for their protective agreements and the need to address these for the world as a whole was indicated. In addition, the creation of a new level was targeted, in order to establish a new and unbiased partnership of global cooperation between people and key sectors of society.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

We can specify 27 principles directly related to the "sustainable development" concept adopted in the Rio Declaration on Environment and Development (UN, 1992):

- **The Right to a Healthy Life:** Human beings are at the center of concerns for sustainable development. They are entitled to a healthy and productive life in harmony with nature.
- **Jurisdiction and Responsibility:** States have, in accordance with the Charter of the United Nations and the principles of international law, the sovereign right to exploit their own resources pursuant to their own environmental and developmental policies, and the responsibility to ensure that activities within their jurisdiction or control do not cause damage to the environment of other States or of areas beyond the limits of national jurisdiction.
- **The Right to Development:** The right to development must be fulfilled so as to equitably meet developmental and environmental needs of present and future generations.
- **Integration of Environment and Development:** In order to achieve sustainable development, environmental protection shall constitute an integral part of the development process and cannot be considered in isolation from it.
- **Poverty Eradication:** All States and all people shall cooperate in the essential task of eradicating poverty as an indispensable requirement for sustainable development, in order to decrease the disparities in standards of living and better meet the needs of the majority of the people of the world.
- **Special Priority to Developing Countries:** The special situation and needs of developing countries, particularly the least developed and those most environmentally vulnerable, shall be given special priority. International actions in the field of environment and development should also address the interests and needs of all countries.
- **Global Partnership and Cooperation:** States shall cooperate in a spirit of global partnership to conserve, protect and restore the health and integrity of the Earth's ecosystem. In view of the different contributions to global environmental degradation, States have common but differentiated responsibilities. The developed countries acknowledge the responsibility that they bear in the international pursuit of sustainable development in view of the pressures their societies place on the global environment and of the technologies and financial resources they command.
- **Patterns of Production–Consumption:** To achieve sustainable development and a higher quality of life for all people, States should reduce and eliminate unsustainable patterns of production and consumption and promote appropriate demographic policies.
- **Exchange of Knowledge:** States should cooperate to strengthen endogenous capacity-building for sustainable development by improving scientific understanding through exchanges of scientific and technological knowledge, and by enhancing the development, adaptation, diffusion and transfer of technologies, including new and innovative technologies.
- **Participation of Women:** Women have a vital role in environmental management and development. Their full participation is therefore essential to achieve sustainable development.
- **Importance of Youth:** The creativity, ideals and courage of the youth of the world should be mobilized to forge a global partnership in order to achieve sustainable development and ensure a better future for all.
- **Support to Local Communities:** Indigenous people and their communities and other local communities have a vital role in environmental management and development because of their knowledge and traditional practices. States should recognize and duly support their identity, culture and interests and enable their effective participation in the achievement of sustainable development.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

- **Respect for International Law:** Warfare is inherently destructive of sustainable development. States shall therefore respect international law providing protection for the environment in times of armed conflict and cooperate in its further development, as necessary.
- **Good Faith and Spirit of Partnership:** States and people shall cooperate in good faith and in a spirit of partnership in the fulfilment of the principles embodied in this Declaration and in the further development of international law in the field of sustainable development.

As seen earlier, many issues not addressed in a global dimension were discussed at Rio and agreed in principle. However, a full consensus could not be reached on all the policies raised, because of disagreements, particularly between developed countries and developing countries. No definitive consensus can be asserted on principles such as powers and responsibilities, the right to development, poverty alleviation, collaboration, and production-consumption-population.

The Rio Conference was a milestone of the world environmental movement, not only bringing the "sustainable development" concept into our lives, but also enhancing it, taking into account the participatory mechanisms and processes of the United Nations, and of all governments and other agencies and organizations. The Rio Conference reveals resources and dimensions in terms of environmental problems, and also includes a feature which enabled ideas and activities arising quite late in the history of mankind to be discussed on an international scale as comprehensive property. A basic common understanding of the principles adopted and expressed in the contracts signed at the conference is required; countries that have a common future cannot be unresponsive to environmental challenges, pollutants emitted into the global environment at different levels must be in amounts that do not endanger the environmental balance, and resources must renew themselves according to an ecologically sustainable conservation–use balance.

In order to take action on the topics discussed at Rio, an action plan has been prepared under the name of "Agenda 21".

The document presenting the Agenda of the 21st century, which features an action plan, is intended to form the basis for an understanding on sustainable development and environmental protection within the "global partnership". Agenda 21, which is one of the best-known documents of the United Nations, sets out the basic principles established in Rio about environmental protection and community development issues, based on their own residential properties.

The "global partnership" concept is introduced in the Agenda 21 Action Plan to meet basic requirements, improve living standards, better protect and manage ecosystems, and lay the building blocks for a more secure path to the future.

The Agenda 21 Action Plan consists of four main sections[2]:

- Social and Economic Dimensions;
- Conservation and Management of Resources for Development;
- Strengthening the Role of Major Groups;
- Means of Implementation.

At the Conference in Rio de Janeiro, world leaders signed three international treaties – the United Nations Framework Convention on Climate Change (UNFCCC) (followed by the Kyoto Protocol in 1997), the Convention on Biological Diversity (CBD), and the Convention to Combat Desertification (UNCCD) – which pursue one common goal: sustainable human development. All three Conventions

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

are of equal status in terms of their relevance to the preservation of our natural life-support systems, poverty reduction, and achieving greater global justice (Amend et al. (eds), 2010).

The United Nations Conference on Environment and Development in 1992 recognized the important role that the indicators could play in helping countries make informed decisions concerning sustainable development. As a matter of fact, Chapter 40 of Agenda 21 has called on countries, as well as international, governmental and non-governmental organizations, to develop indicators of sustainable development that can provide a solid basis for decision-making at all levels. Agenda 21 also has called for the harmonization of efforts to develop such indicators (UN, 2007).

Founded in 1992, the Commission on Sustainable Development (CSD) has since 1995 initiated the international sustainable development indicators, of which the main and sub-themes are as follows (UN, 2007):

- **Poverty:** Income Poverty, Income Inequality, Sanitation, Drinking Water, Access to Energy, Living Conditions.
- **Governance:** Corruption, Crime.
- **Health:** Mortality, Life Expectancy at Birth, Health Care Delivery, Immunization against Infectious Childhood Diseases, Nutritional Status, Health Status and Risks.
- **Education:** Education Level, Literacy.
- **Demographics:** Population, Tourism.
- **Natural Hazards:** Vulnerability to Natural Hazards, Disaster Preparedness and Response.
- **Atmosphere:** Climate Change, Ozone Layer Depletion, Air Quality.
- **Land:** Land Use and Status, Desertification, Agriculture, Forests.
- **Oceans, Seas, and Coasts:** Coastal Zone Fisheries, Marine Environment.
- **Freshwater:** Water Quantity, Water Quality.
- **Biodiversity:** Ecosystem, Species.
- **Economic Development:** Macroeconomic Performance, Sustainable Public Finance, Employment, Information and Communication Technologies, Research and Development, Tourism.
- **Global Economic Partnership:** Trade, External Financing.
- **Consumption and Production Patterns:** Material Consumption, Energy Use, Waste Generation and Management, Transportation.

These indicators are intended to give guidance to countries on how to create national sustainable development indicators.

Despite all these efforts, Agenda 21 failed to reach an agreement on all the issues up for discussion. These issues can be summarized as orientation of technology from rich countries to poor countries, transfer of financial resources, the protection of water resources, chemicals and hazardous waste management, data and information flow (Keleş & Hamamcı, 1993). It is not surprising that sharp differences of opinion on "sustainable development" have emerged between the developed countries who have used enhanced levels of access to natural resources rashly and caused a very large portion of current environmental problems, and those who are oppressed under the weight of the rapid urbanization process and whose natural resources are being depleted by development (Emrealp, 2005).

Similar efforts were made after 1992, with similar topics carried over to the following years.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Millennium Development Goals

The United Nations Millennium Development Goals were considered in September 2000 at the UN Millennium Summit in New York City by 192 members of the United Nations, who scheduled eight goals to be met by 2015:

The Millennium Development Goals for 2015 (UNEP):

1. Eradicate extreme hunger and poverty
2. Achieve universal primary education
3. Promote gender equality and empower women
4. Reduce child mortality
5. Improve maternal health
6. Combat HIV/AIDS, malaria and other diseases
7. Ensure environmental sustainability
8. Develop a global partnership for development

In 2015 the eighth goal was to be achieved, as the United Nations 2013 Millennium Development Goals Assessment Report discussed poverty reduction, wider access to clean water, improvement of living conditions in poor urban neighborhoods, and achievement of gender equality in primary schools, and stated that millions of people had realized improvement; as of 2015 it has become possible to achieve far more within the Millennium Development Goals (UN, 2013b).

However, one of the most important factors affecting the achievement of targets is the reduction of aid to developing countries. The report declares that the poorest countries received the biggest blow from this reduction. In 2012, net aid disbursements from developed to developing countries totaled $126 billion. This represents a 4 per cent drop in real terms compared to 2011, which was 2 per cent below 2010 levels. The decline affected least developed countries the most (UN, 2013b).

Rio+10, Rio+20

In 1992 was the Rio Environment and Development Summit; in 1997, the fifth annual assessment meeting was held in New York City, the Rio +5 Conference, following 10-year aims to be evaluated; and Rio +10, known as the World Sustainable Development Summit, 26 August to 4 September 2002, in Johannesburg was arranged.

The summits were followed by more than 104 heads of government and state as well as 20.000 participants, among them representatives of civil society organizations.

According to the Plan of Implementation of the World Summit on Sustainable Development, poverty eradication, changing consumption and production patterns, and protecting and managing the natural resource base for economic and social development are overarching objectives of and essential requirements for sustainable development (UN, 2002).

To achieve the objectives of Sustainable Development a new World summit was added, known as the Rio+20 Conference on Sustainable Development, aimed at a 20-year review of the 1992 Rio Summit. Held in Rio de Janeiro, “Sustainable development and the green economy” were established as the most important items on the agenda of the conference. In particular it was to lead to countries making

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

the transition to a green economy, while realistic and implementable solutions for public and private sectors were also put forward.

The outcome of the Rio +20 Earth Summit, the "Future We Want" document, discussed limitations and failures, despite the activities of the last 20 years, in meeting the objectives of sustainable development. According to the document, poverty is still the world's biggest problem. Poverty eradication, highlighting the aspects of sustainable consumption and production, and conservation and management of natural resources in economic and social areas of development, are confirmed once again as objectives of basic and comprehensive sustainable development. As of 2015, it was necessary to accelerate the achievement of development goals, including the Millennium Development Goals, by making repeated efforts to show commitment (UN, 2012).

Key to Ecology-Economy Dilemma: Sustainable Development

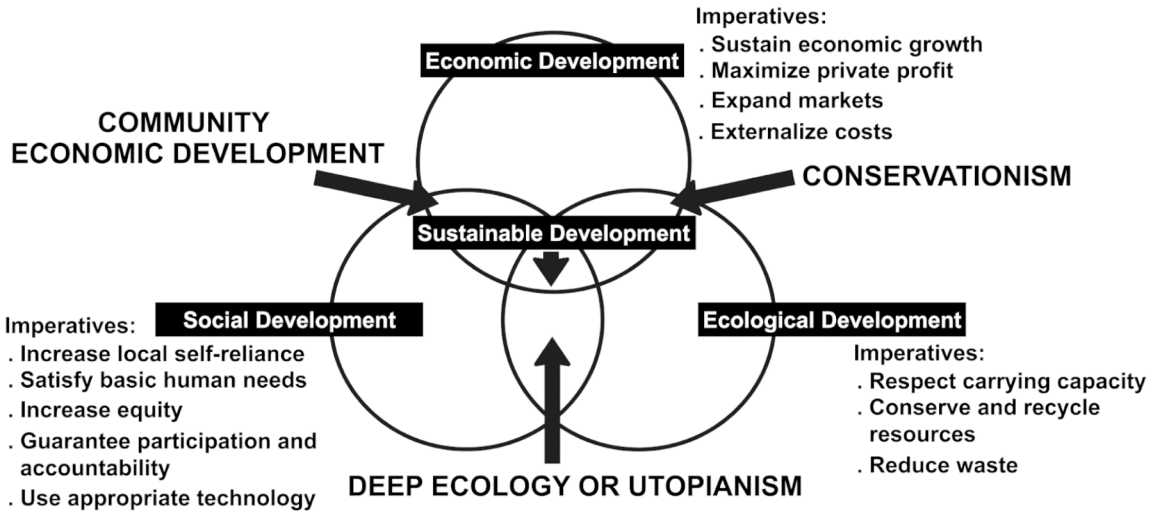
The idea of economic growth had the dominant role in the development process of the country until the 1970s, when the idea of Sustainable Development was first put forward.

Backward countries never had to handle economic development in relation to the environment. However, the concepts of environment and development are not independent of or opposed to each other.

Development sustainability and acceptability are connected to adoption of the idea that the environment is the source of economic development and has limits. In this spirit, the sustainability of economic development makes the maintenance of environmental health also necessary. Each of these two cases can seem, at first glance, to have a property which endangers the existence of the other.

Within the framework of the international efforts mentioned above, today's three basic elements of sustainable development, economy, environment and society, have experienced a major transformation in their relationship.

Sustainable development within this vision requires:



Economic competition within the world market, ensuring that basic needs such as education, people's housing, health, and clean drinking water are met in an appropriate manner, raising the level of welfare; Socially equitable policies, inclusive of disadvantaged groups and boosting the quality of life, From an environmental perspective, environmental pollution prevention and protection of the natural systems that support life in mutually supportive and complementary ways. A balanced planning, implementation and management process, between generations and inter generations. (Republic of Turkey, Ministry of Development, 2012)

1992 and later events showed that development begins first at the local level. It would not be possible to think of economy as separate from environment, environment from community, and community from the economy. The elements of economy, community and environment complement each other and each one has its own specific requirements (see Figure 1[3]).

Economic development also includes stable economic growth. It is necessary in the search for new markets that production capacity will inevitably need to grow. Community development requires an egalitarian social structure. Participation in decision-making should be improved. The presence of a social structure which is self-sufficient, able to meet basic needs and improve the quality of life is required. Ecological development demands resource utilization, reproduction of sources and less development, through technologies that respect the carrying capacity of nature. In fact, some aspects of community

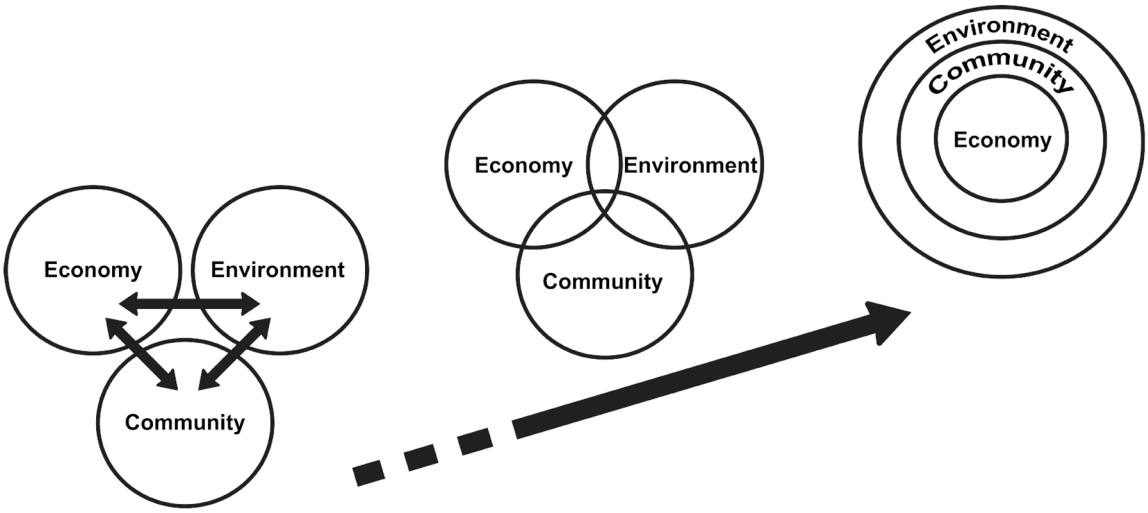
EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. The sustainable development challenge

development will take place in a more effective in a way with the establishment of a healthy balance between economy and ecology.

So are these three requirements of the development process in conflict within each other? The answer to this question is yes, by the shortest path. Economic production resource needs will put pressure on the idea of conservation of natural resources. The basic needs of society as well as individuals within the framework of luxury consumption habits can support economic development at the expense of ecological development. Economically prosperous sectors of society will increase inequality in income distribution in relation to impoverished segments of society. These contradictions, as can be seen within a single society, can also be clearly observed between countries.

In this regard, sustainable development is a process of bringing these three development processes into balance with each other. The implementation of a sustainable development strategy therefore involves negotiation among the primary interest groups (stakeholders) involved in these three development processes (ICLEI, 1996).



The current perception of the three dimensions of sustainable development is shown in Figure 2[4]. There is little belief in sustainable development as a mechanism for adaptation of these three dimensions, in an environment that has not produced effective solutions despite efforts taking place over the last 40 years. The presence of conflicting or crosscutting aspects render these three elements insufficient for the creation of a healthy harmony.

In a new perception, environment is evaluated in society and from the economy-wide perspective. Namely, the environmental conditions will acquire sustainability features or will weaken according to the community's economic preferences within their own lives. Developed at Rio +20, the "green economy" concept aims at catalyzing a reformulation of the environment rather than seeing environmental and economic thought as two separate, intersecting or conflicting, elements.

Sustainability means improving the quality of life concept in accordance with the carrying capacity of the area. The concept of sustainability is designed to provide sustainable development.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Evolution of sustainable development thought

In fact, sustainability is meant to include the environmental sustainability of natural resources as components. The concept of sustainability, resource use, not only takes into account the needs of the present generation but also those of future generations.

Environment, earlier perceived narrowly as short-term solutions to contamination problems and their elimination, today has begun to present itself in terms of natural, economic, social and cultural values as a whole. The most important factor determining this outlook is the destruction of the resources used to carry out social and economic development by rapid and irreversible methods.

Sustainable development as a concept popular in recent years is not, however, actually a new concept. In one respect, it upholds one of the basic elements of classical growth theory. It is possible to trace the original roots of this concept to Ricardo and Malthus. Both asserted that there were "natural limits" to economic growth. Ricardo argued that land resources are limited, while Malthus argued that in the relation between increasing population and resources, there were limits to the growth of the "natural", and that, once these limits were reached, producing goods would not be possible (Aruoba, 1992). The basis of this idea is that progression of population growth is geometric, while the increase in natural resources is subject to an arithmetic progression. So while population multiplies greatly over 25 years, natural resources increase only slightly (Keleş et al., 2012).

The question to discuss in seeking an approach to resource allocation, in view of the "Environment-Production" problem, is whether to allow the use of sources of growth to continue at a rapid pace, if they are also to be used in the future.

The question to be asked at this point is: how long will this development continue?

Long-term and steady development, if adopted as a goal to be achieved at the expense of short-term goals embodying a wasteful attitude to consumption of natural resources, will bring us to the point of blockage. In the future, if it is not possible to replace exhaustible resources with other sources, sustainable development will be out of the question.

In this context, two different perceptions of sustainability have been suggested: Weak and Strong Sustainability (Pearce, 1999).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

These two concepts are shaped by the substitution relationship between natural resources and man-made capital. According to the weak sustainability concept, there is an unlimited opportunity for substitution between natural resources and man-made capital. Natural resources are not endangered, therefore do not require protection. Growth continues with only partial restrictions. Strong sustainability adopts a reverse approach. Replacement of natural resources as a policy is inadequate, since these resources' ability to renew themselves is limited. Therefore, prevention is required.

In some sources a third definition of sustainability is added: Environmental Sustainability (Tietenberg, 2003). By this definition, it is not only the total value of natural resources that is important; protection of the individual is connected. For example, if a lot of fish are caught on a regular basis, more than the total number of fish caught are taken into account in protecting them.

In this context, if physical or human capital can be substituted by natural resources, the total natural resource base will not decrease (Ertürk, 2011). Indeed, sustainable development depends on the sustainability of renewable natural resources. In this regard the production of renewable energy needs to be more involved in the process.

Accordingly, the ideas brought forward by the concept of sustainable development can be summarized as economic development that does not consume natural capital, does not take away the possibility for future generations to meet their own needs, protects the balance between the economy and the ecosystem, and is ecologically sustainable (Berkes & Kışlalıoğlu, 1990).

Environment, in terms of natural resources, is the foundation of the economy needed to sustain the lives of people living in the surrounding area, and thus coexists with it. With the close connections between the environment and economic stability, ensuring the sustainability of human life is of vital importance.

However, economic growth always brings the risk of environmental damage, as it puts increased pressure on environmental resources. But policy makers guided by the concept of sustainable development will necessarily work to ensure that growing economies remain firmly attached to their ecological roots and that these roots are protected and nurtured so that they may support growth over the long term (UN, 1987). Friendly compliance will be provided between environment and economy through sustainable development policy.

A balance between environmental sustainability and the economy can be established only when communities, with fewer resources, can take "a precautionary approach" to prevent environmental problems before they occur, rejecting the principle of "the development concept despite everything" and to that extent reducing the uneven development and prosperity gap between countries.

Against the concept of sustainable development, some other approaches have emerged. One of the most important is "rather than sustainable development, sustainable living" (Karaca, 1998). On this understanding, sustainable development means depletion and pollution. Depletion and pollution risks all life, should these goals be pursued. Because development means production, consumption means contamination. It is necessary to seek the concept of a life that will guarantee of the survival of all living things in the future.

Another topic of discussion is whether the sensitivity that governments show in the international conventions is adequately reflected in their internal legal order.

In relation to this issue, some examples are found in provisions of the 1982 Constitution of the Republic of Turkey[5].

In the 1982 Constitution of the Republic of Turkey, "Social and Economic Rights and Duties" are listed under the headings of Article 56 and 65, as follows:

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

A. Health services and protection of the environment ARTICLE 56. Everyone has the right to live in a healthy and balanced environment. It is the duty of the State and citizens to improve the natural environment, to protect environmental health and to prevent environmental pollution. ….

XIII. The Extent of Social and Economic Rights (Before 2001) ARTICLE 65. The State shall fulfill its duties as laid down in the Constitution in the social and economic fields within the limits of its financial resources, taking into consideration the maintenance of economic stability.

XIII. The extent of social and economic duties of the State (After 2001) ARTICLE 65 (As amended on October 3, 2001; Act No. 4709): The State shall fulfill its duties as laid down in the Constitution in the social and economic fields within the capacity of its financial resources, taking into consideration the priorities appropriate with the aims of these duties.

As seen in Article 56, protecting the environment is located among the social obligations of the government and citizens.

Hence, as of today, according to Article 65 entitled "The extent of social and economic duties of the State", before the 2001 amendments, the state was looking out for economic stability in the social and economic performance of its duties. So that is one of the social obligations of environmental protection activities, should they adversely affect the economic stability of the state in carrying out its task. This application strengthened the state's discretion.

By the change made in 2001, "the maintenance of economic stability" was removed, and "the priorities appropriate with the aims of these duties" were added. In this case the government now will not only oversee economic stability to protect the environment, but the observance of environmental protection is expressed as a priority issue by the administration; if accepted, the government will fulfill this duty, but in fact, it is still at the discretion of the administration. However, the government's duty to protect the environment will not get caught on obstacles to economic stability alone.

As can be seen in the work of national legislation, taking into account the international approach to intellectual transformation, more is needed.

CONCLUSION AND REMARKS

The concepts of economy and ecology are not irreconcilable opposites. Greater competition between countries and the search for growth creates this dilemma. The only concern is for countries to exhibit a friendly attitude when discussing sustainable policies.

At the point of implementation of the principle of sustainable development, although it is not a full consensus even after a period of over 40 years, it is going ahead. The starting point of discussion is the developed countries which do not respect the balance of claims between protection and use. Those countries which destroyed the ecology are also trying to partner with less developed countries on the invoice.

With declarations and contracts signed after prolonged discussion by several governments, it remains to be seen to what extent sustainable life will be achieved. However, in reflecting on the application of these universal efforts, it appears that delays and conflicts of interest under the influence of forces might allow possible violations to occur.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Today all mankind are connected to each other more than ever because of the problems faced in relation to a common destiny. So far, all the national and international entities have combined to serve the common destiny and to find solutions to the problems on a national and international basis. For this reason, international organizations and governments have to be more responsible and responsive to the opinions and expectations of the people of the whole world.

There isn't a single mould for sustainability, because economic systems and ecological conditions vary greatly between countries. Therefore, each nation must determine for itself its own concrete policy requirements. But regardless of these differences, environmentally sensitive, sustainable development is seen as a global objective.

No country cannot develop apart from the others. Hence, in the quest for sustainable development, a new orientation to international relations is required. Long-term and environmentally sensitive sustainable development ensures that necessary changes of great magnitude are also inevitable, with trade, capital and technology flowing more equitably and more in sync with the environment.

As a result, environment and development depend on how each one is clear on the relationship between ecology and economy. In this respect, protection and use preferences should be implemented in a harmonious balance. In fact, the relationship between ecology and economy, as elements indicating a contradiction, reflect how developed and developing countries embody non-harmonized preferences. When these two approaches reject each other, communities are interconnected willy-nilly. Instead of criticizing so as to trivialize the sustainable development approach, finding the solution to practical problems by joint action on economic, social and ecological issues, and eliminating inequalities, are the most important responsibilities of today's society.

International responsibilities to guarantee a sustainable future will vary according to the development level of countries and sectors. What's important is to manage sustainability in a common format, for a common future of all nations. Because humanitarian needs have common characteristics, a multilateral system is required. This system must accept that the world is one.

KEY TERMS AND DEFINITIONS

Brundtland Report: This report established the "sustainable development" term.

Eco Development: This means that "environment does not exclude development".

Ecological Footprint: It refers to a measurable concept of the impact of production and consumption activities on the natural environment.

Resource Management: It refers to management of resources by considering the protection and usage balance.

Rio Conference: This was the second largest earth summit, held in 1992 in Rio de Janeiro, the capital of Brazil. It is known as the United Nations Conference on Environment and Development Earth Summit.

Stockholm Conference: This was the first largest global conference on environment under the leadership of the United Nations, held in 1972.

Sustainable Development: The development approach which envisages the use of today's resources by considering the needs of future generations.

Zero Growth: It is the Roma Club's utopian approach which aimed to limit growth and development, at the beginning of the 1970s.

ENDNOTES

1 The other four documents are Agenda 21, the Statement of Forest Principles, the United Nations Framework Convention on Climate Change and the United Nations Convention on Biological Diversity.

2 Social and Economic Dimensions: International cooperation to accelerate sustainable development in developing countries, and related aims of Combating poverty, Changing consumption patterns, Demographic dynamics and sustainability, Protecting and promoting human health conditions, Promoting sustainable human settlement development, Integrating environment and development in decision-making; also: Conservation and Management of Resources for Development: Protection of the atmosphere, Integrated approach to the planning and management of land resources,

Chapter 11
Green Growth in Mexico, Brazil, and Chile:
Policy Strategies and Future Prospects

Inmaculada Martinez-Zarzoso
University of Goettingen, Germany

Nicole Grunewald
University of Goettingen, Germany

ABSTRACT

This research focuses on identifying the main policy strategies that could potentially contribute to the advance of three Latin American economies, namely Brazil, Chile and Mexico towards a green growth model that is social and inclusive, given the actual patterns of development of those economies. With this aim, we first identify and describe past and current policies in each country in terms of economic, social and environmental indicators. A detailed analysis follows for Brazil, Chile and Mexico, in which we propose a series of green growth indicators and choose a definition and classification of green growth sectors. We estimate an empirical model to explain the determinants of greenhouse gas emissions and deforestation in Latin American countries. We broadly identify the sectors that contribute to its increase and describe the main green policies applied in each country. In turn we identify the sectors with higher potential for the future. Finally, we present policy recommendations and reflections for the future.

1. INTRODUCTION

There is a vast interest for countries in achieving green growth not only as it is related to lower energy intensities but also as it is related to a higher quality of life. This interest has also led to a growing proliferation of studies and scientific research, whose main objective has been to identify the factors that contribute to green growth and the policies that should be implemented in different countries to enter the path of green growth. The main objective of this research is to analyze from a socio-economic and environmental perspective recent developments in three Latin American countries, namely Brazil, Chile and Mexico, concerning green growth and social inclusion. Past and current environmental as well as

social policies are compared between the countries and are related to a selection of indicators. We analyze in particular developments of greenhouse gas emissions, deforestation and social indicators.

According to The United Nations Environment Program (UNEP), a green economy should aim at improving human well-being and social equity, while significantly reducing environmental risks and ecological scarcities. Green growth in income and employment should in turn be driven by investments that reduce carbon emissions and pollution, improve resources and energy efficiency and avoid the loss of biodiversity (UNEP 2013). The main greenhouse gas is carbon dioxide (CO_2) and therefore CO_2 will be used as the main global environmental-degradation indicator. Other greenhouse gases considered are CH_4 and N_2O. In order to account for biodiversity losses, we rely on the measure of forest area in each country.

This research has four complementary objectives. First, a detailed description of the most relevant economic and socio-economic indicators in the three countries under study is presented in order to identify the main environmental challenges. As economic indicators we present the sectoral distribution of GDP (agriculture, services, manufactures) as well as GDP and trade growth figures. The socio-economic indicators considered are GDP per capita, population, life expectancy and education (World Bank 2013; World Economic Forum 2013; FAOSTAT 2013), poverty and social inequality (poverty rate, Gini coefficient, gender inequality), as well as the different dimensions of the Human Development Index and the Human Opportunity Index, both developed by the World Bank and the Global Gender Gap Index, published by the World Economic Forum since 2006. We further study what are the main industries/sub-sectors in each country in terms of production and employment and identify how much each sector contributes to pollution in terms of greenhouse gas emissions in order to describe and analyze the impacts these sectors have on green growth. Second, we analyze a number of green growth indicators classified according to international criteria for Brazil, Chile and Mexico and select four of them, namely CO_2, CH_4 and N_2O and deforestation to analyze how sectoral changes have contributed to the development of the four green growth indicators. Third, a detailed description of the institutional structure and the measures and strategies related to environmental policy and its impact on poverty, social and gender inequality is outlined. Based on the results obtained, the most successful economic activities in terms of green growth and inclusion are identified for each country, and are studied in comparative terms using an economic model. Finally, the study provides policy recommendations concerning social, economic and sectoral issues to draw specific action lines for each country to improve the results in terms of social inclusion and green growth.

The methodology is based on secondary data collection, graphical and descriptive analysis of the data and specification and estimation of an economic model to draw policy implication based on the results. A comparative analysis of country data in terms of polluting effects of the most important sectors and industries in each country is presented. We also analyze the data collected for LA countries by specifying and estimating an economic model, which explains the determinants of three greenhouse gases and deforestation. The model, which is used to identify the contribution of each economic sector to green growth, is derived from the identity IPAT identity:

$$Impact = Population * Affluence * Technology\,.$$

This identity states that the level of pollution, impact (I), depends on three factors: population (P), gross domestic product (A) and the state of technology (T) in a country. Marin and Mazzanti (2009)

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

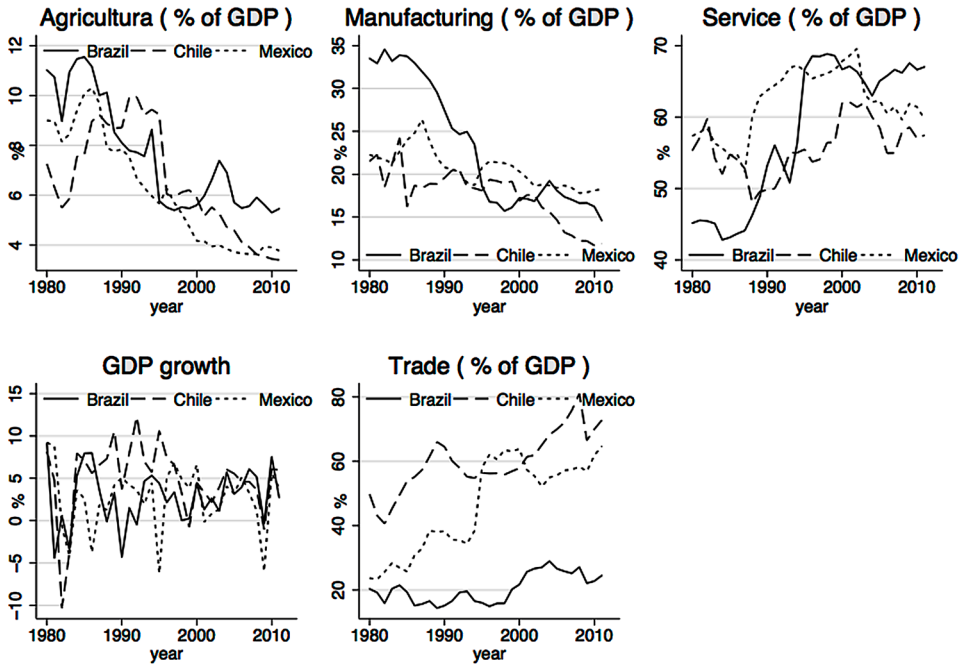
apply this model at the aggregated level; this paper proposes to apply the model to sectoral-level data of CO_2, CH_4 and N_2O emissions, gases that significantly contribute to the greenhouse effect. Grunewald and Martínez-Zarzoso (in press) have applied the IPAT model to estimate the effect of country participation in the Kyoto Protocol on carbon emissions.

The paper is structured as follows. Section 1 presents a brief review of the economic, social and environmental patterns in the three selected countries. Section 2 outlines the methodology. First, several green growth indicators are presented and compared between the three countries and second, four green growth indicators are chosen to analyze how sectoral changes affected green growth in Latin America. Section 3 presents the main results of the model estimation and of the comparative study. Section 4 describes the main green policies implemented in each country in the last decade to improve environmental quality and to encourage clean development, their limitations and their expected outcomes. Finally, section 5 outlines policy recommendations regarding the subsectors with a greater growth potential.

2. CURRENT ECONOMIC POLICIES

In this section we first present current and historic economic and social indicators. We describe the main economic sectors and their economic and social weight in order to identify the key environmental issues that are relevant for each sector and country.

2.1 Model of Economic Development and Growth Patterns



After a period in which import substitution and trade limitation had been the main foreign policies in most Latin American countries, these policies were replaced in the 1980s by trade liberalization and export promotion strategies. Brazil, Chile and Mexico tried to increase economic competitiveness by supporting the creation and intensification of specific clusters of economic activity. Brazil and Mexico focused on the manufacturing sector, and in particular on the automobile industry, whereas Chile focused on the refining and extraction of natural resources, such as copper. The free trade strategies in the three countries were further strengthened with the creation of Mercosur and with Mexico entering the NAFTA free trade agreement in 1995. Meanwhile, out of the three countries Chile has been the most active signing free trade agreements outside the American continent. At the same time, a number of economic reforms have aimed at creating the legal basis to attract foreign direct investment (Peres, 2011).

Figure 1 has been steadily increasing, fact which can be attributed to the above-mentioned policies. The strong rise in Mexican trade has been mainly based on exports of manufacturing goods. The expansion of Brazil's agricultural sector, especially in soy and bio ethanol, explains the more modest decline in the share of value added of the agricultural sector in comparison with the other countries. Also the share of value added in manufacturing goods has been declining for all three countries especially for Brazil. In Mexico it declined just slightly over the period analyzed.

Turning to the specific policies in each of the three countries, Brazil's policy reforms between 2003 and 2008 focused on the development of international well-established industries such as high tech and pharmaceutics, in which the country however did not have a comparative advantage. At the same time, one of its core industries, namely the car industry, was protected with a 30 percent import tax on cars imports with more than 65 percent foreign content (Ban, 2013). Currently, Brazil is promoting the biofuel sector as part of its low carbon development plan. The Brazilian National Plan on Climate Change aims

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

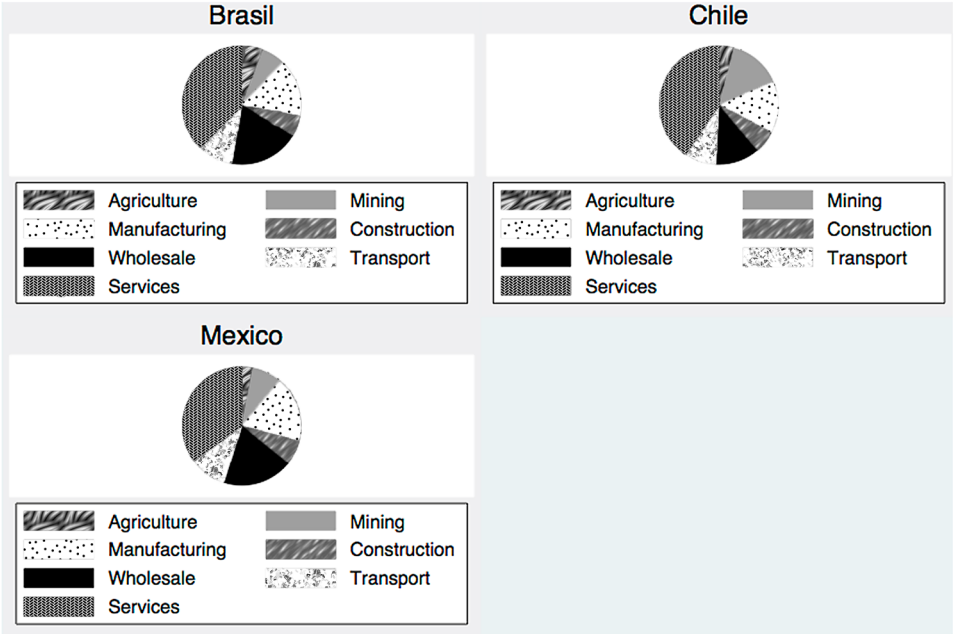
Source: World Bank (2013).

at providing low carbon growth in line with social development and poverty reduction. In particular, the applied policies try to identify the most vulnerable groups and provide climate change adaption, education and development assistance (Fujita et al., 2013).

The golden age of growth in Chile, from 1978 to 1997, was mostly achieved through export led growth driven by the mining sector. Since 1990 Chile started to apply and enforce the implementation of environmental policies focusing on a few key sectors, namely mining, energy, agriculture, transport and tourism. The mining sector contributed up to 18 percent of total GDP and around 50 percent of total exports between 2004 and 2008. It is the most capital as well as water and energy intensive sector. Since 1970 Chile has been determined to treat wastewater from the mining industry before discharging it surface waters. Chile is leading in water management and introduced tradable water rights already in 1981. Nevertheless, the total revenues from environmental taxes are still low compared to other OECD countries (OECD, 2011).

Mexico turned to a marked driven industrial policy after the crisis in 1982. State preferences for specific industries, as well as subsidies and other distortions, were reduced or eliminated. As a result, Mexico started to diversify its economy and moved from exporting mainly primary products to also focusing on export of manufacturing goods. Since the mid-1980s, the steady increase in trade and foreign direct investment has also generated technological spillovers, especially in the maquiladora industry located on the US border. Car manufactures and electronics are among the main industrial sectors, the latter sector in particular was growing very fast in the 2000s. However, Gallagher & Shafaeddin (2010) find that these technological spillovers are minor and that US firms producing in the Maquiladoras achieve their technological developments mainly outside of Mexico. They further point out that foreign direct investment partially crowded out local investments in research and development. Although the first Na-

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use



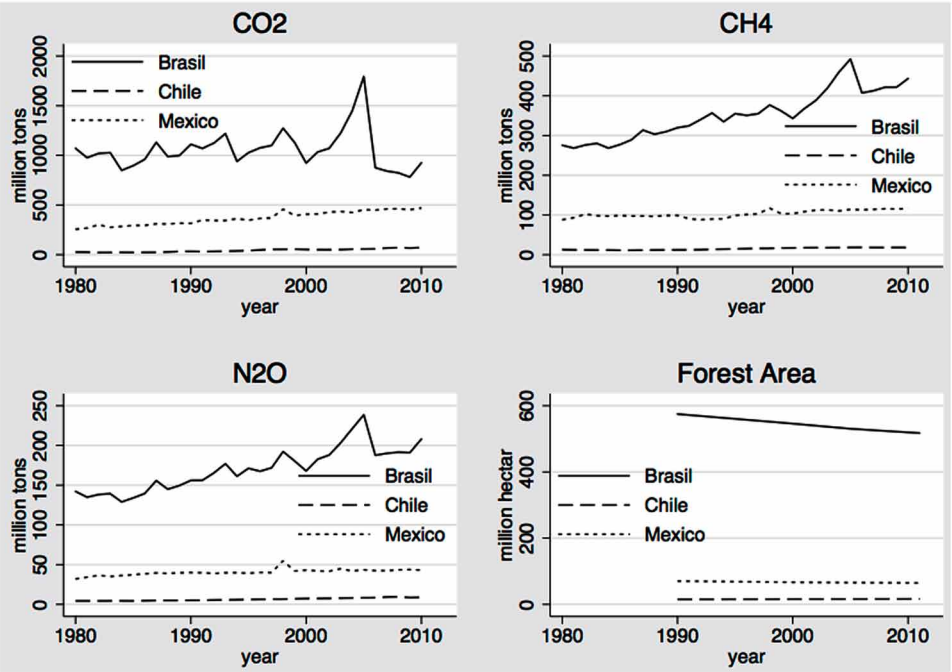
tional Climate Change Strategy was only launched in 2007, Mexico was the first of the three countries to implement policies that promoted the use of renewable energies. It started in 1975 with the Public Electricity Service Law, which main aim was to provide electricity more efficiently and to incorporate the electricity from renewable energies.

2.2 Human Development Indicators

A green economy should contribute to reducing poverty and social inequality. Hence, to achieve sustainable growth human and social progress should also be achieved. Figure 2 shows how the above-mentioned economic policies have influenced socio-economic development. We use four indicators, namely GDP per capita in international dollars, secondary school enrolment rates, life expectancy at birth and population. The first three indicators are commonly known as the basis of the Human Development Indicator (HDI) computed by the United Nations, which define development as progress in the three dimensions of the index: income, education and health.

Regarding Figure 2, Chile clearly shows the highest GDP per capita figures with a strong rise since the early 1990s. Mexico and Brazil show instead a moderate growth in GDP per capita. Concerning education, Brazil reached full secondary school enrolment already in 2000; meanwhile Mexico and Chile still show values below full enrolment in 2012.[1] Life expectancy, which is closely correlated with GDP per capita, is the highest in Chile with almost 80 years in 2010 followed by Mexico (77) and Brazil (74). Therewith, we conclude that the progress in human development in the three countries has not only been driven by higher GDP per capita rates, but also by improved educational as well as health standards. Population has been growing steadily in Brazil as well as in Mexico, and at a lower path in

Figure 2. Socioeconomic development indicators
Source: World Bank (2013).



EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Chile. The HDI as a composite index ranges between 0 and 1, with higher values indicating higher levels of development. During the period from 980 to 2012, Brazil improved its HDI by 21 percentage points (from 0.52 to 0.73), Chile's HDI gained instead18 percentage points (from 0.64 to 0.82) and Mexico 17 percentage points (from 0.6 to 0.77). Chile and Mexico's scores are in the range attributed to high human development countries, meanwhile Brazil is still considered to have medium human development.[2]

The second important aspect of social development is related to equity and poverty reduction. The upper part of Figure 3 shows the evolution over time of income inequality and poverty rates in the three countries. The Gini index is used as a measure of inequality in levels of income among individuals within a country. A value of 100 indicates total inequality (one individual earns all the income) and a value of 1 indicates total equality (every individual earns the same). As shown in Figure 3, the Gini index of Brazil is the highest among the three countries, with a value of 54 in 2010. Mexico, on the other hand, with an income inequality of 47 is much closer to the OECD average, which is 46. Those differences reflect historic distributions of assets among the population and are a consequence of past policies, which failed to give equal opportunities to the population. Figure 3 also shows that the levels of income inequality have been declining over time in the three countries and that the number of people living with less than 2 international dollars a day also declined drastically since the mid-nineties. This indicates that the social policies from the last two decades also seem to have had an effect on income inequality and poverty levels. Therefore, we can conclude that some of the GDP per capita growth as indicated in Figure 2 has reached poor households. Other important indicators of socioeconomic development are the access to water and electricity. Figure 3 shows that the access to water has increased substantially since 1990 with Chile reaching almost 100 percent access and Mexico 94 percent. Access to drinking water in the household goes usually in line with access to sanitation and shows large health and environmental

Figure 3. Poverty and capability measures

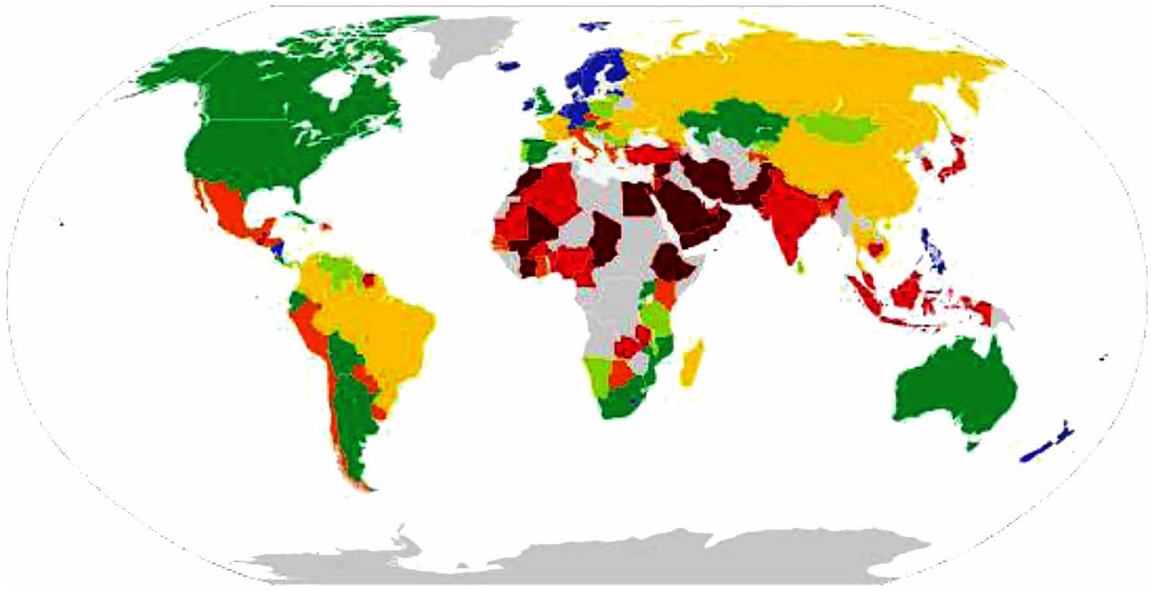
EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

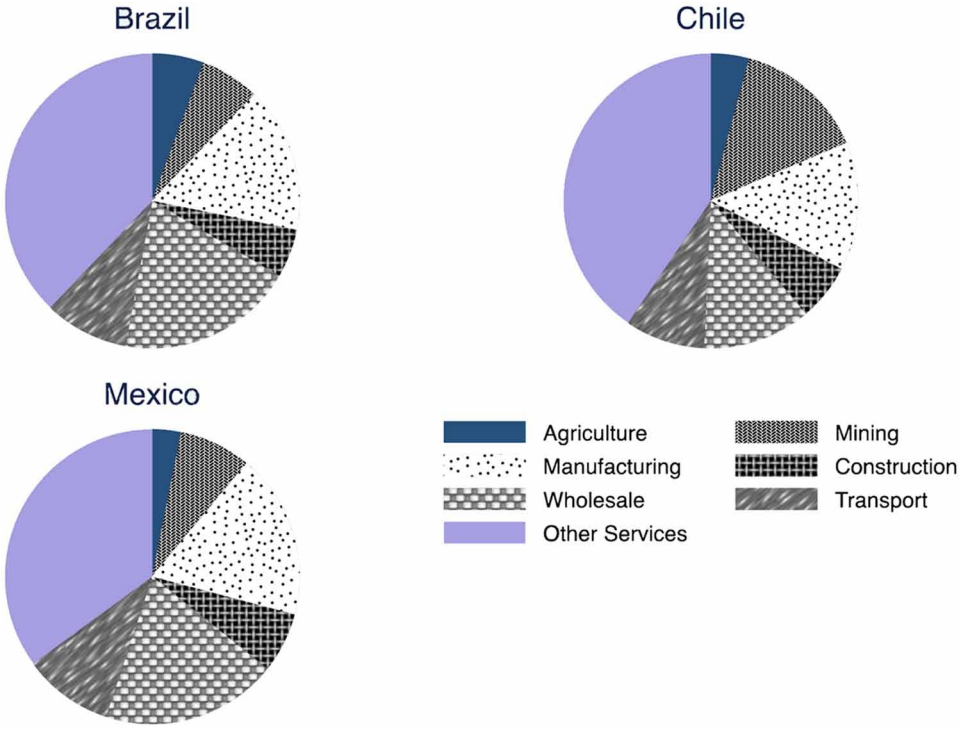
benefits. The data on electrification of households is scarce and indicates that almost all households in Brazil and Chile have access to electricity. However, the related literature indicates that remote areas in the three countries still do not have access to electricity.



In terms of the Human Opportunity Index (HOI, World Bank), which measures how personals circumstances impact children's probability of accessing the necessary services to success in life, Chile (95 percent) and Mexico (90 percent) have the highest overall HOI in Latin America, being first and third in the LA ranking, whereas Brazil lies behind (78 percent). In all three countries there have been moderate improvements over the last decade. Finally, the Global Gender Gap Index (Figure 4), which measures the percentage of the inequality between women and men that has been closed in access to resources and opportunities, indicates that the three countries have made some progress in closing this gap in the last seven years, with Brazil been slightly better positioned (0.69 in 2012, place 62 in the ranking of 135 countries) than Mexico (0.67) and Chile (0.66).

Summarizing, in terms of human development the situation of the three countries is as follows. Whereas Chile is the country with the best performance, Mexico has also performed well and both countries are classified as highly human-developed countries. On the other hand, Brazil, which has also improved in several aspects, especially in decreasing poverty and inequality rates and in closing the gender gap, is still classified as medium human-developed country in terms of its HDI rating.

2.3 Main Economic Sectors and Environmental Concerns



Generally during the development process a country passes through a stage in which the agricultural sector is prevailing, followed by industrialization with a growing manufacturing sector and reaching later on a post-industrialization stage with a strong service sector. We present a more disaggregated look into the composition of the sectoral value added for each country in Figure 5. More specifically, the mining

Figure 4. Global gender gap

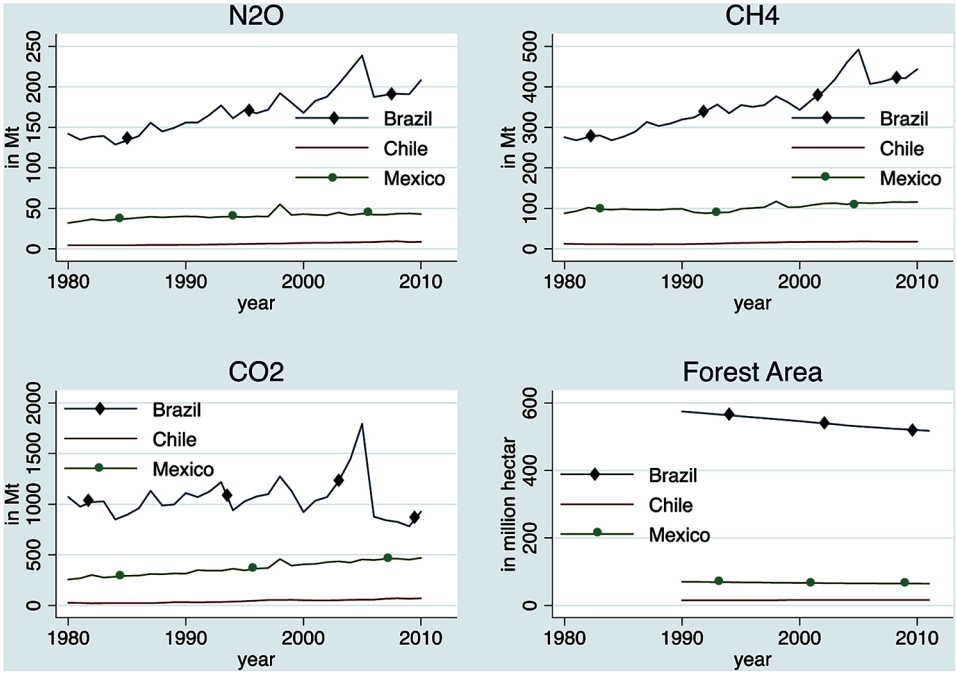
Figure 5. Sectoral value added to GDP in 2011
Source: UNSTAT (2013).



sector is shown separately and the service sector is decomposed into wholesale, construction, transport and other services. The wholesale sector includes retail trade, restaurants and hotels. The main difference between the three countries is the larger share of the mining sector and smaller share of the wholesale and manufacturing sectors in Chile in comparison to Brazil and Mexico.

The socio-economic importance of each specific sector could be measured with the number of people employed. In Brazil the largest sector is "other services[3]", which accounted for around 30.3 million formal jobs (33 percent) in 2007, followed by the wholesale sector, which accounted for almost 20 million employees (22 percent), agriculture with 16.6 million jobs (18 percent) and manufacturing with 13.1 million jobs (14 percent). Mining, which creates about 10 percent of value added, occupies 379000 (0.4 percent) employees. Also in Chile, the largest employer is "other services" with almost 2.5 million employees (37 percent of total employment) in 2008 followed by wholesale with 1.3 million employees (20 percent), manufacturing with 865000 employees (12 percent) and agriculture with 790000 employees (12 percent). Only 1.5 percent of the employees work in the mining sector. Finally, in Mexico the picture is slightly different, with the wholesale sector accounting for 12.8 million employees (30 percent), followed by other services with 12 million jobs (27 percent), manufacturing with 7.2 million jobs (17 percent) and agriculture with 7.6 million jobs (13 percent).

Figure 6 shows the development of three major greenhouse gases and forest area in the three countries. Brazil the biggest economy of the three countries has the highest emissions from N_2O, CH_4 and CO_2. The data on CO_2 emissions is the most volatile in comparison with other greenhouse gases, mainly

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 6. Sectoral composition of the three economies
Source: (EDGAR 2013; FOASTAT 2013).

because CO_2 emissions are highly correlated with GDP. CH_4 and N_2O are mainly omitted by agricultural activities such as the use of fertilizers.

Figure 6 shows that over time greenhouse gas emissions have been steadily rising over time, fact that should raise environmental concerns. Also an alarming signal comes from the forest area measure for Brazil and Mexico, where loses in forest area of 10 and 8 percent, respectively are shown in the last two decades, whereas in Chile an increase in 7 percent has been observed.

3. METHODOLOGY

The methodology section is structured as follows. First, section 2.1 presents a more detailed selection of green growth indicators that will be used to identify the sectors with greater potential for green growth by country. Second, section 2.2 presents the model specification for the regression analysis including all Latin American countries, whose results will be presented in section 3.

3.1 Green Growth Indicators: Measurement and Analysis

Until very recently green growth publications have mainly dealt with specific issues related to climate change and with assessing the efficiency of environmental policy instruments. Currently, the related discussion goes beyond the above-mentioned aspects and covers taxation, eco-innovations, public infrastructure, and access to clean water as well as resource efficiency. Therefore, new analytical tools

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

are needed to integrate the use of natural resources into productivity measurement and growth models in order to develop new methods to assess environmental impacts. This evolution is also reflected in the "green models" followed by Brazil, Chile and Mexico in recent years.

3.1.1 Selection of Indicators

In this section we present a number of indicators to measure progress in green growth in each country and analyze their evolution over time. We partly follow the framework proposed by the Green Growth Knowledge Platform (GGKP) in 2013. GGKP is a global network created with the main aim of identifying and addressing the major knowledge gaps concerning green growth in theory and practice. It was launched in Mexico in 2012 by the OECD, United Nations Environment Program (UNEP), the World Bank and the Global Green Growth Institute (GGGI). Its Green Growth Knowledge Platform Scoping Paper (GGKPSP 2013) proposes a common approach on green growth indicators based on the knowledge already accumulated by the GGKP members since 2009, when the UNEP took a leading role in the promotion of "green growth" with its Policy Brief "Global New Deal".

The main characteristics that green growth indicators have to fulfill according to the GGKP are: to be dynamic and flexible; to cover the main areas of concern at the country level but also at a global level; and to allow for the evolution or addition of new indicators. Furthermore, indicators should be selected based on transparent criteria and should be available from reliable sources. The set of categories covered can be classified into 5 categories, namely: *natural asset base*; *environmental life quality*; *environmental and resource productivity indicators*; *economic opportunities* and policies; and *social (well-being) indicators*. We compare a number of indicators from each category across the selected countries. Some of them will be selected for our IPAT analysis in the next section. The selection criteria are availability and relevance.

First, as indicators of the *natural asset base* we present forest resources, land resources and water resources, as well as the percentage of threatened species, as a measure of diversity. Table 1 shows the average values of a list of available indicators. Brazil has the highest percentage of forest area (61 per-

Table 1. Natural assets, environmental life quality, and biodiversity: 1990-2011

Indicator	Average			Change		
	Brazil	Chile	Mexico	Brazil	Chile	Mexico
GG_C12: Renewable freshwater, thousand m3 per capita	-	62.8	4.1	-	-24%	-26%
GG_C13: Total freshwater abstraction, thousand m3 per capita	0.3	2.0	0.6	-	-	-
GG_C41: Arable and cropland, % total land area	8.1	3.0	14.1	38%	-42%	7%
GG_C42: Pasture, % total land area	22.8	18.0	39.8	6%	9%	-3%
GG_C43: Forest, % total land area	64.6	21.2	34.6	-10%	7%	-8%
GG_C44: Other land, % total land area	4.5	57.8	11.6	81%	-2%	31%
GG_C51: % Threatened species – Mammals	-	25.1	35.0	-	-	-
GG_C52: % Threatened species – Birds	-	10.9	21.9	-	-	-

Source: OECD Statistics (2013).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

cent in 2011, equivalent to 5.17 million km^2) with a decline of 10 percent over the period 1990 to 2011, followed by Mexico (646 thousand km^2), which also experienced a decline of the forest area of about 8 percent. Whereas, Chile's forest area (around 20 percent, 163 thousand km^2), has increased over the period (7 percent). In Mexico pasture and cropland represent more than 50 percent of the total land, with other land showing the highest percentage in Chile (58 percent). In Brazil pasture, cropland and arable land represent around 30 percent of all available land.

Concerning *environmental life quality*, Chile is relatively rich in fresh water resources in comparison to Mexico; whereas this indicator is not available for Brazil. Regarding biodiversity, the percentage of threatened species is considerably higher in Mexico than in Chile, and unfortunately, the data from the OECD is only available for a single year and is missing for Brazil. In addition, according to World Bank data, the number of threatened fish (mammals) species is 83 (81) in Brazil, 20 (20) in Chile and 152 (100) in Mexico. The World Bank also provides data on the benefits index for biodiversity (from 0= no biodiversity potential to 100=maximum). Brazil's rating is 100, with the maximum potential, followed by Mexico with a value of 69 and Chile with 15. Out of the first two categories we will use forest area as an indicator for the economic model estimated in the next sub-section.

Table 2 shows environmental and resource productivity and intensity indicators (category 2). We mainly focus on emissions productivity/intensity, energy and non-energy material productivity as well as the supply of renewable energy. The first indicator, production-based CO_2 emissions show a decrease in Brazil, but an increase in Chile (25 percent) and Mexico (5 percent). Concerning intensity indicators, emissions intensity has almost doubled in Brazil and Chile and increased by 17 percent in Mexico. At the same time, energy intensity has increased in the three countries. Regarding productivity, production based indicators measure the total amount of CO_2 emitted during production processes relative to GDP,

Table 2. Environmental and resource productivity: 1990-2010

Indicator	Brazil		Chile		Mexico	
	Aver.	Change	Aver.	Change	Aver.	Change
GG_B11: Production-based CO2 emissions, index 1990=100	91.37	-8.17	118.12	25.63	102.55	4.94
GG_B12: Production-based CO2 productivity, US$ per kg of CO2	5.05	-8.14	3.32	26.52	3.30	4.97
GG_B13: Production-based CO2 intensity, tonnes per capita	1.68	51.13	3.23	72.88	3.47	17.78
GG_B14: Demand-based CO2 productivity, real net national income per unit of CO2	2.37	-2.41	2.69	-	2.72	1.87
GG_B21: Energy productivity, US$ per ktoe	7.51	-3.26	7.11	28.59	7.58	13.49
GG_B22: Energy intensity, toe per capita	1.12	42.71	1.50	70.75	1.52	8.90
GG_B26: Renewable energy supply, % TPES	43.09	-6.14	25.99	-21.01	11.29	-19.85

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

demand-based indicators measure instead the CO_2 embedded in final domestic demand (CO_2 footprint) and therefore also consider the effect of international trade. Production-based CO_2 productivity shows a slight decrease in Brazil and a slight increase in Chile and Mexico. In contrast, demand-based CO_2 productivity has remained stable and at similar levels in the three countries. Material productivity is the highest in Mexico and the lowest in Chile and it has sharply increased over time in Brazil and moderately in Mexico but decreased in Chile. In contrast, energy productivity has slightly decreased in Brazil and increased in Chile and Mexico, but stays at similar levels in the three countries. In terms of renewable energy supply, it represents more than 40 percent of total energy supply in Brazil, but only around 22 and 10 percent respectively in Chile and Mexico. Renewable electricity represents more than 80 percent of total electricity generation in Brazil in contrast to 40 and 18 percent in Chile and Mexico. Hence, in the latter two countries there is potential to increase these percentages to higher levels.

From this category, production based CO_2 emissions, will be used in the empirical analysis, since it is available for all LA countries and over time.

As *economic opportunities* and *policy responses*, a number of proxies for innovation and environmental policies are shown in Table 3. Brazil is the leader in terms of green patents, showing an impressive increase in 2005 and 2010. Unfortunately, this indicator is not available for Chile and Mexico, for which only the percentage of green patents as a share of total patents is shown. Patents in renewable energy represent around 2 percent of total number of patents in Brazil and 1.75 in Mexico, but less than 1 percent in Chile, a country which has been more active with innovations in the water pollution sector since 2010. It is worth noting that expenditure on R&D was only 1.1 percent in Brazil in 2010 (compared with only 0.37 in Chile in 2008 and 0.40 in Mexico in 2010), significantly below the OECD average. As regards environmental policies, total environmental taxes as a percentage of GDP shows the highest value in Brazil (more than 3 percent) and the lowest in Mexico, with Chile collecting around 1 percent of its GDP in environmental taxes. The values in Brazil are the closest to the OECD average of 3 percent. In comparison to labor taxes, environmental taxes account for a similar percentage of GDP in Chile. In Mexico labor taxes represent only 0.25 percent of GDP and are higher than environmental taxes (which show negative values in 2006-2008 and 2010-2011). This negative revenue is due to the structure of the existent fuel tax, which is levied inversely to oil prices and therefore turns into expenditures above

Table 3. Innovation and environmental policy indicators: 1990-2010

Indicator	Brazil	Chile	Mexico
GG_E13: Public spending in environmentally related RD, % total public spending	-	-	1.366

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

a certain level. We will not be able to use indicators in this section in the economic model because they are only available for a limited number of years and their incidence (e.g. patents) is still very low.

Finally, we present a number of *socio-economic or well-being indicators* that depart from the use of GDP per capita as the only indicator and move towards measures related to sustainability and the quality of growth. The better life index is part of the Better Life Initiative (LBI). This index has been constructed following the approach proposed by Stiglitz et al. (2009), which distinguishes between current wellbeing and its sustainability over time and includes environmental related aspects. It is planed that future work will also include inequality indicators. The ranking of OECD countries indicates that Chile and Mexico have very low scores (0.37), and are only better placed than Turkey (0.23). Although Brazil is not included in the overall score, it is ranked according to a single indicator.

Table 4 presents the values of the different categories used to compute the index for the three countries under study, as well as the average score for OECD countries. A total of 11 categories are listed, which refer to different aspects related to the quality of life. In recent years the quality of life of its citizens has improved in Brazil, which reflected by the value of the "life satisfaction" indicator. Indeed, Brazilian life satisfaction is slightly above the average OECD value and the value for Chile is slightly below, with Mexico showing a higher value. However, in terms of net adjusted disposable income Brazil is far below the OECD average and also Chile's and Mexico's values are half than the OECD average. In terms of housing facilities, the percentage of dwellings without basic facilities (access to an indoor flushing toilet) is very high in Chile and Brazil. Mexico's value is still twice as high as the OECD average, hence there is potential for improvement. Concerning jobs, 68 percent of the population in Brazil have a paid job (80 percent for men compared to 56 percent for women), whereas in Mexico's and Chile's the employment rate is lower and below the OECD average. Long-term unemployment rates are lower in the three countries than the OECD average and personal earnings are close to the bottom of the earning distribution in OECD countries, especially in Mexico. The quality of the support network measures the percentage of people that believe to know someone they could rely on in time of need. A weak social network is reported for Mexico, whereas Brazil shows the highest percentage close also to the OECD average.

In terms of education attainment, which measures the percentage of adults with a high-school degree, Mexico and Brazil present very low numbers, whereas Chile is close to the OECD average, hence room is left to improve education in the first two countries. Indeed, in Mexico around 60 percent of the population aged 25 to 64 have not completed upper secondary education.

The quality of local living environment is measured with two indicators. First, using PM_{10} concentrations as a proxy for local air pollution, which are highly above 20 micrograms per cubic meter (annual guideline limit set by the World Health Organization) in Chile and Mexico, with Brazil showing a lower level (19). Second, the indicator "access to clean water", which is basic for human well-being, measures the percentage of people that are satisfied with water quality in each country, with Brazil showing the lowest percentage and Chile and Mexico also with values below OECD average.

Civil engagement is the highest in Mexico when measured by the consultation on rule-making indicator, which is based on a composite index that comprises information on the openness and transparency of a consultation process. However, Chile shows the lowest score in the sample of countries and also Brazil shows a low score. In contrast, in terms of voter turnout Mexico shows a value of 63 percent, well below the values observed for Chile (88) and Brazil (78), both above the OECD average (72).

Also health indicators are considered to construct the better life index. Among them are life expectancy and self-reported health, the later indicating that about 59 percent of adults in Chile say their health is good or very good. Values closer to the OECD average are reported in Mexico and Brazil.

	Time devoted to leisure and personal care (hours per day)	13.66[a]	12.66 [a]	14.84 [a]	14.87 [a]

Note: * denotes estimated values. Source: OECD Statistics (2013).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Safety is a great matter of concern in Mexico with extremely high rates of assault (more than 3 times the OECD average) and homicide (more than 10 times the OECD average), the later being also very high in Brazil. Finally, regarding work-life balance indicators, nearly 29 percent of the employees work very long hours in Mexico, in contrast to only 16 and 12 in Chile and Brazil respectively, and only 8 on average in OECD countries. In terms of time devoted on other activities, the three countries are closer to the OECD average. Although we are fully aware of the importance of well-being indicators that depart from the use of GDP per capita, we are constrained to use GDP per capita in our empirical analysis as a proxy for wellbeing due to insufficient data across countries and over time in the abovementioned "new proposed" socio-economic indicators.

3.2 Determinants of Environmental Indicators in LA Countries

Before looking at each country separately we use data on 19 Latin American countries between 1980 and 2012 to estimate the abovementioned IPAT model that explains the determinants of a number of environmental indicators (see Table 12 in the appendix for a list of countries). The data on GDP, and sectoral composition of the countries is taken from the World Development Indicators (World Bank 2013). Greenhouse gas emissions CO_2, NO_2, and CH_4 and forest area from the Edgar Database and FAO (FAOSTAT, 2013; EDGAR, 2013). Value added for each sector (Agriculture, Forestation and Land Use; Construction; Energy; Industry and Transport sector) comes from UNSTAT (United Nations Statistics Division, 2013). Summary statistics of the data are shown in Table 13 in the appendix.

3.2.1 Model Specification and Estimation Technique

We estimate a model based on the IPAT equation and apply a regression analysis to determine the relative importance of the drivers of environmental impacts. Greenhouse gases namely CO_2, N_2O, CH_4 are taken as indicators of environmental pollution and forest area is taken as an indicator of sustainability. The choice of the three greenhouse gases was made in the light of global warming and the preparation of the NAMAs. Since the share of renewable energy is still considerably low, the three countries could be considered as fossil fuel based economies. The goal in the next years is to reduce emission intensity in order to mitigate climate change and in order move towards a more efficient economy by promoting green growth.

The regression model builds on the IPAT equation by York et al. (2003), which attributes an environmental impact to its major sources of origin, namely changes in the size of the population, changes in affluence, which is referred to as GDP or as value added of the specific sector, and changes in the technology. Originally, the model was formulated as an identity and later it was reformulated in stochastic terms (STIRPAT) to be able to test hypothesis. The main model specified in natural logs is given by:

$$\ln EnvInd_{ikt} = \alpha_i + \lambda_t + \beta_1 \ln POP_{it} + \beta_2 \ln VA_{ijt} + \beta_3 \ln EE_{it} + \beta_4 \ln X_{it} + \varepsilon_{ikt} \quad (1)$$

where $lnEnvInd_{it}$ is the natural logarithm of a given environmental indicator k. Here k denotes CO_2, CH_4, N_2O emissions in kilo tons or forest area in hectares of country *i* in year *t*. α_i and λ_t are country and year-specific effects that control for unobservable country heterogeneity and common time-varying effects that could affect emissions. The population variable POP_{it} is measured by the number of inhabitants. VA_{ijt}

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

represent the value added of sector j, where j=1,…4 (AFOLU=Agriculture, Forestation and Land Use; Construction; Industry and Transport sector) measured in constant 2005 US$ respectively. EE denotes energy efficiency measured as GDP per unit of energy use (GDP ppp constant 2005 per kg). X denotes other control variables, namely the level of urbanization and level of openness ((exports+imports)/ GDP), which could influence in particular CH_4, N_2O and deforestation. Finally, ε_{ikt} is the error term that is assumed to be independent and identically distributed.

4. MAIN RESULTS

Table 5 presents the results from the regression analysis. In column 1 the dependent variable is total CO_2 emissions in the classic IPAT approach. While changes in population do not affect CO_2 emissions from fossil fuels in LA countries, changes in the affluence variable and in energy efficiency do significantly influence a the impact variable. More specifically, a rise of GDP by 10 percent contributes on average to an increase of CO_2 emissions by 11 percent. The average effect of a rise in energy efficiency of 10 percent is related to a decrease in emissions by 3.9 percent, which is only below the increase of CO_2 caused by increasing GDP. In column (2) the results for CH_4 are presented, showing that increasing population is associated to lower levels of CH_4 emissions and that changes in GDP are not associated to changes emissions. Whereas increases in energy efficiency are related to lower emissions, given that an increase of 10 percent in energy efficiency reduces emissions by 2.4 percent, emissions of CH_4 increase with urbanization and decrease with openness. When the model is estimated for N_2O, the results in column

Table 5. Aggregate results for environmental indicators

(3) indicate that whereas affluence is contributing less than proportionally to higher N_2O emissions, higher urbanization decreases these types of emissions. Finally, concerning deforestation, the model indicates that the level of forest area decreases with urbanization and with openness and is positively associated to population increases.

In a next step we estimate similar equations for sectoral emissions and sectoral value added. Table 6 shows the results for CO_2 emissions coming from each sector of economic activity. Results in Table 6 indicate that an increase in value added in the Agriculture, Forestation and Land Use sector reduces emissions of CO_2, whereas population and energy efficiency are not significantly affecting CO_2 emissions. As regards the construction sector, an increase of 10 percent in its value added increases emissions of this pollutant by 3.4 percent, whereas for industry and transport sectors the corresponding increase is 8.3 and 4.2 percent respectively. Increases in energy efficiency only appear to reduce emissions from the industry sector more than proportionally.

Table 7 shows the sectoral results for CH_4, which indicate that energy efficiency mainly reduces emissions of this gas in the construction and industry sectors, whereas population increases only foster emissions in the transport sector and indeed, more than proportionally. As before, an increase in value added of the industry sector is associated to higher emissions, although the elasticity is lower than for CO_2.

Finally, Table 8 shows the sectoral results for N_2O emissions, for which increases in value added in the industry and transport sectors are associated with higher N_2O emissions on the industry and transport sectors, but not in construction and agriculture and population increases are also associated to higher emissions, but only in the transport sector.

To summarize, on the one hand we find that population growth mainly contributes to the increase in greenhouse gases in the transport sector, whereas a rise in sectoral value added contributes to increasing emissions of N_2O and CO_2 not only from the transport sector from but also from the industrial sector. On the other hand, increases in energy efficiency are associated with reductions of CO_2 and CH_4 in the industry sector.

The analysis shows that policies regarding energy efficiency can have different effects depending on the sector and on the pollutant they are targeting. The industrial sector can contribute most to GHG reductions when policies target energy efficiency. Nevertheless, strengthening value added from the

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

agricultural sector relative to the other sectors does also contribute to lower CO_2 emissions. The analysis further shows that it is not straightforward to quantify the green growth potential of a specific policy measure as the ones listed in the following chapter. The effects can be manifold. Policies enforcing the use of renewable energy such as biofuel can have a positive impact on a countries overall CO_2 emissions due to the use of alternative fuels rather than fossil fuels. Still, the production of biofuels goes in line with other pollutants and an intensified use of fertilizers, which again are the source of GHGs. In the analysis at hand energy efficiency policies show the highest potential for green growth in terms of reducing different GHGs. Nevertheless, policies have to be evaluated in case by case studies taking into account the specific prerequisites of the countries.

After examining the effect of different activities on the four indicators, we outline in the next section the current policies in each country. Later we discuss their strengths and weaknesses before pointing to options to improve those policies.

5. DIAGNOSIS OF THE GREEN GROWTH SECTORS BY COUNTRY

In this Section we first present national-level green policies that have been pursued in each country under study in the recent past and also make an attempt to relate the results obtained in the previous section to evaluate the effectiveness of these policies.

5.1 Brazil

5.1.1 Identification of Green Policies

The corner stone of Brazil's green policies is its 2008 National Climate Change Plan, which aims to promote sustainable development through mitigation and adaption, the reduction of vulnerability and impact, research and development as well as human capital development. summarizes the main green policies in Brazil since 1996. One of the main mitigation options is a high use of renewable energy in the energy production and the use of bio diesel in the transportation sector. Brazil has implemented several market-based mechanisms, starting with electric power auctions for biomass in 2008 and for wind in 2009. Brazil was one of the first countries to demand the addition of biodiesel in vehicle fuel.

Currently, Brazil has a total primary energy consumption of 10,055.1 PJ, of which renewable energy amount to 4,606.7 PJ. Due to large hydro power plants such as Iguaçu, Brazil has a very high share of renewable energies (45.8 percent). The country has a target of 16 percent of electricity generation from renewables by 2020, without taking large hydro power plants into account. Furthermore, Brazil aims to extend its wind energy capacity to 11.5 GW, its biomass-fired energy capacity to 9.2 GW and its small hydro capacity to 6.4 GW by 2020 (IRENA, 2013).

A large share of Brazil's greenhouse gas emissions originates from its agricultural sector and from deforestation. The Agriculture and Livestock Plan from 2010 aims at reducing CO_2 emissions from agriculture by 4.9 to 6.1 percent by 2020. Our analysis from section 3 shows that CO_2 emissions from Brazil's agricultural sector are actually declining with rising value added from this respective sector. All the other sectors in the analysis show a positive relationship between value added and the respective emissions. According to the results of our model, higher share in value added from the agricultural sector is associated to lower CO_2 emissions. This result shall not indicate that to de-industrialize is desired. It

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

should rather indicate that, when countries are industrializing more, they should take advantage of the leapfrogging options they might have with modern technology. This result only holds for CO_2 emissions. For CH_4 emissions, which are mainly originated from the agricultural sector we do not find a significant relation between value added in agriculture and these emissions, the same is true for N_2O. To validate this result, the next figure shows the evolution of CO_2 emissions from the agricultural sector in Brazil.

Table 9. Green policies in Brazil

Title	Year	Policy Type	Policy Target
Agriculture and Livestock Plan	2010	Policy Support, Strategic planning,	Reduce CO_2 for agriculture by 4.9 to 6.1% by 2020
2010-2019 Plan for Energy Expansion	2010	Economic Instruments, Direct investment, Infrastructure investments, Policy Support, Strategic planning	Multiple RE Sources
Electric power auctions - Wind	2009	Regulatory Instruments	Wind, Onshore

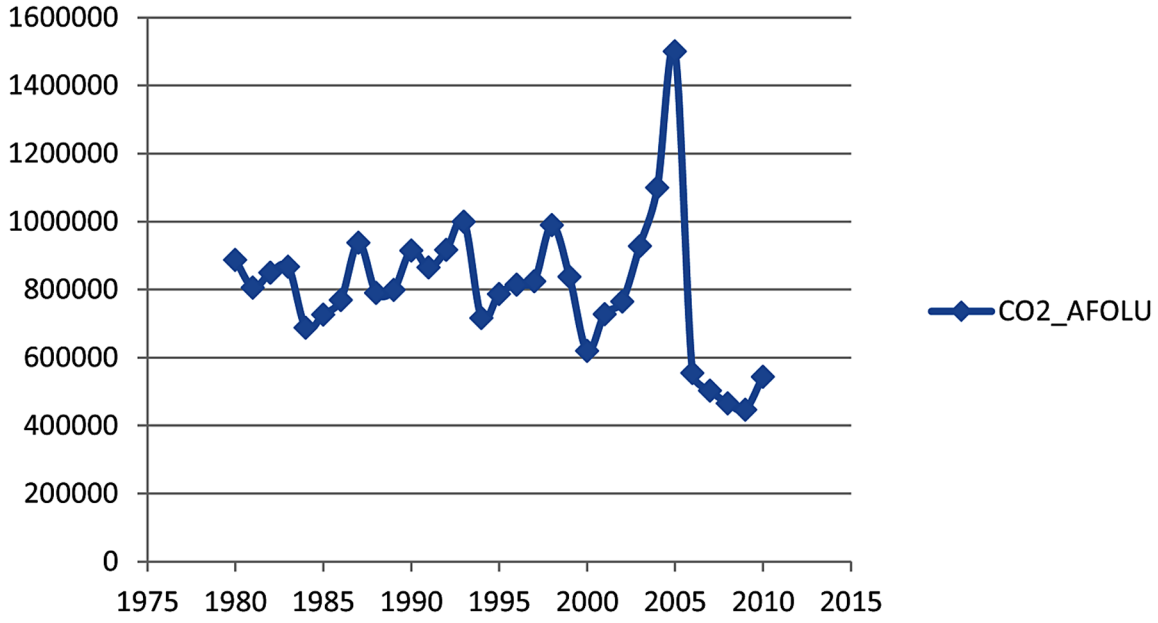
Source: IRENA (2013) and (Fujita et al. 2013).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

The graph clearly shows a reduction in emissions around 2010, which could be associated to the Agricultural and Live Stock Plan of 2010.



The strength of Brazil's green growth policies such as the National Climate Change Plan is that it aims to harness green growth with economic growth and poverty reduction simultaneously. Promoting the use of renewable energy in remote un-electrified regions does contribute human capital development. The size and the distribution of the population make it reasonable to apply a more decentralized energy grid (Fujita et al. 2013).

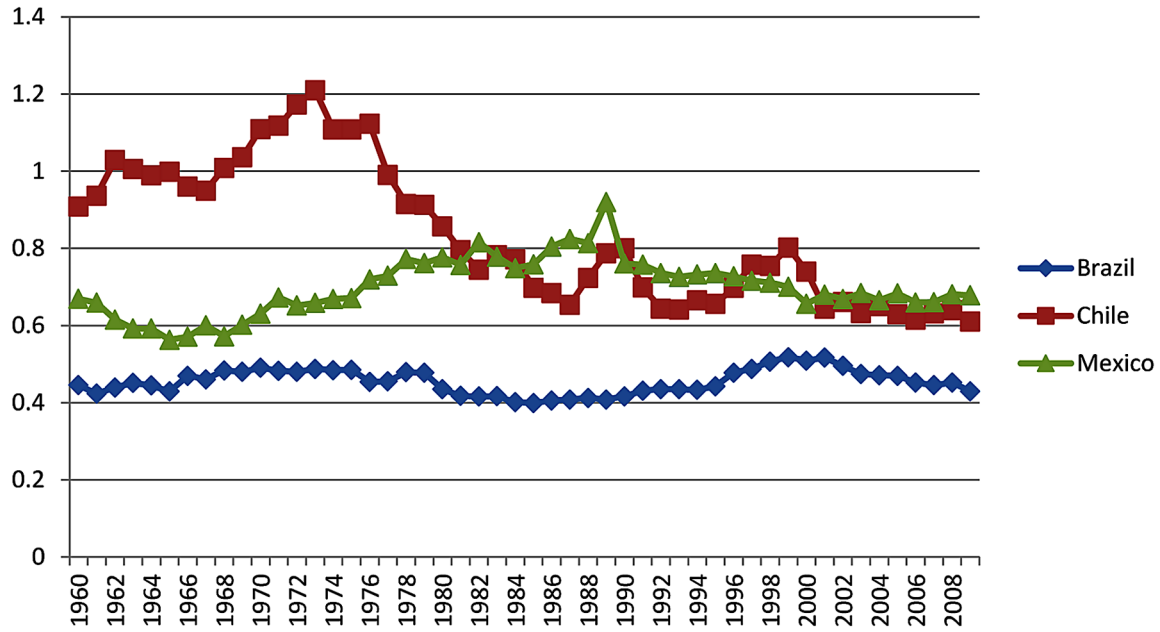
5.1.2 Strengths and Weaknesses of the Policies

Brazil is a resource abundant country and can afford a large biofuel industry. Nevertheless, if the production of biofuel leads to further deforestation in the country then it does not contribute to the mitigation of greenhouse gases and does not help to prevent dangerous climate change. The use of cultivated land for biofuel production is also under critique as it may lead to higher prices for other agricultural goods such as wheat or corn. Gibbs et al. (2008) and Field et al. (2008) find that the use of biofuels can contribute to the reduction of greenhouse gases, but this reduction is rather small. This makes the use of biofuels controversial as on the one hand there shall be no new croplands cultivated, and on the other hand the cropland available for food production becomes smaller and food prices may rise. For the poverty reduction the provision of energy access is a basic requirement, but the current rise in energy demand cannot yet be met with renewable energy sources.

Concerning the policies aimed at control climate change and at reducing emissions from the agricultural sector, it is not straightforward to evaluate their effects, because those coincided with the economic crisis and started to be implemented in very recent years. However, it is clear that CO_2 intensity figures

Figure 7. Evolution over time of CO_2 emissions from the agricultural sector in Brazil

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use



show a decreasing trend in Brazil, as shown in Figure 8, after 2002, when a number of initiatives to support alternative energy sources stated been suported.

5.1.3 Policy Recommendations

Brazil has a great potential in relation to its resource abundance. It can literally increase the production of all sorts of renewable energies and it has its own resources from fossil fuels. The current phase of strong economic growth has come along with higher inflation and rising prices as well as rising inequality. The goal of Brazil's green growth strategies have to focus on reducing inequality and increasing the access to resources such education and health care meanwhile further increasing the quality of those public goods.

According to the recent economic developments, the sectors targeted should be the transport sector with a great potential to improve energy-efficiency and the renewable-energy sector. Switching to more fuel-efficient vehicles in public transport is an option. Given that this option is costly and public transport is in most cities undersupplied, new vehicle would not replace old ones but should be added to the fleet. The implementation of forest protection management practices also should play an important role in preserving deforestation, which according to our analysis in Section 3 is affected by population growth, by urbanization and openness.

Figure 8. CO_2 emissions intensities in three countries
Note: Calculated as CO_2 emissions/GPD.

5.2 Chile

5.2.1 Identification of Green Policies

Chile has a long history of market based policy instruments regarding green growth. Table 10 gives an overview of the relevant policies, which already have been implemented. It is among the first country that launched a system of nationwide water rights (in 1981) to use this scarce resource more efficiently.

Table 10. Green policies in Chile

Title	Year	Policy Type	Policy Target
National Strategy for the Energy Sector	2012	Policy Support, Strategic planning	Multiple RE Sources
Support for Non-Conventional Renewable Energy Development Program	2012	Economic Instruments, Direct investment, Infrastructure investments, Economic Instruments, Direct investment, RD&D funding	Bioenergy, Geothermal, Hydropower, Multiple RE Sources, Ocean, Solar, Solar Thermal, Wind

Nationwide Trading of Water Rights	1981	Regulatory Instruments, Quota	Water

Source: IRENA (2013) and OECD (2011).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

The National Strategy of River Basin Management from 2007 aims at improving the public-sector coordination on water rights. In 1992 the country launched a system of tradable emission permits for particulate matter in Santiago de Chile to solve the severe health problems caused by local air pollution. In the same year transferable fishing quotas were established to protect the country's natural resources. Later on, Chile provided governmental support for aquaculture fish industry, which turned the country into a global player in fish exports. Further policies to protect biodiversity, the country richest resources, were launched in 2003 with the National Biodiversity Strategy and the follow up specific policies on the protection of endangered species as well as areas and wetlands from 2005 (OECD 2011). Chile is in a favorable position compared to the other two countries due to its currently high share of renewable energy. CO2 intensity considerably decreased in the 1970s and in the 1980s (see Figure 8) and has been maintained since then below Mexico's levels. Since Chile is a rather resource abundant country, which had managed its resources well in the recent past, the topic of energy efficiency is not any longer high on the agenda. Still investing in energy efficiency provides a double dividend since it goes in line with technological improvements, which make the countries industries more competitive.

The currently strongest green growth potential is located in Chile's energy sector and the use of renewable energy. Currently, Chile has a total primary energy supply of 1,205.1 PJ of which are renewable 302.9 PJ. This amounts 25.1 percent energy use from renewables, which is mostly addressed to hydropower, one of the country's natural advantages. The country set a target of 8 percent of electricity generation from renewables excluding large hydropower plants by 2020. The policies to pave the way for this target go back to 2000 when Chile promoted the use geothermal power plants. The nature of renewable energy plants such as geothermal or photovoltaic allows the decentralized energy supply of remote urban regions such in the Rural Electrification Program in 2001. Several policies to promote the investment into renewable energies especially in the rural area, such as the Rural Electrification with Renewable Energy Program in 2001 and the Program for Rural and Social Energy (PERYS), have had been following since 2001 and amount into the National Strategy for the Energy Sector from 2012 (IRENA, 2013).

5.2.2 Strengths and Weaknesses of the Policies

The strength of Chile's green growth policies is in the renewable energy sector, currently dominated by hydropower. However, Chile placed instead ambitious targets on the use of energy from photo voltaic, geothermal and wind. Especially, the electrification of rural areas has been a key target in this renewable energy plan. If the target of a higher use of renewable energies in remote areas is reached, then there would be not only a higher use of renewable energies, but also a higher quality of life in remote areas, which are mostly populated by indigenous people. Considering that the first policies in this field were passed in 2001 the progress has been rather slow compared to countries, which implemented those policies later. Nevertheless, the ministry of environment was just recently established in 2010. Therefore, future coordination and implementation of policies might be faster (OECD 2011).

Within the international effort to prevent dangerous climate change, Chile proposed currently 16 National Appropriate Mitigation Actions (NAMAs) in order to mitigate greenhouse emissions. Six of those actions are in the field of energy supply. Within this field, greenhouse gas emissions are mostly reduced through the implementation of renewable energy projects. There are two mitigation actions in the area of waste management such as the flaring of methane gas. Another four mitigation actions are

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

in the transport sectors and are based on efficiency improvements and the electrification of transport (NAMA Database 2013).

The report on Chile going green by the OECD (2011) identifies Chile's fresh water management as still being inefficient. The issuance of water rights has been too generous, which leads farmers, energy generators and speculators to stock up on water rights, which have not yet been used. There is only a limited amount of trade in water rights as too many have been issued. The National Strategy on River Basin Management could potentially help to coordinate the public sector in this area. Apart from the agricultural sector the mining sector is one of main water consumers. Mining is crucial part Chile's economy and the environmental regulations dealing with the negative side effects from this industry are not yet established. There is a National Policy on Chemical Safety, which aims to regulate poisonous hazards to human health and the environment from the industries, which apply chemicals. Still the mining sector has not been targeted.

5.2.3 Policy Recommendations

Green growth policies need to be further integrated in sectoral policies. The use of renewable energy in specific sectors such as transport should be promoted and the protection of biodiversity and water rights play a major role for two crucial industries in Chile namely, the mining sector and the aquaculture. Public policies are not coordinated well enough to protect the environment from the negative side effects from those industries.

Revenues from the strongest sector in the Chilean economy, the mining sector, could be transferred to increase human, environmental and social capital. The National Climate Action Plan from 2008 focuses solely on greenhouse gas mitigation in the energy sector other sectors have been given less attention in order estimate the countries' mitigation potential (OECD 2011). As our findings in chapter 3 show, there is potential to reduce CO_2 emissions in the industrial sector through improved energy efficiency. Nevertheless, activities with high potential to reduce other GHGs such as CH_4 are waste management activities (also in the mining sector), and or recycling.

5.3 Mexico

5.3.1 Identification of Green Policies

Mexico was the first of the three countries to implement policies promoting the use of renewable energies. Table 11 describes the main environmental policies launched in Mexico since 1975. In this year the Public Electricity Service Law was implemented to provide electricity more efficiently and incorporate the electricity from renewable energy. Twenty six years later, the grid interconnection contract for renewable energy was passed, which improved the integration of renewable energy into the energy grid. From 2008 onwards, several policies have been applied in order provide financial resources for investments into renewable energy projects. Nevertheless, the share of renewable energy in the Mexican energy supply is only 9.5 percent. This is considerably low given the natural potential that the country has to generate electricity from renewable sources. The target is to reach a share of renewable energy of 25 percent by 2012 and 34 percent by 2024.

Mexico, like Chile, faces high levels of air pollution in its urban areas (see Table 4, air pollution indicator, according to which PM_{10} concentrations are well above the average OECD level). In 1990, the

first Pro Aire project, among many which followed, was launched in order to find a way to reduce traffic and therewith pollution. There are a number of policies which aim to encourage sustainable resource use, such as the National Ecological Land Use Plan from 2012, the Federal umbrella program that promotes sustainable forestry from 2004, National Program of Payments for Ecosystem Services from 2003 and the National Biodiversity Strategy from 2000. Those policies are regulatory instruments to improve the efficiency of the resource use and protect environmental areas (OECD 2013).

5.3.2 Strengths and Weaknesses of the Policies

The National Development Plan is at the core of Mexico's environmental policies. It aims to cover sustainable development in the area of water and waste management, climate change mitigation and adaption, the preservation of biodiversity and the efficient use of natural resources and last but not least the creation of human capital and awareness for the environment. The sub-targets in each of those categories are not clearly defined and an evaluation of the success of the single policies is missing so far (OECD 2013).

One of the most pressing issues is the energy subsidies, which Mexico applies to fossil fuels. The subsidized fossil fuels do encourage people to buy and use cars. Therefore, the subsidies in the energy sector do not only undermine the efforts from policies such as the Pro Aire clean air project but also make it harder for alternative energy sources such as renewable to enter the market.

Mexico does engage in the mitigation of dangerous climate change. The National Climate Strategy from 2007 targets a greenhouse gas reduction of 50 percent by 2050 with 2000 as the base year. The General Law on Climate Change from 2012 allows producers of renewable energy sources to access the grid and feed in renewable energy. The targets are very ambitious and are not jet broken down into specific sectors. There is the idea of launching an emission trading system but it has not been implemented yet. Therefore, it seems unclear if the targets will be met especially since there is no monitoring of the progress made (OECD 2013).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

5.3.3 Policy Recommendations

The greenhouse gas reduction targets from the General Law on Climate Change have to be substantiated and defined among sectors. An intra-industry emission trading system could lead to substantial greenhouse gas reductions at lowest cost. Removing the energy subsidies would not only encourage efficient resource use but also make the use of renewable energy sources more attractive. Decentralized energy systems from renewable should also be applied in remote areas. Vehicle fuel efficiency standards and an efficient low carbon public transportation could further curb greenhouse gas emissions (OECD 2013). Therefore, based on the above analysis of green growth indicators and policies, Mexico should focus on the renewable-energy sector and the transport sector. In line with our results from Section 3 CO_2 emissions from the transport sector are highly sensitive to increasing demand due to rising population and income. Therefore the transport sector should be as energy efficient as possible to reduce CO_2 emissions. Again our results indicate the need of an efficient resource use. The Mexican policies aim on an efficient resource use. The success of these policies is hard to be evaluated without a baseline from the time before the implementation of the relevant policies.

6. REFLECTIONS

This study presents a comparative analysis of the green growth strategies and achievements in three Latin American countries, namely Brazil, Chile and Mexico. These three countries have made important progress in some of the areas under study, in particular in setting the necessary institutional and regulatory framework to protect the environment and to preserve its natural resources. As regards the implementation of green policies, all three countries have launched regulatory instruments and policy instruments and have given economic support to renewable energy sources. Brazil has also established greenhouse gas reduction plans, whereas Chile and Mexico have launched regulatory instruments to control local air pollution. However, many important challenges remain.

Also an important progress has been made in some social aspects as reducing poverty and increasing education and opportunities for women, but more effort is needed. More specifically, poverty and inequality levels are still very high, despite the important progress made in the past decade. In particular, income indicators (household net disposable income and financial wealth) are well below the OECD average, inequality levels are very high in Brazil. Secondly, air pollution levels in big cities are still very high and life expectancy is below average OECD levels. Thirdly, resources dedicated to R&D, especially in green good sectors, are still at very low levels in comparison to OECD standards and more public effort has to be made in this area. Finally, there is room to improve the regulatory framework and to delimit competences between central, regional and local authorities. It is worth to emphasize the need to address distributional issues. Hence, green policies should be identified favoring the poor and middle class, instead of only benefiting the upper social class and elites. Also the burden of the most vulnerable and disadvantaged communities that could be most affected by climate change should be alleviated with appropriate mitigation policies and direct payments to the poor and disadvantaged.

Our empirical analysis has shown that there is the potential to reduce greenhouse gas emissions especially CO_2 through improvements in energy efficiency in Latin America. Those improvements in energy efficiency can also be achieved through the use of renewable resources. CO_2 emissions from the agricultural sector are not sensitive to an increase in value added from the respective sector. Greenhouse

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

gas emissions from the industrial sector (manufacturing and mining) are especially sensitive to a rise in value added from the respective sector. Nevertheless, an increase in value added rises emissions less than proportionally.

Since each country has also its particularities, some specific activities have a higher potential to be developed successfully in each country. First, Brazil started to implement green policies only in 1996, whereas Chile started already in 1981 and Mexico in 1975. Brazil is the richest in terms of resource abundance and has therefore the greatest potential in bioenergy, biomass and forest conservation. Although most of the regulations launched since the late 1990s have been supporting investments in renewable energies, the share of Geothermal together with solar and wind energy production is still below 1 percent, hence there is room for improvement, otherwise, the share of biofuel and waste has steadily increase since the 1970s, as well as the share of hydropower. However, oil still represents 40 percent of total primary energy supply and hence there is room for increasing the share of renewables. As regards electricity generation, Brazil has a very clean energy matrix, however emissions from agriculture, steel and transportation are expected to growth with its development process. Hence, to launch low carbon options for these sectors is recommended.

Concerning other regulation initiatives, it has only been in the late 2000s that the Climate Change Policy and the Agriculture and Livestock Plan aimed at reducing greenhouse gas emissions have been launched and as a consequence, it is still too early to evaluate its effects. It is also worth noting that deforestation has been observed in the last 2 decades, with a decrease of 10 percent of forest land, hence more efforts have to be done to conserve the forest and to protect the Amazonia region. The country has already moved in this direction and deforestation has been already reduced in recent years.

In terms of social policies, Brazil should continue dedicating resources to reduce inequality and to support education of poor children. Initiative aimed at training and employing low income workers in reforestation and renewable energy firms are recommended.

Secondly, Chile started already in the early 1980s to set green policies related to water management, air pollution and resources conservation, as well as supporting investments in renewable energy. As we mentioned in previous sections, Chile's production structure is biased towards the mining sector, which is more pollutant intensive than other industrial activities. Hence, according to our analysis Chile's activities with high growth potential are waste management activities in the mining sector (copper in particular), and aquaculture. Aquaculture is a very important activity in Chile, in particular salmon and trout aquaculture, with salmon volumes just behind Norway in its contribution to the world production. However, the appearance of an infectious disease in 2007 led to a crisis and an important drop in production that is now recovering. To control the disease new density regulations will be put in place in 2014 that involve density limits in each neighborhood based in its sanitary risk. This could also have a positive impact on prices, benefiting therefore the producers.

It is also worth mentioning that the forest area in Chile increased by 7 percent in the last two decades, in part as an outcome from the reforestation policies that have been in place. For instance, Chile and Uruguay are the only two South American countries where woodland has increased; it has indeed doubled in Chile in the last three decades. Since almost 90 percent of new forest is situated on grounds with erosion, reforestation generates not only environmental benefits, but also economic and social gains, including employment creation. Chile could also benefit from improving the levels of secondary school enrolment, which according to our analysis lay below the desirable levels.

Finally, among Mexico's main GG initiatives are the Special Climate Change Program launched in 2009 aimed at cutting gas emissions by 50 percent by 2050 and the National Development Plan 2007-

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

2012 aimed at strengthening and consolidating adaptation capacities among the most vulnerable. Both initiatives are ambitious and have already accomplished some achievements, with an increasing share of renewable energies in electricity production. However, the country still presents the highest share of total primary energy supply coming from oil (54 percent) and hence subsidies supporting fuel consumption should be phased out and replaced by cash-transfer programs to help poor consumers to overcome its energy needs.

According to our analysis car manufactures and electronics are among the main industrial sectors in the country, the latter sector in particular was growing very fast in the 2000s. Since the growth in value added in both sectors will contribute to increasing emissions according to our model in Section 3, the country should make an effort in diversifying more its economic activities, focusing in tourism and other services as well as continue to support free trade initiatives and to profit from technological spillovers by investing more in R&D in order to increase the quality of its products, also by making them "cleaner". The privileged location of Mexico, sharing border with a huge market, the US, should be also taken as an advantage to exploit its comparative advantage in producing part and components of final goods.

Mexico has therefore a high potential to improving the efficiency of the transport sector with the subsequent reduction in emissions and also to increase the share of renewable energy supply and electricity generation from renewable sources. In addition, the country should greatly benefit from implementing social programs to improve security in big cities and to reduce assault and homicide rates, which are among the highest in the world and clearly have a negative impact on wellbeing.

Summarizing, this study indicates that the three countries under study have made a remarkable progress by setting the necessary institutions and regulations to pave the road towards GG. However, it is still early to evaluate whether the initiatives have been fully implemented and whether the progress has been translated to an increase in wellbeing that is respectful with the environment. Surely, some tensions and complementarities between the model of economic growth and the proposed environmental and socio-economic policies will have to be solved in the near future and, in specific ways in each economy.

Chapter 12
Harnessing Knowledge for Sustainable Development: Challenges and Opportunities for Arab Countries

Abdelkader Djeflat
Université de Lille 1, France

ABSTRACT

Arab countries face two major challenges resulting from increasing competition from the rest of the world and persistent reliance on mineral resources for their growth. At the same time, sustainable development is increasingly becoming a major concern for world development. In this respect, and from a sustainability point of view, knowledge economy opens up new and more accessible opportunities through the 'substitution' of physical resources by immaterial resources. This situation raises two fundamental questions: the first one relates to the opportunity of ensuring sustainable development while the knowledge base remains rather weak and policies often short-sighted. The second one is how an integrated approach based on knowledge can strengthen existing knowledge bases and create new ones to further sustainable development. Looking at a sample of advanced countries and Arab countries, this chapter argues that sustainability of growth rests fundamentally on the capability of properly harnessing knowledge.

INTRODUCTION

Sustainable development is becoming increasingly a major concern for world development since the Rio Summit in 1992 and one of the major challenges on the international agenda in the face of bad indicators of most resource-use and worsening environmental impact. The 1987 Brundtland Report, of the World Commission on Environment and Development, (WCED 1987) defined sustainable development as "the development that meets the needs of the present without compromising the ability of future generations to meet their own needs." The new regulatory principle, "pollution prevention pays," aims at promoting competitive and environmentally sustainable industrial production. While many of the work and resolutions are centred on costs and pricing both in terms of understanding and as a policy instruments, it is

only in the last few years that science and technological capabilities issues are recognised as deserving to be given top priorities. It is gradually recognized that sustainability relies more and more on innovation capabilities and on harnessing the necessary knowledge.

In Less Developed Economies (LDCs), the situation is more challenging: while GDP growth of 6% to 8% per year is needed in the next three or four decades to meet all their needs, they have to comply with sustainability requirements while developing the necessary knowledge assets and capabilities, they often lack. The transition to a global, networked knowledge economy will be one of the most important social and economic challenges of the next decades. Knowledge is known, to be sometimes difficult to access and its price is distorted by world market, under intellectual property rights and other restrictive practices which do not benefit LDCs. This is the case of Arab countries where the level of innovation performances remains weak and where major investments made in education, training and research have yielded only limited results. This situation raises two fundamental questions. The first one relates to the opportunity of insuring sustainability of growth while competitive pressures drive these countries to maximum use of natural resources, over-crowding of cities, and the acquisition of packaged, ready to use technology, produced elsewhere. The second one relates to the relatively weak knowledge base and the difficult integration of knowledge economy approach in most economic policy agendas (Djeflat 2006b). We will argue, in this chapter, that sustainability of growth rests fundamentally on the ability to properly harness knowledge. In other words, "sustainable knowledge" remains paramount to sustainable development. This raises important theoretical and conceptual issues on the linkages between sustainability of development and knowledge. From an empirical point of view, we will try to analyse the difficulties met in the process of putting knowledge to work for sustainability while stressing some of the new opportunities. In this endeavour, we will look, in a first section, at the relationship between knowledge systems, knowledge economy and sustainability from a conceptual and theoretical point of view. The second section will raise the issue in relation to Arab countries with the objective of highlighting the effects of low knowledge base on sustainability. A third section will examine from an empirical point of view this relationship and its measurement, using data from both advanced and Arab countries.

1. SUSTAINABLE KNOWLEDGE FOR SUSTAINABLE DEVELOPMENT: CONCEPTS AND ISSUES

There is an increasing belief that science, technology and knowledge play an important role in sustainable development (Dayan, 2005). Consequently knowledge systems and knowledge economy seem to open up new and varied avenues to be explored in the direction of sustainability. How can knowledge enhance sustainable development? This is the main issue we will address in this section.

1.1. Knowledge Systems and Sustainable Development

In an organised economy, according to the loops of re-using resources and the quality of information, development and efficiency are not dependent anymore on salaries and large scale of production. The critical resources become practical knowledge, local entrepreneurial dynamism, and trust, cooperation over the fence among organisations, human intelligence and know-how. This leads to an "economy of human intelligence" (Dayan, 2005). Knowledge can make substantial and essential contributions to

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

sustainability across a wide range of places and problems (International Council for Science, 2002). Unless that contribution can be dramatically increased, however, it seems unlikely that the transition to sustainability will be either fast or far enough to prevent significant degradation of human life and the earth system (National Research Council, 1999). To achieve that level of contribution, several conditions need to be fulfilled. They relate to the specific nature of knowledge, to successful combination of material and knowledge assets, and to the type of knowledge system.

Firstly, regarding the specific nature of knowledge, it obeys public goods rational and evolutionary principles on one hand and market rules in a neo-classical framework, on the other as seen earlier (Djeflat 2006b). Integrating knowledge and sustainability requires often a mix of the two in a pragmatic way. It is clear from Table 1 that sustainability is easily reached when knowledge is public, non competitive, codified and source of high externalities. It can thus be more easily circulated and shared amongst various actors. Its potential for sustainability is reduced if it is privately owned, subject to market rules and fierce competition, highly protected, tacit, and specialized and under the constant threat of obsolescence.

Secondly, as a result of ever increasing proportion of knowledge in the production of goods and services, more and more emphasis is put on knowledge assets as source of wealth creation. However, these kinds of assets may not be easily grasped when it comes to sustainability. Several studies reveal that sustainability can be more easily achieved when material assets are efficiently combined with knowledge assets. Industrial ecology, for example has already explored avenues for combining efficiently material and knowledge assets. Knowledge management is one of the key elements in this process (Dayan, 2005).

Thirdly, it became more and more evident that sustainability depends on developing integrated knowledge systems, a lesson already learned in the agriculture, defence, and health sectors (Cash et al. 2003). Knowledge system approach appears to give knowledge more effectiveness in harnessing S&T with the goals of sustainable development. A Knowledge system is viewed as consisting of a network of linked actors, stakeholders, organizations, and objects that perform a number of knowledge-related functions (including research, innovation, development, demonstration, deployment, and adoption) that link knowledge and know-how with action. Included are also incentives, financial resources, institutions, and human capital that give such a system capacity to do its work. Bearing in mind that usable knowledge is ultimately "contextualized," i.e., adapted to specific circumstances or places, several issues can be raised: they relate to the generalization of the effective knowledge system to various places, sectors

Table 1. The various spheres and actors involved in environment protection and sustainable development innovation systems

and problems including governing knowledge systems (Matson 2007), to the kind of knowledge which needs to be mobilised (formal, clinical or tacit knowledge), to the mix of knowledge to be used and to pricing. Recent contributions have developed a critical review of controversial economic theories of pricing natural capital and knowledge capital that affect prices (Nguyen, 2006). Finally they relate to the balance between intangible capital and material resources. The importance of the intangible resources in sustainability is increasing. While production and growth are material-centred, sustainability appears to rest more on intangible assets used to exploit material resources. A development strategy that focuses only on production capital and neglects intellectual capital is therefore not sustainable. However, society lacks a critical understanding of what kind of programs, institutional arrangements, and, more generally, knowledge systems can most effectively help in harnessing S&T for sustainability (Cash et al., 2003). Knowledge economy approach appears to give a more accessible and easily understandable relationship between sustainability and integrated approach to knowledge.

1.2. Knowledge Economy and Sustainability

Knowledge system paradigm is usually put in the framework of knowledge economy. It could be defined as "the economy in which knowledge is the key resource and in which the generation and exploitation of knowledge have come to play a predominant part in the creation of wealth" (Department of Trade & Industry, 1998). The knowledge economy framework (Dahlman, 2003) uses a systemic approach of four pillars (innovation, education, ICTs and institutional framework) which shows how knowledge is created, circulated, valorised and governed for the purpose of economic development and growth (Aubert & Reiffers, 2003). In an earlier work (Djeflat, 2006a) we addressed several issues relating to the relationships between knowledge economy and innovation systems. This section will look at the new opportunities for sustainability that knowledge economy offers. The knowledge economy paradigm suggests that physical resources can be almost infinitely stretched through the 'substitution' of physical resources by information, knowledge and immaterial resources, giving thus new prospects for sustainability. Examining closely each one of the components, gives deeper insight into this relationship.

Firstly, ICTs have brought tremendous potential for sustainability and environmental protection and several contributions have listed the countless possibilities which they bring: (learning, database collection and storage, diffusion of vital information, data generating systems, monitoring and control of environments etc.). Recent studies illustrate ICT's potential for sustainability (Mansell and When 2005). In Indonesia, for example, a programme initiated by the Forestry Ministry to aid in sustainable forestry management involved identifying and coding of trees, optimizing forest maintenance and training in the use of laptop computers using specialised software (Talero & Gaudette, 1995). Other techniques include computer-aided, scientifically applied, modelling techniques, networking and information exchange. Several international organisations and institutions have built all their environment and sustainable development programmes on ICTs. For example, UNDP built a Sustainable Development Networking Project. This is a specialised on-line system for scientific, technical, bibliographic, and institutional sources. The network currently consists of 173 national, government-designated focal points that are collaborating with the UNDP. Other important issues include the inter-generational transfer of masses of information and know-how in the era of the Internet as mentioned in Ermine (2008) and also in Vachon (2008).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Secondly, innovation is a key element in sustainability. In the drive to highlight the fundamentals of sustainability, many scholars have concentrated on cost and benefit, the two key elements in decision-making for environmental protection (Tilton, 1992; Warhurst, 1998). This approach in terms of cost/benefits however fails to integrate the technology factor. From an empirical point of view, studies conducted in the mining sector have shown that environmental degradation is greatest in operations working with obsolete technology. Firms that pollute the most are mismanaging the environment precisely because of their inability to innovate and the most efficient firms are generally better environmentally managed, because they are innovators (Warhurst, 1998). Examples from the literature show that innovation can reduce pollution, and that firms that adopt this strategy build competitive advantages as well as environmental benefits. In the mining sector, environmental performance of an enterprise is more closely related to its innovative capacity than to the regulatory regime under which it operates (Lagos, 1992; Acero, 1993). Companies adapt to environmental regulatory pressures by innovating, improving, and commercializing their environmental technology and environmental-management practices, at home and abroad. New and more stringent noise pollution regulations in the seventies saw the emergence of a host of new products and services for noise control in Great Britain and some Scandinavian countries, including from the polluters themselves (Djeflat, 1975). On more global terms, technical innovation, for instance in terms of developing substitutes to naturally scarce raw products, may help to overcome the fact that natural capital cannot always be reproduced. (Johnson & Lundvall, 2000). However, pollution control and environment protection are only one of the objectives of sustainable development. Sustainability is also about reducing poverty, education, health and welfare, and rural development. Finally, innovation requires that innovative capabilities are transferred to future generations on top of the fact that some results of fundamental research may be stored to meet future needs.

Thirdly, education and training need to be singled out when raising the issue of sustainable development not only because of their importance in the production of appropriate knowledge, but also in its diffusion and renewal. As stated in the world summit for sustainable development, young adults tend to emerge from the educational system without a deep sense of ecological matters and without knowing what to do with the knowledge they have. They are unequipped to make decisions that are environmentally enlightened when they take their place in the work force (International Environment Forum, 2002). The new education paradigm should therefore foster different values and attitudes such as cooperation instead of competition. Such an educational approach would be participatory, interactive, integrative, value-driven, and knowledge-based i.e. that it encourages creativity, innovative attitude and the constant drive to renew its stock of knowledge. Knowledge is under the permanent threat of being obsolete and requires learning permanently through the academia and interactive lifelong learning.

Finally, one of the key questions is how institutions can play an adequate role and give the necessary atmosphere to mobilise knowledge for sustainable growth and development. This issue raises another question relating to the private sector involvement, both as user and as a source of relevant knowledge for sustainability (Hardi, 2000). It involves also all the other issues addressed usually by public economics of free-riding, prisoner's dilemma, aligning incentives, and the distribution of authority applied to knowledge (Olson, 1971). Policy aims generally at integrating sustainable development as a guiding principle in all government actions in order to ensure that economic and social development keep within ecological limits, particularly in the area of S&T policy, where there is a lack of incentives to set strong priorities for promoting sustainable development.

2. KNOWLEDGE AND SUSTAINABILITY IN ARAB CONTEXT

The issue of knowledge and sustainability in Arab countries, in particular, raises several questions, as a result of a weak knowledge base, incomplete innovation system and often weak sensitivity to sustainable development gains. As remarked elsewhere, these issues may seem as luxury in a continent were poverty, hunger, illnesses, disease and conflicts prevail (Johnson & Lundvall, 2000). However, one cannot help relate the issues of Arab development to that of sustainability based on knowledge, where current endogenous capabilities are weakened by limited access to advanced technology and its difficult transfer. Yet when examining the linkages between knowledge and sustainability, it becomes clear that new opportunities exist for Arab development. We will examine, in this section, what these difficulties are and what new opportunities exist.

Knowledge systems and sustainability raise specific issues from a developing country perspective, in our view. The relatively weak knowledge base and the difficult integration of knowledge economy in most economic policy agendas are more than obvious. In an earlier work we have highlighted some of the impediments (Djeflat, 2006 b). While the impact on the local industry can be quite substantial in terms of employment creation, outsourcing to local industry with the aim of upgrading their facilities and know-how, and perhaps in some cases, triggering a real innovation dynamics, examples and success stories to substantiate that, are still relatively limited and particularly when it comes to Arab countries, with the exception of South Africa.

It is recognized in recent contributions, that building more effective knowledge systems for sustainability takes time and patience (Cash et al., 2003). Strategies to promote such systems require a sufficiently long-term perspective that takes into account the generally slow impact of ideas on practices, the need to learn from field experience, and the time scale involved in enhancing human and institutional capital necessary for doing all these things. A decade or more thus seems the minimal period over which efforts are deployed to harness S&T for sustainability (International Council for Science, 2002; Lubchenco, 1998; Unesco, 2000). In many Arab countries, pressure for development, coupled often with the need to face global competition, leave very little scope and room for manoeuvre for decision-makers to start off this long-maturing process. ICTs, while making remarkable progress in recent years, are very much in the realm of digital divide and again more demand and less supply oriented. Education and training as a means of knowledge diffusion and competence building face major obstacles. As seen earlier, knowledge which is vital to sustainability sees its price distorted in the face of high intellectual property barriers. Institutions are mismanaged and governance appears to be a common concern for the majority.

While stressing all these difficulties in harnessing knowledge systems, there are several opportunities which the adoption of the knowledge economy approach opens up for Arab countries in terms of sustainable development. ICTs give new opportunities for taping into global knowledge for Arab countries and improving their relatively weak local knowledge base. They also give them the opportunity to extend their knowledge system to include their Diasporas as shown by success stories in India, China and South Korea. They finally give the opportunity for local firms and research institutions to integrate knowledge networks and update their often obsolete tools and methodologies. New opportunities offered by e-learning can help reinforce the often weak education and training system. Paradoxically, while the much publicized digital divide is a real issue for Arab countries and indeed raises the threat of

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

these countries being left behind, the "knowledge divide" is rarely put forward as another possible risk enhancing what we could call the "sustainability divide" which is gradually taking place. Improving the knowledge base of Arab countries will, therefore, lead to higher potential for sustainability as we have hypothesized and we will try to substantiate in the next section.

3. MEASURING THE LINK BETWEEN KNOWLEDGE AND SUSTAINABILITY

From an empirical point of view, knowledge systems appear to be closely related to sustainability. Two indicators have been selected to show this relationship: the knowledge index and the sustainability index.

3.1. The Knowledge Index

As explained earlier, the knowledge economy builds on indicators and variables: the two main parameters are the knowledge economy index (KEI) and the knowledge index (KI). The knowledge index, which appears more appropriate and for which data are available for a sufficient number of countries, measures the ability to generate, adopt and diffuse knowledge. It constitutes an indication of overall potential of knowledge development in a given country and is defined by the World Bank Institute as "the average of the normalized performance scores of a country or region on the key variables in three indicators: education and human resources, innovation system and information and communication technologies" (Dahlman, 2003). The three indicators include several variables related to knowledge generation and knowledge diffusion as shown in Table 2. The fourth indicator which relates specifically to the KEI reflects the institutional dimension and has moved gradually in recent years to reflect more and more the business climate. This is the reason we have not taken it into account here.

The normalization procedure brings all the indicators to the same standard of measurement through the process known as normalization through the next formula:

Table 2. The knowledge economy, index and variables

Indicators	Variables
Knowledge Index	
Education and human resources	-adult literacy rate -secondary enrolment -tertiary enrolment
Innovation system	-Royalty and license fees payments and receipts -Patents applications granted by the US Patent and Trademark Office (USPTO) -Scientific and technical journal articles
Information and Communication Technology	-telephone per 1000 people -computers per 1000 people -Internet Users per 10 000 people
Knowledge Economy Index (Add)	
Institutional framework and governance

$$N(u) = 10*(1-Nh/Nc)$$

where N(u) represents the normalized score of an index, Nh represents the number of countries with high rank and Nc the total number of countries in the sample with available data.

3.2. The Environmental Sustainable Index and Environmental Performance Index

The two main indexes used are the Environmental Sustainable Index (ESI) and the Environmental Performance Index (EPI). The ESI provides a gauge of a country's long-term environment trajectory. Constructed around the concept of sustainability, it tracks the environment past, present and future. In contrast, the EPI addresses the need for a gauge of policy performance in reducing environmental stresses on human health and promoting ecosystem vitality and sound natural resources management (Yale Centre for Environmental Law & Policy and Centre for International Earth Science Information Network, 2005). The ESI score represents an equally weighted average of the 21 indicator scores (Table 3). Each indicator builds on between 2 and 12 data sets for a total of 76 underlying variables. The 21 indicators are grouped into 5 components: environmental systems, reducing environmental stress, reducing environmental vulnerability, social and institutional capacity and global stewardship.

Of all the components, the "social and institutional capacity" appears to be more related to our problematic. The four components relate to knowledge dimension either directly or indirectly: the first indicator "Environmental governance" includes knowledge creation in environmental science, technology and policy variable, stressing thus the need for knowledge in sustainability. The "science and technology" indicator includes also direct measurement of knowledge: namely innovation index, digital access index, female primary education completion rate, gross tertiary enrolment rate, number of researchers per million inhabitants and world economic forum survey on private sector environmental innovation. On top of these direct knowledge variables, many of the others can be considered as indirect measures of knowledge e.g. government effectiveness or number of ISO 14001 certified companies per billion dollars GDP (PPP).

The EPI builds on two broad environmental protection objectives: (1) reducing environmental stresses on human health, and (2) promoting ecosystem vitality and sound natural resource management. Envi-

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

ronmental health and ecosystem vitality are gauged using 25 indicators tracked in six policy categories: environmental health, air pollution (effects on ecosystems), water (effects on ecosystems), productive natural resources, biodiversity and habitat, and climate change. The EPI utilizes a proximity-to-target methodology focused on a core set of environmental outcomes linked to policy goals. The 2008 EPI includes 149 countries based on data availability (Yale Centre for Environmental Law & Policy & Policy Centre for International Earth Science Information Network, 2008). The EPI has since 2005 replaced the ESI for a variety of reasons explained by the authors (Yale Centre, 2006).

The empirical analysis was conducted on two samples of countries: the first fifteen countries in the world in terms of ESI which are then compared to the seventeen Arab countries for which complete sets of data for ESI, EPI and KI are available. The non availability of published data made it difficult to include all Arab countries. Both least square and correlation coefficient methods are used to have complementary and more robust results.

3.2.1. Environmental Sustainability Index and Knowledge Index

The latest data found for ESI are from 2005 while KI data are from 2008. A first glance, Table 4 shows that nine out of the first fifteen countries in ESI are from advanced countries in terms of environmental sustainability. Nonetheless six countries are from the developing world, half of them from Latino-America.

This is an indication that sustainability may not be directly related to the level of development, which is also the conclusion that the World Sustainability Report found. The relatively high score can be related to certain indicators found in the ESI matrix. These include air quality, biodiversity, land and greenhouse

gas emissions. This argument needs to be put in relative terms though. In terms of knowledge, the first countries in the world have also relatively high to medium knowledge index (above 5) with the exception of two countries: Guyana and Peru.

When looking at the first fifteen countries in the world in terms of KI, half of them score less than 60 in terms of ESI (2005). Only four can be considered to have high scores: Iceland, Sweden, Finland and Norway (Table 5).

Data in Table 6 indicate that Arab countries which score relatively low in knowledge index are also ranked in low positions in the ESI. Here also, some remarks can be made. Some countries which are

Table 5. Environmental Sustainable index and knowledge index (option b)

Kuwait	36.6	5.45

Source: World Bank Institute 2008 & "Pilot 2006 Environmental Performance Index". (*) The KEI is used in this case as a good proxy of the KI because of the missing figures for this latter. (**) The EPI score is used as good proxy of ESI because of the missing data.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

least developed countries in the region seem to have relatively higher ESI than wealthier countries: this is the case of Yemen which scores higher than Kuwait for example.

On the other hand, Arab countries which score higher on the KI are not the best in terms of ESI with the exception of Tunisia. This is partly due to the fact that these countries have some industrial base and infrastructure which are contributing to the degradation of the environment: oil, steel and petrochemicals in Algeria and phosphates in Morocco.

A simple regression analysis shows that advanced countries tend to concentrate in the top of the first half of the linear trend, while Arab countries are in the bottom. The strength of the relationship is shown by the relatively high score of the correlation coefficient which is $R^2 = 0.75209$ (option a) and $R^2 = 0.8620$ (option b). However, when taking Arab countries separately, the coefficients are much lower. This is an indication that other factors that matter are at play such as governance and financial capital.

3.2.2. Environmental Performance Index and Knowledge Index

The environmental performance index scores of 2008 make it more appropriate to cross with the 2008 KI index. Table 7 shows that the first fifteen countries in the world on the knowledge grid score reasonably high on the EPI 2008 grid.

They all score higher than 80 with the exception of the Netherlands and Australia. Arab countries which score relatively low in Knowledge Index are also ranked in low positions in the EPI (Table 8). These latter seem to have higher EPI scores: Algeria's score for example is nearly equal to that of the Netherlands even though its KI is fifty per cent less. This is partly due to the fact that these countries have made a significant progress in environment protection in recent years, particularly from the insti-

Table 7. Environmental performance index and knowledge index 2008 in most advanced countries

Source: World Bank Institute 2008 & "2008 Environmental Performance Index" Report

tutional point of view, but slower progress in knowledge, namely as a result of poor innovative activities (Djeflat, 2006).

This is clearly also shown through a simple regression analysis. Advanced countries tend to concentrate in the top right of the first half of the line, while Arab countries are in the bottom left part. The least square line indicates a relatively strong relationship which is reflected through the relatively high coefficient correlation $R^2 = 0.9296$ and $R^2 = 0.8402$ for Arab Countries taken separately. This is an indication that in the case of Arab countries, knowledge counts a great deal for sustainability. Further research is needed to shed more light on these issues.

4. DISCUSSION

Knowledge systems are thus closely correlated with sustainability both in developed and in developing countries. And indeed, the weak position of Arab countries in the sustainability grid is partly the result of their difficult access to knowledge with all its components. One of the key elements of this difficulty is the issue of technology transfer; the second one is the innovation issue which is closely related.

Firstly, technology transfer has always been an issue of concern for Arab countries who have remained for decades, permanently dependent on their technology suppliers (Djeflat, 1988). Under competitive pressure and market rules, technology suppliers have no incentive to transfer technology to recipients. However, in the area of environmental protection, there are grounds, according to several scholars (Warhurst, 1998), for a "new type of technology transfer" to take place in environmental management. It includes the knowledge, expertise, and experience required to manage technical change, the development of human resources to improve overall production and energy efficiency and environmental management of plants and facilities. It emphasizes training and skills acquisition, the novelty being the emphasis put

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

on training and skill acquisition in environmental R&D. Technology transfer and technology partnership through joint ventures or strategic alliances are ways to build up these technological and managerial capabilities (Warhurst, 1998; Djeflat, 1996). However, evidence from the field tends to suggest that this process has some limitations. Examples from the mining sector show that international firms transfer significant amounts of managerial and engineering expertise through joint ventures and other collaborative arrangements but limited to the specific project. Yet, these contributions can be considerably increased without adversely affecting the supplier's strategic control of its proprietary technology (Bell, 1990; Warhurst, 1991a, b; Auty & Warhurst, 1993). Donors and international organisation can sometimes help suppliers to transfer their technology: they usually cover the costs of such operations. One of the programmes of Agenda 21, for example, encourages self-regulation, environmental R&D, worldwide corporate standards, and partnership schemes to improve access to clean technology worldwide. However, for this transfer to be effective, a substantial increase in the technological capabilities of recipient countries is required (Barnett, 1993). This new concept mostly examined in a Latino American context does not seem however to be easily generalized to Arab countries where the mining sector is relatively important as a foreign currency earner and where it is almost fully dominated by technology suppliers.

Secondly, innovation is to be put against "most pressing needs" issue. Pressing needs include of course hunger, poverty, protecting the earth life support system and biodiversity. Two questions can be raised: the first one is what drives Arab countries to innovate for sustainability, if ever? The second questions is what S&T capabilities could they mobilise? There are several motives for Arab countries to innovate for sustainability: firstly, because upstream, some of them suffer from resources limitation which requires using them in a very parsimonious way not to have to undergo heavy environmental costs they could not bear and to guarantee to future generation access to a certain amount of these resources. Secondly, they need to innovate because of the many problems they are suffering from and which conventional techniques and approaches have proved difficult to resolve. Innovation has to be in all fields and not simply in the technical field: in the social, the political, and the organisational fields. While all this drive to innovate exists, there are several impediments and we have highlighted some of these looking, specifically at Middle East and North Arab (MENA) countries in previous contributions (Djeflat, 2000). The most important impediments include the cost to the environment which does not seem to be strong enough to have a significant impact and which is usually externalised at firm level and does not constitute a strong motive to undertake innovative activities in this sense. This situation is found in the mining sector in Latin America (Warhurst, 1998) and can easily be found in the oil sector (Algeria, Libya) and in the phosphate industry (Morocco) (El Khabli, 2001). The second one is the force of regulations which normally should be a driving motive and which, in an Arab context faces several obstacles due to governance problems and widespread corruption in the judicial system in particular. The third motive relates to social pressure which is relatively weak, the communities and villages most affected by pollution, environmental hazards and non sustainable behaviour have very little voice at the political level to express concern and put pressure on polluters to undertake technical or organisational innovation. Examples from the oil sector in Algeria show that major oil companies started changing their attitude and being more concerned with pollution control and environment protection only when, their key technical personnel started exercising pressure when they felt personally at risk. Pressure could not come from villages and populations living in the affected areas as a result of flared gas and severe air pollution. The fourth one is pressure from international organisations. This factor seems, in the current situation the most plausible factor which can have a significant impact on Government and firms to change their technologies and organisation to more responsible behaviour. However, the limited financial

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

means of certain debt ridden Arab states make it difficult to divert precious resources to innovation, while other urgent needs are not satisfied. Moreover, it may have a counter-productive effect, and lead to a drawback in sustainability as a result of less investment for poverty reduction, health protection and education promotion. International public funding could play an important role in this respect. Credit conditionality could help enterprises change their technological and environmental behaviour (Warhurst, 1998). The fifth one is related to the support coming from donor organisations, which has had some significant impact in recent years. This was the case in the agricultural sector where some progress has been made using local competences in R&D to find local solutions to problems such as crop disease, water treatment or water-saving irrigation techniques. However, these success stories are far too limited, not sufficiently publicised and far too concentrated in agriculture and less in the industrial sector.

CONCLUSION

We have highlighted above some of the fundamental issues and obstacles in the face of using knowledge for sustainability. Both the conceptual and the empirical analyses have shown that knowledge systems and sustainability are closely inter-linked and relatively highly correlated. This buttresses our hypothesis that knowledge and technology transfer remain paramount to sustainable development in developing countries as a whole and Arab countries in particular. However knowledge systems and sustainability are on different time scales and face different kinds of imperatives. While the building of knowledge is a long-time scale, some of the sustainability issues are on a much shorter time scale. For this latter type of issues, there are prospects and opportunities which could be seized. We will list them briefly here. The first opportunity is the new drive in the industrial fields for more ethical conduct, equitable trade and common destiny which is rapidly expanding in advanced countries. The social responsibility of enterprises appears a common concern for industrial firms throughout the world. New investment projects increasingly incorporate economic and environmental efficiencies into the production process, not just through new plants or equipment but also through improved management and organizational practices. They encourage both a dialogue between stakeholders in S&T and the elaboration of an appropriate regulatory and policy environment to nurture private investment in R&D. The second opportunity is the prospects offered by indigenous knowledge: What is missing is the capability based approach, as well as more generally a focus on learning capabilities as a whole. Many different kinds of learning are going on in society, i.e. in rural areas, villages, firms and organizations in the public sector as well as the private sector. Yet, only a part of this takes place in the formal education system or in the research system. What needs to be understood is how and to which extent individuals, communities, firms and organizations are geared to learning and innovation, either by themselves or in interaction with others (Johnson & Lundvall, 2000). The recognition of local and indigenous knowledge systems creates opportunities for establishing sustainable development and natural resource management processes that are rooted in social equity and relevance, local ownership and value systems, sound institutional partnerships and the valuation of both cultural and biological diversity. Another reason is that the need and opportunity to build on local and traditional knowledge may be relatively bigger in the South than in the North. The existence, character and usefulness of this knowledge may not be well known to national and international firms and policy makers. It is therefore vital to underline the importance of tacit knowledge and to draw attention to the need not to lose large parts of mostly not codified and undocumented local

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

competencies. All these avenues are promising for Arab sustainable development through sustainable knowledge. They need to be further investigated.

KEY TERMS AND DEFINITIONS

Degradation of Human Life: The negative effects of a degraded environment on human life. This deterioration is expressed under the direct and indirect costs of living that include the impacts on housing, food and infrastructure of different forms of environmental degradation (water, air, and soil pollution besides congestion). These costs culminate when health of individuals and groups is affected. Health costs are important measures of human life degradation.

Environmentally Sustainable Industrial Production: An industrial production that includes the indirect costs and the benefits related to the industrial process. Under this approach, industrial enterprises engage in social programs that account for the interests of businesses but also of society.

Less Developed Economies (LDCs): While most of the chapters in the present book use the concept of developing and developed economies, the present chapter uses the terminology of less developed economies or countries. As such, this is consistent with both approaches based on GDP and HDI and the relation to World Bank and UNDP rankings of countries. In this chapter, LDC refers to those countries with low economic and social performances.

New Opportunities: Knowledge economy has the merit of providing technologies and instruments needed in identifying and valuing new opportunities offered to businesses, to communities, and to society.

Public Goods Rational: The general framework that defines public goods and where non-exclusion and non-rivalry are the most important features by opposition to private goods.

Sustainable Development: An inclusive concept, as it accounts for economic, social and environmental dimensions of development. In addition, all natural resources in different locations and territories are included. But sustainability in development is mainly dynamic as it considers the improvement of

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

the well-being of the populations throughout years and generations. In this sense, a development process is sustainable if it includes all the factors cited above.

Threat of Obsolescence: Knowledge is also known to have the property of quick obsolescence mainly under the on-going speeds of production and exchange of knowledge. Globalization of world economies is increasingly placing countries and regions in different benchmarks that help observe the state of knowledge in each country and region.

Chapter 13
Integration of Demand-Side Management Programs and Supply-Side Alternatives for Decentralized Energy Planning:
An Analysis of Energy Import and Export Effects

Masoud Rabbani
University of Tehran, Iran

Mahdi Dolatkhah
University of Tehran, Iran

ABSTRACT

Optimally selection of an appropriate mix of renewable sources for supplying electricity of remote areas has been always an important challenge for policy makers. Also, in recent years, the great advantages of Demand Side Management (DSM) programs such as postponing investments in construction of new plants and/or desirably modification of electricity consumption pattern has turned great attention of energy planners to these programs. Moreover, the issue of global warming has caused the need for reduction of human use of fossil fuels and switching to employing green energy sources. To address the mentioned concerns, in this paper, an integrated mathematical formulation for selecting the best mix of renewable energy technologies is proposed. In this study, DSM considered as a competitive option against supply-side alternatives for making energy planning decisions. Additionally, by considering real data from a case in Iran, the effects of considering energy import and export has been taken into account. To validate the model, for smaller-scaled test problems the model has been solved by Lingo 8.0 software while for solving larger instances of problems (real scale of case study) a novel genetic algorithm (GA) is devised. The numerical results indicate that DSM policies have made use of their maximum capacity and resulted in significant improvements, especially in terms of reducing consumption and suitably changing the load shape.

INTRODUCTION

Environmental concerns like global warming and climate change along with other factors such as recent financial crisis, the ever-increasing electricity demand, obligations to reduce greenhouse gas (GHG) emissions and current tendencies to achieve sustainable development, has led world leaders to expedite the process of replacing fossil fuels with renewable energies (RE) (Kyoto protocol - unfccc.int/kyoto_protocol/items/2830.php). Likewise, utilizing demand side management (DSM) strategies has ever more attracted the attention of policy makers. The higher the utilization of DSM policies is, the lower the need for investments in new power plants will be (Ardakani & Ardehali, 2014). As a result, not only GHG emissions will be remarkably reduced but also funds previously designated for constructing power generation plants will find the opportunity to be invested in more profitable settings.

There are a variety of RE technologies each of which has its own advantages and disadvantages. Thus, making a conscious decision on choosing an appropriate mix of different types of RE plants and determining their locations and capacities has always been a challenging task. Furthermore, there are different end-use sectors and accordingly different DSM programs suitable for each sector. Moreover, to reach the optimal energy planning decision, demand side resources must be compared to supply side alternatives (Kreith & Goswami, 2007). The above mentioned concerns show the need for an integrated modeling of the system such that helps policy makers come to the best decision.

Optimal designing wind park, solar plants, DSM programs and other RE systems have been extensively studied in the literature. However, none of which considers these different supply-side and demand-side alternatives all together. Because of this, we are going to integrate these options as a comprehensive model by considering effects of environmental parameters, possibility of importing and exporting of electricity, different RE options and DSM techniques and finally determining the best mix of energy technologies.

Among many approaches used for planning of energy in the literature, the most frequent ones include Linear Programming (LP) models (Ramakumar et al. 1986; Devadas, 2001), Delphi study (Iniyan & Jagadeesan, 1997), Optimal Renewable Energy Mathematical model (OREM) (Iniyan et al. 1998; Iniyanet.al, 2000) and etc. Hiremath (Hiremath e al. 2007) provided a great literature review on the new approaches and models toward decentralized energy planning (DEP). (Senjyu et al. 2007) and (Lagorse et al. 2009) used genetic algorithm for solving a DEP model. Herran and Nakata (Herran & Nakata, 2008) employed a goal programming (GP) approach to obtain satisfactory pareto optimal solutions to a DEP problem. Hiremath et al. (Hiremath et al. 2009) and Kanase-Patil et al. (Kanase-Patil et al. 2010) developed new models for decentralized energy planning in rural areas while they used GP method to solve their multi-Objective optimization model as well. Hessami and Bowly (Hessami & Bowly, 2011) studied the economic benefits of utilizing large-scale and different energy storage systems. The objectives sought to be optimized in the above mentioned studies are of either minimization or maximization type. The former type includes objectives such as total cost, utilization of petroleum products, etc. while the objectives of the latter type are system performance, utilization of available local resources and so forth.

As discussed earlier, global warming and climate change have caused GHG emissions to be regarded as an important problem in the last decade (Leung & Yang, 2012). For this reason, recent studies have tried different approaches such as changing the type of fuel Consumed (Sims et al. 2003), utilizing different renewable energy sources (Panwar et al. 2011; Hessami et al. 2011), new energy planning methods (Tsioliaridou et al. 2011) by applying mixed integer programming, goal programming (Cristóbal, 2012) and multi-objective evolutionary algorithms (Hashim et al. 2005; Agustín et al. 2006; Katsigiannis et al. 2010) for reducing the amount of these pollutants.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

In a latest research, Narula et al. (Narula et al. 2012) carried out critical reviews on the potential of renewable energies and their economic feasibility analysis in the future (see also Moriarty & Honnery, 2012; Yang et al. 2012; Katsaprakakis, 2012). Also, a number of researches have been conducted about new types of RE sources (Evans et al. 2009; Trapani et al. 2013).

Nowadays, as a result of increasing cost of energy in hours of consumption peak, the role of smart appliances in balancing of electricity cost (Gottwalt et al. 2011) and applying TIMES model for minimizing the costs (Pina et al. 2012); Doostizadeh & Ghasemi. 2012; Monteiro et al. 2013) have been investigated.

As a result of the ongoing growth of energy-intensive industries and the present remarkable increase in the demand of energy users, the need for establishing new power generation plants and/or changing the consumer behavior have been really amplified. Rodriguez et al. (Rodriguez et al. 2010) and Moura and de Almeida (Moura & de Almeida, 2010) conducted great reviews on the latest methods of distributed energy resources planning and analyzed the scope within which DSM policies can be applied. Finn et al. (Finn et al. 2013) and Gudi et al. (Gudi et al. 2012) showed the application of DSM and pricing policies and shifting the peak of demand to other hours that causes to defer the additional investments in new power plants.

Among the existing huge literature focused on RES, a little portion has been dedicated to surveying the role of imports and exports in creating a non-blackout grid. Kost et al. (Kost et al. 2011) and Dassisti and Carnimeo (Dassisti & Carnimeo, 2012) have studied the role of imports and exports of electric energy in RES and Supersberger and Führer (Supersberger & Führer, 2011) have analyzed the advantages and disadvantages of renewable energies by considering import and export dynamics in North African countries.

In a recent study, Kazemi and Rabbani (Kazemi & Rabbani, 2013) proposed an integrated DEP model wherein DSM policies were aptly regarded as a competitive solution against the supply-side alternatives for electrifying a rural area. Based on their obtained results, DSM policies were contributing to electrifying the supposed area at their maximum capacity. Additionally, they considered environmental measures in their study to make the plan more sustainable. However, a significant shortcoming of their work is that since the hypothetical village in their study was completely secluded, the benefits and detriments of being a part of a mini grid and having interactions with other supply/demand areas were totally disregarded. This paper in addition to covering the strengths of the work (Kazemi & Rabbani, 2013), has made the analysis of import and export effects achievable.

Based on the literature review provided above it is clear that none of the mentioned studies has considered DSM policies together with the possibility of import and export in making decision-planning policies. Moreover, a variety of foremost issues such as ever-rising energy demand, lack of sufficient energy infrastructures and dependence on energy imports for supply purposes or on energy exports for its profitability has further highlighted the need to fill the gap by proposing an integrated model in which both DSM policies and the possibility of import and export in a mini grid are taken into account. Thus, in this paper, a mixed integer nonlinear programming formulation capable of addressing the mentioned concerns is presented. Briefly speaking, the article attempts to answer the following questions:

- When is the appropriate time to import energy instead of self-generating it?
- Does combining DSM policies with the possibility of importing (exporting) a part of demanded energy from (to) other generating (consuming) locations make a big difference in terms of financial measures?
- Why mathematical programming has been selected for modeling such a complex system?

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

- What approach should be chosen for solving real sized large scale instances of the problem?
- And finally, regarding the modeling of the problem under the given assumptions, what would be the best mix of renewable energy technologies in which an investment should be made?

The remainder of the paper is organized as follows. In the next section the proposed mathematical formulation is presented. Subsequently, in section 3 a novel genetic algorithm for solving the proposed model for large-scaled problems is devised and fully explained in detail. Afterward, in section 4 a case study has been introduced and solved by the optimization problem and the obtained results are discussed. Finally, in section 5 conclusion remarks are drawn.

PROPOSED MODEL

After providing a general review on the related area, in this section our proposed model that is aimed to provide answers to the above questions is presented.

Assumptions

The model presented in this study has been built on the base of the following assumptions:

- Region sets or nodes are connected by a mini grid.
- Blackout is not permitted.
- Savings resulted from implementing DSM policies reveals itself as a change in the consumption pattern.
- Imports and exports are considered in the form of an internal grid.
- Since this model is not intended for a particular region, to show the applicability of the model, we will solve it in the next section with the data that are mainly related to the global averages and have been derived from the latest scholarly papers in the literature.

Given the assumptions provided above, the optimization model can be formulated as follows:

Mathematical Formulation

Notations

Sets:
I: Set of manufacturer of energy sources
J: Set of end- uses
K: Hour of day and night that energy consumed in that hour $K \in \{1,2,3,\ldots,24\}$
L: Set of regions
Parameters:

c_{ijk} **:** Electricity generation cost of resource *i* for *j* th end- use in *k* th hour $\left(\mathrm{US\$}/\mathrm{kWh}\right)$

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

$CDSM_{jkl}$ **:** Electricity saving cost using the implemented DSM program by *j* th end- use in k th hour and in *l* th region $\left(\text{US\$}/\text{kWh}\right)$

D_{jkl} **:** Average energy demand for *j* th end- use in *k* th hour and in *l* th region (*kWh*)

$Factor\,Parameter_{ikl}$ **:** Determining factor of maximum capacity of electricity can be produced by *i* th resource in *k* th hour and in *l* th region (in fact Factor $Factor\,Parameter_{ikl}$ is a binary parameter that can only take the values 0 or 1)

Su_i **:** Base capacity of energy produced by *i* th resource

$Alpha\,\boldsymbol{Ex}$ **:** A coefficient denoting an excess income from exports

Alpha Imp : A coefficient denoting a tariff imposed on imports

S_i **:** The cost of initial investment *i* th resource (Purchasing resource) ($Rial$)

P **:** A parameter representing the minimum compulsory budget that must be allocated to implementing DSM programs

Q **:** A parameter representing an upper bound on the budget that must be allocated to implementing DSM programs

$FDSM_{ijk}$ **:** The amount of improvement resulting from the implementation of DSM_{ijk} policy

$BigM$: A big number

Variables:

X_{ijkl} **:** The amount of produced energy by *i* th resource for *j* th end- use in *k* th hour and in *l* th region (*kWh*)

Y_{ijkl} **:** A free real variable showing the amount of electricity imports (if negative) or export (if positive) from *i* th resource to *j* end-use in *k* th hour and from *l* th region (city) *(kWh)*

Z_{ijkl} **:** A binary variable indicating whether *l* th city is an exporting city or an importing one

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Df_{il} **:** Integer matrices used for selecting the optimal number of *i* th resource

$SDSM_{jkl}$ **:** The determining matrix showing whether or not implementing DSM programs by *j* th end- use in *k* th hour and in *l* th region and is a binary variable

An Integrated Renewable Energy System (IRES) model has been proposed to generate electricity for using in agricultural, community, domestic and small-scale rural industrial regions. This model which is formulated as a nonlinear mixed integer programming approach is given below:

Minimize Total Cost =

$$\sum_i \sum_j \sum_k c_{ijk} \times \left(\sum_l X_{ijkl} - Y_{ijkl}.Z_{ijkl} \left(1 + Alpha\,\boldsymbol{Ex}\right) + Y_{ijkl}.\left(1 - Z_{ijkl}\right)\left(1 + Alpha\,\boldsymbol{Imp}\right) \right) + \sum_i S_i \left(\sum_l Df_{il}\right) + \sum_j \sum_k \sum_l SDSM_{jkl}.CDSM_{jkl}$$

Subject to:

$$\sum_j \left(-Y_{ijkl} + X_{ijkl}\right) \le Su_i.Df_{il}.Factor\,Parameter_{ikl} \;\forall i \in I, k \in K, l \in L \tag{1}$$

$$\sum_i \left(-Y_{ijkl} + X_{ijkl}\right) = D_{jkl}.\left(FDSM_{jkl}.SDSM_{jkl} + (1 - SDSM_{jkl})\right) \;\forall j \in J, k \in K, l \in L \tag{2}$$

$$\sum_i \sum_j \sum_l X_{ijkl} \ge \sum_j \sum_l D_{jkl}.\left(FDSM_{jkl}.SDSM_{jkl} + (1 - SDSM_{jkl})\right) \;\forall k \in K \tag{3}$$

$$\sum_j \sum_k \sum_l SDSM_{jkl}.CDSM_{jkl} \ge P \tag{4}$$

$$\sum_j \sum_k \sum_l SDSM_{jkl}.CDSM_{jkl} \le Q \tag{5}$$

$$\sum_i \sum_j \sum_l Y_{ijkl} = 0 \;\forall k \in K \tag{6}$$

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$\sum_i \sum_j \sum_l Y_{ijkl} \leq BigM * Z_{ijkl} \ \forall i \in I, j \in J, k \in K, l \in L \tag{7}$$

$$\sum_i \sum_j \sum_l Y_{ijkl} \geq -BigM * (1 - Z_{ijkl}) \ \forall i \in I, j \in J, k \in K, l \in L \tag{8}$$

Df_{il} : $integer \ \forall i \in I, l \in L$

Y_{ijkl} : $Free \ \forall i \in I, j \in J, k \in K, l \in L$

$$SDSM_{jkl} = \begin{cases} 1 & If\ the\ DSM\ policy\ be\ used \\ 0 & otherwise \end{cases} \quad \forall j \in J, k \in K, l \in L$$

$$Z_{ijkl} = \begin{cases} 1 & If\ \ Y>0 \\ 0 & If\ \ Y<0 \end{cases} \quad \forall i \in I, j \in J, k \in K, l \in L$$

The first term of the objective function calculates the cost consisting of both generated electricity costs and costs of importing or exporting electricity. The second term of the objective function calculates the total cost of investment for purchasing the renewable energy technologies. Furthermore, total costs of implementing DSM programs are computed by the third term.

Constraint (1) implies that total amount of electricity generation must not exceed the maximum power production capacity. The demand balance constraint is enforced by constraint (2). Based on constraint (3), the hourly total production of electricity must not be less than the hourly demand of total network because blackout is not permitted.

Constraint (4) represents that a minimum mandatory proportion of demand must be met through DSM programs. In other words, it ensures the implementation of DSM programs through obligatory policies. Constraint (5), on the other hand, sets an upper bound for the maximum DSM achievement target. Constraint (6) enforces the import/export balance constraint. Finally, using constraints (7) and (8) prevent Y_{ijkl} gets infinitive value.

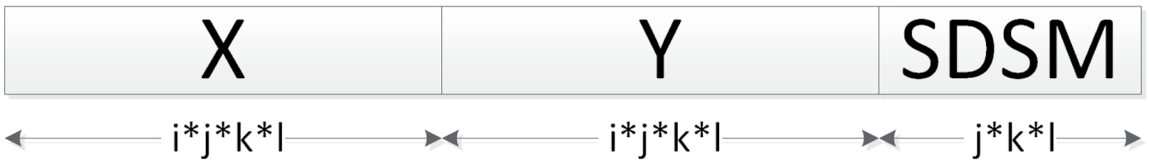
SOLUTION METHODOLOGY

Although the model proposed in the above section has been solved by commercial Lingo software for small-scaled test problems, for large-scaled instances of problems a novel genetic algorithm (GA) is devised. Bagley (Bagley, 1967) introduced the words ‘‘Genetic algorithms” (GAs) and published the first applications of GA. Then, GA was developed in the 1970s as an optimization toolbox, that was applied by Holland (Holland, 1975).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Generally, GA parameters and components are: chromosome, population size, fitness function, selection operator, crossover operator, mutation operator, crossover percentage, mutation percentage and mutation probability.

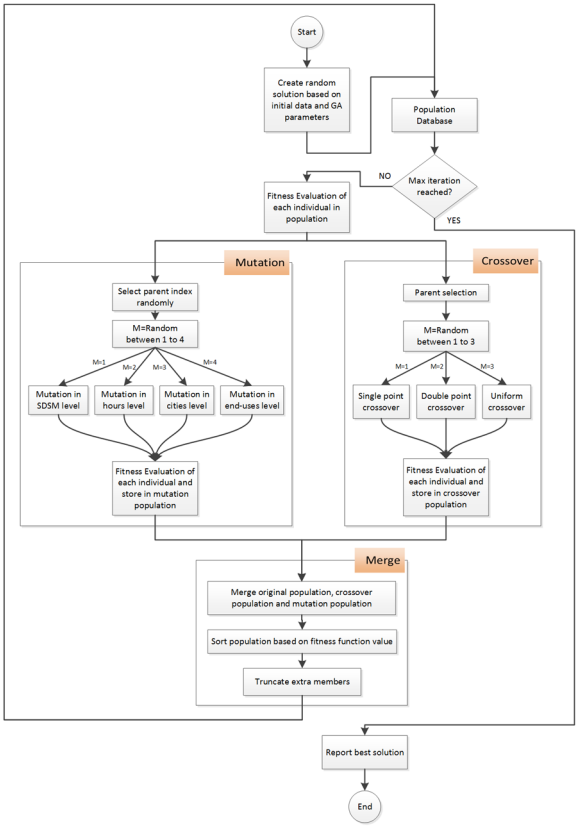
In this section the GA procedure is comprehensively explained and its steps one after another are well delineated.



Definition of Chromosomes

Chromosome is a demonstration of an acceptable answer of the problem and must have special conditions of being unique; therefore, the chromosome is defined for this problem includes three components X, Y and the SDSM as shown in figure 1. To have a better understanding of described procedure in sections 3.1, 3.2 and 3.3, it is highly recommended to refer to figure 2.

In the first SDSM (that is a binary parameter) is generated randomly that has $j \times k \times l$ length. Then parameters X and Y are generated as follows with considering the initial data values and generated SDSM values:



1. According to the values of D, FDSM and SDSM available, right side of the second constraint is generated.
2. By calculating $\sum_{j}\sum_{l} D_{jkl} \cdot \left(FDSM_{jkl}.SDSM_{jkl} + \left(1 - SDSM_{jkl}\right)\right)$, the value of $D_k^{'}$ is obtained. Now, the right side of the third constraint is calculated.
3. By combining the constraints (3) and (7), we conclude that if the constraint (3) is satisfied, constraint (4) will be established in the form of equity; According to the expressed points $D_k^{'}$ will equal to $XK = \sum_{i}\sum_{j}\sum_{l} X_{ijkl} = D_k^{'}$.
4. By generation of Nl random numbers for each K, so that the $\sum_{l} Nl_l = 1$, the $XKL = \sum_{i}\sum_{j} X_{ijkl}$ can be obtained.
5. By generation of Nj random numbers for each K and L, so that the $\sum_{j} Nj_j = 1$, the $XJKL = \sum_{i} X_{ijkl}$ can be obtained. Now, due to the constraints (2) and that $\sum_{i} X_{ijkl}$ is known,
6. $YJKL = \sum_{i} Y_{ijkl}$ can be obtained.
7. By generation of Ni random numbers for each K and L and J, so that the $\sum_{i} Ni_i = 1$, X_{ijkl} can be obtained.

Figure 1. Demonstration of chromosome

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Proposed GA procedures

8. We do 3.1.6 Step to calculate Y_{ijkl} this time.
9. Parameters X, Y and SDSM are arranged in the order in which X placed at the beginning of the chromosome, Y placed at the middle of the chromosome and SDSM placed at the end of the chromosome.

As is clear, the length of chromosome in this mode is equal to $(1+2i)jkl$, that the length of X would equal to ijkl, the length of Y would equal to ijkl and the length of SDSM would equal to jkl.

According to above sequence, the important feature of mentioned chromosome is that all the obtained values for X_{ijkl} and Y_{ijkl} satisfying the constraints (1), (2) and (3), but since that the values of SDSM may be not satisfy constraints (4) and (4) from the beginning, we have defined penalties in the fitness function up to during the implementation of evolutionary process, feasible SDSMs be generated.

Crossover

Crossover is an operator that combine two chromosomes (parents) in order to create new chromosomes (offspring). Because of specific mode of chromosome's definition, except on two-parent SDSMs any changing in structure of crossover is not possible, because it will lead to the generation a chromosome that would not be satisfy constraints (1), (2) and (3) simultaneously. According to the mentioned reason,

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

the crossover is implemented by using the following three methods on the pair of parent SDSMs. First, a random number between [1, 2, and 3] is selected and placed in m.

1. If m=1, Single point crossover is used.

A random number between $\left[1 : j \times k \times l\right]$ is selected and placed in α. The first child will be created of the genes 1 to α of first parent's SDSM and genes α+1 to $j \times k \times l$ of second parent's SDSM. The second child will be created in contrary of creation procedure of the first child.

2. If m=2, Double point crossover is used.

Two random numbers between $\left[1 : j \times k \times l\right]$ is selected and placed in α and β, so that α<β. The first child will be created of the genes 1 to α of first parent's SDSM and genes α+1 to β of second parent's SDSM and genes β+1 to $j \times k \times l$ of second child's SDSM. The second child will be created in contrary of creation procedure of the first child.

3. If m=3, Uniform crossover is used.

A random vector of binary numbers with size $j \times k \times l$ are generated that called α. In the first child, wherever the element β of the vector α be equal to 0, β^{th} gene of first parent's SDSM and wherever the element β of the vector α be equal to 1, β^{th} gene of second parent's SDSM will be placed as the βth gene first child. The second child will be created in contrary of creation procedure of the first child.

Mutation

Crossover is an operator that randomly change one chromosome in order to create new chromosome.

Mutations in four stages are applied randomly; First, a random number between [1,2,3,4] is selected and placed in m.

1. If m=1, the mutation is applied in SDSM. $nMu = ceil(mu \times (j \times k \times l))$ samples are taken from the numbers $\left[1 : j \times k \times l\right]$ without replacement and the values of them if it be 1 will be changed to 0 and if it be 0 will be changed to 1.
2. If m=2, $nMu = ceil(mu \times k)$ samples are taken from the numbers $\left[1 : k\right]$ without replacement and then we repeat the steps 3.1.4 to 3.1.8 only for sample members.
3. If m=3, $nMu = ceil(mu \times l)$ samples are taken from the numbers $\left[1 : l\right]$ without replacement and then we repeat the steps 3.1.5 to 3.1.8 only for sample members.
4. If m=4, $nMu = ceil(mu \times j)$ samples are taken from the numbers $\left[1 : j\right]$ without replacement and then we repeat the steps 3.1.6 to 3.1.8 only for sample members.

Fitness Function

Fitness function includes all three objective functions that the values of them are added together and be put in the objective function value (OFV). Also the penalty values relate to the SDSM infeasibility as Constraint penalty added to the above value and ultimately the value of the fitness function is reported.

Selection Method

Selection method is used for selecting parents for crossover or mutation operator. In this paper, two methods roulette wheel selection (RWS) and tournament selection (TS) are used for process of selection (For more information about selection methods refer to Holland, 1975). To compare the differences of performance between these two mechanisms, after setting the parameters of genetic algorithms by applying of Response Surface Methodology (RSM) (for more information about methods of designing experiment and necessary conditions for ANOVA see 11th chapter of Montgomery, 2008) for both mechanisms, 30 tests for each mechanism are conducted to it be possible the using of assumption normality of the data. Then, by using of the obtained results, we conducted an analysis of variance (ANOVA) to differences or no differences between the two approaches be examined.

The RSM results show that the best choice for both methods is obtained with the following parameters presented in Table 1.

According to Table 2 that shows the results of the ANOVA, It can be concluded that there is no reason to reject the null hypothesis, so there is no significant difference between the results obtained by the two methods, but according to the lower mean and variance, TS method is selected.

F-test for analysis of equality of variances and then the t-test for equality of means show similar results.

Table 1. RSM results

	Crossover Percentage	Mutation Percentage	Mutation Probability
Range	0.6-0.9	0.3-0.5	0.1-0.3
RWS	0.8805	0.5	0.1

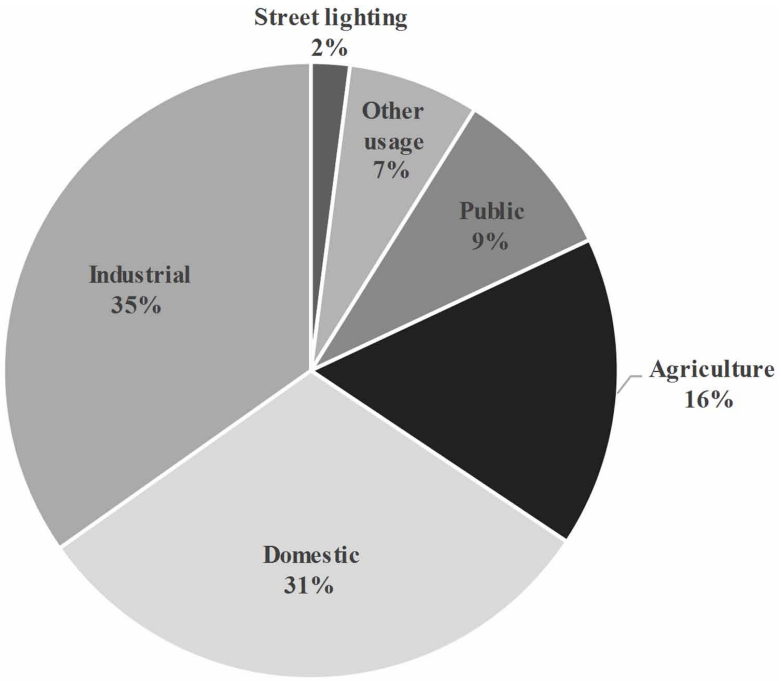
CASE STUDY AND EXPERIMENTAL RESULTS



Data Collection

As previously mentioned, the aim of this study is the use of renewable sources to meet the development needs electricity of a country. According to long-term plans of Ministry of Energy (MOE) (www.moe.org.ir) and annual reports, which are published for top executives in the electricity industry, Iran seeks to reduce dependence on fossil fuels to generate electricity in the years ahead. In this regard and given the information collected about the amount of demand, price, amount of consumption of end-users and other related data, which is obtained from Iran grid management company (www.igmc.ir) or is derived from the literature review, capabilities of the model are shown to provide the overload due to annual demand growth by different generated resources for different users at different hour of day and night and in different cities.

Demand

First, the available data about the electricity consumption were extracted from the (www.igmc.ir), which is available based on hour for the years 2006 to 2011. According to the report published by reports for managers 2012, the amount of consumption of different end-uses has been shown in Figure 3. Other sectors of electricity consumption except for domestic, industrial and agriculture sectors (such as street lighting and etc.) have been considered as public sector. Furthermore, according to the forecasting of electricity demand in Iran up to the year 2017, the average growth rate is 8.5%. By multiplying previ-

Figure 3. Amount consumption of different end-uses (reports for managers 2012, www.igmc.ir)

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

ous percentages and obtained growth rate in the average of the data collected, the amount of Electricity consumption per end-use will be achieved separately. Based on the above, according to the average consumption of the four provinces of Isfahan, Tehran, Khorasan and Fars respectively, the average consumption per province in each hour will be obtained. Because of all data are separated from one source, so consumption load shape for all end-uses is same. In order to solve this problem and obtain a fit load for each end-use, according to the literature review and items such as office hours (8 am to 2 pm) and peak information about the end-uses, set of coefficients generated. By applying these coefficients, the final electricity demand will be achieved.

Price of Electricity

Because of reduction the state budget, a policy in Iran has implemented to eliminate energy subsidies in the recent years. To obtain more realistic estimates, the average electricity price in 2012 is used. Considering that the cost of generated electricity by different sources and consumed electricity for different end-uses are different, specific coefficients for each source and each end-use was used to be considered these differences between prices in solving model.

FDSM's Coefficients

According to the implementation DSM plans, that their main goals are modify the consumer behavior, and accordingly, changing in the load shape and savings in electricity consumption, data related to FDSM are generated by considering to create a specify basic savings for each end-use and changing the load shape according to different hours.

The Values of Factor Parameters

This parameter states the level of access to producer sources in specified times; for example, that electricity generation source is dependent on the solar energy, not available in the hours that there is no sunlight. This information is obtained based on the average amount of solar radiation. In different regions of Iran, the average annual wind speed and diagrams of energy production proportional to wind speed for wind turbines, potential and the number of rivers within each province for generation of hydroelectric power and Finally, access to resources for electricity generation from Biomass (NASA Surface meteorology and Solar Energy, 2004; www.windflow.co.uk; geography-dept.talif.sch.ir).

Computational Results

The problem's data are arranged in the following order:

- The cities are arranged respectively as Isfahan, Tehran, Khorasan and Fars.
- The power sources (Plants) are arranged as wind turbine, solar panel (PV), Hydro and Biomass, respectively.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Remark. The objective function value is based on Rials (IRR currency) and can be converted to dollars by using the exchange rate 1\$ = 25000Rials.

In order to prove the possibility of solving the original problem, one test problem was produced according to the original data and it has been solved by Lingo software (version 8).

The results obtained from solving the sample with dimensions of $1\times2\times2\times3$ is given in table 3. This solution is a global solution to the problem and it can be used for calculating the primary error of genetic algorithm.

As it is clear from the results in Tables 3 and 4, the application of DSM policies can reduce the costs (cost showed by OFV in tables). Therefore, the implementation of DSM policies can reduce overall costs significantly in the long term. In addition to the above, the application of DSM policies will also reduce the number of energy sources. This issue appears more important when the energy sources are pollutants.

By considering the above example data, the best answer genetic algorithm after 10 iterations and with Max Iteration = 10000 is shown in Table 5. In this case, error of the solution obtained by the algorithm is equal to 20.65757%.

The results in Tables 3 and 5 indicate that SDSM has played an important role in problem of electricity supply network and in most cases it has been implemented. In other words, the constraint of maximum budget SDSM is an important limitation of problem, because different tests proved that the model moves towards the more implementation of policies SDSM that this issue leads to reduction in cost of system. In addition, results in Tables 3, 4 and 5 show that the initial cost of purchasing energy sources have the largest share in the objective function. So we can further reduce the objective function value than other states with the help of any way that we can reduce the demand, such as DSM policies.

Considering that the solving of main problem by using of exact algorithms is not possible, so the main problem with dimensions of $4 \times 4 \times 24 \times 4$ is solved by using of Genetic Algorithm. After problem solving, the results show that nearly 50% of SDSM variables have the value 1. In other words, this issue indicates that the DSM policies are often implemented.

The results in Table 5 shows Hydro and PV have the greatest share in the supply of electricity among the renewable energy sources respectively in the future of Iran that this matter was predictable according to geography and climate situation of Iran.

CONCLUSION AND FUTURE RESEARCH

The aim of this paper was to create an integrated model for decentralized electricity planning, so that criteria of DSM and the possibility of import and export are taken into account. The presented model in this paper has the potential usage capability for development of the national grid and/or entirely pre-planning of grid networks where the penetration of renewable energy technologies is dominated. Another feature of the proposed model is its ability to use the same resources with different capacities, that this feature causes flexibility in use of various resources with different capacities.

The obtained results of Table 3 and Table 4 indicate that implementing DSM programs can play a substantial role in reducing costs of planning electrical grids. Also, it can be pointed out that considering the case study data, because of the desirable rainfall in northern Iran and many rivers flowing in this country together with considering the fact that most days in central Iran are sunny during the year, the PV and Hydro should be used more widely as renewable energy technologies (RETs) for electricity supply and development of networks in the future. Therefore, making huge investments in PV and Hydro technologies and supporting DSM policies are very crucial for the country to reduce total costs of electricity generations and contribute to achieving sustainable development targets. In this paper, several step-by-step modifications is done to reduce the algorithm error rate from 50% to 20%.

Several issues can be considered as future studies. Utilizing of Prediction consumer demands methods for hourly demands (such as time series, neural networks and regression) and comparing the results of these methods with common methods is one of the best of these future studies. Another issue that can be considered as future studies is considering the amount of pollutants produced by renewable resources. In this case, the objective function also includes the reducing emissions and the problem will change to multi-objective problem. Moreover, utilizing of graph and network models and combining of these models with simulations methods can reduce the algorithm error rate significantly.

Chapter 14
Policy Provisions and Teachers' Needs on Climate Change Education for Sustainable Development in Mongolia

ABSTRACT

There is scientific consensus that Mongolia is already facing the negative consequences of climate change. Raising public awareness and increasing education initiatives is one of the most important ways to adapt and mitigate climate change. The present research team reviewed the policies and provisions in support developing climate change education for sustainable development. To strengthen public awareness of climate change and sustainable development, teachers at all level must play an important role. The team analyzed the level of teachers' knowledge of climate change education for sustainable development and determined the needs for teacher training. Education policy recommendations and the possibilities for teacher training were defined.

INTRODUCTION

Education is critical for promoting sustainable development and improving the capacity of the people to address environmental and developmental issues (UNCED, Agenda 21. The United Nations Action from Rio., 1992). From the time sustainable development was first endorsed at the UN General Assembly

in 1987, the parallel concept of education to support sustainable development has also been explored. From 1987 to 1992, the concept of sustainable development matured as committees discussed, negotiated, and wrote the 40 chapters of Agenda 21. Initial thoughts concerning Education for Sustainable development were captured in chapter 36 of Agenda 21, "Promoting Education, Public Awareness, and Training" (McKeown, Education for Sustainable Development Toolkit, 2002). Obviously, education is an essential tool for achieving sustainability. People around the world recognize that current economic development trends are not sustainable and that public awareness, education and training are essential to move society toward sustainability (Charles Hopkins and Rosalyn McKeown, 2002).

Mongolia, like most of the countries, agreed on the UNFCCC declaring the commitment to develop and implement an Education for Sustainable development, in 1992. The following result is the first national policy document on sustainable development, "MAP 21: Mongolian Action Plan for the 21st Century", which was developed and approved in 1998. One of the main goals, "Concentration on nurturing the educational and scientific sectors to allow them to be better able to meet the diverse intellectual requirements of Mongolians as they strive to implement sustainable development" (MAP, 1998), is the initial and official statement of education for sustainable development in Mongolia.

Climate change impacts the natural environments and the livelihood of the people in Mongolia, obviously. The study of climate change, began in 1979 in Mongolia, after the second World Meteorological Conference. "Climate change" was the first symposium, organized by the Institute of Meteorology and Hydrology in June, 1980 (Dagvadorj.D, Natsagdorj.L, Dorjpurev.J, Namkhainyam.B, 2009). Sustainable development, however, has been discussed in Mongolia since 1992 while the issue of education for sustainable development was initially discussed in policy documents since 1997. As a result, the "State Ecological Policy" was developed and approved by the State Great Khural (Parliament) in 1997. But ecological policy and ecological education issues are strongly based on biological science perspectives in Mongolia, and climate change education for addressing sustainable development issues is still not declared at the official policy level.

Issue is that Mongolia is very sensitive to climate change due to its geographic location, sensitive ecosystems and socioeconomic condition (Dagvadorj.D, Natsagdorj.L, Dorjpurev.J, Namkhainyam.B, 2009). While there is emerging awareness of the current and potential impacts of climate/environmental change on education provision and learning, it is also clear that education: formal and non-formal, from primary through to tertiary and adult education-has an important role to play in addressing this change (Colin Bangay, Nicole Blum, 2010) around the world. Moreover, climate change education for sustainable development is a new term in Mongolia. According to its obligations and commitments under the UNFCCC, the Mongolian Government initiated and implemented the National Action Program in Climate Change which was approved by the Government in 2000. The Millennium Development Goals (MDGs)-based Comprehensive National Development (MDGbCPND) Strategy of Mongolia was approved by the Parliament of Mongolia on 12 February 2008 (MNET, 2011). Pilot area 5 of the MDGbCPND strategy states, "To create an environment for sustainable development in the way of building capacity to adapt to climate change, and limiting and protecting loss of ecological equivalence" and this statement is the basic rationale for the development of the National Action Program on Climate Change (MNET, 2011). Because of the statement, "Within this framework, activities in expanding public participation and awareness about eliminating negative consequences, ways to overcome, and adapt to climate change and desertification will be implemented" (Pilot area 5 of the strategy) (MDGbCPND,

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

2008), MDGbCPND Strategy is the first policy statement that addressed climate change education in Mongolia, in terms of education.

Due to the existing socio-economic situation, the National Action Program in Climate Change was redeveloped and approved in 2011. The most detailed statement about "climate change education" was appeared on the "National Action Program on Climate Change". The fifth objective of the program was "to conduct public awareness campaigns and support citizen and community participation in actions against climate change". To achieve the objective, the following actions will be taken in 2012-2021:

- Include courses about climate change and the green economy in all levels of school programs;
- Develop educational curriculums and define new profession indexes and classifications related to climate change and environmental sectors.

As mentioned in Bangay and Blum, we do not see education's response to climate change as simply the provision of new curriculum inputs; rather, the challenges of climate change require all concerned to look to fundamentals and examine the degree to which existing educational provisions are adapted for radically different futures (Colin Bangay, Nicole Blum, 2010), especially in Mongolia.

In the other hand, to enhance the development of young professionals in the field of climate change adaptation, the topic could be included in higher education, especially in formal education programs. Higher education should be done through lectures and course work, field studies, internships, and establishing the education-research link by exposing students to field realities. In this regard, guiding principles could include an inclusive curriculum, focus on basic theory, field orientation, multidisciplinary courses, and practical skill enhancement (IPCC, 2014).

In secondary education, there are often existing tensions between a centralized curriculum and the need to promote locally based and locally appropriate issues. Areas of knowledge will require cooperation between local, national and international actors (Colin Bangay, Nicole Blum, 2010). Thus, we would like to know the coverage level of climate change education for sustainable development in national educational standards, curricula and textbooks. Beyond the policy, are we ready to play a key role in addressing climate change? It is obvious that poor environmental literacy and limited knowledge of climate change are manifestations of a more profound problem with the low quality of science education (R. Abbasi, 2006).

The "National Action Program on Climate Change" (2011) was approved by the State Great Khural is the initial and most important achievement to develop climate change education in Mongolia. The main expected outcome of the program is "Expanded and increased number of citizens, cooperatives and organizations who are engaged in actions to respond to climate change and implement relevant projects and programs" by 2021. To succeed, climate change education for sustainable development "must have an authoritative impetus from national or regional governments that will drive policy development" (McKeown, 2002). Our previous research results showed that public understanding of climate change is limited and unclear. Thus, we need teachers to play important role in accomplishing the goal. As Sherrie Forest argued, "the public's limited understanding of climate change is partly the result of critical challenges that have slowed development and delivery of effective climate change education (Sherrie Forest, Michael A. Feder, 2011). The question is whether teachers are prepared to engage in public awareness efforts on climate change?

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Making progress towards a more sustainable society requires a population that is aware of the goals of sustainability and has the knowledge and the skills to contribute towards those goals (UNESD, 2005, p.29). Although documents have been developed that define the term "climate literacy," further elaboration of its meaning is needed, particularly around expectations for actions or activities to combat climate change ("stewardship") (Sherrie Forest, Michael A. Feder, 2011).

Recent concerns over climate change have increased interest in mitigation and adaptation. Adaptation seems most relevant to vulnerable communities in Asia; they contribute minimally to emissions and therefore play a minimal role in climate change mitigation. Their entire future, however, is jeopardized by imminent climate change impacts, and thus they are dependent on appropriate climate change adaptation (CCA) interventions. CCA and DRR are also closely linked and have a number of other related thematic areas of concern that require attention (AUEDM, 2011).

Effective communication of climate change science is important not only to ensure that individuals understand the impacts of climate change but also to encourage action for climate change mitigation and adaptation (Boon, 2014). If pre-service and in-service teachers learn to weave ESD issues into the curriculum and to use pedagogical techniques associated with quality ESD, then the next generation will be capable of shaping a more sustainable world (UNESCO, 2005). Understanding the knowledge, beliefs and attitudes towards climate change that exist among members of the general public is important in designing appropriate teacher training for educators. Equally important is examining teachers' knowledge, beliefs and attitudes towards climate change (Boon, 2014).

"Climate change education (McKeown, Education for Sustainable Development Toolkit, 2002) for sustainable development" is quite a new concept in Mongolia, and the country has been at its starting point of integrating the related concepts into its education system. At this moment, the integration level has been limited. Thus, our team proposed to determine the level of current integration of climate change education for sustainable development into the Mongolian educational teaching and learning process by conducting a National Study in the areas of policy development and teacher knowledge to define future possibilities. To achieve the main goal, the following objectives were defined:

- To analyze current policies, plans, and programs in terms of CCE/DRR/ESD;
- To assess teacher knowledge of CCE and DRR and to identify their training needs.

RESEARCH METHODOLOGY AND DATA

The research study consists of two main analyses:

- **Review of Policy:** Educational, environmental and development related national policy documents, laws, national programs, guidelines and orders;
- **Review of Teachers' Knowledge of Climate Change:** In order to define the needs of the training on Climate change education for sustainable development.

The following methods were used in the research study:

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Policy analysis matrix (PAM) comprised of two sections:
    - The first section reviewed total 37 documents, such as educational laws, programs, plans and policy documents related to climate change education (CCE), disaster risk reduction (DRR) and education for sustainable development (ESD) in Mongolia. This includes 6 laws, 19 national programs passed by the parliament, plans, and policy documents, and 5 programs adopted by the orders of the Minister for education and science;
    - The second section covered 12 laws related to environmental management, climate change and disaster risk reduction and 16 national programs and other policy documents.

Quantitative/qualitative analysis:

- To define the level of teacher knowledge and understanding of CCE/DRR/ESD, a 25-questions survey was developed;
- In addition to the standard questionnaire, the qualitative assessments were made via unstructured interviewed of research participants.

RESULTS

Policy Analysis Matrix

The team reviewed all of the above documents to locate any provisions, content and issues related to CCE/DRR/ESD. We did not look only for the exact words "Climate change education" and "Education for sustainable development". Instead, we counted and evaluated terms with similar meaning:

1. **Educational Policy:** In the six educational laws, there have been numerous provisions related to sustainable development, but no provisions directly related to CCE and DRR were found. The only provision that seemed to be related to DRR had to do with what actions need to be taken when disasters happen and who can be covered by these actions. The provisions are 8.3, 15.3, and 9.3 in the laws of Higher Education, Primary and Secondary Education, and Pre-school Education, respectively. Compared to the laws, quite a few provisions were found relevant to the areas of CCE/DRR/ESD in some of the national programs passed by the cabinet;
2. **Environmental and Development Related Polic**y: Review of these documents reveals that the first policy documents on climate change and disaster management were produced in 1992. However, certain policies including public awareness activities, transferring knowledge and offering education on these subjects, have existed in policy documents since 1997. Table 1 shows a list of documents where CCE/DRR/ESD have been reflected.

Table 1 shows that there have been 19 provisions related to CCE/DRR/ESD included in 11 policy documents out of 16 reviewed. Eight of them are related to ESD, 5 of them specifically to CCE and 6 of them specifically to DRR.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Reflection of CCE/DRR/ESD in climate change and environmental policy documents

№	Policy documents[1]	Validation	Related provisions of		
			ESD	CCE	DRR
1	State Ecological Policy	Parliament resolution #106 in 1997, (1997-12-26)	+	-	-
2	State Food and Agricultural Policy	Parliament resolution #29 in 2003, (2003-06-18)	+	-	-
3	Millennium Development Goals based Comprehensive Policy for National Development of Mongolia	Parliament resolution #12 in 2008 (2008-01-31)	+	+	-

+ reflected
- Not reflected

The Millennium Development Goals based Comprehensive Policy for National Development of Mongolia (MDGbCPND) of Mongolia, as a main policy document, contains a limited number of provisions on DRR, even though there have been some provisions on CC/SD. The National Program on Water Resources, the National Program on Coping with Desertification, and the National Program on Climate Change that were produced based on the MDGbCPND, however, have contained comprehensive provisions in all three areas (Table 2).

In disaster related policy documents, provisions have focused on delivering indigenous approaches, improving knowledge of the public, using remote sensing to identify risk and disasters, introducing forecasting approaches and technologies, developing ways to deliver forecasted information to users immediately, and improving forecasting systems. The focus, however, did not include public awareness activities for preventing disasters and improving consciousness of the public on disaster risk and its consequences.

Eventhough CCE/DRR/ESD related terms and issues have been presented in many of the documents, progresses and processes to increase a public knowledge and awareness and introduce the related concepts into the educational system have been slow.

In addition, it was found that CCE/DRR/ESD provisions have been reflected in a limited way in legal documents related to environmental conservation and proper use and protection of natural resources. Furthermore, CCE issues have been reflected in only the National Program on Climate Change, and DRR has been considered in the National Program on Prevention of Disasters.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Interrelations of provisions on CCE/DRR/ESD in different policy documents

Provisions in the Millennium Development Goals based Comprehensive Policy for National Development of Mongolia		
4.4. Strategic Objective 2: Updating training standards and curricula of all levels of education in accordance with student needs and social requirements: - Contents of all levels of education must contain possibilities for students to select courses, and be updated with focuses on respecting national values, being proud of history and culture, being respectful to others culture, valuing high-tech knowledge, and building creative thinking - Introducing training standards and curricula that comply with international education standards	Priority #5: To create an environment for sustainable development in the way of building capacity to adapt to climate change, and limiting and protecting loss of ecological equivalence. Within this framework, activities in expanding public participation and awareness about eliminating negative consequences, ways to overcome, and adapt to climate change and desertification will be implemented.	
Provisions in National Programs that originated from the above policy document		
National Program on Water Resources	National Program on Coping with Desertification	National Program on Climate Change
3.6.3. To update curricula of pre-schools, primary and secondary schools, and higher education institutions for introducing effective ecological education. 3.6.4. To improve contents, quality and curricula of professional water training, to determine of water profession job titles, to develop and implement master's program for integrated water resources management at higher institutions, and to intensify trainings to prepare technicians and professionals in water fields.	9.4.1. Objective 1; to intensify trainings for youth to deliver knowledge on understanding factors that influence desertification and deteriorating ecology, and their negative consequences within the framework of delivering education for sustainable development at all levels of schools. 9.4.1.1. To integrate concepts of "UN Decade of Education for Sustainable Development" Program by UNESCO into secondary school curricula	The 5th objective refers to supporting active participation of the public in raising public awareness on climate change and necessary actions to be taken against the CCE. At all levels in 2011-2012: - To prepare and deliver brochures and handouts on climate change adaptation and mitigation - To integrate into curricula of all levels of schools the concepts/ideas of CCE, sustainable development, and green economy development - To carry out regular trainings and advocacy activities on rescuing in disasters, properly using information on natural risky phenomenon and disasters

Analysis of Teacher Education

A questionnaire has been developed to measure the knowledge, and identify continuing training needs of teachers, on ESD/CCE/DRR. This questionnaire was applied to approximately 150 teachers in urban and rural areas, and 94 percent of respondents were women and 6 percent were men. The dominance of female teachers in our sample matches the overall ratio of male and female teachers in the country. Over 80% of secondary school teachers in Mongolia are female.

The questionnaire consisted of two parts: (i) respondent's age, years of employment, level of their training, and (ii) questions to determine teachers' needs. For example:

- What do you know about adaptation to climate change?
- What source (where) do you rely upon for information about climate change?
- What kind of training would you choose to improve your knowledge of climate change?
- How much are the following CCE/DRR concepts related to your teaching?
- What are the ways to teach CCE/DRR through your field of teaching?

Rural teachers were a target for focus group discussions. 46% of the respondents answered that the questions in the questionnaire related to their course and 39% think that these issues are deeply involved

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

while only 5% answered as related and necessary to be taught at schools. The followings are example questions of focus group discussions:

- Is there any faucet in your school toilet that leaks?
- Have you seen any empty classrooms with the lights left on?
- Do teachers use both sides of the paper when printing or making photocopies?
- Do you have garbage bins at your school for sorting garbage?
- What are the main issues that you are facing at the local level? Are there ways to resolve them?
- How much do parents participate in renovating classrooms and gardening school areas?
- What aspects of indigenous knowledge has been forgotten in your area?
- Have you attended any training on CCE/DRR?

Answers of the respondents are shown in Table 3.

Although most of the respondents agree that concepts relate to their courses, teachers have different thoughts on each of the questions depending on their professional background. For example, primary school, Mongolian and foreign language teachers think that teaching about cultural differences and the misunderstandings associated with it and maintenance of traditional culture is deeply related, while natural and social science teachers answer that issues being faced by people, climate change, social and human ecological issues and changes in the relationship between people and nature would be the deeply related ones. There have been some teachers who think that it is not necessary to teach about CCE/DRR/ESD. This picture indicates the need for comprehensive training to improve teacher knowledge.

Most teachers answered that it was important to integrate these topics in their curricula and teach to students (Table 4).

Table 3. Relationship of CCE/DRR/ESD into teaching

Main Concepts of ESD/CCE/DRR	Not Related	Related	Deeply Related
Change in relationships of humans and nature, positive and negative consequences of social development	8	58	24
Main concepts of social and human ecology: CCE/DRR	5	61	26
Issues being faced by people	4	42	46
Over consumption and resource scarcity	10	58	23
Cultural difference and misunderstanding	9	60	23
Keeping traditional culture and habits	5	46	39

Table 4. Thoughts of teachers in integrating ESD/CCE/DRR into their courses

ESD Concepts	Not Important	Do Not Know	Important
Skills to understand personal and social values	11	10	71
Ethics	1	10	81
Needs of working and living together	1	8	84
Safety of living environment	4	8	80
Healthy living (right diet, fitness & wellness, nutrition etc.)	2	9	81

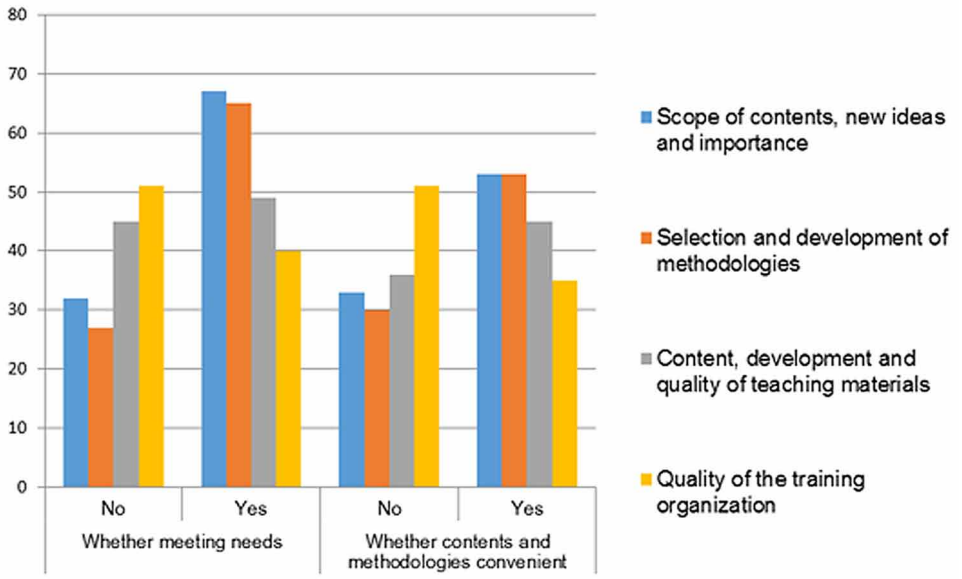
EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Answers to the questions to assess teachers' knowledge show that most of the teachers do not have a clear understanding of ESD/CCE/DRR. Perhaps the questions were unclear, which led to this results. Table 5 describes the answers of teachers.

There have been many trainings organized for teachers. As a result of these trainings, teachers should have already been advanced into a level where they can teach CCE/DRR/ESD in secondary schools. In-service teachers were asked to evaluate the quality of general/not specific trainings they attended and findings are presented in Figure 1.

67 percent of teachers think that in-service trainings are timely and important in terms of content, building new knowledge, and importance. 53 percent of the respondents answered that training methodologies have been suitable. To the questions of selection and development of methodologies, similar percentages of teachers answered positively. However, respondents gave negative answers to the quality of organizational material of trainings and the sufficiency of teaching aids.

In terms of duration and timing of the in-service trainings, respondents think that trainings should last one to five days (75%) during students' holiday times (82%).



The study team has also investigated the impressions of in-service teachers regarding results of the trainings. The findings are presented in Table 6.

Table 5. Teacher knowledge of CCE/DRR/ESD (percent)

	Connecting Concepts of CCE/DRR into Education Activities	**Reflecting Main Characteristics of CCE/DRR/ ESD in Order to Introduce CCE/DRR/ESD in their Teaching**	**Assessing Student Development and Changes in Behavior**
Education standard	52.0	25.0	23.0
Level of textbook use	32.0	44.0	25.0
To have a set of curricula for an entire course	41.0	34.0	25.0
To have curricula for an entire chapter	45.0	32.0	2.04
To have curricula for a unit	44.0	32.0	25.0
Periodic plans	44.0	28.0	28.0
Teaching aids	32.0	33.0	36.0
Teaching subjects	36.0	41.0	32.0
Improving curricula for all grades	42.0	37.0	21.0
Analysis of subjects	35.0	26.0	38.0
Developing students	22.0	24.0	54.0
Training environment	35.0	34.0	31.0
Skill and knowledge improvement training	28.0	48.0	24.0
Developing extra curricula	40.0	30.0	30.0
Teacher ethics	49.0	38.0	14.0
Developing oneself	34.0	35.0	22.0
Participating in extra curricular activities	50.0	29.0	21.0

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Quality of trainings for in-service teachers, by percentage

The findings of this questionnaire show that trainings give achieve average results, with 62% and 67% for each of the questions. Only 12% and 16% think that the trainings have good results, with similar numbers that the results are bad. This indicates that training contents, methodologies, and quality should be improved to meet needs of teachers.

The study team also asked questions related to the problems hindering their attendance in in-service trainings. Findings are presented in Table 7.

Table 6. Results of in-service trainings

Results of Trainings	Unsatisfied	Average	Good
Whether the trainings touch issues that teachers face every day and activities they conduct every day.	12	62	16
Whether the trainings give needed guidance to make effective changes to their curriculum	12	67	12

Table 7. Problems hindering the attendance in in-service trainings (percent)

Questions	No	Yes	Very Much
School supports teachers to attend in-service trainings	38.0	49.0	13.0
Do you pay tuition fees from your own pocket	9.0	57.0	34.0
Systems to distribute announcements of trainings	29.0	52.0	19.0
Possibility to know training quality in advance	35.0	48.0	16.0
Possibility to select trainings based on own need	3.0	58.0	12.0
Provisions of methodologies to improve own skills and knowledge at workplace	28.0	53.0	19.0
Possibility and condition to improve own skills and knowledge at workplace	33.0	57.0	11.0

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

In most cases, teachers do not experience problems in attending in-service trainings, but around 30 percent of teachers feel some kind of difficulty. Although 30% is less than half of the votes this indicates that there is some level of problems with the operations of in-service training compared to what we would expect with no problem. Teachers do not face any problem of paying training fees to attend in-service training fees. In all cases, this is generated by the state budget, except for a few cases.

CONCLUSION AND RECOMMENDATIONS

This study shows that there has been limited coverage of climate change education and disaster risk reduction in legal and policy documents. This indicates that more work is required to develop ways to include issues of climate change and disaster risk in the educational system.

Teacher knowledge and skills have been limited in teaching CCE/DRR/ESD. Depending on background, every teacher explains the concept of climate change education for sustainable development differently. There is a need to give the same level of CCE/DRR/ESD education to all teachers.

Activities to improve public understanding of CCE/DRR policies, and clear expected outcomes should be added to national programs including the "National Program on Water Resources", the "National Program on Coping with Desertification", and the "National Program on Climate Change".

Every environmental law should have certain provisions related to climate change and disaster management in accordance with their purposes. For example, water laws should contain provisions on supporting: (i) local initiatives on conserving water sources, (ii) re-introducing traditional and indigenous knowledge on water conservation, and (iii) research on best practices of water conservation, and introducing new methods for conservation best suited to Mongolia, etc.

In related laws and policy documents, an organizational structure of raising public understanding and advocacy should be clearly incorporated.

Legal documents should clearly say what should be done under the current capacity building programs for climate change education for sustainable development. In current documents, capacity building programs have been mentioned, but there is no clear guidance on how will it be carried out.

It has been difficult to list names of specific trainings needed for teachers since study results show that teachers lack general understanding of CCE/DRR/ESD. Therefore, the team suggests the following:

- Systematic trainings for teachers on CCE/DRR/ESD are needed to ensure that all teachers have the same level of knowledge and skills in teaching the subjects. To do this, trainers at the CCESD and training materials and manuals should be prepared well to transfer the knowledge to in-service teachers;
- Teachers should learn methodologies to transfer their knowledge to students, connecting the CCE/DRR/ESD with the subjects they teach. Teachers agree that they should transfer CCE/DRR/ESD knowledge to their students, but they remain unsure how to transfer the knowledge. In other words, they lack methodologies in teaching;
- Teachers need up to date teaching aids to help them efficiently transfer their knowledge to students;
- Teachers need to learn not only new knowledge and new ways of teaching, but also the methods on assessing students' knowledge and skills.

Chapter 15
Smart Energy and Cost Optimization for Hybrid Micro-Grids:
PV/ Wind/ Battery/ Diesel Generator Control

ABSTRACT

This chapter is concerned with the energy management of a hybrid micro-grid composed of photovoltaic/ wind/ battery bank and diesel generator, which is used to supply domestic loads. Hence, a control strategy is proposed to manage the power flow between the power sources and the loads, which ensures the maximization of the renewable sources use, and therefore the minimization of the battery bank and diesel generator use. The control strategy allows the installation operating cost to be minimized and the safe operating for the battery bank to be guaranteed. The strategy is tested using measured data of some climatic parameters of the target area, showing its efficiency in fulfilling the fixed objectives.

INTRODUCTION

Electrical energy is a vital input for the social and economic developments, for which the demand has significantly increased (Lund et al., 2015; Santamouris et al., 2015). However, due to the instability in the fossil fuel prices and the increase in the greenhouse gas emissions, renewable energy sources are best

placed to solve these issues (Jacobson et al., 2015; Mathiesen et al., 2015). Since renewable energies depend on the climatic parameters, characterized by their intermittence, it is necessary then to optimize and to use smart strategies (Østergaard et al., 2016; Narimani et al., 2015), which can be applied in micro-grids, including smart grids (Mathiesen et al., 2015; Pouresmaeil et al., 2015). Fortunately, the continuous advances in computer hardware and software are allowing researchers to deal with smart grids systems. This is performed by applying optimization and energy management strategies to the renewable and sustainable energy field, in such a way to ensure the optimum use of the generated energy, to provide the energy needed to the loads, and to guarantee a safe and secure operation for the whole smart grids system (Oró et al., 2015; Sonnenschein et al., 2015). Establishing an energy management strategy for smart grids systems is essential, since it allows the system autonomy and the continuity in the power supply to be ensured, thanks to the use of operational planning network through two-way power flow and communication (Farhadi et al., 2015; Zhao et al., 2015). Moreover, these strategies allow looking out the system security, by detecting defaults when occur, predicting energy generation and consumption from the one hand, and fulfill the energy demands whenever and wherever are needed from the other one (Aman et al., 2015; Sabo et al., 2016).

Hence, in this research chapter, a strategy for the optimum energy control of a hybrid system composed of photovoltaic (PV) panels, a wind turbine, a lead- acid batteries bank, a diesel generator which supply a variable domestic load, is proposed and discussed in depth (Figure 1). The proposed Energy Management strategy (EMS) is based on several considerations related with the electricity generation, maintenance, components replacements and fuel price costs. Therefore, a cost function is introduced and minimized in order to optimize the involvement degrees of each power source, by comparing, at each sample time, the power sources combinations costs while supplying the domestic loads. The electricity generation cost includes the components operation, maintenance, fuel and replacement costs of the system parts studied during 20 years. The proposed strategy aims to guarantee the system operation continuity; in such a way the load is always supplied. Secondly, it ensures the system safe operation, since it respects constraints that allow extending the components lifetime. Furthermore, the EMS aims to minimize the use of the

Figure 1. Scheme of the proposed photovoltaic system connected to a single-phase grid utility

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

diesel generator to emergency and strictly required cases and maximize the use of the renewable energy for the domestic load power supply. Nevertheless, these components can be used in case of defaults in some components, or in case of non-availability of the renewable energies. Therefore, the battery bank and/ or the diesel generator takes part in generating the power needed to supply the domestic loads. Consequently, the proposed energy strategy allows guaranteeing the smart grid security operation and to supply an energy flow with the network settings including a protection system.

The proposed EMS is tested using measured data of climatic parameters of the target area (Medjez El Beb: Northern Tunisia, latitude: 36.39°, longitude: 9.6°), showing the efficiency of the proposed optimization method in minimizing the electricity generation cost, from the one hand, ensuring a safe operation for the system components, and providing the loads with the needed energy, from the other one.

Background

Hybrid renewable energy systems are becoming popular, especially for remote area, thanks to advances in renewable energy technologies. However, renewable energies, especially PV and wind energy are characterized by their intermittence, since they extremely depend on the climatic parameters, namely the solar radiation G, the ambient temperature T_a and the wind speed *V*. Therefore, the discontinuity in the power generation often involves reliability problems associated with their operation for micro-grid systems. This issue is more complicated, if several systems are interconnected between each other, as in the case of smart grids, for which this chapter concentrates. Thus, to face this issue, many research works focused in enhancing the renewable sources efficiency, such as establishing techniques for accurately predicting the powers generated, and reliably integrate them with other conventional sources, namely storing energy devices (Choubin et al., 2016; Mohanty et al., 2016). Other works, concentrated in extracting the maximum of power generated by these sources and enhancing the hybrid system components efficiency, by studying the design techniques, as it has been studied by Rezk et al., 2015 and Yahyaoui et al., 2016a.

Additionally, multi-objective algorithms have been proposed, in order to optimize the mix of the renewable system. In fact, these research works focused in maximizing their contributions to the peak load, while minimizing the combined intermittence, at a minimum cost, and minimizing the total greenhouse gas emissions of the system during its lifetime (Feng et al., 2016). For instance, some researchers applied the Particle Swarm Optimization (PSO) approach, to solve this issue (Chen et al., 2014). Indeed, they concluded that its performance is better than the conventional optimization techniques (Chen et al., 2014). Other researchers use the Genetic Algorithm (GA) to solve the economic environmental dispatching of a hybrid power system, including the wind and solar thermal energies throughout the useful life of the installation and the pollutant emissions (Carlucci et al., 2015). GA has also been mixed with the simplex, to optimize a hybrid system coupled to PV, a battery and a fuel cell for stand-alone street lighting systems, considering the monthly average solar irradiation and the wind speed data (Hamdy et al., 2016). The results obtained when designing a photovoltaic–wind–diesel system demonstrate the practical utility of the design method used.

Moreover, some other research works concentrate on optimization techniques which are based on the artificial intelligence tools, including the Artificial Neural Network (ANN) (Bhandari et al., 2015) and Fuzzy logic (Yahyaoui et al., 2014; Suganthi et al., 2015; Balaman et al., 2016). These techniques gave good results, since they hold the uncertain renewable energy supplies, load demands and the non-linear

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

characteristics of some components that constitute the system. Further, some authors have dealt with determining the optimal combination of renewable energy technologies. Indeed, the renewable energy resources safe operation has been taken into account, in addition to the technology characterization, and economic parameters, namely the installation, maintenance and replacement costs. Moreover, some authors studied the optimum composition of hybrid systems, considering socio-demographic factors algorithm (Tito, S et al., 2016).

MAIN FOCUS OF THE CHAPTER

This research chapter focuses on the energy optimization of a typical hybrid plant used in smart grids systems. Indeed, the system is composed of PV panels, a wind turbine, a lead- acid battery bank, and a diesel generator, which are used to supply a variable domestic load. Hence, the present work proposes and details in depth an Energy Management Strategy (EMS), to optimize the powers generated by the power sources, maximize the renewable sources use and to minimize the use of the battery bank and the diesel generator. Moreover, the EMS aims to guarantee a safe operation of the system components and the continuity in the loads power supply. These objectives are performed by the minimization of a cost function, in which the power generation cost, the battery depth of discharge (dod) and the energetic balance are considered. This strategy is important for smart grids system security, since it can be used to supervise smart grids systems from both the energetic and the economic points of view.

Issues, Controversies, Problems

The energy management in hybrid systems faces two issues: first, the optimization strategy should take into account all the system components nonlinearities, from the one hand, and the loads power demand, from the other one. This includes the system components operation under uneven climatic parameters changes (namely the solar radiation, the wind speed, etc.). Additionally, the EMS is a multi-objective function, which includes energetic and economic objectives and criteria, in addition to taking into account a safe operation of the system elements. Since the proposed plant is the heart of smart grids systems, therefore, several issues and criteria interconnected are included in this proposed EMS (energetic and economic). Sure, to solve it, a powerful and reliable tool should be used. In this research chapter, the Genetic Algorithm (GA) is chosen, to perform the proposed strategy. The solution is tested for a typical hybrid plant, which can be then generalized for more sophisticated systems, namely the smart grids systems.

Numbered Lists

The following numbered lists are proposed, in such a way to describe in a coherent and comprehensive manner the topic proposed in this research chapter. Indeed, the chapter begins by describing the models of the system components. Then, the EMS adopted for the cost optimization of the hybrid plant is detailed. After that, the simulation results of the components models used and then the energy management algorithm are presented and explained in depth. Finally, the chapter ends by conclusions, in which the authors mention the impact of the proposed strategy for smart grids security systems. The numbered list is explained now:

System Components Modelling

Photovoltaic Panels

The earth surface receives approximatively 1.79 10^8 kWh of solar energy, which is equivalent to a continuous power of 1.729 10^{17} W. however, 23% of this energy is reflected directly back into space, 29% is absorbed in the atmosphere and converted to heat radiated within the infrared spectrum. The remaining 48% of the energy is used to supply the hydrological cycles and photosynthesis (Yahyaoui, 2016c). Taking into account the alternations of day and night and cloudy periods, the peak power is estimated to be 1kW (Yahyaoui, c, 2016). The solar energy is converted to electricity using PV arrays. In the literature, several models have been studied to model the PV panels. Indeed, some models consider the two diodes model (Chin, et al., 2016). Other models characterize the PV panels by yield (Fernández et al., 2015; Steiner et al., 2015). In this research chapter, the photovoltaic panel is modelled using the one-diode non-linear model (Hasan et al., 2016). This model depends on the solar radiation *G (t)*, the ambient temperature $T_a(t)$ at the panel surface, and the panel parameters namely the number of photovoltaic cells connected in series, the short- circuit current and the open- circuit voltage at the reference temperature. The model evaluates the photovoltaic current $I_c(t)$ and power $P_{pv}(t)$. The adopted model is described by (1)-(6) (Hasan et al., 2016).

$$I_c = I_{ph}(t) - I_r(t)\left(\exp\left(\frac{V_c(t) + R_s I_c(t)}{V_{t_T_a}} \right) - 1 \right) - \frac{V_c(t) + R_s I_c(t)}{R_p} \quad (1)$$

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$I_{ph}(t) = \frac{G(t)}{G_{ref}} I_{sc}(t) \tag{2}$$

$$I_{sc}(t) = I_{sc_T_{ref}} \left(1 + a\left(T_a(t) - T_{ref}\right)\right) \tag{3}$$

$$I_r(t) = I_{r_T_{ref}} \left(\frac{T_a(t)}{T_{ref}}\right)^{\frac{3}{n}} \exp\left(\frac{-qV_g}{nK_B}\left(\frac{1}{T_a(t)} - \frac{1}{T_{ref}}\right)\right) \tag{4}$$

$$I_{r_T_{ref}} = \frac{I_{sc_T_{ref}}}{\exp\left(\frac{qV_{c_T_{ref}}}{nK_B T_{ref}}\right) - 1} \tag{5}$$

where: $T_a(t)$: the ambient temperature at the panel surface (K),

$G(t)$: the solar radiance at the panel surface (W/m^2),
$I_c(t)$: the estimated photovoltaic cell current (A),
$I_{ph}(t)$: the generated photo-current at G (A),
$I_r(t)$: the reverse saturation current at T_a (A),
$V_c(t)$: the open circuit voltage of the photovoltaic cell (V),
R_s: the serial resistance of the photovoltaic module (Ω),
V_{t_Ta}: the thermal potential at the ambient temperature (V),
R_p: the parallel resistance of the photovoltaic module (Ω),
G_{ref}: the solar radiation at reference conditions (W/m^2),
$I_{sc}(t)$: the short circuit current for T_a (A),
$I_{sc_T_{ref}}$:the short circuit current per cell at the reference temperature T_{ref} (A),
a: the temperature coefficient for the short circuit current (K^{-1}),
$I_{r_T_{ref}}$: the reverse saturation current for T_{ref} (A),
n: the quality factor,
q: the electron charge (C),
V_g: the Gap energy (e.V),
K_B: the Boltzmann coefficient (J/K),
$V_{c_T_{ref}}$: the open circuit voltage per cell at T_{ref} (V).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Hence, the photovoltaic power P_{pv} generated by the panel is then described by (Yahyaoui et al., 2014; Hasan et al., 2016; Yahyaoui et al., 2016b):

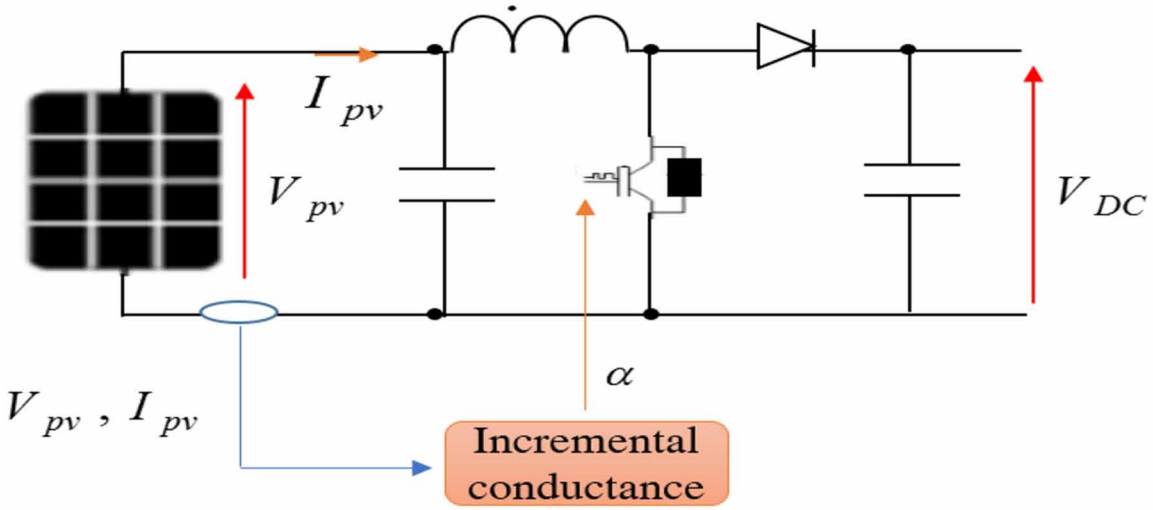
$$P_{pv}(t) = n_s n_p V_c(t)\left(I_{ph}(t) - I_r(t)\left(\exp\left(\frac{V_c(t) + R_s I_c(t)}{V_{t_T_a}} \right) - 1 \right) - \frac{V_c(t) + R_s I_c(t)}{R_p} \right) \quad (6)$$

where:

n_s : the number of serial photovoltaic cells,
n_p : the number of parallel photovoltaic modules.

Incremental Conductance for MPPT

Climatic parameters, namely the solar radiance and the ambient temperature, are intermittent; in such a way that they change continually during the day, which therefore affect the PV power generated by the PV arrays. Consequently, it is necessary to use techniques that track the maximum power point, called Maximum Power Point Tracking (MPPT) methods (Yahyaoui et al., 2016a). In this sense, several methods for MPPT have been studied in depth namely, the Perturb and Observe (Muthuramalingam et al., 2014), the Look up Table (Ozdemir et al., 2014), Fuzzy logic (Boukenoui, et al., 2016) and the incremental conductance methods for MPPT (Bizon, 2016). In fact, they all differ in complexity and tracking accuracy, but they require sensing the PV current and voltage, using the off-the–shelf hardware. Thanks to its good efficiency and reliability, in this research chapter, the incremental conductance algorithm for MPPT is used to track the MPP generated by the photovoltaic panels, and to generate the control signal for the boost converter (Bizon, 2016; Yahyaoui et al., 2016a) (Figure 2). In fact, this method consists in using the current ripple in the chopper output I_{pv}, to maximize the panel power P_{pv}, using the relation between the current and voltage continuously identified online (Bizon, 2016, Yahyaoui et al., 2016a). Indeed, the algorithm tests the actual conductance $-\frac{I_{pv}}{V_{pv}}$ and the incremental conductance $\frac{dI_{pv}}{dV_{pv}}$ as follows (Bizon, 2016; Yahyaoui et al., 2016a):



If $\frac{dI_{pv}}{dV_{pv}} \succ -\frac{I_{pv}}{V_{pv}}$, then the operating point is on the left of the MPP, so (7)

α is varied to increase V_{pv}.

If $\frac{dI_{pv}}{dV_{pv}} \prec -\frac{I_{pv}}{V_{pv}}$, then the operating point is on the right of the MPP, so (8)

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Scheme of the control principle of the DC- DC converter for MPPT

α is varied to decrease V_{pv}.

If $\frac{dI_{pv}}{dV_{pv}} \approx -\frac{I_{pv}}{V_{pv}}$, then the operating point is in the MPP, (9)

So, the value of α is maintained.

where dI_{pv} and dV_{pv} are the PV current and voltage variations, respectively.

Thus, the duty cycle α, used to generate the PWM signal for the DC- DC converter control, is calculated using (10) (Bizon, 2016; Yahyaoui et al., 2016a):

$$\frac{V_{DC}}{V_{pv}} = \frac{1}{1-\alpha} \tag{10}$$

Battery Bank

It is well known that renewable energy sources generate electrical energy intermittently. Therefore, the use of an energy storage device, in which the excess of the photovoltaic energy generated is stored, is necessary. This stored energy can be extracted when the power generated by the renewable energy sources is not sufficient to supply the load with power. Generally, batteries are used to save energy (Burgos et al., 2015; Yahyaoui et al., 2016). Lead-acid batteries are among the most common energy saving devices. A battery type is composed of positive and negative electrodes separated by an electrolyte. It is used to convert the chemical energy to electric energy thanks to oxidoreduction reactions (Burgos et al., 2015; Yahyaoui, 2016c). Some researchers developed models for the battery character-

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

istics, to describe the battery State Of Charge (SOC) or its depth of discharge (dod). In this sense, linear modeling methods, namely the Coulometric, the open-circuit voltage method, and the non-linear dynamic modeling method have been developed (Burgos et al., 2015; Yahyaoui, 2016c). In this research chapter, a non-linear model for the lead- acid battery is used to model the battery bank behavior (Yahyaoui et al., 2016b). In addition to its simplicity, both the battery current and voltage are used to describe preciously the battery bank's behavior during charging and discharging. Its performance is evaluated by the depth of discharge dod. To evaluate it, the stored charge in the battery C_R is first determined by (Yahyaoui et al., 2014):

$$C_{R(k)} = C_{R(k-1)} + \frac{\partial k}{3600} I_{bat_{(k)}}{}^{k_p} \tag{11}$$

where ∂k is the time between instant k-1 and k and k_p is the Peukert coefficient.

Hence, the depth of discharge dod is given by (Yahyaoui et al., 2016b):

$$dod_{(k)} = 1 - \frac{C_{R_{(k)}}}{C_p} \tag{12}$$

where C_p is the Peukert capacity, considered constant (A.h).

Wind Turbine

Wind is a physical phenomenon in the nature. As it knows; it is the result of the differential pressure between warm and cool areas in the atmosphere that produces the constantly movements of the air masses (Krishnamoorthy et al., 2014; Lanzafame et al., 2014; Yahyaoui, 2016c). The electricity generated from wind is created by a turbine that converts a portion of the kinetic energy from the wind into a mechanical energy, which is available on a generator shaft (Lanzafame et al., 2014; Yahyaoui, 2016c). This mechanical energy runs the wind turbine and thus, allows electric energy to be generated (Yahyaoui, 2016c). World wind energy resources are substantial, and in many areas, such as the USA and Northern Europe, could in theory supply all of the electricity demands. However, the intermittent character of the wind resources and the necessity of long distances for energy transmission are considered the main disadvantages of the wind energy (Krishnamoorthy et al., 2014; Yahyaoui, 2016c). The wind turbine creates a wind energy deficit between the wind leaving the turbine (known as wake) and the wind arriving in front of the turbine. Hence, a reduction of power output is produced at downwind turbines (Krishnamoorthy et al., 2014; Lanzafame et al., 2014). In this research chapter, the wind turbine power P_W is modelled by a non- linear expression, which essentially depends on the wind speed v and the blades' pitch angle β, as it is described now (Krishnamoorthy et al., 2014; Lanzafame et al., 2014):

$$P_W = \frac{1}{2} \rho A C_p(\lambda_1) v^3 \tag{13}$$

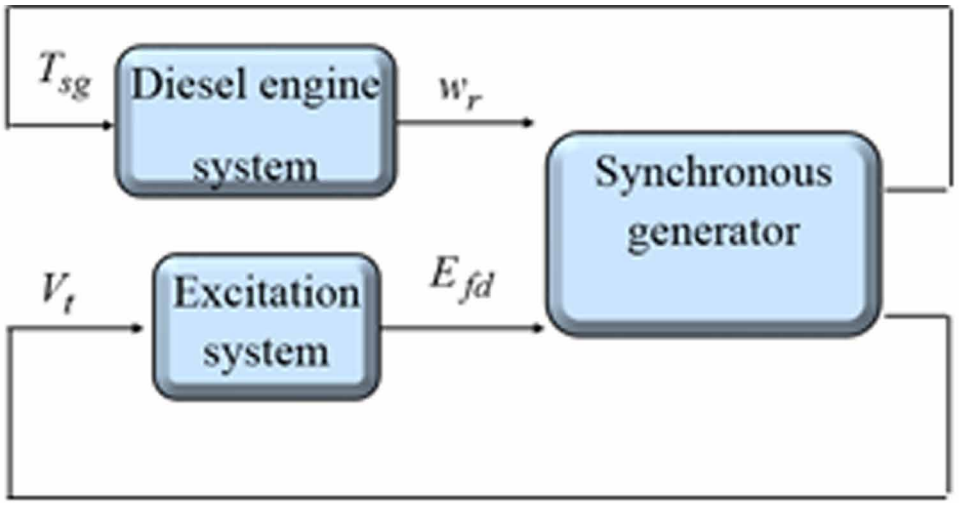
EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

where ρ is the air density (kg. m^{-3}), A is the surface of the
Turbine blades (m^2) and C_p is the power coefficient (Lanzafame et al., 2014):

$$C_p\left(\lambda_1\right)=0.5176\left(\frac{116}{\lambda_i}-0.4\beta-5\right)e^{\frac{-21}{\lambda_i}}+0.0068\lambda_1 \tag{14}$$

$$\frac{1}{\lambda_i}=\frac{1}{\lambda_1+0.08\beta}-\frac{0.035}{\beta^3+1} \tag{15}$$

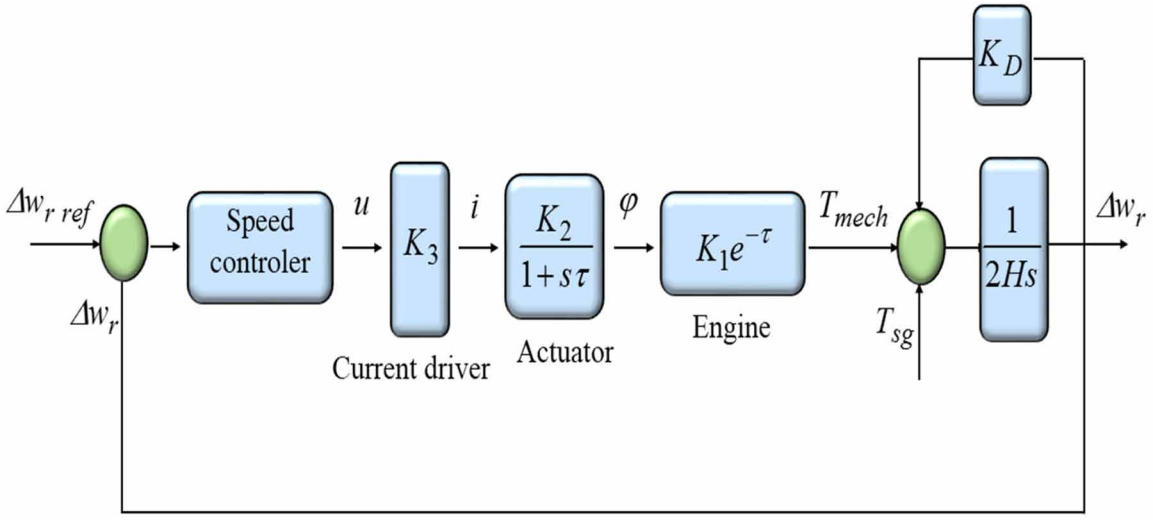
and:



$$\lambda_1=\frac{\Omega R}{v} \tag{16}$$

where: R is the helix radius (m) and Ω is the angular mechanic speed (rad. s^{-1}).

Diesel Generator



Typical diesel generator is composed of three main components, which are the diesel engine, the synchronous generator and the excitation system (Figure 3) (Salazar et al., 2015; Yahyaoui et al., 2016d). In fact, the first component (the diesel engine) is composed of the current driver, the actuator, the engine and the flywheel, as it is described in Figure 4 (Salazar et al., 2015; Yahyaoui et al., 2016d). Indeed, the current driver, which is presented by a constant K_3, converts the fuel flow into a mechanical torque.

Figure 3. Block diagram of the diesel generator

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. Block diagram of the diesel engine

Moreover, the speed of the engine is controlled by the actuator, which relates the fuel intake. Therefore, the fuel rack position depends on the input current, which determines the fuel amount φ, injected into the combustion chamber (Graciano et al., 2015, Yahyaoui et al., 2016d). The third element of the diesel engine consists of the combustion system, which is designed by the Engine block in Figure 4 (Graciano et al., 2015; Salazar et al., 2015). Consequently, the movement of the piston during the power strokes produces the crankshaft drive and the mechanical torque T_{mech}, which is generated by the injection of the fuel ignited by the compressed hot air in the combustion chamber. Finally, the flywheel comprises the engine inertia dynamics, the damping factor (K_D) and the loaded alternator.

The rotor angular velocity w_r and the mechanical torque T_{mech} relation is given by (Salazar et al., 2015):

$$2H\frac{d\Delta w_r}{dt} = T_{mech} - T_{sg} - K_D \Delta w_r \tag{17}$$

$$\frac{d\delta}{dt} = w_0 \Delta w_r \tag{18}$$

$$\Delta w_r = w_r - 1 \tag{19}$$

where the time *t* is in seconds (s), the rotor angle δ is in radian, the rated generator speed w_0 is in rad/s, Δw_r is the speed deviation (pu), w_r is the rotor angular velocity (pu), T_{sg} is the generator torque (pu) and *H* is the inertia constant.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Using the Park transformation, the synchronous generator is modeled as follows (Salazar et al., 2015):

$$V_d = E^{''}_d - R^{'}_s I_d + X^{''}_q I_q \tag{20}$$

$$V_q = E^{''}_q - R^{'}_s I_q - X^{''}_d I_d \tag{21}$$

where $R^{'}_s$ is the armature resistance, I_q and I_d are the currents flowing in the stator windings, the $X^{''}_{d,q}$ are the so-called subs transient d and q-axis reactance and $E^{''}_{d,q}$ are given by:

$$E^{''}_d = \frac{\left(X_q - X^{''}_q\right)}{1+\tau^{''}_{q0} s} I_q \tag{22}$$

$$E^{''}_q = \frac{1}{1+\tau^{''}_{d0} s} E^{'}_q - \frac{\left(X^{'}_d - X^{''}_d\right)}{1+\tau^{''}_{d0} s} I_d \tag{23}$$

where:

$X_{d,q}$ and $X^{'}_{d,q}$: the synchronous and transient reactances,
$\tau^{''}_{d,q0}$: the open circuit sub transient time constants,

and $E^{'}_q$ is given by:

$$E^{'}_q = \frac{1}{\left(\frac{X_d - X^{''}_d}{X^{'}_d - X^{''}_d}\right) + \tau^{'}_{d0} s} E_{fd} + \frac{\left(\frac{X_d - X^{'}_d}{X^{'}_d - X^{''}_d}\right)}{\left(\frac{X_d - X^{''}_d}{X^{'}_d - X^{''}_d}\right) + \tau^{'}_{d0} s} E^{''}_q \tag{24}$$

where: E_{fd} is the exciter field voltage and $\tau^{'}_{d0}$ is the open circuit transient time constant.

The excitation block supplies and automatically adjusts the field current of the synchronous generator, by applying control and protective functions required to the satisfactory performance of the system (Salazar et al., 2015; Yahyaoui, 2016c).

Energy Management Strategy

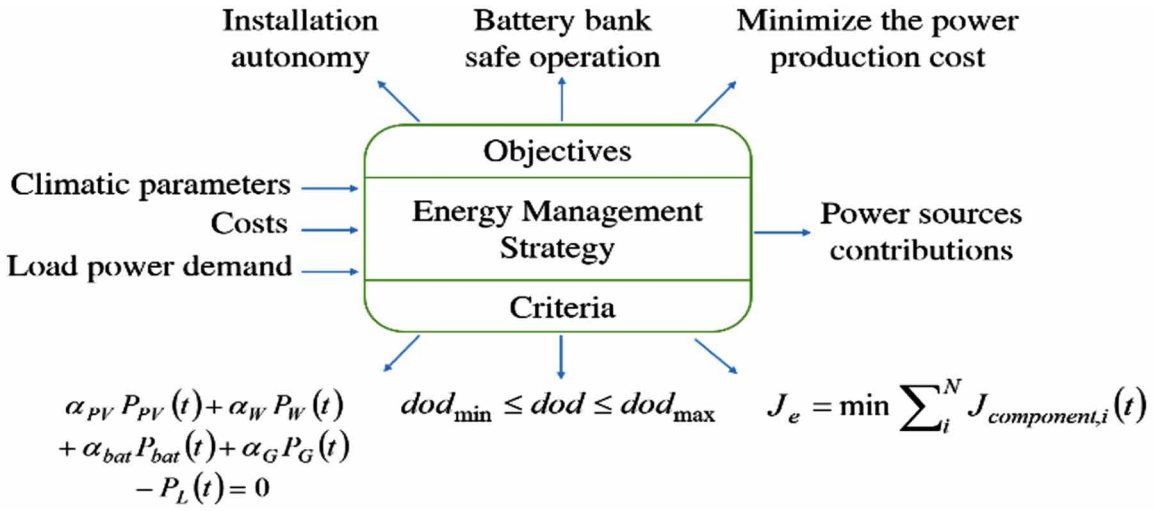
Since the hybrid system is composed of several non –linear components that supply a variable domestic load, then it is necessary to use an Energy Management Strategy (EMS) that controls the energy flow

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

between the power sources and the load. Thus, in this research chapter, the aim of the EMS is to optimize the operational costs of the hybrid installation, guarantee the loads' power supply and ensure a safe operation for the lead- acid battery bank, using the powers P_{pv}, P_w, P_{bat} and P_G, generated by the photovoltaic panels, the wind turbine, the battery bank and the diesel engine, respectively, the power consumed by the variable domestic loads P_L, from the one hand, and the installation operation cost, from the other one, as it is described in Figure 5.

In fact, the EMS consists in evaluating, at each sample time, the optimum power sources combination that minimizes the cost of the power production, as it is explained in Figure 6. Indeed, since the system is composed of five components, then it can be modeled by fives power sources, as it is described by equation (25):

Figure 5. Synoptic scheme of the proposed approach



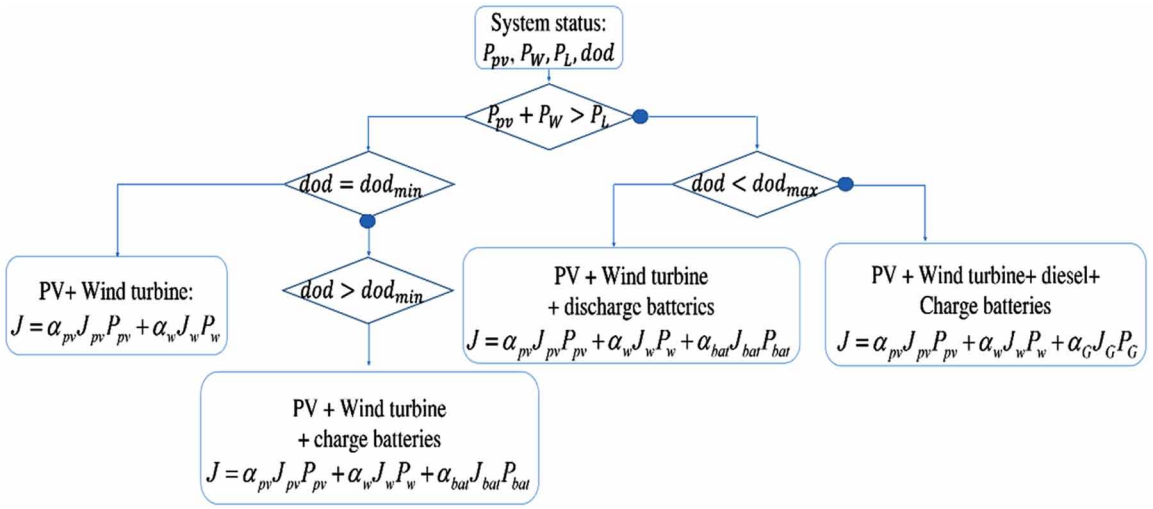


Figure 6. Energy management strategy principle

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$V(t)=\begin{bmatrix} v_1(t) \\ v_2(t) \\ v_3(t) \\ v_4(t) \\ v_5(t) \end{bmatrix}=\begin{bmatrix} P_{PV}(t) \\ P_W(t) \\ P_{bat}(t) \\ P_G(t) \\ P_L(t) \end{bmatrix} \tag{25}$$

Thus, for each sample time, the state vector $\alpha(t)$ describes the contribution of each power source for supplying the domestic load with power, as it is given by equation (26):

$$\alpha(t)=\begin{bmatrix} \alpha_{PV}(t) \\ \alpha_W(t) \\ \alpha_{bat}(t) \\ \alpha_G(t) \end{bmatrix} \tag{26}$$

Hence, during the optimization, the power sources provide to the loads the needed power, which must fulfill the following condition (equation (27)), which ensure the continuity of the power supply of the domestic load:

$$\alpha_{PV}P_{PV}(t)+\alpha_W P_W(t)+\alpha_{bat}P_{bat}(t)+\alpha_G P_G(t)-P_L(t)=0 \tag{27}$$

where:

α_{PV}, α_W, α_{bat}, and α_G are the power contribution of the PV panel, the wind turbine, the battery bank and the diesel generator, respectively, to supply the load.

Therefore, for an installation composed of *N* components, the objective function to be minimized is defined as the absolute minimum of the total micro grid cost, as it is described by equation (28). The minimization of this function allows then providing the load by the needed power, while maintaining a safe operation of the system elements. In the present research chapter, this cost function is minimized using the Genetic Algorithm tool (GA), since it as good performance and easy in application (Sakellaridis et al., 2015).

$$J_e=\min\sum_i^N J_{component,i}(t) \tag{28}$$

The EMS objective evaluates and minimizes the objective function $J(t)$ for 20 years of the system operation. Thus, it must include the investment, the production and the use costs, $J_I(t)$, $J_P(t)$ and $J_U(t)$, respectively, during this period. It is described by equation (29) (Sakellaridis et al., 2015):

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$J_{component}(t) = J_I(t) + J_P(t) + J_U(t) \tag{29}$$

These costs are detailed now in depth.

Investment Cost

The investment cost $J_I(t)$ describes the cost of the maximum power $P_{PV}, P_W, P_{conv}, P_{bat}$ provided by its system's components. This cost includes the buying and implementation costs, J_{Ic} and J_{Ie}, respectively:

$$J_I(t) = J_{Ic} + \frac{1}{8760} J_{Ie} t \tag{30}$$

where J_{Ie} is evaluated during N_a amortization years (20 years in this research work), characterized by its maximum energetic capacity, $P_{\max}$, which is described by equation (31) (Sakellaridis et al., 2015):

$$J_{Ie}(t) = \frac{1}{(1+\xi)^{N_a} - 1} \left[J(P_{\max}) - J_{Ic} \right] \xi (1+\xi)^{N_a} \tag{31}$$

where ξ is the annual interest rate.

Production Cost

The production cost $X_P(t)$ depends on the power generated by a power source $X_P(t)$ of the hybrid system elements and its maximum $X_{P\max}$ at instant *t*. It is given by the equation (32) as follows:

$$J_P(t) = \sum_0^t \alpha_P \left[X_{P_{\max}}, sign\left(X_P(\tau)\right), t \right] X_P(\tau) \Delta\tau \tag{32}$$

where α_P is the per unit element energetic cost (€ kWh).

a. Use cost

The use cost $J_u(t)$ includes the annual up keeping and maintenance costs, $J_u(t)$ and $J_M(t)$, respectively. Indeed, the maintenance cost describes the usury and the maximum installation production $P_{\max}$, and it is given by equation (33) (Sakellaridis et al., 2015):

$$J_U(t) = \frac{\beta_a(P_{\max})}{8760} t + \sum_0^t \gamma_a \left| X_E(\tau) \right| \Delta\tau \tag{33}$$

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

where:

β_a : the annual mean cost up keeping coefficient,
γ_a : the mean usury cost.

Consequently, the total cost $J_{PV}(t)$ that corresponds to the photovoltaic panel is expressed by (Sakellaridis et al., 2015):

$$J_{PV}(t) = J_{I_{PV}}\left(P_{P_{PV}}, t, N_a, \delta_a\right) + \frac{\beta_{PV} P_{P_{pv}}}{8760} t \tag{34}$$

The total cost $J_W(t)$ for the wind turbine is given by equation (35) as follows:

$$J_W(t) = J_{I_W}\left(P_{P_W}, t, N_a, \delta_a\right) + \frac{\beta_W P_{P_W}}{8760} t + \sum_0^t \gamma_W\left(P_{P_W}\right) P_W(\tau)\Delta\tau \tag{35}$$

While the total cost $J_{bat}(t)$ that corresponds to the battery bank is expressed by equation (36):

$$J_{bat}(t) = J_{I_{bat}}\left(P_{P_{bat}}, t, N_a, \delta_a\right) + \frac{\beta_{bat} P_{P_{bat}}}{8760} t + \sum_0^t \gamma_{bat}\left|P_{P_{bat}}(\tau)\right|\Delta\tau \tag{36}$$

The cost related to the inverter is given by equation (37):

$$J_{conv}(t) = J_{I_{conv}}\left(P_{P_{conv}}, t, N_a, \xi\right) \tag{37}$$

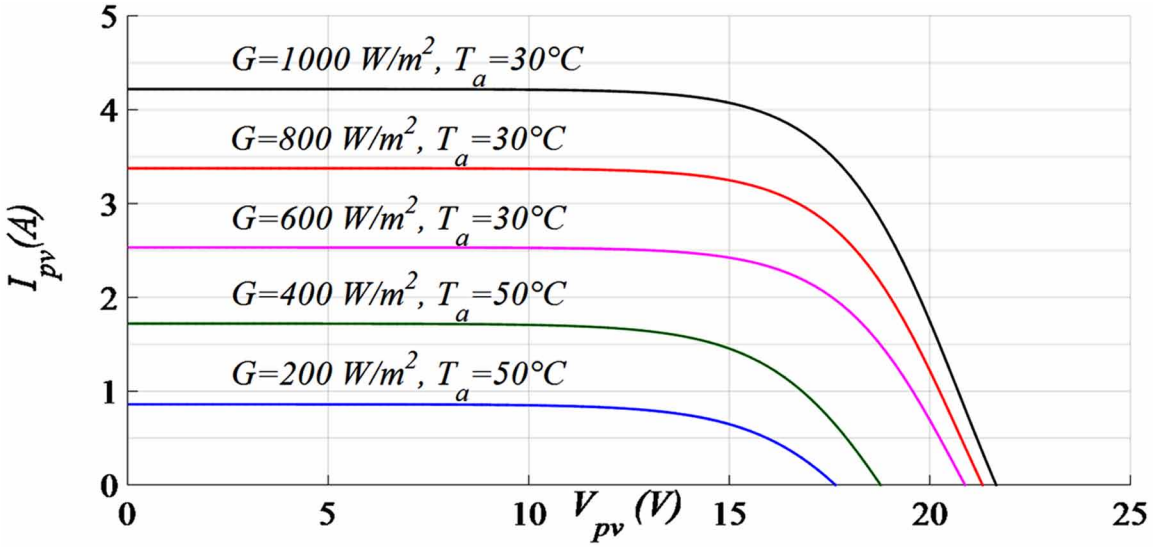
Therefore, the total cost function J includes the operation, maintenance, fuel and replacement costs, and it is given by equation (38), as follows (Sakellaridis et al., 2015; Yahyaoui et al., 2016d):

$$\begin{aligned} J(t) = {} & J_{I_{PV}}\left(P_{P_{PV}}, t, N_a, \delta_a\right) + J_{I_W}\left(P_{P_W}, t, N_a, \delta_a\right) + J_{I_{bat}}\left(P_{P_{bat}}, t, N_a, \delta_a\right) + J_{I_{conv}}\left(P_{P_{conv}}, t, N_a, \delta_a\right) \\ & + \frac{t}{8760}\left[\beta_W P_{P_W} + \beta_{PV} P_{P_{PV}} + \beta_{P_{bat}} P_{P_{bat}}\right] + \sum_0^t \gamma_W P_{P_W} P_W(\tau)\Delta\tau + \sum_0^t \gamma_{bat}\left|P_{bat}(\tau)\right|\Delta\tau \end{aligned} \tag{38}$$

The EMS used to minimize the cost C_{glob} of the hybrid plant composed of the PV panels, the wind turbine, the battery bank and the diesel generator, perform the optimization over a fixed duration T_f, taking into account the following constraints expressed by equation (39) (Figure 6):

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$\begin{cases} P_L(t) & = \alpha_{PV} P_{PV}(t) + \alpha_W P_W(t) + \alpha_{bat} P_{bat}(t) + \alpha_G P_G(t) \\ dod_{\min} \le dod(t) \le dod_{\max} \end{cases} \quad (39)$$
$$\forall t \in \left[0, T_f\right]$$



In fact, the management strategy consists in maximizing the use of the renewable energy sources (the PV panels and the wind turbine) (Figure 6). If excess of renewable energy is generated, then the excess is saved in the battery bank in case it is discharged. When the renewable energy generated is not sufficient to supply the load, thus if the battery is charged, then it participates in supplying the domestic loads with power, otherwise, the diesel generator is switched on and it complete the missing power. This is described by Figure 6.

Application to a Case Study

Results of the System Components Models

The models of the system components are first tested using measured data of the solar radiation *G*, the ambient temperature T_a and the wind speed *V*, that correspond to a sunny day of the target site (Northern Tunisia, latitude: 36.39°, longitude: 9.6°). The simulation results of the photovoltaic panels, the wind turbine and the diesel engine models are given in Figure 7 to Figure 11 respectively. Figure 7 shows that the variation of the solar radiation *G* affects significantly the PV current generated. Similarly, the wind turbine power increases when the wind speed increases, as it is shown it Figure 8 and 9.

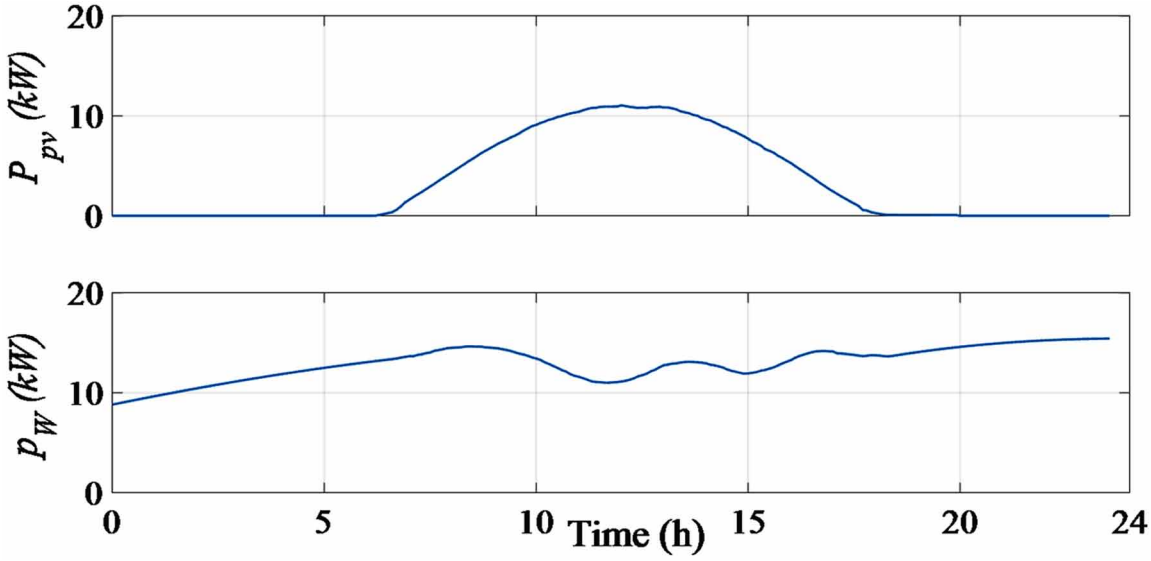
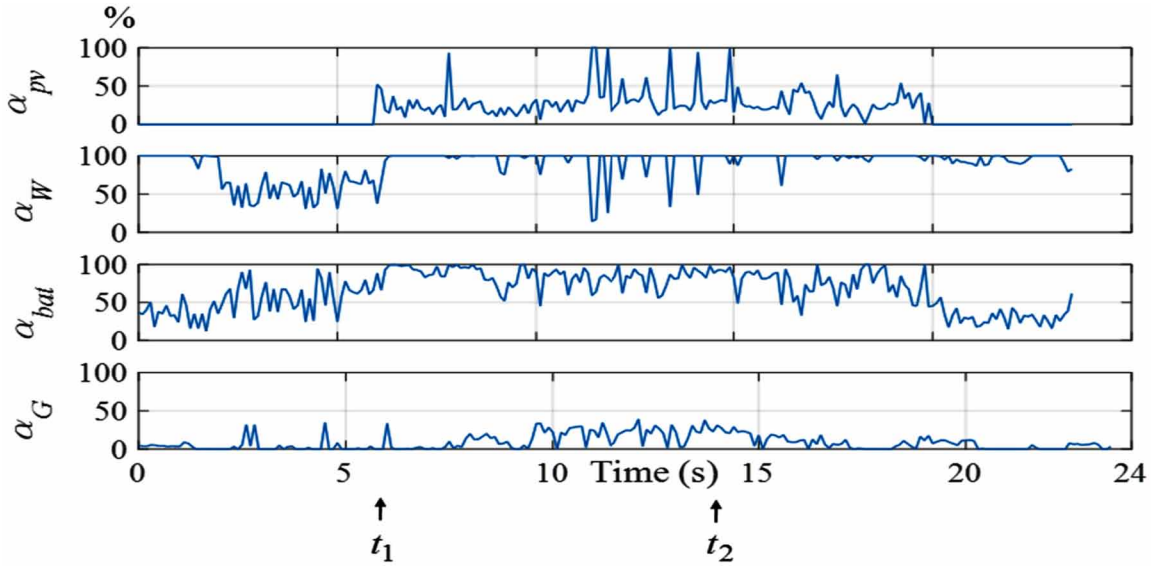
Energy Management Strategy and Interpretation

The algorithm is tested by simulation using the climatic parameters data, which are the solar radiation *G*, the ambient temperature T_a and the wind speed *V* of the target area (Northern Tunisia, latitude: 36.39°, longitude: 9.6°). The powers P_{pv} and P_W generated respectively by the PV panels and the wind turbine, that corresponds to the climatic parameters are presented in Figure 12 and Figure 13.



The EMS is tested by simulation using Matlab- Simulink. The obtained results show that the algorithm always ensures the load power supply, a safe operation of the battery bank and the minimization of the

Figure 12. Climatic parameters of a sunny day



EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 13. Generated powers from renewable sources

genset use. In fact, Figure 14 shows that during the night, the wind turbine and the battery bank supply the load with power, since the wind turbine generates insufficient power to the domestic load power supply and the battery bank is charged. This is presented by the EMS response at t_1. Then, when the PV panels start generating the PV power, the renewable power source and the battery bank, together supply the load with the needed electrical power. Figure 14 also shows that, when this generated power is insufficient for the domestic load power supply, therefore the diesel generator is switched on and all the components participate to supply the load, as it is shown at the EMS response at t_1.

Figure 14. Power sources contributions to the load power supply

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

In addition, it is clear that the battery depth of discharge (dod) is always maintained between the maximum and minimum limits (0.02 and 0.8). Thus, this allows the battery bank to be protected against charges excess and deep discharges, and the excess of the renewable energy generated to be stored and then used to supply the domestic loads when it is needed.

Consequently, using an appropriate EMS applied to the GA, it has been demonstrated the efficiency and the reliability of the EMS proposed in maintaining the domestic loads supplied continually, with taking into account of criteria related to the system components safe operation. Moreover, the EMS al-

lows maximizing the use of the renewable energies and minimizing the use of the battery bank and the diesel generator. Consequently, this affects the system cost operation studied for twenty years.

FUTURE RESEARCH DIRECTIONS

Following the developed work in this chapter, it has been proved the efficiency and the reliability of the EMS in fulfilling the energetic and economic objectives planned for the hybrid installation destined to supply a variable domestic load. This approach can be applied for other applications, including grid connected systems (hybrid or renewable). Moreover, this work can be also performed using other optimization methods and tools, namely the Artificial Neural Network, the Fuzzy logic, etc. Consequently, in the future, the present work can be extended and applied to several applications, since it is simple, easy to develop and practical.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

CONCLUSION

An Energy Management Strategy that consists in minimizing a cost function of a hybrid system is proposed and tested. The system supplies a variable domestic load via the contribution of the micro-grid elements, which is composed of photovoltaic panels, a wind turbine, a battery bank and a genset. The EMS allows providing the domestic load with the power in demand and ensures a safe operation for the battery bank. The EMS minimizes a cost function that takes into account of the operation, maintenance and production costs during twenty years of operation. The EMS efficiency is tested by simulation and gives good results. The reliability of the studied EMS is important and encouraging, since it can be applied in real–time to more sophisticated systems that are constituted of various interconnected micro-grids, as it is the case of smart grids systems. Moreover, this strategy showed its efficiency, since it has been tested using measured data. Thus, it is powerful and reliable, especially in cases of non-availability of sufficient renewable energy to supply the loads with the needed power. Consequently, this approach contributes to the security of micro-grids and hence, for the smart grids too.

Chapter 16
Developing Sustainable Processes Through Knowledge Management

Thanh-Dat Nguyen
Quy Nhon University, Vietnam & Lucian Blaga University of Sibiu, Romania

Stefania Kifor
Lucian Blaga University of Sibiu, Romania

ABSTRACT

Sustainable development of a process depends on a harmonious association of three sustainable pillars: Economy, Society, and Environment. Yet, in case of DMAIC (Define-Measure-Analyze-Improve-Control) process, the combination is challenged by inefficient management of knowledge resource in the process. The potential economy resource is not preserved and renewed, and therefore influents on sustainability of the process. In this article, the authors present and discuss sustainable aspects of a knowledge management model for DMAIC in which knowledge resource is accumulated and reused efficiently. In particular, the key concepts of sustainable development are reviewed, a process of knowledge management based on Ontology Engineering is presented, and sustainable criterial and measures for the proposed model are applied. The authors find that preserving and renewing knowledge is an indispensable process of sustainable development of DMAIC process.

INTRODUCTION

Sustainable Aspects in Product Development

In 1987, the term of "Sustainable Development" is used to refer a long-term development, and stated in a Brundtland report titled "Our Common Future" that: "Sustainable development is a development that meets the needs of the present without compromising the ability of future generations to meet their own needs" (Brundtland, 1987). This conception is useful for organizations and society in order to aim at a sustainable development. Sustainable development is represented as a deep transformation about how

to utilize natural resources, choose investment criterions, propose advanced technologies applied, and change administrative mechanism that accord with current and future needs (Harris, 2000).

However, notion of Sustainable development is very neutral (Hallstedt S., 2008). It needs to be concretized into principles or measures for business and society. It is recognized that three essential factors impacting on sustainable development are Economy, Environment, and Society (Harris, 2000) (Aparna & Keren, 2007). Basing on the factors, several sustainable measures and criteria have been presented in literature. Ritzen Rofia proposes five proactive measures for integrating environmental aspects into product development. (Ritzen, 2000). Ansari *el at* have mentioned seven sustainable measures for knowledge management (Ansari, Holland, & Fathi, 2010). Harris have pointed out principles for sustainable development in the three essential aspects or pillars.

In particular, goods and services need to be continuously developed without damaging agricultural or industrial production. A resource base need to be retained stably by preventing over-exploitation of renewable resource system and eliminating non-renewable resource. Biodiversity, stability of atmospheric, and other ecosystem function must be maintained. Social equity, adequate provision of social services, gender equity, and political accountability and participation must be assured. More importantly, a harmonious combination of sustainable aspects of development would guide products towards a greener, clearer and more equitable growth (Bleischwitz, Giljum, Kuhndt, & Schmidt-Bleek, 2009), (Roblek, Meško, Bach, & Bertoncelj, 2014) (Wu & Hans-Dietrich, 2013). However, the combination (or a balance) is one of primary challenges for product designers.

To be honest, a product such as a physical artefact, software, service, process, or combination of these (Hallstedt S., 2008) has positive and negative impacts on environment and society during its life-cycle through the activities such as energy or material consumption for production and delivery, emission to land, water or air, resource exploitation, and use and elimination of products (Ritzen, 2000). Yet, in order to gain economic benefits, the conventional approach of product designers is only to meet preference of customers based on functions, efficiency, and aesthetic elements of products. Supplementing new elements such as environmental requirements may complicate designing processes and increase producing and management costs. Hence, the designers become embarrassed with considering the sustainable aspect of environment (such as resource usage) in the process of designing their products (Nambiar, 2010).

Besides, not all types of resource are exploited and managed effectively. Knowledge is one of typical examples. Although knowledge is a type of resource that plays a vital role in creating organizational value and competitive advantage (Wu & Hans-Dietrich, 2013), it is difficult to verify a process or identify or methods that assure the capture and reuse of that knowledge (Hallstedt, Anthony, & Pia, 2013). With quality improvement processes such as DMAIC, the problem can affect negatively its sustainable development.

Environmental Sustainability of DMAIC Process

In Six Sigma system, DMAIC (Define-Measure-Analysis-Improve-Control) (Park, 2003) is a problem-solving process. Its ultimate aim is to produce 99.9996% defect-free products, in order to improve business profits, and business excellence (Yang, 2005), (Pande, Neuman, & Cavanagh, 2000). DMAIC deployment creates a favourable environment for managers, working teams, suppliers and customers to communicate, discuss, and propose ideas and insights with each other (Wu & Chinho, 2009). Consequence, new knowledge can be created in discussions such as gate review sections (Stevens, 2006) (Kifor & Baral, 2013) and improvement solutions (Zou & Lee, 2010).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

In order to reach comprehensive development of individuals and economy (Sztangret, 2016) and environmentally sustainable development (Ritzen, 2000), the potential economy resource need to be renewed and reused. However, the knowledge resource is often easy to be lost or difficult to access (Stevens, 2006). While implicit knowledge is often resident in minds or brain of individuals that is difficult to be queried again after DMAIC execution, explicit knowledge is documented into text-based document and reports that may be permanently secreted in filing cabinets. Therefore, the potential resource of economy which is considered as the key for sustainable competitive advantage (Roblek, Meško, Bach, & Bertoncelj, 2014) meets challenges. It is not reused and renewed efficiently. In order words, sustainability of DMAIC process should be improved.

One of the intelligent choices for sustainable development of products is to apply technology systems into monitoring continuously resource usage of products (Nambiar, 2010), (Nagel, M.H., & Tomiyama, 2004). A technology platform enables to efficiently capture, store, search and retrieve knowledge for successful sustainability implementation (Hallstedt, Anthony, & Pia, 2013). Thereby, a product can be minimized its negative impacts on the aspect of environment during its life-cycle.

In this article, we focus our intention on applying concepts of sustainable development to enhance sustainability of DMAIC process, and Ontology Engineering in the realization of resource management of the process. In the next section of this article, a review of related works are presented. Afterwards, a conceptual model for enhancing sustainability of DMAIC process through knowledge management is discussed in the third section. The fourth section explains the sustainable aspects of the proposed model. The final section is to conclude the article.

LITERATURE REVIEW

Several recent research show that knowledge management plays an important role in sustainable development of a process.

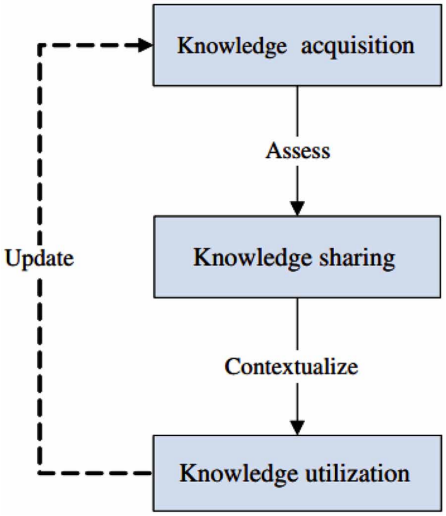
According to Sophie I. Hallstedt and the colleague, two of eight key elements affecting sustainability aspects of a product innovation process relate to knowledge i.e. knowledge utilization as well as knowledge share and reuse (Hallstedt, Anthony, & Pia, 2013). More importantly, knowledge sharing and reuse supports decision-making activities in future product development projects, enhances the sustainability aspects of products, and reduces the design cost basing on experience available. Furthermore, the authors point also out that systematic solutions such as knowledge-based processes, tools, or methods that would enable the capture and reuse of the knowledge are challenges for companies in order to enhance sustainability aspects of the product innovation processes.

In another research, the authors in (Wu & Hans-Dietrich, 2013) note that investing knowledge management facilitates sustainable development implementation. It supports to fill knowledge gaps and resolve current frustrations stemming from inadequate and inappropriate policy development and implementation. It also provides recommendations and best practices that guide innovation towards sustainability. Therefore, the authors present a process of KM for gaining sustainability performance in their framework involving three main stages: Knowledge acquisition, knowledge sharing, and knowledge utilization (Figure 1).

Kalakul and co-authors propose a framework to design a sustainable chemical and/or biochemical process (Kalakul, Malakul, Siemanond, & Gani, 2014). The authors develop four supporting tools integrated with a Life Cycle software in the framework (Figure 2). One of the most notable points in

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Process of KM for Wu's framework. Adapted from (Wu & Hans-Dietrich, 2013)



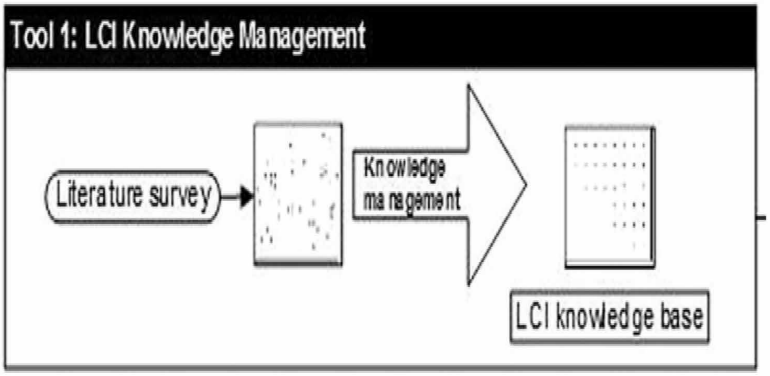


Figure 2. KM tool supporting designing a sustainable chemical and/or biochemical process. Adapted from (Kalakul, Malakul, Seimanond, & Gani, 2014)

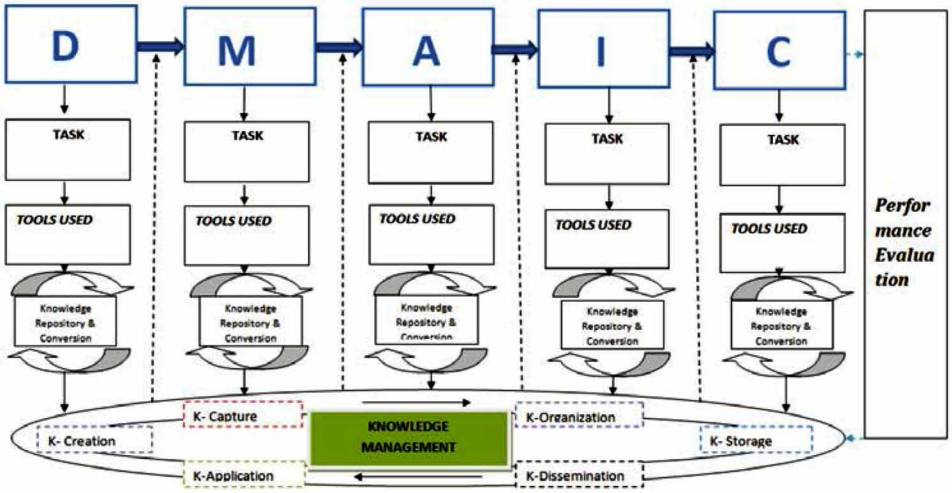
the framework is that knowledge of the process is managed by a specific tool used to organize data and support maintenance. Moreover, knowledge is represented by an Ontology and stored in a knowledge base. Therefore, it enables future expansion of KM tool.

In the model of Sztangret, knowledge management plays a vital role in implementing concepts of sustainable development in a company (Sztangret, 2016). It influents on a comprehensive development of individuals, and success of a company. The model of sustainable development is designed on the basis of multi-subject, multifunctional, and multi-tool, and implemented on the basis of three pillars: (1) company strategy based on awareness, knowledge and learning, (2) environment of knowledge application, share and creation, and (3) tools for knowledge management and distribution. The ultimate goal of the author is to reduce the use of, reuse, and recycle natural resource and energy.

In other research, although the authors do not present sustainable aspects regarding to their products i.e. processes or models, the problem of knowledge management attracts their attention in research. In

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use



(William, 2009), William R. King has of six steps for a process of knowledge management consisting of Create/Acquisition, Refinement, Memory, Transfer/Sharing, Utilization/ Organizational Performance in order to support organizational processes in innovation, learning and decision making. Ricky Yeung (Ricky, 2004) introduces Integrated Knowledge Representation model for DMAIC execution on the basis of two components: 5W1H framework and Total Enterprise Knowledge Integrated Platform. The components are used to represent contents and manage knowledge in a KM process involving evolution, gathering, organization and storage, learning, nomination, and discussion.

Kifor & Baral (Kifor & Baral, 2013) introduce a conceptual model for KM in DMAIC process in order to improve product quality and organizational performance. The process of KM is integrated with each DMAIC phases on the basis of six steps: knowledge creation, capture, organization, storage, dissemination, and application. Moreover, tasks, tools, activities, knowledge managing IT platform and project performance evaluation tools are used to support knowledge works in their Six Sigma projects (Figure 3).

The aforementioned research depicting the same point of view is that knowledge plays a pivotal role in development of products, and affects their sustainability. However, most of them do not present how knowledge is structured, stored and reused effectively yet. In other words, a solution that facilitates knowledge storage, renew and reuse is not mentioned yet thought there are many approaches for the problem.

In IT techniques, three typical approaches for organizing and representing knowledge are to base on Documents, Ontology, and Artificial Intelligence (Ribino, Oliveri, Lo Re, & Gaglio, 2009). These approaches aim at making a converting from tacit knowledge to explicit knowledge, and sharing the expertise and information resource of an organization. In case of the Ontology-based approach, both of tacit and explicit knowledge are represented and hierarchically structured. In the case, knowledge is described and defined as a set of concepts and their relationships. This approach is suitable to share DMAIC knowledge because Ontology supports a specification of conceptualizations, and helps programs and humans to share knowledge (Gruber T. R, 1993). It also can be used to "share and reuse among different applications" (Benjamins, Fensel, & Gomez Perez, 1998).

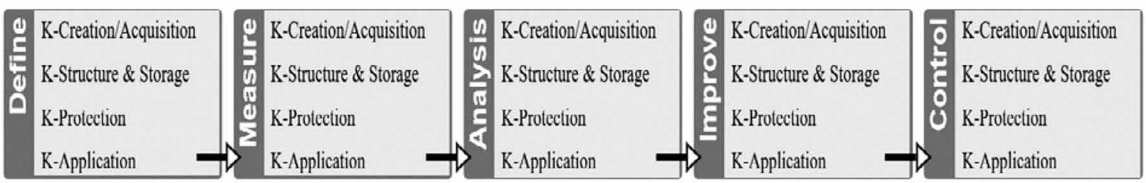
Figure 3. DMAIC-KM model. Adapted from (Kifor & Baral, 2013)

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

In the next section, the authors of this article present a conceptual model of KM in order to enhance sustainability of DMAIC process. The authors' approach is based on Ontology Engineering used to structure and represent DMAIC knowledge.

THE PROPOSED OKMD MODEL

Overview



In the process of carrying out DMAIC activities, the quality profession and statisticians often apply several tools and techniques for the purpose of improving an existing product, process or service (Thomas, 2003). Each of tools and techniques (Table 1) helps the profession and statisticians to create reports in which new ideas or knowledge are proposed and applied. However, the DMAIC reports are often produced in text-based document format, some of them are in unstructured formats that may be permanently secreted in filing cabinets. Moreover, innovations or breakthrough solutions proposed by domain experts or individuals are often hidden in the reports and difficult to access (Stevens, 2006). Hence, a solution supporting accumulate, sharing, exchange of knowledge is necessary.

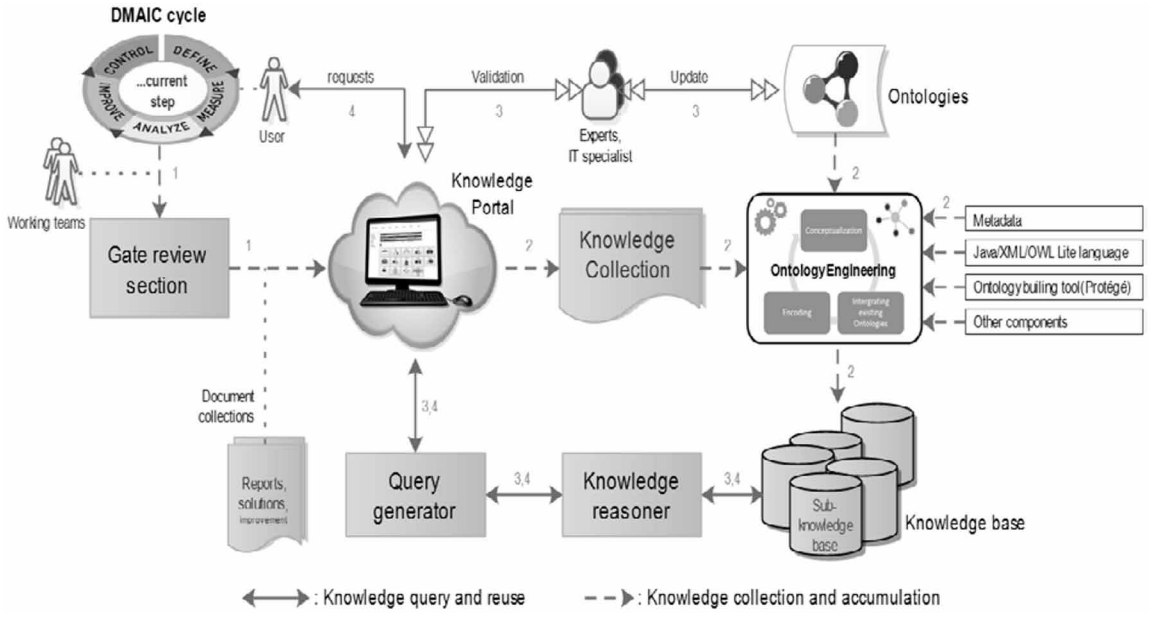
The proposed OKMD (Ontology-based Knowledge Management process for DMAIC) model (Figure 4) is an integrated conceptual model that combines activities of DMAIC process, knowledge management and ontology engineering. The ultimate goal of OKMD model is to construct a knowledge base to accumulate and share knowledge created by DMAIC improvement process. Knowledge available should be represented by existing Ontologies. Thereby, knowledge resource of DMAIC improvement process will be preserved and reused sustainably.

Table 1. Tools and Techniques used during DMAIC execution

Project phase	Brief Description	Tools and techniques
Define	Define the goals of the improvement activity	Project Charter, Stakeholder Analysis, SIPOC, …
Measure	Measure valid and reliable metrics in the existing system	Preliminary Data Analysis, Initial Sample Results / DPMO…
Analyze	Analyze the system to identify ways to eliminate the gap.	Five Why Root Cause Analysis, Failure Modes and Effects Analysis…
Improve	Improve the system	Solutions Ratings Analysis, Benchmarking Report, Corrective Action Plan…
Control	Control the new system	SPC, FMEA, Best Practices Log…

Figure 4. KM process in OKMD model

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use



Activities of DMAIC process are planned and deployed step by step according to the recommended Six Sigma guideline (Kifor & Baral, 2013), Gate Review sessions are arranged by the project participants recommended in (ISO13053-1, 2011) and tools and techniques proposed in (ISO13053-2, 2011). These activities provide opportunities to generate new knowledge that is then accumulated and reused in the during DMAIC process execution. The activities of knowledge management (Figure 5) involving Knowledge Creation/Acquisition, Knowledge Structure & Storage, Knowledge Protection, and Knowledge Application (Gold, Albert, & Arvind, 2001) are executed continuously within each of five DMAIC steps consisting of Define, Measure, Analysis, Improve, and Control. DMAIC knowledge is structured and stored by using Ontology engineering into sub-knowledge bases.

Ontologies are built by using supported tools in IT area such as Ontology editing tools, programming languages, and natural language processing techniques. Moreover, activities of knowledge accumulation and reuse are fulfilled by knowledge workers (Mikael, Ioana, & Sachin, 2003) through Knowledge Portal where various information sources such as reports, plans, and text-based documents are collected. It provides activities of knowledge management with the functionalities: Content presentation, user account, chat room, forums, news module, and online quiz, questionnaire with multiple choices, file uploader, file downloader, search/query generator, and Knowledge Reasoner/inference engine.

Accumulating and Reusing DMAIC Knowledge

In OKMD model, a knowledge management process typically consists of four stages videlicet K-Creation/Acquisition, K-Structure & Storage, K-Protection, and K-Application. Figure 5 depicts the typical activities executed by working teams who participate a Six Sigma project, experts, specialists of Information technology, and web users.

Figure 5. Integration of KM and DMAIC process

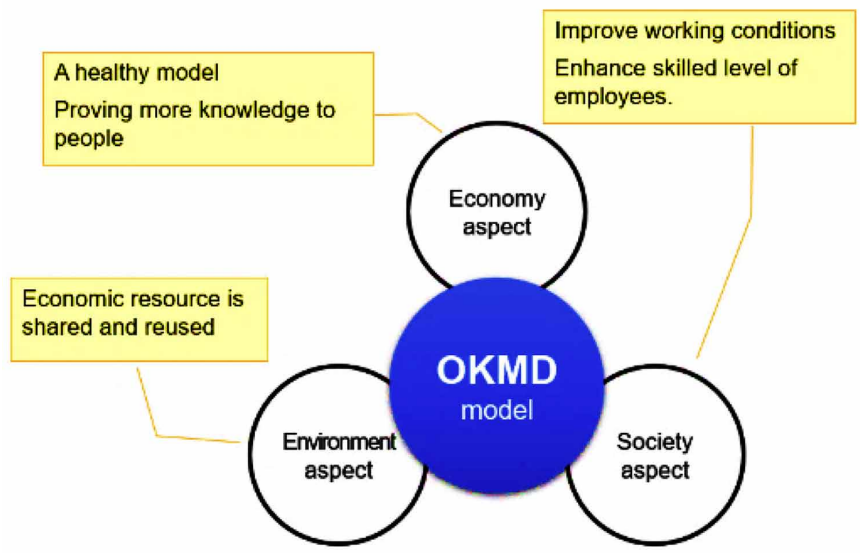
EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

The activities of K-Creation/Acquisition stage (arrow path 1 in Figure 4) is to obtain new knowledge (Gold, Albert, & Arvind, 2001). The stage should be started at the Gate review section of every DMAIC step where members of project team such as Black Belt, Green Belt, domain experts discuss and review problem-solving solutions or improvement plans basing on reports and documents created. The support of Knowledge Portal allows them to submit or upload their reports, documents, writings, and relevant files to Knowledge Portal. Data collected at the Gate review section is used to extract potentially valuable knowledge (King, 2009) for reusing in the next stages. Domain experts can be interviewed in case tacit knowledge need to be supplemented.

K-Structure & Storage stage (arrow path 2) aims at structuring and cumulating new knowledge into sub-knowledge bases on the basis of Ontology Engineering. As Figure 4 shown that data collected on Knowledge Portal is extracted to explicit knowledge under the support of Ontologies available, Ontology building tools (such as Protégé), natural language processing techniques, and programing languages. Concepts of new knowledge as well as their relationship are defined and updated by the support of IT specialists into each of DMAIC stages correspondently.

K-Protection stage (arrow path 3) plays an important role in protecting crucial knowledge before it would be distributed to the next stages. This stage is proposed in order to prevent illegal or inappropriate behaviors of web users who are querying knowledge available on Knowledge Portal. It provides security mechanism for web users and supporting tools for maintaining and validating knowledge. The knowledge access and activities of web users are monitored and controlled through their accounts. Experts are required to validate knowledge available, and their opinions are helpful to contribute to making created valuable knowledge and eliminating outmoded knowledge. Ontologies are updated by expert's opinion and IT specialists.

K-Application stage (arrow path 4) is necessary to share and reuse created knowledge. Activities found in Figure 4 consist of querying knowledge, and applying valuable knowledge. Knowledge found can support improvement activities of the next steps of DMAIC. A knowledge request of a web user is sent to the query generator where a command of knowledge query is generated. Intelligent results of the query are then responded by Knowledge Reasoner after appropriate knowledge is reasoned from a knowledge base.



SUSTAINABILITY OF OKMD MODEL

In various fields, there are different points of view to make sustainability. Hence, there is no unique standardized criteria and almost no practical experience for sustainability of a process (Ansari, Holland, & Fathi, 2010) (Azapagic, Allan, & Aaron, 2006). In this article, sustainability of the conceptual OKMD model is achieved by effectively managing and exploiting knowledge resource. Sustainable aspects of the proposed model are discussed through criteria presented by (Harris, 2000), (Brundtland, 1987) and seven sustainable measures presented by the authors in (Mahesh, Henrietta, Laszlo, & Jozsef, 2008) (Ansari, Holland, & Fathi, 2010) (see Figure 6).

The essential goals of sustainability are economic growth, environmental conservation, and social equity (Aparna & Keren, 2007). For economically sustainable aspect, OKMD is a healthy business model. DMAIC focuses on a continuous improvement cycle that benefits organizations in several years (Kwak & Anbarib, 2006). Increasingly, OKMD improves economic sustainability of DMAIC process when more knowledge is provided to people.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 6. Sustainability of OKMD

Valuable knowledge is queried online for the purpose of applying into improvement activities. Knowledge accumulation benefits the share and renewal and maximizes use of this renewable resource for the purpose of enhancing environmental sustainability (Adams & Scott, 2013). This would "*create greater willingness to share global resources equitably*" (Brundtland, 1987).

The social sustainability of OKMD can be attained when it creates easier knowledge access and opportunities to enhance skills of employees. The Knowledge Portal would support an organization to improve working conditions, help employees to communicate and create relationships with customers and providers. Therefore, the relationships provide them with insights regarding sustainability aspect of the model (Hallstedt, Anthony, & Pia, 2013).

Moreover, sustainability of OKMD model can be evaluated on the base of seven sustainable measures in which DMAIC knowledge is preserved and developed through its KM process:

- Converting economic goals to knowledge goals
- Discharging obsolete knowledge
- Protecting and preserving of sensitive knowledge
- Identification and retention of human knowledge hosts
- Optimizing "Use of knowledge" infrastructure
- Externalization of tacit knowledge
- Offering incentives for knowledge sharing

In knowledge economy, products are often produced by improving and innovating previous ones. Contribution of valuable knowledge is necessary for the improving processes. OKMD model creates opportunities to target the valuable knowledge in order to preserve and renew it. Yet, during knowledge accumulation, outmoded knowledge is not useful and conducive to improvement activities. It does not provide breakthrough insights but cause problems in term of processing data and making decision.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Besides, valuable or sensitive knowledge is just strategic assets of an organization that can create the competitive advantage in business (Roblek, Meško, Bach, & Bertoncelj, 2014). Hence, the outmoded knowledge should be eliminated and sensitive knowledge must be protected through implementation of the K-Protection phase. Another sustainable measure to discuss is knowledge sources. DMAIC knowledge can be found in various kinds of document. This causes troubles to knowledge identification and storage. Fortunately, Knowledge Portal and Ontology Engineering are helpful to optimize exploiting knowledge and overcome the problem. They are used to collect, structure, maintain, and share DMAIC knowledge. Nonetheless, not all kinds of knowledge can be collected easily, particularly tacit knowledge. Using Ontologies and other techniques, KM process of OKMD model creates a conversation from tacit knowledge to explicit knowledge. Therefore, valuable experience and knowledge of experts will be accumulated and shared equitably. Far more than that, it encourages employees and managers participation in the knowledge sharing, and impulse the development of knowledge (Ritzen, 2000).

CONCLUSION AND FUTURE WORKS

In this research, the necessity for integrating concepts of sustainable development with a quality improvement model has been pointed out. A harmonious combination of three economic, social, environment aspects is essential to archive sustainable development of a quality improvement model. In case of the proposed conceptual model, crucial knowledge is created to improve business processes and enhance quality of products. Hence, accumulation and reuse of the knowledge, a potential economic resource (Roblek, Meško, Bach, & Bertoncelj, 2014), is necessary. Effective managing and exploiting this resource of knowledge contribute innovation of products towards sustainable development of the DMAIC process. Finally, sustainable measures for knowledge management have been analyzed theoretically. For future work, the conceptual model can be validated by using data collected from a Six Sigma project in practice and applied into IT operations management.

ACKNOWLEDGMENT

This paper is based on a research conducted for Doctoral studies under the financial support of Erasmus Mundus Mobility with Asia (EMMA). Authors are very much thankful to the EMMA management team for their support.

Chapter 17
Making Sustainable Energy Communities a Reality:
The "MPC+" Decision Support Framework

Vangelis Marinakis
National Technical University of Athens, Greece

ABSTRACT

The aim of this chapter is to present a decision support framework for local energy planning, entitled "MPC+ (Map - Plan - Choose - Check)". The proposed framework incorporates the development of the baseline emissions inventory, the identification and modelling of renewable energy and rational use of energy actions, as well as the creation of alternative Scenarios of Actions at the city level. The evaluation of alternative Scenarios is based on a multi-criteria ordinal regression approach. In addition, an extreme ranking analysis method is used, in order to examine robustness problems, estimating the best and worst possible ranking position of each Scenario. The MPC+ framework contributes to the selection of the most promising Scenario of renewable energy and rational use of energy actions, supporting the local - regional authorities in creating Sustainable Energy Communities (SEC). Finally, the "Methodological Approach for Monitoring SEC Targets" is introduced.

INTRODUCTION

This chapter presents a decision support framework for local energy planning. The overall philosophy of the proposed framework aims to support the local and regional authorities in the development, implementation and monitoring of the Sustainable Energy and Climate Action Plan, especially within the framework of the Covenant of Mayors' initiative. More specifically, the proposed framework "MPC+ (Map - Plan - Choose - Check)" integrates the following four components:

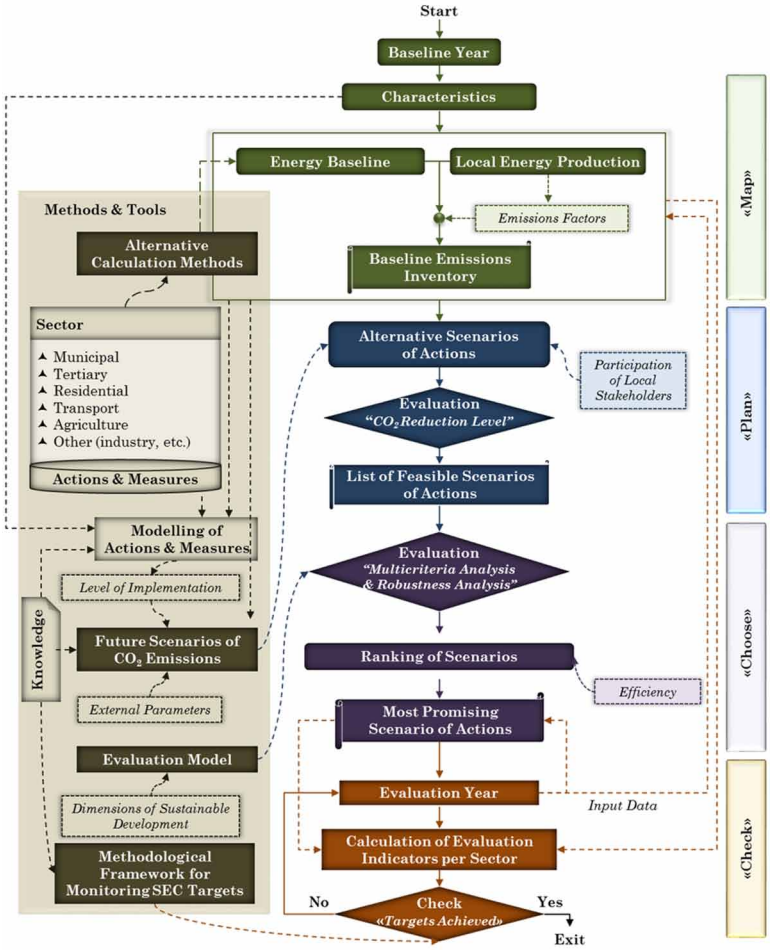
- **"Map":** This component is the starting point of the Action Plan's development process. It involves the mapping of the current status within the region, emphasizing on the development of energy and baseline emission inventory. The results at this stage are the basis for the formulation of a comprehensive Action Plan and the monitoring and control of targets set.
- **"Plan":** This component focuses on the design of alternative Scenarios of Actions, namely a set of appropriate measures and actions for implementation at local - regional level. The design of scenarios is achieved through the modeling of measures and actions, the assessment of future trends in CO_2 emissions at local - regional level and the participation of local stakeholders.
- **"Choose":** This component aims to support decision makers in the process of identifying the most promising Scenario of Actions for the region. It includes the evaluation of the alternative Scenarios of Actions using multi-criteria analysis and robustness analysis.
- **"Check":** This component is related to the monitoring of the targets set in each activity sector of the municipality. In this way, the monitoring and assessment of the progress towards sustainable development in economic, social and environmental context is achieved.

Apart from the introduction, the paper is structured along six sections. Section 2 provides a description of the overall technical framework of the proposed "MPC^{+}" approach. Sections 3-6 are devoted to the presentation of the four components of the proposed approach, namely "Map", "Plan", "Choose" and "Check" components. Finally, the last section just summarizes the key issues that have arisen in this paper.



Technical Framework

The proposed framework includes individual components, which are described in Figure 1:

- **"Map" Component:**
  - **Baseline Year:** Selection of the year for which the energy and emission baseline inventory will be developed.
  - **Characteristics:** Some basic information and statistics are required for the municipality (e.g. population, number of dwellings, land uses, etc.). These data are used both in the development of energy and emission baseline, as well as in the design of alternative Scenarios of Actions.
  - **Energy Balance:** Calculation of energy balance at the local-regional level with the use of alternative methods.
  - **Local Energy Production:** Data on the local electricity production and local heating / cooling systems. These data are used for the calculation of regional CO_2 emission factors.
  - **Baseline Emissions Inventory:** The last stage includes the development of the baseline emission inventory, taking into consideration the energy balance and emission factors per energy use (national and local).
- **"Plan" Component:**
  - **Actions' Modelling:** First of all, a number of renewable energy and rational use of energy actions have been identified for the following sectors, as proposed by the Covenant of Mayors' guidelines (CoM, 2017):

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Algorithm of the proposed decision making framework

- Agricultural/fishery/forestry sector;
- Municipal buildings, equipment/facilities (public, tertiary and residential);
- Transport (municipal fleet, public transport, private and commercial transport);
- Local electricity production (hydroelectric power, wind power, photovoltaic, combined heat and power, etc.);
- Local district heating/cooling (combined heat and power, district heating plant, etc.).

These actions take an "editable" form using data provided by decision-maker (community's profile, baseline energy and CO_2 emission inventory), as well as indicators from the international literature and reports.

- **Scenarios' Development:** An initial design of alternative scenarios takes place according to the range of the actions' application in each sector. The appropriate modifications are made on these scenarios through a participatory approach (using questionnaires, public consultation meeting, etc.).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

- **Evaluation (Level of CO_2 Emissions Reduction):** All the alternative scenarios are evaluated concerning the reduction of CO_2 emissions, based on the threshold set by the local authorities (e.g. 20% by 2020 or 40% by 2030).
- **List Feasible Scenarios of Actions:** Creation of the list of feasible Scenarios, which will be evaluated subsequently in order to identify the most promising scenario to be implemented by the region.
    - **"Choose" Component:**
- **Evaluation (Multicriteria Decision Support and Robustness Analysis):** The alternative scenarios are evaluated through the construction of a coherent family of criteria and an evaluation model. An Additive Value Function is used for the assessment of the alternatives scenarios. Linear programming techniques used in conjunction with qualitative regression analysis (Multicriteria Ordinal Regression Approach). The extreme ranking analysis method is used, in order to take into account the model's robustness, estimating the best and worst possible ranking position of each scenario.
- **Ranking of Alternative Scenarios of Actions:** Based on the above approach, the final ranking of alternative Scenarios of Actions is derived, reflecting the maximum and minimum position of each Scenario. In this respect, the most promising Scenario of Actions can be identified taking also into consideration the relevant efficiency.
    - **"Check" Component:**
- **Evaluation Year:** For the elected evaluation year, the relevant data for the baseline emission inventory and the progress on actions and measures implementation are introduced.
- **Calculation of Monitoring Indicators in Each Activity Sector:** Based on the data input, the calculation of the monitoring indicators in each activity sector take place.
- **Check (Targets Achieved):** Calculation of the composite index "SEC_{Index}" in each activity sector, in order to evaluate the overall progress and facilitate the identification of deviations and corrective measures needed.

"MAP" COMPONENT

Baseline Year

According to the Covenant's guidelines, the recommended baseline year is 1990, but if the local authority does not have data to compile a CO_2 inventory for 1990, then it should choose the closest subsequent year for which the most comprehensive and reliable data can be collected.

Characteristics

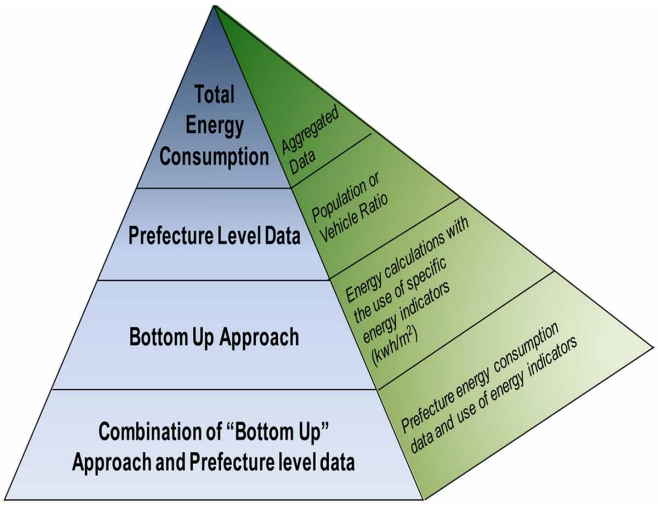
The end-user provides data regarding general characteristics of the municipality, as follows:

- **General Information:** Population; area; climate zone; employment.
- **Agricultural Sector:** Cultivate land; number of tractors; irrigation methods.
- **Municipal Sector:** Number of municipal buildings; type and total area; number and type of pumps, drillings, water tanks, biological treatment

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

- **Residential Sector:** Number of buildings and area; buildings with or without central heating; detached houses or block of apartments.
- **Tertiary Sector:** Number buildings, types and area
- **Municipal Lighting:** Number and type of lights
- **Transport:** Number of municipal cars, buses and other vehicles; number of private passenger vehicles, motorcycles, trucks, etc.
- **Locally Energy Production:** Solar radiation; wind speed; river area and flow.

Energy Baseline: Alternative Calculation Methods



A common technical approach has been adopted, as well as the necessary algorithms for the calculations of the energy and CO_2 emissions baseline have been developed. It should be noted that specific emphasis has been given in the sectors of agriculture, forestry and fishery, taking into consideration that these sectors constitute an important part of the baseline emission inventory of the city. The main aim is to facilitate the calculation of energy consumption per sector (especially for tertiary sector, residential buildings, private and commercial transport, agriculture, etc.), providing alternative calculation methods to the users.

Indeed, the approach used for the data entry regarding all buildings and facilities' energy consumptions is either based on existing aggregated data for a specific type of facilities (e.g. schools), either on the bottom up approach and/or use of appropriate estimations where considered necessary (Figure 2).

Buildings, Equipment/Facilities and Industries

- Municipal Buildings/Equipment/Facilities.
  - Schools.
    - Total energy consumption (aggregated data).
    - Bottom up approach - Individual energy consumptions for Nursery schools, Primary schools, Lower secondary schools, Upper secondary schools etc.

Figure 2. Energy baseline: Alternative calculation methods

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

    - Municipal Buildings.
        - Total energy consumption (aggregated data).
        - Bottom up approach - Individual energy consumptions for Community Offices, Hospitals, Sports Facilities, Culture Buildings, Other.
    - Equipments/Facilities.
        - Total energy consumption (aggregated data).
        - Bottom up approach - Individual energy consumptions for Water treatment units, Recycling centres, Composting plants, Sewage treatment, Other.
- Tertiary (non Municipal) Buildings, Equipment/Facilities.
    - Total energy consumption (aggregated data).
    - Energy consumption at district level (estimation based on population ratio).
        - Energy consumption at district level, calculation of the municipality consumption based on the population of community and district ratio.
    - Estimations using the bottom up approach for each building category (e.g. Offices, Stores, Hotels, Hospitals, Other).
        - **Electricity Consumption Estimation:** Based on the number and area (m^2) of buildings for each category, use of average electricity consumption indicators for each building category (kWh/m^2).
        - **Space Heating:** Estimations based on: number and area (m^2) of buildings per building category, number (or percentage) of buildings with thermal insulation per building category, average energy consumption for heating per m^2 and building category, indicators regarding the % of each fuel (e.g. diesel, electricity, natural gas, biomass etc.) in the heating energy mix.
        - District heating aggregated data (from the suppliers).
        - **Water Heating :** Solar collectors (Solar collectors' installation - m^2 and energy saving through solar collectors - KWh/m^2 for each country).
- Residential Buildings.
    - Total energy consumption (aggregated data).
    - Energy consumption at district level (estimation based on population or building square meters' ratio).
        - Energy consumption at district level, calculation of the residential consumption based on the community/ district population or building square meters' ratio.
    - Individual energy consumptions.
        - **Electricity Consumption:** Estimation and bottom up approach based on the number and area (m^2) of detached houses and block of apartments and average electricity consumption in buildings (kWh/m^2). The electricity consumption may or may not include consumption for space heating (depending on the availability of indicator data).
        - **Space Heating:** Estimations and bottom up approach based on: area (m^2) and number of detached houses and apartments blocks with and without central heating; number of buildings with thermal insulation, for the categories with and without central heating; average energy consumption for heating (kWh/m^2), for buildings with and without central heating; indicators regarding the % of each fuel (e.g. diesel, natural gas, electricity, etc) in the heating energy mix; especially for biomass, indicators for the average use of fuelwood (tons per household) and number of households are used.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

        - District heating aggregated data (from the suppliers).
        - **Water Heating:** Solar collectors (Solar collectors' installation - m^2 and energy saving through solar collectors - KWh/m^2 for each country).
- Public Lighting.
    - Total energy consumption (aggregated data).
    - **Bottom up Approach:** Individual energy consumptions based on the location and relevant energy consumption (kWh per location).
- Industries (excluding industries involved in the EU Emission trading scheme - ETS):
    - Total energy consumption - (aggregated data).
    - Estimations based on the energy consumption at district level and use of ratio.

Transport

- Municipal fleet.
    - Total energy consumption (aggregated data).
    - Bottom up approach from the individual energy consumptions based on:
        - Vehicle Type (Road Grader, Excavator, Bus, Pickup Truck, Garbage Truck, Ambulance, Car, Fire Brigade truck),
        - Number of vehicle and km,
        - Average fuel consumption and fuel type.
- Public transport.
    - Total energy consumption (aggregated data).
    - Bottom up approach from the individual energy consumptions based on:
        - Bus Route (number of km and number of routes per year).
        - Average fuel consumption and fuel type.
- Private and commercial transport.
    - Total energy consumption (aggregated data)
    - Estimations based on the energy consumption at district level and use of community/ district population or vehicle ratio.
    - Bottom up approach from the individual energy consumptions based on:
        - Number of vehicles, motorcycles and vehicles for transport of goods.
        - Average energy consumption of each type of vehicle.
- Other transportation.
    - Total energy consumption (aggregated data).

Agriculture - Forestry - Fishery

- Agriculture.
    - Electricity (irrigation).
        - Total energy consumption (aggregated data).
        - Approximate energy consumption - Water Use (m^3) and relevant indicators (kWh/m^3).
    - Petroleum consumption (agricultural products).
        - Total energy consumption (aggregated data).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

        - **Estimated Energy Consumption – 1st Method:** Agricultural area for each product (cotton, wheat, maize etc – Ha) and relevant energy consumption indicators (kWh/Ha).
        - **Estimated Energy Consumption – 2nd Method:** Total agricultural area, power of tractors (kW) and operation Hours (machine-hours/Ha), as well as average energy consumption.
- Forestry.
    - Total energy consumption for the gathering and production of one ton of biomass (based on national studies).
- Fishery.
    - Total energy consumption (aggregated data).
    - Estimated energy consumption based on:
        - Number of the coastal fishing boats,
        - Average power of boats,
        - Annual operation hours,
        - Average energy consumption.

Other Emissions

- Total energy consumption (aggregated data).

Local Energy Production

Data are required about the thermal power stations operating in the examined municipality, in order to produce electricity. According to the Covenant's guidelines, the end-user should include a project in the baseline emission inventory only if the installed capacity is below 20MW. In this respect, for a group of small (<20MW) similar projects the proposed approach gives the option of adding a group of projects as one only if the installed capacity of each one of the projects participating in the group is below or equal to 20 MW.

In addition, all the currently operating renewable energy and rational use of energy projects in the municipality are taken into consideration. It works exactly the same way like before as far as the projects' grouping is concerned but now there are some differences depending the projects' category. In case the project concerns wind power or hydroelectric or photovoltaic, then the end-user should fill in the fields precisely as in the previous step with the slight exception that now, the end-user does not have to fill in the energy carrier input since this info is now not applicable. If the project relates to combined heat and power units there is a small differentiation, since now the end-user has to fill in separately the data for the power produced and the heat produced (Figure 3).

Baseline Emission Inventory

Two different approaches have been proposed to calculate the energy balance analysis of the region and to identify the principal sources of CO_2 emissions, as well as their respective reduction potentials. The first method considers the "standard" emission factors according to the Intergovernmental Panel on Climate Change (IPCC) principles (IPCC, 2006), whilst the latter one considers the Life Cycle Assessment (LCA) emission factors (Table 1).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Local energy production

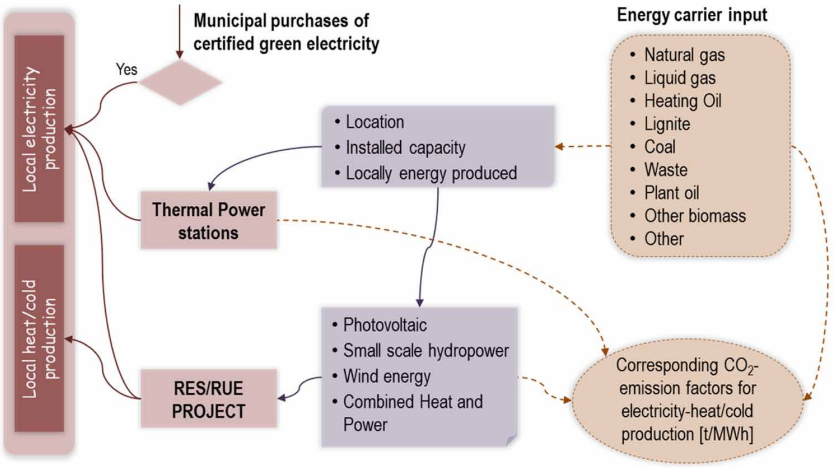


Table 1. Emissions factors

Fuel	IPCC ($tnCO_2$/MWh)	LCA ($tnCO_2$-eq/MWh)
Gasoline	0.249	0.299
Diesel	0.267	0.305
Lignite	0.364	0.375
Natural gas	0.202	0.237
Biomass	0 – 0.403	0.002 – 0.405
Biodiesel	0	0.156
Solar heating	0	-
Geothermal	0	-

The IPCC method covers all the CO_2 emissions that occur due to energy consumption within the territory of the local authority, either directly due to fuel combustion within the local authority or indirectly via fuel combustion associated with electricity and heat/cold usage within their area. The standard emission factors that are used in this method are based on the carbon content of each fuel and it is assumed that all carbon in the fuel forms CO_2. In this approach, CO_2 is the most important greenhouse gas, and the emissions of CH_4 and N_2O are not calculated. Furthermore, the CO_2 emissions from the sustainable use of biomass/biofuels, as well as emissions of certified green electricity, are considered to be zero. The standard emission factors that are used in this method are based on the IPCC Guidelines (IPCC, 2006). It has been widely used in different fields, such as agriculture (Brown et al., 2001; Nevison, 2000), fossil fuel technologies (La Mottaa et al., 2005; Olivier et al., 2005) and waste management (Papageorgiou et al., 2009).

LCA approach includes not only the emissions of the final combustion, but also all emissions of the supply chain. It includes emissions from exploitation, transport and processing (e.g. refinery) steps in addition to the final combustion. This hence includes also emissions that take place outside the location

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

where the fuel is used. In this approach, the Green Greenhouse Gas (GHG) emissions from the use of biomass/biofuels, as well as emissions of certified green electricity, are higher than zero. In the case of this approach, other greenhouse gases than CO_2 may play an important role. Therefore, the local authority that decides to use the LCA approach can report emissions as $CO_{2\text{-eq}}$.

LCA method has been widely used in different sectors, such as fossil fuel and renewable energy technologies (Sobrinoa et al.,2011; Martíneza et al., 2010; Weisser, 2007; Dones et al., 2004; Varun, et al., 2009; Cherubinia et al., 2009; Babusiaux et al., 2007; Lenzen et al., 2004; Góralczyk, 2003; Pehnt, 2006; Masruroh et al., 2006; Ardente et al., 2005; Ardente et al., 2005; Khan et al., 2005; Martínez et al., 2009), waste management (Ozeler et al., 2006; Borghi et al., 2005; Björklund et al., 2003), as well as construction industry (Ortiza et al., 2009; Erlandssona et al., 2003; Zabalza Bribián et al., 2009), communication systems (Emmenegger M.F et al., 2004) and food products (Poritosh et al., 2009).

Based on the emission factors (national and/or local), the inventory quantifies the amount of CO_2 emitted due to energy consumption in the territory of the Covenant signatory.

"PLAN" COMPONENT

Actions and Measures

The proposed approach includes the development of alternative Scenarios though a knowledge-based process. More specifically, based on desktop analysis (experience, studies, reports, best practices, etc.), different renewable energy and rational use of energy actions for the local authorities, as well as interventions for the local population have been identified (Table 2).

Creation of Scenarios of Actions

Following the identification of renewable energy and rational use of energy actions, there is the need for a modelling process, so as all the proposed actions to take an "editable" form. In this way, the development of alternative scenarios is possible. To this end, all the factors that affect the final energy saving and production from the implementation of these actions have to be identified.

The implementation of all the proposed actions from the local authorities cannot be feasible at economical and organizational level, taking into consideration that each municipality has different characteristics in terms of population, infrastructures, construction of buildings, etc. In this respect, a number of alternative scenarios are created. The scenarios includes different range of application of each action in the relevant sectors, approaching the real needs and opportunities of each municipality, as possible. This means that there are scenarios with emphasis on the residential and/or tertiary sector, other scenarios focused on actions from the local authorities (e.g. municipal buildings, equipment/facilities and public lighting), etc.

Figure 4 depicts a qualitative representation of the range of application in each sector for the initial design of alternative Scenarios. The selection of the range was based on the experience from the development and elaboration of the Sustainable Energy and Climate Action Plans within the framework of the Covenant's initiative, as well as other related activities, such as the Intelligent Energy Europe (IEE) programme.

Table 2. Sectors' and actions' identification

Sector	Actions by the Local Authorities	Interventions by the Local Population
S_1 - Agricultural/ Fishery/ Forestry Sector	A_{11} Establishment/adjustment of a Department for Rural Development in the municipality. A_{12} Training seminars regarding the agricultural tractors' modernization and irrigation techniques. A_{13} Implementation of wide informational campaign. A_{14} Installation of an electronic water-supply system for irrigation based on debit cards.	I_{11} Modernization and replacement of tractors. I_{12} Replacement of surface irrigation and sprinkler irrigation with drip irrigation.
S_2 - Municipal Buildings, Equipment/ Facilities	A_{21} Energy certification and improvement of the municipal buildings' energy performance. A_{22} Actions and campaigns for awareness raising of municipal employees. A_{23} Improvement of the school buildings' energy performance. A_{24} Actions and campaigns for awareness raising of pupils and students. A_{25} Energy Management System (in accordance with the ISO 50001). A_{26} Improvement of the sports facilities' energy performance. A_{27} Improvement of the energy performance of the water system and sewage treatment facilities. A_{28} Establishment of the Energy Efficiency Department in the Municipality. A_{29} Appointment of the municipality energy manager. A_{210} Remote configuration and control of the water system.	Not applicable
S_3 - Residential & Tertiary Sector	A_{31} Implementation of campaigns, events, energy days for the citizens. A_{32} Design and distribution of brochures about the benefits of interventions in the residential buildings. A_{33} Targeted seminars to professional groups. A_{34} Initiatives to support the citizens' actions. A_{35} Energy efficiency criteria for the purchase of electrical appliances	I_{31} Improvement of the building envelope (thermal insulation of walls, windows, roofs; external shading). I_{32} Retrofitting of residential buildings, bundling together technology improvements (lighting, electrical equipment, heat/cold systems, etc.). I_{33} Deployment of smart meters in households. I_{34} Installation of BEMs in commercial buildings.
S_4 - Public Lighting	A_{41} Gradual replacement of the existing bulbs in the public lighting with more efficient ones. A_{42} Dimmers depending on ambient conditions. A_{43} Installation of a public lighting management system. A_{44} Study of the municipal lighting.	Not applicable
S_5 - Industry	Not applicable	I_{51} Interventions by the relevant companies, including among others, replacement of boilers or installation of CHP for heating. I_{52} Ventilation with heat recovery. I_{53} Solar cooling for industrial processes. I_{54} BEMS.
S_6 - Municipal Fleet and Public Transport	A_{61} Eco-driving seminars for the drivers of the municipal fleet. A_{62} Replacement of the municipal vehicles with new, more efficient vehicles. A_{63} Converting diesel municipal vehicles to LPG. A_{64} Efficient management of the municipal fleet. A_{65} Municipal fleet maintenance.	Not applicable
S_7 - Private and Commercial Transport	A_{71} Eco-driving promotion in the private transportation. A_{72} Information events on the new vehicle technologies. A_{73} Cycle paths. A_{74} Traffic study. A_{75} Increase the use of public transport and alternative modes of transport. A_{76} Use of biofuels.	I_{71} Adoption of the eco-driving. I_{72} Use of LPG, hybrid, new technology vehicles. I_{73} Use of bikes and public transportation. I_{74} Use of the "car sharing" or "car pooling" concept.
S_8 - Local electricity production	A_{81} Installation of photovoltaic in the municipal buildings. A_{82} Installation of lighting points with photovoltaic panel. A_{83} Promotion of the installation of small PV parks in agricultural lands.	I_{81} Photovoltaics. I_{82} Wind farms. I_{83} Small dams and hydroelectric power plants. I_{84} Power plants using biomass. I_{85} CHP unites using natural gas.
S_9 - Local District Heating / Cooling	A_{91} CHP units using natural gas. A_{92} Heating / cooling production unit using biomass. A_{93} Development / enhancement of district heating network.	Not applicable

Future Estimated Progress of the Consumptions and CO_2 Reductions

The proposed model integrates data from the final energy consumption of each sector for the baseline year, a number of external key parameters, as well as the expected energy and CO_2 emissions reduction from the application of examined renewable energy and rational use of energy actions. The adopted approach for the development of the proposed model was based on experts' engagement though the Delphi method. The Delphi Method includes a structured process for collecting and distilling knowledge from a group of experts by means of a series of questionnaires interspersed with controlled opinion feedback

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

(Adler and Ziglio, 1996). Delphi represents a useful communication device among a group of experts and thus facilitates the formation of a group judgement (Helmer, 1977). According to Fowles study anonymity, controlled feedback, and statistical response characterize Delphi (Fowles, 1978). Delphi Method has been applied to a number of problems, such as primary-energy sources and socio-economic development (de Oliveira Matias and Devezas, 2007) and small-sized biogas systems (Cheng et al., 2014).

More specifically, the adopted approach includes the following steps:

Step 1: Experts' Identification – Identification of a number of key experts, mainly from Austria, Bulgaria, Germany, Greece and Portugal, including the following categories: "Energy agencies, utilities and energy companies", "Planners, developers" and "National, regional, municipal institutions".

Step 2: Questionnaires for the Key Parameters' Selection – The identified experts were asked to evaluate key parameters of each sector (municipal, tertiary, residential, transport, agriculture/forestry/fishery and industry sector). A number of questions was developed. Each question could be answered with only one of the following ways: objective multiple choice marking the desired option with an "x", alternatives' rating based on Likert scale from 1 to 5 (the value of 1 is assigned to the lowest importance/impact and value of 1 is assigned to the highest importance/impact).

Step 3: Questionnaires' Distribution & Analysis – Distribution of the questionnaires to the experts with various methods, such as through email, direct interviews with selected experts, etc. Data gathered from the questionnaires were processed (e.g. use of SPSS Statistics, a software package used for statistical analysis) through the calculation of the descriptive statistics (e.g. averages, standard deviations etc).

Step 4: Development of the Proposed Model – The overall algorithm for the future scenarios was developed.

Step 5: Comments and Feedback from Experts on the Proposed Model – The key experts were asked to comment and provide feedback on the proposed model, generating new ideas and solutions. The responses are compiled and analyzed.

In depth analysis of the key stakeholders in each country was carried out and for each country a number of different experts were identified. A total of 210 experts (national, regional, municipal institutions; energy agencies, utilities and energy companies; planners, developers) were identified. The experts were asked to provide their preferences and options for a number of parameters, such as:

- Rate of population growth at national level by 2020;
- Rate of electricity and fuels prices by 2020;
- Rate of energy consumption growth by 2020 of the tertiary, residential, industry, transport and agriculture sector;
- Rate of per capita gross domestic product by 2020;
- Annual heating and cooling degree days.

The contribution of the key parameters to each sector (tertiary, residential, transport, agriculture/forestry/fishery and industry sector) is described in Table 3:

- **Municipal Buildings, Equipment/Facilities:** The estimated energy consumption of the municipal buildings, equipment and facilities is related to the aggregation of the energy consumption of

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 3. Contribution of each parameter to the estimated energy consumption

	Tertiary	Residential	Industry	Transport	Agriculture/ Forestry/ Fishery
Rate of population growth at municipal level	20%	35%	-	35%	30%
Rate of per capita gross domestic product at municipal level	35%	25%	-	15%	-
Annual heating and cooling degree days at municipal level	10%	10%	-	-	-
Rate of electricity and fuel prices	10%	10%	40%	20%	20%
Rate of energy consumption growth of the relevant sector at national level	25%	20%	60%	25%	50%
Development of the road network	-	-	-	5%	-

each category (schools, municipal buildings and equipment/facilities), taking also into consideration the following parameters:

- **Schools:** Rate of population growth (age 0-19) at municipal level;
- **Municipal Buildings:** Stable energy consumption;
- **Equipment/Facilities:** Rate of population growth at municipal level.

- **Tertiary or Residential Sector:** The estimated energy consumption of the tertiary or residential sector is related to the relevant energy consumption in the baseline year, in combination with a number of local parameters and the rate of energy consumption growth at national level adjusted to the municipal level, as follows:
  - Rate of population growth at municipal level;
  - Rate of per capita gross domestic product growth at municipal level, taking also into consideration a correction factor;
  - Annual heating and cooling degree days at municipal level multiplied by the rate of per capita gross domestic product growth at municipal level and divided by the heating and cooling degree days at national level, respectively;
  - Rate of electricity and fuels prices, taking also into consideration a correction factor;
  - Rate of energy consumption growth by 2020 of the tertiary sector at national level adjusted to the municipal level, according to the following parameters.
  - Per capita gross domestic product at municipal level divided by per capita gross domestic product at national level;
  - Annual heating degree days at municipal level divided by annual heating degree days at national level, taking also into consideration the rate of per capita gross domestic product growth at municipal level;
  - Annual heating degree days at municipal level divided by annual heating degree days at national level, taking also into consideration the rate of per capita gross domestic product growth at municipal level.

It should be noted that the impact of the population growth is considered higher in the residential sector compared to the tertiary sector. On the other hand, the per capita gross domestic product growth will contribute significantly in the estimated energy consumption of the tertiary sector. Moreover, the annual heating degree days have increased impact on the estimated energy consumption for heating (heat-

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

ing oil, natural gas, etc), while the annual cooling degree days contribute significantly to the estimated electricity consumption.

- **Public Lighting:** The rate of population growth at municipal level is the key parameter.
- **Industries:** The estimated energy consumption of the industry sector is related to the energy consumption in the baseline year, in combination with the rate of electricity and fuels prices and the rate of energy consumption growth by 2020 of the industry sector at national level.
- **Municipal Fleet or Public Transport:** The estimated energy consumption of the municipal fleet is considered stable.
- **Private and Commercial Transport:** Similar to the tertiary or residential sector, the estimated energy consumption of the transport sector is related to a number of local parameters and the rate of energy consumption growth at national level, as follows:
  - Rate of population growth at municipal level;
  - Rate of per capita gross domestic product growth at municipal level, taking also into consideration a correction factor;
  - Rate of fuels prices, taking also into consideration a correction factor;
  - Rate of energy consumption growth by 2020 of the transport sector at national level, adjusted to the municipal level according to the per capita gross domestic product at municipal level divided by per capita gross domestic product at national level and a correction factor;
  - Development of the road network.
- **Agriculture/Forestry/Fishery:** The rates of population growth at municipal level, electricity and fuels prices, as well as energy consumption growth by 2020 of the agricultural sector are the key parameters, taking also into consideration the relevant correction factors.

Following the identification of key parameters, the overall algorithm for the future estimated progress of the consumptions and CO_2 reductions was developed (Marinakis et al., 2016).

- EC_{PCT} : Current diesel / gasoline / natural gas / liquid gas consumption in the private and commercial transport.
- $EC_{A-e/d/g/ng}$: Current electricity / diesel / gasoline / natural gas consumption in the agricultural sector.
- PG: Rate of population growth at municipal level.
- PG_{0-19} : Rate of population growth (0-19 years old) at municipal level.
- $P_{e/h/d/ng}$: Rate of electricity / diesel / natural gas price.
- HDD_{M} : Annual heating degree days at municipal level.
- CDD_{M} : Annual cooling degree days at municipal level.
- HDD_{N} : Average value of annual heating degree days at national level.
- CDD_{N} : Average value of annual cooling degree days at national level.
- $HDD_{M/N}$: Annual heating degree days at municipal level / Average value of annual heating degree days at national level.
- $CDD_{M/N}$: Annual cooling degree days at municipal level / Average value of annual cooling degree days at national level.
- GDP_{pcM} : Rate of per capita gross domestic product at municipal level.
- $GDP_{pcM/N}$: Per capita gross domestic product at municipal level / Per capita gross domestic product at national level.
- ECG_{pct} : Rate of energy consumption growth of the transport sector at national level.
- $ECG_{T/R/I/PCT/A}$: Rate of energy consumption growth of the tertiary/residential/industry/private and commercial transport/agricultural sector at national level.
- DV_{rn} : Development index of road network.
- a, b, c: Correction factors (different in each sector).

Stakeholders' Engagement

Stakeholders' engagement in the decision-making process of the Action Plan's elaboration and development is crucial. To this end, a participatory planning approach can be used, in order to have a first evaluation of the alternative scenarios. A mix of qualitative and quantitative techniques are proposed in this step to approach stakeholders, including emailing, phone interviews, face-to-face meetings, questionnaires, focus groups, consultation meetings, workshops.

Aspiration Level

Following the development of alternative scenarios and the participatory planning, all the proposed scenarios are evaluated, initially, through aspiration levels. The approach involves the decision-maker choosing level of the objective that he desires to achieve regarding CO_2 emissions reduction (aspiration level).

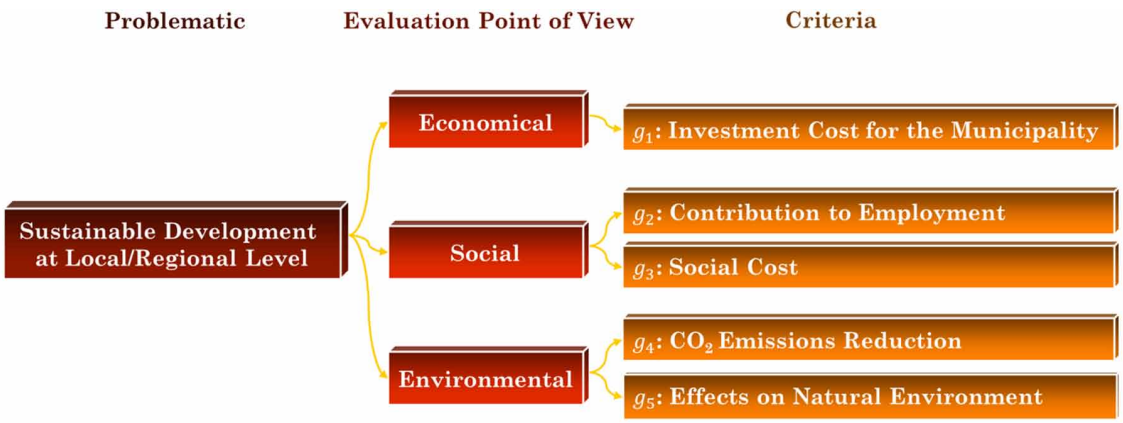
"CHOOSE" COMPONENT

Criteria Selection

A number of criteria have been identified, according to the needs and opportunities of the sustainable development dimensions, namely the economic, social and environmental (Marinakis et al., 2017). The selection of criteria is based on the proposed indicators by the Covenant that could be used by the local authority to describe key actions highlighted as Benchmarks of Excellence. Most of these criteria have been also applied to solve multicriteria problems in other related energy aspects, such as the formulation of sustainable technological energy priorities (Doukas et al., 2010; 2007), identification of sustainable energy technology priorities for electricity generation under Clean Development Mechanism (Karakosta et al., 2009), ranking of renewable energy supply systems (Şengül et al., 2015) and evaluation of thermal-energy storage (Cavallaro, 2010).



The selected criteria satisfy the following requirements: monotony; exhaustiveness; cohesiveness; and non redundancy (Roy, 1985). Under these requirements we ensure consistency of the family. Moreover, the selected criteria are preferentially independent, namely the trade-offs between the g_i and g_j criteria are not dependent on the values of the rest of the criteria (Siskos et al., 2014).

More specifically, the necessary hypothesis to validate an additive value function for a given decision maker is the preferential independence of all criteria.

The identified criteria are the following (Figure 5):

- g_1 – *Investment Cost for the Municipality (Quantitative Criterion - €):* Economic magnitude, expressing the cost for the implementation of renewable energy and rational use of energy actions by the local authorities. The cost may include actions in the municipal buildings, equipment/facilities, public lighting, municipal fleet and public transport, local energy production, as well as awareness raising activities in the agricultural, residential, tertiary sector and transport. The estimated investment cost for the municipality can be calculated by the following equation:

Figure 5. The multicriteria evaluation system

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$IC = \sum_{i=1}^{m}\sum_{k=1}^{l} IC_{A_{ik}} \tag{19}$$

where $IC_{A_{ik}}$ the investment due to the implementation of the action A_{ik} by the local authorities; i represent the number of sector and k the number of action within the relevant sector (S_1 - Agricultural/ Fishery/ Forestry Sector; S_2 - Municipal Buildings, Equipment/ Facilities; S_3 - Residential & Tertiary Sector; S_4 - Public Lighting; S_5 – Industry; S_6 - Municipal Fleet and Public Transport; S_7 - Private and Commercial Transport; S_8 - Local electricity production and S_9 - Local District Heating / Cooling). All the actions A_{ik} are presented in Table 2. The higher the cost of the examined Scenario, the lower is its performance to this criterion.

- g_2 – *Weighted Average Cost of Energy Saving (Quantitative Criterion - €/kWh):* Evaluation of the potential profitability of the examined Scenario through the following equation.

$$\begin{pmatrix}\text{Weighted}\\ \text{Average}\\ \text{Cost of}\\ \text{Energy Saving}\end{pmatrix} = \frac{\begin{pmatrix}\text{Initial Investment}\\ \text{Cost}\end{pmatrix} \text{x} \dfrac{ir}{1-\left(ir+1\right)^{-Duration}} + \begin{pmatrix}\text{Annual Maintenance}\\ \text{Cost}\end{pmatrix}}{\text{Annual Energy Saving}} \tag{20}$$

where ir is the interest rate.

It should be note that this criterion integrates the present value of the Scenarios' cash flow, ensuring in this way the independence property among criteria. It was selected since represents the minimum rate of return at which the authority produces value for its investors. The higher the value of the examined Scenario, the lower is its performance to this criterion.

- g_3 – *Contribution to Employment (Qualitative Criterion):* Reflects the impact of the examined Scenario in the social dimension regarding the creation of new jobs. The employment generated is often divided into two categories: investment (the most employment intensive part) and operation / maintenance (which last for the entire project's lifetime). It is a qualitative criterion and is derived as average value of the proposed actions in each Scenario. The performance of this criterion is assigned based on a 1-5 ordered qualitative scale, namely "1" very low (lower than 1%[1]), "2" low (higher than 1% and lower than 2%[2]), "3" moderate (higher than 2% and lower than 3%[2]), "4" high (higher than 3% and lower than 4%[2]) and "5" very high (higher than 4%[2]) contribution to employment regarding the particular Scenario.
- g_4 – *Social Cost (Quantitative Criterion - €/resident):* Reflects the total investment cost from the interventions of the local population (agricultural and residential sector, transport, etc). The estimated social cost can be calculated by the following equation:

$$IC = \sum_{i=1}^{m}\sum_{k=1}^{l} IC_{I_{ik}} \tag{21}$$

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

where $IC_{I_{ik}}$ the social cost due to the implementation of the intervention I_{ik} by the local population. i represent the number of sector and k the number of action within the relevant sector. All the actions I_{ik} are presented in Table 2. The higher the social cost of the examined Scenario, the lower is its performance to this criterion.

- $g_5 - CO_2$ *Emissions Reduction (Quantitative Criterion - %):* Estimated reduction of the CO_2 emissions that will be achieved through the implementation of all the proposed renewable energy and rational use of energy actions of each Scenario by 2020. The calculation of this criterion is based on the following data:
  - Development of the baseline *emission* inventory;
  - Estimation of the total CO_2 emissions reduction by 2020 using the calculations for the energy saving and production and related emissions factors.

$$CO2_{\%} = \frac{CO2_{base} - CO2_{reduction}}{CO2_{base}}$$

$$CO2_{base} = \sum_{i=1}^{m}\sum_{j=1}^{n} EC_{S_i j}\, x\, EF_j$$

$$CO2_{reduction} = \sum_{i=1}^{m}\sum_{j=1}^{n}\left(\sum_{k=1}^{l} ER_{A_{ik}j}\, x\, EF_i + \sum_{k=1}^{l} ER_{I_{ik}j}\, x\, EF_i\right) \quad (22)$$

where:

$CO2_{\%}$: Percentage of CO_2 emissions reduction due to the implementation of the Scenario (%)

$CO2_{base}$: Total CO_2 emissions in the baseline year ($tnCO_2$)

$CO2_{reduction}$: Total CO_2 emissions reduction due to the implementation of the Scenario ($tnCO_2$)

$EC_{S_i j}$: Consumption of the type of energy j in the sector S_i (MWh); for j = 1: electricity, 2: heat/cold, 3: natural gas, 4: liquid gas, 5: heating oil, 6: diesel, 7: gasoline, 8: biomass, 9: solar thermal, 10: electricity, 11: other.

EF_j : Emission factor for the type of energy j ($tnCO_2$/MWh).

$ER_{A_{ik}j}$, $ER_{I_{ik}j}$: Energy reduction of the type of energy j due to the energy saving/production of the action A_{ik} and / or the intervention I_{ik} .

The higher the emissions reductions of the examined Scenario, the higher is its performance to this criterion.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

- g_6 – *Effects on Natural Environment (Qualitative Criterion):* Reflects the Scenarios' interference level regarding the natural environment (e.g. visual intrusion, pressure on land resources and excessive land use). The performance of this criterion is assigned based on a 1-5 ordered qualitative scale, namely "1" very high, "2" high, "3" moderate, "4" low and "5" very low impact regarding the particular Scenario.

Following the criteria descriptions, the relevant evaluation scales are depicted in Table 4.

Multicriteria Ordinal Regression Approach

An additive value model is proposed. A number of methods to obtain the proposed value system can be found in the literature (Figueira et al., 2005; Keeney, 1992; Farquhar, 1984), which requires explicit trade-offs between economic, political and social criteria. Taking into account the amount of cognitive effort needed, or for ethical reasons, their application in real world decision environments remains questionable. To this end, the analysts prefer to infer the additive value model from global preference structures, by applying disaggregation or ordinal regression methods. A survey of these methods and synergy of methods for the assessment of additive value models was recently presented by Hurson and Siskos (2014), such as MACBETH technique, the standard MAUT trade-off analysis and UTA-based methods (UTA I, UTA II, UTAGMS, GRIP, RUTA, etc.). UTA methods not only adopt the aggregation disaggregation principles, but they may also be considered as the main initiative and the most representative example of preference disaggregation theory (Siskos, 2005).

The proposed additive value model is described by the following form:

$$\mathrm{u}\left(\mathbf{g}\right) = \sum_{i=1}^{n} p_i u_i\left(g_i\right) \tag{23}$$

subject to normalization constraints:

$$\sum_{i=1}^{n} p_i = 1$$

Table 4. Criteria evaluation scale

	Index	Worst Level	Best Level
G1	Quantitative (€)	120,000,000	0
G2	Quantitative (€/kWh)	0.2	0
G3	Qualitative	1	5
G4	Quantitative (€/resident)	2,000	0
G5	Quantitative (%)	20	100
G6	Qualitative	1	5

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$u_i\left(g_{i_*}\right)=0\,,\ u_i\left(g_{i^*}\right)=1,\forall i=1,2,\ldots,n \tag{24}$$

where $\boldsymbol{g}=\left(g_1,g_2,\ldots,g_n\right)$ is the performance vector of an alternative scenario on the n criteria; g_{i_*} and g_{i^*} are the least and most preferable levels of the criterion g_i, respectively; $u_i, i=1,2,\ldots n$ are non-decreasing real valued functions, named marginal value or utility functions, which are normalized between 0 and 1, and p_i is the relative weight of u_i.

Both the marginal and the global value functions have the monotonicity property of the true criterion. For instance, in the case of the global value function the following properties hold:

$$u\left[\boldsymbol{g}\left(a\right)\right]>u\left[\boldsymbol{g}\left(b\right)\right] ifa\succ b\left(preference\right)$$

$$u\left[\boldsymbol{g}\left(a\right)\right]=u\left[\boldsymbol{g}\left(b\right)\right] ifa\sim b\left(indifference\right) \tag{25}$$

The existence of the preference model assumes the preferential independence of the criteria for the decision maker (Keeney and Raiffa, 1976), while other conditions for additivity have been proposed by Fishburn (1966, 1967). This assumption does not pose significant problems in a posteriori analyses such as disaggregation analyses.

A number of methods to obtain the proposed value system can be found in the literature (Figueira et al., 2005; Keeney, 1992; Farquhar, 1984), which requires explicit trade-offs between economic, political and social criteria. Taking into account the amount of cognitive effort needed, or for ethical reasons, their application in real world decision environments remains questionable.

To this end, the analysts prefers to infer the additive value model from global preference structures, by applying disaggregation or ordinal regression methods. A survey of these methods and synergy of methods for the assessment of additive value models is recently presented by Hurson and Siskos (2014), such as MACBETH technique, the standard MAUT trade-off analysis and UTA-based methods (UTA I, UTA II, UTAGMS, GRIP, RUTA, etc).

Over the past three decades UTA-based methods have been applied in several real-world decision-making problems (see Siskos et al., 2005 for a comprehensive survey on UTA methods and applications), with the most recent efforts focused on e-government (Siskos et al., 2013; 2014). Although, UTA method has been applied to a number of problems regarding sustainable development, such as energy efficiency, wastewater treatment and environmental issues (Sola & Mota, 2012; Demesouka et al., 2013; Kholghi, 2001), there are not studies regarding sustainable energy planning at local / regional level.

In this context, a flexible and transparent approach is the UTA II method, proposed by Siskos J. (1980), which has been used for the examined decision aiding problem. This method aims at inferring one or more additive value functions from a given ranking on a reference set of actions A_R (Jacquet-Lagrèze and Siskos, 1982). It uses special linear programming techniques to assess these functions so that the ranking(s) obtained through these functions on A_R is as consistent as possible with the given one. UTA II method includes the following two phases:

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

- *Phase I: Construction of the marginal value functions* $u_i\left(g_i\right)$. The idea of least square approximation is used, in order to fit a polynomial function P(x) to a set of data points (x_i, y_i) having a number of theoretical solution (provided by the decision maker through an interactive process).
- *Phase II: Estimation of the criteria weights* p_i
  - Selection of a reference set*:* For the construction of the reference set by the analyst, virtual scenarios are selected. The decision maker is asked to provide a ranking (weak order) of the virtual scenarios. In each comparison, the two scenarios are differed in two or at most three criteria values, so as to be possible by the decision maker to evaluate the scenarios. As result, the scenarios of the reference set $A_R = \left\{a_1, a_2, \ldots, a_m\right\}$ are rearranged in such a way that $a_i \succ a_{i+1}$ or $a_i \sim a_{i+1}$.
  - Linear programming techniques*:* UTA II introduces two error functions σ^+ and σ^- on A_R by writing for each pair of consecutive actions in the ranking the analytic expressions:

$$\Delta\left(a_i, a_{i+1}\right) = \sum_{i=1}^{n} p_i \left\{u_i\left[g_i\left(a_i\right)\right] - u_i\left[g_i\left(a_{i+1}\right)\right]\right\} - \sigma^+\left(a_i\right) + \sigma^-\left(a_i\right) + \sigma^+\left(a_{i+1}\right) - \sigma^-\left(a_{i+1}\right) \quad (26)$$

where:
$a_i \in A_R$ and $\sigma^+\left(a_i\right), \sigma^-\left(a_i\right)$ are the overestimation and the underestimation error respectively.
Then, the following linear program is solved:

$$\left[min\right] F = \sum_{i=1}^{m} \sigma^+\left(a_i\right) + \sigma^-\left(a_i\right)$$

subject to:

$$\Delta\left(a_i, a_{i+1}\right) \geq \delta, if\ a_i \succ a_{i=1}$$

$$\Delta\left(a_i, a_{i+1}\right) = 0, if\ a_i \sim a_{i=1}$$

$$\sum_{i=1}^{n} p_i = 1,\ p_i \geq 0\ ,\sigma^+\left(a_i\right) \geq 0, \sigma^-\left(a_i\right) \geq 0\ \forall a_i \in A_R$$

with δ being a small positive number. (27)

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Moreover, the existence of multiple or near optimal solutions of the above linear program is evaluated. To this end, the mean additive value function of near optimal solutions which maximize the functions $u_i\left(g_i^*\right)$ on the polyhedron of the constraints of the linear program (8) is calculated.

Robustness Analysis

Another important issue is the robustness of the evaluation model. UTA^{GMS}, GRIP, RUTA, extreme ranking analysis and the robustness measurement control are the most recent UTA-type methods (Greco et al., 2008; Figueira et al., 2009; Kadzinski et al., 2013; Kadzinski et al. (2012); Kadzinski & Tervonen, 2013a, 2013b; Greco et al., 2012). In this context, the adopted approach search for multiple solutions based on the use of the extreme ranking analysis of Kadzinski et al. (2012). The approach evaluates the performance of each alternative relative to all other alternatives in a reference set A, determining the best and the worst ranks, and the score that an alternative can attain.

In order to identify the highest rank of an alternative in the ranking provided by any compatible value function (or any compatible outranking mode) the following mixed integer linear program is calculated:

$$\left[min\right]F = \sum_{b \in A \setminus \left\{a\right\}} u_b$$

Subject to:

$$E_u^{A_R}$$

$$U\left(a\right) \geq U\left(b\right) - Mv_b$$

$$\text{for all } b \in A \setminus \left\{a\right\} \tag{28}$$

where M is an auxiliary variable equal to a big positive value and v_b is a new binary variable associated with comparison of a to alternative b. In order to identify the lowest rank of an alternative in the ranking provided by any compatible value function (or any compatible outranking mode) the following mixed integer linear program is calculated:

$$\left[min\right]F = \sum_{b \in A \setminus \left\{a\right\}} u_b$$

Subject to:

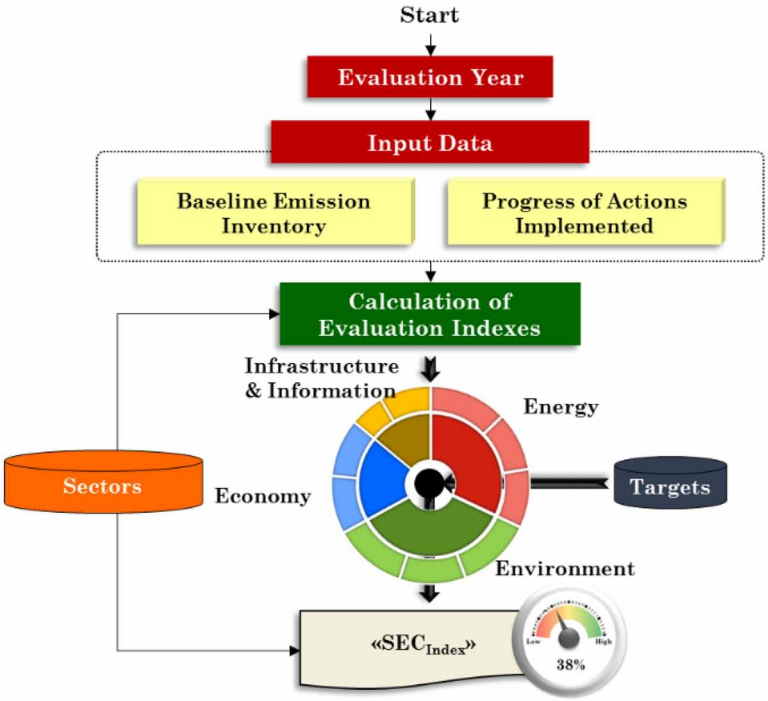
$$E_u^{A_R}$$

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$U\left(b\right) \geq U\left(a\right) + \varepsilon - Mv_b$$

for all $b \in A \setminus \left\{a\right\}$ (29)

where M is an auxiliary variable equal to a big positive value, ε is equal to a small positive value, and v_b is a new binary variable associated with comparison of a to alternative b.



"CHECK" COMPONENT

The final stage of the proposed framework includes the "Methodological Approach for Monitoring SEC Targets". The overall philosophy of the proposed approach is presented in Figure 6.

Indicators

The methodological approach consists of monitoring indicators that are structured in four main categories "Energy", "Environment", "Economy"," Infrastructure and ICT". Table 5 presents the indicators (I_{ij}) for each category "i".

Figure 6. Philosophy of the methodological approach for monitoring SEC targets

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 5. Monitoring indicators

Symbol	Evaluation Indicators
I_1	**Energy**
I_{11}	Energy consumption per capita
I_{12}	Electricity use in final energy consumption
I_{13}	Use of fossil fuels in final energy consumption
I_2	**Environment**
I_{21}	CO_2 emissions per capita
I_{22}	CO_2 emission intensity
I_{23}	Use of renewable energy sources
I_3	**Economy**
I_{31}	Total budget spent
I_{32}	Actions funding through external sources
I_4	**Infrastructure and ICT**
I_{41}	Level of integration of automations, smart meters and ICT solutions
I_{42}	Level of awareness

The indicators are described more extensively in Table 6.

The analysis descripted before, is summarized in the following Figure 7.

Description of the "SEC_{Index}"

The composite index "SEC_{Index} (Sustainable Energy Community Index)" was introduced. The procedure for the development of the "SEC_{Index}" was based on a "proximity-to-target" approach. More specifically, for each indicator, the distance from the setting target is calculated. Thus, the values of the evaluation indicators are transformed into a scale of "0-100" with "100" to be the maximum efficiency and "0" the minimum efficiency.

The "SEC_{Index}" is calculated based on a cumulative two-scale procedure. By taking as reference the ten evaluation indicators; the scores of the four categories are calculated, and thus the "SEC_{Index}" composite index. It is noted that each evaluation indicator is assessed in each category with a different weighting factor. The determination of the weighting factors is completed with the participation of experts, through filling in appropriate questionnaires (in parallel with the procedure that was followed for the equations of the future estimated progress of the consumptions and CO_2 reductions. The values of the weighting factors are shown in Table 7.

Based on the previous analysis, the equation for the calculation of the "SEC_{Index}" in each activity sector is the following:

$$SEC_{Index_k} = \sum_{i=1}^{4} \sum_{j=1}^{2\blacklozenge3} w_{ij} \frac{I_{evaluation_ij} - I_{base_ij}}{I_{target_ij} - I_{base_ij}} \tag{30}$$

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 6. Description of the monitoring indicators

I_{11}: Energy Consumption Per Capita	
Description	It reflects the final consumption of energy in each sector of the municipality.
Calculation	It comes as a result of the sum of individual consumptions per type of energy, divided with the total population of the municipality during the year of evaluation.
Units	MWh/capita
I_{12}: Use of Electricity in the Final Energy Consumption	
Description	It expresses the percentage of electricity usage in the final energy consumption.
Calculation	It comes as a result of the electricity energy consumption, divided by the total energy consumption in the sector of interest.
Units	Percentage (%)
I_{13}: Use of Fossil Fuels in Final Energy Consumption	
Description	It reflects the percentage of fossil fuel (gasoline, heat oil, diesel, etc.) in final energy consumption.
Calculation	It comes as a result of the consumption of fossil fuels, divided by the total energy consumption in the specific sector.
Units	Percentage (%)
I_{21}: CO_2 Emissions Per Capita	
Description	It indicates the total CO_2 emission in the specific area
Calculation	It comes as a result of the sum of CO_2 emission per form of energy, divided by the total population of the municipality during the year of evaluation.
Units	$tnCO_2$/capita
I_{22}: CO_2 Emissions Intensity	
Description	It expresses the scale of CO_2 emission per unit of consumption.
Calculation	It comes as a result of the sum of CO_2 emission per energy form, divided by the total energy consumption.
Units	$tnCO_2$/MWh
I_{23}: Use of Renewable Energy Sources	
Description	It reflects the penetration of renewable energy sources in the area.
Calculation	It comes as a result of the total production of energy from renewable energy sources (for electricity and heat/cooling), divided by the total population of the area during the year of evaluation.
Units	MWh/capita
I_{31}: Total Budget Spent	
Description	It indicates the total budget that has been exploited for the implementation of the expected measures and actions in each sector of activation.
Calculation	It comes as a result of the total budget spent, divided with the total population of the year during the year of evaluation.
Units	€/capita
I_{32}: Actions Funding Through External Sources	
Description	It indicates the total amount of funding for action through external sources.
Calculation	It comes as a result of the total amount of funding, divided with the total population of the area during the year of evaluation.
Units	€/capita
I_{41}: Level of Integration of Automations, Smart Meters and ICT Solutions	
Description	It expresses the level of integration of Automations, Smart Meters and ICT Solutions, etc.
Calculation	It comes as a result of the total energy monitored by the smart meters, BEMS, ICT, divided with the total energy consumption.
Units	Percentage (%)
I_{42}: Level of Awareness	
Description	It reflects all the final users in each sector that have participated in actions of orientation and awareness.
Calculation	It comes as a result of the percentage of final users that have participated in actions of orientation and awareness.
Units	Percentage (%)

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 7. Monitoring indicators

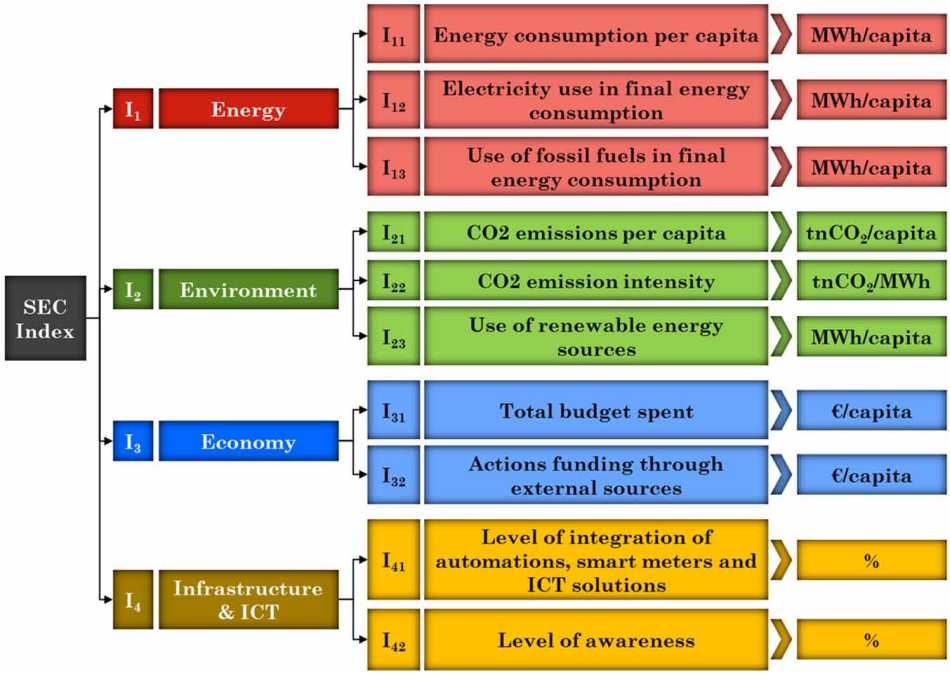


Table 7. Weights of the monitoring indicators

Category	Monitoring Indicator	Weight
Energy (32%)	Per capita energy consumption	12,8%
	Percentage of electricity use in final energy consumption	9,6%
	Percentage of fossil fuel use in final energy consumption	9,6%
Environment (35%)	Per capita CO_2 emissions	12,25%
	CO_2 emission intensity	10,85%
	Use of renewable energy sources	11,9%
Economy (19%)	Total budget spent	9,5%
	Percentage of funding from external sources	9,5%
Infrastructure & Information (14%)	Level of integration of automations, smart meters and ICT solutions	5,6%
	Level of awareness	8,4%

where:

SEC_{Index_k} The value of the complex index "SEC_{Index}" for each activity sector k

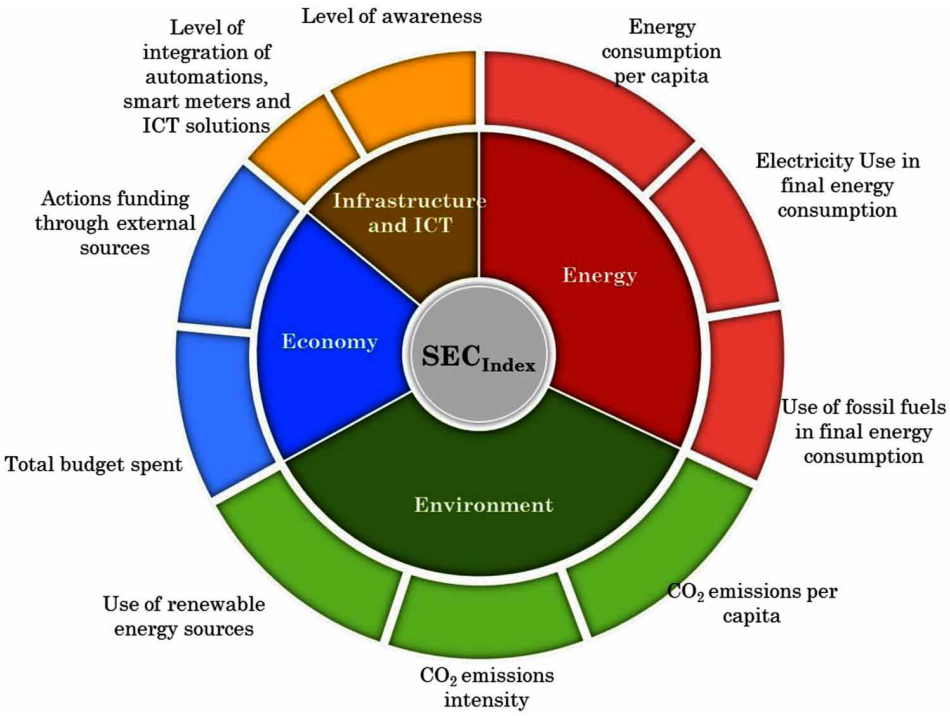
w_{ij} The weighting factor of index j of category i

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

I_{target_ij} The target for evaluation index I_{ij}

I_{base_ij} The value of evaluation index I_{ij} for the base year

$I_{evaluation_ij}$ The value of evaluation index I_{ij} for the evaluation year



Thus, the "SEC_{Index}" index shows the progress achieved in the specific activity sector in regards to the accomplishment of the targets which were defined during the development of the Sustainable Energy and Climate Action Plan (Figure 8).

Finally, for better visualization of the final results, the following graph is used (Figure 9). It is noted that based on the values of "SEC_{Index}" of each activity sector, it is possible to calculate the total "SEC_{Index}" of the municipality.

CONCLUSION

The potential replication of the proposed framework relies on the necessity for the cities and communities to create their Sustainable Energy and Climate Action Plan. This stepwise framework, which

Figure 8. General philosophy of the "Methodological Framework for Approach SEC Targets"

Figure 9. Visualization of the final results from the "SECIndex" index

guides the local and regional authorities in the development of the alternative Scenarios for the region and their evaluation, is simple, concise and comprehensive. The MPC+ framework can be widely used by and support different types of municipalities. Moreover, its general formation is strictly based on the Guidelines provided by the Covenant of Mayors, while it has been enhanced with additional aspects, as summarized below:

- Integration of the multicriteria analysis and robustness analysis in the Action Plan's development, providing a comprehensive evaluation of alternative Scenarios; support to the decision making for the selection of the most appropriate sustainable renewable energy and rational use of energy technologies for the Sustainable Energy and Climate Action Plan.
- A knowledge-based process for the initial design of alternative Scenarios in the region, taking into consideration its specific characteristics and main priorities (energy baseline, etc.).
- Integration of the local stakeholders' views on the formulation of alternative Scenarios for the region, raising the public awareness and making their citizens more self-conscious about the energy they consume and the new projects in the area.

ACKNOWLEDGMENT

A part of the current chapter was based on the relevant activities conducted within the framework of the project "Rural Web Energy Learning Network for Action – eReNet (Project no: IEE/10/224/SI2.593412), supported by the Intelligent Energy – Europe (IEE) Programme. The content of the chapter is the sole responsibility of its author and does not necessary reflect the views of the EC.

Chapter 18
Enablers of Sustainable Manufacturing Overview, Framework and Further Research Directions

Shibin K. T.
Symbiosis International University, India

ABSTRACT

The aim of this paper is to develop a conceptual sustainable manufacturing (SM) framework, which is the pressing need of highly competitive and natural resource scarce world. Systematic literature review has been adopted to identify enablers of SM. The enablers identified through systematic literature review includes product design, material selection & procurement, customer requirements, regulatory norms, social values & ethics, environmental priorities, energy costs, natural resource scarcity, supply chain & logistics systems, fuel price regulations, public awareness, technology and total quality management. Author has attempted to develop a contextual relationship among enablers of SM using interpretive structural modeling. The author has further classified enablers into four categories using MICMAC analysis. The author has also outlined the limitations of present study and identified further research directions.

1. INTRODUCTION

Sustainable manufacturing is the need of the current era as global warming, manmade pollution and natural resource scarcity are becoming like a sword of Damocles to the world. Insights from the literature on the topic show that, sustainability in manufacturing must be taken into consideration from the product design stage through production to the logistics stage. Sustainability has got three aspects in manufacturing. These aspects includes: 1) the manufacturing sustainability in the production process; 2) sustainability during the use of the product, 3) sustainability for the recycling and logistics point of view. We can say that product design, material selection, manufacturing process design and resource

utilization as the factors of first aspect; environmental emission from the product, ease of maintenance etc. as the factors of second aspect and ease of disassembly, recyclability, reusability of materials as the factors of third aspect. According to Garbie (2014); Carter and Easton (2011); Dyllick and Hockerts (2002), Environment, society and economy are the three widely accepted components of sustainability. Manufacturing can be defined as the process of converting raw materials into value added useful tangible finished products for a specific use through one or more operations. Hence, sustainable manufacturing can be defined as the innovative technology and organizational practices which ensures zero negative impact to the environment, community, employees with the minimum use of raw materials and energy and which produces high quality recyclable finished products. Different viewpoints and definitions on sustainability and sustainable development from different literature are listed in Table 1. Through

Table 1. Definitions of Sustainability

Author(s), (Year)	Definition
IPCC, Copenhagen, Denmark (2014).	Sustainable Development is defined as the one which is based on three pillars such as economic, social and environmental and preserves the interests of future generations and ecosystem services and balance on which the existence of human kind is dependent on.
Institute for Sustainability (2011)	Sustainability can be defined as increasing the productivity by minimizing the resources used without compromising on service quality, profitability and competitiveness to help to preserve the environment.
Jayal et al. (2010)	Sustainability is the term which can be achieved only through an integrated approach incorporating closed loop supply chain, manufacturing process and systems, multiple product life-cycles etc. at product process and system levels with the objective of reduce, reuse, recover, redesign, remanufacture and recycle.
Ciceri et al. (2010)	Sustainability is a quality which helps to preserve, save and keep.
Hutton et al. (2007)	Sustainable development can be defined as the one which helps to fulfill the needs of the present without compromising the capability of the future to fulfill their own needs.
Barber (2007)	Sustainable production and consumption is defined as the system which helps to meet the human needs and improve the quality of life through social and economic improvement for all, including future generations, while maintaining the ecosystems on which human life is depended up on.
Asheim et al. (2007)	Sustainability is defined by using the framework of ethical social choice theory and explains that sustainable behavior is the ethically justifiable treatment of all future generations with equity and efficient consistent consumption of natural resources.
Seliger (2007)	Sustainability is defined as the direction in which the living standards of human being is improved at the same time the availability of natural resources and ecosystems are also preserved and improved for future generations.
Jenkins and Yakovleva (2006)	Sustainable development is defined as the progress in economic development, environmental protection and social consistency.
Szekely and Knirsch (2005)	Sustainability is the process by which organizations amalgamate their social, economic and environmental objectives with the organization strategic goals and balances all these three dimensions in an optimum way.
Stavins et al. (2003)	Sustainable growth is defined in an economic framework as the one which is both dynamically efficient and non-decreasing over time.
Deloitte and Touche (1992)	Sustainability can be defined as the process of adopting new business strategies and ideas which will fulfill today' needs of the organization and all other stakeholders, which will protect, sustain and enhance all natural and human resources for the requirement of the future.
UN - The World Commission on Environment and Development (1987)	Sustainable development can be defined as the usage of resources, investment guidelines, technological advancement and organizational changes are made to meet the need of the present as well as of future generations consistently.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

systematic literature review, the authors have identified twelve key driving factors of sustainable manufacturing. Since these factors are much broad in their sense, sub-dimensions of these variables are also elaborated from literature.

2. LITERATURE REVIEW

As a part of systematic literature review, the authors started the review from analyzing the history of manufacturing itself, which helps to give insights into the evolution of sustainable manufacturing. According to Brundtland Commission (1987), the word sustainable implies the use of consistent practices which will ensure zero negative repercussions to the future generations due to the prevailing practices. Davidson et al. (2010) foresee the need to educate future engineers and new generation about sustainable development (SD) practices by including SD workshops and educational materials in their curriculum to meet increasing environmental, resource scarcity and social threats of 21st century. Miller et al. (2010) show how the theories of sustainable manufacturing help to attain competitive advantage for a small scale industry through waste reduction, supply chain network optimization and recycling of waste materials by using discrete event simulation and mathematical modeling technique. Pham and Thomas (2011) and Thomas et al. (2012) also explain the sustainability issues with small and medium scale industries and propose a fit manufacturing strategy starting from strategy development through financial planning to operationalization with one team one vision for better coordination. Joung et al. (2013) classifies the sustainability indicators into five major enablers of sustainable manufacturing such as environmental, social, economic, technology and performance but didn't go in detail about the interrelationship among the indicators.

2.1. Evolution of Sustainable Manufacturing

At the start of industrial revolution in the 17th century, the one and only one objective of manufacturers was to somehow explore the available natural resources and to convert them into to useful end products to meet the human need. As time passed, during the era of 18th century, manufactures tried to increase efficiency and productivity through automation and scientific industrial engineering techniques. As the living standard of people and the competition between manufactures increased, the major focus was on the product quality and price control during the 19th century. Pressure of competition forced manufactures to strive for excellence through various manufacturing concepts such as world class, agile, flexible, lean, and green manufacturing techniques. Jin-Hai et al. (2003) and Parkinson (1999) define agile manufacturing as a concept which is driven by competition and is designed to meet quickly changing customer tastes with a faster response rate and more flexibility. Slack (2005); Kaighobadi and Venkatesh (1994) explain the concept of flexible manufacturing systems as the one which helps manufactures to have wider variety and faster response to market changes and to get economic advantage of batch manufacturing through technology flexibility, labor flexibility and infrastructure flexibility. Hayes and Wheelwright (1985) classified manufacturing organizations into four stages, and used the term "world class manufacturing firms" for the first time, to refer to the fourth stage organizations. According to Hayes and Wheelwright, those organizations which are very progressive and having long range business plans through continuous improvement and newer technologies and strive to make manufacturing

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

as a major competitive success factor of the organization can be called as world class organizations. The next challenge was to quantify the term world class, which resulted to the origin of a new term known as 'lean manufacturing'. Oliver et al. (1996); Pettersen (2009) and Womack et al. (1990) define lean as a management concept originated from Japan's Toyota Production System (TPS) which tries to minimize wastage or non-value adding processes and use less of everything including inventory through techniques such as Just in Time (JIT) to produce high quality products. According to National Oceanic and Atmospheric Administration report published in 2005, since industrial revolution there is a 35% increase in the level of carbon dioxide all over the world within a period of three centuries. Houe and Grabot (2009) show that the increased customer awareness on environmental issues forced companies for go for more natural friendly products and production processes. To get competitive advantage, Zhu et al. (2007) emphasizes that: with the new regulatory norms put by various governments to reduce carbon emissions and to control global warming also forced manufactures to shift their manufacturing strategy from merely output based to a more environmental friendly one. This resulted in the evolution of green manufacturing concept. Dubey and Bag (2014) define green manufacturing concept as the one which intends to achieve environmental sustainability and to minimize carbon emission by eliminating environmentally harmful wastages and using innovative technologies to change the existing processes. Deif (2011) elaborates the green manufacturing concept as the one which is eco-efficient, uses less non-toxic energy and material which produces no unwanted outputs and byproducts, and output to input conversion is possible. Sustainable manufacturing philosophy is evolved in twentieth century, which considers not only the environment like green manufacturing; but all other factors such as social and economic. Garbie (2014); Garetti and Taisch (2011) explicitly state that the three pillars of sustainability includes social, environment and economic. Molamohamadi and Ismail (2013) propose to add technology, education, ethic and accountability along with the main three pillars of social, environment and economic. Jayal et al. (2010) differentiates all these manufacturing concepts more clearly and in a very simple way as: traditional manufacturing is substitution-based; lean-manufacturing as waste reduction based; green manufacturing as environmentally begin and based on 3Rs such as Reduce, Reuse and Recycle; and finally sustainable manufacturing as based on 6R such as Reduce, Reuse, Recycle, Recover, Redesign, and Remanufacture with innovation. Kuik et al. (2011) further develop a clear framework by dividing the first 3Rs of Reuse, Recover and Redesign for product design and Reduce, Recycle and Remanufacture for process improvement towards the journey to sustainability. Stoughton and Ludema (2012) use a grounded theory approach to model and analyze perceptions of sustainability at senior leadership level, functional level and individual level of an organization and how to integrate all these views to achieve sustainable development within an organization. Literature reviewed on sustainable manufacturing and the brief description regarding the objective and findings of each paper is described in Table 2.

2.2. Classification of Literature

All the literature are classified under four broad pillars of sustainable manufacturing such as economy, social, environment and technology based on ESET context proposed by Jovane et al. (2008). According to the global survey conducted by Kiron et al. (2013) from MIT Sloan Management Review and the Boston Consulting group, shows that the main three social issues in achieving sustainability as the health and well-being of employees, the community and customers; the top most environmental issues in achieving sustainability as energy efficiency, pollution and waste management and the top most economic concern in achieving sustainability as competitiveness. According to Kara et al. (2014), even though the sustain-

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Research in Sustainable Manufacturing

Author(s), (Year)	Research Objective	Research Findings
Garbie (2014)	To model the components of sustainable manufacturing and to make a performance assessment framework up to sustainable development level from a micro-level point of view based on the three pillars of social, economic and environment.	Sustainable development index is developed by considering social, environmental and economic factors. Using analytical hierarchy Process weight of each sub-factors under each pillars are found out.
Garetti et al. (2012)	To identify the main aspects of sustainable manufacturing from literature review.	Review of selected papers is done and different viewpoints of sustainable manufacturing systems are explained.
Gunasekaran and Spalanzani (2012)	To build a framework for sustainable business development by using the methodology of literature review.	A classical review is made which helps to give the research areas and techniques used in sustainable business development in manufacturing and service. A framework is made for sustainable business development in service and manufacturing through literature review technique.
Garetti and Taisch (2011)	To make the roadmap and strategy for the manufacturing research by 2020 for achieving smart, sustainable and inclusive growth.	Sustainable manufacturing framework is made with technology and education as enablers and by using four broad research clusters for sustainable manufacturing.
Jayal et al. (2010)	To present an overview of recent trends in sustainable manufacturing product, process and system development.	Evolution of sustainable manufacturing is explained with the 6R concept for sustainable manufacturing product, process and systems development. Performance measurement for processes for achieving sustainability is also explored by the author.
Garbie (2013)	Development of enterprise level sustainability model for manufacturing firms, to become globalized sustainable enterprise in economic point of view.	Mathematically modeled the sustainability index by considering seven factors and suggests considering the sustainability from the starting of the design of an enterprise itself.
Davies and Kochar (2002)	To review the methodologies adopted so far to define the best practices in the manufacturing industry and to find out how these best practices can be used to improve the company performance.	A particular common best practice method can't be applied to all types of industries in general. Best practices must be tailor made to best suit to the particular company under study. Effectiveness of best practices must be evaluated by checking the overall performance improvement of the company.
Azzone and Noci (1998)	To define different green manufacturing strategies and to analyze, how to make an environmental performance measurement system framework for various green manufacturing strategies.	Environmental performance measurement system (PMS) design architecture is developed for each manufacturing strategies and concludes that it is more difficult to design PMS in pro-active companies rather than re-active companies.

able product design strategy is different for different companies based on their size, regional location etc. some common driving factors are considered by every manufactures for sustainable product development, which include: customer awareness, legislation, economic benefits and competitive strategies and life cycle assessment. So, all the driving factors of sustainable manufacturing identified through systematic literature review are classified under these four different dimensions. Environment dimension includes Environmental priorities, Natural resource scarcity; Social dimension includes Regulatory norms, Fuel price regulations, Public awareness, Social values & ethics; Economic dimension includes Material selection & procurement, Energy costs and Technology & Operations includes Customer requirements, Product design, Supply chain & logistics systems and Technology & total quality management.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

2.2.1. Environment Dimension

Most of the literature reviewed on sustainability gives very high weightage for environment factor. The main factors discussed under environment dimension are carbon footprint concerns and the requirements for energy efficiency. Intergovernmental Panel on Climate Change Copenhagen, Denmark (2014) demands the full stoppage of fossil fuel usage by 2100, to control the world carbon footprint. According to Gotschol et al. (2014) environmental management is an economically sustainable business, because any investment in environmental management programs helps to gain economic benefits for companies in their long run. Flint and Golicic (2009) explain the success story of carbon zero certification program for wine companies in New Zealand, for achieving zero carbon footprint and environmental awareness and habitat rehabilitation programs to achieve sustainability. Halldorsson and Kovacs (2010) illustrate the importance of energy efficiency and minimizing carbon footprint in logistics and supply chain context. All 'green' concepts are fundamentally based on eco-friendliness concept and thus can be classified under the environment pillar of sustainability. According to Deif (2011); Houe and Grabot (2009), companies must consider the term 'green' as a tool for achieving competitive advantage to go global and to increase the market share as today's highly educated and highly aware customers prefer eco-friendly products. Unruh and Ettenson (2011) mention three ways to achieve green goals such as "accentuate" which means the re-positioning of the existing product portfolio by extending green attributes; "acquire", which means the complete acquirement of an existing green company and their product portfolios; "architect", which means the building of new green products from scratch. They also add that, going green doesn't mean that companies have to sacrifice their profit margin, but rather it improves the profitability through waste minimization and recycling of products and byproducts. In a case study from the wine industry in United States, Cholette and Venkat (2009) show the need to incorporate third party logistics providers in the supply chain network, the need to optimize the package, route and load of transport system and the need to encourage direct delivery of end products to consumers to minimize carbon emissions and maximize energy efficiency. According to Wu and Pagell (2011) environmental strategies adopted by organizations have a direct impact on the supply chain and competitiveness of the organization. They also adds that top level managers should benchmark and get insights from the practices and policies that are successfully implemented in top leading companies in achieving sustainability in their own organization. Law and Gunasekaran (2012) illustrates the need of clear strategic level policy and the need of coordination of the strategic level team with the tactic and operations levels of the organization for the introduction and implementation of sustainable development in an organization. According to Rimanoczy and Pearson (2010), change in organizational culture is required to achieve the sustainability goals of profit, people and planet and human resource department has a major role in institutionalization of sustainability. According to Dekker et al. (2012), in supply chain, transportation is the most important factor with respect to environment. Because transportation accounts fourteen percentages of total CO_2 emissions across the globe and the three factors such as mode of transportation, type and size of transportation unit and fuel choice must be optimized to minimize the CO_2 emissions. Edwards et al. (2010) indicates that e-commerce and online shopping practices has got the advantage of lesser carbon footprint than conventional shopping practices in logistics and supply chain aspect. According to Ramani et al. (2010), sustainability view point must be considered from the early stage of the design itself and along with Design for Assembly and Manufacturing (DFAM), Design for Environment (DFE) must also be carried out. Gudmundsson and Roheim (2000) explain the effective way of using

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

the eco-labeling practice to maintain sustainable fisheries resource, which can be carried over for other resources as well to encourage customer to go for environmentally sustainable products.

Kaebernick et al. (2003), illustrates a four step methodology for sustainable product development which include: 1) making environmental awareness to consumers 2) assessing environmental performance as a design objective by modifying quality function deployment matrix into environmentally conscious quality function deployment matrix 3) conducting life cycle assessment during design process 4) evaluating the recycle, reuse potential of the product. Feng & Joung (2009) measure the performance of sustainable manufacturing only by considering energy used and Co_2 emission without considering other social and economic factors. Smith and Ball (2012); Despeisse et al. (2012) and Despeisse et al. (2013) elaborate a process flow mapping methodology to quantify environmental performance of sustainability through material, waste and energy flow in a manufacturing firm, despite considering social and economic and technology factors in par with environment factor. Yuan et al. (2012) also consider only the environmental aspect of sustainable manufacturing by considering three major components of manufacturing such as technology, energy and material. Kim et al. (2010) emphasize for DFE method to reduce the environmental impact of manufacturing processes, but only consider the environmental aspect of sustainability. Paju et al. (2012) propose a process mapping method and quantify the sustainability indicators based on discrete event simulation, lifecycle assessment, and value stream mapping methodologies, but didn't consider economic and social indicators at all.

2.2.2. Social Dimension

According to Law and Gunasekaran (2012), external factors such as laws, regulation, social pressure, market trend and competition determines the internal factors of an organization such as performance, organization system etc. and strategic level policies must be made in line with the same to implement sustainable development in an organization. O'Brien (1999) emphasizes the need to have coordination between governments to make a common single worldwide regulation for the sustainable industrial development, regardless of the size and nature of the countries. He also adds the need to organize public awareness programs, to change the consumer buying behavior and to make the customers motivated to adopt green products. According to Hong et al. (2012), for achieving greater social reputation, organizations must implement sustainability practices not only at the strategic level, but at the employee level also. In most of the literature social dimension of sustainability is considered as corporate social responsibility (CSR) initiatives. Biggemann et al. (2014) show the importance of CSR initiatives in achieving sustainability through value creation by the integration of all stake holders. According to Adams et al. (2014) ecological and social factors are least considered for the performance measurement of sustainability. Very few organizations are voluntary going for social sustainability since they believe that social sustainability won't help out them much to gain any competitive advantage. According to Deif (2011), because of the rules and regulations by various governments and by United Nations, green manufacturing has become a mandatory thing for manufacturing firms to go globally. Strong rules and regulations by government are necessary to encourage organizations to go for social sustainability, through which sustainable development can be achieved. Labor sustainability and health and well-being of the society in which the organization is operating are coming under the social aspect of sustainability. Labor sustainability was considered by Tapiero and Kogan (2008). Health and well-being factor was explained by Labuschagne and Brent (2008), and socially responsible purchasing by Mont and Leire (2009). Socially responsible purchasing implies the selection and purchasing of materials which are not harmful and which will make

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

zero negative effect on the customers and internal employees of the organization. McWilliams and Siegel (2001); Van De Ven and Jeurissen, (2005) add that social responsibility is closely related with the firm's business strategy. Labuschagne and Brent (2008) developed a social sustainability criteria frame work, which shows the importance of social assessment for the project and technology life cycle management.

2.2.3. Economic Dimension

Competition and profitability are the two major factors that must be taken into account while discussing the economic dimension of sustainability. According to Nidumolu et al. (2009) in Harvard Business Review, companies are considering sustainability as a part of corporate social responsibility because they fear that they will be forced to go for major process and technology changes to achieve sustainability, for which customer won't be ready to pay for. But he further explains that, environmental friendly manufacturing and sustainable development cost must be included in mainstream business practices, as the one who is successful at the earliest in developing sustainability will definitely get a competitive advantage and economic advantage gradually. Garetti and Taisch (2011) explain that energy recovery by cross plant analysis, co-operation between industries to optimize the energy at various heat levels, re-manufacturing of products, optimization of the speed, load and nature of transport, use of fuels from waste materials instead of fossil fuels, etc. will significantly contribute to the profitability margin of the business organization. According to Clelland et al. (2000), waste and pollution minimizing practices will reduce the operational cost and indirectly create economic value to the firm. Dos Santos et al. (2014) show that Woolworths Company was able to save 9.3 million US Dollars after starting the triple bottom line sustainable business initiative, which include ecological, social and economic indices. According to Stavins et al. (2003) an economy is sustainable only if it is dynamically stable and efficient and total social welfare is non-decreasing over time. The path for sustainability through the above mentioned steps are economical not only through operating cost reduction perceptive, but also through the branding of the company as a green and environment friendly one among all stake holders. Heilala et al. (2008) demonstrate how energy usage and environmental impact can be quantified through a simulation technique.

2.2.4. Technology and Operations Dimension

Technology and innovation has an important role in achieving sustainability in manufacturing. Flexible technologies and new innovative ideas help to reduce cost and other efforts tremendously. According to Westkamper (2008), emerging technologies are the key enablers behind the efficient economic, social and environmental performance of a manufacturing organization. Lee et al. (2011) shows that digital manufacturing technique as a key technique to integrate product design with enterprise resource, facility, and process planning. Digital manufacturing helps to validate each and every design aspect of a new product in line with the existing processes in a virtual world before going for real life expensive implementations. Liu et al. (2011); Koren et al. (1999) and Liu & Liang (2008) assert the importance of reconfigurable manufacturing systems. These systems are another aspect of new technology which helps to minimize waste, operational cost, and improves responsive time and helps to produce a variety of products in comparatively short span of time. According to Gupta and Palsule-Desai (2011) remanufacturing can be considered as an effective tool to tackle the rapidly growing competitive pressure, and is the area, where the OEMs going to concentrate in future. Mani et al. (2013) emphasize that organizations must design sustainable processes to manufacture sustainable products and a clear well defined parameter must also be there to measure the sustainability level of the processes designed.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Veleva et al. (2001) propose a frame work to measure the performance of sustainable production, with twenty two indicators and well defined parameters for the measurement of each indicator. Vinodh and Rajanayagam (2010), through a case study find that computed aided design (CAD) along with design for manufacturing (DFM) can significantly contribute in the sustainable product development process, and can ensure minimum environmental impact. According to Hong at al. (2012) lean production and restructuring of supply chain helps to achieve responsive product strategy, which in turn increases the enterprise performance. They also add that benchmarking is an effective practice to institutionalize sustainability practices. Pumar (2005) explains the way to operationalize the sustainable development ideas and theories through group interaction and social networking. Despeisse et al. (2012) argue that there are limited works which explain about the operationalization of sustainability theories and explains the sustainability practices followed in industry the importance of capturing such practices systematically. Beachy (2010) emphasizes the need to use science and technology effectively in achieving agricultural sustainability. Gonzalez-Torre et al. (2004); Dowlatshahi (2000) shows how reverse logistics helps to increase the utilization of resources for reuse and recycling of the product. These new innovative ideas in supply chain and manufacturing ensure minimum waste and high operational efficiency. According to Westkamper et al. (2001), the future challenge is to reduce the cost of manufacturing technology to a level suitable for the mass production of sustainable products by using sustainable technologies such as solar energy, hydrogen technologies and other renewable-energy systems. Ijomah et al. (2007) illustrate the key indicators that are to be taken care in product design stage as durable material selection, use of joining technologies that won't damage components during separation and discouraging the use of banned substances and processes based on the classification of design subassemblies into three categories such as repair, reconditioning, and remanufacturing to produce sustainable products. Marksberry and Jawahir (2008) develop methodology to measure tool wear and tool life with near dry machining concept to achieve process sustainability to avoid the usage of harmful metal working fluids. According to Seliger et al. (2008) modularity, easy diagnose and standardization are the three main steps to develop efficient remanufacturing products. Fang et al. (2011) explain the use of travelling sales man problem in productivity and environmental performance improvement of manufacturing processes by optimum job scheduling to improve sustainability performance. Gungor and Gupta (1999) elaborate the challenges in recycling and remanufacturing of the used products as collecting the used products to a single point, disassembly level fixing, and in the optimization of disassembly processes.

3. METHODOLOGY

Since the objective of the research in this paper is to find out the interrelationships among variables, Interpretive Structural Modeling (ISM) is adopted as the methodology. In ISM methodology, group expert judgment is used as a tool to predict the relationships among variables under study. Since there are limited literature which explains the interrelationships among the variables of Sustainable Manufacturing, this paper will contribute significantly by using ISM methodology. ISM was first introduced by Warfield (1974) and Malone (1975). The steps involved in ISM are:

- Literature collection on the topic
- Systematic literature review and identification of variables
- Approaching experts and explaining the guidelines of VAXO matrix formulation to them to make the structural self-interaction matrix.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Experts were asked to fill the matrix by using V, A, X and O letters based on their expert knowledge in the area to define the relationship among two variables of the matrix.
- The structural self-interaction matrix was first converted to a binary matrix and then to a final reachability matrix by considering transitivity property.
- Identifying the level of variables depending on the dependence power and driving power of the variable from the final reachability matrix.
- Based on the levels of variables identified from the reachability matrix directed graph (DIGRAPH) is made.
- Converting the DIGRAPH into ISM Model which is self-explanatory about the relation amongst the variables.
- Reviewing the ISM model to validate the conceptual stability and make necessary changes in the model.

Opinion from five experts from TATA Motors having fifteen plus years of experience in manufacturing and three experts from TATA Technologies having twelve plus years of experience in manufacturing service industry are collected. The respondents of the survey include two experts from product design field, two from process design field, two from productivity improvement department and two from engineering research center vehicle integration and testing team.

Variables identified in sustainable manufacturing: V1 - Product design, V2 - Customer requirements, V3 - Supply Chain & Logistics systems, V4 - Energy costs, V5 - Technology & total quality management, V6 - Material selection & procurement, V7 - Natural resource scarcity, V8 - Environmental priorities, V9 - Regulatory norms, V10 - Fuel price regulations, V11 - Public awareness, V12 - Social values & Ethics

The variables of the models are identified through systematic literature review process and are listed out in Table 3. The two parameters amongst which the relationship is checked is represented by say *i* and *j*. Four variables are used to represent the relationship among the variables in the survey, which includes V, A, X, O. The matrix is to be filled with:

V: If *i* leads to *j* but *j* doesn't lead to *i*
A: If *i* doesn't lead to *j* and *j* leads to *i*
X: If *i* and *j* lead to each other
O: If *i* and *j* are not related each other

Using the above criteria, we have developed Table 4. The next step is to convert the Structural Self Interaction Matrix (SSIM) into binary matrix for which the below rules are followed:

- If the *i,j* relationship in SSIM Matrix is V, the corresponding binary relationship is 1 for *i, j* and is 0 for *j,i* .
- If the *i,j* relationship in SSIM Matrix is A, the corresponding binary relationship is 0 for *i, j* and is 1 for *j,i* .
- If the *i,j* relationship in SSIM Matrix is X, the corresponding binary relationship is 1 for both *j,i* and *i,j* .
- If the *i,j* relationship in SSIM Matrix is O, the corresponding binary relationship is 0 for both *j,i* and *i,j* .

Table 3. Dimensions of Sustainable Manufacturing

Sustainable Manufacturing Drivers/Variables	Authors (Year)	Dimensions/Sub-Variables
Product design	Garetti and Taisch (2011)	• Mass customization • Eco-design: easiness of serviceability, disassembly. • Recyclability.
Customer requirements	Garetti and Taisch (2011); Garbie (2014)	• Involvement of customers in design, Innovative products
Supply chain & logistics systems	Dubey and Gunasekaran (2014); Jeffrey and Choi (2004)	• Green Logistics • Reverse Logistics • Supplier selection • Logistics network design
Energy costs	Garetti and Taisch (2011)	• Energy Conservation • Minimization fossil fuel energy use • Energy production from waste & garbage.
Technology & total quality management	Garetti & Taisch (2011); Garbie (2014); Garbie (2013); Law & Gunasekaran (2012)	• Advanced automation for high product quality • High-performance and quality-embedded manufacturing, • Minimization of customer complains • Reconfigurable & Flexible Manufacturing Systems • Strategic level management policies
Material selection & procurement	Kara et al. (2014)	• Environmental friendly material selection • Reusable & recyclable material usage • Material selection to minimize energy consumption & operating cost
Natural resource scarcity	Azzone and Noci (1998)	• Minimization of the impact on the state of natural resources
Environmental priorities	Mittal and Sangwan (2014a); Mittal and Sangwan (2014b)	Minimization of • Greenhouse gas emission • Degradation of soil and water
Regulatory norms	Zhu et al. (2007)	• Environmental rules & regulations by government
Fuel price regulations	Garetti and Taisch (2011)	• To promote bio-fuels & to discourage fossil fuels usage
Public awareness	Santos et al. (2014), Houe and Grabot (2009)	• Customers' awareness on environmental issues • Internal employee awareness
Social values & Ethics	Hoejmose et al. (2013)	• Social responsible supply chain

Table 4. Structural self-interaction Matrix

	V12	V11	V10	V9	V8	V7	V6	V5	V4	V3	V2	V1
V1	O	A	V	A	V	X	X	V	X	X	X	-

Transitivity Principle

Farris and Sage (1975); Sushil (2005a,b) say that to maintain the consistency of the model developed, transitivity property is always used in the ISM modeling. Transitivity principle can be explained with an illustrative example as: if a leads to b and b leads to c, the transitivity property implies that a leads to c. Transitivity property helps to remove the gaps among the variables if any. By adopting the above criteria and transitivity property, final reachability matrix is prepared and is shown in Table 5.

Level Partitioning

The ranking of different variables into different levels is known as level partitioning. Reachability set and antecedent set are found out from the final reachability matrix (Warfield 1974). In any iteration, if the reachability set intersection antecedent set is the reachability set itself then those variables occupies the top levels of the hierarchy. The final output of level partitioning is shown in Table 6.

Table 5. Final reachability matrix

	V1	V2	V3	V4	V5	V6	V7	V8	V9	V10	V11	V12	Driving Power
V1	1	1	1	1	1	1	1	1	1*	1	1*	0	9

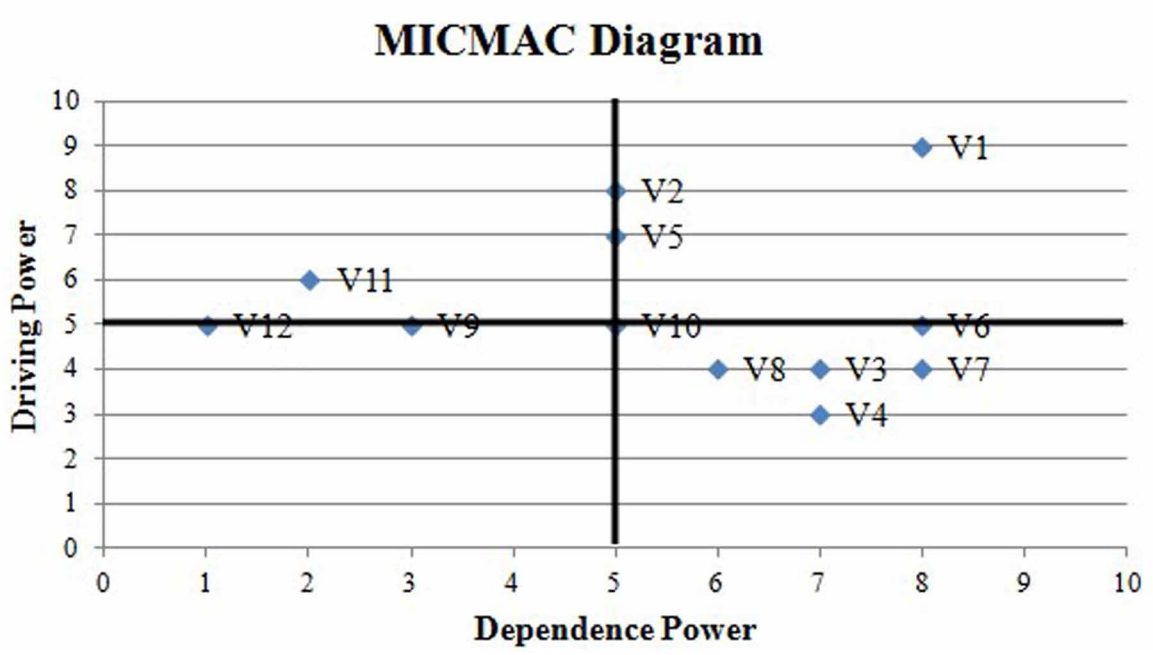
CMAC Analysis

After preparing the ISM model (Figure 1), MICMAC diagram of the variables is prepared based on their driving power and dependence power. Driving power and dependence power is calculated in the final reachability matrix and is shown in Table 5. Duperrin and Godet (1973) developed the MICMAC method for the first time. According to Warfield (1994) MICMAC Analysis is used to categorize variables in a complicated system. Mandal and Deshmukh (1994) explain that MICMAC will also help to analyze the driving and dependence power of variables of a complex system. According to Jharkharia and Shankar (2005), depending on the value of dependence power and driving power the variables can be classified into four categories such as autonomous, linkage, dependent and independent barriers. The first category known as 'autonomous barriers' include the variables having weak driving as well as dependence power. MICMAC Diagram for the sustainable manufacturing variables under study is shown in Figure 2, and there is no variables coming in the first quarter which means that, there is no autonomous variable.



The variables coming in first quarter won't be having much connection with the system or with other variables. The variables V3, V4, V7 and V8 are coming in second quarter which is known as 'dependent barrier'. Dependent barrier variables are having weak driving power and strong dependence power. Since these variables depend heavily on other variables, any change on other variables will affect these variables. The variable V1 is coming in third quarter and is known as 'linkage variable'. These variables are characterized by their strong driving power and strong dependence power. These variables are highly sensitive. Any change in the system or other variables will affect linkage variables. The fourth quarter contains variable V11 which is known as 'independent barriers'. These variables have strong driving power and weak dependence power.

Figure 2. MICMAC Diagram

4. RESULTS AND CONCLUSION

The study helps to identify the driving factors of sustainable manufacturing system, and the frame work model built through ISM technique will help policy makers to get a clear overall picture of the system to develop and implement the sustainable manufacturing philosophy. From MICAMC analysis, we found that there are no autonomous variables, which implies that all the variables stated in the study will influence the development of sustainable manufacturing system. Product design is coming in the third quarter which implies that it is a linkage variable and is highly unstable. This implies that product design strategy must be changed in accordance with the other driving factors to achieve the manufacturing sustainability. The variable public awareness has high driving power and this factor will affect other enabling factors. Supply chain and logistics systems, Energy costs, Natural resource scarcity and Environmental priorities are coming in second cluster and are having high dependence power.

5. RESEARCH GAPS IDENTIFIED AND SCOPE OF FURTHER RESEARCH

From the global survey conducted by Kiron et al. (2013) from MIT Sloan Management Review and the Boston Consulting group, it can be seen that for thirty five percentages of the companies sustainability efforts are adding profits to business for consistently over the years. But, the percentage of companies that have successfully established a sustainability business case is only thirty seven percentages, and twenty percentages of companies are failing to establish a successful sustainability business case in their organization. This shows the requirement for a clear well defined framework for sustainable manufacturing, the relationship among driving variables and their relative importance in framing a sustainable

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

manufacturing systems, which will help the organizations to achieve sustainability. We have found that many of the articles are focused only on environmental factor of sustainability rather than considering social, economic and technology factors in equal par to achieve better sustainability performance. So, future studies must focus on all the three factors of sustainability simultaneously to make better meaningful theoretical contributions. According to Nakano (2010), definition of sustainable manufacturing is not clear and technical approaches for tackling risks and sustainability issues in manufacturing must be explored further in detail. We acknowledge the same based on the review done and hence we have developed a comprehensive definition of sustainable manufacturing by reviewing the available definitions of sustainability, sustainable development, and sustainable manufacturing. We have found that at present there are limited literature on sustainable manufacturing which uses simulation and mathematical modeling techniques. Jimenez-Gonzalez et al. (2011) argue that there is a lack of total systems approach and emphasize the need to coordinate different engineering and science professionals to develop better sustainable products and processes. Throughout the literature we have identified the gap of total systems approach in developing the sustainable manufacturing models. In further research, the relative importance of all driving factors and the effect of one over the other variables are also to be explored. Design for Environment (DFE) method is getting much importance in the early product design stage along with Design for Assembly (DFA) and Design for Manufacturing. Future researches can be extended to make complete guidelines and check points for DFE methodology and to develop better ecofriendly products. There are limited works which consider the effect of soft dimensions such as top management strategic policies, organization human resource policies etc. on the sustainable manufacturing system development in an organization. From the literature review we understood that sustainable product and process design didn't get enough focus and attention as much as they were supposed to get. Our research aims to fill these gaps and to formulate a clear framework for sustainable manufacturing systems. ISM and MICMAC analysis is done only by taking opinion from eight experts, which is not sufficient to derive any statistical conclusion. So to overcome the same, Structured Equation Modeling (SEM) analysis must be performed by taking sufficient survey based on structured questionnaire.

Chapter 19
Green Energy in Data Centers

Kanahavalli Mardamutu
Quest International University Perak, Malaysia

Vasaki Ponnusamy
Universiti Tunku Abdul Rahman, Malaysia

Noor Zaman
King Faisal University, Saudi Arabia

ABSTRACT

Green energy paradigm has been gaining popularity in the computing system from the software, hardware, infrastructure and application perspectives. Within that concept, data center greening is of utmost importance at the moment since data centers are one of the most energy conserving elements. Data centers are seen as the technology era's black energy-swallowing secret. Reducing energy consumption at data centers can reduce carbon footprint effect tremendously. Not addressing the issue immediately will lead to significant energy usage by data centers and will hinder the growth of data centers. The call for sustainable energy efficient data center leads to venturing into data center green computing. The green computing concept can be achieved by using several methods adopted by researchers including renewable energy, virtualization through cloud computing, proper cooling system, identifying suitable location to harvest energy whilst reducing the need for air-conditioning and employing suitable networking and information technology infrastructure. This paper focuses into several approaches used by researches to reduce energy consumption at data centers while deploying efficient database management system. This paper differs from others in the literature by giving some suitable solutions by looking into a hybrid model for green computing in data centers.

INTRODUCTION

The increase in need of data processing has led to a demand in obtainability for cheaper, faster, efficient and larger data management system. This has further introduced a significant problem in terms of energy consumption and energy usage as mentioned in (Barroso. L.A, 2005). Since the trend of Internet Infrastructure is moving towards services-based computing, data center plays a key role in this new

computing architecture. It is used widely in variety of services independent encapsulating any vendor, product and technology including web hosting, application services, electronic markets, outsourced storage, online-monitoring system, mashups, digital nervous system and other network services. Fostering renewable energy production, developing better renewable technologies and improving the environmental performance of conventional electricity benefits heightened through improving the long-term strategy of data center performance. Environmental Protection Agency (EPA) shows that the data center and database management system in the US consume power doubled between 2000 and 2006 and may multiply again within the next decade. According to EPA, it is projected that energy consumption by data centers for the year 2008 is more than 80 billion kWh. (US Department, 2013). Report to the Congress, EPA's Energy Star Program estimates that increase efficiency in data centers could yield energy savings as the burgeoning efforts to make data centers greener is the energy and the word 'green' adds multiple meaning when applied to the data centers. (Koomey J, 2011).

Many works have been done to produce efficient result in reducing the energy usage for the purpose of data center and data management for example by Cisco System Inc., Google Inc., and many more (Barroso.L.A,2005). Some of the approaches were to design highly efficient systems at the peak performance point with maximum utilization of resources. But very few studies have addressed the energy problem comprehensively (US Department, 2013).

PROBLEM STATEMENT

In today's technological world, it is proven that there is a significant relationship between data center and investment in capital overlay and outgoing costs. Table 1 shows the detailed breakdown on the distribution of the cost from data center (Greenberg et al., 2008).

The design of computing system is being optimized based on the execution time and operates at low consumption due to entrapment of resources and fragmentation of data. No concern was made for the issue of energy consumption by the system. Uncontrolled usage of energy in data centers has negative effects on the reliability, density, scalability of information processing and the environment. Need and awareness are raised across nation through multiple solution and disciplines to optimize and save energy use in data management system (Barroso. L.A, 2005). System or even its components like CPUs, memory and disk are hardly distributing energy efficiently. It trades power for performance (US Department, 2013). Power management has become a critical issue due to large energy usage and all over the world government has started imposing the taxes on the carbon emission, ultimately aiming to reduce the emission and help make computing into green computing (Bansal et al., 2011).

Table 1. Guide on the distribution of data center costs

Amortized Cost	Component	Sub-Component
~ 45%	Servers	CPU, memory, storage systems.
~ 25%	Infrastructure	Power distribution and cooling.
~15%	Power draw	Electrical utility costs.
~15%	Network	Links, transit, equipment.

a. Source of data: A. Greenberg et al, "The cost of a cloud: research problems in data center networks", ACM SIGCOMM Computer Communication Review, 39(1), pp. 68, 2008

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

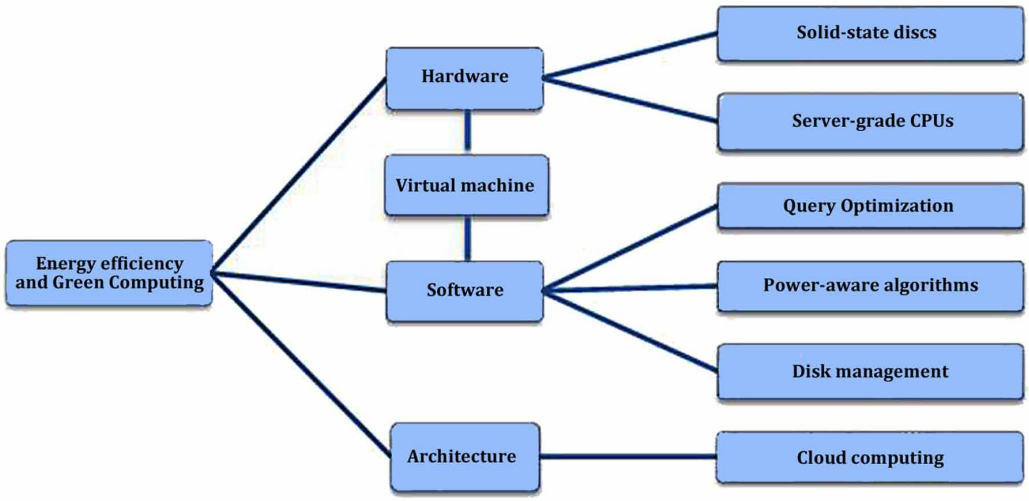
Although research was conducted in designing power aware applications, an effort for implementing has not been taken place. Large expenses and allocations need to be augmented when data center reaches maximum provisioned power (Bansal et al., 2011). In the very near future, energy efficiency is expected to be one of the key procuring arguments in the society. Research should focus in building power-aware database management systems (DBMS) or GreenDB.

Analysis shows that giant companies are also working towards energy efficiency using green database system. Huge volume of energy usage goes to the data center. The global business market intelligence is a billion dollar market and still growing to see double-digit growth rates (US Department, 2013). With the growth of the internet data center (IDC), data systems are also running its management workload such as search engines, storage of multimedia like video and audio, streaming, web analytics, and cloud computing. Dataset are growing rapidly and workload is also increasing. Together with it, the energy usage has increased. Companies like Google are working towards reducing the energy usage excessively in data centers (US Department, 2013). Data center has become the major immobilizer in the topic of energy wastage.

Clients particularly are searching for high scalability setup, lower unit price and simplicity of management. As to maintenance costs, the second largest bill for large database centers comes from the power company. Statistic shows that in US alone, data centers consumed about 60 billion kilowatt-hours of electricity in 2006 which equaling to 1.5% of electricity consumption in US (US Department, 2013). Demand for a solution is in the high urge and is being researched by many giant companies

OBJECTIVES

This research is not to reinvent the wheel to conduct a critical analysis on the existing research to integrate the idea proposed to produce wholesome elucidation. Modules from many different researches have been integrated and evaluated to enhance its components to be fully functional with fewer flaws. Therefore, it is a better solution to show the benefits of energy efficiency through green database. The main objectives of this research are as follows;



1. To initiate and analyse energy-aware research conducted on database management in a way that improves energy efficiency of a data center.
2. To propose solution in implementing the energy efficiency through green computing and green database system.

Many companies, organizations and individuals have proposed methodology to resolve this problem based on the categories shown in Figure 1. This research paper analyzes similar papers which has solution but needs minor integration to propose new innovation with better and efficient energy saving. Analysis focuses on power consumption patterns and identification of power-saving opportunity in GreenDB. Critical analysis done based on the following observation.

- Power-aware database.
- Data management through software and hardware.
- Data management through disk power management.
- Green computing architecture.
- Renewable energy.

Figure 1. Critical analysis flow model

Power-Aware Database

Power-aware computing research at the application level in the aspect of hardware and operating system level found to be synergistic for energy proficiency in the core systems. Xu. Z., 2011 describes on creating a power-aware database management (P-DBMS) and initial ideas on the design as such systems, with the focus on a power-aware query optimization module in the DBMS. This particular paper has proposed and created a power model to accurately measure the energy costs of query executions and plan selection. It is in contrast with the heuristic-based adaptive solutions that rely on manual timing and extensive empirical evaluation. It is meaningless without considering the database performance. It is either to make the query run faster by optimizing the query execution or let the system run in lower power state while sacrificing the performance to some extent. They proposed that the throughput is improved while maintaining the power line. It indirectly reduces the power cost while not sacrificing the throughput performance. Implementation has been taken place through initial design in algorithm based software named PostgreSQL rather than power-saving through hardware and operating system levels modification. The proposed solution resolves the power aware of the database as seen in Table II. Only setback would be database management system needs to be revisited or redesigned and initial efforts be invested. The plan evaluation model has a stumbling block where the system is stable and foreseeable but the database is barely stable and predictable. Thus, modeling error occurs and estimation per operation cost cannot be 100% correct.

Data Management Through Software and Hardware

Synergy between database management through algorithm and hardware architecture are promising in energy efficiency computing. Harizopoulus, S. et al., 2009 recommends that adjusting existing system-wide configuration and design algorithm for energy proficiency is not the same as designing algorithm based on the throughput and performance. Deploying an energy-efficient data management platform is by choosing hardware components with good performance-per-watt characteristics by choosing high-

performance components (server-grade CPUs, solid-state disks etc.). Installing an energy-efficient system was also done through software-based approaches for reducing wasted energy in data management systems. This paper proposes to power down the unused hardware components, revisit and redesign data structures and algorithm from a wider perspective. The 'push-to' design components offers more control over power performance trade-offs for example usage of multicore chips which can be activated at any time. The increase of hardware heterogeneity offers technology refresh cycle like the virtual machine. The disadvantage here is that some workloads may be able to use these additional resources while others will underutilize them and create a waste of power. Table III shows that hardware configuration and application-agnostic power management is only part of the solution proposed in this paper.

Data Management Through Disk Power Management

Reducing energy consumption through hardware depends on many aspects. Earlier research shows that the result from monitoring data center is that the average idle period for a server disk is very small compared to the time taken in spinning up and down. This significantly limits the conservation of energy. Zhu, Q. et al., 2004 proposed reducing energy consumption of disk storage using power-aware cache management with algorithm which provides more opportunities for causal disk power management structures in energy efficiency. So far only a few studies (D. Colarelli and D. Grunwald, 2002 ; Gurumurthi et al., 2003 ; Gurumurthi et al. 2003 ; Carrera et al., 2003) addressed the problem in energy efficiency for the storage systems at the data centers. Based on these studies, multi-speed disks or multiple rotational speed disks shown promising results by using synthetics workloads. Therefore, power-aware cache management algorithm was designed whereby it is aware of the base disk energy ingestion and power management plan for read and writes accesses.

It is an energy-optimal cache replacement algorithm which uses the dynamic programming in polynomial time leading to 16% less energy and lead to 50% better average response time. But this study has its limitation such as it is only designed for multiple disks and focuses on high-end storage systems. Single disk may not work with this algorithm. Also it has low effect on prefetching as well. It does not consider the storage cache energy consumption and focuses on smaller part of the overall management as shown in Table IV.

Green Computing Architecture

Virtual machine (VM) has been globally used in the data center environment due to its important feature and architecture. Liu. L. et al. 2009 uses the latest technology trend which is the cloud computing as a guaranteed performance and designed to reduce the data center energy consumption. It is effective and enables the widespread online-monitoring, live VM migrating and placement optimization. It utilizes the live migration feature of VM Technology such as XEN (Bansal et al.,2011) to implement the architecture for example Amazon Elastic Compute Cloud (Zu. Z. 2011) provides a virtualized computing environment hosted with different kind of Linux-based service. Evaluation results show that 27% energy can be saved when applying Green computing architecture. VM Migration allows lesser usage of computer. This architecture assures real-time performance requirement as well as saves the consumption of energy by Internet Data Center (IDC). Green computing architecture with the integration of VM technology is an effective method in reducing server power consumption.

The problem may arise in the angle of automatic scheduling decision on dynamic migration or consolidating the VMS among physical servers to meet the workload requirements meanwhile saving energy, especially for performance sensitive. The aspect of performance trade-off between the operating system and applications or middleware has not been tested which can be a flaw. But based on Table V, this technology alone may not be sufficient to provide efficiency.

Renewable Energy

Exploiting green energy sources is another opportunity but it is variable and intermittent. So far, there has been less work on integrating renewable energy with database system. Chen, C., et al., (2012) uses the hardware optimization to save energy and retaining the execution part of the hardware. They proposed through integration of renewable energy which is the solar to power the execution of database management system. This research bridges the gap between renewable energy and database management system with ReinDB (Renewable Energy Integrated Database). The purpose would be to minimize the usage on carbon intensive energy consumption on a database server with both renewable energy and carbon intensive energy supplies. This works on Supply Driven Execution (SDE) on a database server with two mechanisms.

1. Workload scheduling to meet workload deadlines.
2. Dynamic configurations on hardware setting.
3. Brown-aware workload shifting.
4. Battery-aware workload shifting.

Although it increases the usage of renewable energy (solar usage) but there are still some disadvantages to take into consideration. Studies show that the mismatch between workloads and green energy supplies challenges in the utilization of energy. Divergence in the context of data center from brown energy and green causes excessive usage of energy (Goiri et al,. 2011; Goiri et al,. 2012 ; Krioukov et al 2012 ; Liu et al. 2011). Clients are required to change the hardware to new system which may need initial investment that may cost high. Also the latency time (slack time) is also another issue whereby the clients have to tolerate a large slack time to complete a task with the green techniques. In the economical aspect, the cost involves in manufacturing solar panel and battery provision. Table VI, shows that, there are many other aspect to be incorporated.

ANALYSIS AND PROPOSED GREEN SOLUTIONS

The concept of green database and energy efficiency is emerging high and gaining more popularity and everyone wants to be on top of it and they have started researches on the concept of energy saving in the DBMSs. Companies like IBM, Oracle that develops their own DBMSs want to decrease the energy consumption. All researches are focusing on individual area only. Integration of success methods from each research can result in wholesome solution.

Evaluation and analysis done to multiple proposal and project paper resulting in integration of the best modules for many different sources tosses excellent solution. Comparisons shown in Table VII, VIII, IX, X and XI define the strength and weakness based on the critical analysis done.

Virtualization and Green Cloud

Virtualization allows software and hardware virtualization by providing virtual environment. This reduces the need for overwhelming use of servers. More processing can be done with lesser energy consumption. Every single component of IT can be virtualized from the servers, routers, switches, input-output, applications, operating systems and desktop. Virtual machine allows more than one operating system to be operated in one computer. Each operating system runs its own virtual machine and resources like I/O, storage and processor can be assigned to each virtual machine. It is to automatically make the scheduling decision on dynamically migrating or consolidating Virtual Machines among physical servers to meet the workload requirements while saving energy, especially for performance sensitive. The heuristic algorithm is used in virtual machine migration to achieve the optimization. States of server power is adjusted through the dynamic voltage or frequency scaling.

Renewable Energy Sources

Datacenters can be equipped with renewable energy sources such as solar powered energy and hydro-electric energy supply. Solar powered energy can be good source of energy for data centers located at locations that has wide availability of solar energy. The solar panel nodes can be charged during the day with the sunlight and stored in backup sources to be supplied during the absence of sunlight. Although installation of such facility is comparatively costly, but the outcome can be very promising as these are renewable energy sources. Moreover energy generation through hydroelectric source is another promising factor. This is applicable in areas where there plenty of water sources for hydro energy generation. A good example would be the Facebook datacenter located in Sweden which is supplied with hydroelectric power without interruption due to the abundant resources of hydroelectric power. In conclusion, the choice of renewable energy is very much dependent on the geographical areas where the datacenters are located (1). More research work can be carried on vibration energy generation from the vibration caused by the servers and the other high end equipment present in the datacenter. This requires extensive research on the strength of vibration generated and amount of energy can be drawn from that.

Disk Power Model and Management

Managing the multi disks speed to increase the amount of energy saved with data center workloads by identifying the active, idle and standby mode of the disk. During the active mode, read and write mode is actively processing in the platters spin and the head. Likewise, during the idle, no disk is required whereby energy can be saved by idling the rotation and spinning. Mathematically, a lower rotational speed mode consumes lesser energy compare to higher rotations. Reduction in Input/ Output Operations per Second (I/Ops) directly leads to reduction in the energy consumption which is shown in (1). An average latency is the time taken by the disk that is accessed to rotate to the position under read/ write head. Meanwhile the average seek time would be the time (ms) taken for the hard drive's read/write head to locate itself over the read/ write track.

I/Ops Calculation:

$$1 / ((\text{σεεκ τιμε} / 1000) + (\text{λατενχψ} / 1000) = \text{I/Oπσ} \quad (1)$$

$$\text{Ενεργψ Χονσυμπτιον} = \text{Ποωερ (Ωαττ)} \; \xi \; \text{I/Oπσ}$$

Power-Aware Database Management System

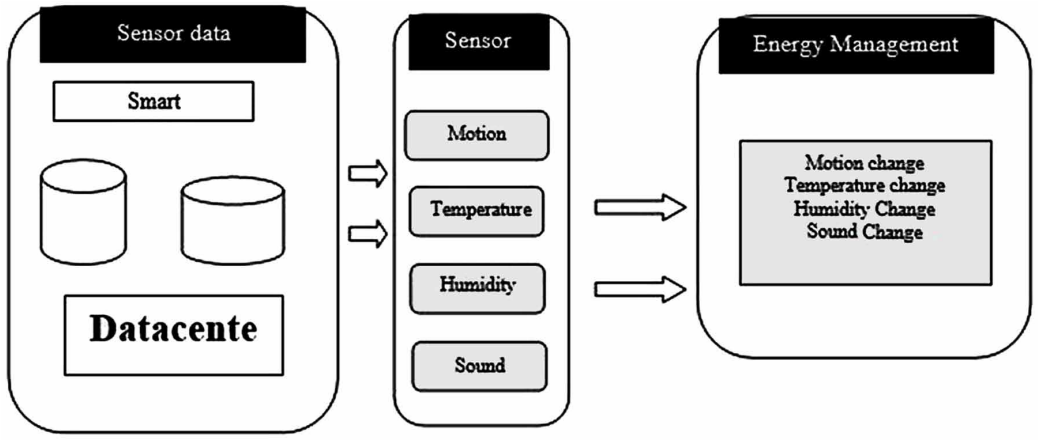
It monitors the query optimizer, buffer manager, storage manager and many other database query optimization modules.

Cost can be reduced by improving the query optimization time whereby the processing time can be improved and obtained through the setup of the server which is shown in (2).

Cost estimation, C:

$$X = (\text{Θυερψ Οπτιμιζατιον} \; \xi \; \text{τιμε}) \; \xi \; \text{Προχεσσινγ Τιμε} \quad (2)$$

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use



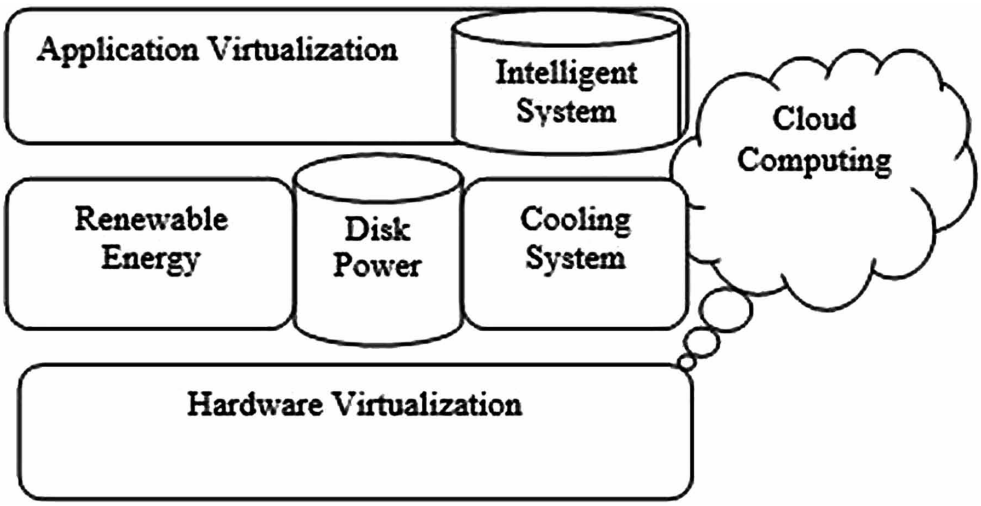
Datacenter Cooling System

Cooling system in the datacenter is very important aspect as it guarantees proper operation of datacenter equipment such as servers and storage devices. A suitable cooling method to maintain the thermal condition of the CPU's can provide efficient energy usage. The Facebook datacenter in northern Sweden provides an energy efficient cooling system as compared to other datacenters. Besides that, the arctic climate in the northern region allows the Facebook datacenter to be in a colder temperature condition requiring less cooling needs. The river along Lulea provides a lot of resources for hydroelectricity supply for the entire datacenter without the need for generators. The datacenter depends on the climate chilling system rather than depending on air conditioning system. An intelligent heat, ventilation and air conditioning (HVAC) system can be designed with proper cooling system (Parisio et al.; Mousavi et al.) Datacenters with central air systems, direct liquid cooling and humidification can allow for proper cooling system.

Power Management Using Wireless Sensor Network

One way to make datacenters energy efficient is by providing good network infrastructure. The servers, routers, switches and other equipment linked with an efficient networking facility can decide the energy consumption of the datacenter. Congested network linkage allows unnecessary communication among devices and allows for additional energy consumption. One potential networking infrastructure that could facilitate with proper energy management is through employing wireless sensor networks (WSN). WSN provides intelligent services by deploying various types of sensors to monitor the environment in the datacenter to make it a smart datacenter. The smart datacenter is intended to be designed to create a system that performs energy management in terms of energy consumption and optimizing power consumed by datacenter devices. The framework of the system is shown in Figure 2. The system is categorized into fault detection and energy management. Fault detection stage should identify malfunctioned datacenter equipment and resources that is unnecessarily consuming power and wasting energy. The energy management stage should be able to manage energy consumption, optimize power consumption and perform automated notification. The fault detection system consists of data acquisition from various

Figure 2. WSN data center monitoring system



EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

sensors and information processing using fuzzy logic engine. The energy management system performs event detection and action mechanism based on changes in the sensor data and motion detection. In this system, datacenter environment parameters such as temperature, humidity, light and sound are detected for deciding whether electrical appliances and lights to be switched on or off for energy management in buildings. Besides that, motion sensors are used for detecting movement so that lights can be switched on and off based on occupancy. Motion sensors can also be used to detect heat emitted from the equipment so that notification alarm is triggered to take necessary action. The temperature and humidity sensors can be used to decide whether the datacenter cooling system to be turned on or off. This system can be created using some machine intelligent capabilities to make the system self-autonomic. Moreover WSN is a cost effective solution as it does not require extensive IT infrastructure and data communication.

Hybrid Model

A hybrid model (Figure 3) can take advantage of a combination of energy efficient solutions including virtualization by cloud, WSN monitoring system and renewable energy system (Gholamhosseinian, and Khalifeh, 2012). Machine learning systems such as Case Based Reasoning (CBS) or decision trees can be integrated together with the virtualization concepts so that lesser servers are needed for data storage and processing (Pawlish et al., 2014). These intelligent systems allow servers to make automatic decisions and require lesser tasks. Moreover intelligent agents such as pattern recognition, fuzzy logic and neural network can be integrated with WSN so that energy usage at datacenter can be monitored intelligently. A proper selection hardware that requires less cooling system is also an added advantage. For example the Open Computer hardware has been designed in a simplified way for energy efficiency. It is just a piece of metal sheet with the motherboard that allows for proper air flow. A casing free system can allow for faster cooling process in datacenters. In conclusion the hybrid model should provide the following advantage:

Figure 3. Datacenter hybrid model

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

1. Reducing energy consumption compared to the traditional datacenter model
2. More utilization of virtualization by employing green cloud architecture by allowing lesser usage of storage, machines and processing without compromising the number of applications can be operated
3. Utilizing natural resources for renewable energy for datacenter. Since natural resources are ample depending on the geographical location, a proper energy harvesting method could solve energy usage at datacenters

FUTURE WORK

Looking at the hybrid model proposed, a complete framework and simulation of the model will prove the feasibility of the model. Taking renewable energy into consideration, future work in constructing data centers should focus on natural resources available. More emphasis should be given to locations near the northern poles to reduce the need for cooling system. Focus on areas that have plenty of sunlight to harvest energy using solar system or locating data centers near hydroelectric power generators. Virtualization should be highest importance by deploying systems using cloud computing infrastructure. Provide an integrated system operation with software, hardware, controls and sensors to be coupled together with the grid electricity. An automation system using self-healing energy management can be considered in this case. The system stores huge amount of energy in the storage via renewable energy and constantly monitor the level of energy at the grids and allowing power to be supplied during energy crisis.

CONCLUSION

The green energy at data centers will help to reduce the serious energy consumption issues at data centers to reduce the critics from authorities. Total energy consumption of data centers in the US for example can be reduced from 2% to even lower. The suggested solutions may not only reduce the greenhouse effect but offer a more cost effective data center setup. In this paper, several approaches of reducing energy consumption at data centers have been proposed. The proposals are validated by adopting some of the solutions addressed in the literature providing reasonable metrics. Ultimately the aim and objectives are to minimize the wastage of energy and to retain the efficiency. It is foreseen that implementation of technology collaborated with the green energy will ultimately enhance the technology to be ecofriendly.

ACKNOWLEDGMENT

This paper is a revised and expanded version of a paper entitled ‘A Critical Analysis of Green Database System for Energy Efficiency and Green Computing’ presented at the International Symposium on Mathematical Sciences and Computing Research 2013 (iSMSC 2013) 6-7 December 2013, Perak, MALAYSIA

Chapter 20
Mainstreaming Development Policies for Climate Change in Fiji:
A Policy Gap Analysis and the Role of ICTs

Sam Goundar
United Nations University, Macau, China

Subhash Appana
University of the South Pacific, Fiji

ABSTRACT

Fiji is a Party to the United Nations Framework Convention on Climate Change (UNFCCC), and to the Kyoto Protocol. This chapter examines the development policies implemented since ratifying these agreements to mitigate greenhouse gas and carbon emissions. This includes an analysis of Fiji's effort in mitigating climate change issues by "mainstreaming" - an operational approach for making development more sustainable. A country's use of renewable energy sources is a good indicator of its efforts to mitigate greenhouse gas and carbon emissions. Fiji's renewable energy projects and agricultural sector are examined. Identification is made of the gaps in development policies that take control of climate change issues with the process of mainstreaming. Suggestions are provided to close the gaps. ICT (information communications technology) has a critical role to mitigate the impacts of climate change by advancing renewable energy efforts and reducing emissions. Social media is now widely used to inform and educate about sustainable development efforts and to address broader development challenges.

INTRODUCTION

The United Nations Framework Convention on Climate Change (UNFCCC) was decided by world leaders and decision makers at the Earth Summit in Rio de Janeiro in 1992. The ultimate objective of the convention is the stabilization of greenhouse gas concentrations in the atmosphere at a level that would prevent dangerous anthropogenic interference. Fiji is a party to this Convention as well as to the Kyoto

Protocol. The Kyoto Protocol is an international agreement linked to the UNFCCC, which commits its Parties by setting internationally binding emission reduction targets (UNFCCC, 2015). What has Fiji done and achieved so far in terms of fulfilling its obligations of the Climate Change Convention?

This paper examines the development policies that Fiji has implemented to mitigate greenhouse gas emissions since ratifying the convention. What changes have Fiji brought to its laws and legislations? What new rules, regulations and acts have Fiji passed to show genuine efforts in its ratification of the convention? According to the convention, sustainable development efforts have been suggested for small island nations like Fiji. This is to ensure that such countries grow economically, and are able to provide social welfare to its citizens, while taking care of the environment. Has Fiji been able to develop as suggested?

The intent of this paper is to analyze Fiji's effort in mitigating climate change issues with a process known as "mainstreaming". Mainstreaming is an operational approach suggested by Metz (2010) for making development more sustainable. According to Metz, the best practical way to achieve this is through integrating all relevant elements of sustainability into development decisions. This process does not require governments to do anything extra or to spend any more. It simply suggests incorporating policies that take care of the environment into existing ministries and departments.

One of the ways in which we can really limit the emission of greenhouse gases into the environment is by burning less fossil fuel. Therefore, a country's use of renewable energy sources is a good indicator of its efforts to mitigate greenhouse gas and carbon emissions. To establish Fiji's status, its renewable energy projects are explored to identify how much fossil fuel Fiji is burning and how much energy it is generating from renewable sources. The agricultural sector is another major producer of carbon and greenhouse gases. What is Fiji doing within its sugar and agriculture industry to take care of the environment?

After ascertaining what Fiji has done and achieved so far, discussion focuses on what remains to be done and what has not been done properly. The gaps are identified in Fiji's development policies to take control of the climate change issues within the process of mainstreaming. Suggestions are provided on what can be done to close the gaps that remain, so that Fiji can fulfill its climate change mitigation obligations. There is not an easy way out as development and sustainability do not positively correlate to each other (Kubiszewski et al., 2013). Some best practices applied elsewhere are recommended; one size however, does not fit all.

It has been 20 years since the first Earth Summit and the UNFCCC in Rio de Janeiro. The June 2012 Earth Summit reports that we have not made much difference since then and are still on track for all the climate change woes predicted. ICT (information communications technology) can play a critical role in avoiding future climate change disasters by identifying solutions to advance our renewable energy efforts and reduce emissions. ICTs can also provide early warning systems to mitigate the impacts of climate change. What can ICT do for countries like Fiji and the rest of the world to ensure that our future generations can experience the same or an even better environment than we do? At present Fiji has 333 islands. Will our children and grandchildren be able to have the same number of islands?

BACKGROUND

Since the establishment of the UNFCCC and the Kyoto Protocol, there has been significant progress towards understanding the impacts of climate change in the Pacific region, and developing programs to both mitigate and adapt to it. The establishment of the Alliance of Small Island States (AOSIS) has provided a forum allowing Fiji to collaborate with other small island states and negotiate agreements at the UNFCCC Conference of Parties (Fiji – NCCP, 2012).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

The Mauritius strategy 2005–2015 and the Barbados Plan of Action address the problems of small island developing states (SIDS), with climate change as a significant issue. Fiji will contribute to the implementation of the Mauritius Strategy 2005–2015 and the Barbados Plan of Action through this policy (Fiji – NCCP, 2012).

The Pacific Islands Framework for Action on Climate Change 2006–2015 (PIFACC) was developed with the stated goal: 'Ensure Pacific island people build their capacity to be resilient to the risks and impacts of climate change'. The framework is seen as the overarching guide on climate change at the regional level (Fiji – NCCP, 2012).

Fiji's People's Charter for Change, Peace and Progress serves as the umbrella framework for its national development. The Charter prescribes the roadmap for Democracy and Sustainable Socio-Economic Development 2009–2014. This roadmap defines the implementation framework for the charter. The National Climate Change Policy (Fiji – NCCP, 2012) will serve as an implementing tool for many of the strategies outlined in the charter, such as:

- Environmental protection, sustainable management and utilization of natural resources;
- Strengthening institutional capacity for environmental management;
- Strengthening food security.

Fiji's Minister for Foreign Affairs and International Cooperation wrote in the foreword to the document presenting Fiji's National Climate Change Policy (NCCP) launched in 2012 (Kubuabola, 2012):

Climate change constitutes some of the greatest barriers to sustainable development with widespread and cross-sector effects, putting the biodiversity and ecosystems of Pacific Islands at risk, especially marine and coastal. This has severe implications for Fiji's economic development because of the country's dependence upon natural resources for its primary industries of fisheries, forestry and agriculture.

As reported by the Secretariat of the Pacific Community's Land Resources Division, (SPC – LRD, 2012)

Fiji is on track to be 'REDD-ready' (REDD - Reducing Emission from Deforestation and forest Degradation) by the end of 2012 with the finalization of its national REDD-plus policy currently underway. The development of this policy is in recognition of the need for robust and effective policy and regulatory frameworks to ensure REDD initiatives contribute optimally to the social, economic and ecological development of the country. Fiji's overall objective of the REDD-plus policy will be to effectively address the drivers of deforestation and forest degradation and encourage the drivers of forest-based carbon sinks.

Fiji's continued commitment towards renewable energy is evident in the 2012 National Budget. The Prime Minister in his Budget Address to the nation announced the following:

The existing incentives provided for the setting up of renewable energy companies will continue. The tariff incentives provided for the importation of energy equipment will continue. The concession on duty on diesel for the production of biodiesel will be extended for the next five years, as opposed to on an annual basis. USD 1.5 million is allocated for the Biodiesel Implementation Project. Through Japanese aid, USD 2 million will be provided for the installation of solar home systems in rural homes and schools. USD 150,000 will be allocated for the Renewable Energy Development Project. (Fiji - National Budget, 2012).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

SimCLIM, a climate change model was used (Koshy, 2007) to assess the impacts of climate change in two areas, Natadola and Navua, in Fiji and Aitutaki in the Cook Islands. Koshy stated that:

Although, complete vulnerability and adaptation assessments using SimCLIM could not be performed on each site, the flood-risk maps, flood maps and the evaluation of water tank performance under present climate and climate change conditions for Natadola (Fiji), Navua (Fiji) and Aitutaki (Cook Islands) indicated significant impact.

(Dornan & Jotzo, 2011), applied the portfolio theory method to assess the potential contribution and measure the impact of renewable energy technologies on energy security in the form of electricity in Fiji. They concluded that investment in low cost renewable energy such as bagasse, biomass, geothermal and hydro-power technologies has the potential to modestly lower expected average generation costs, and to significantly reduce financial risk for Fiji's electricity grid. Their findings suggested that the Government of Fiji should

1. Promote investment in low cost renewable energy (bagasse, biomass, geothermal and hydro-power), and
2. Actively investigate the costs and benefits of energy efficiency measures.

Renewable energy technologies provide a cost-effective source of electricity in rural areas where distances are large, populations are small, and demand for energy is low. These technologies are ideal for Fiji whose inhabitants are spread widely in remote rural areas and small outer islands. As a result, a large proportion of households living in rural areas still lack access to modern forms of energy. However, access to basic energy services has been identified as a necessary condition for the achievement of many of the Millennium Development Goals. This is because access to energy can promote improved outcomes in the areas of health, education, and economic development. (Woodruff, 2007).

The Secretary General of the United Nations wrote the following in his foreword in "Energy for a Sustainable Future" (Moon, 2010).

Energy lies at the heart of achieving the Sustainable Development Goals (SDG) and mitigating climate change impacts. The decisions we take today on how we produce, consume and distribute energy will profoundly influence our ability to eradicate poverty and respond effectively to climate change. Addressing these challenges is beyond the reach of governments alone. It will take the active engagement of all sectors of society: the private sector; local communities and civil society; international organizations and the world of academia and research. To that end, in 2009 I established a high-level Advisory Group on Energy and Climate Change.

The United Nation's Advisory Group on Energy and Climate Change identified two key goals:

1. Ensuring universal energy access, and
2. Reducing global energy intensity.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

To achieve these goals, the Advisory Group recommended that energy consumption can be reduced through energy efficiency and a transition to a stronger reliance on cleaner sources of energy, including renewable energy and low greenhouse gas emitting fossil fuel technologies, such as a shift from coal to natural gas. The Advisory Group (AGECC, 2010).identified various sources of funding assistance that countries like Fiji can use to advance their renewable energy efforts. These include existing energy programs and funds (such as the Renewable Energy and Energy Efficiency Fund (REEF), the Climate Investment Funds of the World Bank and other Development Banks and GTZ's Energizing Development

Cloin (2007) stated that there are great opportunities to utilize coconut oil as a fuel in the Pacific. Coconut oil can be blended with diesel fuel, and under certain conditions totally replace it. Coconut oil in Pacific islands countries is increasingly used in both transport and electricity generation because of its lower local cost. Benefits include the support to local agro-industries and a decrease in emissions. All of Fiji's islands are lined with coconut palms.

An investigation was carried out by (Raturi & Lal, 2012) to assess the feasibility of wind/solar photovoltaic/diesel generator-based hybrid power system in a remote location in Fiji. They used the Hybrid Optimization Model for Electric Renewables (HOMER) software to simulate the system and perform system optimization analysis. They concluded that it is possible to alleviate the energy poverty by utilizing abundant renewable energy resources available in the region. The addition of renewable energy components results in greenhouse gas reduction which could be used for carbon trading.

Politics aside, the land lease issue has been the most problematic for the sugar industry in Fiji. The native land owners refused to renew the land leases for sugar cane farming claiming that their land was not being sustainably used and upon its return would be infertile and have no value. This has been ascertained by (Campbell & Doswald, 2009), who reported that continued use of land for sugar cane farming reduces the carbon in the soil. According to Stein, biodiversity and high conservation value areas are also among the main concerns of many stakeholders since sugar cane cultivation has been encroaching onto these lands.

A World Bank Report (2011) recommended integrating climate change and disaster risk reduction policies for the poor, into better urban planning and management. Policies to mitigate such risks have links to multiple sectors and thus can come with important synergies. For example, policies can be designed to have co-benefits with climate change mitigation policy goals. However, they warn, such policy choices come with tradeoffs and often difficult decisions. The outcomes of policy choices will have both positive and negative consequences that decision makers must carefully weigh.

The United Nations Environment Programme report (UNEP, 2011) "Towards a Green Economy: Pathways to Sustainable Development and Poverty Eradication" suggested incorporating renewable energy and sustainable agriculture policies at the national level. It emphasized that growth in investment and deployment of renewable energy technologies has been driven by an increasing number and variety of policies (IPCC, 2011). Individual policies to overcome various barriers to renewable energy development and deployment are most effective when they are part of a broad enabling policy framework, which builds on complementarity between a range of measures operating at multiple stages of the chain, from research and development, through to deployment and diffusion.

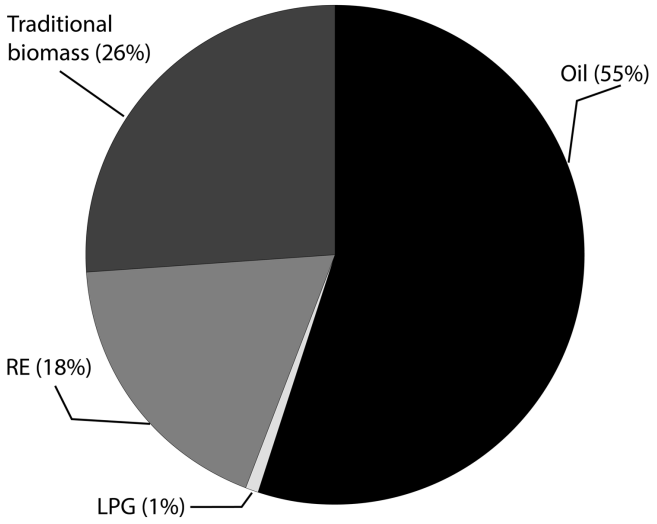
For sustainable agriculture, UNEP (2011) recommended that at the domestic public policy level, the key challenge is creating the conditions that would encourage more farmers to adopt environmentally sound agriculture practices instead of continuing to practice unsustainable conventional farming methods. To achieve sustainable agriculture development, a nation must develop policies that provide:

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

1. Support for improved land tenure rights of smallholder farmers;
2. Target programs for women smallholder farmers; and
3. Ensure public procurement of sustainably produced food.

There is thus a strong argument for incorporating renewable energy and sustainable agriculture policies into a nation's development policies.

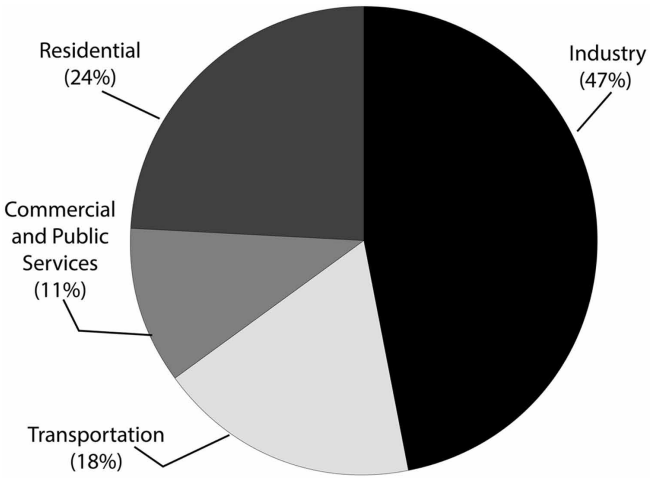
The Energy Sector in Fiji



Fiji at the moment is largely dependent on imported oil (Figure 1) to provide energy in the form of electricity and fuel to its citizens. Energy in the form of electricity is provided by diesel generators to home users, industries, manufacturing sector, agricultural sector, fisheries and the service sector (Figure 2). Energy in the form of fuel is provided to:

- Individual car owners,
- Taxis,
- Buses,
- Goods transportation, and
- Shipping services.

Fiji has no fossil fuels.



According to Fiji - BoS (2012), every month, Fiji imports around $131.5 million FJD (Fijian Dollars) worth of fuel from Singapore. This is 33.3% of all imports per month for Fiji. However, this is only for 60% of Fiji's population of 868,406 (World Bank, 2011). Forty percent of Fiji's population do not have access to electricity and 75% of Fiji's populations do not own cars (UNDP, 2011). Those that do not have access to modern energy sources rely on traditional biomass.

Figure 1. Energy sources
(RECIPES, 2006)

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Energy consumption
(RECIPES, 2006)

Energy contributes to a virtual cycle of human, economic and social improvements that are essential to sustainable development in developing countries, reports (OECD, 2007). It further states that

Sufficient supplies of clean energy are the basis for raising standards of living, improving the quality and quantity of human capital, enhancing the business and natural environment, and increasing the efficiency of government policies.

The contribution of the energy sector to Fiji's economic and social development is an example of the above. The contribution of the energy sector towards Fiji's GDP was 3.6% in 2005 and was expected to rise to 3.8% in 2007 and continue rising at a rate of 2.5% per annum thereafter (Fiji-SDP, 2006). The amount of electricity generated and sold by the Fiji's Electricity Authority (FEA) is an indicator of the level of economic activity in the country.

Access to electricity in rural areas has improved, with over 100 schemes each year under Government's Rural Electrification Programme. Major changes have taken place within the FEA, following its restructuring. Measures have also been put in place to improve the efficiency and effectiveness of FEA's operations. FEA plans to invest USD 170 million up to 2011 in parallel with some $150 million of private investment in IPP (Independent Power Producers) and PPP (Public Private Partnership) arrangements.

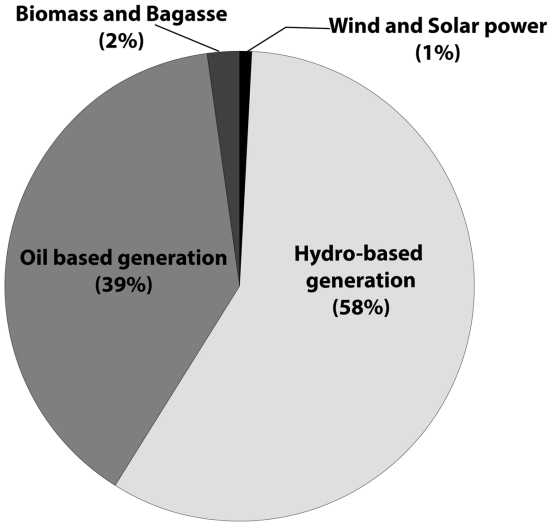
In 2006, the Fiji government developed and implemented in 2007, a national energy policy and a strategic action plan that provided the framework for energy sector activities.

Renewable Energy Efforts in Fiji

The International Renewable Energy Agency (IRENA) is an intergovernmental organisation that supports countries in their transition to a sustainable energy future, and serves as the principal platform for international cooperation, a centre of excellence, and a repository of policy, technology, resource and financial knowledge on renewable energy. The Director-General of IRENA (Amin, 2015), states the following on Fiji's Renewable Readiness Assessment "As the costs of renewable energy technologies

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

continue to decline, Fiji is increasingly able to make use of its full range of renewable energy resources. These include large and small hydropower resources, as well as biomass, geothermal, solar and wind energy. All of these can help to ensure a reliable, affordable energy supply". He further adds "The National Energy Plan tabled in 2014 offers a promising path that would lower the risks, both real and perceived, for renewable energy investments. Reducing investment uncertainty is crucial for Fiji to create an enabling environment in which renewable energy flourishes.



Several renewable energy projects were planned and a number of them have been implemented under Fiji's National Energy Policy and Strategic Action Plan. With Fiji being a tropical island in the South Pacific and being endowed with an abundance of natural resources, renewable energy alternatives are many. Some renewable energy alternatives that have been successfully implemented and currently in use are hydro, solar, and wind (Figure 3). Bagasse is being used in sugar mills, bio-mass in timber mills and trials are being done on ethanol from sugar cane and bio-fuel from coconuts (Figure 4) and cassava.

Other potential renewable energy sources that can be considered in Fiji are:

- Municipal waste,
- Geothermal,
- Tidal power,
- Wave power, and
- Ocean thermal energy.

A charter for Renewable Energy-Based Rural Electrification with participation of the private sector was developed with UNDP-GEF (Global Environment Facility) assistance, and approved by Government in March 2003. The charter provided a mechanism for renewable energy service companies to install and maintain renewable energy-based projects. The formulation of a 'Renewable Energy-Based Rural Electrification Bill' was also approved in 2007 and consultations are ongoing. With Asian Development

Figure 3. Electricity Generation
(Dornan & Jotzo, 2011)

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. Coconut Bio-Fuel Generator
(Woodruff, 2007)

Bank (ADB) support, Fiji completed a Renewable Energy and Energy Efficiency Programme (REEP), aimed at building capacity to develop, fund and implement renewable energy and energy efficiency projects, emphasizing market driven structures (Fiji-SDP, 2006).

Depending on rainfall patterns, hydro-power generates between 48 and 65% of Fiji's grid electricity in any given year (Dornan & Jotzo, 2011). Another hydro-power project will generate an additional 42 MW of power by the end of 2012, enough to meet another 20% of the island's electricity needs (Fiji Sun, 2012).

Wind and solar technology provide less than 1 per cent of FEA power (Dornan & Jotzo, 2011). The Pacific Environment Community (PEC) Fund will contribute USD $2.3 million towards a rural solar home systems project in Fiji (PIFS, 2012). FEA proposes to install hundreds of Vergnet GEV MP 275 kW turbines to create a 100 MW wind farm anticipated to produce 111.5GWh of electricity a year (FEA, 2012).

The Agricultural Sector in Fiji

Agriculture is the mainstay of Fiji's economy and contributes around 28% to total employment in the formal sector and indirectly employs many more. This agricultural sector which was once a major stronghold of Fiji's economy is the third largest now, contributing USD $250 million (9%) annually to the nation's GDP. Agriculture has potential in other sectors such as tourism and agro-industries and as

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

a major economic activity in the rural areas; agriculture plays an important role in the process of rural development. (Investment Fiji, 2015). According to Fiji's Minister for Industry and Trade, Faiyaz Koya

The Agriculture sector in Fiji is emerging from predominantly subsistence based and on average continues to contribute about 9% of GDP and accounts for 3% of domestic export.

The agricultural sector in Fiji continues to represent the principal economic mainstay of the country and is regarded as its economic backbone. Sugar cane farming is one of the major agricultural activities. In addition, the sector impacts other sectors such as tourism and agro-industries. As the major economic activity in the rural areas, agriculture plays an important role in the process of rural development. The agricultural sector is being relied upon for economic prosperity as it has huge potential for export revenue (Table 1).

The sugar industry directly engages about one fifth of the total labor force in Fiji and creates significant multiplier effects within its economy. The sector production performance is projected to improve in the medium term as a result of expected improvement in cane quality, efficiency gains through the restructure programme within the sugar industry and increases in the production of various other crops. The Sugar Industry is also important to Fiji's economy as it contributes about 1.7 percent of GDP, generates about 8% of total exports with a total foreign earning of USD $80 million in 2013 based on the provisional data from the Reserve Bank of Fiji. Unlike many other export-oriented industries, most production inputs are domestic and have a high regional impact and cross-sectoral linkages (Fiji Sugar Corporation, 2014).

Fiji is known as the 'garden islands' because it has the potential to grow anything. Fiji is potentially on the verge of an exciting new era of growth and diversification in the production and export of agricultural products. The agricultural sector constitutes of two main sub sectors:

- Crops, and
- Livestock.

The crops sub-sector includes sugar and non-sugar:

- Traditional root crops (dalo, cassava and yaqona),

Table 1. Fiji's GDP contribution by the agricultural sector

Fiji's GDP Contribution by the Agricultural Sector USD (Millions)					
	Base Weight	Years			
		2011	2012	2013	2014
GDP	100.0	2,869.4	2,909.9	3,047.7	3,208.9
Agriculture	8.2	236.3	232.6	248.5	242.7
Subsistence	2.7	76.3	76.6	77.3	76.6
Informal	0.7	18.9	18.9	19.1	19.0
General Government	0.1	4.1	3.9	4.4	5.0
Non-General Government	4.8	137.1	133.2	147.8	142.1

Source: *(Fiji – BoS, 2014)*

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Tropical fruits (pineapple, pawpaw and mango),
- Vegetables,
- Rice,
- Spices,
- Cocoa, and
- Coconut products.

The livestock sub sector includes:

- Beef,
- Dairy,
- Pork,
- Poultry,
- Sheep,
- Goat, and
- Bee stocks.

However, so far, the agricultural sector in Fiji has performed below expectation. The sugar industry has suffered because of non-renewal of land leases for sugar cane farming and the removal of quota system and preferential price for sugar that Fiji used to get from the EU.

Sustainable Agricultural Efforts in Fiji

Fiji's efforts towards sustainable agriculture have been marginal. Costs associated with sustainable agricultural practices, lack of awareness and lack of assistance are some of the reasons behind these mediocre efforts. Farmers seeking higher profit margins with less investment do not care about exploiting the land, depleting its resources, dumping waste wherever they want, and harming the environment. Lack of rules and regulations with no severe penalties for such offences is a contributing factor as well.

Fiji's population growth over the past 40 years has resulted in increased demand for agricultural production, and consequently has put significant pressure on arable lands. Intensive application of fertilizers and pesticides, mono-cropping, and short fallow periods have depleted and prevented recovery of soil fertility, caused increased soil erosion, lowered yields, reduced food security, and increased rural poverty. A by-product of rural poverty has been an increased rural-urban drift, which has in turn led to other adverse social, economic, and environmental consequences. (Xing, 2015).

A host of unsustainable agricultural practices are on-going in Fiji. In addition to the intensive cultivation practices described above, the others include:

- Sloping land cultivation of sugar-cane, ginger and dalo;
- Commercial livestock farming without good pasture management;
- Reclamation of large freshwater swamps for growing rice; and
- Reclamation of large mangrove swamplands for agricultural use.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Soil loss in four major watersheds in Fiji

Watershed	Soil Loss (tons/ha/yr)	Soil Loss (mm/yr)	Total Soil Loss (millions tons/yr)
Rewa	32.2	2.2	9.3
Ba	69.0	4.6	6.4
Sigatoka	76.9	5.1	1.1
Nadi	81.4	5.4	4.2

Source: *(Fiji – BoS, 2014)*

Over the years, these practices have increased erosion, resulting in the loss of soil nutrients and thinning of top soils (Table 2), siltation of rivers, deterioration of drainage on river flats, and inundation of coastal areas (ADB, 2005).

The major agricultural sector, sugar cane farming, is the foremost contributor to unsustainable agricultural practices. Sugar cane farmers would have to adopt more efficient and sustainable cane farming methods. However, the sugar cane farmers will require some convincing to adopt such sustainable farming methods as it comes with associated costs and changes to existing farming methods. Rein (2012) suggested that in the long run it is expected that conforming to such standards (sustainable farming methods) will save money, as inputs such as energy and raw material are used more efficiently, losses and wastage are minimized and manpower is used more productively.

Greenhouse gas emissions from sugar mills is another issue that needs to be addressed. Eustice et al. (2011) have shown that cane burning reduces the organic carbon in the soil, while green cane harvesting can improve it. Sugar cane farmers in Fiji are notorious for burning their cane as it enables them to harvest and transport it to the mill rather than wait for their turn. One of the sugar production mills in Fiji is located on the banks of a major river. Tests conducted conclusively proved that there was a heavy sugar discharge into the river (Ralogaivau, 2008). The Mill Manager of the Sugar Mill at that time assured that they were going to change the discharge system. To date, nothing has changed.

GAP ANALYSIS IN ENERGY POLICIES

In business and economics, gap analysis is a tool that helps companies compare actual performance with potential performance. At its core are two questions:

- "Where are we?" and
- "Where do we want to be?" (Hyra, et. al. 2015).

A number of gap analyses in energy policies mostly looked at energy efficiency (ESCAP, 2011; Masood, 2010; Mesa, 2009; Jaffe & Stavins, 1994). Others looked at renewable energy (RERL, 2011; Santalco, 2012), biomass (Barber, 2007), and natural gas (Brock & Petak, 2007).

In analyzing Fiji's policy gap for energy, this paper will evaluate where Fiji is and where it wants to be in order to fulfill its obligations of ratifying UNFCCC – Energy Efficiency, Kyoto Protocol – Renewable Energy and Sustainable Development Goals (SDG) and Rural Electrification. Renewable energy,

energy efficiency and rural electrification policies gap will be analyzed to lay the groundwork to scale up action in priority areas, undertake strategic reforms where needed, and attract new investments and financial support. Table 3 provides an indication of Fiji's effort and the remaining gap.

Fiji's renewable energy projects, energy efficiency programmes, and rural electrification schemes are being guided by its National Energy Policy (NEP), which comes under the Socio-Economic Development Charter. The strategic areas that NEP follows are:

- Energy planning,
- Energy security,
- Renewable energy, and
- The power sector.

NEP's objective is to ensure that the demand for reliable and affordable electricity is adequately met.

The policies have been in effect since its first draft in 2004. Twelve years on gaps exist in its achievement as is evident above. The policy analysis also identifies some policies whose outcomes would be in contravention to the UNFCCC convention and Kyoto Protocol.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Gap Analysis in Agricultural Policies

The agricultural policies of Fiji were examined to analyze the policy gap in terms of where Fiji is and where Fiji wants to be to achieve sustainable development in agriculture. Sustainable agricultural development will ensure Fiji's economic and social development as well as address environment, climate and energy concerns of UNFCCC, Kyoto Protocol and Sustainable Development Goals (SDG).

A search for existing agricultural policy gap analysis to see if any could be applied in Fiji's context came up with interesting results. The policy gap analyses are varied and customized. Some of them look at the yield gap of global grain production (Neumann et al., 2010), the gap between policies recommended by external sources (donors) and those generated locally in Africa (AGRA, 2011), and policy gaps in the inclusion of climate change concerns in agriculture in Pakistan (IUCN, 2009). While in Fiji, land degradation from agriculture (Fiji – DoE, 2008) and food import substitution (Fiji – FAO, 2010) policies have been carried out.

Land use and improvement, yield productivity, food security, environment management, and incorporating climate change concerns into agricultural policies are all identified gaps in current policies. Table 4 highlights some agriculture policy gaps in the two major agricultural sector commodities in Fiji:

Table 4. Agriculture policy gap analysis

Sugar Industry		
Where Fiji Is? (1)	**Where Fiji Wants to Be? (2)**	**The Gap**
Lack of Sugar Cane Farming Land	Increase Availability of Land for Sugar	Land Use Policy Gap
Lack of Interest in Sugar Farming	Attract/Increase Sugar Cane Farming	Policies Needed
Low Yield Sugar Cane Stalks	High Yield Sugar Cane Stalks	Research Policies Gap
Sugar Mills Breakdowns/Inefficiency	Repair/Reform/Modernise Sugar Mills	Reform Policies Gap
Labour Intensive Planting/Harvesting	Machine Based Planting and Harvesting	Infrastructure Policies
Vegetable and Root Crops		
Where Fiji Is? (3)	**Where Fiji Wants To Be? (4)**	**The Gap**

1. Sugar; and
2. Vegetables & Root Crops; as well as in land and environment.

Fiji needs agricultural policies that focus on its food security so it is able to produce its own food. Being an isolated group of islands in the South Pacific, it cannot afford to rely on imported food. As the country moves to produce more agricultural commodities for export, it needs policies that take care of its land and environment. Policies are needed that provide incentives for people who want to engage in agriculture and mechanisms need to be in place for support and assistance. Training, research and development policies in agriculture should fill this gap.

WHAT IS THE WAY OUT AND HOW TO GET THERE?

The ozone layer has been depleted because of greenhouse gas emissions and we will get exposed to ultra violet radiation. There is global warming because of CO_2 emissions and the ice caps will melt causing the sea level to rise. Extreme weather events like floods, droughts, heat waves, wild fires, cold waves, tropical cyclones, hurricanes, tornadoes, and others will increase in frequency and intensity. Are we doomed? No!! What can we do? All we can do for now is come with the strategies to mitigate the effects of climate change, and adapt accordingly. Our planet has been resilient, its people need to build resilience as well.

The way out has challenges. The climate has been changing and will continue to do so. We cannot reverse the damage that we have caused to the environment so far. However, we can slow it down and prevent further damages. Our anthropogenic actions have emitted and accumulated greenhouse gases in the atmosphere to such an extent that natural carbon sinks and other absorption mechanisms will take many years to remove. Cubasch et al. (2001) modeled projections of future climate change for IPCC and reported that climate change is not only irreversible, but would intensify by the end of the 21st century.

A Fijian reading this chapter would question "what has Fiji done to suffer this fate – our contribution to the climate change phenomena has been negligible, almost nothing compared to other industrialized countries – but we have been suffering the most and would continue to suffer the most, given our geography". The answer is simple. We all share the same planet. Floods, tropical cyclones and drought have increased in frequency and intensity. Islands are being lost to rising sea levels and land is being lost due to coastal and river erosions. We all have common but differentiated responsibilities to do our part to manage climate change impacts as recommended in the report titled "Resilient Planet, Resilient People – A Future Worth Choosing" United Nations Secretary-General's High-Level Panel on Global Sustainability (2012). So what has Fiji done so far? Fiji has done a lot. A lot in terms of working with international, regional and local organizations and governments to establish committees, teams, programs and develop documents, papers, strategies and policies, acts, laws and legislations to mitigate, adapt and build resilience to climate change.

Fiji established a National Climate Change Committee and a National Climate Change Country Team that developed the National Climate Change Policies. Fiji has finalized its National REDD Plus Policy that aligns itself with the objectives of the Fiji Sustainable Economic and Empowerment Development Strategy (SEEDS) and the policies will also play an important role in supporting Fiji fulfilling other international commitments (aside from UNFCCC), such as CBD (Convention on Biodiversity) and UNCCD (Convention on Combating Desertification). As the costs of renewable energy technologies

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

continue to decline, Fiji is increasingly able to make use of its full range of renewable energy resources (Amin, 2015).

Fiji is part of the Pacific Islands Climate Change Assistance Programme (PICCAP) and has a Fiji Country Team. Fiji also has:

- A Biodiversity Strategy and Action Plan;
- Sustainable Development Bill;
- Environment Management Act (EMA);
- National Council for Sustainable Development;
- Ozone Depleting Substances Act;
- National Land Use Policy and Plan;
- National Environmental Strategy;
- Comprehensive Hazard and Risk Management (CHARM);
- Integrated Coastal Zone Management Programme;
- Climate Change Vulnerability and Adaptation Assessment and Strategic Plan; and
- Drought Mitigation and Early Warning System.

For a full list, refer to www.fiji.gov.fj.

However, all Fiji has done so far is on paper. We have yet to see implementation and enforcement for many of the above. We have yet to see evaluations and results of the above. We have yet to see the monitoring of the policies and changes or improvements, if any, that they have achieved. Successful implementation, enforcement and monitoring of the policies and programs mentioned above will enable Fiji to mitigate, adapt and build resilience to the impacts of climate change.

There are many sectoral causes to the climate change phenomena, but in this paper, for Fiji, the focus is on the energy sector and the agricultural sector – the two main causes of climate change and the two main contributors of social and economic development and environmental degradation. What can we do about the policy gaps identified in the Gap Analyses in Energy and Agricultural Policies sections of this paper?

Energy Policies and Energy Policy Gaps

There are a number of energy policies under the umbrella of Fiji's National Energy Policy (NEP) and a number of projects with Fiji's Department of Energy (DoE) as well as Renewable Energy Projects and Programs with UNDP's Global Environment Facility (GEF). Other policies, programs and projects include:

- Rural Electrification and Energy Efficiency Program for the Pacific (REEP);
- Rural Electrification Policy (REP);
- Rural Electrification Unit (REU);
- Renewable Energy in Emerging and Developing Countries (RECIPES); and
- Office for the Promotional of Renewable Energy Technology (OPRET).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

In terms of policies, projects and programs, Fiji has done well. Implementation and operation of renewable energy projects, especially hydroelectricity schemes are going well. There have been many wind turbines and solar (photo voltaic) installations as well as biomass electricity and bio-fuel trials.

However, as mentioned earlier some of the energy policies are in contravention of UNFCCC and the Kyoto Protocol.

Renewable Energy

Hydro

Hydro power projects in Fiji alone can generate electricity sufficient for the entire country. However, Fiji cannot rely on hydroelectricity alone as its generation is depended on rainfall patterns and with climate change there are periods of drought. The energy policy prescribes that Fiji uses a lower percentage of electricity from hydro power than at present. This is quite odd. According to Kumar et al. (2011) hydro power offers significant potential for carbon emissions reduction and remains the largest source of renewable energy in the electricity sector. However, Bosshard (2011) claimed that large hydropower projects are not a renewable source of energy and can produce significant amounts of greenhouse gas emissions, a concern also raised by Lima et al. (2008).

Biomass

This policy is quite controversial and in contravention of UNFCCC and the Kyoto Protocol. In Fiji, energy from biomass is produced by burning bagasse and timber. This releases CO_2, GHGs and solid carbon combustion particles. Fiji wants to increase this activity by 27%. Burning biomass produces a large amount of air pollution that is probably responsible for 4–5% of the global burden of disease, as Diette, et al. (2012) reported. Similarly, nitrogen and sulphur emissions lead to acid deposition far from their sources. Such deposition is associated with damage to forests, soils, and lakes in various parts of the world.

Wind

There is no prescribed policy to generate any greater percentage of electricity from wind. Fiji's coastal areas and mountains are ideal for harnessing the power of the wind. As suggested by Narayan and Singh (2007), wind energy conversion system can also become a major source of energy for Fiji, as it is environmentally friendly and can be obtained at low cost. Small Island Developing States (SIDS), like Fiji, can use the Kyoto Protocol's Clean Development Mechanism (CDM) to attract wind energy projects like the one on the island of Santiago, Cape Verde, where they were able to produce around 30% of electricity from wind and reduce CO_2 emission from electricity production by the same percentage (Duic, 2003).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Solar

Being a tropical island, Fiji has the potential to use solar energy throughout the year. Policies for solar energy projects have resulted in a number of photo voltaic installations in remote islands and mountains. Since Fiji's electricity grid cannot expand to everyone, more policies are needed to provide solar energy to people where the grids are uneconomical to operate at present. The Fiji – DoE (2009) determined that the use of solar electrical or photovoltaic (PV) panels in the rural sector, away from the FEA grid, is of major importance to rural development but at present, the installed capacity is negligible in the country.

Bio-Fuel

Successful trials have been conducted and coconut bio-fuel generation plants installed on Fiji's remote islands which have abundance of coconuts. Policies are now needed for bio-fuels to be integrated into the energy generation and consumption mix. Of particular interest to Fiji is the ability to mix bio-fuel with existing petrol and diesel for transportation. There are environmental, economic, social, energy efficiency benefits for Fiji in this policy (Cloin, 2007; Hill et al., 2006; Yee et al., 2009).

Energy Efficiency

For energy efficiency, a number of policies have been introduced. Rao and Rao (2009) reported that energy efficiency did improve in Fiji after the energy crisis, but this was not due to energy efficiency policies but rather due to higher energy prices. They used the structural breaks test to ascertain this. Therefore, they recommend the use of government policies to encourage energy saving through price increases and other policies like encouraging purchase of more energy efficient appliances and equipment. The scope for the latter is significant because most of the household appliances, vehicles and industrial equipment are old (Fiji – BoS, 2012).

The Fiji Electricity Authority introduced a three-tiered tariff system in 2007 in which there was no increase in tariffs for households whose electricity bills did not exceed 24 USD. For other households, tariffs were increased by a minimum of 3.2%, and commercial customers increased by 6.45%. However, there is no measure of how effective the three-tiered tariff system of electricity billing has been, even in conserving energy. Incentives need to be given to households to install solar power systems, including systems in which surplus power generated from homes can be fed into the national grid.

Rural Electrification

Providing electricity to 70% of Fiji's population is no ordinary task given Fiji's mountainous terrains and remote islands with pockets of villages. The policies have served well and improved their socio-economic conditions. In cases where the expansion of the electricity grid was impossible, stand-alone electricity services through renewable energy projects such as, coconut bio-fuel, biogas, solar and wind based systems were implemented (Fiji – DoE, 2009). PPP Power Projects and RESCO's establishment policy gaps remain.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Agricultural Policies and Agricultural Policy Gaps

There are a number of policies in agriculture for economic growth and productivity. However, the policies lack the sustainable development requirements of the agricultural sector for socio-economic growth and environment conservation. Climate change policies have not been mainstreamed into existing policies, but rather side-streamed with the NCCP (Republic of Fiji, 2014).

Some of the existing agricultural policies are:

- Agricultural Landlord and Tenant Act (ALTA);
- Land Conservation and Improvement Act;
- Outer Island Agriculture Development Act;
- Watershed Management Master Plan;
- Sugar Industry Act;
- Integrated Pest Management Act;
- Land Development Act;
- Soil and Crop Evaluation Project; and
- Land Conservation Board.

The Sugar Industry

The sugar industry is riddled with problems at all levels. These include:

- Lack of land for sugar cane farming,
- Expiring leases for sugar cane farming land,
- Lower sugar yield in cane,
- Lower sugar cane tonnage/hectare of land,
- Lack of labor to plant, grow and harvest sugar cane,
- Sugar cane transportation problems to sugar mills, and
- Sugar mill efficiency problems.

These problems have existed for years and have led to a lack of interest in sugar cane farming. Gaps in policies exist for all the problems identified above however, existing policies are ineffective.

There are a number of publications investigating the sugar industry. These include the following:

- Performance, Problems, and Potentials in the Sugar Industry by (Prasad & Narayan, 2003);
- Poverty Implications of Expiring Sugar Cane Land Leases by (Reddy & Naidu, 2001);
- Fijian Sugar Cane Farmers Perception of their Future by (Naidu & Reddy, 2002);
- Reform of the Fiji Sugar Industry by Sugar Unit - Fiji (2011); and
- Farm Productivity in Fiji's Sugar Industry by Reddy (2004).

Policies can be developed from these publications.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Vegetables and Root Crops

Policies, together with government support (training and development) and assistance (funds, seeds, resources) are needed for vegetable and root crop farmers to diversify to other crops. Farmers in Fiji do seasonal farming and flood the markets with their produce, obtaining very low prices. In the off-season, there is no production and consumers, especially hotels and resorts, have to import fruits and vegetables. Research and development policies are needed to cultivate off-season varieties of vegetables and explore alternative production systems such as hydroponics and greenhouses. Policies are needed to add non-traditional vegetables, fruits, and root crops for production and export. Policies are also needed for Fiji to become self-sufficient in producing rice for local consumption.

Gaps in policies exist for ensuring food security but it is achievable given Fiji's natural resources.

Land and Environment

Fiji at the moment has Land Conservation, Land Improvement and Environment Management policies. But enforcement is lacking. To date, no one has been prosecuted for violating these acts. The extent of soil erosion in Fiji, its river siltation, flooding and river, sea and land pollution would give an indication of the lack of enforcement. Squatter settlements in cities not served by the municipal council are left to their own mechanisms for waste disposal and sewerage systems. IMR – USP (2004) reported that urbanization in Fiji has led to subsequent waste disposal problems and pressure on land.

THE ROLE OF ICT'S IN ADJUSTING TO CLIMATE CHANGE

No matter what we do from now onwards, we will still face the effects of climate change (IPCC – WG I, 2001; Schneider, 2004; Solomon et al., 2009). But that does not mean we do nothing. If we do nothing, then the future generation will face:

- Extinction of certain plants and animals (Thomas et al. 2004);
- Extreme weather events will lead to reduction in carrying capacity of food, water, energy;
- And national security implications of one country trying to poach resources from another (Schwartz & Randall, 2003).

Therefore, given the above, our strategic approach is now focused on:

1. Mitigation – reduction in anthropogenic activities causing climate change (IPCC – WG III, 2001; (Canadell & Raupach, 2008); (Lutsey & Sperling, 2008);
2. Adaptation – learning how to live with the impacts (IPCC – WG II, 2001; Adger et al., 2005); and
3. Resilience – building human and ecological processes to absorb the effects of climate change (Tompkins & Adger, 2004).

ICTs (information communications technologies) can play a critical role in mitigating and adapting to climate change impacts. They can assist countries like Fiji to build resilience and adopt best practices through appropriate technology transfers and sustainable development.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

The Role of ICTs in Climate Change

Climate change awareness and education can be enhanced with the use of ICT enabled social media, for example Facebook, Twitter and Web 2.0 applications. Such education and awareness will enable long term sustainable changes (considering the demographics of social media users) in anthropogenic activities that cause climate change. ICTs can play a significant role in reducing the greenhouse gas emissions, in particular through enabling smart energy efficiency and by providing a substitute for the physical transport of goods (for example by the use of e-Books) and people (for example by the use of Skype). For developing countries like Fiji, it is the role that ICTs can play in climate change monitoring and adaptation that is likely to be more important.

The Climate Technology Program initiated by infoDev (infoDev Annual Report 2014-2015) examines the role that ICTs can play through the development and deployment of climate-smart technologies and business models. This can enable developing countries to increase their resilience to climate change while profiting from global demand for clean technology The Climate Technology Program (CTP) uses private sector development approaches to help countries develop effective and profitable solutions to climate challenges through Climate Innovation Centres. Sectors supported by Climate Innovation Centres include:

- Water management;
- Resource use efficiency;
- Energy efficiency and clean energy;
- Solar energy;
- Sustainable and climate - smart agriculture;
- Renewable technology (solar and wind);
- Transportation technology;
- Biofuels and biomass; and
- Adaptation technology.

The Role of ICTs in Climate Change Policy Formulation

Apart from ICT being used to formulate climate change policies, it can assist in developing appropriate policies. ICT has the potential to remodel key urban problems such as a deteriorating environment, congestion or lack of communications between citizens and institutions (Cohen et al., 2002) in developing appropriate policies. Otto et al. (2006) used Computable General Equilibrium (CGE) models to simulate the cost effectiveness of climate change policies and choose among the best. Other cases where ICTs has been used to formulate appropriate climate change policies are: Use of networked governance and public policy formulation (Wilikilagi, 2009); E-governance for adaptation; Citizen centric approach to public policy formulation (Marche & McNiven, 2003); Centeno et al., 2005).

The Role of ICTs in Climate Change Mitigation

Fiji is part of the Pacific Disaster Net – a Virtual Centre of Excellence for Disaster Risk Mitigation in the Pacific Region with comprehensive information resources. The Asian and Pacific Training Centre for Information and Communication Technology for Development (APCICT) of the United Nations is designed to enhance capacity in the use of ICT for disaster risk management and climate change abate-

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

ment (Labelle, 2011). Policies are proposed for the use of ICTs for abating climate change and promoting Green Growth.

Ospina and Heek (2010) explored the role of ICTs in Climate Change via the reduction of emissions through smart grids, dematerialization or intelligent transport systems and buildings. Experiences from vulnerable communities in developing countries point to the use of applications such as mobile phones, the internet and community radio for mitigation. ICTs are critical to providing tools for monitoring, modeling, communication, coordinating, visualizing, advocating and predicting climate change impacts (Hasan et al., 2009).

The Role of ICTs in Climate Change Adaptation

ICT software and model simulations project the extent of climate change impacts and forecast an estimate of when such impacts are likely to occur. Thus when Hurricane Sandy hit the United States of America in November 2012 there were fewer fatalities than Hurricane Katrina in 2005 because of projections made using ICTs (IEEE, 2012). Statistical Down-Scaling Model (SDSM) is used for assessing local climate change impacts using a robust statistical downscaling technique (Wilby et al., 2002).

The impact of climate change is quite complex as we live in an integrated ecosystem with inter-dependencies. Such complexities can be modeled and managed with environment modeling software (Wostl, 2007) for example, Sustainable Urban Development Planner for Climate Change Adaptation – SUDPLAN (Schlobinski et al., 2011).

The Role of ICTs in Building Resilience to Climate Change

Pacific Small Islands Developing States (SIDS) recognize that there are new opportunities afforded by the rapid new developments in ICT to overcome limitations of isolation and remoteness and build their resilience (Koshy, 2004). ICTs are revolutionizing the generation of, and access to data for researchers who are interested in ecological monitoring (Galaz et al., 2010). They can "mine" the internet to detect "early-warning" signs of ecological changes. Other climate change resilience building strategies using ICT have been identified by Allenby (2007), Karanasios (2011), and Yap (2011). They include:

- Energy - ICT can enable the integration of renewables onto the grid, improve efficiency and heighten transparency;
- Food - ICT can help raise productivity and reduce food waste;
- Manufacturing - ICT will place the customer at the centre of a user focused service, cutting resource inputs at the same time;
- Buildings – ICT will increase comfort and reduce energy and water bills; and
- Mobility and Logistics - ICT can help everyone reach their destinations faster, cheaper and safer (GeSI, 2015).

The Role of ICTs in Sustainable Development

ICT and ICT enabled technologies have already created unparalleled development opportunities in developing countries. Mobile phones have led to applications and provision of services such as m-Banking, m-Health, m-Learning, m-Agriculture and many others that would have been otherwise impossible.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

E-Learning has provided the potential for distance and flexible learning and opened up learning opportunities for those who do not have access to education and those who did not make it when they had the chance. Education leads to socio-economic growth and development. Climate change awareness and education will lead to sustainable economic growth, social welfare and sustainable development.

CONCLUSION

Fiji has done a lot under its obligations towards ratifying the UNFCCC and the Kyoto Protocol, but at the moment, they are on paper as policies, acts and legislations. Implementation of the policies, enforcement of the acts, monitoring and evaluation are yet to materialize. Once evaluations are carried out and changes and improvements are measured from the status quo, then we would get an idea of the effectiveness of the policies in place. Policies would then need adjustments to make them effective for Fiji to fulfill its obligation and reach its desired climate change objectives. Due to continuous climatic change and its impact, the agricultural sector is struggling to cope (FCCN, 2015). According to Narain (2015), Fiji has been active in addressing climate change at the policy and project level. However, it faces the challenges commonly experienced by developing countries, including problems associated with lack of funding and resource allocation.

Apart from mainstreaming some climate change policies into exiting ministries, acts and legislations, Fiji has created new policies, committees and programs to combat climate change impacts. It is recommended that Fiji reexamine its climate change policies after an evaluation and where possible mainstream them into existing ones. This would prevent duplication of efforts and costs, and reduce the occurrence of confusion and stakeholders blaming each other. The policy gap analysis identified some policies that are needed, some that need revision, for example the reliance on biomass for energy, and some that are totally ineffective, for example the policies in the Sugar Industry.

Energy and agriculture are the two major sectors in Fiji. They contribute the most to greenhouse gas and carbon emissions, while contributing the most to Fiji's economy. Taking stock and sustainably developing these sectors would fulfil Fiji's obligations and take care of the economy. Fiji was doing very well on the Renewable Energy front with hydro, solar and wind, but its greater reliance on biomass for energy is uncertain. Further investigation is needed in this regard. Agriculture is critical for Fiji's food security; as such, land improvement and sustainable agricultural practices are need for long-term growth and self-sufficiency.

Fiji can learn from best practices in renewable energy and agriculture that have been successful in other parts of the world. Fiji can request technology transfer instead of cash from donor countries/agencies and build capacity for the future. Fiji's sugar industry can learn from Brazil's sugar industries; especially with respect to yield productivity and ethanol production. Bio fuel in Fiji would enable Fiji to absorb oil price shocks and future energy crisis. Many 'Annex I' countries are looking for hosts for Clean Development Mechanism (CDM) projects. Annex I Parties include the industrialized countries that were members of the OECD (Organisation for Economic Co-operation and Development) in 1992, as well as countries with economies in transition (the EIT Parties), including the Russian Federation, the Baltic States, and several Central and Eastern European States. So far Fiji doesn't have any Annex I partner country to which it can sell its carbon credits. Income from selling carbon credits, climate change funding, and finance are available from many international donors.

Climate change impacts are inevitable. Countries like Fiji would be the most affected, but contributed least to the cause. They should focus on mitigation (reducing the anthropogenic activities causing climate change), adaptation (learning to live with climate change impacts), and building resilience (human and ecological processes to absorb the effects of climate change). Fiji needs to incorporate climate change concerns in its policies that mitigate, adapt and build resilience to future climate change predicaments. Collaborative efforts created through awareness of the issues are needed as the government cannot do it on its own.

ICTs can play a critical role in the mitigation, adaptation and resilience building process. ICT enabled social media can create awareness of climate change issues and can help in formulating appropriate policies based on models and simulations. Early warning systems can prevent fatalities caused by extreme weather events. Resilient plant varieties and animal species developed with the assistance of ICT enabled research and development facilities would ensure food security and survival of the ecosystem in the future. Applications such as Skype and transport navigation systems enable reduction in carbon footprints of humans and the products they consume. Our developments have led us to this; can one of them save us?

UNESP – Univ Estadual Paulista, Brazil

ABSTRACT

The sustainability definition is still unclear, and requires more in-depth studies to expand their understandings and their effective implementations. One of the means by which to achieve organizational sustainability presented in literature is the use of the concept of Integrated Management System (IMS). Normative management standards such as ISO 9000, ISO 14000, OHSAS 18000, and SA 8000 stand out with large numbers of accreditation by the companies targeted for joint establishment of an IMS, and more recently, normative standards have been identified as mechanisms to ensure the sustainable development of organizations by the integration of economic development, social progress, and environmental quality. This chapter aims to show the evolution of concept of sustainable development; present a definition for the organizational environment; highlight the interaction term "organizational sustainability" with basic normative standards systems management; and guide organizations by describing how interactions between normative standards and the dimensions of sustainability can occur.

INTRODUCTION

In last two decades, sustainability concept has been expanding and gradually embraced by organizations and governments worldwide (Gibson, 2006; Mullerat, 2010).

Sustainability is a relatively new, evolving concept and no consensus exists regarding its definition and a true meaning. A great deal of research has been committed to developing the theme, and research-

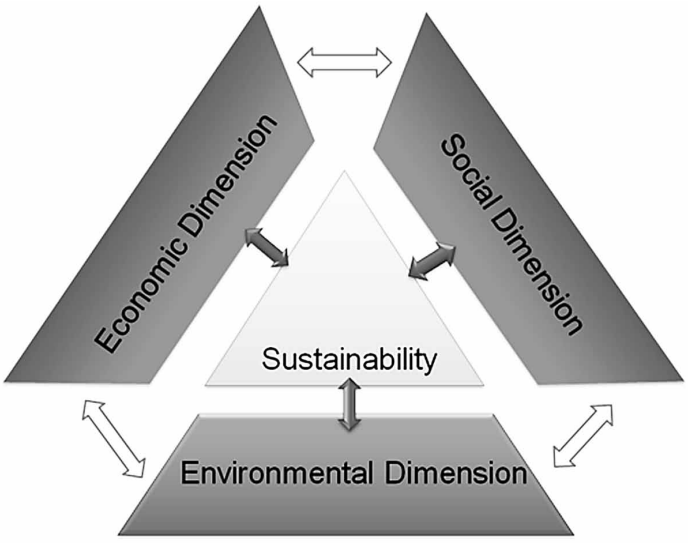
ers have created their own definitions and principles (Xu, Zao, Dawson, Hao, Zang & Tao, 2006; Siena, 2008; Singh, Murty, Gupta &Dikshit, 2009; Barron, 2010) what has caused difficulties in understanding and implementing the concept in the organizational environment.

The term sustainability has inflated, and it is becoming ambiguous with contradictory and obscure associations (Smeraldi, 2009). This conflation occurs due to different definitions and applications the term sustainability, sustainable development and organizational sustainability have received depending on the purpose of the study. Clearly, a precise definition of sustainability still lacks (XU et al., 2006).

Although the concept of sustainability does not present a common definition, John Elkigton's 1987's definition, is widely used. It describes sustainability as mechanisms to ensure current actions do not limit the economic, social, and environmental options for future generations (Elkington, 1998).



In the organizational environment, Barron (2010) explains that the key to sustainable development is to integrate economic development, social progress, and environmental quality. This integration is represented by the triple bottom line concept (Figure 1).

Economic dimension includes operating cost reduction through management of labor productivity, research and development expenses, and investments in training and other forms of human capital (Jamali, 2006). This dimension projects future prospects, as guided by the steady growth expectation; it also involves innovation concept as an essential element for its realization (Barron, 2010).

Environmental dimension primarily addresses the process, products and services impacts on the environment, biodiversity, and human health (Jamali, 2006). Performance improvement is associated to manufacturing and supply resources reductions in order to reduce pollution as much as possible (IISD, 2009; Dillard, Dujon & King, 2009).

Social dimension aims to guarantee workers' rights, promoting continuous improvement of workplace conditions through the establishment of adequate health conditions and safety. It involves effective engagement of stakeholders contributing to proactive participation of diverse actors, such as company, employees, associations, customers, government, and NGOs (Jamali 2006; IISD, 2009; Dillard et al. 2009).

Figure 1. Sustainability dimensions (adapted from Fresner & Engelhardt, 2004)

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

These three dimensions are inter-related, and no single dimension should be prioritized over another. Current research does not allow one to state the three dimensions embrace all sustainability fields (Henriques, 2004). Nonetheless, Elkington (1998), emphasizes that companies managing these dimensions are more likely to succeed and have opportunities to gain new markets.

Sustainability applied to the business environment – called here organizational sustainability – is referenced in literature as corporate responsibility, and addresses mechanisms for displaying, measuring, and improving. Internationally, companies, governments, and non-governmental organizations have made many important improvements in various conduct code models, standards, and methods (Jamali, 2006; Siena, 2008).

Smeraldi (2009) presents data about sustainability's evolution between 2004 and 2009. The author used GetAbstract, considered the main service upon technical summaries for executives. Through this database, Smeraldi (2009) identified more than 5000 titles on sustainability. Between 2007 and 2009, the sustainability theme stood out as the most discussed topic, with over 450 new titles. 120 of them mentioned the organizational sustainability approach. This made sustainability the most popular theme in business literature, overcoming issues like trading, capital markets, marketing, recruitment, and project financing.

Expanding data collection conducted by Smeraldi (2009) for the period from 2010 to march 2013, the GetAbstract (2014) database published more than 266 new titles addressing the organizational sustainability theme keeping it in the leading position in business literature topics.

Linton, Klassen and Jayaraman (2007) identified, roughly 1300 scientific articles addressing sustainability, applied economics, business, and management, published in Scopus database from 2004 to 2005. Expanding the data collection from 2006 to 2013, Scopus database published 8337 articles, which shows an average annual growth of 23% between 2004 and 2013 (last 10 years). This recently collected data confirms and justifies the importance of organizational sustainability and researchers' growing interest.

It is very important to recognize that an organization should be prepared and well-structured to deal with sustainability issues. Organizations have basic needs that must be met in order to survive. These needs are met through interaction between the organization and the environment where it operates, which brings up the fact that an organization first needs to be structured internally before going to external environments. In other words, organizations should plan, implement, verify, and measure internal sustainability before deploying and measuring outward actions (Anderson, Bider, Johannensson & Perjons, 2005).

Lueneburger and Goleman (2010) recently confirmed these findings by indicating that achieving organizational sustainability relates primarily to operational reality; then comes public perception. Companies that develop an image unrelated to their actual achievements are at serious risk of harming their corporate reputation with impacts that go beyond the company's image.

Baron (2010) highlights that organizations, therefore, cannot understand sustainability as a mechanism only for external actions. It is important to get the necessary internal sustainability. Management systems standards have a strong synergy enabling organizations to achieve sustainable development and, therefore, it is important to measure the levels of sustainability in an organization.

Ferroli and Librelotto (2011) featuring sustainability by interdisciplinary, i.e. only through the integration of different disciplines and branches of knowledge it may be possible to obtain viable products that meet the demands of a constantly evolving market, without harming the environment and society.

One of the ways to make a sustainable system is performing its management in an integrated manner, ie, involving the environmental, economic and social dimensions. According Fresner and Engelhardt (2004), the integrated management system allows us to understand the needs of employees and set goals,

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

enabling improved training, communication, quality and service assurance, having thus the requirements for sustainability of the sector.

The updated normative standards versions of quality management, environmental management, health and safety, and social responsibility, show that there is great similarity and compatibility between them, which led to the trend of integrating them. This would allow creating a common regulatory standard to promote more sustainable management systems. The integration of management standards is discussed through the concept of Integrated Management System (IMS), which seeks to integrate commonalities of various management systems and respect the individuality of each standard. Normative management standards such as ISO 9000, ISO 14000, OHSAS 18000 and SA 8000 stand out in organizational with a large number of accreditation by the companies being targeted for a joint establishment of a IMS and more recently these normative standards have been identified in literature as a mechanism to ensure the sustainable development of the organization by performing the integration of economic development, social progress and environmental quality.

The concept of IMS can be understood as the integration of various management systems, which combine to create an overview of the process, a systemic approach and focus of employees in order to put all management practices in a single system (Pojasek, 2006). This allows the management system created to be more efficient in achieving the objectives of that when there are several individual overlapping systems (De Cicco, 2004).

Within this theme, this chapter aims to (i) show the evolution of the concept of sustainable development, (ii) present a definition for the organizational environment, (iii) highlight the interaction term organizational sustainability with basic normative standards systems management, and (iv) guide organizations describing how interactions between normative standards and the dimensions of sustainability can occur.

EVOLUTION OF THE CONCEPT OF SUSTAINABILITY

The timeline on the concept of sustainability has strands advocated by some authors. A run of the concept was medial fifteenth century (Marquardt, 2006), others approach the origin from the eighteenth century (Grober, 2007). A third group of authors reported the story only from the twentieth century, when the concept became relevant for today's society (Xu et al., 2006).

These various strands are also found when analyzing the origin of the term. Although the terms sustainability and sustainable have first appeared in the Oxford Dictionary of English only during the second half of the twentieth century, the equivalent term in French (Durabilité and durable), German (Nachhaltigkeit and nachhaltig) and Dutch (and duurzaamheid Duurzaam) have been used for centuries (Du Pisani, 2006).

The aspect most frequently cited in the literature is the origin of the term in German (Nachhaltigkeit), first used in the eighteenth century by German jurist Hans Carlowitz that inspired the theory of English author John Evelyn and the French statesman Jean Baptiste Colbert, began to plan the optimal use of forests, which serve as a feedstock for power generation of iron and silver industries. In this theory, the authors argued that the industrial production could not exceed the playback speed of the woods. Thus, Carlowitz became known for creating the term, but not in its concept (Marquardt, 2006; Grober, 2007; Djalali & Vollaard, 2008).

Only in the 1970s, the concept of sustainability is replaced presence and global importance, being supported by the context of a growing awareness of impending ecological crisis. This occurs in conjunc-

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

tion with the emergence of the term "sustainable development", credited to Barbara Ward, founder of the International Institute for Environment and Development (Du Pisani, 2006). From the emergence of terminology, several authors presented their definitions, such as Goldsmith et al, 1972; Meadows, 1972; Coomer, 1979 and Allen, 1980.

In 1987, the current World Commission on Environment and Development (Brundtland Commission called at the time) introduced the world to the concept of sustainable development as a mechanism for political and ethical guidelines for dealing with ecological and social crisis of the planet, through the report "Our Common Future", published by the United Nations (Djalali & Vollaard, 2008; Cerin & Scholtens, 2011).

The apex so that the concept of sustainability was widespread worldwide occurred during the execution of the UN Conference for Environment and Development, in 1992, which became the principle and concept of sustainability known through political and scientific discourses (Marquardt, 2006).

During the last two decades, the concept has evolved, particularly with global development forums, having reached consensus on the need to create procedures that contribute to societal change (Pope, Annandale & Morrison-Saunders, 2004).

ORGANIZATIONAL SUSTAINABILITY

Organizations are commonly referred to as economic entities whose main objectives relate to the production of goods and provision of services in the most efficient way possible.

In recent decades, business management, in addition to meeting the requirements and ensure customer satisfaction and customer loyalty, begin to consider the welfare of employees and the work environment and worry about the impact generated for society and the local community (Wilkinson & Dale, 1999).

These changes become noticeable with the advent of the paradigm of environmental development in the early 1980s, where organizations begin to move away from their narrow economic conception and make profound strategic adaptations in response to environmental pressures and social expectations (Robinson, 2000)

Inspired in part by a growing recognition of the need to transition from environmental management for more comprehensive management called sustainable, in the 1990s, a new change occurred (Jamali 2006). Pressures from other stakeholders in the business, so-called stakeholders - as shareholders, owners, partners, government agencies - influence companies demonstrating best practices in organizational management, compliance with laws and regulations and at the same time, reduce costs and impact on the environment (Bamber, Sharp & Castka, 2004).

This advancement and dissemination of concepts in organizations made them forced to serve beyond the traditional competitive advantages, other parameters to ensure satisfaction and customer loyalty (Karapetrovic, 2002).

These factors resulted in increased complexity of business management and the origin of new demands for transparency and corporate citizenship (Jamali, 2006).

This development took place to meet the expectations motivated from the 1960s, the development and introduction of management standards and standardization, which came to help companies meet these customer relations, supplier and society (Wang & Tsai, 2009; Santos, Mendes & Barbosa, 2011), resulting in the need for organizations to deploy and certify their environments in order to gain competitive advantages in the dispute and the markets in which they operate (Sohal & Zutshi, 2004).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Although these normative standards undergo certifications from renowned international bodies, no guarantee that the company remains on track towards sustainability, given the fact that there are no regulatory standards to assess what level of sustainability that an organization is.

Commonly, when it comes to management standards and certifications for organizational environments, perceived to implementation of the quality management system, environmental management, management of health and safety at work and, more recently, social responsibility standards those who have a synergy with the pillars of sustainability, i.e. with the environmental, economic and social dimensions.

In essence, the normative standards are documents that define the most effective and efficient way to make a product or perform a task. These normative standards are written by a rigorous and formal process, involving extensive consultation with all relevant agencies, and outlines the organizational "best practices" and regulatory obligations to fulfill. When treated in the context of sustainability, standards of management systems have an extremely useful role in providing a roadmap for the implementation of sustainable organizational development in a growing number of areas (Baron, 2010).

On this point, Vasques (2007) stresses that the absence of a normative standard for sustainable development hinders the beginning of the actions of organizations because they do not get guidelines developed.

Given this, companies wishing to start deploying a sustainable organizational policy end up finding difficulties, since no access to information, is little scientific content by writing about it, is the high cost that the information has, when obtained from consulting firms.

Recently, with the publication of the updated normative standards of quality management, environmental management, management of health and safety and social responsibility versions, there has been a high degree of compatibility and similarity between these (Jorgensen & Simonsen, 2002; Jorgensen, Remmen & Mellado, 2006; Bernardo, Casadeus, Karapetrovic & Heras, 2009), which spawned the ambition and tendency to integrate them, the fact that, according to Jorgensen (2008), which would allow to create a common normative standard to promote management systems more sustainable.

Such integration of management standards is discussed through the concept of IMS, which seeks to integrate commonalities of various management systems and respect the individuality of each standard (Celik, 2009). This reasoning can be used as the basis of a model of internal measurement of sustainability, given that regulatory standards, as well as the dimensions have a strong synergy between themselves and particular characteristics that need to be respected.

To achieve sustainability and the concept of the triple bottom line, Tsai and Chou (2009) advocate the need for organizations to implement and certify their systems through regulatory management standards such as ISO 9000, ISO 14000, OHSAS 18000 and SA 8000.

However, while the integration of the dimensions of sustainability cannot be deduced, manage aspects of the triple bottom line remains a challenge (GRI, 2010). Further integrate dimensions mean embracing the ambiguity in dealing with an elusive and diverse range of themes and values (Jamali, 2006).

For Jorgensen (2008), the mechanism for organizations to become sustainable is the need to analyze, holistically, production processes and products developed in order to improve them on an operational level, in all its parts and throughout the chain, you will see the quality, the environment and the health and safety of employees as to make them sustainable mechanism.

With an IMS, Pojasek (2011) argues that the management of sustainability can be achieved through communication between existing systems. The proposed Jorgensen (2008) and Pojasek (2011) meets the objective contained in this chapter, where achieving sustainability concerns, first, the internal reality of the organization, then come public perceptions (Lueneburger & Goleman, 2010), i.e. the internal

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

structure through integrated management systems can be a powerful mechanism for achieving organizational sustainability.

The definitions of the concept of IMS, processes and outcomes, according to Bernard et al. (2009), vary not only depending on the situation of the organization, but also because of the particularity of the studies. Karapetrovic, Casadesus and Heras (2010) complement these few studies, when they occur, are based on theoretical or empirical cases, contributing to the need for debate on the subject.

The theoretical conceptualization of IMS in the literature, according to Zeng, Shi and Lou (2007), are still restricted to a few jobs. Can be cited as studies: Beckmerhagen, Berg, Karapetrovic and Willborn (2003), Karapetrovič (2003), De Cicco (2004), Pojasek (2006), Arifin, Aiyub, Awang, Jahi and Iteng (2009) and Bernard et al. (2009).

The latter, Bernard et al. (2009) combining the definitions of various authors, summarizes the concept of IMS as the process of connecting various management systems of the organization into a single system to common resources and continually improve stakeholder satisfaction.

This integration of the management system is more than simply adding elements of standards in an already structured system (Fresner & Engelhardt, 2004), and cannot be set to put different systems in a single manual (Wilkinson & Dale, 1999).

The IMS shape "system of systems", each system maintains its individual identity (Wilkinson & Dale, 1999), aiming to use the synergies between these rules during the creation and implementation of a management system (Mackau, 2003).

Although studies leading to the formulation of the theory of IMS are being made, there is no consensus among authors about the theoretical definition of the subject. What exists is a systemic view on the need for a consolidated management, but still at an early stage, where we seek the integration of systems (Karapetrovic, 2010; Simon, Karapetrovic & Casadesus, 2012; Satolo, 2012; Satolo, Calarge e Cauchick, 2013).

This lack of consensus on the definition of IMS can be seen in the various terms used to characterize it. In the international literature, the terminology of IMS is treated as Integrated Management System (Mackau, 2003; Holdsworth, 2003; Bamber, Sharp, &Castka, 2004; Zeng, Shi & Lou, 2007; Arifin, et al., 2009; Bernardo et al., 2009; Bernardo et al., 2010; Santos, et al., 2011; Hamidi, Omidvari & Meftahi, 2012), Integrated Management Systems (Wilkinson & Dale, 1999; Karapetrovic, 2002; Beckmerhagen et al., 2003; Fresner & Engelhardt, 2004; Jorgensen et al., 2006; Salomene, 2008; Karapetrovic, Casadesus & Heras, 2010; SIMON et al., 2012) and as a Unified Management System (Jorgensen & Simonsen, 2002).

This variety of classifications, sorted by Hacking and Guthrie (2008) as an "alphabet soup" of acronyms and terms, currently generates a confusing picture about the topic.

In this chapter, the term will be adopted Integrated Management System (IMS), it will be dealt with the integration of various systems into a single management system.

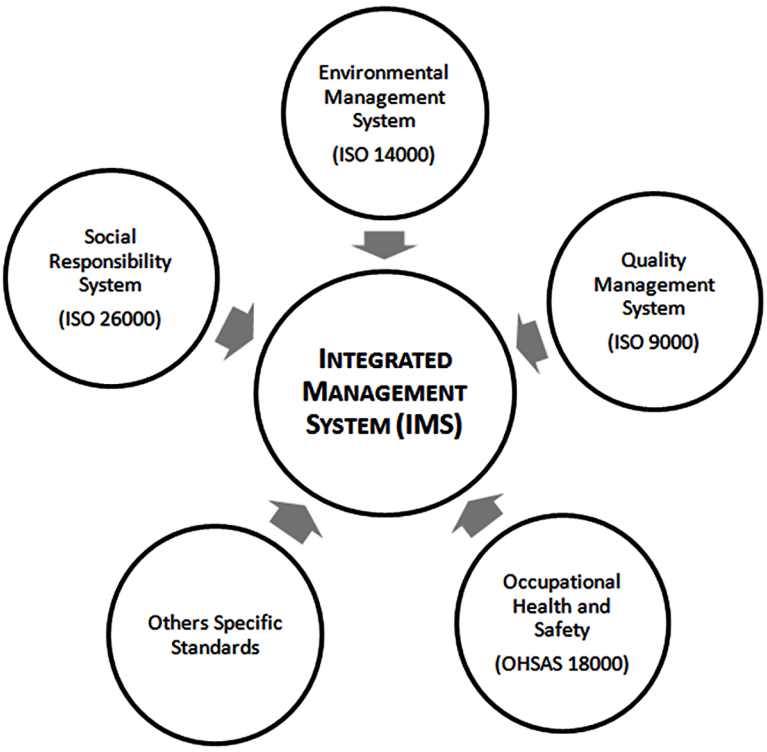
This integration of various management systems is treated in the literature linking up quality, environment, and health and safety at work (Wilkinson & Dale, 1999) and, more recently, social responsibility (Jorgensen et al., 2006).

Thus, it becomes necessary to understand the structure and evolution of the standards for IMS, which is the subject of the next section. It caveat, however, that this is a brief explanation of such rules, not being objective in this section or further explain any points for standards, but important for the purpose of this chapter points.

Basic normative standards and the Integrated Management System (IMS) to reach organizational Sustainability

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

As shown in the previous section and illustrated in Figure 2, in an IMS are integrated basically four normative standards: quality [ISO 9000 (ISO, 2008a)]; environment [ISO 14001 (ISO, 2008b)]; occupational health and safety [OHSAS 18001 (BSI, 2008)], and social responsibility [ISO 26000 (ISO, 2010)].



Other normative standards may select IMS organization. Are cited as examples specific standards for industries such as food [ISO 22000 (ISO, 2006)] aerospace [AS 9100 (SAE, 2004)], automotive[TS 16949 (ISO, 2002)], telecommunication [TL 9000 (ISO, 1998)], information systems [ISO 27001 (ISO, 2007a)], and supply chain management [ISO 28000 (ISO, 2007b)].

However, according to the author, these normative standards are rarely discussed in the context of IMS.

In order to clarify and facilitate the understanding of IMS, according to Wilkinson and Dale (1999), it is important to understand the history and structure relevant to IMS standards, because the need for clear definitions is always useful to establish good communication about a particular topic, especially when this is an emerging issue, as in this case.

In this chapter, the use of the concept of IMS features is restricted to the four management systems commonly employed by organizations (quality, environmental, occupational health and safety, and social responsibility) because they are central themes of the work and used as the basis for the proposal the measurement of organizational sustainability model.

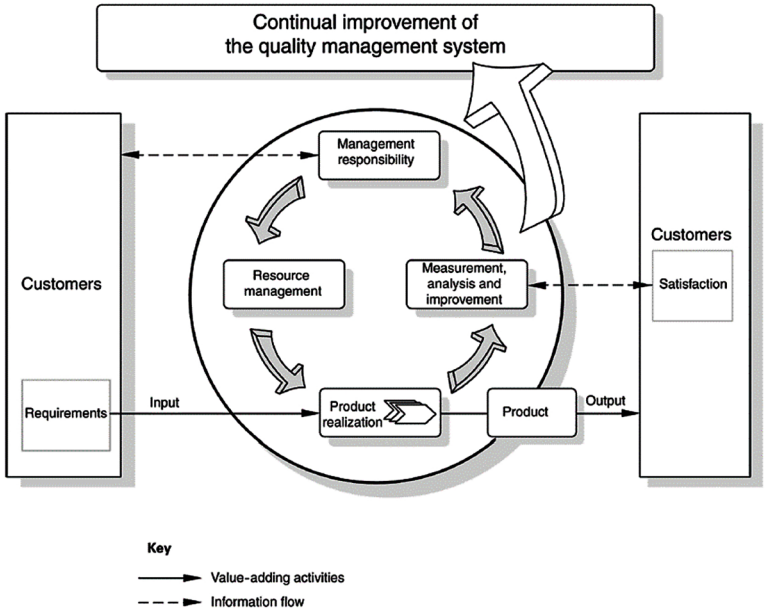
Figure 2. Model of a IMS

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Quality Management System: ISO 9001

ISO 9001 describes a number of key elements to enable the design and implementation of the quality management system (Zeng, Shi & Lou, 2007).

It is considered one of the most successful and most deployed normative standards (Bayati & Taghavi, 2007), and the development of its first release occurred in 1987. Currently, the standard is presented in its fourth update, in force since December 2008, and which sought mainly increased compatibility with ISO 14000 families (Mollenkopf et al., 2010).



ISO 9001 consists of 18 requirements, namely: general requirements, documentation requirements; responsibility of management, planning, resource management, infrastructure, work environment, planning of product realization, customer-related processes, design and development; acquisition, product and service delivery, control of monitoring and measuring equipment, measurement, analysis and improvement, control of nonconforming product, analysis of data, and improving (ISO, 2008a).

The implementation of the requirements of the standard in the organization can occur in conjunction with the tool called PDCA cycle, and the elements involved shown in Figure 3.

To Naveh and Marcus (2005), the implementation of ISO 9001 requires that the company has an internal standard procedure, replicable routines and processes for product development, manufacturing, delivery, service and support.

The benefits associated with implementing ISO 9000 reported in the literature are diverse, being featured: definition of consumer focus, increase access to international markets, increase the level of employee engagement, maintaining the consistency of the business processes, ensuring the reduction loss of time, material and effort, implementation of continuous improvement. Its implementation, however, only confirms that the company has an effective quality management system, but does not guarantee

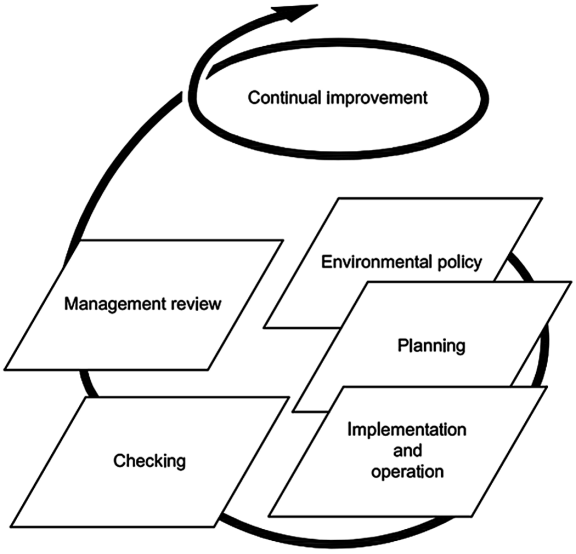
Figure 3. Model of a quality management system based on process (ISO, 2008a)

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

the quality of products manufactured by the company, this warranty is through an actively managed and implemented by the culture of quality (Jorgensen, 2008; Terziovski & Power, 2007).

The acceptance and success of this standard are significant, verifying that, worldwide, by December 2012, more than 1.1 million companies are certified in 184 countries (ISO, 2013).

Environmental Management System: ISO 14001



The objective of ISO 14001 is to create an environmental management system that allows the organization structuring mechanisms for continuous improvement in performance and reduction in resources consumed and, therefore, of environmental resources (Bernardo et al., 2009).

The ISO14000 series of standards, established in 1996, was reviewed in 2004 (Lagodimos, Chountalas & Chatzi, 2007) creating a higher level of similarity with the standards of ISO 9000 series (Karapetrovic & Casadesus, 2009).

The requirements covering the ISO 14001 comprises a total of 22, which are requirements of the environmental management system, general requirements, environmental policy, planning, environmental aspects, legal and other requirements, objectives and targets; management program (s) environmental, implementation and operation, structure and responsibility; training, awareness and competence, communication, environmental management system documentation, document control, operational control, emergency preparedness and response; checking and corrective action, monitoring and measurement, non- compliance and corrective and preventive actions; records; audit of the environmental management system, management review (ISO, 2008b).

The implementation of these requirements (shown in Figure 4), as well as ISO 9000, involves the PDCA cycle. According to Zutshi and Sohal (2004), during the deployment process, one should take into account five key elements: environmental policy, planning, implementation and operation, inspection and corrective action, and management review.

Figure 4. Elements of an environmental management system (ISO, 2008b)

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Oliveira and Serra (2010) list a number of associated with the deployment of an Environmental Management System, among these benefits: access to new markets, law-abiding management, regulatory incentives, risk reduction, access to more capital, the improvement of the production process, improvement of environmental performance improvement in the overall management of the company, improving the relationship with employees, improving public image, competitive advantage within specific segments, meeting the demands of customers, increased quality of life, achievement of clean operations (green), increasing the competitiveness of the product or service and public awareness.

There are approximately 285.000 companies in 167 countries worldwide ISO 14001 certified (ISO, 2013).

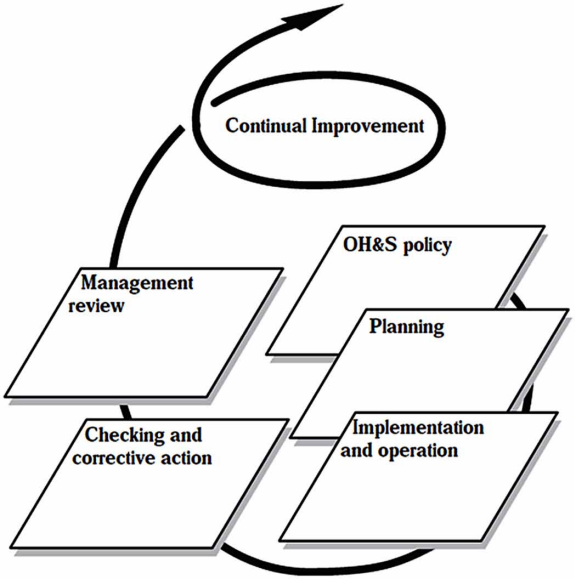
Occupational Health and Safety: OHSAS 18001

The Management System for Occupational Safety and Health is characterized by specifying procedures for organizations to manage their activities, products and services, in order to control and prevent circumstances that may result in accidents, injuries or occupational diseases.

This standard emerged in 1996 as BS 8800 - Guide to Occupational Health and Safety Management System Safety. In 1999, OHSAS 18001 (Occupational Health and Safety Assessment Series) was launched as the first specification of Health and Safety to submit character certificate (Zeng, Shi & Lou 2007), having passed in July 2007, for its first review.

Its creation was designed to allow a harmonious integration with the standards of quality management and environmental management. To do so, requires the preparation of a specific security plan to be updated on an annual basis, and is broad enough to include the entire organization.

This similarity can be seen by the 22 requirements that comprise the OHSAS 18001 standard, which include: general requirements planning; planning for hazard identification, risk assessment and risk control, legal and other requirements; occupational health and safety policy objectives; implementation and operation; resources, roles, responsibility, accountability and authority, competence training and awareness, communication, participation and consultation, documentation, document control, operational control, preparedness and emergency response, monitoring and performance measurement, evaluation of conformity; incident investigation, nonconformity, corrective and preventive actions; records and record management, internal audit, management review (BSI, 2008).



Representative elements of the implementation of OHSAS 18001 processes also use the concepts of PDCA cycle and are highlighted schematically in Figure 5.

Among the benefits associated with the implementation of OHSAS 18000 reported in the literature include: reducing the number of accidents through prevention and control of hazards in the workplace, reducing the risk of serious accidents occur, reducing material losses caused by accidents and downtime, reducing severance costs and insurance, cost reduction with the withdrawal of workers, the potential reduction in downtime and associated costs, demonstrating to stakeholders of corporate commitment to health and safety (Zeng, Tam &Tam, 2008; Duijm, Fievez, Gerbec, Hauptmanns & Konstandinidou, 2008; Vinodkumar &Bhasi, 2011).

Jorgensen et al. (2006) describe the ISO voted twice times for the development of a standard in their patterns, both being denied. However, in 2013, began working for the creation of the new ISO standard, ISO 45001, on occupational health and safety management system requirements is being produced by the Project Committee, ISO PC 283, with the intention of publication in October 2016. The standard

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

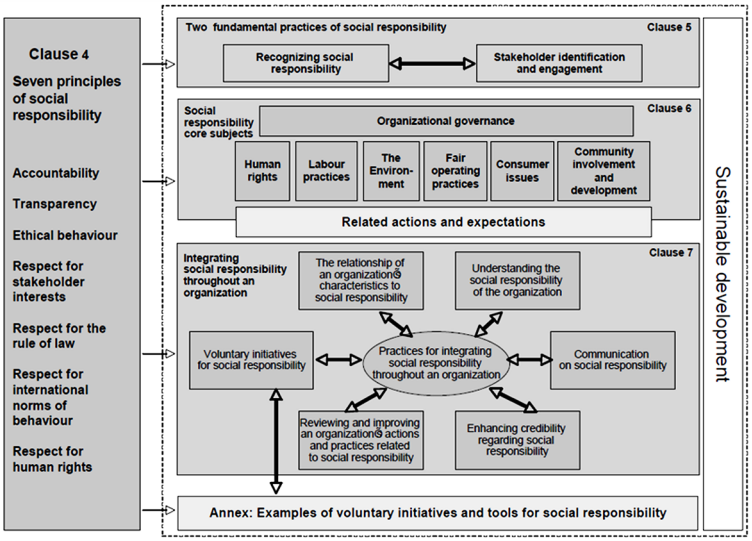
Figure 5. Elements of a management system for occupational health and safety (BSI, 2008)

will be aligned with ISO 9001 (Quality Management) and ISO 14001 (Environmental Management), themselves which are undergoing revision and are due for publication in 2015.

According to the latest available survey, worldwide, approximately 55,000 companies are certified in 80 countries (BSI, 2011).

Social Responsibility: ISO 26000

ISO 26000 (ISO, 2010) standard was launched in 2010, resulting in a five-year trial involving 450 experts from 99 countries. His aim is to establish an international standard for organizational establishment of a Management System of Social Responsibility.



Its origin is based on SA8000, launched in October 1997, the Social Accountability 8000 (SA8000), which established the first global standard certification focused on corporate social responsibility. Created by CEPAA - Council on Economics Priorities Accreditation Agency, currently called the SAI - Social Accountability International - U.S. non-governmental body - the standard focuses on securing the rights of workers involved in production processes, promoting standardization in all sectors business (Willians, 2010).

The ISO 26000 aims to guide companies to adopt socially responsible practices. During its preparation, rose the possible parallels with the standards already established Quality Management and Environmental Management, consisting of eight requirements, highlighted in Figure 6: organizational governance, human rights, labor policies, environment, fair practices operation, consumer issues, community involvement and development (Castka & Balzarova, 2008; ISO, 2010).

According Pojasek (2011), ISO 26000 is not a management system such as ISO 9000 and ISO 14000, but a roadmap for organizations that want to establish a system of Social Responsibility. According to the author, the generation of a system of organizational management, like ISO 9000, should be supported in the specification ISO 26000, which guides the structuring of a system of social responsibility management based on PDCA cycle.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 6. Elements of the social responsibility norm (ISO, 2010)

As new rules, in order to guide organizations, is not yet scheduled for audits to obtain certifications (Castka & Balzarova, 2008; Pojasek, 2011). Similarly, point benefits are still limited to a few published studies, and further efforts need from researchers. Perera (2009) in one of these studies highlights benefits in terms of productivity gains, improved image and cost savings.

NORMATIVE STANDARDS FOR MANAGEMENT A INTEGRATED SYSTEM

Although this discussion on the creation of an integrated system governed by a single normative standard has become an obvious thread, currently, there is a worldwide accepted standard that covers an integration methodology (Bernardo, Casadesus, Karapetrovic & Heras, 2010).

Internationally, the ISO published in 2008 the book called The Integrated Use of Management System Standards, reporting and promotes a reference to sixteen experiences of implementing IMS (ISO, 2008c). This book, however, lacks a method for deployment and management of the system.

At the national level, different countries have developed their methods of integration, i.e., Australia and New Zealand - AS / NZS 4581: 1999 Denmark - DS 8001: 2005 Spain - UNE 66177: 2005 and the UK - PAS 99: 2012 (Bernardo, 2009; Bernardo et al., 2010.). These normative standards for deployment of IMS will be briefly discussed in the following subsections.

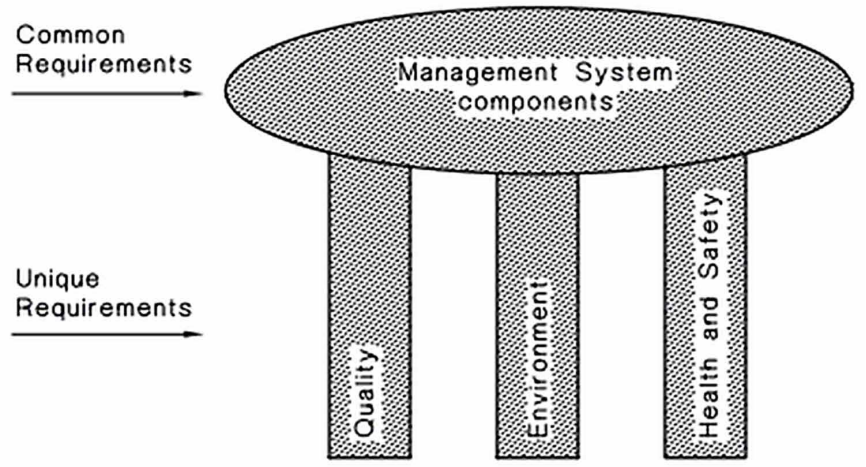
AS/NZS 4581: 1999

Was published AS / NZS 4581:1999 standard, developed by standardization bodies in New Zealand and Australia in 1999. According to Ferreira (2009), this normative standard addresses the integration of management systems guidelines for organizations with the purpose of business, government and community. The rules do not restrict its use only for quality management, environmental, safety and occupational health system and can be applied to all types of management systems.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

According to the author, establishes the rules common to all systems components to be integrated. To this end, comprises nine components for a management system, which: responsibility and leadership management, identification and needs analysis, policy and objectives, planning and implementation of the system, resource allocation, communication and information systems, management processes and activities, monitoring and measurement, critical analysis of the direction and improvement plans (Arifin, 2009). Figure 7 shows the model of IMS standard AS / NSZ 4581:1999.

UNE 66177: 2005



In 2005, Spain issued its normative standard IMS, called UNE 66177:2005 - Systems gestión Guide to integración la Gestión de los systems. The normative standard defines IMS as the set formed by the combination of organizational structure, responsibilities, procedures, processes and resources that are established for the integrated management systems (Barral, 2007; Guillén & Carmenates, 2009).

The steps for implementation of a IMS -based normative standard UNE 66177 (2005) and the study of Guillén and Carmenates (2009) are divided into four:

1. Design: creating the objective and subjective conditions to begin to define the system and obtain the commitment of all levels.
2. Planning: determines the status of the organization for the implementation of the current regulatory standards for the development and integration of existing systems, set the integration method and program of activities to implement and effectively manage the changes.
3. Monitoring and measurement: objective periodically evaluate and adjust the implementation plan and ensure the suitability, adequacy and effectiveness of the system since its implementation was performed.
4. Continuous Improvement: aims to identify opportunities for continuous improvement to help increase the performance of IMS, and the appropriate tools in each case.

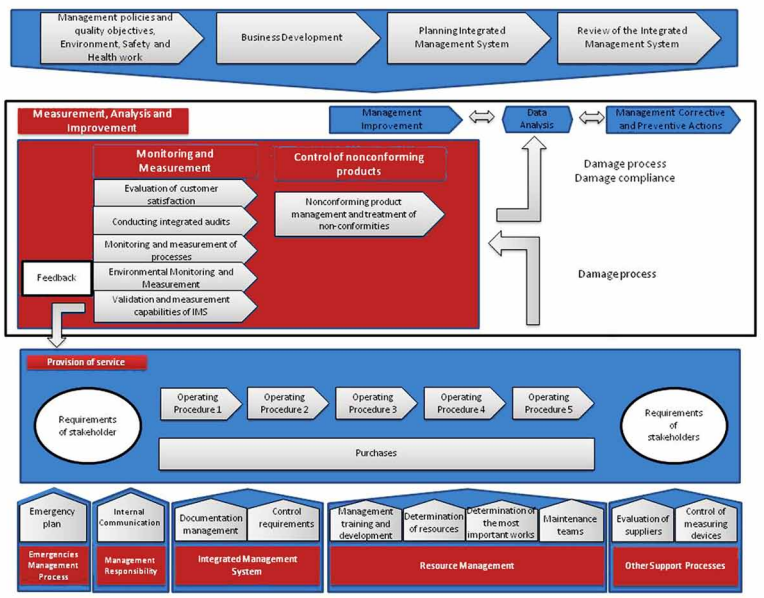


Figure 8 is proposed by UNE 66177 (AENOR, 2005) for the implementation of a IMS model.

Figure 7. IMS Model used in the standard AS / NZS 4581:1999 (Ferreira, 2009)

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 8. Model proposed by UNE 66177 (AENOR, 2005) for the implementation of IMS

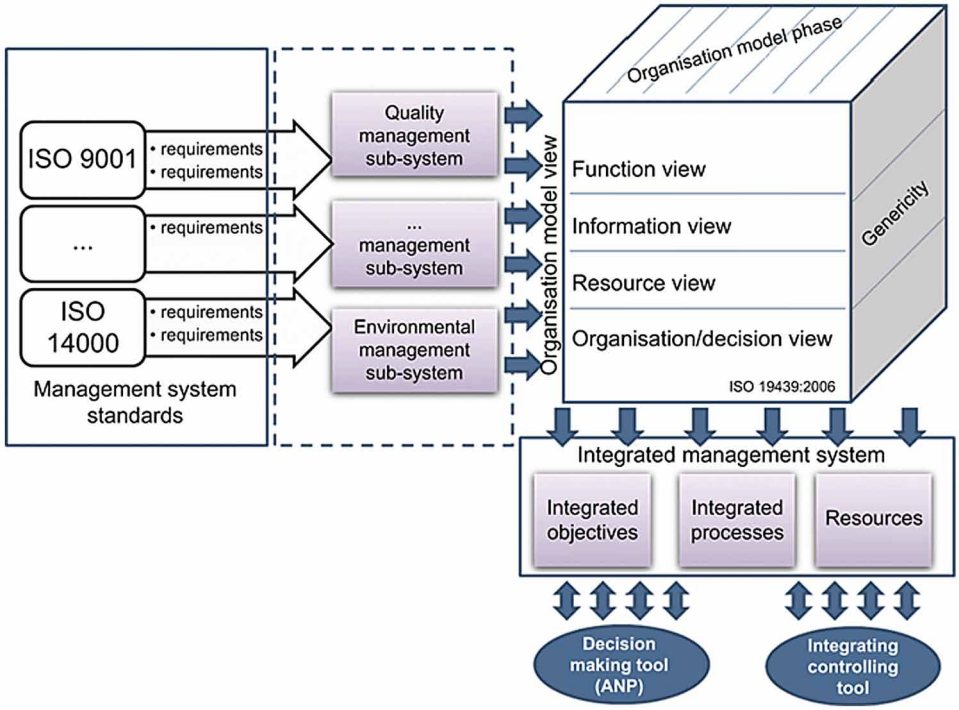
DS 8001: 2005

The normative standard Danish (Dansk Standard 8001, 2005) had started its production in 2003 from studies by a large working group under the motto'' an organization, a system "(Jorgensen, 2008). The standard describes the characteristics of a good management and common and individual elements that may involve a IMS (Rasmussen, 2007).

Figure 9 is proposed by DS 8001 (Dansk Standard, 2005) to implement a IMS model.

In the first level, the normative pattern possessed a strategic approach, with emphasis on corporate governance. In this step, we try to emphasize the importance of the management system, organizations demonstrating the starting point for business strategies. The organization has developed a mission, vision and strategy, and create corresponding goals and policies, meeting the demands of stakeholders (Rasmussen, 2007; Jorgensen, 2008).

At the second level, the normative standard describes the common elements in an IMS and also provides standard tools for such integration.



Finally, the third level of the normative standard, discusses the different management areas and describes how an organization can choose to integrate your IMS, employing several security management systems such as quality, environment, energy, occupational health and safety, food, social responsibility, risk management, among others (Rasmussen, 2007; Jorgensen, 2008).

PAS 99:2012

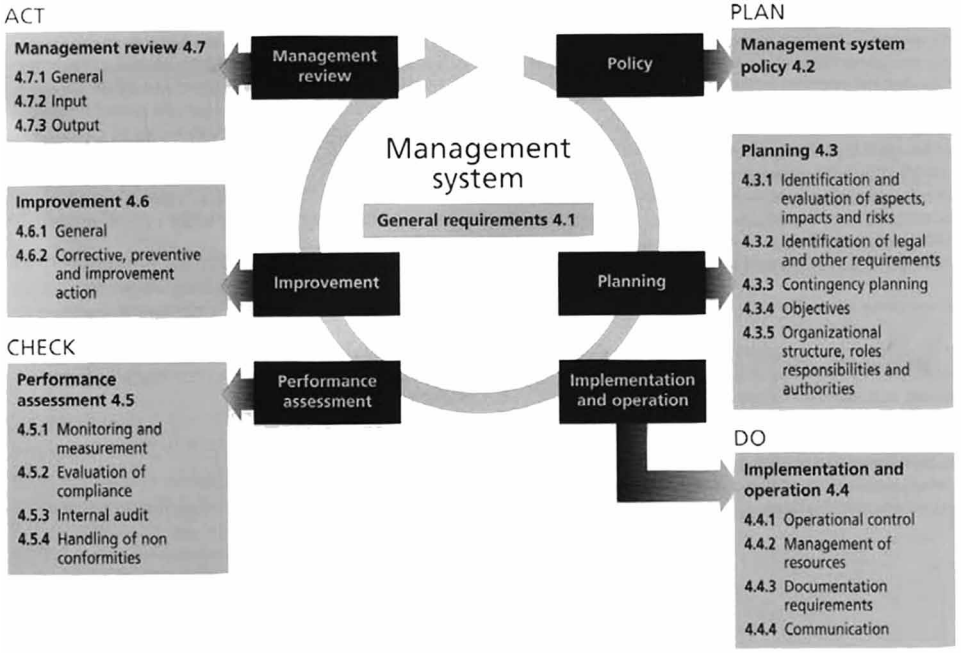
In 2006, the United Kingdom through the British Standards (BSI), based on the ISO Guide 72:2001, developed his legal standard to meet the common requirements of an IMS, called PAS 99 (Publicly Available Specification), and which underwent its first revision in 2012. This objective normative standard

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 9. Model proposed by DS 8501 (2005) for the implementation of IMS

to be used as a model for the implementation of common standards or specifications of requirements management system in an integrated manner (Vasconcelos, 2011).

To Vasconcelos (2011), the PAS 99:2006 provides a simple model for organizations to integrate into a single structure all the standards and specifications of management systems that adopt. However, to properly deploy PAS 99:2006 does not guarantee the company than the other management systems comply with regulatory standards governing them, i.e., the joint implementation of the environmental management system and quality through PAS 99:2006 does not guarantee that it fully conforms to the required respectively by ISO 14001 and ISO 9001 standards. The structure created by the PAS 99:2006 is shown in Figure 10.



INTERRELATIONS BETWEEN THE REQUIREMENTS OF THE STANDARD PAS 99:2012 AND DIMENSIONS OF ORGANIZATIONAL SUSTAINABILITY

The design of an IMS is given for the use of synergies between the different normative standards and the elimination of redundancies within them.

In recent years, the revision of normative standards ISO 9001, ISO 14001, OHSAS 18001 and ISO 26000 increased the similarities between different patterns and made them more compatible. This improved the possibility of integrating the standards and supporting links between the necessary systems allowing target a sustainable management system (Karapetrovic, Casadesus & Heras, 2010; Bernardo

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 10. Requirements to delineate the structure of the IMS (BSI, 2006)

et al, 2010). These standards form the integrated IMS and have high interaction with the dimensions of sustainability (triple bottom line).

The equivalence between the requirements of the normative standards ISO 9000, ISO14000 and ISO18000 is presented in Table 1, made from the proposed requirements for integration of management systems with the normative standard PAS 99.

Justifies the choice of the standard PAS 99 standard as the basis for establishing the inter-relationship with the sustainability, three important aspects: (i) this normative standard, although not universal, stands out for its further spread in relation to other models presented (ii) has as proposal for its creation, maintaining strong relationship to the normative ISO and OHSAS standards, and (iii) its implementation, as well as in other normative standards in its process uses the PDCA cycle, thus facilitating system management the high level of similarity.

It is observed from Table 1 the high level of synergy between the three normative standards. Verifies the existence of various sections / subsections that interrelate as well as items that are characteristic only a few patterns, highlighting the concept presented by several authors (Jamali, 2006; Celik, 2009; Bernardes et al., 2009; Pojasek, 2011) where the systems that make up an IMS feature common and particular points that need to be respected.

The establishment of the interrelationships between normative standards beyond demonstrates strong synergy, the possibility to carry out the implementation of the management system following the steps of the PDCA cycle, so this strongly defended by normative standards.

The PDCA cycle had its origin with Dr.W. Edwards Demings lectured in Japan in 1950. Deming, Father of total quality management has put forth the concept of Plan, Do, Check and Act cycle. The PDCA cycle was broadened to include strategies and methods to develop, test, and implement changes that would result in improvement. The PDCA-cycle is a never ending cycle designed to improve qual-

ity and efficiency. PDCA cycle approach to quality improvement helps on institute to focus on the goal and obtain the commitment of all the stakeholders to the accomplishment of the goal set (Singh, 2013).

Thus, the regulatory requirements presented in Table 2 can be grouped into six major areas, which are related to stage of the PDCA cycle. The six topics are: (i) policy management system; (ii) Planning, (iii) Implementation and operation; (iv) Performance assessment; (v) improvement and (vi) Management review. These relationships are shown in Figure 11 and described in Table 2.

Figure 11. Relationship between Normative Standards of IMS and PDCA Cycle steps

Source: Elaborated by the authors

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

The implementation of IMS in this way now goes by meeting the requirements of PAS 99 standard, and that are directly related to the environmental, social and economic dimensions proposals for sustainable development, and these relationships below described.

PLAN

Axis 1. Management System Policy

Requirement 1.1. Management System Policy

It is understood that the policy of the management system of the organization should include in its mission / vision the social and environmental dimensions as well as the maintenance of its economic health, showing the internal and external stakeholders concern for the future of the organization and provide gains beyond the financial interests with ethical behavior and respect for their partners and the environment, envisioning long-term career plan to ensure more able and motivated human resources.

Axis 2. Planning

Requirement 2.1. Identification and Evaluation of Aspects, Impacts and Risks

The organization shall establish, implement and maintain procedures to identify areas of risk and impact of its activities, products and services within the defined scope of your management system. Should establish a set of procedures for social and environmental assessment to be followed and their interconnection with the economic evaluation of the project. These impacts and risks can be evaluated taking into account: the image of the organization, legal points, points financial, strategic points, operating points and outsourcing.

Requirement 2.2. Identification of Legal and Other Requirements

This requirement refers to the establishment, implementation and maintenance of procedures to determine the legal and other requirements related to its activities, products and services that are relevant to the scope of the management system requirements in order to take them into account in establishing, implementing and maintenance management system. It is important to understand the legal requirements in this (mainly environmental) regulation as a mechanism of competitive opportunity and not as a punishment mechanism. Identify which are the critical demands of society in relation to the business and likely predict which actions will be taken by relevant standards or policies and make investments for efficiency gains and provide significant competitive advantage. This will bring to the organization the opportunity to gain know-how coming from pioneering and reputation, which will reach it, the economic part of the organization.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Requirement 2.3. Contingency Planning

The organization shall establish, document and maintain procedures to identify and respond to any unplanned event, emergency or potential disaster. This procedure should aim to prevent or mitigate the consequences of any such occurrences and consider the continuity of business operations. Are among these contingencies from product recall actions until disaster management such as fire, flood or environmental disasters. An unplanned, emergency or disaster event occurs without the knowledge of such organization possesses and, in most cases, is directly related to its stakeholders in its various representations, i.e., an employee who may be an accident within the organization or client that might get hurt due to failure in a product. Whatever the contingency, the company brings the need for economic planning initially to invest in improvements to prevent these events and also to face the need for repairs to society and to the internal and external environment due to its occurrence.

Requirement 2.4. Objectives

Shall be established by the organization objectives that take into account significant aspects, legal obligations, other requirements and its commitment to continuous improvement by implementing their policy, which must be measurable, relevant and realistic. It is important that the objectives of the management system envisage and to target improvements for employees and the environment, through continuous improvement of existing conditions in the workplace and improve its performance with respect to the amount of resources that are used to purchase raw materials and products finished in order to reduce them to short, medium and long term.

Requirement 2.5. Organizational Structure, Roles, Responsibility and Authority

The organization must indicate specific representatives of management who, irrespective of other responsibilities, shall have a function, defined responsibility and authority for ensuring that the management system is established, implemented and maintained, and also report to top management performance management system for critical analysis, including recommendations for improvement. Must representatives have a knowledge of standards / specifications adopted in the organization's management system so that they can contribute significantly in the continuous improvement of social, environmental and economic dimensions. The organization also allow other employees and direct channels stakeholders within the structure to provide feedback and assist in the improvement process.

DO

Axis 3. Implementation and operation

Requirement 3.1. Operational Control

The management system must be structured to ensure that operations are performed in specific conditions, in order to meet the policies and objectives of the organization as well as the legal requirements and other requirements. It is understood that, for the social dimension, the organization must ensure

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

that the operations in your production system offer employees safety, to prevent unsafe working conditions. From the point of view of the environment, you must ensure that the amount of resources used to manufacture and purchase of supplies appropriate, avoiding waste. At this point, you can also waste be included not only in the manufacturing environment, which directly affects the economic dimension, which can be inserted aspects of losses from a logistical, administrative, quality and energy. All the losses that occur in the manufacturing environment result in financial losses and significantly impact the outcome of the organization. Meet and measure these operating losses is of significant importance for the future of the organization.

Requirement 3.2. Resource Management

The organization shall ensure that all people who work for it and on its behalf are competent on the basis of appropriate education, training, skills and experience to the tasks assigned to them. To occur, the organization shall determine, provide and maintain the infrastructure and resources needed to achieve their goals. Thus, the organization of social and environmental point of view, must constantly train employees (internal or outsourced) so that they know their role for the organization and to society, performing with seriousness and responsibility, their activities. For such points occur, it is for the organization to plan and provide resources for training, understanding that these are investments for the organization and help the non-occurrence of accidents and incidents that may result in financial losses. The organization must also demonstrate the resources available to its employees and the correct way to use them, so as to maintain their integrity. It is also important for the management and maintenance of the resources that the organization presents employees with the opportunity for professional growth through democratic and transparent criteria for career advancement and to combat discrimination of any kind.

Requirement 3.3. Documentation Requirements

The documentation of the management system must have the description of the scope of the system, including standards / specifications adopted management systems; statements of policies and objectives of the organization; system manual; documented procedures and record that is required by the management system and its component standards and documents as determined by the organization to be necessary to ensure the planning, operation and effective control of its processes. The organization makes this documentation is known to all employees, as well as what is their role and responsibility in the design, implementation and improvement of this document.

Requirement 3.4. Communication

The organization shall establish, implement and maintain effective arrangements for internal communication between the various levels and functions of the organization, and for receiving, recording and responding to relevant communications from interested parties. It is worth at this point to present to internal and external community reports performance against the goals of the management system and its past, present and future to improve the system performance in social, environmental and economic dimensions shares.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

CHECK

Axis 4. Performance Evaluation

Requirement 4.1. Monitoring and Measurement

The organization shall perform measurements and monitoring to determine the degree of compliance with the established goals. This should include the recording of information to monitor the performance of the relevant operational controls and to evaluate compliance with the organization's goals and the ability of the processes to achieve planned results. It is up to responsible management system perform the monitoring and measuring points defined in operational requirements and documentation control requirements, these actions should be proactive, to achieve the goals and plans, and reactive, responding to and reporting accidents and incidents. Such indicators should allow, where possible, the evaluation and measurement of economic gains and losses, we understand that this is part of the sustainability of the organization.

Requirement 4.2. Conformity Assessment

The organization shall conduct periodic evaluations of compliance with legal requirements, I understand, in this respect, that the organization must meet and review the scope of your system by removing, inserting or changing requirements from the update of the standards / specifications that make up your management system. This process should occur in partnership with the stakeholders of the organization by checking the economic, environmental and social impacts that the changes may bring, be they positive or negative.

Requirement 4.3. Internal Audit

The organization shall establish and maintain a program of regular audit of its management system as a mechanism of control and verification that all objectives outlined in its design are being met and understood by all, although within this process evaluation of social, environmental and economic organization. It also, at the end of the audit, the presentation of results and their comparison with previous audits in order to ensure continuous and clear process to everyone in the organization.

Requirement 4.4. Treatment of Non-Conformities

When identified noncompliance must corrected, and the actions taken to mitigate their impact. It is important to verify the origin of non-compliance. If this non-compliance is the result of the operation on the part of the employee failures, it is important to conduct further training to prevent recurrence, denoting this point the social dimension. In the environmental point of view, nonconformities generate material losses, creating the need to reprocess the part or not being able to dispose of your place its reuse. It should first be aware of these things and, if you need to rework or disposal, possess mechanisms that do not harm the environment or minimize expenses for his recovery. Nonconformities cause economic

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

losses and measure the losses of materials and parts, as well as the need to rework the same or proper disposal of your expenses, it is of extreme necessity, and also a point of assessing organizational improvement towards the latter.

ACT

Axis 5. Improvement

Requirement 5.1. General

The organization shall continually improve the effectiveness of the management system through the use of policy, objectives, audit results, analysis of data on the performance evaluation, corrective and preventive actions and management review and should define and allocate responsibility and authority the improvement of the GIS.

Requirement 5.2. Corrective, Preventive and Improvement Action

The organization must know and be prepared to take corrective, preventive and improvement actions, listing and defining how the organization will act on nonconformities or potential nonconformities (including feedback from stakeholders), as well as registering and reviewing the effectiveness and the results of actions performed by establishing appropriate mechanisms for evaluation and measurement of economic gains and losses.

Axis 6. Critical analysis by the direction

Requirement 6.1. General

It is up to senior management critically to analyze the organization's management system at planned intervals, to ensure its continuing suitability, adequacy and effectiveness, making assessing opportunities for improvement and the need for changes in the management system, including policy and objectives. It is understood, therefore, that the senior management, this requirement should act primarily as an evaluation mechanism (regulation) on the actions undertaken and as a controller requirement management system and should actively participate in the interaction with stakeholders (stakeholders), bringing points of improvements listed by them, whether social, environmental or economic order.

Requirement 6.2. Inputs

The inputs relate to the set of information available to senior management for monitoring management system. For these data are critically analyzed by senior management, should the information set of social, environmental and economic order to understand, respecting its characteristics, the results of audits, feedback from stakeholders, the status of preventive actions and provide corrective follow-up actions

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

from previous management reviews, changes in circumstances, including developments in legal and other requirements related to aspects of the organization and risk requirements, recommendations for improvement, data and information on the organization's performance and the results of the evaluation of compliance with legal and other requirements.

Requirement 6.3. Outputs

Outputs relate to the whole of any decisions and actions related to the management system. Top management must present actions of social, environmental and economic comprising respecting its characteristics, the quest for improving the efficiency of the management system, the improvement related to stakeholder requirements, and the need for resources order to enable system improvement management and its processes.

FUTURE RESEARCH DIRECTIONS

Research involving the topic of sustainability and the subject IMS are growing in the scientific literature on various aspects such as the development of models of management, economic evaluation models, the degree of adhesion.

However, few studies envision the relationship between these two topics (IMS and sustainability), this being a wide field of research.

The organizational management in a sustainable manner, respecting the environment and society, and given the economic primordium of its existence, causes business processes become complex and require further research.

Another aspect is the development of normative standards, which undergo constant updates that has brought closer to the dimensions of sustainability, but is that organizations are following these changes? Does the concept of sustainability is really understood? Do organizations have focused on becoming sustainable internally?

We observe, therefore, that the theme has gaps to be exploited, may be mentioned: (i) lack of consensus on the definition / concept of sustainability; (ii) various approaches to applying sustainability in the organizational environment; (iii) the low level of literature and research in the area; (iv) absence of a universally accepted evaluation model; (v) review existing models have problems with selection, prioritization and weighting of dimensions (Siena, 2008); (vi) concern the valuation models of sustainability to the organization with the external aspects, omitting regarding the evaluation of the internal aspects (Lueneburger & Goleman, 2010).

One of the reasons for these gaps, according to Siena (2008), is the difficulty in materializing the concept of sustainability, as the conceptual bases on the issues involved are not consolidated, there is no consensus on what to measure, how to measure and mainly about how to weigh and combine data.

In this context, according to Henderson (2011), to conduct studies that contribute to the evolution of the theme, so it is necessary to identify hypotheses that can be tested and support the development of new research.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

- What environmental, social and economic indicators are relevant to use?
- What are possible indicators to measure and report, and what obstacles exist to measure and report?
- How the indicators should be aggregated into a sustainability index based on a fairly simple model, but reliable, available resources in the real world?
- You can verify this index, to some extent, comparing the results of the index to the literature and own ambitions of the organization?
- What are the limitations and uncertainties of the conceptual structure of suggested content?
- What are the main opportunities and benefits of working with an aggregate index?

For this to occur in a relevant, comprehensive and consistent development model needs to have a methodological framework which involves answering questions, as pointed by Singh et al. (2009).

CONCLUSION

In this chapter, the concepts of organizational sustainability and IMS, in order to present their definitions and the main normative bases that characterize have been described.

Were also highlighted the initiatives of creating normative standards of validity for global management of an integrated organizational system. One key point is to demonstrate the synergy that exists between the IMS and the dimensions of sustainability.

It was found that the PAS 99:2006 model is presented as a normative standard most similar to ISO 9000, ISO 14000, ISO 26000 and OHSAS 18000 standards, having a methodology for implementing a IMS approaching these standards, employing the concept of PDCA for its management.

We notice, however, that evidence is necessary to establish a relationship between these patterns and normative dimensions of sustainability, demonstrating synergy.

This characterization of synergy between the IMS and sustainability enables organizations see through normative standards already known and reported in the literature, the possibility of improving their internal processes in order to achieve their actions to provide future survival without harming society, the maintaining the environment and economically alive.

KEY TERMS AND DEFINITIONS

Integrated Management System: Represents the unification of various management systems into a single system, taking advantage of the many synergies between them, without ignoring the peculiarities of each.

Normative Standards: A document that contains a technical specification or other precise criteria designed to be used consistently as a rule, guideline, or definition.

Organizational Sustainability: Related to the concept of sustainability, advocating the care the social, environmental and economic dimensions, is mainly focused on the internal processes of the organization, understanding that it is necessary to first have internal sustainability for later view external actions.

PDCA Cycle: Created in the 1950s by Deming, is a systematic process for continuous improvement, accomplished through four steps: Plan, Do, Check and Act.

Requirements: Documented definition of a property or behaviors that a particular product or service must meet.

Sustainability: Concept of extensive discussion. His concept seeks to promote longevity through the attainment of economic profit, respecting the environment and society.

Sustainability Dimensions: Known as social, economic and environmental dimensions, the tripod represent the ideals of sustainability (triple bottom line).

Chapter 22
Identifying the Contemporary Status of E-Service Sustainability Research

Ali Husnain
Örebro University, Sweden & COMSATS Institute of Information Technology Virtual Campus, Pakistan

Anders Avdic
Örebro University, Sweden & Dalarna University, Sweden

ABSTRACT

Sustainable development is a world-wide major concern, required in every domain of life, including that of government. E-services are widely acknowledged for the contribution they make to e-government. The research question raised in this study is: What is the existing status of e-service sustainability research? The research method used is a literature study that adopts a concept-centric approach. Selected literature was then analyzed using the twin concepts of e-service sustainability itself and the enabler (secondary) effects of sustainable e-services. The Triple Bottom Line's model was used to further categorize the findings using economic, environmental, and social sustainability concepts. The results of the study revealed a lack of research into e-service sustainability. By way of contrast, it revealed 20 articles that cover the enabler effect. Existing research is related to economic and social dimensions, with the most common topic being related to user satisfaction.

INTRODUCTION

E-services are beneficial to citizens worldwide in many ways; indeed, they have been proven to be important enablers of successful e-government (Stamoulis et al., 2001). The number of e-services in use is increasing in both the developed and the developing world (DESA, 2012). In addition to the direct benefits of e-services, they can impact on other interdependent systems, such as economic, environmental and social systems. This is possible because e-services utilize pervasive computing devices, such as the Internet and other ICTs. To date, the e-service concept is relatively new and not well defined (Islam &

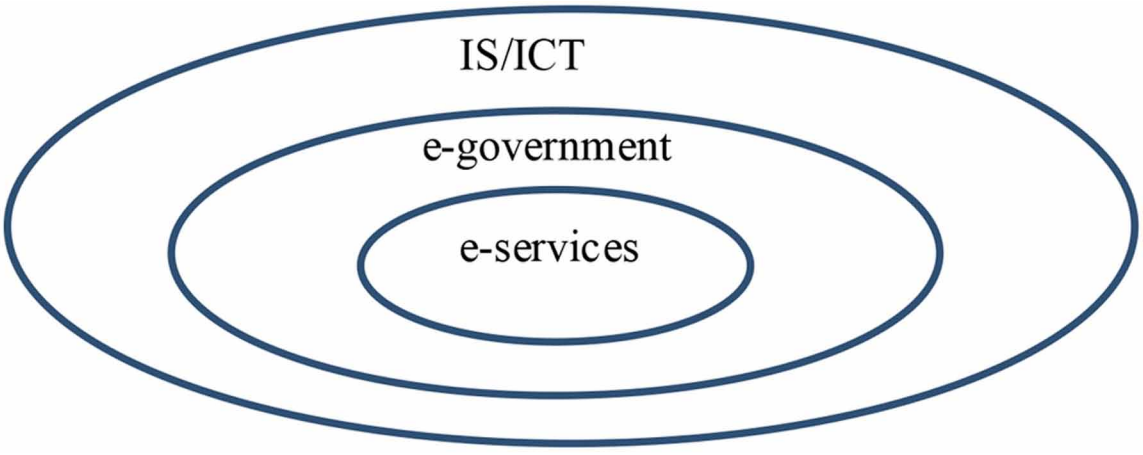
Scupola, 2011). In its broadest sense it could cover almost any sort of digital application. E-services are of particular interest in the public sector because of their potential to increase efficiency as well as effectiveness (Haque & Pathrannarakul, 2013). In this paper we delimit our scope to focus only on e-services in the public sector. We limit our definition of e-services in the e-government domain to "the electronic delivery of government information, programs, and services often (but not exclusively) over the Internet" (Dawes, 2002).



In this paper, we perceive e-services to be a subfield of e-government, which in turn is a subfield of the IS/ICT domain. This means that research into IS, ICT, and e-government in general is also relevant to the field of e-services and vice versa.

Researchers have pointed out the positive and negative impacts of ICTs on economic, social and environmental systems (Mitrea et al., 2010; Hilty et al., 2006). Sustainability, which is considered to be a positive impact, has become an increasingly important concern for political, social and economic reasons. Thus, the number of technology-related sustainability studies is increasing (Mitrea et al., 2010; Viet et al., 2011). This growing interest in the sustainability of e-government is indicated by a comparison of UN e-government surveys undertaken in 2010 and 2012: the number of instances of the term *sustainable* increased from zero to 41, respectively.

Sustainability largely emerged as a concern following the United Nations Conference on Human Environment (UNCHE) held in Stockholm, Sweden, in June 1972. The most recent UN conference, Rio+20, was held in Rio de Janeiro in June 2012. The message that came out of Rio+20 was one reason for selecting the e-government domain, and specifically research into e-service sustainability, as the subject of this paper. E-government in general, and e-services in particular, are both emerging fields; indeed, they are the focus of governments all over the world. Investigating the status of research into the sustainability of e-services will make it possible to direct future efforts within this field.

The research question raised in this study is: *What is the existing status of e-service sustainability research?* The boundaries of the study are limited to e-services in the e-government domain. E-services are one of the major components of e-government and sustainability is the requirement of all systems, irrespective of the domain to which they belong (UNCSD, 2012).

Figure 1. Relationship between the fields of e-services, e-government, and IS/ICT

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

The main motivation factor for this study is to gain an awareness of the importance of sustainability and sustainable development in all sections of society for the better economic, social and environmental survival of humanity; indeed, this was one of the indirect messages of the Rio+20 conference (UNCSD, 2012). The contribution of the paper is its investigation into existing research on the sustainability of e-services. Such an investigation does not, as yet, exist.

It seems as if sustainability should be a major asset to public e-services, if one considers the potential benefits of digitizing manual services, such as income tax declaration, renewal of medical prescriptions and online voting. According to Axelsson, Melin and Lindgren (2013), the two major goals of public e-services are efficiency of government and benefits for citizens. In a world where all kinds of resources appear to be scarce, increasing the number of efficient public e-services seems to have the potential to meet the demands of a sustainable society.

To date, research has focused on two aspects of e-service sustainability (Mitrea et al., 2010): first, the sustainability of the e-services themselves and second, the sustainability enabler effects of e-services as a means to achieving something else. When we use the term *sustainability of e-services*, we refer to the design and implementation of e-services in terms of ecological, economic and social responsibility. This aspect, which can include information overload for users, security risks and the criminal use of Internet applications, is a neglected perspective of research in this area. Just because a service is transferred from manual to automatic doesn't mean that no resources are consumed or that risks disappear. As an illustrative example, one study found that the performance of two Google search operations consumes as much energy as boiling a kettle of water. A Google search produces 7 grams of CO2 while boiling a kettle of water produces 15 grams (BBC 2009). When we talk about *sustainability enabler effects*, we refer to e-services not as isolated phenomena but as being integrated within a context that involves people and other systems, both manual and automatic.

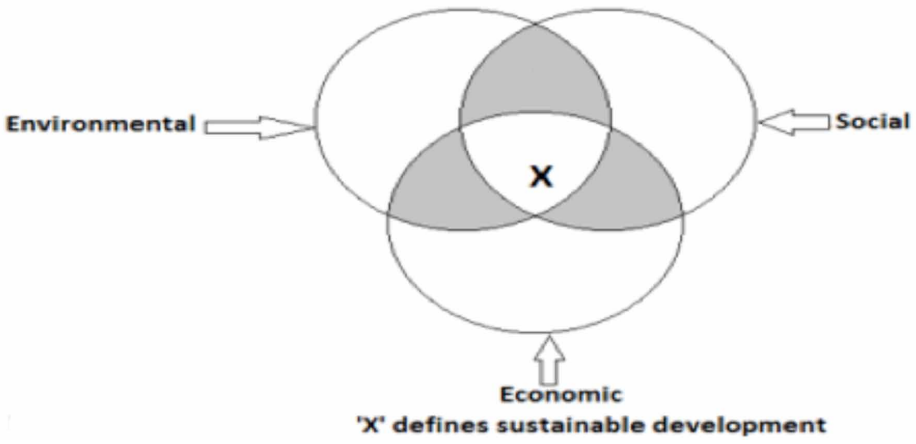
According to Bengtsson and Ågerfalk (2011) and Klischewski and Lessa (2012), sustainability research in IS and e-government respectively is in its infancy or is even ignored. The long-term success of some projects, such as those involving e-government, is dependent on its sustainability (Klischewski & Lessa, 2012). We believe, therefore, that sustainability research does actually exist. And since e-services are significant to e-government, they are a suitable point of departure.

The main motivation factor for this study is an awareness of the importance of sustainability and sustainable development in all sections of society for the better economic, social and environmental survival of humanity; this was one of the indirect messages of the Rio+20 conference (UNCSD, 2012)

The paper is organized as follows. Section 2 gives the theoretical background of the study, including a presentation of the Triple Bottom Line model. In section 3, we introduce the method of the literature study. In section 4, the results and analysis are presented. Finally, section 5 includes a discussion of the analysis, together with any conclusions and implications.

THEORETICAL BACKGROUND

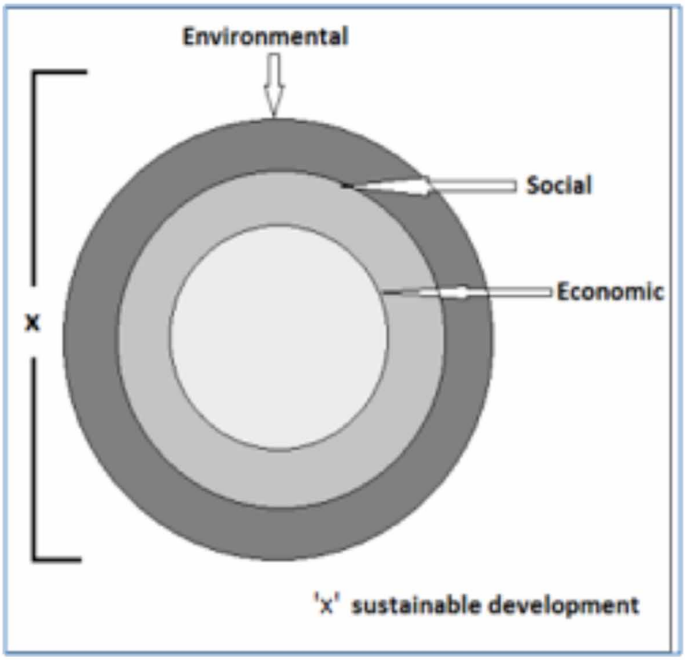
Sustainable development has no single universally accepted definition; indeed, it has mostly been operationalized in accordance with the relevant context or discipline: for example, in frameworks utilized to carry out sustainability studies of natural resource management systems, such as the Pressure-State-Response (PSR) framework; the framework based on indicators for natural resource management evaluation (MESMIS, *Spanish acronym*) and the Quantitative Analysis of Land Use Systems (QUALUS)



EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

framework (Ridaura, 2005). In this study, we have adopted the definition of sustainable development put forward by the Brundtland Commission of 1987, in which sustainable development was defined as 'the development that meets present needs without compromising the ability of future generations to meet their needs' (IISD 2012). This definition is general in nature and widely accepted; thus, it serves our purpose. In order to provide a more domain-related definition, we also used Kanungo's (2004) definition of sustainable investments as 'those whose benefits keep continuing into the future'.

Several theories and models have been used in sustainability research (Loukola & Kyllönen, 2005). Some models exist for the study of sustainability in different systems; for example, the three-legged sustainability stool, circles of sustainability and the GREENSOFT Model for studies of software. In general, two models of sustainability are referred to more often than others. Firstly, some models are based on the Triple Bottom Line (TBL) conception; for example, the three ring circus, three pillar model or Venn diagram, as shown in figure 2. The second is the Russian doll model or three nested frequencies, as shown in figure 3. The Russian doll model incorporates the environment as a pre-condition for the other two dimensions of sustainability. The pillar of sustainability or three ring circus model, on the other hand, defines sustainability as the intersection of three dimensions. Several studies of sustainability invoke the idea of sustainable development by using the three ring circus model (Levett, 1998). In this study, we used the three ring circus model that is based on the TBL conception because it incorporates all dimensions of sustainability equally, unlike the Russian doll model, which focuses on the environmental aspect. The three ring circus model is the one most often utilized for sustainability studies. According to Dao et al. (2011), it is used by 68% of the top 250 global companies on the Fortune 500.



Like Viet et al. (2011) and Mitrea et al. (2010), we adopted the Triple Bottom Line's (TBL) model for our perspective on sustainability (Slaper & Hall, 2011). The Triple Bottom Line's model for sustainable development has also been referred to as the three pillar model and the three ring circus. We adopted the Triple Bottom Line's model in order to categorize the concepts; in turn, this enabled us to compare data. Whilst the Triple Bottom Line's model can be used to quantify the concepts, we only used it to categorize them. Data on the sustainability of e-services was categorized according to environmental, social and economic dimensions (Slaper & Hall, 2011). Figure 2 shows the Triple Bottom Line concept of sustainable development. In this model, the three dimensions of sustainability are interdependent. The

Figure 2. The triple bottom line's model

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. The Russian doll model

overlapping (grey filled) areas in Figure 2 show the interdependence of the sustainability dimensions, while the intersection of all three dimensions gives 'X', which can be defined as sustainable development.

- **The Environmental Dimension:** An environmentally sustainable system must maintain a stable resource base, avoiding the overexploitation of renewable resource systems or environmental sink functions, and depleting nonrenewable resources only to the extent that investment is made in adequate substitutes. This includes the maintenance of biodiversity, atmospheric stability, and other ecosystem functions not ordinarily classed as economic resources (Harris, 2003, p. 1).
- **The Economic Dimension:** An economically sustainable system must be able to produce goods and services on a continuing basis, to maintain manageable levels of government and external debt, and to avoid extreme sectoral imbalances, which damage agricultural or industrial production (Harris, 2003, p. 1).
- **Social Sustainability:** A socially sustainable system must achieve fairness in distribution and opportunity, adequate provision of social services, including health and education, gender equity, and political accountability and participation (Harris, 2003, p. 1).

According to the TBL concept, the sustainability aspects of e-services can be initialized. In the model, the three dimensions of sustainability can be related to e-services in much the same way as researchers relate them to other technologies, such as ICTs.

Table 1 shows research covered by the three TBL sustainability dimensions. The need for e-service sustainability is indicated by the number of examples of sustainable ICT cases discussed in scientific papers, as proposed by Mitrea et al. (2010). E-services utilize ICTs and other technologies according to

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Focus of ICT research according to sustainability dimensions (Mitrea et al., 2010)

Economic Dimensions and Importance of ICT Development	Environmental Dimensions of ICT Development	Social/cultural Dimensions of ICT Development
Increase in productivity	Traffic reduction optimization	Support for community networks
Basic infrastructure for the digital economy and for the functioning of other sectors	Increased energy efficiency	Optimization of cooperation, participation and solidarity
Innovation basis outside the ICT field	Efficient information systems for environmental management	Support for new forms of political and civic participation and engagement
Controversial relationship between ICT and economic growth, dependent on the existence of the institutional setting that sustains the mutual reinforcement of the free market and ICT innovation	Environmentally-friendly production modes	Open source as appropriate
Potential and risks arising from the acceptance of 'appropriate technologies in developing countries'		Technology for global education
		Optimization of family-work life through teleworking
		New working time models/agendas
		Multimedia support for new forms of health care and education

the adopted TBL concept (Mitrea et al., 2010). Thus, it is acknowledged that ICTs have both positive and negative impacts on sustainable development (Hilty et al., 2006).

Starting with the negative *environmental impacts* of ICTs, it has been found that annual emissions amount to approximately 0.86 metric gigaton per year, which is equal to about 2 per cent of global carbon emissions. This percentage is expected to double by 2020, especially for technologies such as mobile telephones (Dunn, 2010). In the US, ICTs alone make up 2.5 per cent of carbon emissions and this share is expected to increase to 2.8 per cent by 2020 (GeSI, 2008). Thus, carbon emissions from ICTs are equal to or are greater than the total carbon emissions generated by the airline industry.

The negative *economic impacts* of ICTs can be exemplified by considering a recent study, which has shown that new high-tech technologies use gold and silver in the production processes that are valued at more than 21 billion US dollars. Currently, only 15 per cent of that figure can be recovered, with the remaining 85 per cent, amounting to $21 billion, lost as e-waste (GeSI, 2012a).

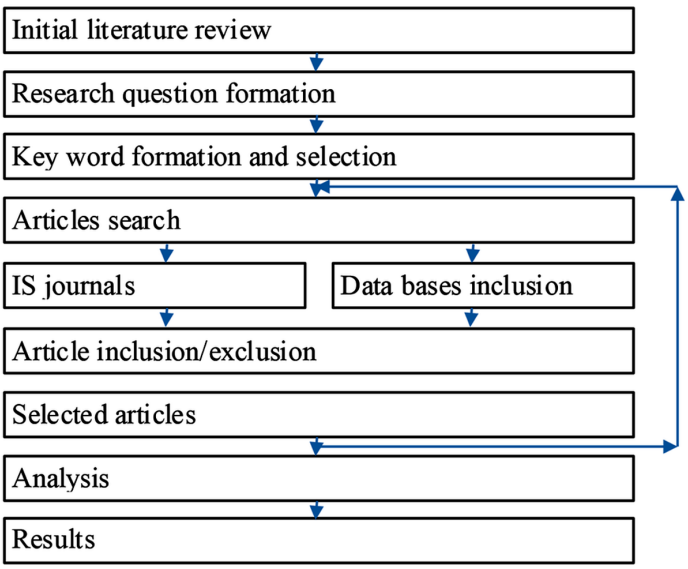
With regard to the negative *social impacts* of ICTs, it is relevant to consider a case mentioned in a referenced study, which described how the unregulated production of gold from e-waste led to the death of 100 children in Nigeria (Mobbs, 2010). Also documented are the huge quantities of e-waste that are imported by the developing world for various purposes (UNU-ISP, 2011).

In addition to the negative environmental, economic and social impacts exemplified above, there are, of course, the huge positive impacts of ICTs. These are probably perceived to be more significant than negative impacts, because the field is continuously growing. However, this study is mostly concerned with the existing state of knowledge of e-service sustainability, regardless of the type of impact.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

METHOD

This study used a literature and document review method that is based on the concept centric approach put forward by Webster and Watson (2002). The core idea of the concept centric approach is to organize the study from central concepts either deductively or inductively or both. We also adopted and considered concepts of analysis from Grönlund and Andersson (2006), who focused on the quality of e-government research. The criterion and categories of this study were adopted to evaluate research papers on e-service sustainability. Following the consideration of a study by Islam and Scupola (2011), a literature review was designed specifically for researching services. The study was organized as shown in Figure 4.



Initial Literature Review

An initial literature review was performed in advance of the formation of the research question. The goal of this pre-study was to identify current basic knowledge with regard to sustainability, and current and past efforts in sustainability practices related to ICT. The initial literature review included sustainability reports and articles. The outcome of the initial literature review provided explanations of required key terms and a knowledge background to formulate the research question. The initial study also provided a knowledge background to specify the domain and scope of the study.

Keywords and Search Process

The keyword formation process and selection was performed according to the requirements of the research question (Webster & Watson, 2002). We searched using combinations of *sustainable/ sustainability* and (singular and plural forms of) *e-service/eservice/electronic service* and *government/ egovernment/e-government/ICT*. These combinations were used in the search process using Google Scholar and Sum-

Figure 4. The research process

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

mon, a search engine that includes several other search engines, such as ACM Digital Library, Scopus, ABI/Inform, IEEE Explore, LISTA and Web of Science. The search was limited to papers published between January 2000 and September 2012. The start of the period was chosen because the number of research papers that target e-services began to increase at that time.

The paper search process started with a search of renowned journals in the domain of Information Systems (Webster & Watson, 2002). In our case, we selected journals from an AIS senior scholars' basket of journals (Islam & Scupola, 2011): Management Information Systems Quarterly (MISQ), European Journal of Information Systems (EJIS), Information Systems Journal (ISJ), Internet Research(IR), Electronic Journal of Electronic Government (EJEG), Journal of Information Technology (JIT), Government Information Quarterly (GIQ), Journal of Strategic information systems (JSIS), Journal of Association for Information Systems (JAIS), and e-Services Journal (eSJ).

In the tables below, Keyword 2 (Kw2) is the most important search key. Nonetheless, we included three more searches in order to be able to make comparisons.

Table 2 shows the number of paper hits for the selected keywords against the journal names, respectively. For example, there were 160 paper hits for the keyword "sustainability e-services". In the result we included synonyms and homonyms that are made up of all possible combinations of words that are grouped together to form keywords.

The second source of the paper search are databases and scientific search engines. During this process, the following databases were accessed: Web of Science, Scopus, Summon, Inspec, IEEE *Xplore*, ERIC, Google Scholar, Scirus, SwePub and ACM Digital Library. Most of these databases are multidisciplinary, because of the nature of Information Systems (IS) papers (Webster & Watson 2002). In addition to the selected keywords, our search process also included synonyms and homonyms that are made up of all possible combinations of words that are grouped together to form keywords. Table 3 shows the names of the search engines and the number of paper hits for the keywords, respectively.

Table 2. Number of hits for AIS senior scholars' basket of journals, Jan 2000 – Sept 2012

Sr.no	Journal	Kw1	Kw2	Kw3	Kw4
1	MISQ	10	0	3	0
2	EJIS	0	0	2	19
3	ISJ	17	2	3	17
4	IR	15	15	4	3
5	EJEG	11	11	55	160
6	JIT	0	3	7	3
7	GIQ	77	67	39	83
8	JAIS	25	16	4	54
9	JSIS	56	46	10	8
10	eSJ	0	0	0	4
	Total	211	160	127	351
Kw1 = sustainability. Kw2 = sustainability e-services					
Kw3 = sustainability ICT. Kw4 government e-services					

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 3. Number of hits for selected databases, Jan 2000 - Sept 2012

Sr.no	Database/Search Engines	Kw1	Kw2	Kw3	Kw4
1	Web of Science	564	2	179	156
2	Scopus	2,545	4	13	351
3	Summon	929	0	1	42
4	Inspec	2,072	11	5	27
5	IEEEXplore	1,609	3	87	87
6	ERIC	2,759	0	28	6
7	ACM Digital Library	2,119	43	457	15
8	SwePub	1,901	0	43	66
9	Scirus	829,397	2	408	693
10	Google Scholar	729,000	1	139	554
	Total	1,572,895	66	1,360	1,997
Kw1 = sustainability. Kw2 = sustainability e-services.					
Kw3 = sustainability ICT. Kw4 government e-services.					

With regard to the 66 hits for Keyword 2 (Kw2), most of the papers (43) were accessed from the ACM digital library. Comparing the number of hits for keywords 1 (Kw1), 3 (Kw3) and 4 (Kw4) with those for Kw2 gives a glimpse into sustainability efforts in general, compared with e-service sustainability in particular. Kw2 has only 66 hits, compared with Kw1, which has 1,572,895 hits; the same trend can be observed by comparing the remaining keywords with Kw2.

Paper Inclusion and Exclusion Criteria

The outcome of the whole search process with Kw2 produced a total of 226 papers, i.e., 160 from Table 2 and 66 from Table 3, retrieved by keyword search only. These papers were initially analyzed by reading the title, abstract and keywords for inclusion or exclusion in the second analysis. After the first analysis, papers that contain information relating to e-service sustainability in their title, abstract or keywords were selected for further research; otherwise, they were excluded from the study. With regard to Table 2, all of the papers (351) were analyzed for inclusion or exclusion. However, as for Table 3, only papers that included hits of keyword Kw2 were analyzed. The outcome of this whole process was a total of 20 papers that include information related to e-services sustainability. These papers were then selected for conceptual analysis.

Data Analysis

The outcome of the process described above is a selection of papers that have been initially filtered to ensure they relate to e-service sustainability. Firstly, the selected articles were categorized according to the Triple Bottom Line (TBL) concept of sustainability, i.e., environmental, social and economic dimensions, as represented in Table 4 of the results section. Secondly, each of these papers was analyzed in order to classify them into one of two interrelated concepts of sustainability: *C1: sustainability of*

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 4. Categorization of e-service sustainability, Jan 2000-Sep 2012

Sustainability concept / Years	Papers relating to knowledge of e-service sustainability						
	C1			C2			
	Environ	Social	Economic	Environ	Social	Economic	Total

Total	0	0	0	1	11	8	20
Note. C1 = Sustainability of e-services themselves. C2 = e-services as enabler of sustainability							

e-services themselves and *C2: sustainability enabler effects of e-services*. The aforementioned processes were carried out through a detailed and systematic analysis of titles, keywords and abstracts. This process ended with a final selection of papers, as presented in Table 5. The selected papers were further analyzed using rigor and relevance criteria in order to identify the research trend and the maturity of the field. The criteria utilized for this analysis process was adopted from the study by Grönlund and Andersson (2006), which elicited the type of approach, type of method, publishing domain and research topic. The first two categories were used to find out the maturity of the field. The publishing domain states how much was published in journals and conference proceedings, respectively. The topic aspect reveals research trends and focus. Table 6 shows the result of this final step.

RESULTS AND ANALYSIS

The papers identified during the previous process were categorized into concepts using TBL sustainability dimensions - the major entities analyzed in the study - as units of analysis; see Table 4 (Webster & Watson, 2002). The sustainability dimensions were selected as concepts that can be compared over time; in our case between 2000 and 2012. In Table 4, two categories (C1 and C2), show the interrelated concepts of e-service sustainability. C1 represents the sustainability of the e-services themselves, whilst C2 represents the enabler effects of e-services.

Table 4 shows the number of papers that refer to e-service sustainability during the selected period of time. No papers were found which cover C1, whilst 20 papers were found which cover C2.

En = Environmental. Ec = Economic. So = Social. TG = Theory generating. TT = Theory testing.
D = Descriptive. P = Philosophical. TH = Theoretical. C = Conference. J = Journal.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 5 shows the title, author name and year of publication for the 20 selected C2 papers categorized by the TBL dimensions. These 20 papers include one that is related to the environmental factor of e-services, 11 papers for the social dimension and eight related to the economic dimension of e-services. The papers were further analyzed for rigor and relevance according to the criteria and categories put forward by Grönlund and Andersson (2006).

Table 6 depicts the basis for the analysis process in terms of rigor and relevance. Column 1 shows the coded acronyms for papers that relate to the *TBL categories* of environmental, economic and social sustainability: En, Ec and So, respectively. Columns 2 to 6 show the research types as coded acronyms, TG, TT, D, P, TH, which refer to 'theory generation', 'theory testing', 'descriptive', 'philosophical' and 'theoretical', respectively (Grönlund & Andersson, 2006). Column 7 represents the *source of the paper*, either (J)ournal or (C)onference. This column also shows the papers' scientific domains in parentheses; for example '(IS)'. Column 8 shows the *research topics* and column 9 the *research methods* covered by the selected papers. Similar approaches to the analysis of a research field have been carried out by Alavi and Carlson (1992), and Islam and Scupola (2011).

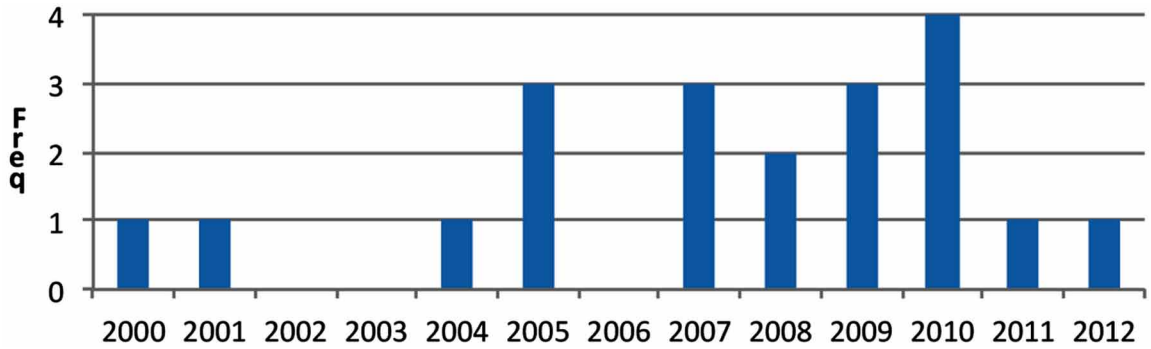
Research types (columns 2 to 6) demonstrate the maturity of a field by identifying the type of research carried out. The analysis shows that, out of the 20 papers, 11 belong to the TG (Theory Generating) category. This number indicates a certain degree of immaturity of the research field, because it presupposes an absence of theories (Grönlund & Andersson, 2006). This claim is supported by the low number of theory-testing papers.

Source of paper (column 7) shows where the research was published. This can ultimately indicate if there is an established set of forums for the focused research. Out of the 20 papers, 10 were published in journals and 10 at conferences. Column 7 shows that the majority of conference papers relate to an IEEE conference, which is another indicator of research field maturity. Moreover, most of the papers from the journal category were published in IS journals, particularly the eSJ (e-Services Journal). The fact that a journal dedicated to e-service research has only published two papers that focus on sustainability indicates a low level of maturity.

Research topics (column 8) shows the topics that are focused on in each paper. The only paper that relates specifically to the environmental category explains the benefits of e-services in relation to the centralization of environmental reporting systems. Of the eight economic dimension papers, four focus on the impact of e-services, whilst the rest discuss models and the integration of models for the economic analysis of e-services. The modeling papers also discuss relational cost benefits connected with e-services. In total, 11 articles can be seen to relate to the social dimension, with six of them relating specifically to user satisfaction. In all, 8 papers are concerned with modelling. In the same way that theory generation and explorative approaches can be interpreted as a sign of an immature field, the number of modelling papers may also indicate the same level of immaturity (Alavi & Carlson, 1992).

Research methods (column 9) shows how the choice of methods is affected by whether theories, models and sets of concepts exist in the field of e-services sustainability. This can, in turn, indicate the maturity of the field. If the field is well established in terms of theories, models and sets of concepts, it is likely that more experimental than explorative approaches will be found. Explorative approaches such as grounded theory, ethnography and case studies are necessary to define a field in terms of theories, models and sets of concepts. Descriptive studies and surveys are more likely to be built on existing and accepted concepts and constructs. Experiments and tests ultimately need theories or models if they are to be executed. This way, the methods used can assess the maturity of a field (deBruin et al., 2005). Interpretive studies are most often inductive case studies (Walsham, 1994; Walsham, 2006), something

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use



that supports the conclusion that interpretive studies are more common in a less mature field. Of the 20 papers, 17 were classified as more or less explorative.

An indicator of public e-service maturity is the number of papers published per year during the studied period. As shown in Figure 5, 15 of the 20 papers were written between 2005 and 2010. The fact that only two papers were published in 2011 and 2012 may be a coincidence; certainly, the overall frequency is too low to be the basis for trend analysis.

DISCUSSION AND CONCLUSION

The major finding of this study is that no research has been carried out with regard to the sustainability of e-services themselves. This finding is represented as variable C1 in the paper. Only a few research studies have sought to examine the sustainability enabler effects of e-services, as represented by variable C2 in this paper. These findings are in line with observations made by Bengtsson and Ågerfalk (2011) and by Klischewski and Lessi (2012). A literature review was carried out, which identified 20 selected papers relating to e-services sustainability. Thus, the frequency of research in the studied field can be seen to be rather modest. It should be noted that there is not a complete shortage of papers that analyze sustainability in the e-Government domain. However, we only included papers that explicitly analyze sustainability in e-services, either within the e-services themselves or as enablers. We also used all relevant kinds of conjugations of the terms "e-service" and "sustainability" in order to avoid missing relevant papers. Further on we have excluded papers that analyze sustainability and e-government in general, because their connection to e-services is implicit and does not provide any substantial contribution to the understanding of the sustainability of e-services. We also excluded papers in which e-services and sustainability are just mentioned but not analyzed. Finally, we excluded papers in which sustainability and e-government are discussed in terms of sustainable development. We consider sustainable development to be something that is not explicitly related to e-services. Sustainability is a homonym, which is used in many contexts and can have several meanings whereas the sustainability of the e-services themselves, is not explicitly studied yet. Another notable reason for the lack of research into e-services sustainability could be the conceptual vagueness or lack of clarity of the terms 'sustainable development' and 'sustainability'. As mentioned previously, whilst this study analyzed the sustainability of e-services, few papers relate to the sustainable development of e-services, i.e., where sustainable e-services are explained in

Figure 5. Papers per year

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

terms of constancy. In addition, the term sustainability is sometimes utilized or presented as the meaning of constancy or fixed state of the system (ECLAC, 2001). However, presenting sustainability in this way can also lead to a certain vagueness in the research. The standard explanation given for 'sustainable development' and 'sustainability' is debatable. According to one quote, "sustainable development is the pathway to sustainability" (circular ecology, 2014). As mentioned previously, this study referred to the Brundtland definition for sustainable development and utilized the Triple Bottom Line model for the categorization of sustainability dimensions.

With regard to the dimensions of the Triple Bottom Line model, most papers relate to the social and economic dimensions. Only one paper was found which relates to the environment dimension. A maturity analysis was carried out, which shows that theory generating and testing are the most common research approaches to e-service sustainability. Most papers were published in high ranking conferences and journals. The lack of published papers shows that research on e-services sustainability is in its infancy.

An analysis of the topics covered by the papers shows that the one most commonly investigated was user satisfaction in the social dimension. In several studies and technology models, social aspects are considered to be important social issues. The environmental aspects of e-services are not yet on the scientific agenda, which we believe is a sign of immaturity.

The findings described above raise several questions that can be addressed by further research. For example, why is there an absence of papers related to the sustainability of e-services? At least two answers to such a question come to mind. It may be that contemporary researchers are not currently interested in explicit studies of e-service sustainability. On the other hand, they may be concerned about sustainability in the same way as this study, for example through a search for research papers. Thus, whilst research has focused on the separate dimensions it has not explicitly related them to sustainability. One can eventually explain or excuse the absence of sustainability research by relating to other IS fields. It is easy to notice that sustainability was not the first area to be researched within usability, systems development, or knowledge management. Consequently, there are also few studies on how e-service sustainability is researched. We found two, which is yet another sign of immaturity.

To elaborate further, e-services, which are a basic component of e-government, are widely accepted and utilized. Indeed, the use of e-services has increased year on year (DESA 2012). In this study, we selected e-services as a point of departure to investigate the sustainability of an important aspect of e-government. In addition to e-services, other dimensions and components of e-government could be considered relevant to sustainability evaluation or research. Currently, a situation exists in which there is an absence of studies on e-service sustainability. However, in this study we also investigated the existence of indirect sustainability research. By raising questions regarding sustainability indicators for e-services, we were able to broaden our research to include other sustainability aspects. For example, what are the indicator protocols and methodology sheets for e-services? This study could be extended to include further questions that address this issue. Sustainability indicators are considered to be basic requirements for sustainability evaluation (DESA, 2007), as are methodology sheets and indicator protocols (DESA, 2007).

A large number of studies have discussed the sustainability enabler effects of ICTs and other technologies. There is immense potential to save energy on a large scale through the use of ICTs. They can reduce carbon emissions and decrease greenhouse gases by up to 15 per cent. Furthermore, ICTs could help to save about 600 billion Euros ($946.5 billion) by 2020 (GeSI, 2012b). ICTs have multiple dimension impacts, including environmental, economic and social aspects. The potential for ICTs to be sustainable has been acknowledged not only by GeSI (2012b), but also by a number of other authors

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

and organizations. For example, the most recent United Nations conference acknowledged the potential of ICTs for promoting sustainable development (UNCSD, 2012). Hence, the role played by ICTs, the Internet and other technologies with regard to sustainability enabler effects is widely acknowledged. Whilst some of this research might include e-services implicitly, there is a lack of explicit research about the sustainability of e-services.

The practical implications are directed to government officials. As first or second hand representatives of citizens, these officials need to consider the long-term effects of the implementation of e-services. Efficiency and effectiveness have been the major focus so far. Now is the time to explicitly include sustainability.

The scientific implication of this study is a call for more research into e-service sustainability. The importance of sustainable e-services is acknowledged as a requirement for a better future (UNCSD, 2012). The implication for researchers is that they need to focus on e-service sustainability in order to fill the existing gap. For practitioners, it is necessary to include sustainability as a mandatory requirement when developing public e-service applications.

Chapter 23
Embedding Sustainability Learning:
Robustness in Changing Circumstances – Perspectives From a United Kingdom (UK) Higher Education Institution (HEI)

Ros Taylor
Kingston University, London, UK

Elise Barron
Kingston University, London, UK

Katherine A.T. Eames
Kingston University, London, UK

ABSTRACT

In this chapter the authors argue the benefits of an "embedded strategy" for achieving a robust and sustainable Education for Sustainable Development (ESD) curriculum and outline some of the main approaches used at Kingston University (KU), London. The chapter includes feedback from students, academics, support staff and local employers engaged in these developments and highlights the main successes and the pitfalls encountered. Case studies exemplifying sustainability learning through a diversity of embedded approaches are presented and analysed. The authors' experience demonstrates that, although there is no "one size fits all" solution to ESD, sharing of experiences between sustainability professionals is vital to this agenda. The examples detailed in this chapter show that with careful design, active and multidisciplinary learning, sustainability understanding can be securely embedded in students' learning even where it is not the main programme objective.

INTRODUCTION

The United Nations (UN) decade of education for sustainable development (DESD), 2005-14, sought to move sustainability education from concept to practical reality for people worldwide. As such it was acknowledged that alongside environmental, social and economic understanding attention to 'context'

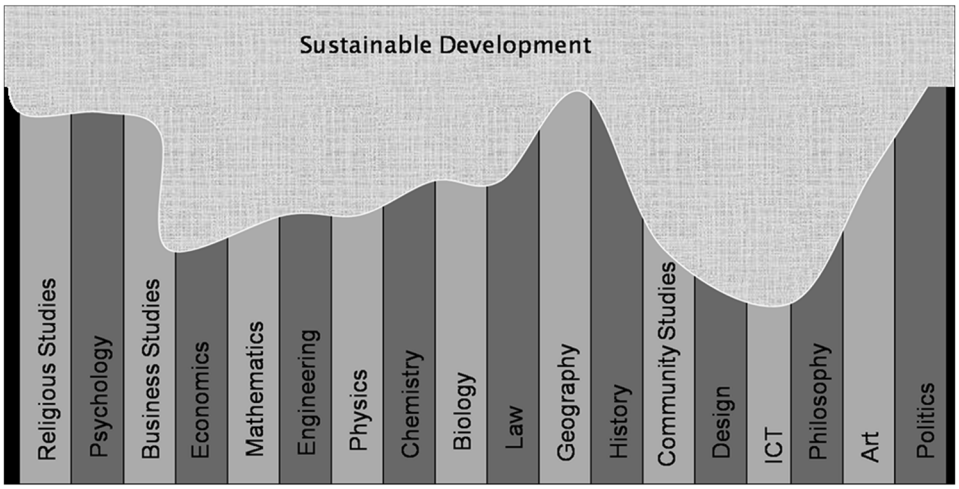
was needed (UNESCO, 2005). It was suggested that sustainable development (SD) priorities and solutions would vary regionally; that differing political philosophies would engender different opportunities and approaches; and that differing social and cultural settings would similarly lead to a diversity of preferred policies and implementation priorities and practices. There would be no 'one size fits all' recipe or solution. It was also acknowledged that a multidisciplinary understanding was needed so that future world leaders, and those guiding regional and local policy, could appreciate the complexities of SD and promote leadership and good governance to meet the urgent challenges ahead *viz.,* avoidance of catastrophic climate change, or appropriate adaptation to changing climatic situations; maintenance of adequate good quality water supplies; sufficient food; energy security; avoidance of waste and pollution; maintenance of biodiversity; and promotion of good health; while at the same time promoting a fair and equal global society.

Since the start of the new millennium grass roots societal engagement with issues such as climate change and waste management has become commonplace in most developed economies and is widely acknowledged by governments worldwide. However, despite numerous global meetings and debates on *inter alia* curtailing carbon emissions, securing clean freshwater supplies for all, and providing adequate nutrition for all, only limited progress has been achieved. UN data show 11% of the global population (783 million people) still have no access to safe drinking water and 2.5 billion live without basic sanitation (UN-water, 2013). Indeed in the case of carbon emissions, overall these have continued to rise in the United Kingdom (UK) and European Union (EU) despite recent tough targets e.g. in the UK at least an 80% reduction in carbon budget compared with a 1990 baseline by 2050 (UKPGA, 2008). Though reductions in home-based emissions have been achieved, embedded emissions in imported goods have risen (Committee on Climate Change, 2013). Industry continues striving to find new fossil fuel sources investing far more in these polluting resources, such as the development of shale fracking, or expansion of nuclear power, than in major decarbonising alternatives. It could be argued that the underpinning reason for this poor achievement and limited vision is a failure of education. The current generation of world leaders has not been exposed to sustainability learning. As a consequence much rhetoric is expounded but the practical detail of the route forward, which requires a sound scientific and environmental base as well as social understanding and applicability, is missing. The level of public debate is also poor: nuclear versus renewables; wind versus solar; rather than a joined up integrated analysis based on sound scientific, social and economic information.

The key challenge is to rectify this; to develop sustainability education accessible to everyone. Yet, for example in the UK, changes mooted to the school curriculum suggest a retrenchment to an even less integrated science and arts curriculum (Wintour, 2013). Science education is less well funded than other core subjects, especially mathematics, and its teachers less rewarded. Disciplines, such as geography, agriculture and nutrition are seen as of secondary importance and the historical understanding of failures to appreciate new science (e.g. Galileo's problems) or the human search to understand our place in the world through religious traditions are given lesser status. The fundamental and challenging need to understand how all things link is not accorded a high priority; key sustainability skills such as critical thinking and change management likewise assume a lesser role to more traditional subject learning. Yet this is the real world over which our ill-prepared political leaders and financiers must govern. Our futures lie in a changing world environment with complex inter-linkages. In practice the currently proposed UK curriculum changes will make addressing sustainability issues in a pragmatic and practical manner more difficult and apparently of marginal importance, for example addressing climate change as a scientific matter with scant attention to social and economic relevance. This is indeed a concern.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use



Higher education (HE) is similarly challenged. One major difficulty for the sector is inconsistent government standpoints with regard to sustainability and, for example, energy strategy. This in turn restricts investment and entrepreneurial activity and limits the graduate job market. The demand for graduate opportunities and courses devoted to SD thus is also restricted. This is especially so in the current UK context where new full cost fee levels for home students are causing prospective students and their families to question more closely the value of HE. Degrees in sustainability rarely lead to wealth, but even when this is not a key driver, job security is important and again policy fluctuations can make employment in this sector seem insecure. This was demonstrated recently in the UK when changes to the feed-in tariff for solar-generated electricity were substantially reduced causing financial difficulties for embryonic 'renewables companies' and their employees. The future of dedicated sustainability degrees, and related technical qualifications is similarly jeopardised. Vice chancellors and college principals seek courses that generate high student recruitment since this secures institutional financial futures. Families, too, seek the best long term opportunities for students. Counselling to prospective university students tends to reinforce this circumspection, partly due to teachers' professional unfamiliarity with sustainability degrees which are mainly new and postdate their qualifications, and partly reflecting these external pressures. These factors together mean that embedded sustainability teaching accessible from diverse main degree pathways is a potentially more fruitful and guaranteed approach for influencing future graduate citizens and potential society leaders than dedicated degree pathways especially at undergraduate levels.

As well as these essentially external drivers, a range of internal considerations have also militated against development of dedicated sustainability pathways. Undoubtedly research assessment pressures have meant academic staff have little time for the development or incorporation of new materials or indeed re-thinking pedagogic approaches. Many still see sustainability as intruding into their subject curriculum space (Dawe et al., 2003) not appreciating that change in pedagogic approach could deliver the same core disciplinary information but enriched in a multidisciplinary framework. This is where the assistance of dedicated sustainability staff can help achieve the transformational steps to sustainability understanding. Role-playing, practical campus learning, and town-gown links are just some examples of pedagogic shift that has facilitated this transformation at Kingston University (KU).

Many UK universities have embarked on curriculum restructuring aimed at freeing staff research time. Typically this means reducing the number of modules or units at each degree stage, though giving each more content and credit value, thus reducing administrative burdens and assessment pressures. When fewer modules are taken per stage, dedicated space for sustainability may not be available but an embedded strategy using more innovative and, in disciplinary terms, integrated teaching approaches can ensure students still became familiar with sustainability concepts, and at depth. This also fits with the apparent desire of UK students that sustainability be included across their courses rather than taught in separate specialist modules on the topics delivered, as discovered through recent work by the UK National Union of Students (NUS) in conjunction with the Higher Education Academy (HEA) (Bone & Agombar, 2011). Less easy to overcome is the faculty 'silos' mentality that can arise when major funding is devolved from the centre generating inter-faculty competition for students and associated income. This can create barriers that militate against inter-disciplinary programmes linking sciences, technology, design, business and humanities, linkages that are fundamental to sustainability understanding (Figure 1). Again dedicated sustainability staff can help resolve these difficulties, as can campus facilities which – if suitably designed and managed – can subliminally educate students in sustainability behaviour.

Figure 1. Sustainability – 'need to know': a schematic representation of multidisciplinary learning underpinning sustainability action (Adapted from Taylor and Toogood (now Barron), 2010)
This schematic representation is developed from ideas presented by Prof Marie Harder, Brighton University, in a guest lecture on waste management as part of the KU Sustainability Hub 2009-10 research seminar series.

The external and internal pressures highlighted above have challenged dedicated curriculum developments for education for sustainable development (ESD) in all but a minority of institutions. It could be argued the more relevant priority is to develop sustainability educational tools that are universally accessible no matter how rich or poor, or how sustainability aware an institution may be. Our experience shows even small bottom-up changes can facilitate new sustainability learning across diverse disciplines but that the support of a focal 'Sustainability Hub' or, in the early stages, an active steering group will considerably speed and aid progress (Taylor, 2013).

In this paper we argue the benefits of an 'embedded strategy' to achieving a robust and sustainable ESD curriculum and outline some of the main approaches used at KU. We include feedback from students, academics, support staff and local employers engaged in these developments and highlight the main successes and the pitfalls encountered. We present and analyse case studies exemplifying sustainability learning through a diversity of embedded approaches including:

- Changing the environment in which students learn through campus developments for sustainability, including student engagement in changes
- Engaging the university community through fun events and debates linking to wider regional, national and international issues, activities and professional practices
- Linking the university to its town and region and co-development of sustainability practice including practical sustainability learning with local practitioners
- Fieldwork and practical developments supporting learning for ESD at local, national and international scales and demonstrating the importance of context in particular through international engagement
- Role-playing, mind maps, swap-shops, 'news' reports; activities for ESD as a means of engaging students with the complexities of real world sustainability.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

These approaches typically build from students' daily experience and arguably demonstrate to them how small actions for sustainability can facilitate high level changes. They also help them to develop more sophisticated and deeper cross disciplinary analytical skills including understanding of diverse professional viewpoints. We show how well-designed facilitated, rather than didactic, learning can motivate students' understanding and practice of sustainability and assist them in acquiring the multidisciplinary skills needed to understand, evaluate and manage, the complexities of SD. We discuss some of the barriers and pitfalls to this process as well as the benefits as exemplified by student response, e.g. uptake in independent research dissertations (Eames et al., 2013) and subsequent employment.

ORGANISATION BACKGROUND

KU is a medium-sized UK academic institution located in south-west London. It is a mainly urban, multi-site, post-1992, university. Building on its former polytechnic roots it has strengths in subjects of direct professional relevance such as engineering and applied sciences, art and design, architecture and planning, and business, education and healthcare sciences. It also has strong traditions in earth and environmental sciences and an expanding curriculum in the humanities including politics, drama, media and film studies. As of December 2012 Kingston has: four main campuses; ten additional substantive residential and administrative sites; five Faculties; 23,105 students, including 4,035 non-UK students from 150 countries; and 2,916 permanent staff.

Sustainability activity within the University originated with individuals from across the institution working as an unofficial group (The Steering Group for Sustainability (SGS)), campaigning and working towards change. From 2009 the Sustainability Hub linking all strands of sustainability has been formally embedded in the University's structure in one central department; sustainability is therefore no longer a project, it has become an acknowledged core activity.

SETTING THE STAGE

Campus Learning: Subliminal and Active

University and college campuses give immediate opportunities for student learning about sustainability. These can include activities specifically linked to curricula and formal learning; active volunteering; and learning encouraged through sustainability-linked campus management practices such as good waste management, offering and prioritising sustainable foods in canteens, energy efficiency initiatives such as automatic lighting, and grey water recycling (Figure 2). These are all issues which impinge on the everyday experiences of staff and students and are thus readily transferred into the wider community locally and, as students return home, nationally and internationally. Campus good practice, since it reaches all students irrespective of their main subject of study, has great potential to influence future lifestyles and sustainability behaviour.

Many universities in the UK have instigated student 'end of year' donation schemes for those leaving university residences. This especially benefits overseas students who may have nowhere to store belongings through the summer vacation period and who previously had little option other than to discard materials which, prior to these initiatives, typically went to landfill. By organising collection schemes

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Example poster from an energy awareness campaign (introduced in 2010-11 and repeated in 2011-12)

This poster is one of a series aimed at encouraging more responsible electricity consumption. It also links to more targeted campaigns such as 'Student Switch-off', a NUS run campaign focusing on encouraging efficient electricity use in the residential halls through education and prize rewards and introduction of publicly-displayed energy performance certificates as required by the EU's Energy Performance of Buildings Directive (EPBD, 2003).

for reusable items such as, shoes, textiles, kitchen utensils, duvets, electronics and diverting these from landfill obvious environmental benefits are achieved. At the same time local charities benefit from the donated goods and, as has happened at Kingston, key items such as files and kitchen equipment can be temporarily stored and sold at discount prices to incoming new students. This generates funds towards running the following year's collection making the scheme, at least partially, self-sustaining. It also raises sustainability awareness amongst staff and students, and shows incoming students the university has 'green' credentials while benefiting them by providing the opportunity to purchase essential items more cheaply. Outgoing students learn the lessons of re-use and recycling. At the same time the institution's local reputation and engagement is enhanced and, at Kingston, this learning extended to university leaders as the scheme attracted local and national awards, e.g. Green Gown[1] award (Smith, 2009). Since the first pioneering 'man with a van' scheme launched in 2005, the scheme has expanded to include waste from summer conference services and has annually diverted on average 6 tonnes of waste from landfill helping the Royal Borough of Kingston upon Thames (RBK) to meet its landfill targets within Greater London. At the same time excellent links with charitable organisations, ranging from Oxfam to the British Heart Foundation to small local charities such as Katz Castle, have been forged. In a curious example of 'upcycling', Katz Castle transformed old duvets into handcrafted cat and dog beds. In 2011, Katz Castle charity director said, "It's great to have a regular supply of duvets and last year I raised over £5000 from the sale of the pet beds I made out of them".

This is a noteworthy innovation since laundering old duvets is expensive and makes their routine re-use difficult. Helping students reduce their 'end of year waste' and dispose of it responsibly has become a routine integral part of waste management for Kingston's facilities management company, KUSCO. The scheme has evolved, becoming more streamlined and professional each year. For example, campus

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

bins are now available for routine year-round disposal and charity collection of unwanted textiles and other reusable items. This avoids storage problems for students, for University Facilities Managers, and for the charities; it also better integrates recycling and re-use into routine daily activity.

Managing the campus offers numerous opportunities for sustainability learning; rainwater collection schemes, renewable energy projects, installation of insulating and biodiversity-promoting green roofs are obvious big winners. Much will depend on local circumstances and smaller scale opportunities should not be overlooked since these may be readily achievable without requiring major works and expense. While photovoltaics will be educational, and give a 'feel good factor', smaller projects may give more immediate opportunities to innovate and understand constraints as well as aspirations. KU is fortunate in having a diverse range of habitats for biodiversity monitoring and engagement activities. Since the majority of the campuses are based in an urban area this has surprised many people and recent activities have helped to dispel the myth that urban areas have 'no biodiversity interest' nor potential contribution to make. Initiatives have ranged from the creation of a woodland walk (through a small remnant ancient woodland) on one campus complete with signage and outdoor classroom opportunities for local schools; to pond restoration and creation on two campuses, again including learning opportunities for local school children; to 'bioblitzing' the sports field and surroundings and creating 'food gardens' for staff and students to share at the two largest campuses. Installation of campus beehives, linking to nationwide initiatives to promote pollinating insects, has proved particularly engaging to administrative staff, who also participate in general wildlife monitoring, e.g. reporting bird and bat sightings. One innovative scheme has involved courtyard 'greening' at the most urban campus. This was triggered by an open competition supported by the University's Estates department, Sustainability Hub and Landscape Interface Studio (Sustainability Hub, 2012) with student designers challenged to transform a barren concrete space into a pleasant outdoor facility with educational interest, and working to a fixed budget. Picking an outright winner proved difficult so the designers of the top two entries were asked to collaborate and merge the best elements of their designs into a new scheme for implementation. Thus a 'pharmacy garden' linked to a potential revolving art exhibition and relaxation space was created (Figure 3). The associated formal and informal learning is clearly substantial not just for the competition participants and winners but also for those voting and evaluating the schemes; those subsequently enjoying the new space; and those who can now study and monitor the development of the area. Building on this, the University has launched an annual Sustainability Fund offering up to £1000 for staff and student ideas to improve the environmental impact of its estate. In 2012-13 the Fund has supported the creation of a pond dipping platform at Kingston Hill Campus to improve teacher training and promote outdoor learning.

A similar, larger scale courtyard development at Manchester Metropolitan University was reported in the recent, 2013, People and Planet green league evaluation (Bawden, 2013). Here, members of the university's Urban Garden Society have transformed an inner courtyard and former eyesore into an interactive garden for staff and students. Herbs, edible flowers, fruit trees, salad crops and vegetables can all be found in raised beds with wooden benches. All plants are labelled and wheel chair access is possible. In both these projects multidisciplinary learning and benefits are evident as well as a transformation of estates management approaches on urban sites.

The enthusiasm engendered by these developments reflects a growing understanding of the importance of providing opportunities for student input and co-development of sustainable solutions pertinent to their own university campus environment involving all members of a university community (Agombar, 2013). For students the skills gained extend beyond subject knowledge and incorporate the wider skills

of collaborative working; for staff from all areas of the university the collaborative developments build involvement and may gently persuade them towards adoption of more sustainable lifestyles.

Another campus initiative currently under development at KU involves working with the UK Environment Agency (EA) on an urban campus riverbank site to de-engineer the river channel and create new meanders making a more pleasant open space for students and staff; more diverse wildlife habitats; and improved water regulation. This funded project links with ongoing work, regularly required and undertaken by staff and student volunteers led by the biodiversity and landscape officer, to eliminate invasive Himalayan balsam (*Impatiens glandulifera*) (Figure 4). It also links to formal curriculum activities monitoring river quality and riverine access undertaken by geography, environmental and biological science and landscape students and to overarching EA proposals for improving London's rivers. Observations (by Taylor) during student curriculum work monitoring similar changes introduced on a comparable south bank tributary of the River Thames in southeast London, the River Quaggy, revealed significant wildlife, water quality and social benefits. Thus a local grass roots volunteer sustainability initiative has now linked to regional sustainability objectives. At the same time this work has extended active formal learning opportunities across diverse disciplines, while also improving the external environment quality and opportunities for relaxation to the benefit of all members of the university community.

Numerous opportunities in the formal curriculum can spring from these initiatives through practical scientific monitoring; designing new areas; and analysing staff and student responses and engagement.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. 'Balsam bash' in the River Hogsmill [Authors Photograph, 2010]
Himalayan balsam is an invasive species introduced into the UK. It grows rapidly and may shade and outcompete native plants. Regular removal and control is needed to maintain native flora and habitat diversity and in a riverine situation promoting native species will help to maintain good ground cover in winter when the balsam dies back. This will help to stabilise the river bank. Himalayan balsam is easily removed by hand making its removal a suitable task for volunteer events. However, until all the seed sources are eliminated further upstream this management is required annually as the riverbank is reseeded with the balsam each year. The photo shows volunteers at work on the vegetated riverbank opposite one university campus.

One scheme linked undergraduate learning for environmental management systems with small campus development projects. Support staff from estates, facilities management, learning resources and catering identified proposed projects for which they needed further data e.g. lighting in learning resources centre (LRC) areas, and food waste management schemes. Working with the academic module leader and facilitated by sustainability staff, project briefs were developed. As part of their formal assessment students worked in small groups to collect relevant data; physical, social, and environmental, and then reported recommendations by oral presentation and 'professional report' to the 'commissioning' staff member as well as academic assessors. This was highly motivating for students and generated new insights for staff forging beneficial links and understanding between academics and diverse support staff. Everyone benefitted from feeling involved; they felt valued; students especially were motivated by this 'real world' learning opportunity, the chance to make a difference to their university. Campus management and wider support staff valued the opportunity to contribute to student learning and demonstrate the practical constraints on their roles. They welcomed the chance to input their expertise. They also appreciated the opportunity to gain data from small research projects, commissioned and designed in liaison with their student group; data they often needed to support new developments but were short of time to collect (Taylor et al., 2012). The scheme built on earlier volunteer work pioneered through town-gown links and extended into the formal postgraduate curriculum linking students with external employers.

In one example students, using lux meters, monitored light levels throughout the day and night in the LRC at the main university campus. Their data supported the business case for design improvements to space layout, benefitting future users, and saving energy. The KU energy manager (2011) said of the

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

student assessment of lighting and energy consumption in the LRC, "I didn't have figures in terms of light levels etc to back things up before and these aspects are important". Comments from the student participants in the project (2011) included, "Locating and processing real data was the most valuable part of the assignment" and "It's invaluable to be using real case studies for assignments".

Other groups have, for example, analysed waste management in students' halls of residence and at university sport and recreational facilities; evaluated canteen waste and its composting potential; explored the potential for local food sourcing; and evaluated biodiversity projects. The residential hall manager involved in the student survey of waste management and environmental performance (2011) felt that "It's always useful to have fresh eyes look upon ongoing issues .... The final report is useful as a basis from which to start gathering more detailed information. More improvements can be made with more information at our disposal". The students working on the same waste evaluation of a residential hall (2011) said "Having to pull back and think through every little step helped make our final product more thorough and complete," "There was a certain protocol and language that had to be used that seemed to differentiate it from other coursework assignments" and "It revealed the true obstacles to improving and monitoring environmental performance".

CASE DESCRIPTION: LINKING TO 'BIG ISSUES'

Guest Debates and Talks

As part of the wider educative process, the university's volunteer Steering Group for Sustainability (SGS), the precursor to the established Sustainability Hub (Taylor, 2013), in conjunction with the local administrative authority (RBK) and its annual Festival of Ideas programme pioneered thematic town-gown debates relating to key environmental and sustainability questions. Topics included, e.g. climate change (and carbon rationing), urban biodiversity, food quality, Fairtrade, sustainable housing (Table 1) with the intention of engaging students, staff and the wider local public in topical and socially important debates. Invited celebrity experts debated with local guest speakers and university staff with the event chaired by an SGS member thus drawing in a very mixed audience and promoting lively open debates around introductory position statements from the debate panel. This promoted a more active audience engagement than the standard 'expert talk followed by audience questions' approach. Events sometimes continued long after the scheduled slot in local pubs and coffee houses. These events paved the way for wider town-gown collaborations and created further opportunities for students. Academic staff responsible

for some degree programmes also challenged students to review the events as part of their coursework assessments. Feedback showed that students welcomed the interaction with local people and the feeling that their contributions were valued. In a related exercise posters made by students exploring SD themes, as coursework assessments from diverse modules and degree programmes, were displayed in an opening social session ahead of the main debates. This advertised the university's educative work to the general public and brought useful critical feedback for students and positive good will which staff later built on through student placement opportunities, and real world learning opportunities, within the local community. Importantly, these events were fun for all participants and thus engaged people and encouraged their sustainability learning and continued participation in developing good practice for sustainability.

Linking with International Partners

Collaborations across international boundaries add another dimension to embedding sustainability into curricula. The ability for sustainability professionals to share best practice and the routes they have taken to solve problems provides the opportunity for resources to be pooled and progress made more quickly on a larger scale as effort does not have to be duplicated. Direct sharing of curricula has also occurred with students from Oldenburg, Germany, visiting Kingston and joining UK students in sustainability related fieldtrips around London for the past three years and reciprocal participation by Kingston postgraduate taught masters students in fieldwork exploring sustainable water management in northern Germany. Similarly students from Kingston and the Universities of Cádiz and Almería, Spain have collaborated on investigative fieldwork in Spain exploring issues for regional SD. The shared experiences promote better understanding of cultural context and in the Almerían link facilitated interviews with local residents on issues of water pricing and waste management and tourism development. Students also jointly explored issues of agricultural production and social development in the extensive 'plasticultura' areas on the Campo de Dalías, Almería, in southern Spain.

This sharing of expertise also can usefully extend into campus operations issues. Immersing students in a sustainable environment during their studies is a vital element of embedding sustainability learning into the HE system. The sustainability experience of KU has been sought by a range of universities including Bilbao University, Spain; Grand Valley State University, USA; King Fahd University, Saudi Arabia; the Catholic University of Lille, France; and Kyoto University, Japan, engendering conversations useful to both parties.

Through the Dorich House Group of European Universities[2], institutional level research links have been made between eight Universities from the UK, France (2), Germany, Spain, Turkey, Lithuania and Sweden. Eames et al. (2013) presented an initial comparison of Biology, Environmental Sciences and Surveying course programmes between Oldenburg University, Germany and KU which revealed many of the complexities that would need to be resolved to enable fuller measurements and comparisons to be made. The availability of data and variations in the aspects of each discipline generally taught in each country were two of the areas identified where more work could be usefully done to assist in quantifying sustainability coverage in curricula on an international scale. More comprehensive attempts to measure sustainability coverage in KU's curricula have also been conducted (Dawe et al., 2003; Eames, 2012). This focus on researching a methodology for measuring sustainability coverage is gaining momentum in the UK due to national initiatives such as the People and Planet Green League but also more inherently by the need to be able to measure in order to improve and manage progress.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

National Initiatives

The People and Planet Green League has been a powerful motivator for UK universities to become more sustainable in their operations. Universities are required to submit evidence as to their current situation including their carbon emissions, water use, recycling rates, procurement policies, and engagement with staff and students on sustainability. Since 2011 the League has also required evidence of Universities working to include sustainability in their curricula. With a revision of the whole methodology occurring for the 2014 League it is likely that curriculum will gain a larger prominence in the criteria, increasing the incentive for Universities to invest time, effort and financial support to this agenda.

Another national scheme having a beneficial impact on students' ability to learn about sustainability while at university is 'Green Impact' run by the UK NUS. Though primarily this scheme is focussed on engaging with staff and encouraging them to change their workplace behaviours to be more sustainable, an integral part of the scheme involves recruiting students as volunteers to audit the participating departments' efforts. The student volunteers are trained in auditing, gaining employability skills, which they then utilise in a professional capacity to assess their assigned staff team. Student volunteers can also choose to get involved in the scheme on a longer-term basis supporting an allocated staff team in their efforts to redesign their office processes to be more sustainable. Feedback from the students involved has revealed the benefits that they have gained from the scheme and also showed that their interest was particularly captured by the opportunity to investigate in more detail the university staff experience and to positively impact on their institution.

A currently ongoing national initiative, which is likely to have a profound effect on sustainability in HE curricula, is the production of new Quality Assurance Association (QAA) guidelines on how sustainability could be covered by universities in their courses. The QAA in the UK is responsible for safeguarding quality and standards in universities and colleges to ensure that students across the country have the best possible learning experience and that degrees from different institutions remain comparable. It publishes and consults with institutions to improve the UK Quality Code which "is used to assure the standards and quality of higher education in the United Kingdom" (QAA, 2012. p. 2). The development of these guidelines has been chosen to align with the recent guidelines on employability (QAA, 2010). 'Guidelines' were selected instead of the 'requirements' that the QAA has in place for other elements of the Quality Code due to the complexities of the issues and the work that still needs to be done to make the aim of complete sustainability coverage in curriculum a reality. The guidelines have not yet been released but have already raised interest throughout the UK HE sector and so it is hoped that they will assist in creating positive momentum for further change.

Professional practice institutes and other accreditation bodies have an extremely valuable role to play in embedding sustainability into a wide range of HE curricula. By applying requirements to teach sustainability into accreditation processes and assessment systems these bodies can, more effectively than many other methods, enforce change in curriculum to prepare students with the skills and knowledge that graduates in their fields will need. The Royal Institute of Chartered Surveyors (RICS) and the Engineering Council's UK Standard for Professional Engineering Competence (UK-SPEC) are just two of the bodies which require sustainability to be a part of the curriculum in order for a course to carry their accreditation. For business schools the Academy for Business in Society (EABIS) is a global network of leading business schools, companies and thought leadership institutions, committed to mainstreaming sustainable business enterprise in business research, policy research, management education, executive learning and development. Membership requires that a business school demonstrate its commitment to

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

sustainability before the resources of the global network are made available to the staff and students of the school.

One particular case study showing where a national initiative has had an immediate and profoundly beneficial impact on KU students through their curriculum has been that of the Isle of Man TT (tourist trophy) Zero race "for motorcycles (two wheeled) to be powered without the use of carbon based fuels and have zero toxic/noxious emissions." (TT Zero, 2010. p. 27). Since the inaugural race in 2010 students in the School of Mechanical and Automotive Engineering have designed and entered an electrically powered motorbike into this competition. The bike was placed 5th in 2010, 3rd in 2011, and 4th in 2013 (with technical issues meaning that the bike did not finish the course in 2012). This opportunity for Kingston students to design a vehicle using cutting edge technology to take part in an internationally recognised race has taught them sustainable design skills as well as the additional invaluable experience of the industry enhancing their employability. It has also encouraged them to think more widely about issues of sustainable transport and personal mobility and design-related wider issues such as battery disposal or opportunities for re-use (Taylor, 2013; King, 2007).

Regional Issues

Organisations and collaborations at a regional level also play a key role in the development of sustainability inclusion in HE curricula. At a London level one such organisation is the London Regional Centre for Expertise (RCE) in ESD, one of a series of such centres set up in response to a call from the United Nations University (UNU) to work towards the aims of the UN DESD. This network of institutions facilitates the sharing of expertise across London by holding annual conferences and sending representatives to the UNU RCE international conferences so that knowledge can also be spread at that scale.

Regional political boundaries also provide opportunities for both curriculum development and campus greening. The London Mayor's Low Carbon Prize competition has run in both 2102 and 2013 and is now set to be an annual event in the capital's HEIs' calendars. With Mayoral backing ensuring a high level of publicity and attracting corporate sponsorship of a development fund, this competition to find ideas from London's students to lower carbon emissions in the UK's capital is set to continue to capture students' imaginations. The winning idea (or ideas) receive(s) a share of the £20,000 development fund and support to take their low carbon idea to market and in 2012 shortlisted applicants could also apply for internships with the sponsoring company, Siemens. Moving into its third year this competition will form a recurring curriculum coursework opportunity with real world implications, as well as the possibility of students creating a business out of their idea if they are lucky enough to win. In 2013 an event for academics interested in the Prize was hosted by London City Hall providing a forum for collaborations and networking that is likely to be built on in subsequent years.

CURRENT CHALLENGES FACING THE ORGANISATION

Town and Gown Together: Shared Sustainability Learning

The relationship between a university and its surrounding community is often a tenuous one. The university is frequently viewed as an inaccessible institution that is more concerned about constructing new buildings, expanding its student intake and pre-occupied with its own, sometimes seemingly obscure,

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

research. Fortunately this perception is beginning to change as increasingly our institutions are becoming more engaged in their communities, through volunteering schemes and the provision of university facilities for local events. But is this enough? Recent changes to fee structures in the UK have meant that many students now look to study locally and live at home to reduce their outgoings, increasing the necessity for universities to forge quality community links to attract students and stay competitive in financially uncertain times.

While some universities have been engaged with community-level activities for decades, the depth of engagement and true two-way learning has been limited. Often temporary and superficial, these relationships frequently convey the belief that communities benefit more from the interactions than the institution. If they are to be successful, universities must transcend their often paternalistic role by developing synergistic partnerships in which full involvement of the community is ensured and collaborative learning processes are the norm. Social issues can only be addressed through the collective and innovative efforts of multiple stakeholders, a need which will only increase as we face up to problems such as increasing social isolation, peak oil and climate change. Two examples of community-linked education developed at Kingston are introduced here.

A first year module entitled 'Sustainability in Practice' ensures student engagement with community groups who are implementing sustainability principles in the local environment. Students are taken out of the classroom to visit sites such as Kingston Permaculture Reserve at Knollmead, a 20 year old permaculture forest garden. They get to hear how the community group went about creating such a space and the challenges they have to overcome; they learn permaculture principles and then put them into practice by getting involved practically onsite. The impact of such firsthand experiences should not be underestimated. By redefining where learning can take place and with whom, we break down not only the university/community barrier but also the professional/personal artificial barrier universities indirectly advocate. All aspects of sustainability problems and our selves are interrelated. Practice is not undertaken with one part and personal life another and students are exposed to this through offsite, community learning opportunities.

To date Kingston has run these site visits with students from a mix of academic courses and year groups simultaneously, mainly with sustainable development and design students, facilitating interdisciplinary peer-to-peer learning as well as the benefits of learning with community experts. As we tend to view things not as they truly are but in the context of our own personal preconceived notions and prejudices - the more viewpoints and interactions we can expose our students to, the more we can help develop reflective learners ready to deal with 21st century challenges. As one student put it "It was the first time in my three years at the university that someone had talked about the big picture of our environmental challenges; the whole experience enabled me to start to join up the dots." (Rachel Burgess, Sustainable Development student, 2011).

Community members can have a holistic joined-up perspective that breaks down academic silos. Academics are selected, on the whole, to focus on generating original specialised knowledge. This is part of what students need, but more than this they need orientation and the opportunity to gain a broad perspective in preparation for life in changing times. There is great value in exposing students to people whose thoughts are not boxed in by conventional roles that belong to a given time and place such as the framing of particular academic disciplines.

Students appreciate the experience too. The local group often finds that students return in their own time to continue their learning from the community.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

We've enjoyed the visits of students to Knollmead in recent years. They have a ready understanding of what we're trying to do and why - they can see the value of proactive community responses, and are curious about the approaches we're taking. We benefit by getting good questions, and the stimulus to organise our thoughts. We also benefit, in some cases, by recruiting volunteers who seek to contribute to active local solutions to sustainability challenges (John Fellowes, Knollmead Permaculture Group, 2013)

Thus the whole community, in its widest sense benefits and genuine shared learning can be fostered through such experiences.

Another innovative example of such work comes from KU and St. George's, University of London. 'Heritage2Health' (H2H) is a coordinated approach to shared learning and understanding between health, social care, the creative industries, and the heritage and countryside sectors. It seeks to bring these rich and diverse sectors together to develop shared solutions to empowering and improving wellbeing and participation of vulnerable groups. Established in 2005, H2H supports access to heritage sites for people with any disability or health issue, including mental health or learning disability, as well as carers and people who identify themselves as socially isolated, by the facilitation of challenge days at heritage sites (Nash & Aitchinson, 2009).

This unique and informal volunteering programme sees stakeholders of all ages and abilities, (social care, design and arts students, with community members and heritage professionals) come together to plan and host challenge events at local heritage sites. The challenge events are devised solely by participants and can vary from physical challenges (such as walking long distances or over previously perceived difficult terrain), to creative (such as using art or drama to explore and connect to historic sites) or intellectual challenges (such as fact finding missions). All participants undergo a social and emotional challenge as they learn to engage with new people in unfamiliar surroundings. And just like the 'Sustainability in Practice' trips off campus, the experience dissolves traditional barriers to learning and boundaries between people, encouraging participants to question pre-conceived notions of roles, identities, limitations and disabilities. By removing students from their normal clinical environment and showing that everyone has something to learn and teach they are able to transcend professional restrictions and broaden their perspective.

H2H challenge days are real shared learning journeys. The act of working in small teams, as equal partners through planning and delivery, ensures no one person is seen as teacher and supports the development of a shared identity, communal purpose, and facilitates social bonding as well as establishing trust; boosting individual confidence, well-being and sense of self-worth, and creating social capital locally. The events also offer a very rare cross-generational learning experience for students and an improved understanding for the heritage sector of visitor needs. The emphases on autonomy, potential, mutual respect and co-operation are not only integral to community participation approaches for health care professionals (NICE, 2008) but vital if we are to develop professionals able to co-create sustainable, inclusive communities.

Inter-professional learning is also vital to achieve this end and one that H2H does particularly well. Students from a range of disciplines and from their first year of professional training are encouraged to participate, ensuring inter-professional learning is experienced at an early stage and seen as a professional norm. It facilitates students to do far more than understand other professional roles. By working according to the principles of ignoring traditional identities and encouraging full participation, H2H helps in "generating genuine interdependence and allowing equal contribution by all group members"

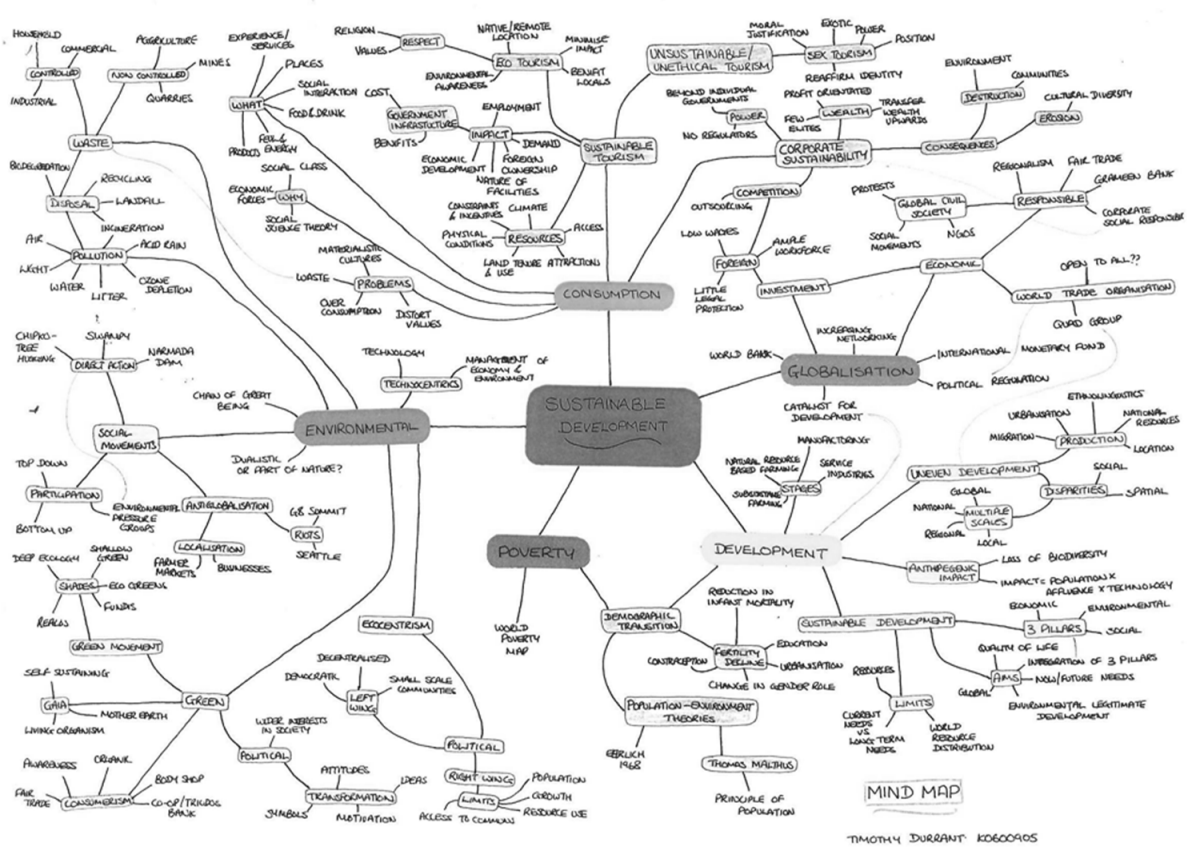
EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

(O'Halloran et al., 2006, p. 18), which can act to equalise perceived differences in professional status and develop well-rounded professionals, who are able to work collaboratively.

Such a rich and innovative scheme has the potential to be duplicated elsewhere, supporting the accumulation of clinical hours for student nurses, and enriching voluntary opportunities within the heritage sector, by the establishment of specific H2H buddy volunteers. There is scope too to widen the opportunity of engagement to other subject areas such as film students to document challenge days. A scheme like this gives hope that a community-led curriculum is not only desirable but possible for mainstream adoption. By exploring opportunities for collaborative learning with our local communities it is hoped that we can challenge traditional beliefs in the hierarchy of knowledge; move away from the adopted instrumental approach to HE and expand our notion of quality to capture HEs potential transformational role for society.

ESD Within the Formal Curriculum

Within the formal university curriculum a diversity of approaches has been applied across a wide range of disciplines. An emergent theme is 'real world sustainability' moving beyond the theoretical debates to application. Courses ranging from accountancy, law and business through, environmental sciences and geography to engineering, design and built environmental subjects such as architecture, planning and surveying have all promoted active sustainability learning. Skills-linked approaches have been used with students at all levels. Sustainability professionals need to be able to analyse and interpret new situations within a SD framework. To achieve this they need not only good scientific understanding and analytical skills but they must also be perceptive listeners, close observers and excellent communicators. They must be able to engage people in the process of change; and able to debate, challenge and frame new policies. Sustainability professionals need multidisciplinary backgrounds to equip them to search for, interpret and link disparate relevant information. Beyond that they must win the 'hearts and minds' debate. These are major challenges not just for students to acquire these attributes but for staff too in terms of designing curricula and learning and assessment tasks which promote these skills. As already noted, inter- or multi-disciplinarity, especially mixing subjects traditionally taught by different faculties is not always popular with faculty managers. Their concerns lie with cost efficiencies and operational economies. Protecting particular faculty positions and incomes may bring conflicting priorities and loyalties. Space management restrictions can also militate against more innovative teaching and learning activities such as role-playing and informal group work approaches which are particularly beneficial to sustainability learning (Wainwright, 2013). 'Bums on seats', maximising recruitment and thereby income, can seem key and thus selling the story externally is also important. As discussed above, externally sustainability education is often poorly understood and may not be highly valued. However, our experience suggests that with careful design, active, multidisciplinary learning that fosters sustainability understanding can be securely embedded in curricula even where it is not the main programme objective.



Pedagogic approaches are key. The challenge is to find teaching and learning strategies that are active and participatory; that can be used in diverse main discipline frameworks and which challenge students to think beyond their immediate main discipline focus. One such example was piloted in a first year undergraduate module in Human Geography, which is taken by students across the Earth and Environmental Sciences and by some Social Science students. Classes are large, with up to 200 students making lectures a main vehicle for dissemination of core material. Support activities and assessments, however, are designed to generate enthusiasm and individual initiative. In one assessment example each

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

student is asked to produce a 'mind map' of SD for which she or he draws on core curriculum material and supplementary personal research on development studies, environmentalism, resource management, cultural diversity and so forth which is introduced via the main lecture programme and supplemented by tutorial discussions of recommended reading. The task is individual and innovative; it is about student's personal perception; it requires the student to organise his or her thoughts in a way not previously expected. It also opens students' minds to the extended and tangled web of knowledge and skills needed to support SD initiatives worldwide (Figure 5). Above all it engages them in a way no essay would ever achieve. The task is fun and the emerging diversity of 'sustainability maps' highlights clearly that no one solution fits a given context, let alone has universal applicability.

Similarly fieldwork and practical developments supporting learning for ESD at local, national and in international settings demonstrate the importance of context; cultural, environmental and social, in influencing pathways to equitable and sustainable futures. Too often field studies are so focused on a particular task in hand, *e.g.* landscape evolution or understanding markets, that wider cultural matters essential to understanding developmental behaviour are overlooked. At Kingston in final year degree fieldwork Environmental and Geographical students are challenged to integrate this picture through a graduated series of tasks ranging from pre-work researching the area to be visited; to on-site visits; to reflective post-fieldwork analysis. Before visiting, students research their destination working in small

Figure 5. An example student sustainability mind map

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

groups focusing on key themes such as political context, historical change, religion and culture, agriculture, water resources, climate, mineral resources etc. They prepare a background report and present their key findings in an opening seminar on arrival when they also receive local feedback. Then through visits and informal interviews and personal research students build a picture of the current situation. Commonly this changes their pre-visit perceptions of the destination. Their understanding of other peoples' constraints and realities is extended and they gain a deep insight into the problems of SD. The importance of international travel and exchanges for informing policy formulation becomes clear. They then write a reflective report on SD priorities for the immediate, 5 year and 10 year futures of the region explored. The learning curve is steep; the enormity of real world complexities becomes evident; the practical constraints of cultural background and politics as they interweave with historical contexts, contemporary economics and geographic opportunities, become apparent. As one perceptive environmental science student commented in 2010, "poor governance is the key factor restricting this country's development". In other words, it is not the abundance or lack of resources that is the problem but the need for citizen involvement and an engaged government to create an equitable and secure society which is key. In another variant of this programme students produce a video 'news' report on their destination similarly identifying and prioritising development priorities supported through illustrative diary material and interviews. Many students cite this as the highlight of their degree experience.

Of course students cannot always be travelling to learn; it is too time consuming, expensive, difficult for those with family responsibilities, and some might argue the carbon footprint is too large. Role-playing can also contribute to in-depth multidisciplinary learning and in the environmental curricula at Kingston it is used at all levels from initial undergraduate to postgraduate taught masters students. While for year one students, roles may be explained through briefing notes, final year and masters students are challenged to independently research their roles and then write a fully referenced position paper supporting their role perspective. A staff member chairs the 'public enquiry' game and a colleague acts as a note taker and independent second assessor. In the role-play debate each student presents his or her role's assumed viewpoint (based on the student's personal research) and together they debate the issue. Initial assessment relates to both the position paper and the succinctness of argument in the debate. For some courses, this activity has been taken a stage further. Where classes are larger several role-play games are devised. Each student participates in one game, as described, but each also observes all other games and then, for one of their choice, writes a judicial review paper. Thus in a large group each student participates in a game as a role-player and also reviews a different game as a reflective 'judge'. Deep learning is promoted in terms of the written position paper and judicial review or stake holder analysis; robust debating skills are also demanded such that the overall exercise thereby tests a wide range of pertinent sustainability professional abilities. Preparatory workshops encourage peer-to-peer interaction and debate with staff, and the role-play activities encourage and reward independent research and enable engagement with very current topics which need insight and resolution. Topics have included: energy security in the UK; food security; responses to sea level change in a small island developing state; and land-use development conflicts such as a national park or mineral extraction and rights of indigenous peoples. This approach is readily transferable between disciplines and study topics; works well with multidisciplinary as well as single discipline groups; and extends and deepens student understanding of SD in a wide range of contexts.

The common factor in these examples is active participatory learning which has fostered interdisciplinary understanding and engagement and in the course of Kingston's university-wide recent curriculum redesign from 15 credit modules to 30 credit modules these pedagogic developments have been retained.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

They are cherished by both students and staff since they are fun, active ways to learn and teach. They stimulate students to become more engaged with their learning and thereby they often achieve more highly; they promote a staff-student dialogue that also encourages staff development. Furthermore the presence, since 2010, of a dedicated Sustainability Hub has raised campus-wide awareness of the need for this material and sustainability learning and secured its acknowledgement in the new 'Led by Learning' university framework (Kingston University, 2012). The Hub presence ensures a watchful eye on progress across the faculties; and provides an extra resource to assist with change and development.

Real world learning activity with external employers has been fostered in a range of degree programmes; it brings several added advantages to all participants. Historically, many degree programmes have routinely included a work placement year. Furthermore, it is commonly observed that participants return from this work experience better-focused and more self-disciplined such that when both three year and optional four year with sandwich versions of the same formal degree curriculum are available there is circumstantial evidence (informally from course directors and placement tutors) that students opting for the placement experience achieve more highly in their final year programme than their second year performance would predict. A variety of factors though can make placement years, when optional, seem unattractive to undergraduates. These include perceived unjust fee payments, particularly in the new, UK, full cost structures; unwillingness to relocate to take up a placement year; impracticability of relocation in the context of family commitments; separation from friendship groups; the preference for graduating as soon as possible given a difficult employment market; and the limited availability of full year paid placement opportunities. These factors prompted some innovative re-thinking among academic staff to offer the benefits of real world learning experience to undergraduates and also postgraduates who had selected programmes that they expected would enhance their sustainability-related employability or career progression. The following discussion highlights two short-term work experience links specifically designed, in conjunction with host employers, to enhance sustainability learning *viz.,* Sustainability at Work, a mini placement (originally offered as a freestanding undergraduate module now available as an embedded fieldwork alternative) and coursework linked sustainability auditing of local businesses primarily available to postgraduate students.

The module, Sustainability at Work was originally designed for the degree in Sustainable Development launched in 2005. It is a final year module that could be taken in various ways alongside the main formal curriculum; it does not require the student to take a year out from formal study on placement; nor to relocate. The work is with local employers who volunteer their time to supervise the student and in return receive a research report on an issue of concern for the success of their business. Essential elements for the students include research and evaluation of the host employer business in terms of its sustainability policy in relation to its sector and to overarching UK government, EU or global policy, as applicable; work on a small research project that the employer needs in order to develop the sustainability credentials of the business; and work shadowing the sustainability professional, or other employee, charged with overseeing environmental and sustainability policy. Students are supported by university-based tutorials; by sharing experience through seminar and poster presentations; and by a designated mentor in the work place. The work sits alongside the students other curriculum activities. The scheme has proved particularly successful with students and employers; it has even led to initial short term paid employment on graduation. Participant numbers were initially low but have increased more than five-fold since the module was launched. The key limitation is convincing potential employers of the scheme's rewards in relation to the time they must contribute initially to induct the student into their business.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Student feedback from the inaugural edition of the module in 2009 included, "I also wanted to give some feedback about the Sustainability at Work module. I enjoyed it so much. I can say that it was the best module of all." The staff contact for the student working in the estates department (2009) said, "During her time with us, [.....] showed a high level of initiative and efficient work ethic giving strong support especially helping to run the University's new Eco-champions scheme".

The initial pioneering editions of this module were facilitated by Sustainability Hub staff taking the burden from faculty colleagues and thereby also overcoming the inevitable faculty managerial and potential employer resistance (perceived hassle) to such a scheme. They beneficially could search out employer collaborations building on links established through the town-gown engagement activities. The module makes an alternative vehicle for application of sustainability skills and gaining new insights for those who cannot undertake extended overseas travel. That the programme has now been wholly taken over by faculty staff and incorporated into the routine curriculum testifies, not just to its success with students and their learning, but also to the beneficial presence of a core of Sustainability Hub staff who could undertake the initial pump-priming activities.

Similarly work initially pioneered by sustainability staff working in collaboration with the RBK's Environmental and Sustainability department and the University Volunteer Service has now been incorporated into faculty-led teaching of environmental undergraduate and taught postgraduate masters students. Previously in this chapter we have outlined how formal curriculum activities in environmental management systems can be linked with small campus development projects. This work developed from a major series of innovative links initially involving students as volunteers but is now incorporated in the routine undergraduate and postgraduate curricula. These award winning developments attracted support funding from the UK HEA to evaluate and further develop the programme (Taylor et al*.,* 2012). Positive Environment Kingston (PEK) (Corrigan, 2007) was the initial scheme jointly developed by the University's Sustainability Team, Volunteer Service and the Environmental and Sustainability department of the RBK. From the Borough's perspective the scheme aimed to improve the sustainability performance of small businesses and charities within the Borough and, through guidance on best practice, help to reduce the Borough's ecological footprint. In the original scheme volunteer students, from any academic discipline, were trained as environmental mentors for local SMEs (small and medium enterprises), small charitable organisations, schools, sports clubs, etc. to assist them in producing an Environmental Action Plan. In return for free training, volunteers mentored a partner organisation identified by the Borough as needing help. Success saw the partner business or charity produce an environmental or sustainability plan and the student volunteer was awarded a formal certificate of competence and participation. The scheme was subsequently adapted for use in the formal curriculum of undergraduate and postgraduate students working on environmental and sustainability auditing. Typically taught masters students worked with the external host employers and second year undergraduates with the in-house hosts. The work forms part of an academic module with the key assessment elements being an individual report on Environmental Impact Assessment but with the other major elements being the team audit presentation and report. Reports are made available to host employers who are invited to attend the team presentations. Indeed it is part of their responsibility to participate in this feedback session; in return they receive a free audit.

In depth analysis of academic staff, student participants and host employers shows these learning activities have generated multiple benefits.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

- *'Employers'* (the businesses, charities, etc) benefit in terms of a free audit; exposure to sustainability ideas; and a chance to contribute to curriculum development.
- *Students* benefit in terms of practical professional experience which can enhance curricula vitae (CVs) and improve employability and also through the contacts made to develop further work-experience opportunities (and even immediate employment).
- *University staff* benefit in that employer links inform curriculum development and create contacts for research and consultancy opportunities (Taylor et al*.,* 2012).

Wider benefits have also accrued in terms of town-gown goodwill; in-house capacity building for sustainability understanding; and the 'feel good factor' of making a difference. In reporting similar business-linked learning with students at Southampton University, Kemp (2008) also noted these wider benefits. Luna and Maxey (2013) similarly found active participatory learning emerged as a key characteristic of sustainability education during their research linked to development of the Green Academy.

Students in the Kingston 2010-11 cohorts were asked to give questionnaire and group discussion feedback on the scheme. Staff also evaluated their performance in terms of achievement in the team audits, report and presentation and in the related individual essay-style work undertaken. Many students feared they were disadvantaged by weaker group members but detailed analysis of both undergraduate and postgraduate results did not support this point. In practice the highest scoring element for both cohorts was the group oral presentation. The motivational aspect of the real world learning was especially evident with 90% postgraduates saying they would elect to take the module if it were optional rather than an obligatory core and 74% undergraduates rating the module as one of their most preferred. For this group, modules including fieldwork also rated highly reinforcing the view that students like and respond well to active participatory learning and for most undergraduates their greater enthusiasm for such modules was mirrored by higher achievement (Taylor et al., 2012).

Students were also very aware of the wider skills benefits the audit work required (see Table 2). They cited planning and patience as significant skills learned alongside diplomacy and time management; they liked the chance to work in real world conditions and learn about putting policy into practice; and they enjoyed feeding back their opinions to their host employers.

SOLUTIONS AND RECOMMENDATIONS

Reflections on Sustainability Learning

At the turn of the new millennium Kofi Annan, UN secretary general, in an address delivered during a 2001 visit to Bangladesh, suggested that, **"**Our biggest challenge in this new century is to take an idea that seems abstract - sustainable development - and turn it... into a reality for all the world's people."

A decade earlier university leaders had recognised the important role of education and universities in achieving sustainable futures saying, "Universities educate most of the people who develop and manage society's institutions. For this reason universities bear profound responsibilities to increase the awareness, knowledge, technologies, and tools to create an environmentally sustainable future" (Association of University Leaders for a Sustainable Future, 1990).

But how are we doing? Is sustainability learning reaching all people? And beyond that are we giving new graduates the skills and practical expertise to apply sustainability principles in new and emerging

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

contexts? Have we responded and progressed; what evidence do we have; how do we measure progress in sustainability education? Sara Parkin writing the foreword to The Sustainable University: Progress and Prospects suggests we have made little progress. She points out that

Despite many decades of documenting the consequences of environmental degradation (and with most evidence supplied by universities) our civilisation has not learnt how to stop their damaging activities, nor how to plan for peaceful resilience in a time of rapid change (Parkin, in Sterling, et al., 2013, p xviii).

Parkin goes on to say that it is not nature or the environment that needs to change but us, a truth that she claims needs to dawn more widely. She identifies three core principles of human behaviour change:

- Understanding the need for change
- Acquiring the necessary knowledge and skills that make behaviour change possible
- Operating a recognition and reward system that reinforces the right behaviour

Parkin claims we are stuck somewhere between the first and second principle. The key question is whether universities are supplying the intellectual leadership to shift societal change forward and move us away from potential self-destruction and into a sustainable future. We need to give as much attention

Table 2. Sampled student feedback on their audit experiences (29/31 students responded MSc; 29/30 BSc) (Adapted from Taylor et al., 2012)

Degree route	Comment
A Postgraduates	
Sustainability, Environment and Change	You dig deep and find other things to consider
Sustainability for Built Environment Practice	Gave an opportunity to work with others who have different expertise
Sustainable Environmental Development with Management Studies	Site evaluation - interaction with workers. Gives a more clear idea about current and actual environmental management
Environmental and Earth Resources Management	The learning process and the realistic approach- also the report write up and planning
Sustainable Environmental Development with Management Studies	It's an opportunity to put in practice knowledge and experience
Environmental and Earth Resources Management	Interviews highlighted the power of verbal communication
B Undergraduates	
Environmental Science (EU direct entrant)	You start from zero and then you realise at the end how much you developed your knowledge about it
Environmental Science	Learning how to be professional, systematic planning
Sustainable Development	Experience writing questionnaires and performing interviews
Sustainable Development	The practical assessment - learning the real work of EIA and audit
Sustainable Development	Importance of being thorough and good communication skills, learning the importance of many aspects and their influence on the process - eye for detail, team cooperation, staff communication
Environmental Management	The presentations - it's sort of an exciting challenge
Environmental Studies (joint honours- BA)	Made me more aware of obstacles facing audit professionals (although many could have been alleviated and may have been created by being a student)

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

to affecting this shift as we have given to investigating the nature of the environment itself. This is central to sustainability, as distinct from environmental, education.

Researchers worldwide have identified some common barriers to moving sustainability education forward as summarised in Table 3 (*inter alia* Dawe et al., 2005, Velaquez et al., 2005; Granados Sanchez et al., 2012). Discussions at the inaugural workshops for the Green Academy (Luna & Maxey, 2013) showed that these barriers still persist. Finding a way forward remains a significant challenge.

Sterling (2013) argues that deeper problems persist and underpin the very slow progress in sustainability education which is still primarily seen as an 'interesting extra' rather than the core necessity identified by Parkin, Annan, and other influential sustainability advocates e.g. Porritt, Gore. Sterling sees two other problem areas relating to the *modus operandi* of HE. One reflects the growing need for universities to compete for students and to be measured in terms of student satisfaction and students' (and employers') perceptions of course relevance and desirable content. Universities feel the need to respond to 'customer satisfaction'. These issues have taken prominence over more idealistic values such as critical discourse, cultural enrichment, societal leadership and responsible citizenship. This situation, in turn, deters sharing (Luna & Maxey, 2013). A second key problem Sterling argues reflects the western intellectual legacy, in particular the dominance of reductionist study approaches. Issues such as those raised by Hardin's seminal work on the 'Tragedy of the Commons' (Hardin, 1968) and the duality of Arts and Science as articulated by Snow (1964) continue to militate against valuing multidisciplinary expertise. While the biggest problems facing society e.g. energy, water and food security require both scientific and socio-cultural understanding the degree programme opportunities for such education remain restricted. We continue to value more the single discipline expert in politics, law, physics and chemistry and give less esteem to those who integrate multidisciplinary understanding. Parkin (2013) is also slightly dismissive of the single dedicated sustainability module approach; Bioregional (a UK sustainability research charity) is a little critical of the dedicated degree programme (personal communication, 2010). Though these are good initiatives, the key issue is to reach everyone. This is where embedded ESD has so much to offer.

But how to monitor and measure success? This is a highly difficult challenge and one the UK academic sustainability community is keen to address. People and Planet annually publishes a UK universities 'green league' but sustainability in curricula currently gets limited reward in their evaluation system. Others have tried to enumerate ESD in the curriculum through module counts (Dawe et al., 2003; Eames, 2012) or through uptake in dissertation topics (Eames et al., 2013: Carrera et al., 2007). Counting modules and courses has limited value. Though this beneficially tells us what opportunities to learn are being offered; it does not tell us the extent of learner engagement and beyond that behaviour change whether in the limited academic sphere or more widely in subsequent career activities and lifestyle choices. Similarly

Table 3. Perceived barriers to sustainability learning in the formal curriculum (Adapted from Sterling, 2013 p.13)

Policy studies Institute et al., 2008 Report to HEFCE	**Dawe et al., 2005 Research for the UK HEA**
• Lack of interest in sustainable development • Silo or mono-disciplinary thinking and institutional organisation which militates against cross – departmental activity that is essential for education in sustainable development • Lack of incentives or priority to engage in ESD	• Curriculum too crowded, no spare space for sustainability • Perceived irrelevance of sustainability • Limited staff awareness or/and expertise • Limited institutional commitment • Limited commitment from external stakeholders • Too demanding and difficult

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

counting graduates in relevant careers in part misses the point; it is changed lifestyles and contributions in changing company behaviour and decision making, the invisible metrics, which also matter. A survey of Kingston alumni conducted as part of an as yet unpublished masters thesis (Radanovic, 2012) asked whether alumni had been able to introduce 'green'/sustainability principles into their job/workplace in any of the jobs they had previously held. The sample size was 379 alumni; 269 responded to this question. The results showed that 19% had made a change in a current or previous workplace and 37% had made a change 'to some extent'. The initiatives undertaken ranged from waste and travel improvements, to green days at a school, to procedures being put in place to ensure sustainability is considered in the design phase of construction projects. The analysis of whether alumni were 'green' or not was extended to include different 'shades of green' adapted slightly from the definitions used by Crowley (1999). Fifty nine percent of respondents could be classified as currently having a 'green job' with students who had learnt about sustainability during their course being more likely to have a 'deep green' job than those who had not (following Crowley (1999), a job was defined as deep green if its process was not polluting, if its product was environmentally friendly or if the job role contributed to sustainability or social justice). Nuances within these data do require further analysis but indicate that it is possible to measure the impact that a HE curriculum can have on graduates into their careers.

The dissertation metrics likewise do suggest some real engagement since typically topics for students' final year degree projects are self-selected. This hypothesis was investigated as part of the work done by Eames et al. (2013). The theory behind this testing assumed that where final year research project topics are chosen by the students they are likely to reflect an area of the subject matter taught during their course either that they found particularly interesting or that they wish to pursue in their future careers. By analysing keywords in dissertation titles for sustainability content it would therefore be possible to measure the effectiveness of the curriculum content in inspiring students on the topic of sustainability. Where data on self-selected titles was available this method was successful in quantifying the student take up of sustainability related projects. However our scoping study showed that often these data are not stored unless individual lecturers collect the information making year by year comparisons impossible unless systems are put in place to allow this. Similarly growth of sustainability research and funding for example the British Ecological Society's promotion of work on ecosystem services and the UK Engineering and Physical Sciences Research Council's (EPSRC) and Natural Environment Research Council (NERC) support for work on e.g. carbon capture, renewable energy, ecosystems services and poverty alleviation, all testify to awareness of the need to engage high level research in matters of SD. These major research programmes should in turn expand sustainability educational opportunities as well as producing the intended targeted benefits.

In our discussions on ESD we have included student participant feedback. It shows that problem-based learning and practical action learning engages students and triggers changed perceptions and behaviour. Emerging research also suggests this is the most appropriate vehicle for ESD, but there are difficulties. Some commonly cited barriers remain e.g. time to develop a changed approach; difficulty of application with large groups; and problems of informal learning space which often arise when small groups from within a larger class cohort need to meet.

Problem-based learning and its potential to be used more widely to facilitate education for sustainability has been the subject of a recently completed collaborative three-year project between Keele University, the University of Manchester and Staffordshire University funded by the HEA's National Teaching Fellowship Scheme (Tomkinson & Hutt, 2012). Traditional problem-based learning requires small groups of students to be facilitated in person, usually twice a week, to identify the learning they

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

will have to undertake in order to solve or at least begin to address the problem presented (Barrows, 1996). The hybrid problem-based learning approaches used in the case study examples such as those presented by Tomkinson and Hutt (2012), Tomkinson (2011) and Dobson and Tomkinson (2013), instead have trialled the use of online networks for groups to discuss ideas and use outcome-based rather than process-based assessments to reduce face-to-face facilitation time and remove the potential complication caused by needing to find spaces to meet. The University of Manchester has in this way managed to run a module with hybrid problem-based learning for 100 students (Dobson & Tomkinson, 2013). By its nature problem-based learning is ideally suited to teaching sustainability as the skills that we would wish our students to leave HE with focus around the need for them to be able to assess situations and find sustainable solutions to the problems they may face in their future careers and wider lives. Problem-based learning focuses on students solving 'wicked' problems (Rittel & Webber, 1973) which have no clear end, no definitive formulation, have consequences to every solution but no accepted right or wrong answer, and have causes with no unique explanation. These are exactly the types of situations our current students will have to face when they graduate and learning to solve them in a sustainable way adds to the value of this pedagogy.

Facilitation is, however, still beneficial for pump-priming new initiatives. The Kingston work-based audits were greatly aided by start-up support from a Sustainability Team member. Contacts with host employers built on previous Sustainability Hub and SGS initiatives such as town-gown debates, and Fairtrade collaborations. This saved the academic staff member involved much time and consolidated employer contributions and engagement into the learning process. Additional work during the HEA-supported period allowed employment of an assistant to monitor the whole process gaining participant feedback and establishing guidelines and expectations for all parties; students, university academics and host employers. Devising a simple tool kit for participation smoothed the way for future collaborations and emphasised the importance of each party's role. For example research showed that employers were reluctant to give time to attend the students' assessed feedback seminars thereby missing out on engaging with their fellow employers in a shared exploration of their business perspectives on sustainability. It also revealed that part of this reluctance was nervousness, fear of being exposed as ignorant of sustainability requirements and best practice and not just among their peers. They assumed university staff were 'experts' and would be judgemental whereas in practice they were very much co-learners. Shared learning opportunities were thereby being lost and since the sustainability journey is largely new and innovative these sharing opportunities are important. The extra conversations possible during the HEA-supported phase helped to overcome these barriers and to identify a more suitable time and location (in the town centre) for host employer attendance.

Shared learning is a major potential benefit of collaborative approaches. New ideas will emerge when academic staff themselves engage not as leaders but as co-learners with their students and other participants. This point was articulated in the H2H case study. Non-hierarchical teaching often partners problem-based learning and emerges as a key strategy for ESD. Given appropriate physical learning spaces, as outlined by Wainright (2013) reporting on the new medical building at Limerick, student-led learning though discussion with tutors as facilitators can prove effective for all. The C-SCAIPE[3] informal learning space at Kingston very much reinforces this view.

The development of a Green Academy (GA) in the UK is a new initiative to create a support network for universities seeking to make sustainability more central to their operations and curricula. Participating universities and colleges must assemble, as a minimum requirement, a core team including a member of their executive, an academic champion, and a student representative with additional members (up to five

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

or six team total) drawn from estates, finance, human resources, the careers office, or staff from other support services, as most appropriate to the institution. Thus the teams represent the whole university or college community. By working together to prepare for, and subsequently participate in, a residential workshop they start to overcome the within-institutional barriers to sustainability and to develop shared a vision for sustainability and ESD at their institution and to devise and prioritise implementation programmes. Meeting with teams from other universities at the residential workshop further enriches the process and the teams are supported by 'critical friends', drawn from universities already engaging with this sustainability journey. This support between participating institutions, and also with critical friends, continues after the focal workshop. In depth analysis and feedback on the inaugural, 2011, GA process has revealed the many positive benefits felt by participants, and a few snags (Luna & Maxey, 2013; Kemp et al., 2012). In particular, the inter-institutional support helps to overcome barriers and sharing ideas accelerates the introduction and spread of ESD as well as further campus operational improvements. Importantly it publicly integrates and consolidates top-level engagement which helps to safeguard ESD in periods of institutional structural change.

However, it is widely acknowledged that the spread of high quality ESD needs to accelerate more rapidly than the current GA structure allows. Eight Higher Education Institution (HEI) teams participated in the first GA; adding another eight annually would reach just 40 of the UK's 165 HEIs in 5 years (Luna and Maxey, 2013). A more rapid penetration of these ideas throughout the sector is needed. Possibilities include running two academies annually and/or extending the pool of critical friends such that regional academies could supplement national events. This would, though, imply major co-operative links between local HEIs which often find themselves competing for students and in some cases badge their distinctiveness to being 'more green' than their local rivals. There remain some very real barriers to overcome.

Nevertheless the development of the GA marks a significant step forward and suggests a framework and mutually beneficial process for potential change away from the competitive protection of innovations to the benefits of sharing. The network for bottom-up engagement and co-developments between academics, students and support staff endorsed by senior management that a GA approach could potentially generate may in the longer term generate more enduring grass roots developments than top-down directives. Certainly it will beneficially complement them. Bottom-up engagement and regional sustainability networks are more likely to win 'hearts and minds' and thus more likely to endure even when an institution's other main foci change; thus they may be (and have been so far at KU) the better vehicle for accelerating ESD and associated sustainability improvements in institutional operations.

As Sara Parkin also observed:

Ultimately (though) the test of success has to be how a university (or any other institution) contributes to building natural human and social capital, how ubiquitous that contribution is across the institution (meaning not just the energy managers job or the odd module) and how seriously the university uses its power to influence others. (Parkin, in Sterling et al., 2013, p xix).

ENDNOTES

1. Green Gown Awards are a national scheme in the UK, though since 2012 with an international extension. It is administered by the Environmental Association of University and Colleges (EAUC) in collaboration with diverse partners and sponsors representing sustainability professionals and higher education. For further information see http://eauc.org.uk/green_gown_awards
2. The Dorich House Group of Universities is a collaboration established through Kingston-led discussions. It takes its name from an historic building bequeathed to Kingston by the artist and sculptor, Dora Gordine and her husband Richard Hare. Dorich House is now used by the university as a small conference facility and exhibitions space and also houses a small museum collection.
3. C-SCAIPE is the Centre for Sustainable Communities Achieved though Integrated Professional Education. It was established as a Centre of Excellence for Teaching and Learning (CETL), one of a series of subject centres funded by the Higher Education Funding Council for England (HEFCE) under a five year programme from 2005. C-SCAIPE now continues as a research centre but the learning space and associated debating chamber are a popular university resource for informal student study and the area is also commonly used for town-gown events and seminars, with priority use given to sustainability-themed activities.

This research was previously published in the Handbook of Research on Pedagogical Innovations for Sustainable Development edited by Ken D. Thomas and Helen E. Muga, pages 641-671, copyright year 2014 by Information Science Reference (an imprint of IGI Global).

Chapter 24
'Net' Social Change:
Grassroots Empowerment for Sustainable Development

Subas P. Dhakal
Curtin University, Australia

ABSTRACT

The notion of empowerment broadly refers to the ability of actors to fulfil their missions. However, assessing Information and Communication Technology (ICT) specific contributions to this remains an exigent task in the context of grassroots organizations. The objective of this chapter is to analyse the differences in levels of empowerment between ICT adopters and non-adopters Grassroots Environmental Organizations (GEOs) in Perth, Western Australia. The chapter draws on organizational empowerment theory and proposes an evaluation framework to assess ICT-mediated empowerment for sustainable development. Utilizing a survey of GEOs and interviews with leaders, the chapter unravels the contributions of ICTs in enabling these grassroots actors. The chapter ends with the discussion on the need for overcoming digital divide and recommends strategic support for GEOs that are either not able to or not willing to keep up with the emerging trend of ICTs.

INTRODUCTION

Grassroots sustainable development initiatives have been considered to be more effective at the regional scale because regions are large enough for federal and state authorities to deal with, yet small enough for community based actors and local governments to participate in the decision-making process (Dore & Woodhill, 1999; Lawrence, 2005). The basic premise of the notion of sustainable development is that centralized and fragmented emphasis on economic-growth at the expense of social and/or environmental costs is eventually detrimental to the overall societal well-being. The very essence of this notion has inspired various grassroots actors to mobilize themselves to bring about social change to reverse the trend of escalating environmental degradation around the world. For instance, Australia has been dependent on thousands of Grassroots Environmental Organizations (GEOs) across the country in order to safeguard local environment. This is done through activities that range from conserving threatened

biodiversity to restoring degraded habitats in the regions like Perth, capital city of Western Australia, where two-thirds of native ecosystems have been lost in the past 150 years (Davis & Froend, 1999; Stenhouse, 2004; Dhakal, 2014a).

On the one hand, GEOs operate in challenging circumstances because of the lack of a) availability or access to adequate funds and volunteers, b) capacity to forge partnerships with other actors, and c) certainty over long-term viability to accomplish organizational missions (Simpson & Clifton, 2010; Tennent & Lockie, 2013; Dhakal, 2015). On the other hand, despite being under-resourced and volunteer-dependent, GEOs are often considered reliable partners by governmental and non-governmental organizations in terms of bringing about social change for sustainable development (Smith, 2000; Anheier, 2005). Consequently, the role that Information and Communications Technologies (ICTs), for example, the Internet and Internet based tools play is important in enabling GEOs' driven environmental stewardship initiatives. In recent years, this role has been increasingly acknowledged around the world (Kutner, 2000; Burt & Taylor, 2003; Horton, 2004; Hawken, 2007; Dhakal, 2011). It is in this context that an important question of 'To what extent do ICTs enable grassroots actors to become significantly empowered?' is critical. This question forms the basis of discussion in this chapter.

The theoretical conjecture that links ICT-mediated empowerment and GEOs proposes that empowered grassroots actors are better equipped to undertake sustainable development initiatives. However, the ways to ascertain empowerment levels, be it those mediated by ICTs or not, remain methodologically difficult. This complexity is partly brought about by the multiple descriptions and dimensions associated with the notion of empowerment. The possibility and practicability of evaluating empowerment may thus become confusing or even controversial. It thus goes without saying that without reliable measurement attempts, the properties and the significance of empowerment will remain obscure. Rappaport (1984) had argued that:

We must not reify empowerment in the measurement of the end product, or the process, or in a particular intervention or means by which it comes about. That is, the way it is measured is not the thing in itself. Nevertheless, each measurement, intervention, and description in a particular context adds to our understanding of the construct (Rappaport, 1984, p. 4).

In line with this debate on the reification of empowerment this chapter demonstrates that an attempt to assess empowerment can unravel useful insights. Such an assessment can also help to ascertain if indeed empowered GEOs are in a better position to attain sustainable development objectives and can inform policy interventions. The chapter begins by adopting working definitions of relevant key terms before discussing the main thesis of this chapter as well as the challenges that may be encountered in the process of measuring empowerment levels of GEOs.

GRASSROOTS ENVIRONMENTAL ORGANIZATIONS (GEOs)

GEOs are not-for-profit and non-governmental organizations. By nature, they are identified as a part of the "charities", "civil society", "community sector", "voluntary sector" or "third sector" (Lyons, 2001). Based on the description of Australian Taxation Office [ATO], formal or informal organizations that operate at the grassroots to care for the environment (ATO, 2000, p. 49) are referred to as GEOs for the purpose of this chapter. GEOs across the country have been at the forefront of social change for

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

sustainable development since the early 1990s. As a result, landmark sustainable development policies and funding mechanisms such as the National Landcare Program and the Natural Heritage Trust have extensively relied on GEOs in order to implement on-ground environmental initiatives (Dhakal, 2014a). The role of GEOs is often facilitated by the notion and practice of voluntarism. Essentially, community members volunteer their resources like time and skills towards resolving sustainable development challenges (Dhakal, 2015). These community efforts have helped GEOs to make significant contributions particularly in the Perth region where the remnant nature is continually under threat from unsustainable development. However, like many other grassroots organizations, GEOs generally operate in difficult circumstances where they have to compete for limited availability of essential resources such as funding and volunteers (Dhakal, 2012). This is the reason why Head (2009) argued that sustainable development strategies in Australia over the years have not only tapped into the interests of GEOs but also shifted responsibilities to them without providing adequate support to enable their capabilities. It is argued in this chapter that one of the strategies that can capacitate GEOs is the usage of the ICTs.

INFORMATION AND COMMUNICATIONS TECHNOLOGIES (ICTs) AND THE DIGITAL DIVIDE

In its strategy to promote digital literacy in Asia and the Pacific, the United Nations Educational, Scientific and Cultural Organization [UNESCO] described ICTs as:

Any device and application used to access, manage, integrate, evaluate, create and communicate information and knowledge, including but not limited to radio, television, cellular phones, computer hardware and software, network hardware and software, satellite systems, peripherals, connections to the Internet, etc. Therefore, digital technologies are included in this definition together with services and applications used for communication and information processing functions associated with these devices (UNESCO, 2008, p. 11).

This chapter identifies various types of ICTs in enhancing the capabilities of GEOs to attain sustainable development objectives. A specific preference is given to the use of the Internet as well as Internet based tools such as email, website, and social media for the purpose of analysing strategies and levels of GEOs' empowerment. Nonetheless, it also recognizes that the trend of ICT uptake amongst smaller grassroots organizations has been generally slow because of barriers such as costs, skills and access (Roessler, 2004). These disparities in access to and the uptake of ICT are often referred to as the digital divide. This type of divide is a symbol of perceived disadvantage of actors that either are unable or do not choose to make use of ICTs (Cullen, 2001). While the evolution of the term digital divide has been discussed at length elsewhere (Servon, 2002; Gunkel, 2003; van Dijk, 2003), Warschauer (2003) suggests that the notion is not simply about a binary divide of 'haves' versus 'have nots', where a single overriding factor is seen to determine or bridge such a divide. He argues that ICTs do not exist as external variables to be injected from the outside in order to bring about social change; rather they are intertwined in a complex manner in organizational systems and processes within a society. Thus, ICTs should be understood as tools that can foster empowerment if used strategically to bring about social change necessary for the achievement of sustainable development. Several studies around the world have highlighted the benefits of ICT uptake for grassroots actors (Burt & Taylor, 2001; Burt & Taylor, 2003,

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

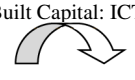
Weare et al., 2005; Hackler & Saxton, 2007; Kavanaugh et al., 2007; Dhakal, 2009). It is, therefore, imperative for the purpose of this chapter to unravel factors that cause the digital divide in the context of GEOs' sustainable development aspirations.

'Net' Social Change and GEOs' Responses

ICT for social change continues to be a theme for debates around sustainable development. Millions of GEOs across the globe, for example, are reported to have made significant impact through the use of ICTs (Hawken, 2007). However, the adoption rate and use differ from country to country. In Australia, ICT uptake dates back to 1990 and the GEOs were one of the first third sector organizations to experiment with the Internet uptake (Dhakal, 2011). The Australian National Landcare Program worked together with the University of Melbourne to address a gap in GEOs' communication channels in the early 1990s (Hawkins et al., 1992). Similarly, another electronic network called 'CoastNet' was developed by the Australian Department of Environment, Sports and Territories (DEST) in the mid-1990s aimed at enabling GEOs to exchange information with other organizations involved in the planning and management of coastal environment (Dhakal, 2010a). While both networks were aimed at empowering GEOs by providing Internet-based forums, they ultimately failed because of barriers such as cost, time and the workload involved in accessing online services during that era (Minter, 1995; Curnow, 1996). Since then, only few studies have examined the uptake of ICTs amongst grassroots organizations in general (Denison et al., 2003; Barraket, 2005, Burgess & Bingley, 2007; Dhakal, 2011). While the information on the trend of ICT adoption amongst grassroots organizations in Australia has been relatively unknown (Denison & Johanson, 2007), the evaluation of the role ICTs play in empowering environmental specific grassroots organizations i.e. GEOs has been typically overlooked (Dhakal, 2010a; Johanson et al., 2013). Nonetheless, studying the implications of ICTs on societal actors is unlikely to yield fruitful insights from technological deterministic stance (McIver, 2003) which views ICT as a 'must have' tool for 'every' grassroots actors. Kole (2001) also argues that it is equally important for ICTs-society nexus studies to develop a conceptual framework that recognizes the mutual relationships between technologies and society for a specific purpose. It is in this context, the notion of empowerment and a framework for ICT-mediated empowerment is deliberated next.

A FRAMEWORK FOR EVALUATING ICT-MEDIATED EMPOWERMENT

The notion of empowerment means different things to different people. Page and Czuba (1995) argued that the term has often been used without actually understanding of its real meaning leading to the current theoretical underdevelopment and empirical misinterpretations of it (Segal et al., 1995). Nonetheless, empowerment concept encapsulates the capability of actors to make choices in order to gain mastery over individual or organizational affairs (Rappaport, 1984; Perkins & Zimmerman, 1995). In simplistic terms, empowerment concerns various ways societal actors with less power can be enabled to take charge to gain control over their business. Since power is conceptualized as a multidimensional social phenomenon, empowerment too is a multi-level construct with different meanings, processes and outcomes both at the individual and organizational levels (Kasmel & Tanggaard, 2011). Individual empowerment emphasizes the psychological elements of person's attributes including intrapersonal, interactional and behavioural components (Zimmerman et al., 1992). Organizational empowerment, on



EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

the other hand, focuses on the structure and practices of organizational functioning and its attributes at three different levels of intra-organizational, inter-organizational, and extra-organizational components (Peterson & Zimmerman, 2004).

In terms of intra-organizational component, empowerment represents the state of viability facilitated by mechanisms that ensures that necessary resources are available in order to fulfil organizational missions (Griffith et al., 2008). This view is consistent with the resource mobilization theory which proposes that the optimum use of existing organizational resources e.g. financial and human capital is vital for the longevity of collective action (McCarthy & Zald, 2001). Secondly, inter-organizational component suggests that undertaking joint actions through partnership arrangement ends up with institutionalizing processes that seek mutual and beneficial organizational ties (Mohan & Stokke, 2000). This proposition is in line with resource dependence theory which assumes that the availability of essential resources to fulfil organizational missions is scarce and for this reason, organizations are inclined to establish external relationships in order to secure the essential resources they need (Pfeffer & Salancik, 1978). The third extra-organizational component demonstrates the influence of organizations on social issues through activities that often have implications, for example, sustainable development, beyond organizations themselves such as, policy level changes or environmental progress (Titeca, 2008). This view is consistent with community organizing theory which manifests empowerment as social power possessed by organizations (Speer & Hughey, 1995). This chapter draws on the conceptual foundation of Peterson and Zimmerman (2004) and proposes a framework for evaluating ICT-mediated empowerment of GEOs based on processes as well as outcomes specific indicators.

As depicted in Table 1, the framework for assessing ICT-mediated empowerment utilises five forms of capital or resource as indicators of empowerment processes, namely; built, financial, human, natural, and social. Flora et al. (2004) view capital as a resource or asset that can be used, invested or exchanged in order to create new resources or assets. Built capital refers to material infrastructure and manmade equipment such as highways and ICTs gadgets like computers. Financial capital refers to money or wealth that facilitates productivity e.g. funds to pursue organizational mission while human capital refers to knowledge and skills that are either inherited or acquired through education or training. Natural capital encompasses a spectrum of natural assets in the natural environment that provides benefits through ecosystem e.g. remnant ecosystems. Finally, social capital refers to the social connections that enable organizations to act collectively e.g. relationships with stakeholders (Putnam, 2000; Roseland, 2000; Goodwin, 2003; Moore et al., 2006; Voora & Venema, 2008; Dhakal, 2014b). The basic tenet of incorporating different types of capital in the evaluation framework is to gain holistic understanding of the resources-based view of organizational empowerment.

Table 1. A framework for evaluating ICT-mediated empowerment of GEOs

Tiers of Empowerment	Processes Indicators	Catalyst	Outcome Indicators
Intra-organizational	Acquisition of: Financial capital Human capital	Built Capital: ICTs 	Organizational viability
Inter-organizational	Maintenance of: Social capital		Partnership arrangement
Extra-organizational	Protection of: Natural capital		Policy influence

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

In addition, the proposed framework outlines three outcome specific indicators of empowerment, namely; viability (inter-organizational), partnership (inter-organizational) and influence (extra-organizational). First, Fowler (2000) emphasized the regenerative ability as necessary for organizations to keep going and adapt to the changing external environment. In this regard, it is important for GEOs not only to utilize currently available resources wisely but also to have the ability to secure crucial sources in difficult circumstances. Second, Curtis et al. (2002) reiterated that it is unrealistic to expect grassroots organizations e.g. watershed groups in the US and Australia to remain functional without substantial cooperation and coordination with other intermediary organizations. It is this partnership arrangement that can foster joint grassroots level sustainable development initiatives. Third, it has been documented that GEOs that have been particularly successful in Australia are those that are able to exert power or influence at the policy level and improve grassroots environmental outcomes (Webb & Cary, 2005). Consequently, power – the capacity of one actor to get another actor to do what it would otherwise would not have done (Ackerman & Eden, 2011) – is of particular significance for the empowerment perspective because as Bourdieu (1986) argued, the capability of actors to exert influence depends on whether they are empowered or not.

METHODS

The chapter proposes that there are opportunities for meaningful understanding of ICT-mediated empowerment for sustainable development, and consequently, the central question that this paper asks is: 'to what extent does ICT enable GEOs to become significantly empowered?' This chapter draws on data collected for a PhD research entitled 'strengthening environmental stewardship in Perth, Western Australia: An investigation of linkages between organizational social capital and information and communication technologies in environmental community organizations' (Dhakal, 2010a). The research relied on a survey of 81 GEOs, fourteen (14) interviews with leaders carried out between 2008 and 2010. The updated analysis of online presence of GEOs, the content analysis of their organizational online presence, and four (4) additional consultations with leaders were carried out between 2011 and 2014. The survey research captured the trend of ICT uptake amongst GEOs in terms of access to the Internet, point of access and the status of adoption of ICTs, such as email, websites, and blogs. Post PhD consultations primarily focused on the utilization of social media into organizational activities.

In order to capture the empowerment processes, the research specifically relied on capitals and capabilities framework (Bebbington, 1999) and respondents were asked to indicate strength/weakness of their organization's capabilities by choosing from five statements:

1. Accomplish its environmental objectives i.e. safeguard natural capital,
2. Adopt and utilize information & communication technologies (ICT) i.e. exploit built capital,
3. Attract and retain volunteers i.e. garner human capital,
4. Maintain relationship with relevant stakeholders i.e. harness social capital, and
5. Raise adequate funds to support its activities i.e. secure financial capital.

The opinions were rated according to the Likert scale; very weak (0), weak (1), neither weak nor strong (2), strong (3), and, very strong (4). In order to capture empowerment outcomes, survey respondents were asked to report on:

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

1. The likelihood of the organizations to keep going as an indicator of organizational viability;
2. Current partnership arrangements, and if yes, two of the most important partner organizations; and
3. Organizational stage to gauge influence on environmental policy.

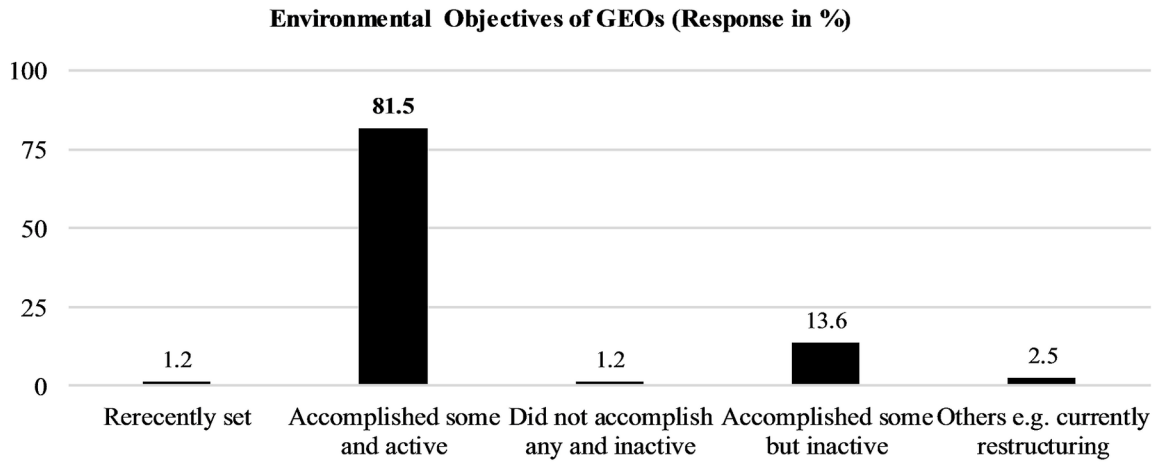
Respondents were asked to identify organizational stage in relation to environmental objectives as:

1. Recently set,
2. Accomplished some objectives and active,
3. Did not accomplish any and inactive,
4. Accomplished some but inactive, and
5. Others i.e. currently restructuring, and open ended responses.

Survey and interview data were organised, processed, and analysed using two software tools: SPSS and Excel. In order to protect the privacy of the respondents and the organizations interview excerpts are presented using each respondent's designation and organizational ID without specifically naming individuals or GEOs.

FINDINGS

Survey Response



A total of 116 GEOs was identified from the regional natural resources management (NRM) directory and requested to participate in the survey. In order to improve response rate of the mail-based survey, the Tailored Design Method (TDM) was utilized to design and disseminate the survey instrument (Dillman, 2000). 83 GEOs responded, of which 81 (70%) were complete and usable. The overall response rate was well above a desirable rate of 50% for the non-profit organizations survey (Hager et al., 2003).

GEOs' Profile

Three of the most common activities reported by responding organizations were: protection and/or restoration of ecosystems (86%), environmental education/awareness (82%) and conservation and/or preservation of biodiversity. The mean number of activities reported by GEOs stood at 3.64 (median of 4). The average age of responding GEOs was 14.2 years. Nearly two-thirds (65%) of responding leaders were females and the majority (84%) were aged between 41 and 70 years of age. A total of 2,907 volunteers were affiliated with the 81 responding organizations. On average the GEOs had 37.1 (median 15) volunteers. The survey responses indicated that governmental support (local, state and federal) and private sector grants were the main sources of funding. The average number of funding sources stood at 2.44 (median of 3) per organization. Nearly 70% of GEOs indicated that they were positive about their future prospect. In addition, nearly 68% of GEOs also reported of having partnership arrangement with at least one other organization. In terms of organizational stage, as Figure 1 depicts, an overwhelming majority (81.5%) of GEOs indicated that they had accomplished some environmental objectives and were currently active.

Figure 1. Organizational stage of responding GEOs

ICT Uptake and Digital Divide

The majority of GEOs (88%) who responded had Internet access and used email. However, this revelation is disappointing when compared to the 2002 survey which found that nearly 90% of community organizations in Australia had access to the Internet, nearly a decade earlier than the current study (Denison, 2003). While the lack of Internet access and email usage amongst 12% of GEOs in the Perth region is clearly an indicator of the digital divide, there are other multi-layered reasons as to why some organizations do not utilize email. For instance, the coordinator of GEO#36 indicated that most of the organizational interactions happened face-to-face and there was no need to use ICTs. Some leaders of GEOs that have adopted ICTs also believed that it was necessary to try to reduce the number of emails and the length of e-mails in order to avoid ICT based interactions as being 'noise', and responding to email/website/social media requests on a 24/7 basis. This could lead to burn-out of volunteers who have multiple roles and commitments. In addition, the coordinator of GEO#38 pointed out the reluctance of volunteers to trust emails because of forwarded unwanted emails and risks associated with spam. These accounts suggest that there is a sense of resistance towards ICT uptake due to the lack of perceived benefits associated with ICT use in the context of smaller grassroots organizations. More importantly, issues such as actual need, age, information overload ('noise'), and trust on ICT appeared to be the root causes of digital divide.

Less than one-tenth (7%) of organizations posted blogs and nearly 14% used social media. A recent community sector report on ICTs uptake (ACOSS, 2013) noted that nearly one quarter of community organizations in Australia did not use any form of social media and only 4% posted blogs. Once again, this fact highlights the extent of digital divide amongst GEOs. While the rate of blogging in GEOs is slightly higher than the national trend, social media use is clearly well below the national average. Other contemporary reports also reveal that smaller grassroots organizations are still in danger from being left out of the information highway because they are struggling to access and effectively utilize available ICT opportunities (The NOUS Group, 2010; Notara, 2011). For instance, the convenor of GEO#58 indicated that most of the volunteers associated with her organizations were over the age of 65 and were particularly inept and not fond of using social media. The organization only recently began to utilize

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

social networking sites in order to attract younger volunteers in the local community. These findings are consistent with the observations of Merkel et al. (2007) that the complex and evolving nature of ICTs can be barriers for organizations that are not necessarily tech-savvy.

More than one-third (41%) of GEOs have websites. However, this is not really encouraging when compared to the 2002 survey which indicated over 61% of community organizations across Australia had websites (Denison, 2003). Qualitative observations in part help explain the under-utilisation of websites by GEOs. For example, GEO#80's executive director remarked that the organization had been able to establish an online presence only through sponsorship and grant support and that on-going maintenance/technical support is quite expensive. Interview with a leader of GEO#66 (female over 70) indicated that the organizations' website was designed by kin of affiliated volunteers. However, the website has not been updated in regular intervals because of the lack of necessary skills/time to do so. These results are consistent with the observations of gender divide and time shortage for grassroots organizations to effectively use ICTs; that is, older female in Australia are particularly vulnerable to being left out of the rapidly evolving social media landscape (ABS, 2007; Dhakal, 2010b; Palmer, 2011) and voluntary organizations in Canada are spending as much as six hours a week on maintaining their websites (Leverus, 2003).

ICT-Mediated Empowerment

In order to explore the ICT-mediated empowerment processes, Spearman Rho (nonparametric) correlation test was carried out amongst various forms of capabilities of GEOs. According to the guidelines of Cohen (1988), correlation coefficients (rs) ≥ 0.5 is considered strong, (rs) $\leq 0.49 \geq 0.3$ is considered moderate and (rs) $\leq 0.29 \geq 0.10$ is considered weak. As depicted in Table 2, correlation tests detected moderate associations between ICTs and financial and social capital ($p \geq 0.01$).

It is clear from the correlation test that two of the most important factors for the ability to make the most out of ICTs were the ability to maintain relationships with relevant stakeholders and raise adequate funds. However, the correlation test also indicated the lesser significance of ICTs for GEOs' capability to address environmental issues in the Perth region. This association is not surprising, as less than one-third of responding organizations had websites, while less than one-tenth posted blogs.

In order to explore ICT-mediated empowerment outcomes, two-by-two cross-tabulations between websites (yes and no)/social media (yes and no) and dichotomised responses (yes and no) on viability, partnership, and organizational stage (Table 3) were used. Percentages across the columns help interpret the association between two categories because they provide an estimate of effect (Peat et al., 2008). The cross-tabulation revealed in Table 3 shows several significant differences between adopters and

Table 2. Spearman Rho correlation

* Significant at 0.05 probability level, ** Significant at 0.1 probability level.

non-adopters of ICTs. A significantly greater percentage of GEOs that have websites and use social media were more likely to be viable, engaged in partnership arrangement and had made significant environmental contributions.

While it is necessary to be cautious in establishing the causal relationships between variables based on the statistical associations alone (Cohen & Lea, 2004), such links between ICTs uptake and empowerment do have plausible explanations. Firstly, the correlations between ICTs adoption and financial and social resources suggest that some GEOs might be using social media as an additional avenue to attract acquires necessary resources locally. For instance, GEO#58 has particularly utilised social media in order to recruit volunteers for larger community events as well as to advertise garage-sale or other fund-raising activities. Conversely, it might also be the case that the uptake of ICTs has benefitted GEOs that are already enabled to a certain extent, rather than serving the needs of organizations that need to be empowered. Secondly, it can be speculated that organizations that are likely to be viable are more interested in establishing partnership arrangements and utilizing ICTs to build and maintain organizational relationships than those with a negative outlook. For example, five of the GEOs that responded to the survey had partnership arrangements with an environmental network in the region. These organizations not only receive technical assistance on matters like grant application and management plan preparations but also host their websites through the network's website. This finding reveals the significance of the role bridging or intermediary organizations (Brown, 1991; Dreier, 1996) play in the ICT-mediated empowerment of smaller grassroots organizations. Thirdly, GEOs that are likely to influence policies and environmental outcomes have clearly utilized ICTs to further their cause. For instance, GEO#81 has used website as a tool to increase awareness about the significance of local wetlands currently under threat because of the proposed highway construction over the wetlands. The organization is also making use of social media to harness community members to file an online petition directly to the WA Premier

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

to campaign against the proposed highway from being built and help spread the news about protest rallies. ICTs in this case clearly provided additional means for the organization to influence sustainable development agenda at the extra-organizational level.

LIMITATIONS

As with any empirical research, there are limitations in this investigation. Firstly, although leadership qualities or their qualitative personalities as well as their past affiliations or associations in a community at the broader scale can influence the level of empowerment (Wood et al., 2008), this paper did not explore the attributes of leadership. It is in this context, the analysis of the ICT-mediated empowerment can be extended in the future by incorporating leadership attributes. Secondly, this chapter examined organizations that are currently active in the Perth region. Several defunct organizations that responded but did not participate in the survey indicated that some leaders who are solely interested in environmental outcomes but not in the processes that nurtures empowerment pathways – led to organizational dissolution (Dhakal, 2010a). This observation is consistent with the findings of Carr (2002) who pointed out that the depletion of stakeholder relationships have led to the disbanding of some of the GEOs in WA. Further research on the association between ICT-mediated organizational empowerment (or a lack thereof) and the dissolution of some GEOs would be worthy of investigation; not only to strengthen the case for fostering empowerment processes, but also to find ways to prevent empowerment processes as well as environmental outcomes from getting eroded.

DISCUSSIONS AND CONCLUSION

This chapter explored the extent to which ICTs enable the empowerment of GEOs in the Perth region of Western Australia. One of the main contributions of this chapter is the development of an organizational empowerment framework recognizing that the mutual relations between GEOs and ICTs can be harnessed for broader sustainable development agenda.

The three tiered conceptualization of an organizational empowerment provided a useful theoretical framework for evaluating the ways ICT-utilization enhanced the capacity of GEOs to accomplish their goals. The qualitative and quantitative findings indicated associations between the uptake of ICTs and the acquisition of financial and social resources by GEOs. A significantly greater percentage of GEOs that have websites and use social media had positive association with the indicators of intra, inter and extra organizational empowerment. In line with Bourdieu's (1986) argument, it has been demonstrated in this study that the capability to exert power depends, in the first place, on whether people are empowered or not. These findings further demonstrate that the utilization of ICTs can strengthen GEOs to carry out sustainable development initiatives and overcome resources-scarcities.

However, the associations between ICTs and empowerment are often reciprocal as it is not only possible for ICTs uptake to affect empowerment processes and outcomes but also vice versa. As Kraut et al. (1998) suggested, it is important to take this two-way relationship into consideration because even if empirical evidence were to convincingly connect ICT uptake with empowerment, it would not neces-

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

sarily confirm the causal direction of the relationship. More importantly, the findings presented in this chapter do not always suggest that GEOs that are non-adopters are inferior to those who are adopters; instead organizations that have adopted ICTs might simply have additional means with which they can be empowered. This interpretation is consistent with the 'networked society' stance (Castells, 2000) which associates the lack of ICT utilization with missed opportunities (Floridi, 2001; Hacker et al., 2009; Dhakal et al., 2013).

What the state of ICTs uptake amongst GEOs in the Perth region highlights is the fact that the majority of responding organizations neither have websites nor use social media. It is likely the case that the general lack of enthusiasm for ICT uptake is an indication of a greater predominance of importance placed upon face-to-face interactions more than the digital divide itself (Kavanaugh et al., 2007). In other words, low ICT uptake may not necessarily be perceived as binary understanding of the digital divide but in terms of preferred mode of communications and the scope of organizational activities. Nevertheless, these findings clearly point to the need to address the digital divide in the broader context of social inequalities, if ICT-mediated empowerment is to be achieved, even in developed countries like Australia. Mainly because diffusion and appropriate utilization of ICTs present immense opportunities for sustainable development, whereas their absence is likely to accentuate the already existing divide (Sciadas, 2005). In this regard, ICT-mediated empowerment strategies might benefit by taking into consideration the underpinnings of theory of Diffusion of Innovations (Rogers, 1995) which suggests that organizations with more social, financial and human resources will generally be the first ones to adopt new technologies.

FUTURE TRENDS

It is apparent that not every GEO has the need to rely on ICTs to become empowered. However, as ICTs become increasingly ubiquitous in an organizational context, GEOs that are either unable to or unwilling to adopt ICT can be further disadvantaged because of lessening opportunities to engage in sustainable development initiatives. GEOs can adopt various mechanisms in order to be empowered in multiple ways and this short chapter does not aim to underestimate the complexities of empowerment (or the lack of it) by equating it with the uptake of ICT. In the case of GEOs in the Perth region, however, the uptake of ICTs stands out as a distinctive factor associated with enhanced empowerment, both processes and outcomes. This finding resonates with the observation that ICTs have become an essential ingredient of successful environmentally-oriented grassroots actors that often have to 'do more with less' (Neto, 2008). On the flip side, some of these organizations were willingly or unwillingly and/or overlooking or under-exploiting the potential of ICTs in general. This observation is consistent with the low utilization of ICTs amongst similar organizations elsewhere in Australia (Johanson et al., 2013). Since GEOs with a higher uptake of ICTs were in a better position to be empowered, future efforts (both governmental and non-governmental) to build ICT capacity of these organizations may benefit from involving intermediary organizations as well as making use of an organizational empowerment framework developed in this chapter to develop, monitor and evaluate ICT interventions in the Perth region and beyond.

KEY TERMS AND DEFINITIONS

Digital Divide: A symbol of perceived disadvantage of actors that either are unable or do not choose to make use of information and communication technologies.

Extra-Organizational Empowerment: The influence of organizational activities on economic, environmental or social issues with implications beyond organizations.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Grassroots Environmental Organizations: Formal or informal not-for-profit and non-governmental organizations that operate at the grassroots to care for the local environment.

Information and Communication Technologies: Internet as well as Internet based tools such as email, website, and social media.

Inter-Organizational Empowerment: The capacity to undertake joint actions with other organizations that results in mutual benefits.

Intra-Organizational Empowerment: The state of viability facilitated by mechanisms within organizations that ensures necessary resources are available in order to fulfil missions.

Organizational Empowerment: The ability to fulfil organizational missions based on the structure and practices of organizational functioning and its attributes.

Sustainable Development: Holistic societal aspirations on economic progress as well as social and environmental justice.

Chapter 25
Renewable Energy Sources: Comparison of Their Use and Respective Policies on a Global Scale

Mahmure Övül Arıoğlu Akan
Marmara University, Turkey

Ayşe Ayçim Selam

Seniye Ümit Oktay Fırat
Marmara University, Turkey

ABSTRACT

Sustainability concerns resulting from the consumption of natural resources, life-threatening levels of pollution, global warming, climate change and the ever-increasing worldwide energy use have brought renewable energy sources to forefront. Given the possibility of depletion of fossil fuels in the near future, the utilization of clean and renewable energy sources have become inevitable. Consequently, governments and global organizations adopted respective regulations to ensure the production and use of renewable energy and promote the respective new investments. In the light of these developments, the aim of this study is to conduct a detailed review and evaluation on the current literature and global energy statistics. The respective projects, binding regulations, incentives, and pricing mechanisms have also been studied to analyze and compare the renewable energy policies adopted worldwide. Ultimately, the goal is to make certain suggestions and lay out possible solutions regarding global energy problems.

INTRODUCTION

Renewables excluding large hydro accounted for 9.1% of world electricity generation in 2014, up from 8.5% in 2013 with a corresponding increase of 17% in global investment ($270.2 billion invested in 2014 in renewable power and fuels excluding large hydro-electric projects) (Frankfurt School-UNEP Centre/ BNEF, 2015). The reason behind this is the concern for sustainability resulting from factors including but not limited to the depletion of natural resources, life-threatening levels of pollution, global warm-

ing, climate change and the ever-increasing worldwide energy consumption (Komor & Bazilian, 2005; Apergis & Payne, 2010). The effective utilization of renewable energy is critical across the world, where 1.3 billion people still do not have access to modern sources of energy (WEF, 2013). Societies have much to gain from the effective use of renewable energy with certain issues to consider while making this happen (see Table 1).

In order to make use of these advantages stated in Table 1 and to address the critical issues, countries have developed government policies and adopted respective regulations to ensure the production and use of renewable energy and promote the respective new investments. This has been realized both individually and also as a part of global organizations and networks such as the Organisation for Economic Co-operation and Development (OECD), European Union (EU), United Nations (UN) and International Energy Agency (IEA) (Arioglu Akan et al., 2014).

The government policies on renewable energy constitute a "highly complex policy subsystem that lies at the intersection between environmental policy, economic policy, and energy policy" (Yi & Feiock, 2014). Within this perspective, a detailed review and evaluation have been conducted in this study on the current literature, projects, binding regulations, incentives, and pricing mechanisms together with the respective energy statistics to analyze and compare the renewable energy policies adopted worldwide. It has ultimately been aimed to make certain suggestions and lay out possible solutions regarding renewable energy based on the relationships between the current policies and use throughout the world. To this end, the third part of the study provides the broad definitions on the main concepts discussed in this study. A comparative analysis of renewable energy use (both on a general basis and also by source) throughout the world has been given in the fourth part. The fifth part summarizes the global renewable energy policies adopted worldwide. In this part, the policies of the OECD, the EU and some countries

Table 1. Advantages and disadvantages of renewable energy

Advantages	Disadvantages
Provides low operating and maintaining costs	High up-front investment
Provides long life period	Entails long-term planning
Service cost is low	Entails long-term agreements
Reliable source	Entails multidisciplinary involvement
Induces technology development	Could involve resettlement
Fosters regional development	Entails new legal codes
Provides efficient energy production and safety	Excessive competition
Generates revenue and tax	
Creates new employment opportunities	
Protects environment and saves environmental protection costs	
Enhances living conditions	
It is waste-free	
Improves air quality	
Preserves ecosystems	
Helps slow down climate change	

Gökmen & Temiz, 2015.

selected with respect to certain renewable energy indicators have been included. A general view on the 2050 worldwide renewable energy goals is provided in the sixth section. This is followed by solutions and recommendations drawn from the study and certain future research directions. Finally, in the conclusions part, an executive summary can be found.

BACKGROUND

The Renewable Energy Working Party of the IEA defines renewable energy as follows:

Renewable Energy is derived from natural processes that are replenished constantly. In its various forms, it derives directly or indirectly from the sun, or from heat generated deep within the earth. Included in the definition is energy generated from solar, wind, biofuels, geothermal, hydropower and ocean resources, and biofuels and hydrogen derived from renewable resources. (IEA, 2013a)

In line with the above definition, renewable energy sources can be classified under the following categories (IEA, 2013a):

- Hydroelectricity,
- Geothermal,
- Solar,
- Tide/Wave/Ocean,
- Wind,
- Solid biofuels, biogases, liquid biofuels,
- Renewable municipal waste.

Below are more detailed explanations on the above-listed sources of renewable energy provided by the IEA (2014a):

- **Hydroelectricity:** Refers to potential and kinetic energy of water converted into electricity in hydroelectric plants.
- **Geothermal:** Energy available as heat emitted from within the earth's crust, usually in the form of hot water or steam. It is used for electricity generation, heat production for sale to third parties or directly as heat in its primary form.
- **Solar:** Solar radiation exploited for electricity generation and hot water production. Passive solar energy for direct heating, cooling or lighting of dwellings or other buildings is not included. Solar photovoltaic is solar radiation exploited for electricity generation by photovoltaic cells. Solar thermal is solar radiation exploited for hot water production by flat plate collectors (mainly of the thermosyphone type) for domestic hot water or seasonal heating of swimming pools and electricity generation by solar thermal-electric plants.
- **Tide/Wave/Ocean:** Mechanical energy derived from tidal movement, wave motion or ocean current and exploited for electricity generation.
- **Wind:** Kinetic energy of wind exploited for electricity generation by wind turbines.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

- **Solid Biofuels:** Covers organic, non-fossil material of biological origin, which may be used as fuel for heat and electricity production. These include primary solid biofuels (fuelwood, wood residues and by-products; wood pellets; black liquor; bagasse; animal waste; other vegetal materials and residuals) and charcoal.
- **Biogases:** Gases composed principally of methane and carbon dioxide produced by anaerobic fermentation of biomass, or by thermal processes. They include landfill gas, sewage sludge gas, other biogases from anaerobic digestion and biogases from thermal processes.
- **Liquid Biofuels:** Includes fuels and bioadditives such as biogasoline, biodiesel, and other liquid biofuels.
- **Renewable Municipal Waste:** Consists of the biodegradable part of municipal waste products that are combusted directly to produce heat and/or electricity. It comprises waste produced by the residential, commercial and public services sectors that is collected by local authorities for disposal in a central location, including biodegradable hospital waste.

COMPARATIVE ANALYSIS OF THE RENEWABLE ENERGY USE THROUHOUT THE WORLD

This part of the study provides a brief analysis on the comparison of renewable energy use in Africa, Non-OECD Americas, Asia, China, Non-OECD Europe and Eurasia, Middle East, OECD and World Total[1]. The purpose is to lay out the current situation of renewable energy use on a general basis and also by source. To this end, Table 2 presents the overall renewable energy share in total primary energy supply (TPES) in addition to the individual shares of hydro, geothermal/solar/wind/wave and biofuel/renewable waste. The figures are the averages of the respective data corresponding to the years between 2008 and 2012, which have been gathered from IEA yearly "Renewables Information" reports (2010-2014 Editions). Figure 1 depicts the worldwide renewable energy shares in TPES between 2008 and 2012, and the five-year average individual shares of the above-mentioned sources can be viewed in Figure 2. The geographical coverage provided in Table 2, Figure 1, and Figure 2 and throughout the current section is as reported by the IEA and constitutes the following:

Table 2. Five-year (2008-2012) average share of renewable energy in TPES (general and by source)

Region	Renewables in TPES (%)	Hydro (%)	Geothermal, Solar, Wind, and Wave (%)	Biofuel and Renewable Waste (%)
Africa	49.3	1.3	0.2	47.7
Non-OECD Americas	30.2	10.1	0.6	19.5
Asia	26.2	1.5	1.8	22.9
China	11.4	2.4	0.6	8.3
Non-OECD Europe and Eurasia	3.7	2.2	0.1	1.4
Middle East	0.5	0.2	0.1	0.1
OECD	7.8	2.2	1.2	4.4
World	13.0	2.3	0.9	9.8

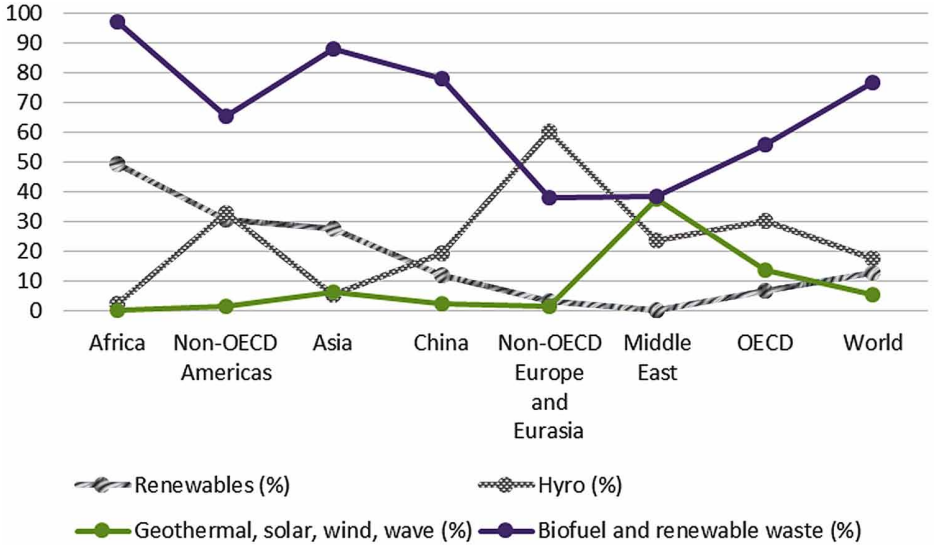
- **Non-OECD Americas:** Includes Argentina; Bolivia; Brazil; Colombia; Costa Rica; Cuba; Dominican Republic; Ecuador; El Salvador; Guatemala; Haiti; Honduras; Jamaica; Netherlands Antilles; Nicaragua; Panama; Paraguay; Peru; Trinidad and Tobago; Uruguay; Venezuela and Other Non-OECD Americas. *Other Non-OECD Americas* includes Antigua and Barbuda; Aruba; Bahamas; Barbados; Belize; Bermuda; British Virgin Islands; Cayman Islands; Dominica; Falkland Islands (Malvinas); French Guyana; Grenada; Guadeloupe; Guyana; Martinique; Montserrat; Puerto Rico (for natural gas and electricity); St. Kitts and Nevis; Saint Lucia; Saint Pierre et Miquelon; St. Vincent and the Grenadines; Suriname; and Turks and Caicos Islands.
- **Asia:** Includes Bangladesh; Brunei Darussalam; Cambodia; India; Indonesia; DPR of Korea; Malaysia; Mongolia; Myanmar; Nepal; Pakistan; Philippines; Singapore; Sri Lanka; Chinese Taipei; Thailand; Viet Nam and Other Asia. *Other Asia* includes Afghanistan; Bhutan; Cambodia (until 1994); Cook Islands; East Timor; Fiji; French Polynesia; Kiribati; Laos; Macao, China; Maldives; New Caledonia; Palau (from 1994); Papua New Guinea; Samoa; Solomon Islands; Tonga and Vanuatu.
- **China:** Includes the People's Republic of China and Hong Kong, China.
- **Non-OECD Europe and Eurasia[3]:** Includes Albania; Armenia; Azerbaijan; Belarus; Bosnia and Herzegovina; Bulgaria; Croatia; Cyprus[4]; Former Yugoslav Republic of Macedonia (FYROM); Georgia; Gibraltar; Kazakhstan; Kosovo[5]; Kyrgyzstan; Latvia; Lithuania; Malta; Republic of Moldova; Montenegro[5]; Romania; Russian Federation; Serbia[5]; Tajikistan; Turkmenistan; Ukraine and Uzbekistan.
- **Middle East:** Includes Bahrain; Islamic Republic of Iran; Iraq; Jordan; Kuwait; Lebanon; Oman; Qatar; Saudi Arabia; Syrian Arab Republic; United Arab Emirates and Yemen.
- **OECD Total:** Comprises Australia; Austria; Belgium; Canada; Chile; the Czech Republic; Denmark; Estonia[6]; Finland, France; Germany; Greece; Hungary; Iceland; Ireland; Israel[7]; Italy; Japan; Korea; Luxembourg; Mexico; the Netherlands; New Zealand; Norway; Poland; Portugal; the Slovak Republic; Slovenia[6]; Spain; Sweden; Switzerland; Turkey; the United Kingdom and the United States.

The analysis of Table 2 and Figure 1 reveals the following results:

- The percentage of renewable energy use in Africa has reached up to 50%, which is significantly above the world average. This is due to the fact that mostly organic non-fossil fuels are used in African countries.
- The Middle East, which is the center of fossil fuels, is expectedly where renewable energy has the lowest share.
- As for the OECD countries, the renewable energy use is close to the world average with a slight increase throughout the years subject to study.
- China has also caught up with the world average in terms of renewable energy use.
- Non-OECD Americas and Asia are the second and third, respectively, both well above the world average. Non-OECD Europe and Eurasia is fairly below the OECD and World averages.
- While Africa, Non-OECD Americas, Non-OECD Europe and Eurasia, Middle East and the World shows a steady behavior with regard to renewable energy share in TPES, a slight decrease has been observed in Asia and China starting from 2009.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use



The analysis of the individual shares of hydro, geothermal/solar/wind/wave and biofuel/renewable waste in Table 2 and Figure 2 indicates the following:

- Except for Non-OECD Europe and Eurasia and the Middle East, biofuels and renewable wastes constitute the highest percentage of renewables throughout the world. This is especially significant for Africa, Asia and the World Total.
- The relative utilization percentage of hydro is the highest in Non-OECD Europe and Eurasia followed by the Middle East, Non-OECD Americas, OECD and China, respectively.
- As for geothermal, solar, wind and wave energies combined, the most significant utilization (as a percentage of the TPES) is observed in the Middle East followed by OECD average.
- The most uniform distribution of the individual shares is in OECD where the total 7.8% of renewables is divided as 2.2%, 1.2% and 4.4% among hydro, geothermal/solar/wind/wave and biofuel/renewable waste, respectively.

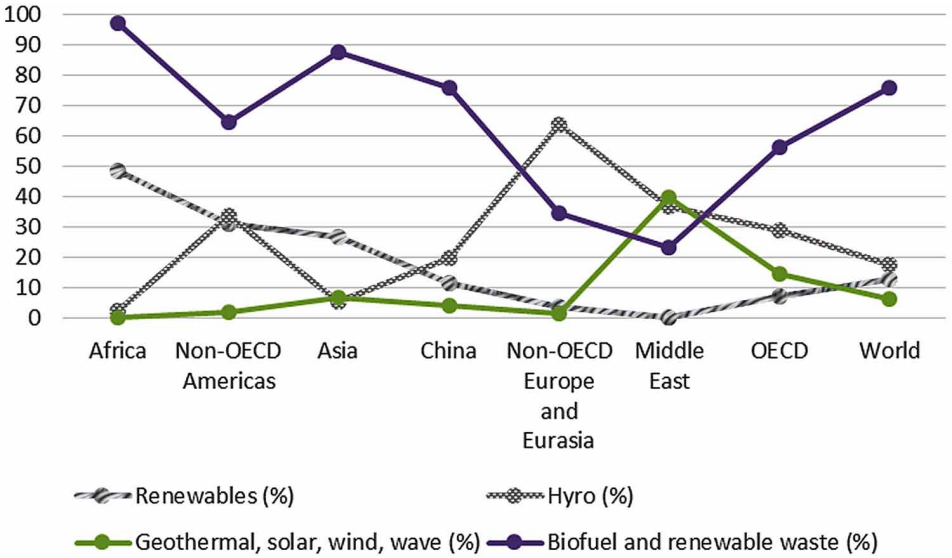
The distribution of the individual shares (expressed as percentages of total renewables) over time have also been studied, between 2008 and 2012 (see Figure 3, Figure 4, Figure 5, Figure 6 and Figure 7), with the following results:

- It has been observed that, for biofuels and renewable wastes, the geographical groupings can be listed as Africa, Asia, World Total, China, Non-OECD Americas, OECD Total, Non-OECD Europe and Eurasia and the Middle East, in decreasing order. This ordering is different for the year 2008 only, where the percentage of biofuels and renewable wastes in renewables is higher in the Middle East compared to Non-OECD Europe and Eurasia.
- The investigation of the share of geothermal, solar, wind and wave energies combined in total renewables reveals that the Middle East, which was the first in this category in 2008, 2009 and

Figure 3. Worldwide renewable energy use in 2008

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. Worldwide renewable energy use in 2009



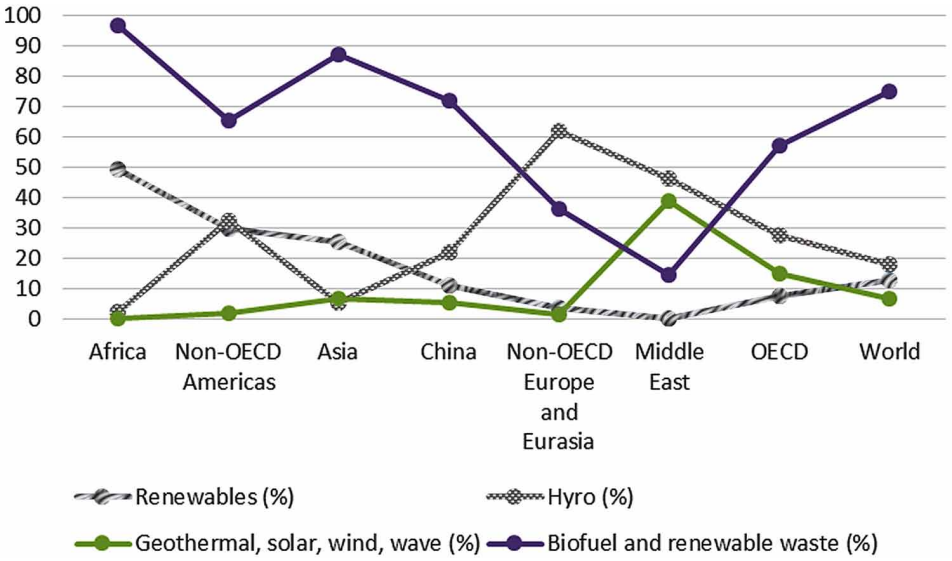


Figure 5. Worldwide renewable energy use in 2010

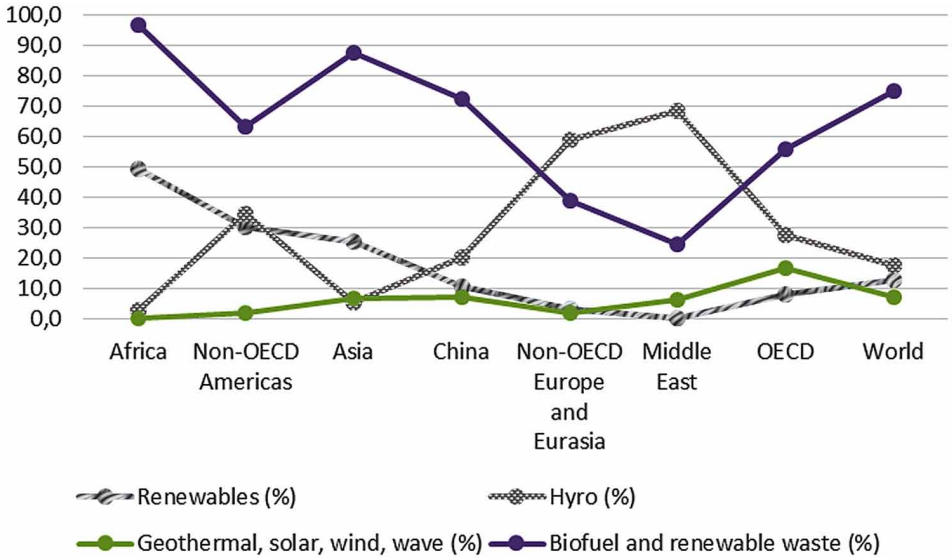
2010, has been replaced by OECD Total in years 2011 and 2012. The reason for this change is that starting from 2010, hydro constitutes a higher percentage in total renewables than geothermal, solar, wind and wave energies combined.

- In terms of the share of hydro in total renewables, Non-OECD Europe and Eurasia has the highest percentage until 2011. In 2011 and 2012, it has been replaced by the Middle East.
- When the geographical groupings are investigated within themselves throughout the years subject to study, it can be concluded that there has been no changes in the distribution of the individual

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 6. Worldwide renewable energy use in 2011



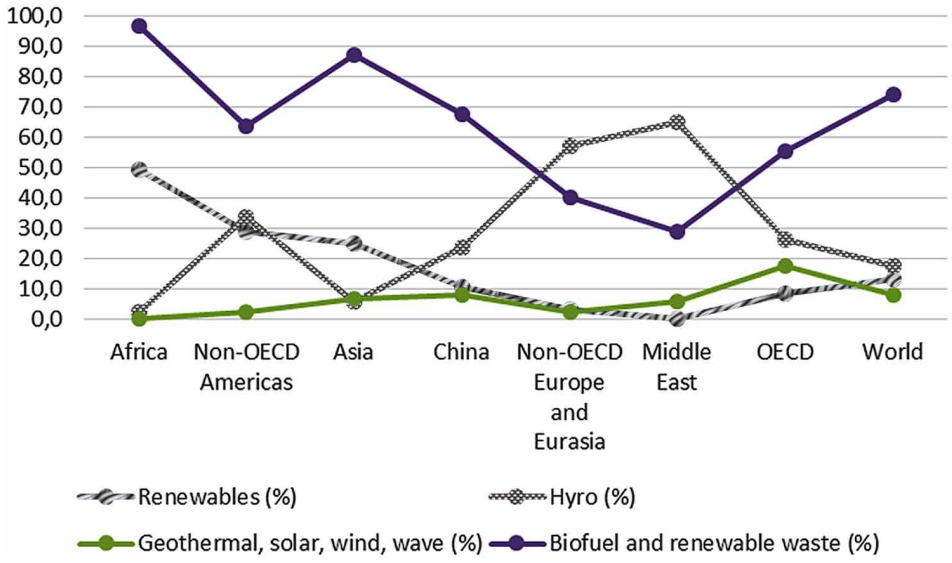


Figure 7. Worldwide renewable energy use in 2012

renewable sources. The only exception is the Middle East, where in 2008, biofuel/renewable waste and geothermal/solar/wind/wave had almost equal shares with hydro having a lower percentage, this situation changed in favor of hydro starting from 2010. In the current case, hydro has the highest share followed by biofuel/renewable waste and geothermal/solar/wind/wave, respectively.

In order to conduct a comparative analysis of renewable energy use on a country basis, the indicators provided in the 2014 dated Global Status Report of Renewable Energy Policy Network (REN21, 2014)

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

have been used (see also Selam et al., 2014). Table 3 depicts the top five countries in terms of annual investment, net capacity additions and production in 2013. The top five countries in terms of total capacity or generation as of end-2013 can be viewed in Table 4. A simple rating methodology has been devised to position the countries with respect to the indicators presented in Table 4. In addition to these indicators, *Investment in Renewable Power* and *Fuels and Share of Gross Domestic Product (GDP) (USD)* rankings from Table 3 have also been included. Thus, a total of 17 indicators have been used (see Table 7 in the Appendix). The methodology is such that if a country is in the first position, it gets 5 points from the corresponding indicator. If it is in the second, third, fourth and fifth positions, the scores are 4, 3, 2 and 1, respectively. If it is not listed in the ranking of a certain indicator, the corresponding score is 0. The scores, totals and averages (in descending order) can be viewed in Table 8 in the Appendix. The top 5 countries with respect to this ranking scheme have been listed as China, United States, Germany, Brazil and Spain with average scores of 2.76, 2.35, 1.71, 0.82 and 0.82, respectively.

RENEWABLE ENERGY POLICIES AROUND THE WORLD

General Renewable Energy Policies of the OECD

OECD has been established in 1961 with the aim of "promoting policies that will improve the economic and social well-being of people around the world" (OECD, 2014). Currently, there are 34 member countries spanning the globe, from North and South America to Europe and the Asia-Pasific region (OECD, 2014).

In 2010, 18% of the world population lived in the OECD with 74% of the GDP being created in its 34 member countries. The TPES of the OECD in 2010 represented about 44% of global energy supply,

Table 3. Top five countries in terms of annual investment/net capacity additions/production in 2013

Indicators	Rank				
	1	2	3	4	5
Investment in renewable power and fuels	China	United States	Japan	United Kingdom	Germany
Share of GDP (USD) invested[1]	Uruguay	Mauritus	Costa Rica	South Africa	Nicaragua
Geothermal power capacity	New Zealand	Turkey	United States	Kenya	Philippines
Hydropower capacity	China	Turkey	Brazil	Vietnam	India
Solar PV capacity	China	Japan	United States	Germany	United Kingdom
Concentrating solar thermal power (CSP) capacity	United States	Spain	United Arab Emirates	India	China
Wind power capacity	China	Germany	United Kingdom	India	Canada
Solar water heating capacity[2]	China	Turkey	India	Brazil	Germany
Biodiesel production	United States	Germany	Brazil	Argentina	France
Fuel ethanol production	United States	Brazil	China	Canada	France

REN21, 2014.

[1]Countries considered include those covered by BNEF; GDP is for 2012 and from the World Bank. The following renewable energy projects are included: all biomass, geothermal, and wind generation projects of more than 1 MW; all hydropower projects of between 1 and 50 MW; all solar power projects with those less than 1 MW estimated separately and referred to as small-scale projects or distributed capacity; all ocean energy projects; and all biofuel projects with an annual capacity of 1 million litres or more.

[2]Solar water collector (heating) rankings are for 2012, and are based on capacity of water (glazed or unglazed) collectors only; however, including air collectors would not affect order.

Wind power capacity per capita	Denmark	Sweden	Spain	Portugal	Ireland
HEAT					
Solar water heating[3]	China	United States	Germany	Turkey	Brazil
Solar water heating capacity per capita[3]	Cyprus	Austria	Israel	Barbados	Greece
Geothermal heat[4]	China	Turkey	Iceland	Japan	Italy

REN21, 2014.

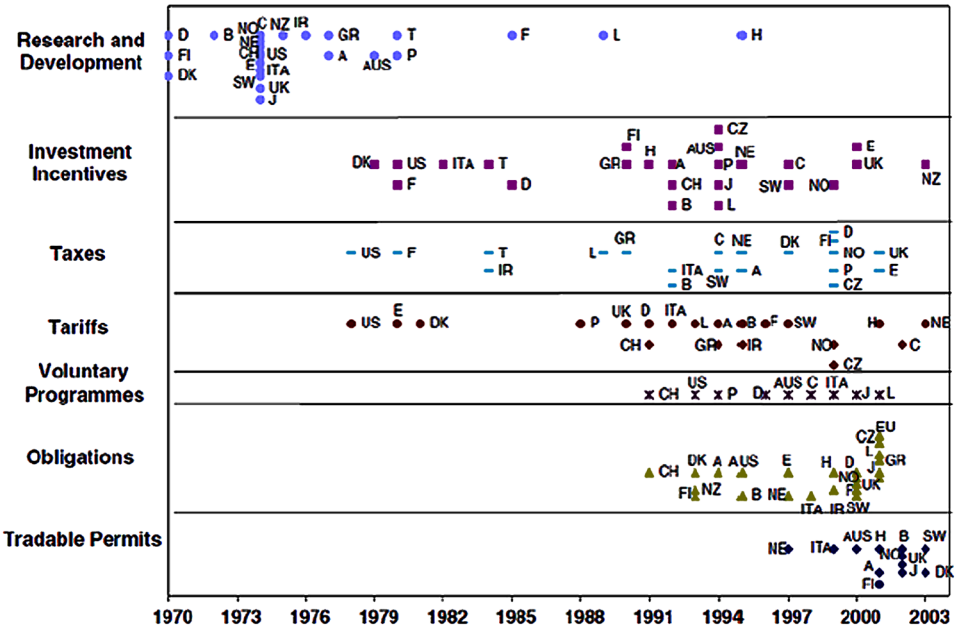
[1]Per capita renewable power capacity ranking considers only those countries that place among the top 20 worldwide for total installed renewable power capacity, not including hydropower.

[2]Country rankings for hydropower capacity and generation differ because some countries rely on hydropower for baseload supply whereas others use it more to follow the electric load and match peaks in demand.

[3]Solar water collector (heating) rankings are for 2012, and are based on capacity of water (glazed or unglazed) collectors only; however, including air collectors would not affect order.

[4]Not including heat pumps. Rankings are based on a mix of 2010 data and more recent statistics for some countries.

[5]Capacity, otherwise noted.



while the total energy production constituted 30% of the global energy production (IEA, 2012a). Bigerna et al. (2014) address three main pillars of the energy and environmental policy for sustainability as investments in renewable energy sources, increases in energy efficiency and promotion of energy savings behaviors. The OECD countries have adopted certain energy efficiency policies such that each government made its own decision regarding the measures to be taken and their implementation (Saidel and Alves, 2003). These measures fall under the following basic categories (Saidel and Alves, 2003):

- Restrictive regulations,
- Information to the public,
- Creation of market asymmetries,
- Funding/loans programs,
- State capital/private capital partnerships,

The evolution of the renewable energy policies in OECD countries can be viewed in Figure 8.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 8. Patterns of policy adoption in selected OECD countries (Nicolli and Vona, 2012)

General Renewable Energy Policies of the EU

Environmental concerns, supply security and competitiveness considerably affected the EU policies especially those related to the renewable energy sector, resulting in an effective renewable energy policy since 1997 (EWEA, 2011). The Renewable Energy Directive 2009/28/EC set forth a European framework for the promotion of renewable energy by 2020 through mandatory national renewable energy targets (EC, 2013a). Thus, the current policy of the EU for 2020 aims at 20% substitution of fossil fuels by renewable energy resources that include biomass and waste, hydro, geothermal, solar, and wind power (Krozer, 2013). The other targets for 2020 are greenhouse gas emission reductions of 20% relative to emissions in 1990 and 20% savings in energy consumption compared to projections (EC, 2013b). Consequently, 19.9% of the absolute European energy generation in the EU27 in 2009 was produced by renewables, with hydro-power taking the lead (11.6%), followed by wind (4.2%) (Fouquet, 2013).

Each member of the EU has decided on its own strategies to meet the above-stated energy targets and published these in Renewable Energy Action Plans (NREAP) between July 2010 and January 2011 as required by the EU (Directive 2009/28/EC) (Kitzing et al., 2012). The most common renewable energy sources (RES) support strategies implemented in the EU can be listed as the following (Kitzing et al., 2012):

- Feed-in tariffs; guaranteed prices,
- Feed-in premiums; production premiums,
- Tender schemes,
- Quota obligations with tradable green certificates,
- Investment grants,

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Fiscal measures (tax incentives, etc.),
- Financing support (loans, etc.).

Recently, there have been efforts regarding an integrated policy framework for the period up to 2030 with the following targets (EC, 2014):

- Reducing EU domestic greenhouse gas emissions by 40% below the 1990 level and by 2030.
- Increasing the share of renewable energy to at least 27% of the EU's energy consumption by 2030.
- Realizing 30% energy savings.
- Establishing a market stability reserve at the beginning of the next ETS (Emissions Trading System) trading period in 2021.
- Developing a set of key indicators to assess progress over time and provide a factual basis for policy action as needed.
- Establishing a new governance framework based on national plans for competitive, secure and sustainable energy.

Renewable Energy Policies of Some Selected Countries

In this section, the renewable energy policies of China, United States, Germany, Brazil, Spain, Turkey and India are briefly introduced. The first five of these countries have been listed at the top with respect to certain renewable energy performance indicators (see the Appendix). Turkey has been included because it is a developing country with significant renewable energy sources. As for India, it has also been included because a wide array of renewable energy policies has been adopted, even more than some countries in the top five. The renewable energy support policies of the first fifteen countries in the ranking have been depicted in Table 5.

China

China is world's largest energy user, accounting for one fifth of all global energy consumption with an expected increase by 60% by 2030 (IRENA, 2014). Energy conservation, efficiency in energy utilization and emission reduction have become the main foci in China's energy policy. As a result, it has become a global leader in renewable energy, installing more new renewable energy capacity than all of Europe and the rest of the Asia Pacific region in 2013 alone (IRENA, 2014). Some of the steps taken to achieve these can be summarized as the following (China's Energy Policy, 2012):

- Various energy-saving renovations are implemented.
- Efforts have been made to support new and renewable energy developments.
- Improvements have been made in civil energy use conditions (energy service level, access to natural gas and electricity, combined heat and power projects etc.).
- Environmental protection has been increased.

The country's energy consumption per-capita is low and decreasing every year. The energy consumption for every 10 000 yuan of GDP decreased by 20.7% from 2006 to 2011 (China's Energy Policy, 2012). China aims to increase the use of non-fossil fuels by developing new and renewable energy

[1]Spain removed FIT support for new projects in 2012. Incentives for projects that had previously qualified for FIT support continue to be revised.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

sources by the end of the 12th Five-Year Plan. It is the leading renewable energy producer in the world with the world's richest hydropower resources, and currently less than 30% of its resources have been utilized (China's Energy Policy, 2012; Liu, 2013). These resources can help China to achieve the goal of increasing the non-fossil energy consumption share to 15% by 2020. Chinese government wants to provide hydropower development by using local resources and local employment. This country is also the fastest growing wind power market in the world (Hanna, 2010). Thus, the goal is to encourage research and development (R&D) studies in wind-power equipment production, improve the standards and control in the sector, optimize the wind power production and develop offshore wind farms. Other significant aspects of China's renewable energy policies involve the following (China's Energy Policy, 2012; Meisen & Hawkins, 2014):

- Promote and encourage the development and utilization of its rich solar energy resources with the construction of power stations, solar power generation projects, efforts to generalize solar heating, cooling, water heaters and industrial applications of solar energy.
- Make nuclear power plants safer and more efficient especially after the Fukushima Daiichi nuclear disaster in 2011.
- Benefit from the biomass potential in rural areas.

It is also stated in the REmap 2030 analysis of China (IRENA, 2014) that significant potential exists for renewable energy in end-use sectors. Industry can achieve a 10% renewable energy share, and the building sector can transform its fuel mix to two-thirds renewables. Solar thermal heat and electrification pose a significant potential so does modern biomass for process heating and space/water heating.

United States

The US, which accommodates 4.5% of the world population and consumes 19.2% of the world's energy (second largest after China), is one of the richest countries in terms of renewable energy portfolio (Aslani & Wong, 2014). Being criticized for the significant variation in renewable energy policy designs among states, the US underwent major developments in the energy policy arena over the course of the last few years, diverging from fossil fuels towards a sustainable and coherent energy system with greater energy independence (IEA, 2014b; Park, 2015). Some of these renewable energy policies include but are not limited to subsidies for wind, solar, and geothermal producers; biomass grants; increasing the amount of biofuel that must be mixed with gasoline; making geothermal energy more competitive with fossil fuels in generating electricity; tax reductions; loan guarantees and renewable portfolio standard in each state (Aslani and Wong, 2014).

The most significant developments in the policy arena can be listed as the following (IEA, 2014b):

- The enactment of the American Recovery and Reinvestment Act (ARRA) (2009), through which the Department of Energy (DOE) invested more than USD 31 billion in energy infrastructure, clean energy projects and energy efficiency.
- The President's Blueprint for a Secure Energy Future (2011), which set forth a clear agenda for the medium-term direction of federal energy policy based on doubling of electricity generation from wind, solar and geothermal sources by 2020, halving net oil imports by the end of the decade, doubling energy productivity by 2030 and providing international leadership in clean energy.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

- The "All-of-the-above" strategy (2012), which aimed at support for economic growth and job creation, enhanced energy security, and deployment of low-carbon energy technologies, through a series of defined policy actions.

Despite the above-mentioned developments and the RPS adopted by many states, there are still certain unsolved issues on the national level regarding how the goal of doubling renewable energy production from wind, geothermal and solar sources by 2020 compared to 2012 will be reached (IEA, 2014b). Certain remarks and suggestions concerning the renewable energy policies of the US have been made, some of which can be listed as the following (Osmani et al., 2013; IEA, 2014b; IRENA, 2015; Park, 2015):

- Effective, coordinated and diversified national policies should be developed to reduce the uncertainties to maintain investor confidence in secure electricity infrastructure (including transmission, distribution, smart grids, renewable energy integration and climate resilience).
- The end-use sectors of transport, industry and buildings, which pose a significant potential for renewable energy technologies, should more effectively be included in policy-making.
- A consistent, predictable and long-term policy support should be employed to create market certainty.
- Policies are particularly needed to attract investments in grid transmission and biomass logistics.
- The external costs of using fossil fuels (e.g. human healthcare costs, the effect of greenhouse gas emissions and climate change etc.) on the US macro economy should better be reflected in the overall systems. The environmental costs should be included in the retail price of electricity.
- Fossil fuel or nuclear-based electricity should not financially be supported to the extent that will undermine the immediate effects of renewable energy policies, especially financial incentives. The shale drilling permission that has recently been taken into effect may also slow down the utilization of renewable energy technologies.
- The fluctuations and uncertainties in tax incentives should be reduced, and the subsidies for electricity generation should be distributed equitably. Moreover, a national FIT and RPS should be implemented.

Germany

Germany initiated the development of renewable energy technology for electricity over two decades ago (Hartwig et al., 2014). In 1991, the German government passed the Electricity Feed In Law (Stromeinspeisungsgesetz or StromEinspG), which later evolved into the Renewable Energy Act (Erneuerbare Energien Gesetz) (came into effect in 2000), to promote the feed-in of energy produced by renewable energy technologies into the grid for electricity suppliers (Hartwig et al., 2014). With the Renewable Energy Act, the entire regulatory framework for renewable energy technologies was revised and differentiated tariffs were adopted for each form of renewable energy (Hartwig et al., 2014). As a result of these efforts of the German government to become one of the most energy efficient and environmentally sound economies in the world without compromising the country's affordable energy prices and economic growth, renewable energy use underwent dramatic changes (IEA, 2013b; IEA, 2013c). The share of renewable energy in final energy consumption in Germany increased from around 4% in 2000 to more than 12%, and its share in gross electricity consumption enhanced from around 6% in 2000 to over 25% by 2013 (Blazejcak et al., 2014). In 2000, hydropower constituted the largest part of renew-

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

able generation (60%) followed by wind power (26%) and biomass (13%); whereas in 2013, wind power took the lead (35%), followed by biomass (31%), solar PV (20%) and hydropower (14%) (Blazejcak et al., 2014). On the overall, the share of renewables in the primary energy demand of Germany increased from 1.3% in 1990 to 11.7% in 2013 (Scholz et al., 2014).

The most significant steps that the policy makers have taken are the Energy Concept (Energiewende) (2010) and its energy reforms (2011) (IEA, 2013b; IEA, 2013c). The Energy Concept, which was built on the success of previous policies (especially the Integrated Energy and Climate Programme of 2007), set forth the principles of a long-term, integrated energy pathway to take the country to 2050, placing renewable energy at the center of future supply (IEA, 2013c). Germany's energy goals include the following (IEA, 2013b):

- Reduction in greenhouse gas emissions by 40% by 2020 and by at least 80% by 2050.
- Decrease in primary energy consumption by 20% by 2020 and by 50% by 2050 (base year 2008).
- Increase in the proportion of energy consumption covered by renewables is to rise to 30% by 2030 and to 60% by 2050.

An important issue that has affected Germany's attitude towards renewable energy use is the Fukushima Daiichi nuclear accident in March 2011 (IEA, 2013c; Hartwig et al., 2014). A key feature of the Energy Concept was a proposal to extend the operating lifetime of the German nuclear power fleet by an average of 12 years, therefore postponing the nuclear power phase-out agreed by the former government (IEA 2013c). However, after the Fukushima nuclear disaster, the German Government intensified their efforts towards nuclear phase-out by 2022 starting with the immediate closure of the eight oldest plants (Hartwig et al., 2014; IEA, 2013c). This decision resulted in the adoption of a second package of measures, which completed the Energy concept, to support renewable energy and grid expansion, promote energy efficiency, fund the reforms and reverse the previous decisions to extend the lifetime of the nuclear plants (IEA, 2013c).

In order to follow the developments concerning the use of clean energy, Energy of the Future, a long-term and fact-based monitoring process, was designed to inform the public comprehensively about the restructuring of the energy system, to promote public participation and to increase acceptance of the reforms (IEA, 2013b). It included an annual monitoring report (the first being submitted in December 2012) to outline the general facts and status and a more detailed progress report (to be submitted every three years starting from 2014) to evaluate the future challenges and needs (IEA, 2013b).

Although Germany is one of the leading countries in terms of renewable energy policies, there are still certain issues that need to be addressed. These can be listed as the following (IEA, 2013b; IEA, 2013c; Pregger et al., 2013):

- Continue to increase funding for research, development and deployment (RD&D) to ensure that energy technology innovation will meet the challenges set out in the Energy Concept.
- Further strengthen the function of the co-ordination platform to effectively involve all stakeholders.
- Continue to assess its RD&D challenges and to adjust its RD&D portfolio as national energy policy priorities change.
- Continue efforts in energy education and training to meet future demands for researchers and engineers.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Improve energy statistics where needed because incomplete data on international energy prices and energy consumption in the household, transport and trade sectors can only provide a restricted view.
- The German Renewable Energy Sources Act (EEG) must be preserved in principle for the transformation of the electricity supply. Feed-in tariffs should be kept up-to-date to support technological innovations that reduce costs.
- Introduce non-budgetary subsidy instruments for the expansion of renewables in the heat sector to especially include the existing stock of older buildings.
- Set incentives and specifications in the transportation sector for the further substantial reduction of fuel consumptions of motor cars and utility vehicles. (The further development of electric vehicles and of the public battery-charging infrastructure is needed.)

Turkey

In the last decade, there has been a significant shift in the world toward emerging markets and consequently energy demand; in that, while the developed world used two thirds of world oil in 2000, by 2011 this was split about evenly between developed and developing countries (WEF, 2013). This shift is estimated to continue with virtually all growth from here on being expected in emerging market nations (WEF, 2013), and thus, the energy consumption and production in developing countries have become much more critical. Turkey is one of these developing countries with a substantial amount and wide range of renewable energy sources, and it is located in an advantageous geographical position that enables their effective utilization (Baris & Kucukali, 2012; Benli, 2013; Yuksel & Kaygusuz, 2011). However, because of the rapid increase in the energy consumption (Ozturk et al., 2009) and the inefficient use of resources, Turkey remains to be an energy importing country with more than half of its energy being met externally (Kaya, 2006; Yuksel & Kaygusuz, 2011; Benli, 2013).

The energy consumption in Turkey is constantly increasing due to the economic developments, population growth, increasing urbanization and industrialization (Ozturk et al., 2009; Kotcioğlu, 2011), and thus, it is in a position to import over 70% of its primary energy supply (with oil and natural gas having the biggest shares) (Kaya & Çanka Kılıç, 2012). On the other hand, the primary energy production is increasing and the most significant developments are observed in hydropower, geothermal, solar energy and coal production (Yüksel & Arman, 2014). Despite these developments, the share of renewable energy in electricity generation was only 17.4% by the end of 2008 (Yuksel, 2013). The renewable energy potential in Turkey (hydropower, solar, biomass and wind power) is sufficient to meet the accelerated demand (Kotcioğlu, 2011), but it has not been efficiently utilized, leaving the country with an urgent need for effective energy policies. Ozturk et al. (2009) summarize Turkey's general energy policy as follows:

- Meeting long-term demand using public, private, and foreign capital.
- Accelerating privatization activities in the energy sector.
- Taking into consideration supply costs of energy imports.
- Meeting demand as much as possible through indigenous resources.
- Diversifying energy supplies and avoiding dependence on a single source or country.
- Adding new and renewable sources (geothermal heat, solar, wind, etc.) as soon as possible to the energy supply system.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Ensuring sufficient, reliable and economic energy supplies on time.
- Ensuring energy security of supply.
- Implementing measures for energy efficiency.
- Planning energy R&D activities to meet requirements.
- Minimizing losses in energy production, transmission, distribution and consumption.
- Protecting the environment and public health in the production of energy.

The above-stated principles are also covered in the Strategy Plan 2010-2014, where the following targets are set for 2023-the 100th anniversary of Turkish Republic (the Vision 2023 Programme) (Kabakci & Tanugur, 2010):

- To be able to make complete use of potential of indigenous coal and hydraulic resources.
- To make maximum use of renewable resources.
- To incorporate nuclear energy into electricity generation within the period until 2020.
- To secure rapid and continuous improvement in energy efficiency in a way that parallels EU countries.

In order to make maximum use of renewable resources as stated in the Strategic Plan, all the potential renewable energy types should be utilized. Renewable energy supply in Turkey is mostly hydropower and biomass, but air pollution concerns and deforestation have resulted in a decrease in the biomass use, changing the composition of the renewable energy supply in favor of wind energy (Kotcioğlu, 2011; Toklu, 2013). There is a significant potential for wind power development in Turkey (Kotcioğlu, 2011), which should effectively be utilized in the near future due to the fact that between 22.5TWh and 4 5.0TWh of electricity must be generated from renewable energy sources other than hydropower in the next decade to fill the demand gap (Melikoglu, 2013). It is estimated that this gap can be diminished by wind and solar energy if the investments are carried out as planned and the goals in Vision 2023 agenda can be achieved (Melikoglu, 2013). In its report on Turkish Renewable Energy Policies, International Energy Agency (IEA) has made certain recommendations, which should be taken into consideration to address the above-stated issues. These are (IEA, 2009):

- Continue efforts to ensure a predictable and transparent support framework to attract investments, while creating technology-specific incentives that will decrease over time.
- Design the feed-in tariff to be as flexible and predictable as possible and assess the options to introduce further flexibility in support mechanisms, such as premium on wholesale price.
- Continue efforts to ensure smooth integration of new renewable electricity capacity into the grid.
- Continue efforts to remove non-economic barriers to renewable energy development.
- Consider stronger policy support for the wider use of solar and geothermal heat and biofuels for transport in a sustainable and cost-effective way.
- Increase the focus on the energy efficiency in energy policy making and implementation and monitor the effectiveness of the chosen policies and measures, both in terms of costs and emissions reductions (Kaygusuz & Sari, 2011).
- Expand the partnerships with the private sector through increased use of collaboration for energy R&D.

India

India has the world's fifth-largest electricity generation capacity, which currently stands at 243 GW with a highly diverse power sector, varying from commercial sources like coal, natural gas, hydro, oil and nuclear as well as unconventional sources of energy like solar, wind, bio-gas and agriculture (Novonous, 2014). Nonetheless, the country is facing an emerging supply-demand imbalance situation with the increases in total electricity demand, resulting from industrialization, urbanization, population growth and economic growth (MNRE, 2011; Novonous, 2014). To be able to provide adequate electricity to its population, India needs to more than double its current installed capacity to over 300 GW by 2017, and the demand for oil in 2015 is expected to be 41% higher than in 2007 and almost 150% higher in 2030 (NREL, 2010). There is also a rising concern over climate change (Novonous, 2014). The country currently emits approximately 4% of global greenhouse gas emissions, while its per capita emissions are only one-quarter of the global average and less than one-tenth of those of most developed nations (NREL, 2010). The government has committed to reducing the emissions intensity of its economy to 20%-25% below 2005 levels by 2020 and not exceeding the per capita greenhouse gas emissions of industrialized nations (NREL, 2010). These have made the use of renewable energy inevitable in India, and establishing a sustainable energy base has gained significance since early 1970s (MNRE, 2011).

India has substantial renewable energy sources, including a large land mass that receives among the highest solar irradiation in the world, a long coastline and high wind velocities that provide many opportunities for both land-based and offshore wind farms, significant annual production of biomass, and numerous rivers and waterways that have potential for hydropower (NREL, 2010). Although the total renewable energy potential from various sources in India is 249,188 MW, renewable energy including large hydro constitutes for only 28.8% of overall installed capacity, and the country has been able to achieve only 12.95% of its renewable energy potential as of March 31st, 2014 (Novonous, 2014). The government has set ambitious targets for renewable energy — a doubling of existing renewable energy capacity to 55,000 MW by 2017 (Shrimali et al., 2014). In 1992, the Government of India established the Ministry of New and Renewable Energy (MNRE), the world's first ministry committed to renewable energy, with the aim of expanding contributions of renewable energy in all of India's end-use sectors and undertaking the respective policy and planning activities (NREL, 2010). Moreover, in order to expand the use of renewable energy, certain policies and instruments have been introduced, some of which can be listed as the following (NREL, 2010):

- Electricity Act 2003, which mandates that each State Electricity Regulatory Commission (SERC) establish minimum renewable power purchases; allows for the Central Electricity Regulatory Commission (CERC) to set a preferential tariff for electricity generated from renewable energy technologies; provides open access of the transmission and distribution system to licensed renewable power generators.
- National Electricity Policy 2005, which allows SERCs to establish preferential tariffs for electricity generated from renewable sources.
- National Tariff Policy 2006, which mandates that each SERC specify a renewable purchase obligation (RPO) with distribution companies in a time-bound manner with purchases to be made through a competitive bidding process.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Rajiv Gandhi Grameen Vidyutikaran Yojana (RGGVY) 2005, which supports extension of electricity to all rural and below poverty line households through a 90% subsidy of capital equipment costs for renewable and non-renewable energy systems.
- Eleventh Plan 2007–2012, which establishes a target that 10% of power generating capacity shall be from renewable sources by 2012 (a goal that has already been reached) and supports phasing out of investment-related subsidies in favor of performance-measured incentives.
- National Action Plan on Climate Change (NAPCC) 2008, which aims to promote development goals while addressing greenhouse gases mitigation and climate change adaptation through eight specific missions (including solar energy, energy efficiency, water, sustainable habitat, and related topics).
- Clean Development Mechanism (CDM) of the Kyoto Protocol, which supports the development of renewable energy projects.

Certain recommendations have been made for policy makers concerning more effective utilization and expansion of renewable energy. These can be viewed in Table 6.

Table 6. Renewable energy policy recommendations for India by source

Renewable Energy Source	Recommendations
Wind	• Improve short-term wind forecasting • Adequate Grid Connectivity • Solve institutional inefficiencies • Establish long-term markets for off-shore wind power • Provide flexible financing options to new players
Solar	• Implementation of Domestic Content Regulation (DCR) • Imposition of Anti Dumping Duties to shield local industry from cheap import from China etc. • Proper Enforcement of Solar RPOs • Provide access to low cost funds • Timely Release of Subsidies • Support in accessing/developing new technologies
Small Hydropower	• Speedy implementation of policies by states • R&D activity for provide accurate hydrological and site data • Speedy clearances for small hydro power projects • Provide access to low cost funds • Timely release of Subsidies • Support in accessing/developing new technologies
Biomass/Bagasse Cogeneration	• Creation of biomass/bagasse cogeneration related policies by all states • Setting up of fuel depots • Regularization of feedstock prices and availability • Provide access to low cost funds to new players • Timely release of subsidies • Support in accessing/developing new technologies
Waste	• Creation of Waste to Energy related policies by all states • Setting up of fuel supply chain • Provide access to low cost funds to new players • Support in accessing/developing new technologies • Increase public awareness towards Waste to Energy • Increase FDI in this sector

Novonous, 2014.

DISCUSSIONS

The aim of this section is to elaborate on the relationship between the renewable energy performance of the studied countries with the renewable energy policies and investments, primarily based on the analysis carried out up to this point. The most significant issue that needs to be addressed is that the countries with the highest renewable energy performance have extensively adopted either both (e.g. China, United States) or one of (e.g. Germany) the two main groups of renewable energy support policies, namely regulatory policies and targets and fiscal incentives and public financing (see Table 5). The most commonly used policies in the first group are renewable energy targets, biofuels obligation/mandate, feed-in tariff/premium payment and tendering, respectively. As for the fiscal incentives and public financing, the most frequently observed forms are capital subsidy or rebate; public investment, loans, or grants; and investment or production tax credits, respectively. Among all, renewable energy targets and capital subsidies or rebates are the most broadly used support policies.

Another significant outcome observed in Table 5 is the variety of the renewable energy support policies adopted in India. All of the policy types have been utilized in this country except for reductions, in sales, energy, CO_2, and VAT, and although, it is in the 14th place in the country listing, in terms of the adopted policies, it shares the 2nd place with Italy after the US. This is to indicate that the enactment of the respective laws and regulations does not necessarily lead absolute results. Germany is another example to support this fact because although it is right after the US in the performance list, the variety of the renewable energy policies are far less than those adopted in the US. What makes Germany so successful in the renewable energy arena aside from the fact that it is one of the first countries to have realized the necessity of renewable energy is that there is a fact-based monitoring process, namely the Energy of the Future. This system not only makes sure that the energy reforms are being realized but it promotes public participation and acceptance.

The final issue that needs to be pointed out is necessity of the respective investments. Environmental investments have always been subject to skepticism because their returns cannot be observed in the short-run. However, it can be stated that the top-performing countries are past this issue because global investment in renewable power and fuels (excluding large hydro-electric projects) was $270.2 billion in 2014, nearly 17% higher than the previous year (Frankfurt School-UNEP Centre/BNEF, 2015). The biggest renewable energy investments in 2014 were realized in major economies – with China far out in front at $83.3 billion, the US at the second place with $38.3 billion, and Japan in the third place with $35.7 billion. India was up 14% compared to 2013 at $7.4 billion, and Brazil 93% higher, at $7.6 billion (Frankfurt School-UNEP Centre/BNEF, 2015). The other significant fact is that substantial renewable energy investments have been made in developing countries in 2014, wherein a total of $131.3 billion has been invested, 36% higher than the 2013 figures. On the other hand, the corresponding number is $138.9 billion for developing countries, which is only 3% higher than the previous year. Indonesia, Chile, Mexico, Kenya, South Africa and Turkey were the countries, which made significantly high investments (Frankfurt School-UNEP Centre/BNEF, 2015). Hence, it can clearly be stated that there is a strong relationship between renewable energy investments and how well countries perform in this arena and that developing countries are eager to catch the top-performers in a short amount of time.

CONCLUSION AND FUTURE RESEARCH

The possibility of depletion of fossil fuels in the near future and rising concerns for sustainability have urged countries to consider renewable energy as an alternative energy source. Consequently, governments and global organizations have adopted respective regulations to ensure the production and use of renewable energy and promote the respective new investments. In the light of these developments, this study has been conducted to lay out the current situation of renewable energy use and policies around the world with the ultimate goal of making certain suggestions and pointing out possible solutions in this area. To this end, first, a comparative statistical analysis has been carried out using the geographical coverage OECD has provided. Thus, the countries have been studied under eight groups, namely Africa, Non-OECD Americas, Asia, China, Non-OECD Europe and Eurasia, Middle East, OECD and World Total. Certain descriptive statistics have been provided for this geographical coverage on the share of renewable energy in TPES; individual shares of hydro, geothermal/solar/wind/wave and biofuel/renewable waste; and the distribution of the individual shares (expressed as percentages of total renewables) between 2008 and 2012. The data used in this analysis have been gathered from the IEA yearly "Renewables Information" reports (2010-2014 Editions). Following the statistical analysis on the renewable energy use, countries have been listed according to their renewable energy performance using a simple ranking methodology, using 17 of the indicators and the data provided by REN21. Then, the overall renewable energy policies of the EU and OECD and those of certain selected countries have been investigated. The selected countries include the top three renewable energy performers with respect to the ranking carried out, which are China, US and Germany in addition to Turkey and Spain. Turkey has been analyzed in terms of renewable energy policies because it is a developing country with a substantial amount and wide range of renewable energy sources but is still importing over 70% of its primary energy supply. As for India, it has the fifth-largest electricity generation capacity in the world with substantial sources of renewable energy and a broad range of renewable energy policies. Following the individual analyses of policies, their relationship with renewable energy performance has been elaborated. Renewable energy investments have also been studied in the discussions section. The most significant results of the study can briefly be summarized as the following:

- Except for Non-OECD Europe and Eurasia and the Middle East, biofuels and renewable wastes constitute the highest percentage of renewables throughout the world. This is especially significant for Africa, Asia and the World Total.
- The investigation of the geographical groupings in terms of the distribution of individual renewable sources between 2008 and 2012, a steady behavior has been observed except for the Middle East, where the shares of individual renewable energy sources have undergone significant changes through the respective years.
- According to the renewable energy performance ranking, the top five countries have been determined as China, US, Germany, Brazil and Spain.
- The countries with the highest renewable energy performance have extensively adopted regulatory policies and targets and/or fiscal incentives and public financing.
- Renewable energy targets and capital subsidies or rebates are the most broadly used support policies.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

- It has been observed that the key to renewable energy performance is not only adopting the respective policies but to monitor their effective use. This promotes public participation and acceptance as well, which are significant for any sustainability action.
- Substantial energy investments have been made in 2014 in both developing and developed countries. This is important because it points out to the fact that the usual skepticism concerning the necessity of environmental investments has been overcome on a global scale.

This study has certain limitations in that a more extensive analysis has to be carried out on the individual renewable energy performance of the world countries. This poses as the most promising area of future research. Data mining techniques can be used to analyze the renewable energy performance based on indicators that include but are not limited to those used in this study. Moreover, formal quantitative analysis techniques should be used to investigate how renewable energy performance is affected by the respective policies and investments. In relation to investments, quantitative models on cost-benefit analysis are also needed. Another issue is the significant shift in the world toward emerging markets. Developing countries have become just as or even more critical (because this shift is estimated to continue) actors in terms of renewable energy use and investments. Thus, their current and future roles should be studied in detail. One final remark is the necessity of joint actions taken in renewable energy use and policies. An example of this is the recent cooperation between China and the US, setting a target for decreasing carbon emissions. In conclusion, it can be stated that renewable energy is wide open for future research not only in terms of technological developments but also concerning its use and respective policies.

KEY TERMS AND DEFINITIONS

Capital Subsidy: A subsidy that covers a share of the upfront capital cost of an asset (such as a solar water heater).

Feed-in Premium: A type of feed-in policy, where producers of electricity from renewable sources sell electricity at market prices, and a premium is added to the market price to compensate for higher costs and thus to mitigate financial risks of renewables production.

Feed-in Tariff: The basic form of feed-in policies, where a minimum price (tariff) per unit (normally kWh or MWh) is guaranteed over a stated fixed-term period when electricity can be sold and fed into the electricity network, normally with priority or guaranteed grid access and dispatch.

Fiscal Incentive: An economic incentive that provides individuals, households, or companies with a reduction in their contribution to the public treasury via income or other taxes, or with direct payments from the public treasury in the form of rebates or grants.

Investment Tax Credit: A taxation measure that allows investments in renewable energy to be fully or partially deducted from the tax obligations or income of a project developer, industry, building owner, etc.

Mandate/Obligation: A measure that requires designated parties (consumers, suppliers, generators) to meet a minimum, and often gradually increasing, target for renewable energy, such as a percentage of total supply or a stated amount of capacity.

Net Metering: A regulated arrangement in which utility customers who have installed their own generating systems pay only for the net electricity delivered from the utility (total consumption minus on-site self-generation).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Production Tax Credit: A taxation measure that provides the investor or owner of a qualifying property or facility with an annual tax credit based on the amount of renewable energy (electricity, heat, or biofuel) generated by that facility.

Renewable Energy Certificate (REC): A certificate awarded to certify the generation of one unit of renewable energy (typically 1 MWh of electricity but also less commonly of heat).

Renewable Energy Target: An official commitment, plan, or goal set by a government (at the local, state, national, or regional level) to achieve a certain amount of renewable energy by a future date.

Renewable Portfolio Standard (RPS): An obligation placed by a government on a utility company, group of companies, or consumers to provide or use a predetermined minimum renewable share of installed capacity, or of electricity or heat generated or sold.[8]

ENDNOTES

1 World Marine and Aviation Bunkers have not been included in the analysis because of the lack of data.

2 Because only aggregated data were available until 2012, the data for Sudan also include South Sudan.

3 *In the Renewables Information (2010 Edition)*, the data for the year 2008 have been provided for Non-OECD Europe and Former Soviet Union separately. Starting from the 2011 Edition (2009 data), these have been combined under Non-OECD Europe and Eurasia except for Estonia and Slovenia. Estonia and Slovenia, which were included in Former Soviet Union and Non-OECD Europe, respectively, in the 2008 data, were both included in OECD Europe starting from the 2009 data.

4 Footnote by Turkey: *The information … with reference to "Cyprus" relates to the southern part of the Island. There is no single authority representing both Turkish and Greek Cypriot people on the Island. Turkey recognises the Turkish Republic of Northern Cyprus (TRNC). Until a lasting and equitable solution is found within the context of the United Nations, Turkey shall preserve its position concerning the "Cyprus issue"*. Footnote by all the European Union Member States of the OECD and the European Union: *The Republic of Cyprus is recognised by all members of the United Nations with the exception of Turkey. The information … relates to the area under the effective control of the Government of the Republic of Cyprus.*

5 Data for Serbia include Montenegro until 2004 and Kosovo until 1999.

6 Estonia and Slovenia are included starting in 1990. Prior to 1990, data for Estonia are included in Former Soviet Union and data for Slovenia in Former Yugoslavia in the publication *Energy Statistics of Non-OECD Countries*.

7 The statistical data for Israel are supplied by and under the responsibility of the relevant Israeli authorities. The use of such data by the OECD is without prejudice to the status of the Golan Heights, East Jerusalem and Israeli settlements in the West Bank under the terms of international law.

8 The definitions have been taken from IEA *Renewables Information 2014* Report.

Chapter 26
How to Manage Sustainability: A Framework for Corporate Sustainability Tools

Yasemin Sen
Istanbul University, Turkey

ABSTRACT

Sustainability has increasingly become a critical issue for wellbeing of human life and maintaining sustainability is responsibility of many parties such as individuals, corporations or governments. When taking its social, economical, or environmental impacts into consideration, maybe the most important player in that arena is organizations and in order to take the necessary actions about sustainability, first of all a common understanding of the topic is needed. For this reason, in this chapter it is aimed to create awareness about sustainability issue and commonly used tools for management of it. In this context, definition of sustainability and four corporate sustainability management tools (Environmental Management System - EMS, Sustainable Value Stream Mapping - Sus-VSM, Total Quality Environmental Management - TQEM and Sustainable Balanced Score Card - SBSC) have been explained.

INTRODUCTION

Sustainability is a new paradigm which came into prominence in the near past and since it is critical for the Universe, maintaining the necessary conditions for sustainability - from a single individual to businesses - is the responsibility of every entity in the World. Then the question is this; why is sustainability so much important today? Especially after the industrialization, in centuries, CO_2 levels in the atmosphere has been increasing and causing temperatures to rise, oceans to acidify, ice caps to melt (Watson, 2012:viii). Therefore, unless necessary actions are taken, the only inheritance to our next generations will be unfortunately a ruined ecology and all of us know what this means for life.

More generally the term “sustainability” means to endure. The term is used in different areas such as sustainable city, sustainable food, sustainable agriculture etc. (Young & Dhanda, 2013:3). Although it is used in different areas, sustainability is related with the quality of life and long lasting resources. Also from the point of environmental science, the term is used for the quality of not being harmful to

environment or depleting natural resources, and thereby supporting long-term ecological balance (www.dictionary.com).

In today's highly industrialized world, one of the most critical actors in sustainability issue is obviously businesses. For this reason, corporate sustainability takes the attention of many scholars. Corporate sustainability incorporates a societal three dimensional goal of sustainability for corporations, governments and civil society. And these three dimensions comprised of economic, environmental and social facets (Wilson, 2003:1). This is also called as Triple Bottom Line (TBL) and for corporate sustainability; companies need to measure their impacts not only on the bottom line (profits), but also on the community and the environment as well. (Young and Dhanda, 2013:3).

Since globally people desire to live in a more humane, caring, equitable environment with prosperity, attention of scholars and the number of sustainability researches are increasing every day (Ikediashi, Ogunlana & Ujene, 2014:305). Parallel to this global tendency, colleges and institutions are opening sustainability courses in order to increase the awareness about the topic (Sisaye, 2013:224). With these developments, businesses are facing some pressures internally and externally about their responsibilities in social and environmental issues (Winter & Knemeyer, 2013:23) and as a result of this, a movement towards a sustainable environment is emerging.

In order to manage sustainability, organizations need to control their operations and link this with their strategies. Therefore, mechanisms to achieve sustainability have critical importance. For this aim organizations can use some tools to manage corporate sustainability. In this context, commonly used sustainability tools can be mainly classified under the four headings as environmental management system (EMS), total quality environmental management (TQEM), sustainable value stream mapping (Sus-VSM) and sustainability balanced score card (SBSC) (Young & Dhanda, 2013:3). In order to apply these tools based on their needs, businesses need to know the necessary basic knowledge about corporate sustainability tools. Therefore, mainly the basic knowledge about sustainability and commonly used tools for managing corporate sustainability has been presented in this chapter.

More specifically, readers of this chapter will;

- Get basic knowledge about definition and history of sustainability
- Learn different usages of the term in different areas
- Learn about sustainable development and triple bottom line
- Get awareness about importance of the topic
- Dive into topic with a corporation view point and
- Learn commonly used corporate sustainability management tools.

BACKGROUND

Although the term sustainability has a long history, it has been getting more and more importance and attention from many scholars and business people for approximately past a few years (Chowdhury, 2013:603). Some of the main reasons of this increasing awareness about sustainability are increased research and investigation on environmental problems caused by climate changes in recent years and several calls on international platforms for consciousness about the topic (Ikediashi, Ogunlana & Ujene, 2014:305). Actually origins of sustainability can be traced back to centuries ago (Jones et.al., 2013:90),

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

but at that time the term wasn't mentioned with its today's naming and it was explained in the context of another issues such as environmentalism, economic theory, scarce resources etc.

One of the most important milestones of sustainability history has been the United Nation's Conference on Human Environment (UNCHE) held in Stockholm in 1972 (Balbinot & Borim-De-Souza, 2012:159). In this conference, the attention has been taken to the need of a common understanding and principles guiding and inspiring people worldwide for preservation and enhancement of human environment (Mebratu 1998:502). Another important movement has occurred in the year of 1980. At that time World Conservation Strategy formulated by joint effort of The World Wildlife Fund (WWF), UNEPR and International Union for the Conservation of Nature (IUCN) has been launched internationally. This was a starting point for the introduction of sustainable development (Balbinot & Borim-De-Souza, 2012:159). However, as a term in real sense, the most widely used definition of sustainable development has been introduced by The World Commission on Environment and Development (WCED) in 1987. The Commission also called as Brundtland Commission issued a report entitled "our common future" and in this report sustainable development has been defined as "using resources to meet the needs of the present without compromising the ability of future generations to meet their own needs." (Winter & Knemeyer, 2013:23). It has been a large scope definition (Westelius, Westelius & Brytting, 2013:162) and since it can be interpreted from many different aspects, the definition of Brundtland Commission has been accepted widely (Mebratu, 1998:502). After WCED Report, In 1992 Rio Conference (Earth Summit) also known as UN Conference on Environment and Development (UNCED) has been held (Mebratu, 1998:502) and in this conference attention has been taken to the issue of the need for urgent national actions for sustainable development (Hamelin & Nwankwo, 2013:261). Especially after WCED to today, sustainability and sustainable development issue has gained momentum in worldwide and it has also taken a great academic attention. Recently (2015), United Nation's global summit for the adoption of post-2015 development agenda and sustainable development goals has been held in New York with the participation of relevant stakeholders including parliaments, businesses and civil society organizations. On the summit, 17 sustainable development goals and related 169 targets which will stimulate actions in critically important areas for humanity and the planet have been agreed upon and a Universal call has been made for actions supporting the transformation into a better World (UN post-2015 Agenda, September 2015; https://sustainabledevelopment.un.org).

With increased interest in the topic, many different definitions of sustainability have been proposed by different scholars and therefore there is no one generally accepted definition (Hockerts, 2001:1; Ratiu & Anderson, 2014:162; Joseph, 2013:441). The term is most commonly used as equivalent of the terms such as "long term", "durable" (Ehnert, 2006:3) or "environmentally sensitive" and also as stated earlier, it has been applied to different areas such as construction (Yates, 2013:281), human resource management (Ardichvili, 2012:876), strategic management (Hulgen & Mirze, 2004:30) or supply chain management (Winter & Knemeyer, 2013:19). For example, sustainable construction is related with maintaining a healthy built environment and this can be achieved by efficiency in resource consumption, using recyclable materials, eliminating toxics and a quality focus (Yates, 2013:283). Similarly, sustainable supply chain management is related with the topics such as green purchasing, purchasing ethics, remanufacturing, safety management or carbon footprints and is mainly an extension of sustainability to whole supply chain (Winter & Knemeyer, 2013:19). On the other hand, sustainability strategic management is associated with long lasting competitive advantage (Hulgen & Mirze, 2004:30) whereas sustainable human resource management is related with human resources practices which support sustainable development (Becker, 2011 cited in Ardichvili 2012:875-876).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Although most of the time sustainability and sustainable development has been used interchangeably, there are scholars who take sustainable development as a broader concept than sustainability. Also based on another view, sustainability is an ending point of sustainable development process (Jones et.al., 2013:90). Whether it is an end point or a process, sustainability is related with operational drivers of profitability and their relationships to people and environment we all live in (Winter & Knemeyer 2013:19). In that vein, in a definition sustainability was associated with exploitation of natural resources without harmful effects (Ikediashi, Ogunlana & Ujene, 2014:305). Besides, in another definition made by Environmental Protection Agency (EPA), social, economic and environmental aspects were mentioned, the harmony and balance between these three aspects were stressed (Chowdhury, 2013:603). As it can also be interpreted from the definition of WCED (WCED Report, 1987) sustainable development is not only an environmental conservation, more comprehensively it is also related with quality of life (Joseph, 2013:442) and with mindful human activities for this aim (Yates 2013:283). In this chapter also, the term sustainability is used as broader as and interchangeably with sustainable development.

In order to achieve sustainable development, there are three pillars that should be taken into consideration (Chowdhury, 2013:603). These are economic, social and environmental aspects of sustainability and are also called as triple bottom line (TBL/3BL) (Dos Santos, Svensson & Padin, 2013:104). TBL is related with environmental, social or economic value added (or otherwise harmful effects on these aspects) and also there are different namings about these aspects such as profits, planet, people (3P) or economics, environment and equity (3E) in the literature. Although there are nuances between these classifications, their contents are consistent (Winter & Knemeyer 2013:22) and the common idea is that there should be a balanced attention to all these three elements (Ardichvili, 2012:875).

As proposed by Docherty et.al. (2008), sustainability can be investigated in three levels as individual, organizational and societal (p.10). For sustainability to occur, each level has its own responsibilities and has to work in harmony for this common aim. From the point of organizations, the important question is; "what is the role of business when striving towards sustainable development?" (Bieker, 2002:5). Sustainability efforts are generally based on managing impacts on Earth's life, eco-systems, its stakeholders (Dos Santos, Svensson & Padin, 2013:104) and for sustainable development; necessary systems and services that are economically, environmentally and socially sustainable are needed to be built in organizations (Chowdhury, 2013:603). Corporate sustainability management has to focus on innovation, stakeholders' requirements and also on efficiency as well as on effectiveness of business processes (Baumgartner, 2014:260). Therefore, a system approach is needed for the management of corporate sustainability (Azapagic, 2003:304).

When it comes to three pillars of sustainability, economic aspect is defined as "the degree to which an organization actively and constructively deploys its resources to support the socio-economic well-being of its surrounding community" (Jones et.al., 2013:90) and it is also related with being a successful and competitive organization in terms of efficient use of resources and achievement of profitability (Winter & Knemeyer 2013:24). Although this dimension of sustainability is the most focused issue, other dimensions of sustainability are also needed to be considered. Environmental aspect is related with taking into consideration environmental effects of business operations and taking necessary actions for preservation of natural resources (Ikediashi, Ogunlana & Ujene, 2014:305). On the other hand, social aspect (as stated by Katsoulakos & Kotsoulakos) is related with "the impact of products or operations on human rights, labor, health, safety, regional development and other community concerns" (Ikediashi, Ogunlana & Ujene, 2014:305). As well as being economic units, businesses are social entities and in

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

order to achieve sustainable development, they should also align their operations by considering impacts on social environment.

Besides being a responsibility, sustainability management provides some advantages to organizations. Researches have showed that corporate value is positively related with successful implementation of social and environmental strategy. Also, an improved sustainability performance may increase employee satisfaction and productivity, lower costs and improve image and reputation of the company. In this way, these organizations become demanded by customers, shareholders, employees and communities around them (Epstein & Wisner, 2001:9-10).

As it is seen from aforementioned explanations, organizations have responsibilities for sustainability and sustainability management also creates many advantages for them. Therefore, organizations need to create some mechanisms to manage corporate sustainability. In this context, there are some commonly used tools to achieve corporate sustainability and these corporate sustainability tools will be explained in detail in the next section.

SUSTAINABILITY MANAGEMENT TOOLS

Increasing global interest on sustainable development has resulted in growing needs of managing sustainable operations in organizations. Therefore, organizations have adopted some management tools to achieve a better performance on sustainable development issue. In this context, four commonly used sustainability tools - environmental management system (EMS), Total Quality Environmental Management (TQEM), Sustainable Value Stream Mapping (Sus-VSM), Sustainability Balanced Scorecard (SBSC) - have been explained in the subsequent sections.

Environmental Management System (EMS)

In recent years, industrial globalization has taken place and this has created important effects on environment (Gonzales, Sarkis & Adenso-Diaz, 2008: 1034) and as a result, increasing need of protecting the environment from industrial pollution has made maintaining sustainable operations an inevitable goal rather than an option for organizations (Alberti et.al, 2010:4455). Therefore, more and more organizations have become to search new ways in order to overcome environmental sustainability issue (Zutshi & Sohal, 2004:336) and they have tried to adopt and embodied green solutions into their business operations (Gonzales, Sarkis & Adenso-Diaz, 2008:1022). One example of a widely used tool among organizations for maintaining sustainable development is the Environmental Management System (EMS) (Szekely & Strebel, 2013:470). Environmental Management System (EMS) is a set of rational methodologies for the management of all activities regarding environmental aspects (Alberti et.al, 2010:4455). It requires considering environmental issues (Darnall & Edwards, 2006:303) and incorporates with a philosophy behind it. EMSs can be formal or informal which can also be classified as certified or non-certified. Although EMS can be applied as a non-certified management system, there are also some voluntary certification schemes such as EMAS (Eco-management and Audit Scheme) and ISO 14001 for providing an opportunity to organizations for improving their environmental performance (Iraldo, Testa & Frey, 2009:1444). While certified EMS provides a framework for stages of EMS implementation, non-certified EMS has more flexibility in execution (Darnall & Edwards, 2006:303). However, regardless of the fact that it is certified or non-certified, EMS needs a systematic approach and commitment throughout the

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

organization to implement (Iraldo, Testa & Frey, 2009:1444). Organizations adopting an EMS, develop an environmental policy, make planning in order to reduce their harmful effects on the environment, set objectives accordingly, make the necessary controlling and take corrective actions in a systematic manner in order to evaluate and manage their effects on natural environment (Darnall & Edwards, 2006:30). Deming's continuous improvement model (PDCA, Plan - Do - Check - Act Cycle) provides a base for implementation of environmental management system (Darnall & Edwards, 2006:302). Here it can be said that planning has a critical role in EMS process. But, in order to implement such a system, first of all organization should realize the need for it. Therefore, awareness of an EMS need can be thought as a pre-stage of environmental management system implementation process (Kirkland and Thompson, 1999:131). This need can arise from different reasons which can also be thought as driving forces of EMS implementation. It can be a social driver such as expectations of public, a financial driver such as concern of credit ratings or an organizational sensitivity towards natural environment (Zutshi & Sohal, 2004:337). When it comes to adoption process, it can be classified under five main stages as environmental policy, planning, implementation and operation, checking and management review (ISO:14001:2004). Environmental policy stage is related with commitment to the system. In this stage, organization states its values, viewpoint and philosophy about continual environmental performance. In planning stage, organization determines goals based on its environmental policy. In the implementation stage, in order to achieve these environmental goals, organization works on the necessary management structure (Darnall & Edwards, 2006:303). In this context, many operational issues are held such as allocation of resources, training of workers etc. (Iraldo, Testa & Frey, 2009:1445). After implementation, it is important to control activities. If there is something which is incompatible with goals, the necessary actions should be taken. Therefore, in the fourth stage, monitoring and correction plays a critical role. In the final stage (management review), based on continuing environmental operations, organization may revise its goals and policies (Darnall & Edwards, 2006:303). In this way the process goes on and on as a continuous environmental improvement. Ricoh group which is an office automation equipments company can be given as an example of environmental management system. The group does business worldwide (Japan, Americas, Europe/Middle East/Africa and Asia/Pacific/China) and reduces its environmental impact on a global scale (Nakagawa, 2001:499). For management of environmental impact, Ricoh uses PDCA (Plan-Do-Check-Act) cycle. In that vein, the company starts the process by preparing an environmental action plan (plan). Since selection of key areas are important in preparing such a plan, areas with high importance both for stakeholders and Ricoh itself are determined with materiality matrix and based on the selected key areas, the necessary improvements are executed (do). Ricoh knows that controlling has a critical role for the success of this process. Top management supports it and with an internal control system, developmental areas are identified (check). In that way continuous improvement is ensured (Act) (Ricoh Group Sustainability Report, 2014).

Although adoption of an environmental management system is costly, it has many advantages as well. It creates public trust toward organization. It prevents harmful effects of organization on natural environment by reducing waste and provides economic or non-economic other advantages (such as good company image, increasing resource efficiency). However, it shouldn't be forgotten that a successful implementation requires time, investment and patience (Alberti et.al, 2010:4463,4465). Therefore, being aware of this fact and acting accordingly is important for a successful implementation process.

Total Quality Environmental Management (TQEM)

Another sustainability management tool for businesses is Total Quality Environmental Management (TQEM). TQEM concept has been promoted as an extension of Total Quality Management by a group of leading businesses which constitutes GEMI (Global Environmental Management Initiative) (Hanna and Newman, 1995:44). GEMI which includes companies such as Procter and Gamble, AT&T and IBM have stressed the integration of TQM methods with environmental management practices. There are parallels between TQM and TQEM, and it is argued that TQM principles /quality improvement approaches can be applied to Total Quality Environmental Management (Chandrashekar, Dougless & Avery, 1999:1).

In general, the term "quality" is related with understanding, meeting or even exceeding customer needs and based on these needs, designing products/services which satisfy customers. (Hanna and Newman, 1995:43). On the other hand, total quality management is related with ensuring quality throughout the organization and continuously improving business processes to maintain this. From top to bottom in the hierarchy, everyone's participation and a supporting culture are needed for a successful total quality management (Madu, 1998:3). The same idea is also valid for total quality environmental management. In today, environmental concerns of businesses are also among needs/expectations of customers and in order to satisfy these customers, businesses need to improve their processes towards a better environmental performance.

Like emergence of total quality management with increasing quality expectations of customers in 1950s, environmental management has also emerged with awareness of environmental issues and green movement in 1990s (Hanna & Newman, 1995:41). TQM has aimed creating a culture in which all waste is eliminated, zero defects achieved, a system approach is applied and customer expectations are met with continuous improvement. Therefore, TQM reflects a management philosophy and uses lots of techniques for quality improvement such as Pareto diagrams, control charts or cause & effect (fishbone) diagrams with the idea of doing the right thing at the first time. Similarly, Total Quality Environmental Management (TQEM) involves with taking a holistic environmental responsibility in all business operations (Sammalisto, 2001:47) and it is based on continuous improvement (Del Brio et.al, 2001:495). It has been defined as "an economically driven, system wide and integrated approach to the reduction and elimination of all waste streams associated with the design, manufacture, use and/or disposal of products or materials." (Curkovic, Sroufe & Landeros, 2008:94). Therefore, TQEM is a proactive way of environmental management and it is more than compliance to environmental regulations (Griffiths & Petrick, 2001:1575).

TQEM emphasizes four basic principles as customer orientation, continuous improvement, doing the job right at the first time and a system approach to work (Chandrashekar, Dougless & Avery, 1999:1; Sammalisto, 2001:48). But prior to all these principles, maybe the most important thing which is also embedded with other principles can be said to be top management. Management is the key for TQEM to work and high levels of management commitment and support are needed for implementation of all these principles (Sammalisto, 2001:49). For the success of TQEM, there should be a link between environmental practices and corporate strategy and this link can be formed by programs supported and led by top management (Curkovic, Sroufe & Landeros, 2008:96). Once management forms this link, then other principles can be applied accordingly. As listed above, one of the most important principles in TQEM is *customer orientation* (Sammalisto, 2001:48). In traditional view of marketing, customer orientation is defined in terms of meeting the customer expectations of product/service performance, quality, price and value. In today, environmental performance of businesses has also become an ex-

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

pectation of customers (Chandrashekar, Dougless & Avery, 1999:2) and therefore satisfying customer needs now includes providing product/services which does not harm the environment (Sammalisto, 2001:48). Here, it should also be noted that besides customers, other stakeholders' satisfaction (such as shareholders', regulatory agencies' and the community's) are also among the factors that should be taken into consideration for customer orientation principle of businesses while applying TQEM (Affisco, 1998:390). Other principle of TQEM is *continuous improvement*. Continuous improvement is important both for customer satisfaction and business development (Sammalisto, 2001:49). It is related with continuously searching for better ways of environmental management. In this context, business processes are regularly controlled, changes are observed and necessary actions are taken for development (Sammalisto, 2001:48). For environmental continuous improvement, businesses utilize similar quality improvement techniques as of TQM. Pareto analysis, cause-and-effect diagrams, flow diagrams can be listed as examples of these techniques (May & Flannery, 1995:29). Although these techniques are useful, involvement of all employees is also needed for continuous improvement. For this reason, empowerment and teamwork are also important (Sammalisto, 2001:48,49). Another important principle for TQEM is *doing the job right at the first time*. This principle is related with prevention and therefore requires regular control of processes. Here the main idea is not detecting defects but taking the necessary actions to reduce or minimize waste before occurrence. The cost of failure (whether it is internal or external) is most of the time higher than prevention costs. Therefore, TQEM requires designing and planning the system accordingly (Curkovic, Sroufe & Landeros, 2008:98,99). As well as principles of customer orientation, continuous improvement and doing the job right at the first time, one another critical principle of TQEM is the *system approach*. As it is stated before, TQEM needs a holistic viewpoint and this holism can only be achieved through the system approach (May & Flannery, 1995:29). In order to increase environmental performance, an organization wide effort is needed and environmental thinking should be incorporated into every aspect of business operations (Jayathirtha, 2001:245). There should be a clear direction and all internal processes should be designed accordingly. Rather than focusing on one point, the big picture should be seen. Therefore, system approach is critical for a successful TQEM and it provides integration between all these principles.

Eastman Kodak Company, which is a world leader in the development, manufacture and marketing of both conventional and electronic imaging technology, is one of the companies using TQEM successfully. Based on the TQM principles, the company has prepared a TQEM matrix with seven categories (leadership, information & analysis, strategic planning, human resources, quality assurance of environmental performance, environmental results and customer/stakeholder satisfaction) and assigned weights to these categories. For these categories, TQEM objectives have been set and it was ensured that the matrix system has been understood and accepted by all participant departments. This made it an organization wide process. Although at first there were confusion and resistance, in a short time it turned into commitment to the system. In time, TQEM scores of each category has increased dramatically and also environmental performance of the company has improved (Lave, Conway-Schempf & Horvath, 1997).

Total Quality Environmental Management aims reducing waste, designing products with minimal environmental effect, creating environmental awareness among employees and within community (Jayathirtha, 2001:246), and in this way increasing environmental performance of businesses. With green movement and the increasing concern for environment, environmental excellence has started to be seen as an important source of competitive advantage (Hanna and Newman, 1995:38). Most environmental issues are related with internal processes and making improvements result in lower costs and reduce environmental impact (Chandrashekar, Dougless & Avery, 1999:1). Many businesses using TQEM are

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

producing higher quality, environment friendly products with environmentally sound processes and as a result, improving their productivity (Hanna & Newman, 1995:49). Although returns can take time, environmental programs pay for themselves (Chandrashekar, Dougless & Avery, 1999:1) and therefore in the long run create advantages for businesses. However, in order to benefit from these advantages, management and employees should believe in TQEM and exert effort accordingly. TQEM is a holistic environmental management tool and needs structural, cultural changes enabling employees to take on greater responsibilities in solving problems. Therefore it will not work if applied just for compliance to environmental regulations (Griffiths & Petrick, 2001:1576). Mistrust or suspicion towards TQEM are main obstacles that should be overcame by businesses (Chandrashekar, Dougless & Avery, 1999:12) and as it should be in other corporate sustainability tools, management should be patient about its returns in also TQEM.

Sustainable Value Stream Mapping (Sus-VSM)

Another sustainability management tool is sustainable value stream mapping (Sus-VSM) and this tool of sustainability is based on the conventional value stream mapping tool which is used in lean manufacturing (Thorsen, 2005:2). Lean manufacturing is a systematic approach which aims determining and eliminating all wastes for improving customer value (Seth, Seth & Goel, 2008:532) and it has derived mostly from Toyota Production System (TPS) during 1990s (Faulkner, Templeton, Gullett & Badurdeen, 2012:815). Toyota Production System aims reducing the time spent between an order placed and delivery made by eliminating wastes (Norton & Fearne, 2009:3). According to this system these wastes (which are not contribute to the value of the product) are called as "muda" and listed as follows (Ohno 2010:62);

1. Waste of over production.
2. Waste of time on hand (waiting).
3. Waste of transportation.
4. Waste of processing itself.
5. Waste of stock on hand (Inventory).
6. Waste of movement.
7. Waste of making defective products.

All these wastes are unnecessary and non-value adding, therefore it creates additional cost and lowers productivity (Norton & Fearne, 2009:4). According to the lean paradigm which has been proposed by Womack and Jones, in order to eliminate waste, investigation of the value stream is important and a value stream is defined as "all the actions currently required to bring a product through the main flows essential to every product:

1. The production flow from raw materials to the customers, and
2. The design flow from concept to launch" (Rother & Shook, 2009:1).

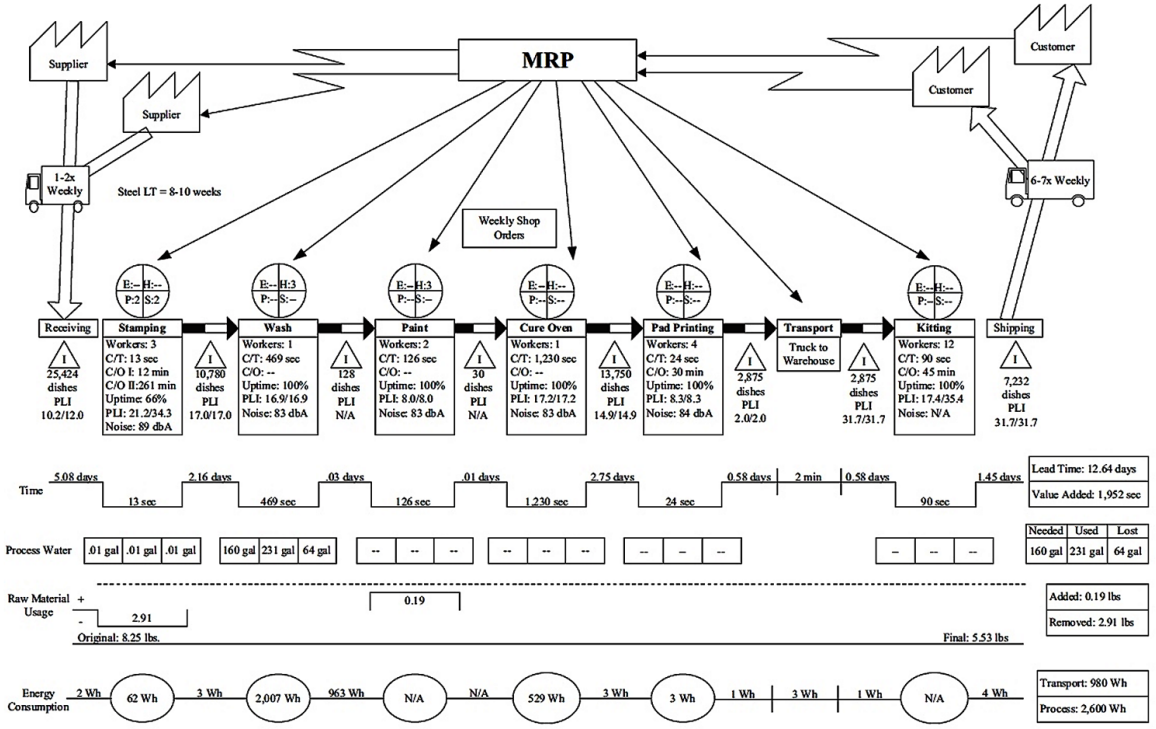
In a value stream there are three kinds of activities. These activities can be value adding activities (e.g.sub-assembly of parts), non-value adding but unavoidable activities (e.g. walking long distances to pick up parts) and non-value adding activities which are avoidable (e.g. waiting time). In order to increase customer value, these avoidable non-value adding activities should be removed from the process

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

(Womack & Jones, 2003:20; Seth et.al.,2008:538). For this reason, conventional value stream mapping (VSM) is a widely used tool in lean manufacturing to determine wastes which will be eliminated by continuous improvement (Faulkner & Badurdeen, 2014:16). Value stream mapping visualizes the wastes in a manufacturing system and provides an insight for future improvements (Brown, Amundson & Badurdeen, 2014:164). In order to do that, VSM draws a product's (or a product family's) manufacturing life-cycle that identifies each phase throughout the production process and by taking all production phases into consideration, it provides a holistic view (Lovelle, 2001:28). The value stream map is a pencil & paper tool, and composed of simple symbols and stream lines (Li, Cao & Pan, 2012:1105). Therefore, it provides a simple communication of information and shows sources of wastes (Brown et.al, 2014:165). However, it can draw the value stream either on factory level or as an extended VSM, on whole supply chain level (Torres & Gati, 2009:1690) and in the second situation (if it is an extended VSM), additional information is needed to be obtained from outside parties.

As it is used for lean manufacturing, value stream mapping is a potential tool to be used also for sustainable manufacturing. In recent years, sustainable manufacturing has gained more importance and the lean manufacturing practices have increasingly being used for sustainable production (Faulkner & Badurdeen, 2014:8). The United States Department of Commerce (US DOC) defines sustainable manufacturing as "the creation of manufactured products which use processes that minimize negative environmental impacts, conserve energy and natural resources, are safe for employees, communities, and consumers and are economically sound" (Faulkner et.al.,2012:815). As it is seen from the definition, sustainable manufacturing includes economical, environmental and societal aspects. On the other hand, lean manufacturing targets only economical waste (mostly based on time, e.g. lead time, cycle time). Therefore, sustainable manufacturing needs a more holistic view which captures all supply chain. Since conventional value stream mapping does not have environmental and societal metrics, there has been a need for an improved VSM which includes additional metrics (Faulkner & Badurdeen, 2014:9). For this reason, attempts for an improved VSM which uses additional metrics (namely environmental and societal) have emerged (Sparks & Badurdeen, 2014:1). But these early attempts of sustainable value stream mapping have been mostly based on environmental metrics (Faulkner & Badurdeen, 2014:8). In this context, US Environmental Protection Agency (EPA) has developed a lean and environmental toolkit (Faulkner et.al.,2012:815) and has defined environmental wastes as "any unnecessary use of resources, or substance released to the air, water or land that could harm human health or the environment". In this lean and environmental toolkit, water usage has been added as an environmental metric (Li et.al., 2012:1103) and in this way, lean implementation and environmental performance has been integrated (Norton & Fearne, 2009:8). EPA has also developed another toolkit. This lean and energy toolkit has been designed to track energy consumption and efficiency. Although these two toolkits are useful, neither of them has taken societal metrics into consideration (Sparks & Badurdeen, 2014:2). After EPA's toolkits, an environmental value stream mapping (E-VSM) tool has been developed by Torres and Gati (Torres & Gati, 2009:1689). In E-VSM, water usage metrics have been used in the form of different ways of water lost. Therefore, this tool has been provided a more detailed investigation and it has been an extended version of EPA's lean and environment toolkit (Sparks & Badurdeen, 2014:2). But still societal metrics were not taken into consideration. Later, Simon and Mason have developed the sustainable value stream mapping tool (SVSM). In this tool, in addition to value added time, greenhouse gasses and CO_2 emissions have been investigated. Still there was no societal metrics considered but here it was assumed that used metrics are indirectly related with societal issues (Faulkner et.al.,2012:816). On the other hand, Norton and Fearne have extended SVSM by adding additional metrics developed by Norton and created

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use



sustainable value chain mapping (SVCM) tool. For metrics selection, UK Department for Environment, Food and Rural Affairs (DEFRA) has recommended some basic environmental performance indicators (EPIs) as waste, GHG emissions and water use. Other EPIs were also suggested to be selected with the recommendation of relevant industry or trade organizations (Norton & Fearne, 2009:11-12). There was still a need for comprehensive evaluation of multiple metrics including societal aspects. Based on this need, University of Kentucky (UK) project team has worked with National Institute of Standards and Technology (NIST) and developed more than 50 metrics. Later on, by using some of these metrics developed, a comprehensive sustainable value stream mapping tool (Sus-VSM) has been proposed by Faulkner et.al. (Faulkner et.al., 2012:816,817). In Sus-VSM, in addition to standard VSM metric of time waste, environmental and societal metrics have also been used (Brown et.al, 2014:166-168).

Table 1. Sus-VSM metrics and descriptions

	Sus-VSM Metrics
Economic	Time Waste
Environmental	• Raw Material Usage • Energy Consumption • Process Water Consumption
Societal	• Physical Work (Job Hazards) • Work Environment (Ergonomics)

Brown et.al, 2014:166-168.

Faulkner & Badurdeen, 2014:16.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

As different from previous works, Sus-VSM tool has been designed to evaluate all aspects (economic, environmental, societal) of sustainability (Faulkner et.al., 2012:822) and in this way it has provided a more detailed evaluation (Brown et.al, 2014:166).

Sustainable value stream mapping starts with a current situation investigation. In this step, the *current state map* is prepared. Value stream is evaluated according to selected metrics and wastes are identified. After preparation of current state map and identification of wastes, in the next step a *future state map* is drawn. Future state map shows the desired design of new value stream. And finally, an *implementation plan* is prepared for applying necessary improvements (Rother & Shook, 2009:7). Since this tool needs information and material flows to be drawn, in order to get the necessary information it should be conducted in a cross-functional team setting (Lovelle, 2001:30). Although Sus-VSM is a useful tool, for complex situations (e.g. high variety of production), it is important to determine scope of analysis before starting the process (Brown et.al, 2014:165). There may be one product line, a product family line or whole supply chain to be investigated. In each option, metrics selection should also be aligned accordingly (Sparks & Badurdeen, 2014:4). In order to make a more dynamic analysis and digital visualization, Sus-VSM can also be used in integration with other tools such as discrete event simulation (DES) (Paju et.al.,2010:3411). Whether it is used as a pencil and paper tool or with a simulator, Sus-VSM provides a valuable roadmap to maintain sustainability.

Sustainable Balanced Scorecard (SBSC)

Another sustainability management tool is the one which is called Sustainable Balanced Scorecard (SBSC) and this tool is based on the traditional Balanced Scorecard (BSC) (Bieker, 2003:17). Balanced Scorecard (BSC) has been developed in the early 1900s by Harvard professor R. Kaplan and D. Norton as a new tool for performance management (Bieker, 2002:2) and this tool is different from traditional controlling mechanisms of organizations. Controlling in management has a critical role and performance measurement is mostly made by looking at financial performance indicators. However, financial measures may be insufficient and therefore organizations need different perspectives which support financial results. In that vein, BSC is the one which is proposed for this reason. The BSC is based on the idea that the efficient use of investment capital is no longer the only determinant for competitive advantage, and increasingly soft factors such as intellectual capital, knowledge creation or excellent customer orientation became more important (Figge et.al.:2002:270). Therefore, Balanced Scorecard takes also the intangible assets into consideration and helps organizations to manage demands of relevant stakeholders (Bieker, 2002:7). In this context, in BSC there are four perspectives as financial perspective, customer perspective, internal processes perspective and lastly innovation and learning perspective (Kaplan & Norton, 1992:72).

1. **The Financial Perspective:** Focuses on the shareholders' interests and shows whether the company's strategy, implementation and operations are contributing to bottom-line. But as different from traditional management instruments, it stresses drivers for future profitability.
2. **The Customer Perspective:** Focuses on measures that indicate how the company is creating customer value through its strategy and actions. Customers' concerns tend to fall into four categories as time, quality, performance & service, cost and this perspective makes it possible to get the internal processes, services and products into line with the necessities of current and future markets.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

3. **The Internal Processes Perspective:** Measures how well a company performs on key internal dimensions. For this perspective, first of all the company's core competencies and the critical technologies needed to ensure continued market leadership are identified and measured.
4. **The Innovation and Learning Perspective:** Measures how well the company is preparing to meet the challenges of the future through leveraging its organizational and human assets. Human resources is thought as an underlying strategic factor of success and via this perspective it is linked to organization's strategy (Bieker, 2003:19, Epstein & Wisner, 2001:2, Kaplan & Norton, 1992:73-77).

These perspectives are not thought as isolated and therefore they are in cause and effect relationships with each other. Also they are measured by indicators (as leading and lagging) and objectives in operational levels are linked to corporate strategy.

1. **Leading Indicators:** Reflect the future strategic goals and
2. **Lagging Indicators:** Reflect the results to depict the effectiveness and efficiency of measures in the past (Bieker, 2003:18).

And also in order to form the necessary cause and effect relationships, these indicators are thought as a continuum or linked with each other (Epstein & Wisner, 2001:2). Therefore by means of BSC, performance measurement of corporate strategies can be made in terms of these four perspectives (Möller & Schaltegger, 2005:74).

Balanced Scorecard helps companies to accomplish critical management processes and it can be used as a strategic management tool (Sidiropoulos et.al, 2004:29). In this context, it helps translation of vision into action, communication of this vision with all organizational levels and linking it with short-term goals, integration of business and financial plans, and also helps strategic learning with feedback (Kaplan & Norton, 1996:75-77).

Sustainability balanced scorecard (SBSC) also works in the same manner. Conceptually sustainability management with BSC tries to address the problem of corporate contributions to sustainability in an integrative way. This time, characteristics of BSC are used for three pillars of sustainability (economic, environmental, social) and sustainability related indicators are linked with sustainability strategies (Figge et.al.:2002:272). Setting up a sustainability balanced scorecard starts with corporate vision and mission (Bieker, 2003:23). Since this is a top down approach, here it should be noted that the link between objectives and strategy can be formed providing that currently there is a strategy about the issue (Bieker, 2002:3). Therefore, in order to set up a SBSC, first of all sustainability should be addressed in vision and mission of the organization. In the second step, in line with that vision and mission, corporate sustainability strategies are determined and communicated with all hierarchical levels in the organization. After strategy clarification, sustainability objectives are identified based on the corporate sustainability strategies. In the following steps, casual relationships are determined and objectives are integrated into the SBSC perspectives and by defining indicators, targets and measures, SBSC is integrated into the core management system (Bieker, 2003:23). Before setting up a SBSC, scope should be made clear. Organization may apply it on a department, on a specific strategic business unit (SBU) or on the entire organization (Figge et.al.:2002:277) and also indicators can be organization specific. Based on the determined perspectives, sustainability balanced scorecard can be designed in different ways. It can be formed by integrating sustainability indicators under each of four perspectives or as one other choice it can be formed by adding a fifth perspective (sustainability perspective) to the traditional balanced

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

scorecard. In order to increase the acceptance of enhancements, integration of sustainability metrics into the four perspectives can be preferred (Möller & Schaltegger, 2005:76). On the other hand, if resource allocation to social and environmental responsibilities is relatively large, then the second way can be seen as more appropriate. Sustainability balanced scorecard of Bristol-Myers Squibb (BMS) which is a multinational pharmaceutical company can be given as an example of the former design. In preparation of the SBSC, the company has prepared sustainability measures for each of the four perspectives (i.e. good citizenship metrics for customer perspective or energy use metric for internal business processes perspective) and formed the necessary links. In this way, BMS management has tied those specified performance metrics to corporate and business unit strategy to provide for an effective implementation of their concerns for social and environmental issues (Epstein & Wisner, 2001:5). As one another example (the latter design), Volkswagen's sustainability balanced scorecard can be given. Volkswagen (VW) has prepared a SBSC for its research department and used a fifth perspective which is called 'society'. Since sustainability management needs to take into consideration all stakeholders, society has been critical for the company. VW also formed the necessary cause and effect relationships and prepared its strategy map (Bieker, 2003:30). As it can be seen from all these examples, choice of the scope, metrics and type of SBSC depends on the organizations' needs and therefore it is mostly organization specific.

Sustainable balanced scorecard provides a strong tool for an integrated corporate sustainability management (Figge et.al.:2002:283). With this tool, companies get the opportunity to translate sustainability visions and strategies into action (Bieker, 2003:30) and also a balance of economic, social and environmental issues can be achieved (Möller & Schaltegger, 2005:75). By using SBSC, senior managers reposition their organization toward improved corporate responsibility and also this positively affects the organization's image and reputation (Epstein & Wisner, 2001:10). However, it may not be so easy all the time to implement this sustainability management tool and there may be some obstacles. This is because; it is a complex and highly micro political process requiring patience, power and persistence. But, if cultural issues are taken into consideration and employees are involved in the process, a successful implementation may take place (Bieker, 2003:30).

As it can be seen from all these explanations above, these four sustainability management tools have some similarities and differences, and while choosing the appropriate one, taking these similarities and differences into account may be helpful. First of all, these four tools are all top-down approaches. Therefore they need management support for implementation. However, in TQEM, an organization wide participation is much more important compared to other three sustainability management tools. Culture is a main obstacle for all change related issues and therefore it is the same for the implementation of these four sustainability management tools. Besides, while EMS, TQEM and Sus-VSM mostly involve in operational levels of sustainability, SBSC provides a more comprehensive tool which carries sustainability to a strategic level. Although there are similarities and differences among them, each of these tools provides valuable contributions for the management of sustainability.

CONCLUSION

Corporate sustainability is a critical concept which is getting more and more important. In today's highly industrialized business arena, harmful effects of corporations to the environment and society cannot be ignored. Organizations are operating in relationship with their stakeholders and for long lasting survival; they need to take into consideration their effects on all related parties. Sustainability has

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

three pillars as economic, social and environmental aspects. All of these three pillars which are also called as triple bottom line (TBL/3BL) should be taken into consideration for sustainability. Economic aspect is related with the efficient use of resources and achieving profitability. Social aspect is related with considering social impacts of business operations on community (e.g. human rights, labor, health etc.) and environmental aspect is related with conservation of natural resources and taking the necessary actions to protect environment.

Scholars' and businesses' increasing attention to the importance of sustainability has resulted in increasing efforts for management of this issue. For several reasons (company image, social responsibility, humanism and environmentalism etc.) companies have generated and implemented different corporate sustainability tools. Use of these tools is dependent on the choice of the business and they are not mutually exclusive. Some of these corporate sustainability tools can be listed as Environmental Management System (EMS), Total Quality Environmental Management (TQEM), Sustainable Value Stream Mapping (Sus-VSM) and Sustainable Balanced Scorecard (SBSC). Environmental management system is mostly based on compliance and it uses Deming's PDCA cycle for the management of sustainability. It can be formal or informal and also it can be classified as certified or non-certified. Implementation of an environmental management system (EMS) starts with the awareness of a need for this. As well as awareness, the necessary policy, planning, implementation, controlling and improvement activities are also key for the success. This tool provides a systematic approach to organizations for better environmental performance but since it focuses on environmental issues, serves as a partial system of sustainability management. As another sustainability management tool, total quality environmental management (TQEM) utilizes total quality management techniques and by using these techniques it provides continuous sustainability improvement for organizations. Pareto diagrams, control charts, cause and effect diagrams are all among tools which are used for TQEM. Total quality environmental management emphasizes four basic principles as customer orientation, continuous improvement, doing the job right at the first time and a system approach. TQEM is a holistic environmental management tool and like total quality management does, TQEM which aims achieving sustainability also includes a cultural side in itself. Another corporate sustainability tool which is called sustainable value stream mapping (Sus-VSM) is related with sustainable manufacturing. This tool is based on the conventional value stream mapping and provides opportunity for identifying and eliminating wastes in terms of sustainability (by using economic, environmental and societal metrics). When it comes to the preparation, the process is comprised of three stages. At first stage of the process, a current state map is prepared. This step is followed by preparation of future state map and in the final step, an implementation plan is prepared to apply improvements. Sustainable value stream mapping tool also provides a roadmap for management of sustainability.

So far, as it can be seen from these explanations, all these tools are mainly related with operational level of sustainability. However, for a successful sustainability management; these efforts should be linked to corporate strategy. By linking the sustainability with strategy, both the issue will gain more importance and it will be possible to measure sustainability performance. For this reason, a fourth corporate sustainability management tool which is called sustainability balanced scorecard (SBSC) is important for sustainability management of corporations. Sustainable balanced scorecard is mainly based on the conventional balanced scorecard proposed by Kaplan and Norton. Conventional balanced scorecard provides performance measurement opportunity based on four different perspectives (financial, customer, internal business, innovation and learning). The idea behind this tool is the fact that financial performance measures are not sufficient anymore and the factors which affect financial results should also be taken into consideration for a healthy performance measurement. Sustainable balanced scorecard

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

adds a sustainable perspective for measuring sustainability performance. This tool can be designed differently as with an integrated or with a separate sustainability aspect. Whether it is integrated or separate perspective, in both cases this tool forms the necessary link between sustainability related strategies and sustainability operations. In this way, it translates the strategy into action.

As stated before, organizations may choose one or more of these tools for management of sustainability. But here, the important point is that for a successful corporate sustainability all three aspects (economic, societal, environmental) should be taken into consideration. Therefore, when deciding the appropriate tool, this issue should also be considered by organizations carefully. Sometimes implementation process may last for a long time and may be costly. Therefore, they need a systematic approach and patience. However, although there may be difficulties in implementation, these tools provide support and improvement for sustainability performance of corporations.

KEY TERMS AND DEFINITIONS

Balanced Scorecard: A comprehensive organizational performance measurement tool which is prepared mainly based on the four basic perspectives of financial, customer, internal business, innovation and learning.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Environmental Management System: A corporate sustainability management tool which is applied based on Deming's PDCA cycle with the aim of eliminating environmental impact and improving sustainability performance of organization.

Sustainability Balanced Scorecard: A corporate sustainability performance measurement tool which is mainly based on traditional balanced scorecard and links sustainability goals with organization's strategy.

Sustainability Management: Concerns and efforts for eliminating hazardous impacts and making continuous improvements on economic, environmental and societal issues in order to ensure and maintain quality of life.

Sustainable Value Stream Mapping: A corporate sustainability management tool in which the value stream of a product line, product family line or whole supply chain is drawn and evaluated according to some metrics (economical, environmental and societal metrics) in order to make improvements in sustainability performance of organization.

Total Quality Environmental Management: A corporate sustainability management tool which is applied based on total quality management principles and techniques in order to improve sustainability performance of organization.

Total Quality Management: A contemporary management thought aiming doing the things right at the first time and achieving excellence in quality.

Chapter 27
Grid Stabilization Effect of Combined Electricity Generation From Wind and Photovoltaic Systems in Murcia, Spain

ABSTRACT

In this chapter, a model that calculates the impact on the grid of the simultaneous injection of electricity both from photovoltaic and wind sources is presented. The best locations for wind and photovoltaic technologies within Región de Murcia, southeast Spain, have been selected from a GIS database and evaluated and classified using a fuzzy version of the multicriteria decision method called Technique for Order Preference by Similarity to Ideal Solution (TOPSIS). After the classification, the best locations are selected for each technology. Then, the impact on the grid arising from the injection of power generated in wind of photovoltaic systems installed at these specific locations and that are connected to the grid has been calculated in a power range of several kWp, including random steps of up to 50kW. The results show that stable grid parameters are obtained within 500ms in all cases, even when this relatively large power surge (or variation) is considered.

INTRODUCTION

Nowadays, industrial and urban development are mostly driven by fossil fuels thus creating important environmental problems, being green-house-gases (GHG) emissions the best known. Alternative resources in power generation are being developed with the aim of meeting the increasing demand of energy but at the same time reducing the GHG emissions: renewable energy technology is the best choice for this purpose. Within the broad range of renewable options, wind and photovoltaic technology have been the most rapidly growing technologies worldwide. The electricity generation mix of any country in the world is increasingly incorporating a larger contribution of renewable energy supply (International Energy Agency, 2012; European Commission, 2013; Red Eléctrica Española, 2013). The electricity grid of such countries needs to match in real time the supply and demand of electricity, i.e. the electricity injected to the grid at a given time has to be the same as the electricity consumed by the users at the same time (European Commission, 2013). This is a challenge when renewable sources represent a large share of the electricity mix, and the road toward sustainability will require management of different intermittent sources probably with a storage back-up (International Energy Agency, 2012). This matching is usually guaranteed by the grid manager, which has the authority to allow or block the electricity input to the grid from different suppliers, and usually prioritizes generation from renewable sources. It has been alleged that a large amount of renewable electricity supply could become unmanageable because it depends strongly on uncontrollable environmental parameters such as wind speed or irradiance, which may vary strongly with geographical location or time (during same day or seasonal variations) (Prescott, 2004). Nevertheless, contrary to these allegations, a larger input of renewable energy, in particular from wind and photovoltaic sources in a given geographical region of large enough size can have a stabilizing effect to the grid (Chu, 2012), even for PV-only integration (Lund, 2006; Marcos, 2012). In order to benefit from this complementarity, a careful selection of the best location for installing the energy system is required.

The search and selection of optimal locations to install renewable energy facilities, requires not only to have an advisory group able to assess and analyze alternatives, but also to apply a set of tools and methods to facilitate the decision making process (Pohekar & Ramachandran, 2004). The problem of selecting the optimum location for renewable energy facilities is a complex problem because it needs to handle a great variety of criteria of different nature and origin, as well as to evaluate, in most cases, a large number of alternatives. For this purpose, Multicriteria Decision Methods (MCDM) (Roy, 1968; Saaty, 1980; Hwang & Yoon, 1980) are the main methods to tackle this type of problems (Al-Yahyai, Charabi, Gastli, & Al-Badi, 2012) by combining them, on the one hand with Geographical Information Systems (GIS) (Janke, 2010; Van-Haaren & Fthenakis, 2011) that will be used as support database to our problem, and on the other hand, with Soft Computing (Zadeh, 1994) tools applied to the own decision methodologies which gives them the uncertainty modeling and vagueness typical of the data used in this type of problems.

Once the first step of selection of the optimum location is accomplished, it is necessary to monitor the environmental parameters (or access to databases) which provide a measure of the potential renewable energy resource is required. From this data, simple models to calculate the electricity output provided by the technology of choice can be easily implemented, thus completing the required amount of information before taking any decision about the final installation of the energy systems, which usually involves a large economic investment.

For the particular case study proposed in this chapter, a combination of multicriteria decision methods with GIS as support database and Soft Computing, specifically the Fuzzy Logic (Zadeh, 1965) and

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

simple analytical modelling implemented in MatLab-Simulink will be applied for searching optimal locations to implant wind and photovoltaic solar farms in Murcia and evaluate the impact on the stability of the grid provided a few of this systems are connected to the grid. The first step is therefore to select the optimum locations, then the required input parameters for the modeling will be gathered and finally the simulated output of the impact on the grid will be calculated and presented.

BACKGROUND

In engineering projects related to renewable energy facilities, as in any engineering project in general, decision making is an essential intellectual activity that needs to be carried out before any investment is done. Within the broad field of decision making support tools, appropriate methodologies must build and developed in the scientific area in which the question arises to be solved (San Cristobal, 2011). Although various decision support methods were developed in the 90s (Huang, Poh, & Ang, 1995; Georgopoulou, Lalas, & Papagiannakis, 1997), it was not until the beginning of the 2000s when studies in the field of renewable energy and multicriteria decision methods (MCDM) were extended as a result of the implementation of an enabling legislative framework. The PROMETHEE II method was used to investigate and evaluate the exploitation of geothermal energy sources in an island of Greece (Haralambopoulos & Polatidis, 2003), where different multicriteria decision methods were analyzed and evaluated (PROMETHEE, ELECTRE, AHP, MAUT, etc.) with the purpose of conducting an energy planning project (Pohekar & Ramachandran, 2004). Different technologies of solar thermal concentrators were evaluated using the PROMETHEE method (Cavallaro, 2009). The Fuzzy AHP method was used to select the most reliable projects using hybrid systems combining solar and wind power technology (Chen, 2010) or also across the combination of fuzzy variants of TOPSIS and AHP methods has been possible to evaluate different technologies of manufacturing solar photovoltaic cells (Garcia-Cascales, Lamata, & Sánchez-Lozano, 2012).

This brief summary demonstrates the advantage of using MCDM in the renewable energy field. Furthermore, in a problem as the one analyzed in this chapter, additional variables may hinder the execution and expansion of any energy facility (available surface, proximity to populated areas, distance to grid, etc…); the problem must be oriented to the optimization of the future facility taking into consideration this broad set of parameters, most of them linked to a particular geographical location. It is therefore important to consider Geographical Information System (GIS) tools for the correct gathering, analysis and visual presentation of the data and results of the calculation (Uyan, 2013). The success of the combination of GIS and MCDM systems is based upon the complementarity of both kinds of computational tools: GIS offers the decision maker the possibility to gather, store, manipulate and visualize in a direct manner any geographical information set, which in combination with the MCDM allows the user to organize and evaluate the different options presented before them (Malczewski, 1999). Since the first studies, the combination of GIS with MCDM have been used in a large number of analyses involving territorial planning such as urban layouts and infrastructure distribution (Joerin, Thériault, & Musy, 2001; Chang, Parvathinathan, & Breeden, 2008; Sadeghi-Niaraki, Varshosaz, Kim, & Jung, 2011; Coutinho-Rodriguez, Simao, & Henggeler-Antunez, 2011); but also applications with a special focus on renewable energies (Voivontas, Assimacopoulos, & Mourelatos, 1998; Baban & Parry, 2001; Amador & Domínguez, 2005), such as the studies in Georgia (USA) related to the evaluation of tidal energy by combination of GIS and MCDM (Defne, Haas, & Fritz, 2011). Oman, Charabi and Gastli (2011) analyzed the opportunity

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

to install photovoltaic plants by a combination of GIS and fuzzy MCDM (OWA method). In an Italian region, GIS and AHP methodology was used to evaluate the convenience of installing a biomass facility (Zubaryeva, Zaccarelli, Del Giudice, & Zurlini, 2012). In order to evaluate the best location for photovoltaic solar plants in South Spain, GIS have been used in combination with the AHP method (Arán-Carrión, Espín-Estrella, Aznar-Dols, Zamorano-Toro, Rodríguez, & Ramos-Ridao, 2008) or with both AHP and TOPSIS (Sánchez-Lozano, Teruel-Solano, Soto-Elvira, & García-Cascales, 2013).

The Distributed Generation (DG) of electric energy has become part of the current electric power system; it consists of generating electrical power near the consumption area, breaking with the traditional concept, in which generation and consumption areas are far away from each other (Peças-Lopes, Hatziargyriou, Mutale, Djapic, & Jenkins, 2007; Ackermann, 2007; Ackermann, Andersson, & Söder, 2001) The future of power supply system could be composed by a great quantity of low voltage small grids interconnected through the distribution and transportation systems. On the other hand, energy and ecological issues such as the oil crisis, climate change and the high power supply demand around the world have increased the need of new energy alternatives. In this context a new scenario is arising in which very small energy sources make up a new supply system at local level: the Microgrid, which are small-scale supply networks with combined heat and power energy sources used to feed electrical loads and supply heat demand for a small community such as a suburban town, or an academic or public community such as a university or college, a commercial area, an industrial site, a set of stores or a municipal region; this approach usually employs Microsources or small generators which may be renewable or non-renewable Distributed Energy Sources (DER's) which inject power into the local grid at low voltage (Tan, Hassan, Majid, & Abdul Rahman, 2013).

The use of this kind of power supply sources would not only guarantee its quality and reliability, but also a more efficient use of natural resources. Likewise, the amount of DG sources directly connected to the distribution network will be increased actively. The profits associated to the Microgrid concept are clear. On the one hand, an improvement of the efficiency in energy transportation (reduction of energy losses) is achieved, when it is brought near the generation and consumption points. On the other hand, the electricity generation with low or null emissions of CO_2 and SO_2 to the atmosphere is possible, achieving a more responsible use of the available natural resources. And last but not least important merit of Microgrids comes from the inherent redundancy of generation systems, a fact that predicts that future power systems will be more robust and safer from eventual faults in the electrical supply system.

In the last years, different Microgrid management structures have been proposed. In them, various aspects have been outlined, but few works address the problem in all its extension. Most recent research projects show the technical difficulty of controlling the operation of Microgrid, because they are complex systems in which several subsystems interact: energy sources, power electronic converters, energy storage systems, loads and the grid (Hadjidemetriou, Kyriakides, & Blaabjerg, 2013). The implications for the control of the Microgrid derived from the transition between both operation modes will be considered. Important contributions are expected about the control of power electronic converters operating in Microgrids, as well as about the power system management.

The technical challenges associated with the operation and control of Microgrids are immense. Effective energy management within Microgrids is a key to achieve vital efficiency benefits by optimizing production and consumption of heat, gas and electricity (Foote, Burt, Wasiak, Mienski, Pawelek, Gburczyk, & Thoma, 2008). The coordinated control of a large number of distributed sources, possibly with conflicting requirements and limited communication is a very challenging problem imposing the adoption of distributed intelligence techniques. Furthermore, the management of instantaneous active

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

and reactive power balances, power flow and network voltage profiles imposes unique challenges in the context of Microgrids.

Traditionally, power grids are supplied by sources having rotating masses and these are regarded as essential for the inherent stability of the systems. In contrast, Microgrids are dominated by inverter interfaced distributed sources that are inertia-less, but do offer the possibility of a more flexible operation. A further particular problem of Microgrids is the relatively high resistance of the low voltage networks. The amount of voltage drop on any RL circuit is approximately obtained by PR+QX, P and Q being the active and reactive power flow, R and X the resistance and reactance of the circuit. In general, high voltage of medium voltage networks, R is much lower than X, so that the injection of reactive power critically affects voltage drops. Active and reactive power effects are reasonably decoupled and this is the basis of several analytical techniques, like the fast decoupled load flow. In underground low voltage networks on the other hand, R is much higher, it can be three times higher or at least equal to X. This results in strong coupling of real and reactive power, and hence the control of voltage and frequency can no longer be considered separately.

Besides being complex and dynamic systems, power grids are sensitive systems that are affected by various eventualities which can range from operating errors to the connection and disconnection of loads. This fact demonstrates the need for continuous network monitoring to ensure correct operation of the power converter, and shows that there is an interactive relationship between the power converter and the network, so that may have an active role in provide the voltage and frequency to the system. For this reason, many international grid codes have been in force during the last few years in order to regulate the behavior of photovoltaic and wind energy systems in both regular steady-state and abnormal transient conditions.

The signals describing the grid status are essential at all times when the network is interconnected with renewable energy sources, since doing so the boundary conditions is established within which the signal must remain the voltage and often when photovoltaic cells and wind generators are connected to the network. Thus the information obtained in the process of network monitoring, updated at all times, must have accurate information of network status, and an adaptive process by which signals internal references are generated by the algorithm control of the power converter connected to the network are carried network variables, and these in turn led to the line variables. In order to identify quickly and accurately its work, synchronization algorithms must meet response requirements accurately and time, so that when the power converter is connected to the network so both work at unison. At present there are a variety of timing algorithms. However, among the most prominent are the PLL, dq-SOGI, Double and Multiple-SOGI.

Finally, we summarise in a few points the main advantages of using a Microgrid approach for the reliable supply of energy with a strong input from renewable sources. In addition to several advantages provided by conventional power systems, the following technical, economic and environmental benefits have led to gradual development and integration of DG systems:

1. Due to rapid load growth, the need for augmentation of conventional generation brings about a continuous depletion of fossil fuel reserve. Therefore, most of the countries are looking for non-conventional/renewable energy resources as an alternative.
2. Reduction of environmental pollution and global warming acts as a key factor in preferring renewable resources over fossil fuels. As part of the Kyoto Protocol, the EU, the UK and many other countries are planning to cut down greenhouse gas (carbon and nitrogenous by-products) emis-

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

sions in order to counter climate change and global warming. Therefore, they are working on new energy generation and utilization policies to support proper utilization of these energy sources. It is expected that exploitation of DERs would help to generate ecofriendly clean power with much lesser environmental impact.

3. DG provides better scope for setting up co-generation, trigeneration or CHP plants for utilizing the waste heat for industrial/domestic/commercial applications. This increases the overall energy efficiency of the plant and also reduces thermal pollution of the environment.
4. Due to lower energy density and dependence on geographical conditions of a region, DERs are generally modular units of small capacity. These are geographically widespread and usually located close to loads. This is required for technical and economic viability of the plants. For example, CHP plants must be placed very close to their heat loads, as transporting waste heat over long distances is not economical. This makes it easier to find sites for them and helps to lower construction time and capital investment. Physical proximity of load and source also reduces the transmission and distribution (T&D) losses. Since power is generated at low voltage (LV), it is possible to connect a DER separately to the utility distribution network or they may be interconnected in the form of Microgrids. The Microgrid can again be connected to the utility as a separate semi-autonomous entity.
5. Stand-alone and grid-connected operations of DERs help in generation augmentation, thereby improving overall power quality and reliability. Moreover, a deregulated environment and open access to the distribution network also provide greater opportunities for DG integration. In some countries, the fuel diversity offered by DG is considered valuable, while in some developing countries, the shortage of power is so acute that any form of generation is encouraged to meet the load demand.

Within this approach of production and transmission of electricity, a new renewable energy market can be developed; despite representing only 2% of global energy consumption in 2013, it has received a strong investment increase, for example up to 1470 billion according to the International Energy Agency (IEA 2012), and therefore solar photovoltaic installed capacity has grown by 100 GW, and wind by 283 GW in 2013 worlwide, thus demonstrating that they could become a clear replacement for fossil and nuclear at medium term.

In this regard the European Union (EU) outlines 3 main objectives to follow (European Commission, 2013):

- Reduce the emission of green-house gases (GHG) by 20% by 2020.
- Improved energy efficiency by 20% by 2020.
- Increasing diversification of renewable energy production and exchange among their sources in order to achieve optimal performance.

So under the new vision system generation and transmission of electric power system has experienced in recent years a large number of sources of DG connections to the distribution network at Medium Voltage (MV), which have been able to be carried out by the recent technical advances in the DGs and meet specific characteristics that enable connection to distribution networks Low Voltage (LV) (Veeranna, 2012; Guo, 2013; L'AAbbate, Fulli, & Starr, 2007; Peças Lopes, Madureira, & Moreira, 2013).

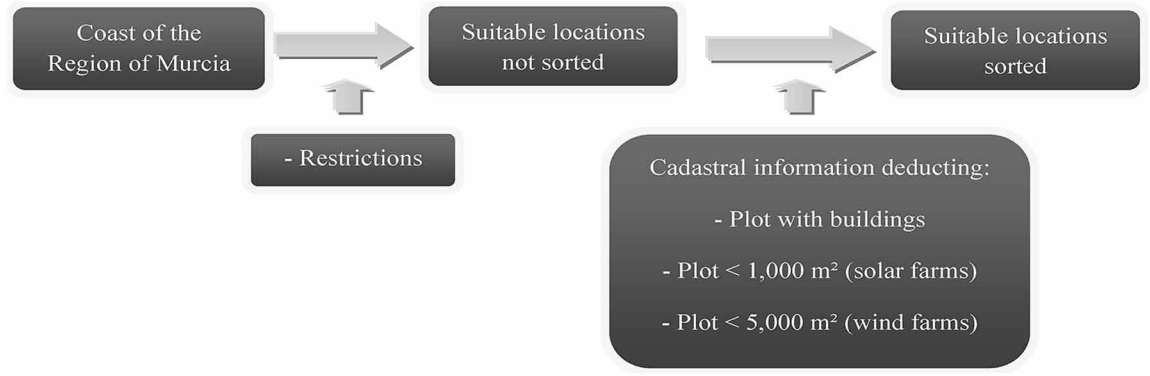
In this chapter, a GIS methodology will be used as a first step to create a database of locations available to host photovoltaic plants and wind facilities. In a second stage, those locations will be evaluated

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

using a fuzzy TOPSIS method, for which the weights of the criteria to be used had been previously obtained using a fuzzy AHP method. Back to GIS, the average temperature, irradiance and wind speed for the selected locations will be gathered and used in the final stage in which the impact of connecting the facilities to the local grid is evaluated. These final results will also provide additional information to a decision maker, and therefore can also be considered as a part of the multi-criteria decision method, although at this stage of the study there is no feedback of these results to the fuzzy AHP methodology used in the previous stage.

SOFT COMPUTING AND STANDARD MODELLING FOR THE SIMULATION OF RENEWABLE POWER GENERATION

The methodology of the study is based on a combination of soft computing tools used for the selection of the optimum locations for wind and photovoltaic systems and conventional modelling (based on Matlab-Simulink) which is used to calculate the impact on the grid from the injection of power from these systems; this impact is obtained from real-time simulation of control electronics and a statistical analysis of voltage, current and phase injected to the grid. The starting point for this kind of studies is the selection of the best geographical locations to install the renewable energy systems under consideration (in this case, wind and photovoltaic). For this purpose, the use computational tools such as Geographical Information Systems (GIS) are required. In order to evaluate the best location a large amount of variables and criteria need to be analyzed and evaluated and therefore Multi-criteria Decision Methods (MCDM) are required; usually these variable and criteria can be very different from each other, including their qualitative or quantitative nature, with different degrees of definition, including uncertainty, which makes compulsory the use of techniques of Soft Computing and in particular fuzzy logic. In a second stage, conventional simulation tools are used to calculate the impact on a local Microgrid of the electricity injection from a few selected sources. The impact is statistically evaluated using the voltage and frequency of the grid during a certain time span.



1. GIS System Data Gathering and Evaluation of Optimum Locations for Photovoltaic and Wind Technologies

Geographical information systems (GIS) are computing tools which allow to present the real world through georeferenced information, this information is expressed quantitatively as a set of numbers which can be visually represented as different thematic layers and can be superimposed creating specific representations of a given geographical area (specific surface).

The GIS software used in this chapter is gvSIG (www.gvSIG.org), this tool enables the incorporation of different layers of the same geographical area, each layer containing specific information which can also include legislative regulations regarding restrictions to the installation of photovoltaic or wind facilities (for example to avoid specific environmental impacts on protected areas). The restricted areas will be excluded from the final layers that in the next step will be analyzed and evaluated; a further restrictive processing is applied using information from administrative registrars which makes impossible the construction of the planned facility (for example because there exist a previous building in the same location), finally, only areas which provides a minimum of $1000m^2$ for photovoltaic facilities or $5000m^2$ for wind facilities have been considered (see Figure 1 for a description of the area selection procedure).

Figure 1. Process scheme

Search for feasible locations. Restrictions and criteria. Coastal areas within Región de Murcia (Southeast Spain) are the geographical area under consideration in this study. The total area is composed of 13 municipalities, comprising a total of 4,456.59km^2. From the administrative office (Consejería de Obras Públicas y Ordenación del Territorio) a GIS layer was obtained which contained the whole area (Figure 2). The restrictions defined in Table 1 were applied to this initial layer; the restrictions comprise areas in which legislative regulation or geographical characteristics (watercourses, roads, etc.) make impossible the construction of the facilities, all these restrictions can be described using GIS layers that can be worked out using the gvSIG software, which allows us to "extract" the different restrictive layer from

7	Areas of special protection for birds (ZEPAs)
8	Mediterranean coast and mountains

the original layer and apply the additional size criteria mentioned above (1000m^2 and 5000m^2 minimum size for PV and wind respectively), thus providing a final GIS representation including all relevant information linked to a particular geographical location and allowing a quick and visual representation of the information (Figure 3)

This stage provides an extensive database with contains all relevant data for a particular location. From bibliographic references the best criteria and its hierarchical organization that needs to be used in order to define the optimum location for a PV or wind facility is obtained as shown in Figures 4 and 5 respectively (Janke, 2010; Gastli & Charabi, 2010; Jo & Otanicar, 2011; Al-Yahyai, Charabi, Gastli, & Al-Badi, 2012). These criteria are introduced as GIS layers in gvSIG thus providing a large database containing 66,845 alternatives (viable locations) for photovoltaic plants and 33,290 alternatives for wind facilities. Each alternative is defined by its cartographic information (coordinates, municipality, administrative plot and subplot) and by a value which is assigned to each of the criteria described in Figures 4 and 5.

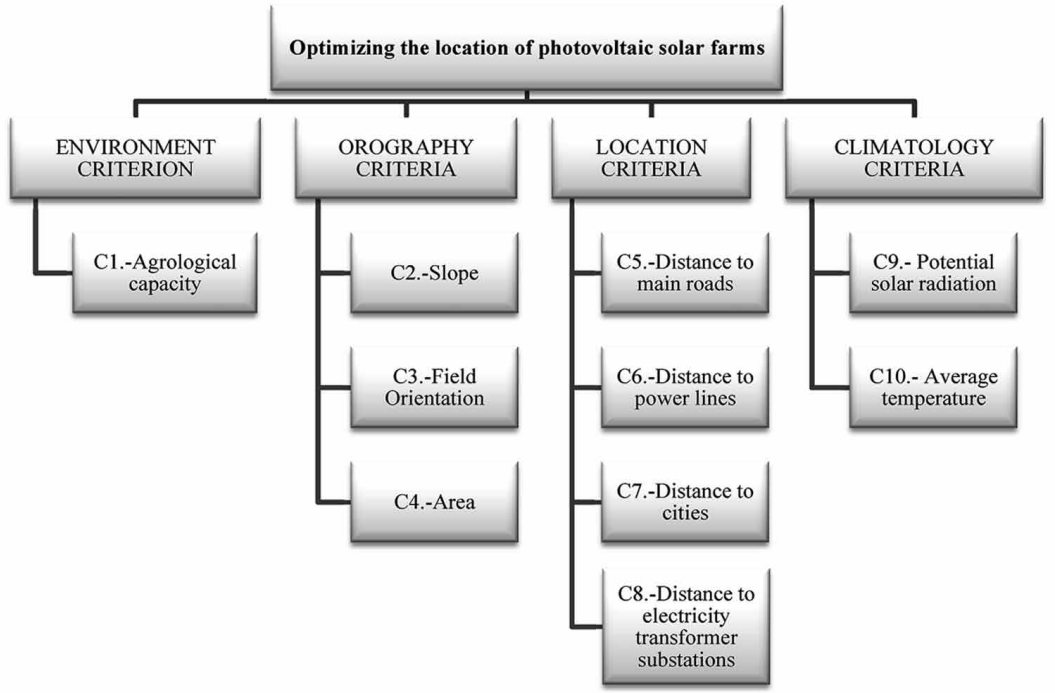

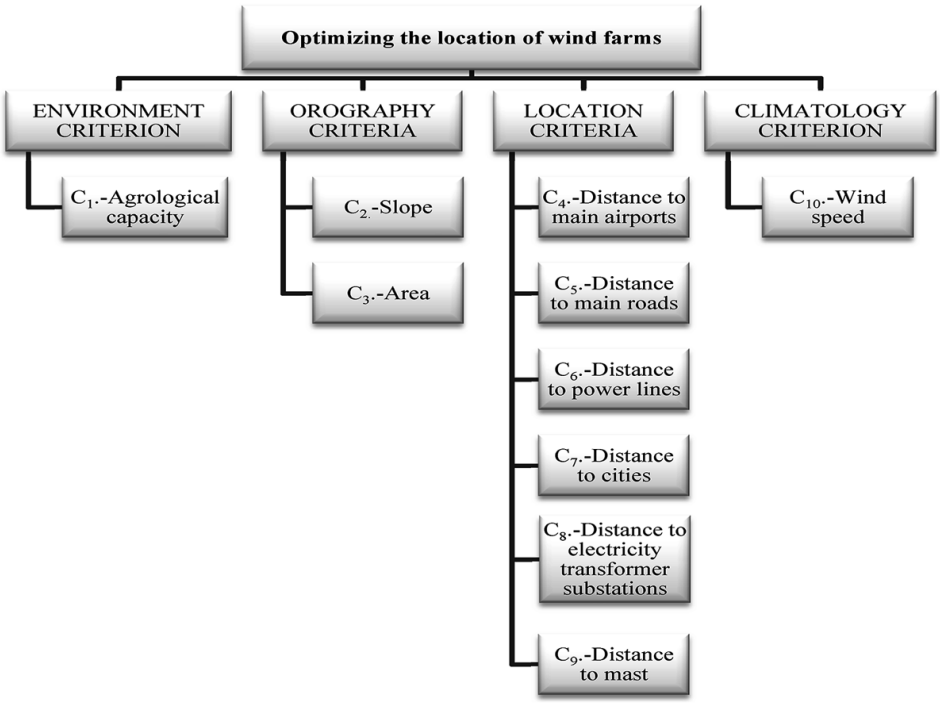

Figure 5. Hierarchy of criteria in wind farms

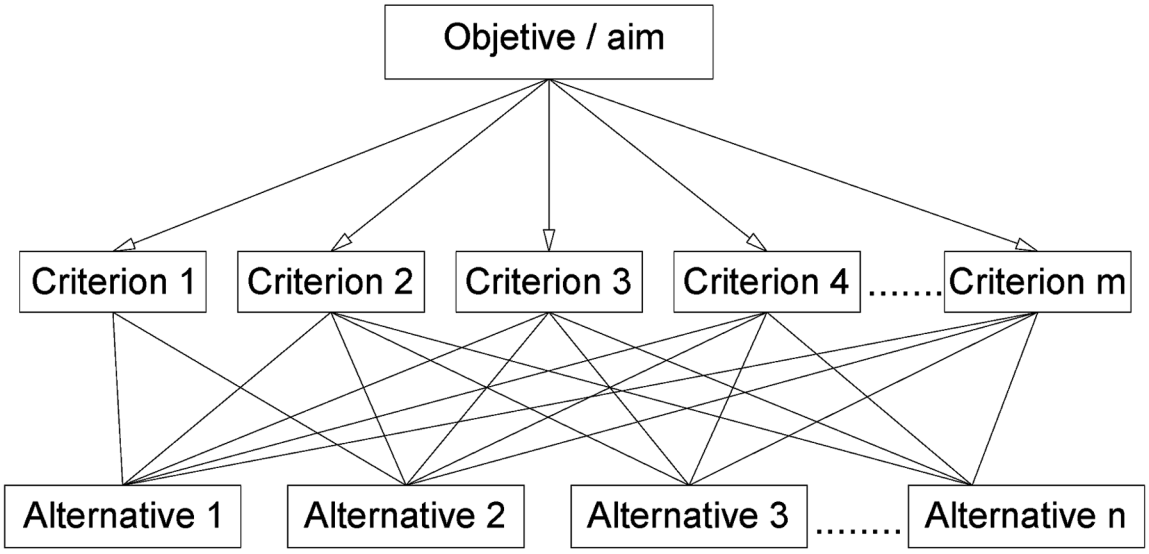
EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

1.1. Multicriteria Decision Making

Using the gvSIG software two decision matrixes are created (one for each technology: PV and wind) which are composed by a given number of alternatives (the viable locations) as a function of ten criteria that may influence the decision maker. This is therefore a multicriteria decision making problem (MCDM) (Chen & Hwang, 1992; Hwang & Yoon, 1981; Keeney & Raiffa, 1976; Luce & Raiffa, 1957), where it is sought to choose the best alternative A_i, $i=1,2,\ldots,n$ with $n\geq 2$ when considering the criteria C_j, $j=1,2,\ldots,m$ with $m\geq 2$ and experts E_k, $k=1,2,\ldots,r$ with $r\geq 2$; it is considered that n, r and m are finites. In order to solve this particular problem, the fuzzy version of the TOPSIS method will be used to evaluate the alternatives (Hwang & Yoon, 1981) and the AHP methodology will be used to determine the weight of each criteria (Saaty, 1980).



1.1.1. The AHP Method

The AHP method was proposed by Saaty in 1980 and it is based on the idea that a decision making problem with multiple criteria can be solved by the ranking of the proposed problems i.e. it consists of an alternative selection method based on a number of criteria which are often in conflict.

The main feature of the AHP method is that the decision problem is modeled using a hierarchy whose apex is the main objective of the problem, and the possible alternatives to evaluate are situated at the base, the intermediate levels correspond to the criteria/subcriteria based on which a decision is made (Figure 6.).

At each level of the hierarchy, comparisons are carried out between pairs of elements of that level, based on the importance or contribution of each element of the upper level to which they are linked. The target in the case under study is the optimal location of sites for solar photovoltaic and wind farms, and specifically in determining the weight or coefficient of importance of the intermediate levels of the hierarchy i.e., the criteria that influence the decision (Figures 4, 5). For this purpose the collaboration

Figure 6. AHP Hierarchy process

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

of a group of experts was required, the method used to obtain the information is a pseudo-delphi, in which the actors do not interact; since the criteria comprise data of different nature (quantitative and qualitative), the information from the experts was defined using linguistic labels (Delgado, Verdegay, & Vila, 1992), being the triangular fuzzy numbers the option chosen to represent the information (Herrera, Alonso, Chiclana, & Herrera-Viedma, 2009; Klir, 1995; Zadeh, 1965; Zadeh, 1975).

The weights of the criteria will be determined by pair-wise comparison among criteria. As a result of the data collection process defined in (Sánchez-Lozano, Teruel-Solano, Soto-Elvira, & García-Cascales, 2013; Sánchez-Lozano, García-Cascales, Lamata, & Sierra, 2013), a total of (*n-1*) comparisons will be required. The labels used and their meanings are shown in table 2.

The weight of the criteria used to evaluate each of the alternatives was obtained by fuzzy AHP methodology for both PV and wind facilities as shown in Table 3.

Table 2. Scale of valuation in the pair-wise comparison process (Saaty, 1980)

Labels	Verbal Judgments of Preferences Between Criterion i and Criterion j	Triangular Fuzzy Scale and Reciprocals
(II)	Ci and Cj are equally important	(1, 1, 1) /(1,1,1)
(M+I)	Ci is slightly more/less important than Cj	(2, 3, 4)/(1/4,1/3,1/2)
(+I)	Ci is strongly more/less important than Cj	(4, 5, 6)/ (1/6,1/5,1/4)
(Mu+I)	Ci is very strongly more/less important than Cj	(6, 7, 8)/ (1/8,1/7,1/6)
(Ex+I)	Ci is extremely more/less important than Cj	(8, 9, 9)/ (1/9,1/9,1/8)

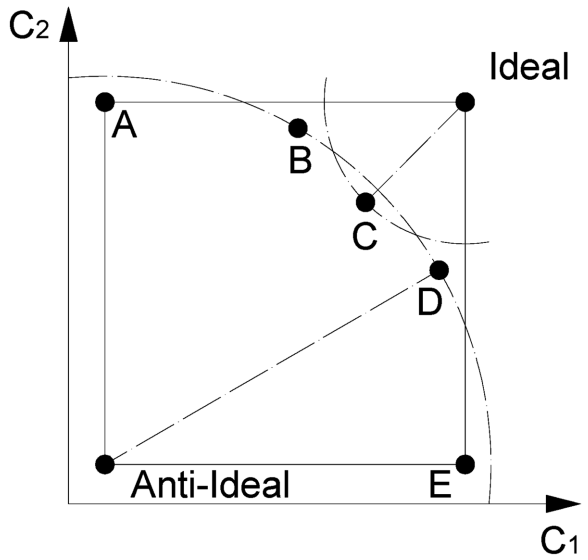
EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

1.1.2. The TOPSIS Method

The TOPSIS method (Technique for Order Preference by Similarity to Ideal Solution) by Hwang and Yoon (1981), combines the use of the ideal solution, the anti-ideal solution or a mixture of both solutions (Figure 7).



The algorithm is presented in Figure 8.

Since the criteria are defined by triangular fuzzy numbers, the TOPSIS method should be able to deal with this kind of information, furthermore, in the final layer, the best alternatives are sorted decreasingly according to a fuzzy number $\overline{R_i}$. For sorting the $\overline{R_i}$, they are first defuzzified using the following procedure (García-Cascales, & Lamata, 2007):

$$I_{1/3,1/2}\left(A_i\right) = \frac{1}{3}\left(\frac{a+4b+c}{2}\right) \tag{1}$$

The defuzzified $\overline{R_i}$ values play the role of a score that allows the decision maker to rank the alternatives. Once the defuzzification process has been carried out during the application of the decision making, each of the alternatives will get a score, named "R coefficient" which allows the decision maker to evaluate the different alternatives. 66,845 alternatives were evaluated for the PV facilities and 33,290 for the wind facilities using the fuzzy TOPSIS methodology which provides an *R* coefficient for each of the alternatives. All the obtained values were classified within four sets of results as a function of its reliability to be used as a location for a PV or wind facility; this grouping enables an easy visual representation using a color code: blue-excellent, green-very good, yellow-good and red-poor (Figures 9 and 10).

Figure 10. Map of the capacity to accommodate wind farms on the coast of the Region of Murcia

From the overall classification of the more suitable locations for photovoltaic and wind facilities in the coastal areas of Region of Murcia, the best three locations for each of them are selected for the collection of environmental parameters that will be required for the simulation of the electricity production in such locations (and its impact on grid stability). The best PV locations are presented in Figure 11 and the best wind locations are presented in Figure 12.

2. Modeling the Generated Output from Wind and PV Systems

The methodology applied in the second part of this study is based on the simulation of expected power output from a network of solar photovoltaic and wind systems which are interconnected via controlled three-phase inverters and therefore constitute a Microgrid. The input data for the simulation will be real environmental parameters for the locations selected in section 1. The stability of the Microgrid will be evaluated in terms of frequency and voltage deviations as well as the number of generated harmonics. Al models will be implemented using Matlab-Simulink software.

In particular, the model of the plant consists on several blocks (see Figure 13): a) a block for generators or sources of energy, in this case, solar photovoltaic modules and wind turbines; environmental parameters are required to feed the block input tags. Photovoltaic and wind generators are both linked to a resistor and a pair of capacitors forming the generator circuit which comprises Resistor, Inductance and Capacitance (RIC); b) the bridge block which implements a universal three-phase power converter that consists of up to six power switches connected in a bridge configuration; different types of power switch and converter configuration can be implemented such as Source Voltage Inverter (VSI), IGBT-inverter, etc; the inverter is Pulse-Width Modulated (PWM) to produce a three-phase 50 Hz sinusoidal

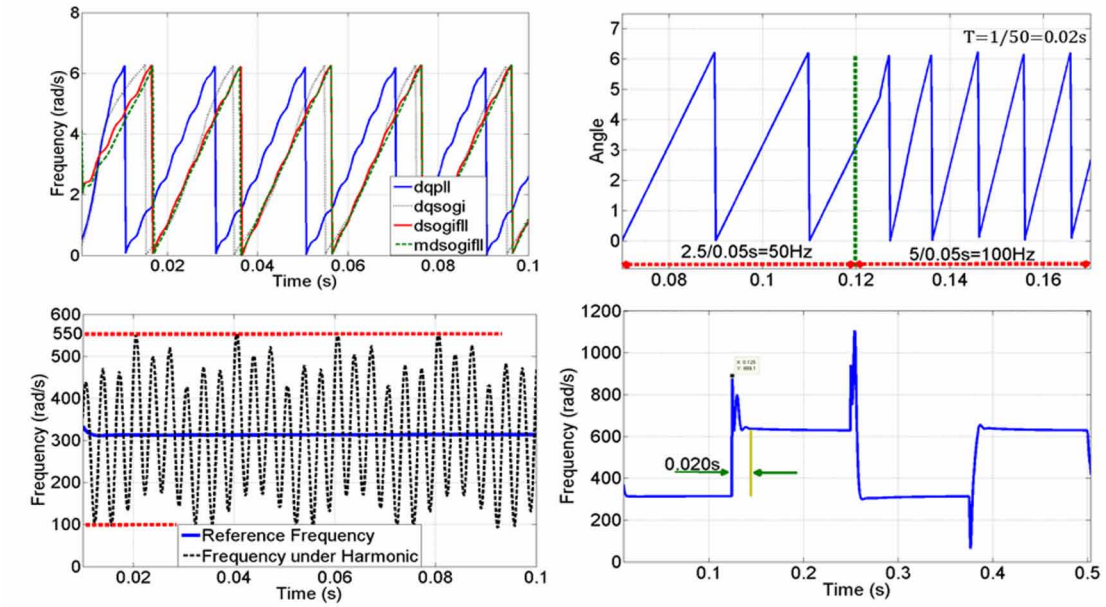
Figure 13. Block diagram of the simulation stage which calculates the impact of N systems (PV or Wind) on the grid. It is illustrated with a picture of a PV system at University of Murcia and a Wind park in Yecla (Murcia). The environmental parameters are introduced as an input for the calculation of the renewable power injected to the grid through the different control blocks described in the text and schematically represented in the figure as a MatLab object oriented code



voltage to the load (Veeranna, 2012; Guo, 2013) c) a passive filter bank, with RIC in series and parallel, which eliminates the harmonics from lower to higher orders; d) a block that simulates the behavior of a utility grid with frequency variations, changes in voltages, through a pulse generator, and three-phase programmable voltage source; e) the control vector block which is intended to maintain the quality of the signal using for this purpose a voltage loop, which estimates the phase and frequency, and therefore controls the phase of the current, and a current loop, which compares the currents obtained in photovoltaic and wind generators with utility grid values (Li, 2011; Kahrobaeian, 2013) and finally, f) a Space Vector Modulation block (SVM) in order to maintain an optimum power factor (ϕ), and provide values for commutate sequence of the Source Voltage Inverter (VSI).

The stability of the grid has been evaluated using the frequency and voltage distortions as test parameters.

The model tracks the angle profiles of the network when it is connected to photovoltaic panels and wind generators. The results can be presented (Figure 14) as the evolution of the profile angle of the grid voltage and frequency phase using various synchronization algorithms, such as: dqPLL, dqSOGI, dSOGI, MDSOGI. The presence of harmonics is observed when they appear as the result of instantaneous perturbations to the network. In reviewing the performance of each of the synchronization algorithms, clearly dqPLL delivers a poorer performance when compared to the other algorithms, especially when the voltage signal is monitored: the voltage presents irregularities in the signal and a small time lag with respect to the signal obtained of the other algorithms. Similarly, for the bottom plots, the profile of grid voltage angle is presented. This profile grid angle has no harmonic but changes in the grid frequency are observed when a frequency step of 50Hz to 100Hz is applied at 0.12s.; the signal response of the

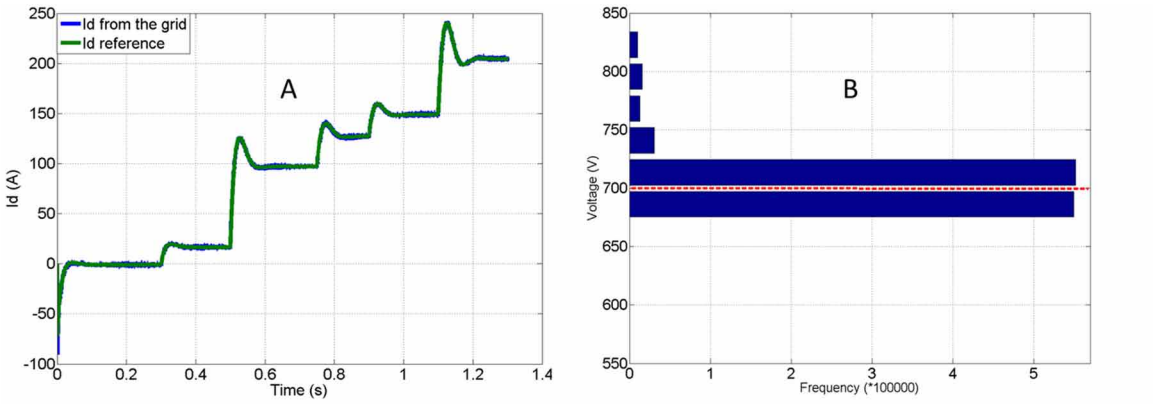
Figure 14. Illustration of technical parameters used for testing the stability of the grid and the response to variable power input from renewable sources. Top: Synchronization phase profiles as obtained with the different synchronization algorithms (left) and the response to a change in frequency from 50Hz to 100Hz in 0.12s. (right). Bottom: Frequency variation to the presence of 5th and 7th harmonics (left) and 50Hz steps (right)

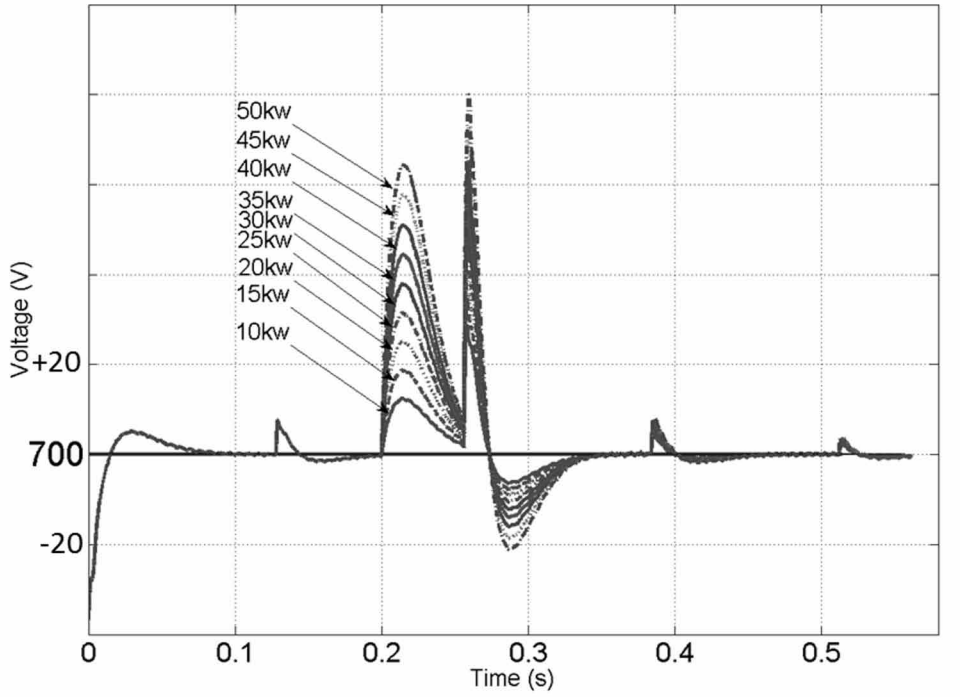


network frequency when the system is subjected to 5 and 7 harmonic is also illustrated in the bottom left plot. It can be noted that when the network is subjected to significant content of harmonic distortions (20%) the performance of the synchronization algorithm is key in maintaining stable benchmark values for voltage and frequency that have been specified in the design. Having a large presence of harmonics in the system values may shift the center frequency to which the algorithm was designed and the system is incapable of recovering bench mark values within a reasonable time delay. Finally, the last plot of Figure 14 (bottom right) shows the response of the synchronization algorithm and how the frequency varies when the system is submitted to a step frequency of 50Hz. Again, a small overshoot which has a retention time of 0.02s is present but very quickly returns to the correct value (in less than 200ms), any overshoot is completely smoothed within 500ms. Monitoring the network frequency signal by the synchronization algorithm is key in maintaining unity power factor which requires tracking the frequency signal at all times.

The aim of the control is to keep stable values for voltage and frequency of the grid even when the injection of power varies strongly in a brief period of time, as is typical of an intermittent power source as wind or PV. The behavior of the current injected to the grid (Id) varies and delivers the additional input of power that needs to match the demand of power delivered to a load connected to any other point in the grid. In Figure 15A, I_d is presented over time, and illustrates this effect: the I_d reference current

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 15. A Current injected when several PV systems are connected simultaneously presenting a different power generation with variations within a few milliseconds. (The range of power is several kWp as shown in Figure 16), B Voltage signal statistics during a long time span (four months)



value changes, present slight overshoots upon addition of power, but the overshoot is quickly controlled returning the current I_d to the (new) correct value. It demonstrates a good match between the network synchronization algorithms in converter power and network power. This amount of current injected into the system is created by connecting the PV or wind systems to the network, they have a nominal capacity, but their real time power is changing as a response to the environmental value (irradiance and temperature for the solar panels, wind speed for the wind systems), this variation also comprises the intrinsic variation in parameters which arise from the location of the system in different geographical sites.

In Figure 16 the response of the voltage signal of the network when an additional instant power is supplied from solar panels and wind turbines scattered in the region is simulated. When injecting a variable voltage to the electricity grid, it suffers an "overpeak" voltage, which is higher when the injected power is larger. However, even though the system is subjected to a large increase in voltage, these values tend to return to the reference value of the signal, thus demonstrating that the gains of the PIs are in the appropriate design values. Random increases and decreases of power injection, even if displaced in time, creates a smoothing effect and allows the algorithm control to work more efficiently.

The histogram presented in Figure 15B shows the voltages over the course of four months simulated from environmental values used as input parameters for the simulation. Deviations appear both below and above the reference voltage value which is set to 700V. This fact means that even though in those four months the variability of generated power from wind and PV sources has been large, the voltage value of the Microgrid is always kept approximately equal to the reference thus indicating that the control of powers, currents, angles and voltages from the power inverter and its correction through the synchronization algorithm is being performed correctly. The remaining histogram bars indicates a trend in which values of the grid voltage are not symmetric, but deviates towards higher values; this is an expected behavior since the main problem with the variability of power injection to the grid is the overshoot of voltage values. Nevertheless, future improvement of the control algorithms and fine tuning of proportional, integral and derivative parameters of the control loop may reduce this spread in values.

Figure 16. Grid voltage response to the injection of variable power arising from different PV facilities located in separated geographical locations (under distinct irradiance). The graph shows the response to steps up to 50kW, which in all cases are stabilized in less than 500ms

SOLUTIONS AND RECOMMENDATIONS

A set of optimum locations both for the installation of photovoltaic and wind systems have been found. Within this set, a few locations have been selected and data series of irradiance and wind speed have been provided in order to be used as input for the modeling using MatLab-Simulink as explained in section 2. The output of the model provides information about the stability of the Microgrids and its dependence with the number of systems interconnected and the variability of environmental parameters. Simultaneous modeling of photovoltaic and wind models using the real data series as input for the simulation has shown that distortions in the grid (defined as voltage and frequency deviations from the nominal 220V, 50Hz) can be minimized and that the geographical distribution of locations, even within the same Region de Murcia, together with the combination of two different technologies for the renewable electricity generation (photovoltaic and wind) creates a smoothing effect that helps to bound the expected distortions arriving from intrinsic variability of renewable sources. Anticorrelation of the output from the photovoltaic and wind systems have been observed when the data at analyzed at different time scales, this result is an indication of the complementarity of both sources of renewable electricity and it could help to minimize the distortions as well as to avoid the need of energy storage, since capacity back-up from other generators (ideally hydro) already installed should be enough to meet electricity demand in real time.

FUTURE RESEARCH DIRECTIONS

Smarter distribution can be achieved through the fast control of hundreds of individual DER units. This would require real time information on each DER unit and key loads. The control complexity and reliability of such a system is greatly reduced using coupled Microgrids. First a systems consisting of many Microgrids does not need fast communication as discussed above and demonstrated at the AEP test site. Second any communication system would re-dispatch each Microgrid without needing detailed information on each DER unit. Recall that the basic smart distribution system objectives include improved reliability, self-healing, simplified controls and increased generation efficiencies through the use of waste heat. Improved reliability, simplified controls and increased efficiencies are imbedded in the basic Microgrid concepts.

CONCLUSION

The combination of Soft Computing and numerical modeling is a powerful tool to evaluate the performance of Microgrids in which several photovoltaic and wind systems have been connected. Optimum locations using Geographical Information System databases have been selected for the facilities and the simulation of electrical output using real environmental parameters for these locations have shows that distortions to the grid can be minimized. Integration of more systems into the grid and broader distribution of locations were the systems are operating may have an even greater smoothing effect.

KEY TERMS AND DEFINITIONS

Analytic Hierarchy Process (AHP): A technique for organizing and analyzing complex decisions through hierarchical structures. It helps decision makers find one that best suits their goal and their understanding of the problem.

Fuzzy Logic: A form of many-valued logic; it deals with reasoning that is approximate rather than fixed and exact. Compared to traditional binary sets (where variables may take on true or false values) fuzzy logic variables may have a truth value that ranges in degree between 0 and 1. Fuzzy logic has been extended to handle the concept of partial truth, where the truth value may range between completely true and completely false. Furthermore, when linguistic variables are used, these degrees may be managed by specific functions.

GIS: A computer tool which is able to capture, store, analyze, manage, and present all types of geographical data.

MCDM: A set of methods for decision making in a process of selection on different alternatives, based on a set of criteria or points of view, to achieve one or more objectives.

Microgrid: A small scale electrical grid comprising power generators and loads which consume locally the generated electricity. The design of small, efficient, smart grids is a challenge, especially if they comprise renewable power sources. Depending of its size or the interconnection to larger grids, a Microgrid may require the inclusion of electricity storage means.

PV System: A photovoltaic system generates electricity from Sun light. It is composed of solar modules (or panels) and "balance of system" (BOS) components; the BOS may include electronic regulators and inverters, batteries, fixed or tracking mounting systems, etc… depending on the system design, which may be a stand-alone system, or a grid-connected system.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Technique for Order Preference by Similarity to Ideal Solution (TOPSIS): A proposed decision model for sorting preferences by similarity to ideal solution. The basic principle of the method consists in finding an alternative whose distance from the positive ideal solution is less and whose distance from the negative ideal solution.

Wind System: A wind system generates electricity from wind. It is composed of a rotating aerogenerator which can be of horizontal (the most common) or vertical design, the aerogenerator is coupled to a dynamo which creates electricity from the mechanical motion. The system is completed by electronic systems to control the frequency and voltage of the electricity, which is in most cases fed into the grid.

Chapter 28
Balancing Formalization and Representation in Cross-Domain Data Management for Sustainable Development

Paolo Diviacco
Istituto Nazionale di Oceanografia e di Geofisica Sperimentale - OGS, Italy

Adam Leadbetter
Marine Institute, Ireland

ABSTRACT

Sustainable development is grounded in complex systems where phenomena and processes are so interrelated and intermingled that they can only be studied in a multiple disciplinary manner. Limitations in understanding such systems can be identified that are either epistemic and cognitive or socio-economic. Both cases are problematic for collaborative and multidisciplinary studies in sustainable development. This chapter explores these difficulties with a particular focus on data management, an activity that is at the same time very important and very sensitive to such problems. To allow users to find their way through data and information spaces, solutions are proposed that take advantage of either the formalization of knowledge; or of representations, such as schemas, mind maps or graphs. Through a careful balance of these two pathways this chapter demonstrates that it is possible to mitigate the difficulties mentioned above and allow a community to work together at profit.

INTRODUCTION

Sustainable development is the possibility to benefit from natural resources without incurring in their depletion or triggering negative side-effects in other domains. This dualism is also reflected in the United Nation's (UN) Sustainable Development Goals (UN resolution A/RES/70/1, 2015), where on one hand the UN lists goals such as end poverty and hunger or ensure healthy lives, while, at the same

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

time, claiming that these have to be achieved ensuring conservation of the environment, ecosystems and combatting climate change and its impacts.

This balance is very hard to obtain because it is very difficult to understand all the aspects of the related processes and phenomena and it is very complicated to try to control them. Indeed in sustainable development, understanding is problematic because:

- The necessary skills and competences come from multiple disciplines such as biology, geology, sociology or economics
- Since multiple fields are involved, research projects in this area are very likely to be collaborative and cross-disciplinary
- Approaches and methods needed for sustainable development related to scientific fields are often not as rigorous as those needed in other domains such as for example computer science or engineering
- The need to collaborate with other people can introduce issues that range from simple misunderstanding, to lack of awareness, tacit knowledge, up to politics or rhetoric

It is important to understand that these effects are not due to insufficient efforts spent during coordination or managing of projects but to the intrinsic nature of knowledge, and its usage, in the domain of sustainable development. It is a cultural problem. To address such issues, therefore, instead of organizing the work within a "one-size-fits-all" manner that has been devised for other sectors, we need to develop strategies and perspectives focused on the specific case of sustainable development. In this chapter we will consider the case of data management, an activity where all the above mentioned issues very clearly emerge since data, and the information built on top of those data, are at the base of all sustainable development activity. In this sense it is possible to highlight the existence of a gap between what is required by stakeholders and what can be offered by experts. This is not only a gap but a structural difference. The main focus of stakeholders is on norms, decisions and protocols, while scientists offer observations and hypotheses.

The availability of data is therefore overwhelmingly important. It is necessary to enable information to be built from different perspectives and ways of thinking by actors with different point of views, approaches and aims. To facilitate this, data should be understandable by all the designated community.

To address all this we will, in this chapter:

- Describe the mechanisms that are at the base of the issues that limit and obstruct handling of such topics
- Introduce the concept of representation and its implication in data management and in particular in the case where contrasting cognitive models access the same representation
- Introduce the problem of formalization of knowledge that can be applied to assist data access and to frame collaborative research activities
- Discuss the advantages and disadvantages of formalization and how this can be put in practice and the tools needed
- Discuss whether knowledge can be exploited even without the need to formalize it; how this can be put in practice and the tools needed

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

BACKGROUND

Sustainable Development

The Brundtland Commission's report (Brundtland, 1987) defined sustainable development as "development which meets the needs of current generations without compromising the ability of future generations to meet their own needs". The main point of interest of such a definition is the connection between economic and social development, in particular for people with a low economic standard of living; and the importance of protecting the natural resource base and the environment. If the latter is jeopardized, no improvement can be obtained in economic and social well-being. In addition the exploitation of resources has to consider a long term perspective where the effects of development will condition the environment for future generations.

The study of processes and phenomena in this context is based on two pillars: the socio-economic; and the environmental. Authors such as for example Murphy (2012) highlighted that a specific focus has been put on the environmental side, while socio-economic factors were considered less relevant. On the contrary, they are very important and very complex to handle since they are dependent on the context and on the capacity of each country to respond to each its social problems.

The complexity of the matter was mirrored also in the progressive loss of enthusiasm and rise of scepticism that from the United Nations Conference on Environment and Development in Rio de Janeiro in 1992, through the Johannesburg Summit lead to the current situation, where the focus moved from an all-encompassing attempt to address all issues simultaneously towards a more pragmatic approach where local and simpler issues are under examination.

Sustainable development is therefore a cross-domain field where researchers and stakeholders from different backgrounds, with different interests and different ways of thinking, meet. Processes and phenomena in sustainable development are, in short, complex systems.

MAIN FOCUS OF THE CHAPTER

Limitations of Reasoning in Sustainable Development

Complex systems are entities where multiple factors interact and intermingle at the same time. In these cases it is very difficult to isolate *a posteriori* the contribution that each of these factors might have exerted, while on the other hand it is important to identify them and understand how they can influence the whole system.

As mentioned above scientific disciplines involved in the study of sustainable development span a wide range, from environmental to socio economic studies. Practices, theoretical frameworks, even the mathematics used are often very distinct between disciplines. However, there is one common aspect that can be found in all these domains: the difficulty in providing exact quantitative, unbiased measurements. As a consequence, it is very difficult in the domain of sustainable development to apply what is generally understood to be the standard view of the scientific method. It should be noted that this does not apply only for "environmental related" disciplines, but maybe even more so in the case of socio-economic ones.

The standard view of the scientific method prescribes that scientific experiments should be reproducible, meaning that having set the same conditions we should get the same results. This rarely happens

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

in environmental and socio-economic sciences since the factors governing a process and their interdependence are very sensitive to small variations (the so-called "butterfly effect"); they are generally nonlinear systems, so that it is very difficult to exactly replicate the configuration of an experiment. In these domains correlation often does not mean causation, highlighting the role of an underestimated parameter (Lawlor, Davey Smith & Ebrahim, 2004). In addition, laws are often built considering a low number of cases, or cases that only resemble what is under observation, which creates problems in finding analogies (Engelhardt & Zimmerman, 1982).

Another important factor which conditions the possibility to handle reliable measurements is theory laden-ness. This is the unintentional bias that researchers impose on measurements and observations. These latter are based on planned experiments that are based on one or more theories; meaning essentially to what someone is expecting to see. Therefore, quoting Hanson (1958)

Observation of x is shaped by prior knowledge of x.

This generally results in highlighting or neglecting information (Bishop, 1992) (see the section on representation later in this chapter). It is important to say that this happens at all levels, even at the level of perception (Diviacco & Busato, 2015).

The standard view of the scientific method is based on an inductive-deductive loop that from initial observations drives the formulation of a law that later through an experiment could be validated (or following Popper (1963), "corroborated"). It is easy to understand that in the domain of sustainable development, considering what has been said so far, the possibility to validate any theory through observations is very limited. To avoid the short circuit that this situation can generate, environmental and socio-economic sciences tend to substitute to the inductive/deductive loop with what Peirce (1958) called abduction. Abduction is a form of reasoning where the resulting state of affairs and the law is known, while the controlling state of affairs is sought (retrodiction). Abductive methods are very useful in the creation of new ideas[1].

Since abductive reasoning merely suggest that something maybe (Peirce, 1958) it is possible, and is often the case, that multiple explanations can coexist. Of course, adding this to the difficulty in setting experiments for a process or phenomenon, it is easy to see how complex and contradictory the activity of the experts in specific domains can be.

An important point in evaluating the contribution of science in understanding phenomena in domains such as sustainable development is the problem of objectivity and the commonly misleading definition of what is a fact and what is an opinion. In Diviacco (2015), and Diviacco and Busato (2015) these issues are described in depth, but several ideas of note are restated here to show how this can further limit the reliability of the standard methods to understand processes and phenomena in sustainable development.

The standard view depicts scientific research as an objective activity. To understand if this can be true we need first to understand what the term objective actually means. Objectivity is contrasted to subjectivity, and since subjectivity reasonably means "from someone's point of view", the resulting popular idea is that objectivity could be associated with "truth" and "reality", rather than how things may appear or might be imagined. This is an oversimplification. The common definition of objectivity refers to what should be actually called "metaphysical objectivity" meaning a form of objectivity that does not depend on experience, but of course we know that science is based on observation, and therefore we should revert to what we better identify as "epistemic objectivity". This can be defined as the sets of claims or judgments which truth values are not determined privately. Objectivity can be explained

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

only as "not just from someone's point of view", objectivity is always limited to the point of view of a certain number of people that agree and converge on a shared vision.

Summing up subjectivity is private and objectivity is public or, to put it another way, only shared points of view are objective (Diviacco, 2015; Searle, 1995).

Now, having defined the difference between metaphysical and epistemic objectivity we can make a further step and understand what a fact is. Facts are metaphysically objective, and as such practically we cannot access to them. What we can handle are merely possible situations that can be expressed by non-contradictory claims that we call "state of affairs."

The Sociologic

We described above the limitations of reasoning in research fields related to sustainable development that force a "relaxed" approach towards the possibility to access reality. We highlighted that these limitations lead to a model where multiple points of view are very likely to emerge, and that therefore multiple competing theories can coexist (without necessarily clashing).

Any explanation of a phenomenon or scientific model, following Woo (1999), have two forms of approximations and uncertainties: the intrinsic ones that depend on the limitations of the model and the aleatory uncertainties that are related to the beliefs of each researcher. In fact each researcher focuses only on what he thinks are the more likely causes of a phenomenon and excludes others. This is bias, a problem which we are not generally prepared to handle. Popper (1963) maintains that bias is unavoidable, and that we instead need to identify it and prevent its influence on research. In this perspective Pshenichny (2004) proposes that bias should be explicitly formulated in the theories and provides tools to take bias into account.

We showed that the state of affairs, meaning what experts consider in their everyday activities, can be seen as shared spaces on which a community needs to converge. It is therefore easy to understand how reasoning in the fields related to sustainable development is strongly conditioned by the social connection of the people working within the same project. Each actor brings his/her bias. It is easy to understand that if identifying the bias of a single actor could theoretically be possible, the interaction between biases of a community can be seen itself as a complex system.

Kuhn (1962) showed that scientists tend to isolate themselves in what he called "paradigms", meaning a mental environment defined by the personal history of the single researcher, their points of view, the tradition they are part of, their models and myths, in general their background. Paradigms condition their "normal" scientific life and tend to gather scientists in groups that, following Becher and Trowler (2001), resemble "tribes". They tend to evolve separately and eventually cannot understand each other (incommensurability). In this space, following Whitley (2000), control over facilities and resources of research define status and identity of researchers and tribes. Following Latour and Woolgar (1979), the lives of scientists and experts are conditioned by the network of allies and by the strategic position that the researcher is able to maintain in the community. In few words "Science is a social construct" (Latour & Woolgar, 1979).

Communication

In this landscape we have to consider a further complication, which is communication. Traditionally, this is layered into syntax, semantics and pragmatics (Morris, 1971, Diviacco 2013). Due to paradigms and

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

incommensurability it is easy to understand that communication can be complex and prone to misunderstanding. These effects can be traced at all levels of communication, but while sometimes efforts are spent in trying to agree on a common syntax, those spent in trying to achieve a common understanding and meaning are generally very problematic, while within the scope of pragmatics they are commonly not even considered.

Shannon and Weaver (1949) provided methods to overcome communication difficulties. However these methods were mainly focused on the syntactic level and are more related to the technical implementation of communication. They do not address problems related to the human "contribution" to these difficulties.

Following Mirowski (2002) in Shannon's information theory, information is something that stands apart from and is independent of the processor of information and its internal characteristics, then it deals with encoding, transmission and decoding, not caring about the ability to understand of the payload.

In the case of sustainable development, instead, as we demonstrated, the role of the human-human interaction and therefore the need for a convergence of a community is paramount

We can identify essentially two classes of issues that can generate such difficulties, and namely:

- Epistemic and cognitive ones: that are generally structural, intrinsic, often innate and unconscious, such as tacit knowledge and theory laden-ness
- Socio-economic ones: that are conscious and voluntary, where actors aim to exert an influence on a process, project or activity in general

In the first case, we already described what theory laden-ness is; we will now briefly describe what tacit knowledge is. Tacit knowledge is knowledge that cannot be made explicit because obscured or embedded in practices or even tools. Following Polanyi (1966)

We know more than we can tell.

Tacit knowledge therefore remains often outside communication since cannot be captured.

Socio economic issues are also very relevant. In any community, in order to have control over the evolution of a project, partners are committed to the development and successful strategic positioning of their visions and of themselves as an "obligatory passage point" (Latour & Woolgar, 1979). Actors' contributions will then be ideological and political, which introduce another dimension to take under control in communication. Following David and Bunn (1988) who analysed the possible economic interests that can interfere with the quest for interoperability, this has to be considered at all communication levels: pragmatic and semantic of course, but even at the syntactic one.

SOLUTIONS AND RECOMMENDATIONS

Summing up, in the domain of sustainable development, on one hand we can have serious intrinsic reasoning issues in understanding processes and phenomena, on the other side we have complex social interactions that can affect knowledge building. How can we be optimistic about the possibility to devise any data management tool that can be used in this domain, where, as mentioned above, collaborative work is expected?

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Knowledge

Knowledge can be associated with the acquisition and processing of information that under certain conditions can be used, expressed, shared, and transmitted. The syntax/semantics/pragmatics tri-partition we described in the section about communication, can be roughly associated with the distinction between data, information and knowledge (to delve more into the argument please see Diviacco, 2013 and Diviacco, 2015). The problem we have to deal with is that traditionally only a one-directional path from data towards knowledge was identified in knowledge building. On the contrary, as we demonstrated above, epistemic, cognitive and socio-economic factors, following the opposite direction condition severely information and data acquisition and management (Fox 2014, Diviacco 2013). How can we cope with this?

We can follow essentially two paths:

- Knowledge formalization (controlled vocabularies, ontologies, archetypes). This is based on the identification and definition of the concepts that constitute that particular abstraction of the world and on the construction of a map of their relations. This environment can be later used to classify and reason on the available data and information, and reconfigure that knowledge to adapt to other paradigms
- Non-formalized knowledge (boundary objects, representation). This is based on the introduction of artefacts that could be used to allow multiple paradigms to access the same data and information space from different point of view.

Knowledge Formalisation

In order to truly pursue sustainable development - which in the definition above takes place over the time scale of generations, when data, information or knowledge are captured there must be enough supporting information alongside the new data to allow future users to re-analyse, re-visualise and reinterpret the data without recourse to the data originator. Once this is achieved, environmental observations may be used to evaluate future problems of sustainable development, and even to assess the sustainability of certain development choices. It is also instructive to consider how data becomes knowledge.

A History of Knowledge Formalisation in Marine Data Management

Whilst this may seem at first to be a utopian vision for data managers, it is in fact the mantra that has been used within the International Oceanographic Data and Information Exchange (IODE) community for many years as a way of showing the data management process adds value to data (Lowry, Rickards, & Brown, 2005). This has required the formal definition of marine data models, which have evolved over many years and iterations. Whilst the history of the common vocabulary definitions used within these data models is explored in detail by Buck and Lowry (2016, see chapter 1 this volume) a brief overview of the formal data models produced in the marine science domain is of use in setting the scene for this, and subsequent chapters. Initially, knowledge formalisation in the marine sciences was through definitions of common metadata schema and file formats for exchange of information and results between partners in specific projects. The classical example of this is the GF3 format, developed by the Intergovernmental Oceanographic Commission's International Oceanographic Data and Information Exchange (IODE) and first proposed in 1979 as a generalized formatting system for general use in the transfer of

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

marine science data (UNESCO, 1987). A key, indeed prescient, feature within GF3 was the publication of common vocabularies, in a paper form, which is a theme we will return to later in this section in a World Wide Web context. GF3 was eventually refined by the IODE Group of Experts on the Technical Aspects of Data Exchange (GETADE). The GETADE Data Format was developed in response to the perceived agedness of GF3, which had led to many national oceanographic data centres developing their own file formats proving to cause a barrier to the exchange of data between nations. However, the knowledge formalisation within GETADE remained within the GF3 code tables. The first real move away from this model was the Marine XML project. Marine XML was not a project designed to create a new XML standard encoding, but to provide the crosswalks between various standards through knowledge encapsulation. The results of the Marine XML project showed that there was still work to be done on mapping various metadata schema from the different national oceanographic data centres and domain projects; and that access to the GF3 codelists should be improved (Isenor & Lowry, 2005). By the time of the Marine XML project, the codelists had moved from paper to FTP site downloads, but follow-on work in the EnParDis and NETMAR projects and through the use of the successor, web-enabled controlled vocabularies in the SeaDataNet infrastructure has brought these to modern web standards (Leadbetter, Lowry, & Clements, 2014).

The Marine XML project began to bridge the gap between data and knowledge through its crosswalk paradigm, but how can we understand a more general flow of data to knowledge? The data ecosystem may be seen to encapsulate the data-information-knowledge-wisdom (DIKW) model of Shedroff (1994). An ecosystem grows, evolves and thrives on diversity. In the DIKW model, data may grow through presentation and organisation into information. Information itself may evolve into knowledge as consumers from a wider context than the data were originally collected in bring their experience to conversations about the data and information which can then tell new stories. Taking the example of marine science data above, the raw data straight from the research vessel cruise obviously fits into the data part of the model. Through organisation and presentation of the raw data into something cleaner and more usable, at the "beta" stage in the software release metaphor, the lines between data and information have become blurred and the data are evolving towards information. At the "release" stage where the data are organised and presented in such a way that they are totally reusable, and may even have a dataset description paper from an academic journal to accompany them, the evolution to information is complete. These "information-sets" can now provide the stimulus for researchers to converse about what they contain and to begin building knowledge, While many of the drivers for data sharing examined in this paper have come from the sciences, the idea of research data evolving into information, knowledge and wisdom has touchstones in the arts, particularly the field of literature. As Will Self (Guardian, 2008) notes, creative writing is "not building things. You are removing things, chipping away at language to reveal a living form." Indeed, as scholarly communication in all disciplines is currently predicated on the peer-reviewed, written research paper it could be seen that all synthesis of research data into the information and knowledge these papers contain is a creative writing process.

The Current State of the Art in Marine Data Management Knowledge Formalisation

There are emergent technologies throughout the fields around oceanography which we will incorporate into oceanography, and through that convergence we will make oceanography into something even more magical. (Delaney, 2010)

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

In the emerging Web Science (the study of large-scale socio-technical systems, such as the World Wide Web and the relationship between people and technology, the ways that society and technology co-constitute one another and the impact of this co-constitution on broader society, Shadbolt & Berners-Lee, 2008) the concepts of both the Semantic Web and Linked Data are very powerful tools in the formalisation of knowledge. Indeed the Semantic Web was born of Tim Berners-Lee's vision to create a Web of Data analogous to the World Wide Web of documents (Berners-Lee, 1998). The Semantic Web is a standards based approach to the Web of Data which promotes common data formats and exchange protocols on the Web, most fundamentally the Resource Description Framework (RDF). According to the World Wide Web Consortium, "the Semantic Web provides a common framework that allows data to be shared and reused across application, enterprise, and community boundaries" (Herman, 2008). The Semantic Web encapsulates knowledge in a spectrum of formalisation, from low to high. The points of this spectrum, often called the "ontology spectrum" or "semantic spectrum", are defined by McGuinness (2003). In overview, the simplest point on the spectrum is the catalogue (or glossary, as in Navigli & Velardi, 2008) that simply provides a list of terms used to annotate data and their definitions. A catalogue is not necessarily published to either the WWW or Semantic Web. Nor does a catalogue require a group of experts to provide governance over its content. Complexity is increased in the controlled vocabularies (Warner, 2002) and data dictionaries (Kumpati, 1985, IBM, 1993) which add, respectively, naming conventions and publication on top of the catalogue. A data model (van Renssen, 2005) then adds some definition of the relationship between the entities of a data dictionary. A taxonomy further adds a tree hierarchy with the concepts at the bottom of the tree inheriting the properties of those concepts at the top of the tree (Navigli & Velardi, 2008). A concept can be viewed as the definition of an idea or notion; a unit of thought (Miles & Bechhofer, 2009). A more complex point of the semantic spectrum is the ontology. An ontology describes all the concepts in a given domain and the relationships between them, and following best practice (Cox, 2012), is conceptualised using Uniform Resource Identifiers (URIs) for each of the data elements, relationships and property types. An ontology can be parsed by a reasoning engine and then used to infer knowledge about the domain.

Similarly, Linked Data makes use of these Semantic Web publication patterns, but then uses the expectations of a Web document (URIs are used to identify things; when looked-up those URIs resolve over HTTP; the resolution returns a document compliant with standards; links are provided to other URIs so users may discover other resources) to provide connections to other data published on the Semantic Web (Berners-Lee, 2011). Leadbetter, Cheatham, Shepherd & Thomas (2016, see chapter X this volume) further explore the use of Linked Data in the marine science domain. These approaches, as well as the emergence of real-time analytical applications for marine data streamed from instruments to data centres, have given rise to the concept of using the Web as the query and programming interface for marine data (Chandler & Arko, 2015). While born of the Linked Data paradigm, this is also seen in the Sensor Web Enablement activities of the Open Geospatial Consortium, and in products such as NOAA's ERDDAP server (Mendelssohn & Simons, 2008). What remains, however, is a suite of non-standard, domain specific interfaces without a common unifying "glue".

Semantic Web practitioners have developed the notion of the upper ontology in response to this problem of using data encoded with the knowledge of different domains. The upper ontology should describe concepts which are common across all domains, and in this regard bridges the difference between the information modelling ontology and the philosophical ontology. An important function of an upper ontology is to support very broad semantic interoperability between large numbers of ontologies which are accessible ranking "under" this upper ontology. As the rank metaphor suggests, it is usually a

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

hierarchy of entities and associated rules (both theorems and regulations) that attempts to describe those general entities that do not belong to a specific problem domain. The World Wide Web Commission has published both a Provenance Data Model (Missier, Belhajjame, and Cheney 2013), and a Semantic Web encoded version of this model as the Provenance Ontology, or PROV-O (Lebo et al. 2013). PROV-O may be considered an upper-level ontology as it provides a very broad level of semantic interoperability between more domain specific ontologies, or it is "a domain-independent common-sense theory constructed by aggregating suitable contributions from areas such as descriptive metaphysics, philosophical logic, cognitive science and linguistics" (Guizzardi 2006). PROV-O is based around a simple model of three classes:

- Entity a physical, digital, conceptual, or other kind of thing with some fixed aspects; entities may be real or imaginary
- Activity something that occurs over a period of time and acts upon or with entities; it may include consuming, processing, transforming, modifying, relocating, using, or generating entities
- Agent something that bears some form of responsibility for an activity taking place, for the existence of an entity, or for another agent's activity

A number of attributes have been defined which describe the relationship between the classes by characterising the influence that an instance of one class has on another instance, either of the same class or of a different class. There are several examples of PROV-O being used as an upper ontology in the Earth Sciences (Compton, Corsar, & Taylor, 2014; Ma et al., 2014; Leadbetter & Vodden, 2015). Its limited number of classes mean that there is a clear pathway for ontology alignment by placing the classes of a domain-specific ontology into the class structure provided by PROV-O. Taking the alignment of the Semantic Sensor Network with PROV-O as a first case study (Compton, Corsar, & Taylor, 2014), it can be seen the Semantic Sensor Network Observation class defines an observation an interpretation of real-world events and the results of those events. For example, a stimulus (wind) spins the cups on a wind sensor, generating a current, and through an equation modelling the relationship between this and the physical property of wind speed the sensor outputs a value that we can choose to interpret as an observation of the wind speed at that moment. The observation is the social construct of the interpretation, not the act of the observing itself. Following the Semantic Sensor Network model, Observation would be aligned with the PROV-O class Entity. This however contrasts with the view of the ISO 19156 Observations and Measurements (O&M) model, which states that an Observation is an action whose result is an estimate of some property of a feature-of-interest, obtained through the use of a specific procedure (Cox, 2006). In O&M an Observation therefore aligns with a PROV-O Activity. Therefore, alignment can be achieved between the two lower-level ontologies as PROV-O Activity is not a disjoint class with PROV-O Entity. However, care needs to be taken in this regard as the Observation class from the two different lower-level ontologies also represents subtly different concepts the record of an observation in the Semantic Sensor Network and an Observation Event in O&M (Cox, 2015). It can therefore be seen that this use of PROV-O as an upper ontology helps to both align the ontologies for interoperability but also highlights the specific differences of the creation philosophy of the ontologies being aligned.

One ontology which describes, in general terms, oceanographic deployments, such as research vessel surveys, is the Ocean Data Ontology (ODO, http://www.ocean-data.org/). This ontology should be able to be aligned with other ontologies describing specific details of the sensors deployed (for example the Semantic Sensor Network Ontology) or the observations made in the environment during the deploy-

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

ment (for example, O&M). From ODO, the classes of interest are Dataset, which describes a collection of observations made during a Deployment and is linked to the specific research project making the deployment and the funding award which paid for the deployment; and Parameter which links an instrument on a deployment to the environment property it is observing as well as describing the observable properties recorded within a Dataset. It can be seen that these classes should be available for users from a range of disciplines who wish to use the data in decision making tools or other applications, and therefore these classes will be aligned with PROV-O. As shown by Leadbetter and Vodden (2015), the oceanographic domain often uses the term "parameter" where the O&M community use the term "observable property", therefore the "Parameter" class of ODO should be most closely aligned with O&M's Observable Property, showing that formalization is community dependent and that bridging between models of knowledge formalization must be done at a human level. This is an attribute of the O&M class Observation, so therefore in a PROV-O model could come from any of the three classes. It makes no sense for the Parameter to be an agent as it bears no responsibility for the Observation activity taking place or the creation of an Entity; likewise the Parameter is not an Activity as it does not act upon or with Entities. Therefore, a Parameter, or Observable Property, is an Entity and an Observation Activity can use said Entity. Similarly, within the Semantic Sensor Network a sensor, or instrument, observes a property, or an ODO Parameter. A sensor is known to be defined as both a PROV-O Agent and Entity (Compton, Corsar, & Taylor, 2014), therefore an ODO Instrument should also be defined in this way and a Parameter may be attributed to it. As we have seen, Observations are PROV-O Activities, resulting in PROV-O Entities (either O&M Results or Semantic Sensor Network Observations). From here, a group of results should also be a group of PROV-O Entities, and therefore a PROV-O Entity should sufficiently describe an ODO Dataset. Therefore, an ODO Dataset can be said to be derived from the PROV-O Entities which are the O&M Results of the Observations made using an ODO Parameter.

Archetypes as an Alternative Method in Marine Data Management Knowledge Formalisation

An alternative strategy for true knowledge capture and interoperability across domains both within and without the marine sciences to that of the upper ontology alignment method may be found by looking further afield than the Earth Science informatics domain. By taking Delaney's approach that there are interesting developments in other domains on the fringe of ocean sciences and looking to the field of health informatics, where much work has been done on the topic of separating information models and knowledge models we can see that archetypes (Beale, 2002) offer one solution to a true encoding of knowledge. As the volumes of observational data from Argo floats, gliders and ocean observatories increases and the desire to semantically annotate the data at source also grows, solutions have been designed as a strategy to compensate for the fact that data captures only a part of what researchers can expect from an observation (Diviacco et al. 2014, Fredericks, 2015), we are reaching an age of ubiquitous marine computing which should allow for more user friendly and comprehensive data capture (Garde, Hovenga, Buck, & Knaup, 2007). However, this precludes the heavy manual involvement of the data manager in the process of creating the "utopian" vision of users not wishing to continually return to the data originator in order to understand their datasets. Archetypes have been used in healthcare informatics to define integrity constraints; data required for the interpretation of a measurement; multilingual support; and replication of domain knowledge in ubiquitous computing environments to address this issue. Likewise, healthcare informatics experts have used archetypes successfully to provide interoperability

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

between otherwise heterogeneous data systems (Lezcano, Sicilia, & Rodríguez-Solano, 2011). As Beale (2002) states, with large information models for domains it is often logistically and technically difficult for different data producers and users to agree on a common data model. This makes automated processing and decision support using observational data very difficult to achieve. In the typical archetype use-case, the archetype is used to describe knowledge while the ontology is used to describe information, designed to address issues where knowledge can be volatile (i.e. the definitions of concepts within the information model can change over time), or the number of knowledge entities for a given domain is vast. This second point is likely to be of most use in the marine science domain, particularly when considering the NERC Vocabulary Server (a commonly used Semantic Web resource in the marine data management community; Leadbetter, Lowry, & Clements, 2014) contains some 98,000 knowledge entities (as of October 21st, 2015).

Lezcano, Sicilia, & Rodríguez-Solano (2011) provide a mechanism to match the definitions of archetypes to ontologies and to provide archetypes with computational semantics by providing rules for the encoding of archetypes in the W3C's Web Ontology Language (OWL). This is particularly useful because the definition language used in producing archetypes does not allow for inferencing (Beale, Heard, Kalra, & Lloyd, 2005) but OWL based archetype definitions can be enhanced by the inclusion of Semantic Web Rule Language entries (Horrocks et al., 2004). Given the example of how the Semantic Sensor Network, Observations & Measurements, and Ocean Data Ontology all formalise descriptions of measurements within the environment in slightly different ways, and instructive use case for the application of archetypes to the marine science domain is to prototype an Observation archetype synthesising the knowledge encapsulated by these ontologies. This is expanded below using the Archetype Definition Language (Beale, Heard, Kalra. & Lloyd, 2005).

A prototype observation archetype should capture the following knowledge as already described in this chapter: that an observation event leads to a result, which contains a value and a unit of measure; an observation event requires the observation of a parameter, or observable property; and a process, including a sensor or instrument, acts on the observable property to generate the result. Observations may be combined to generate a set of observations for grouping. An archetype conforming to this definition is shown in Listing 1.

It can be seen that there are growing numbers of methods and results in formalizing cross-disciplinary knowledge, but there are still difficulties arising in achieving a utopian vision where all formalized knowledge is truly interoperable. Therefore, there are many advances in representing knowledge in less formalized ways. This will be discussed below.

METHODS BASED ON NON-FORMALIZED KNOWLEDGE

Representation

We defined above the notion of "epistemic objectivity" as the sets of claims or judgments which truth values are not determined privately. Judgments imply a form of intentional portrayal of things, such as beliefs, precepts, news reports, books, articles, sentences and pictures, which can defines "representation". Intentionality connects epistemic objectivity with representation. Representations can be, amongst other things, theories and models, linguistic and mathematical entities, computer simulations, concrete objects (Diviacco, 2015). Representation can take place in multiple ways: linguistically when

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

something is explained; graphically in a map or a graph reporting the observation of a phenomenon; but also in other ways in which the linguistic aspects are less relevant or at least are only a medium for communication and do not necessarily contain all of the message. Diviacco (2015) gives examples of forms of representation where this de-literalization allows us to move the focus toward other forms of communication such as art where concurrent conceptual models can co-exist.

In light of the discussion in this chapter, representation is very interesting because it is communication that can be biased by cognitive and epistemic issues, by ideology or politics; or concurrently by all these factors. Strictly speaking, descriptions of entities and processes afforded by scientific representations are generally false (Chakravartty, 1995). Following Callender and Cohen (2006), representation has features reality does and does not have. It is characterized by omissions and commissions. Omission is the act of neglecting some possible causes among those that can explain a phenomenon; commission is the act of deliberately changing the network of possible causes and explanations of a phenomenon. Representation can then be used to change the parameters of the target system, representing it in a way that constitutes a distortion of its true nature (see the above section on the limitations of reasoning in sustainable development). Similarly in the case of painting or sculpture, it should be possible to distinguish realistic and non-realistic representations. Realism in representation is indicative of an easy to interpret display, even for the non-specialist. Non-realistic representation is such because it requires an interpretation phase where conventions need to be set. Accessibility depends on the ease with which representation can issue the same information and those viewing the representation can internalize conventions.

A key aspect of collaborative work is the possibility to access the same conventions. This can depend on the actual complexity of the phenomenon under study. In fact, using again the similitude with the case of painting; when simple objects are to be described, the iconic use of the image is often easy to grasp, meaning few conventions are needed. When objects are complex, the needed symbology becomes more abstract and therefore need to be managed in a specific way, incurring into the issues we described above.

Boundary Objects

The formalized knowledge paradigm requires large investment of resources in the governance of all the tools it can offer. In addition, the status of such an infrastructure cannot be considered stable, since new concepts continuously appear and have to be mapped in the environment.

An un-formalized paradigm allows a more relaxed approach since is intended essentially to offer access to data and information without imposing a specific viewpoint.

The approach is based on the ethnological studies done in nineties by Susan Leigh Star and James R. Griesemer (1989). They found that different communities, characterized by different languages, cultures and traditions can collaborate effectively notwithstanding the fact that they could have rather different cognitive models. In these cases they found that this process is facilitated by the presence of artifacts that can be used in different ways but that gather users in the same cognitive space bridging concurrent cognitive models through abstraction from all the domains of the partners. To do so artefacts must be weakly structured in common use, but strongly structured in individual use.

Boundary objects are artefacts related to sets of information, conversations, interests, rules, or plans, and are at the centre of communities of practices (Diviacco, 2012; Star, & Griesemer, 1989). Their application to bridge professional boundaries was studied by Kimble, Grenier and Goglio-Primard (2010), while their application in the field of the Arts can be seen in Van Saaze and Dekker (2013)

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

The idea of the boundary object can be put in practice through many kinds of artefacts. What is relevant is that, in practice, they are forms of representations. These can be for example: maps, graphs or work flows, to mention a few. These artefacts can be designed in order to expose "nodes" that can be used to gather data and information in the form of files, message threads, wikis or else. Each node can be labelled associating it to a concept, process or phenomenon, so that the artefact will gather all the knowledge of the designated community. On the other hand the artefact is intended as a passive entity, which performs no reasoning: the "work" is done mainly by the users.

Following Scardamalia and Bereiter (2006) knowledge building, in the perspective we are adopting here, can have two forms, and namely: (i) a weak form, where findings only become contributions to community knowledge when they are brought into public discourse, and (ii) a strong version, where the discourse is itself the state of public knowledge in a community.

We find very interesting that the state of knowledge of a community could be not only in the minds of the individual members of the community, but also in the discourse itself. In fact, if the discourse takes place in an artefact, this latter will become the state of knowledge of the designated community (Diviacco 2015) and will follow its evolution: practical implementations of this approach have been proposed by Diviacco (2015), Diviacco (2013), Diviacco and Pshenichny (2011) and Diviacco and Pshenichny (2010)

Limitations to such approach have also been highlighted (Diviacco, 2015). These relates mainly to the flexibility of the artefact itself. For example, a mind map already populated with data and information is very difficult to be changed in a later stage because that could possibly mean moving information across nodes, which of course cannot be automatized. A more flexible approach, which can be applied often, but not in all the cases, could be data annotation. In this case data is represented, for example plotted in a graph or projected in a map, while users are provided with tools to draw objects on the representation, such as lines, circles, arrows to capture the attention of the community on a feature that can be used as a node and therefore gather data, information, messages or else.

FUTURE RESEARCH DIRECTIONS

Considering the two paths identified, namely formalization and representation, we need to identify two groups of future research directions.

In the case of formalized knowledge, while Ontology Design Patterns, as explored by Leadbetter, Cheatham, Shepherd & Thomas (2016), offer one approach to integration of data by publishing data to a given pattern the considerations of this chapter offer two future research directions to use the patterns in different ways. The first would be to align the Ontology Design Patterns with PROV-O in order to use an upper ontology approach to combining data from different domains published under Ontology Design Patterns. The second would be to pull the Ontology Design Patterns up to the higher level in a two-level information model and to rewrite the knowledge captured in the patterns as archetypes.

In the case of representation based knowledge management, we think that a very promising future direction would be to explore the possibility to create on the fly the artefacts that help user to navigate the collaborative knowledge space. This could be possible for example analysing terms used in messaging or annotation. A positive aspect of this approach would be that possibly this could pose a bridge between the two worlds of formalization and representation since an interesting approach could be to ground this activity in controlled vocabularies or ontologies (Diviacco and Fox, in preparation).

CONCLUSION

This chapter aimed at exploring the difficulties behind data management in sustainable development and at proposing possible solutions to overcome them. We have highlighted the intrinsic limits of reasoning in this domain and the role of relationships and communication between the partners in the designated community. Tacit knowledge and contrasting cognitive models do not allow partners to understand each other's, and therefore knowledge, often can be formalized only with difficulties.

The resulting scenario is very complex. We claim that in spite of the difficulties we have described there are opportunities to address collaborative research in the domain of sustainable development through the exploitation of a careful balance of formalized knowledge and non-formalized knowledge representation. In many senses the practitioners of sustainable development in general, and ocean data management in particular, must look beyond their immediate domains in order to solve these issues.

Where knowledge can be formalized, tools such as controlled vocabularies, ontologies or archetypes can assist partners with different backgrounds to bridge the differences and incompatibilities of their original contexts. Where knowledge remains tacit, or difficult to agree upon different strategies should be introduced. These can be based on artefacts that allow the communication to take place without interfering with it. Such artefacts should be representations of knowledge that while being unique can be interpreted differently by the different communities.

We have introduced concepts from computer science; health informatics; philosophy; and art in order to provide an outline strategy to allow the management, integration and representation of marine data for sustainable development.

Tools based on such strategy will allow the end user to find and access data, information and knowledge on IT systems that eventually become themselves representations of the state of knowledge of a community.

KEY TERMS AND DEFINITIONS

Archetype: A computable expression of a domain content model in the form of structured constraint statements, based on a reference (information) model. Archetypes are all expressed in the same formalism. In general, they are defined for wide re-use, however, they can be specialized to include local particularities. They can accommodate any number of natural languages and terminologies.

Boundary Object: An artefact that allow two different and incommensurable communities to nevertheless collaborate. They are weakly structured in common use, and become strongly structured in individual use.

Linked Data: Linked Data is a technique that uses the Word Wide Web to connect related data that was not previously linked, or uses the Web to lower the barriers to linking data which are currently linked using other methods. In practice, Linked Data often uses the Resource Description Framework model and Web addresses (as Uniform Resource Locators, or URLs) to achieve these linkages.

Ontology: In computer science, an ontology formally represents knowledge as a hierarchy of concepts within a domain, using a shared vocabulary to denote the types, properties and interrelationships of those concepts.

Semantic Web: The Semantic Web is the World Wide Web of data built on the Resource Description Framework model as a foundation for publishing and linking data online.

Tacit Knowledge: Knowledge that cannot be made explicit because obscured in socio-political phenomena or embedded in practices or even tools.

Theory Laden-ness: Refers to the fact that 7 experience is categorized and preconditioned by prior belief, and that the process of building knowledge always involves the use of concepts from some previous view. This holds both from a logical and a perceptive point of view.

Chapter 29
The Economics of Renewable Energy Promotion Policies:
A Case of Wind Power in Brazil

Govinda Timilsina
The World Bank, USA

ABSTRACT

Large-scale deployment of renewable energy technologies, such as wind power and solar energy, has been taking place in industrialized and developing economics mainly because of various fiscal and regulatory policies. An understanding of the economy-wide impacts of those policies is an important part of an overall analysis of them. Using a perfect foresight computable general equilibrium model, this study analyzes the economy-wide costs of achieving a 10 percent share of wind power in Brazil's electricity supply mix by 2030. The study finds that the expansion of wind power would increase GDP in Brazil. The study also finds that a production subsidy financed through increased value-added tax would be superior to a consumption mandate where electricity utilities are allowed to pass the increased electricity supply costs directly to consumers. These two policies would impact various production sectors differently to achieve the wind power expansion targets.

1. INTRODUCTION

Brazil is well-known for its hydropower resources. However, a large portion of the economic potential of hydropower has already been exploited and a further expansion is increasingly constrained by environmental sensitivity and the remoteness of much of the remaining resource (REN21, 2014). On the other hand, the country is also endowed with a large potential of wind energy, estimated to be 143 GW (Meisen & Hubert, 2010). Most of the potentials are identified in the northeast and southern parts of the country, especially across the states of Bahia, Rio Grande do Norte and Ceara. While Brazil is currently expanding its thermal power generation capacity (IEA, 2014), the rapidly increasing emissions of greenhouse gases (GHGs) from the power sector is a major challenge to meet its voluntary commitments for climate change mitigation. Therefore, the government is planning to expand wind power, and

expects wind power to contribute 9% of the total electricity generation by 2021.[1] Moreover, wind power provides an excellent complementarity to hydropower in Brazil, as the high wind seasons coincide with low rainfall seasons.

In Latin America, Brazil is the leader in developing wind power generation capacity. The total installed capacity of wind power increased by more than 6 fold in just four years since 2010 (GWEC, 2014).[2] Brazil made the fourth largest addition of wind power capacity in the world in 2014 with 2,500 MW added in that year alone (REN21, 2015). With this addition, total installed wind power capacity in the country stands at 5,900 MW. Although almost half of the new capacity addition in 2014 was wind power, the total installed capacity of wind power accounts for a only small fraction of the total electricity generation capacity in the country, about 4% of the total electricity generation capacity available in the country by the end of 2014 (REN21, 2015).

A number of policies and programs have been introduced in Brazil to promote large-scale deployment of wind energy. The Programa de Incentivo às Fontes Alternativas de Energia Elétrica (or Incentive Program for Alternative Sources of Energy) introduced in 2004, was one of the first major initiatives. At present, existing policies aimed at wind power development include market (or purchase) guarantee, where the government procures wind power through competitive bidding (Franca, 2011); exemption of some taxes on wind power generation equipment; investment subsidies through grants and soft loans and wind power auctioning (IEA/IRENA, 2015). In addition, the government has launched specific programs to facilitate large-scale deployments of renewable energy, including wind power (REN21, 2015).

The promotion of renewable energy is essential from climate change mitigation and other environmental perspectives; it is also necessary as renewable energy is a vehicle for the development of sustainable energy systems in a long-run. However, it is equally important to ensure that a large-scale expansion of renewable energy is also consistent with short-term economic and social development goals. A large-scale deployment of renewable energy should not adversely affect the competitiveness of energy supply systems, especially in developing countries. Moreover, the economic and regulatory policies to stimulate renewable energy sources should not excessively cost to the final consumers as well as productive sectors. Despite the importance of these issues, relevant literature is limited.

This study analyzes the economic and environmental (mainly climate change mitigation) implications of a large-scale deployment of wind energy in Brazil to increase the share of wind power in the total electricity generation to 10% by 2030. We used a computable general equilibrium (CGE) model as an analytical tool because CGE models are the most appropriate tools for this type of ex-ante assessment of economy-wide impacts of a policy or an economic activity. Existing studies, such as Qi et al. (2014), Timilsina and Landis (2014) and Böhringer and Löschel (2006), have also employed CGE models for analyzing renewable energy promotional policies. We simulated two broad policy instruments: fiscal policy instruments and regulatory policy instruments, and compared them in terms of their economy-wide impacts. In our model, the fiscal policy instruments are represented by a production subsidy[3] and the regulatory measures are represented by a renewable energy consumption mandate.

The remainder of the chapter is structured as follows. In Section 2, a brief description of the computable general equilibrium model is presented followed by discussions of results from model simulations in Section 3. Section 4 concludes the chapter.

2. MODEL AND DATA

In this section we present the CGE model developed for the study and the necessary data. The model used for this study is a perfect foresight inter-temporal dynamic CGE model. Since the basic description of a standard CGE model is common in most literature that use CGE models for environmental and energy policy analysis, we do not reproduce the detailed description of the model. Instead, we focus on how the two policy instruments are incorporated in the CGE model.

The model has 31 production sectors and 27 goods and services as shown in Table 1. It explicitly identifies wind power as a separate sector. In most existing CGE models, renewable energy technologies including wind power is embedded in a single electricity sector because the share of renewable energy in the total electricity mix is very small. Renewable energy technologies are not treated as separate economic activities or sectors in input-output tables or social accounting matrices, the main database for a CGE modeling exercise. If various technologies to generate electricity are represented by a single technology, it ignores the heterogeneity among the technologies to generate electricity[4]. Moreover, such an aggregate representation of electricity generation technologies does not allow to assess the impacts of the substitution between different types of electricity generation technologies, which is the focus of this analysis. Table 1 shows that our CGE model has seven types of electricity generation technologies: hydro, coal, natural gas, oil, wind, biomass and nuclear. As it will be discussed later, the marginal cost of electricity generation from each of these technologies will be reflected in their prices, which will be then combined through constant elasticity of substitution (CES) functional form to derive an aggregate electricity price that will be faced by the consumers.

The model also identifies various petroleum products (e.g., gasoline, diesel, other petroleum products) separately, which is often not the case in existing literature. This is important in Brazil because Brazil is one of the largest producers of ethanol and the trade-offs between gasoline and ethanol should be reflected in a CGE model developed for policy analysis in Brazil.

All productive sectors or industries, except the electricity generation sectors, follow a nested production structure as depicted in Figure 1. The production structure followed by the electricity sectors is presented in Figure 2. A nested constant elasticity of substitution (CES) functional form is used to represent production behaviors of all industries including electricity generating ones.

At the bottom tier of the nested structure in Figure 1, a CES function combines coal and petroleum products to have a fuel aggregate. The fuel aggregate is then combined with electricity to have an energy aggregate. Energy is combined with land and value added (capital and labor) inputs, and this energy-value added & land composite is then combined through a CES function with intermediate goods and services to produce outputs. The output is distributed to domestic and foreign consumption (i.e., exports) through a constant elasticity of transformation (CET) functional form. On the domestic market, a domestically produced good is aggregated with its imported counterpart using a CES functional form; all internationally tradable goods and services follow this assumption. For the electricity-generating industries, the production structure is different from that in other sectors (see Figure 2). The main difference is that the electricity production structure allows direct substitution between capital and fuel. This is necessary to portray the substitution potential between fossil fuel-based carbon-intensive electricity generation technologies with carbon free but capital intensive renewable energy technologies. The total electricity is the combination of electricity generated using different sources (e.g., coal, natural gas, solar, wind, hydro and biomass). Electricity generation from each technology or source is modeled as shown in the nested CES production structure in Figure 2.

Table 1. Production sectors and consumption goods considered in the CGE model developed for this study

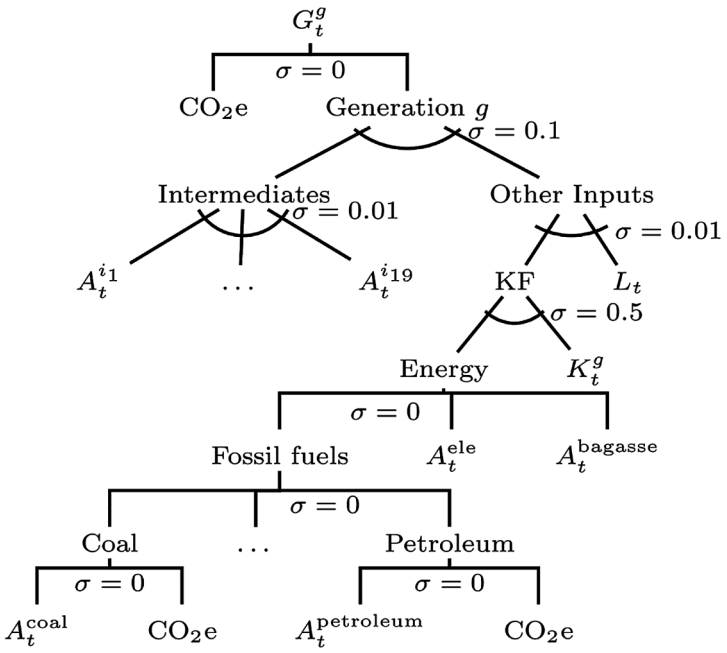
Industry/Sectors for Production	Goods and Services for Consumption
Sugarcane industry	Sugarcane
Soybeans industry	Soybeans
Other agriculture industry	Other agricultural products
Livestock	Livestock
Forestry	Forest products
Crude oil & natural gas	Crude oil & natural gas
Coal mining	Coal
Metals and mineral mining	Metals and minerals
Food & beverages	Food & beverages
Textile & leather	Textile & leather
Wood industry	Wood
Pulp, paper & furniture	Pulp, paper & furniture
Oil refining	Gasoline
	Diesel
	Other petroleum products
Biofuels	Biofuels
Chemicals	Chemicals
Metal industry	Metals
Non-metallic minerals industry	Non- metals (e.g., cement, lime, glass)
Machinery & equipment	Machinery & equipment
Other manufacturing	Other manufacturing goods
Hydropower	Electricity
Coal fired electricity generation	
Natural gas fired electricity generation	
Oil fired electricity generation	
Windpower	
Biomass fired electricity generation	
Nuclear power generation	
Gas processing industry	Process gas
Construction sector	Construction goods/services
Commercial sector	Commercial services
Transport sector	Transport services
Service sector	Other services

The model assumes that labor is perfectly mobile between sectors, capital is sector specific, and land can be transformed between various applications according to a nested constant elasticity of transformation CET function as shown in Figure 3. While land is not an input to production for many sectors, it is the main input to the agricultural and mining sectors. This is another key feature of the CGE model

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Production structure of industries except electricity

Note: In this figure, X refers to sectoral output, A refers to consumption of goods and services, L and K refer to labor and capital, respectively. Indices i and j are used to denote sectors and commodities. Index t refers to time (year). σ refers to elasticity of substitution.



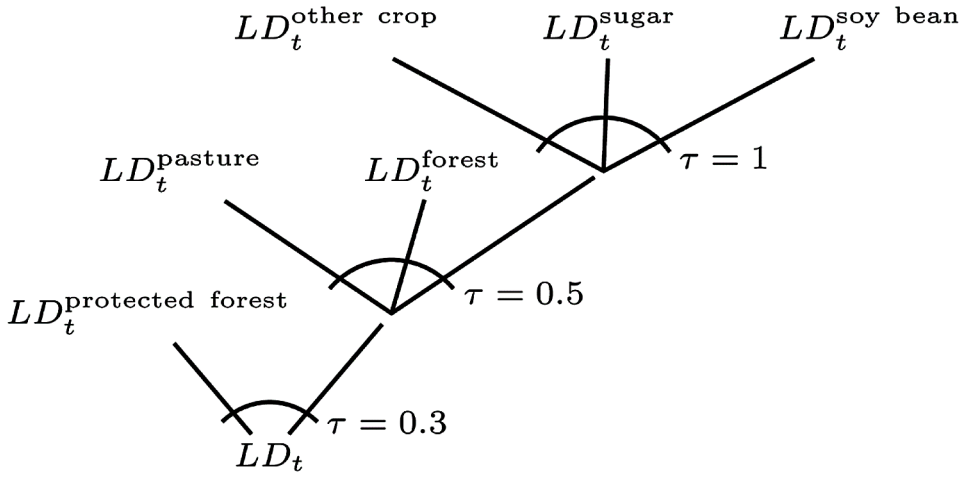


Figure 2. Nesting structure for electricity generation sectors

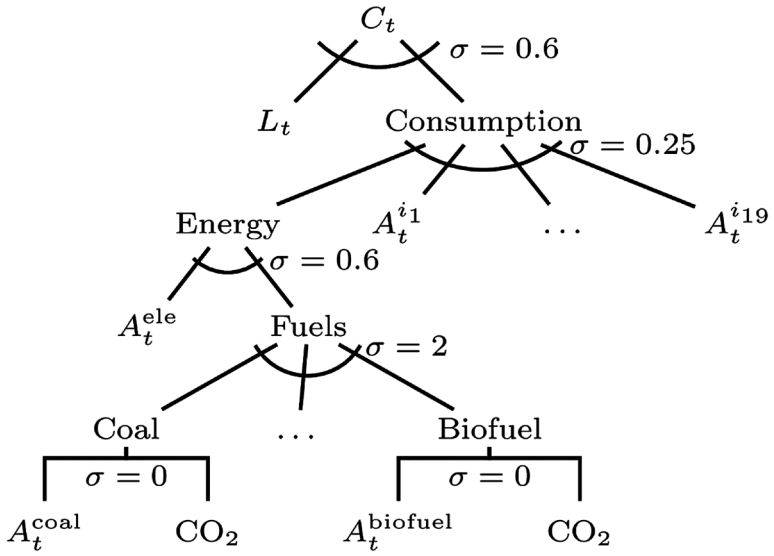
Note: In this figure, G refers to electricity generation, A refers to consumption of goods and services, F, L and K refers to fuels, labor and capital, respectively. Indices i and j are used to denote sectors and commodities. Index g and t denote type of electricity generation and time (year). KF is the composite of capital and fuel. σ refers to elasticity of substitution.

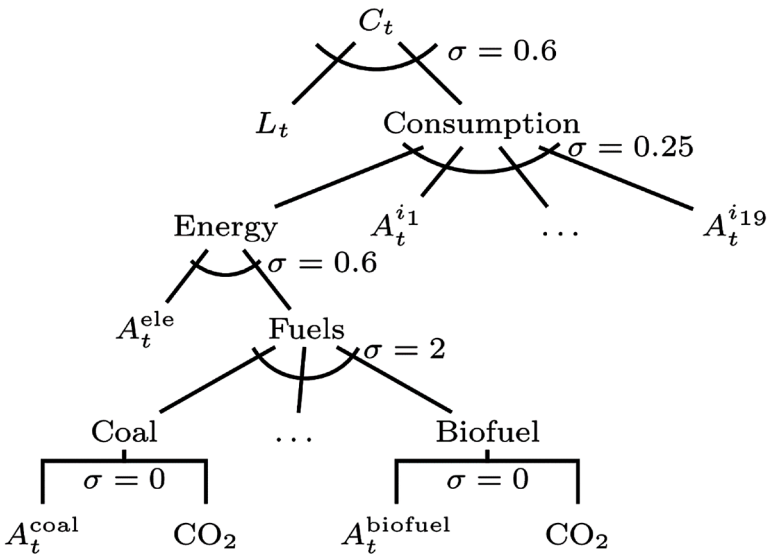
EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use



developed for this analysis. Normally, land is not explicitly represented in CGE models analyzing energy or climate change mitigation policies. However, ethanol is one of the main energy carriers in Brazil and to reflect the trade-offs between ethanol and gasoline, it is necessary to explicitly model land allocation in Brazil because land is the main input to sugar cane and the latter is the main feedstock for ethanol production in Brazil.

Capital stocks for production and capacities for power generation are endogenously modeled. Following Clarke and Edmonds (1993), investment in generation capacity is distributed among generation technologies according to a nested multinomial logit choice model. The multinomial logit model assumes that investments in generation capacity, unlike the more aggregated investment in the other production sectors, implicitly entails additional, technology and site specific investments needed to provide the generated power to consumers[5].

Our study follows a standard approach used in the literature to model household behavior. Under the perfect foresight framework, a representative household maximizes a Ramsey type welfare function, where the household maximizes discounted sum of inter-period utility, which is derived from consumption of goods/services and leisure. We used nested CES function to represent the household behavior (see Figure 4). At the top of the nest, the representative household trades off between leisure and consumption of an aggregate of goods and services. In the next tier of the nesting, the representative household chooses an optimal mix of an energy composite and an aggregate of other goods and services subject to household budget allocated for consumption. The energy composite is itself a CES combination of electricity and use of fossil fuels.



The government raises taxes on labor and capital revenues and levies direct transfers on households. It pays for an exogenously given stream of government consumption as well as for the potential subsidies in the policy scenarios.

Figure 3. CET nesting structure for allocation of land to different uses
Note: In this figure, LD refers to land demand. Index t refers to time (year). τ refers to elasticity of transformation. Note also that demand for protected forest is assumed to be exogenous in our model.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. Representation of household behavior
Note: In this figure, C refers to the aggregate consumption of leisure and goods and services. A refers to consumption of goods and services, L refers to labor. Indices i and j are used to denote sectors and commodities. Index 'ele' refers to electricity. Index t denotes time (year). σ refers to elasticity of substitution.

The actual policy instruments are incorporated in the model through the marginal costs of electricity generation from wind power. We assumed that the electricity price generated from a technology is equal to its marginal cost. Under the production subsidy case, the price of wind power is its marginal cost minus the subsidy rate. The model endogenously determines the level of value added tax required to finance the subsidy so that government revenue remains neutral to the production subsidy policy. Maintaining government budget neutrality is important so that government expenditures from sectors directly related to welfare (e.g., education, healthcare, internal security, etc.) are not diverted to finance renewable energy subsidies. Under the renewable energy consumption mandate case, the aggregate electricity price is increased to reflect the increased electricity supply cost due to the expansion of wind power.

The model is based on two types of data:

1. The social accounting matrix of Brazil, and
2. The elasticities of substitution and transformation.

The SAM is built by Chen and Timilsina (2012) based on input-output tables and other necessary data of year 2008. The sectors and commodities used in the SAM are presented in Table 1. Our assumptions about elasticities are also based on Chen and Timilsina (2012).

3. RESULTS AND DISCUSSION

By the middle of 2015, Brazil has installed 135,364 MW of electricity generation capacity, of which wind power accounts for 4.2%. Other sources, biomass, nuclear and thermal (coal, gas and oil) account

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

for, respectively, 9.1%, 1.5% and 19%. The remaining, 66% of the total installed capacity, is supplied through hydro power (Brazilian Electricity Agency, n.d.). In 2012, total electricity generation in Brazil was 552.5 TWh, of which wind power plants generated 5.3TWh or less than 1% (IEA, 2014). This study assesses the impacts of large-scale deployment of wind power so that its share in the total electricity generation mix would reach 10% by 2030. In fact, Brazilian government's Decennial Energy Plan (PDE 2021) aims to increase the share of wind power in the total electricity production to 9% by 2021 (GWEC, 2014). We stayed a bit conservative, considering the rapid growth of total electricity demand.

If the government were to provide a production subsidy to achieve the wind power target, the level of subsidy required to achieve the 10% target would be equivalent to 65% of electricity supply cost of wind power. Now government has to manage sources to finance the subsidy. It could crowd out public expenditure from other sectors, but it would not be desirable to divert public expenditure allocated to areas directly related to public welfare, such as health care, education, internal security, to subsidize wind power. If the government does so, it would cause a direct welfare loss. The most common source of funding is to introduce an extra tax. It could be on fossil fuels or it could be on value added tax (VAT) which is applied to all good and services. Since the VAT has a larger base compared to fossil fuel tax, the welfare impacts caused by a small incremental VAT would be smaller as compared to a fossil fuel tax to generate the same amount of government revenue. Therefore, we considered increasing VAT to finance the wind power subsidy. The incremental VAT needed to achieve the 10% wind power target is small.

When the government introduces a consumption mandate instead of a production subsidy to support wind power, it allows the electric utilities to increase their tariffs so that they can pass the incremental system costs, caused by the wind power addition, to consumers. Meeting the 10% wind power target by 2030 through the consumption mandate would increase the average electricity bill by 6.2%.[6] It is possible that the government could implement both policies, production subsidies and consumption mandates, together. However, we have not considered that case because we aim to compare these two policies in terms of their economic impacts.

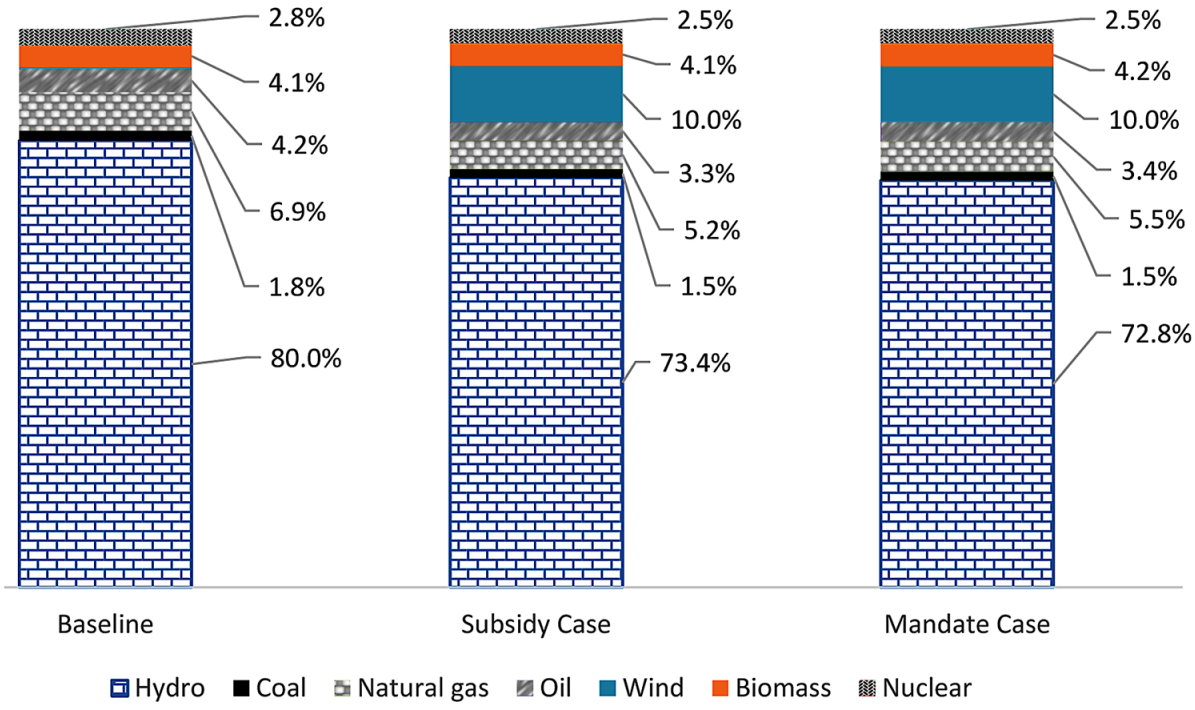
3.1 Impacts on the Electricity Sector

The expansion of wind power to share 10% of the total electricity generation by 2030 would lead to an increase in total electricity generation by 1.13% in that year from the baseline if the expansion is triggered through the production subsidy. On the other hand, the total electricity generation would drop by 1.51% from the baseline if the expansion of wind power is stimulated through the consumption mandate. These opposite impacts on total electricity generation between the production subsidy and the consumption mandate cases are explained below.

In the case of the production subsidy, the subsidy would cause the overall price of electricity to drop. This would increase the demand for electricity and ultimately its supply in the equilibrium. Note also that there would be real income drop due to increased VAT to finance the subsidy, however this drop is distributed across the consumption of various goods and services. It could reduce the demand for electricity as well. However, the loss of electricity demand due to increased VAT is smaller than the increase in electricity demand caused by the fall in electricity price.

In the case of consumption mandate, the higher costs of wind electricity relative to that from conventional sources (e.g., hydro, gas, oil) would increase the long-run marginal costs of electricity supply by the grid. Being a profit making entities, electric utilities will transfer the incremental costs to consumers

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use



through an equivalent increase in the aggregate electricity price. The increased electricity price would then cause electricity demand to drop. As demand drops, supply also drops in the equilibrium.

An increased share of wind power in electricity generation mix would mean a decrease in share of electricity generated from other sources, such as hydro, nuclear, coal, oil etc. The replacement of various types of electricity generation with wind power is presented in Figure 5. As can be seen from the figure, a 10% penetration of wind power would cause a drop of hydropower by 6.6 and 7.2 percentage points under the production subsidy and consumption mandate cases, respectively. The difference in the replacement rates between these two policy cases is based on the fact that the production subsidy increases the total electricity generation, whereas the consumption mandate decreases the total electricity generation. Similarly, the share of natural gas based generation decreases by 1.7 and 1.4 percentage points under the production subsidy and consumption mandate cases, respectively.

3.2 Impacts on GDP and Sectoral Outputs

The expansion of wind power to share 10% of the total electricity generation in Brazil in 2030 would increase Brazil's GDP by 0.1% from the baseline under the production subsidy case and by 0.009% under the consumption mandate case. While these increases look small in terms of percentage change of GDP, they are quite significant in the absolute term. Brazil's GDP was 2,346 billion US$ in 2014 (World Bank, 2015). If the country maintains a 3% annual growth rate on average, its GDP would reach 3,765 billion

Figure 5. Impacts of 10% penetration of wind power on electricity generation mix in 2030
Note: Baseline refers to a situation in the absence of any policies to promote wind power in Brazil including existing policies. The model shows that if there are no promotional policies, the share of wind in total electricity generation would remain at 0.2% in 2030. However, due to existing policies the share of wind in the total electricity generation was already around 1% in 2012.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

US$ in 2030. The increased GDP due to wind power expansion in 2030 would then be 3.7 billion US$ under the production subsidy case and 339 million US$ under the consumption mandate case.

One would wonder why does expansion of wind power, a relatively expensive technology to generate electricity, increase GDP. This is mainly caused by investment effects of the wind power industry and other industries that supply inputs to the wind power industry. The results from our modeling show that aggregate investment in the economy increases under the both policy instruments. The increase in aggregate investment is much higher under the production subsidy case as compared to that under the consumption mandate case. GDP is the sum of consumption, investment, government spending, and net exports. Our detailed results show that the change in GDP is mainly driven by the changes in consumption and investments. While aggregate investment increases, the aggregate consumption decreases. However, the increase in investments is bigger than the decrease in consumption, leading to an increase in GDP for both policies in 2030. Since the reduction in consumption is smaller and the increase in investment is bigger under the production subsidy case than under the consumption mandate case, the increase in GDP is bigger in the former case as compared to that in the latter.

Table 2 presents the impacts of wind power expansion on the outputs from various production sectors. Two observations can be made in Table 2. First, the impacts on outputs vary significantly across the sectors. Secondly, for a given sector, the impacts are much different between production subsidy and consumption mandate cases. A consumption mandate to promote wind power expansion would reduce sectoral outputs of energy sectors, most notably electricity and oil and gas. This is because the mandate makes electricity expensive thereby reducing its demand. In response, electricity generation to meet the demand also drops. Table 3 shows that electricity demand in all production sector decreases under the consumption mandate policy case. Fuel demand for electricity also decreases thereby lowering their production.

Although a production subsidy to wind power does not raise electricity price, it would still have regressive impacts in certain sectors. This is because, the wind power production subsidy is financed through an increase in value added tax in all other sectors. The value added tax would have negative implications in outputs of sectors which produce relatively higher value added per unit of output (i.e., capital and labor intensive sectors). As expected, sectors which supply goods and services to wind power industry would experience increased value added under both policy scenarios. Examples are construction, machinery industries, commercial services, wood and lumber, forestry.

3.3 Impacts on GHG Emissions

The expansion of wind power to increase its share in the total electricity generation to 10% in 2030 would reduce total energy related GHG emissions in the country by 1.4% and 1.2% in 2030 from the baseline if the penetration was caused by the production subsidy and the consumption mandate policies, respectively. The reductions of GHG emissions comes mainly from the replacement of natural gas fired electricity generation with wind power. The relatively small reduction of GHG is based on the fact that wind power mostly replaces hydropower instead of fossil fuel based power generation in Brazil. This is because there is a good complementarity between hydro and wind power in the country. The production subsidy policy causes higher reduction of GHG than that caused by the consumption mandate policy. This is because the replacement of hydropower with wind power would be smaller under the production subsidy case compared to that under the consumption mandate case. On the other hand, the replace-

Table 2. Change in sectoral outputs relative to BAU due to expansion of wind power in year 2030 (%)

Sector	Production Subsidy	Consumption Mandate
Agricultural	-0.03	0.01
Sugar cane	-0.33	-0.02
Soybeans	-0.05	0.12
Forestry	0.08	0.07
Livestock	0.02	0.01
Food & beverage	0.00	-0.03
Oil & gas	-1.47	-1.03
Non energy mining	0.30	0.00
Coal mining	-0.25	-0.59
Textile & leather	0.09	0.01
Wood and lumber	0.28	0.26
Pulp paper & furniture	0.08	-0.02
Petroleum refinery	-0.67	-0.10
Biofuel	-0.47	0.23
Chemicals	0.19	-0.01
Non metalic minerals	0.51	0.20
Metal	0.27	-0.12
Machinery	0.26	0.15
Other manufacturing industry	0.15	0.05
Electricity	1.13	-1.51
Processed gas	0.68	-0.63
Construction	0.52	0.41
Commercial service	0.09	0.06
Transport service	-0.01	-0.04
Other service	-0.01	-0.01

ment of natural gas fired electricity with wind power would be larger under the production subsidy case compared to that in the consumption mandate case.

4. CONCLUSION

Fiscal policies (subsidies in particular) and regulatory policies (particularly mandates) are the main instruments introduced in both developing and developed countries to encourage a large-scale deployment of renewable energy, such as wind power. Which policy instrument would be attractive from a broader economic perspective, however, has not been clearly answered yet. This study aims to address this question in the case of wind power expansion in the Brazil.

Construction	1.2	-0.9
Commercial service	1.2	-2.0
Transport service	0.6	-1.2
Other service	0.5	-1.0
Household	0.7	-2.0

Using a dynamic general equilibrium model to assess an ex-ante economic impacts of wind power expansion in Brazil, this study shows that expansion of wind power would increase GDP no matter whether a subsidy or a mandate is used to drive the expansion. However, the increase in GDP would be lower under the consumption mandate as compared to that under the production subsidy case. Since the production subsidy causes higher increase in GDP compared to the consumption mandate and it also causes higher reduction of GHG emissions than a the consumption mandate does, we can draw a conclusion that the subsidy policy is superior to a consumption mandate policy for Brazil's efforts in promoting wind power. Although this finding is consistent with general principles in public finance and with findings in other studies of renewable energy policy (e.g., McCullough et al. 2011; Timilsina & Landis, 2014), it should not be generalized because the results from CGE models are country specific.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

The sectoral results are different not only between the two policy instruments but across the sectors for a given policy instrument. Sectoral outputs of fossil fuel industries decreased under both policy instruments whereas the outputs of industries providing goods and services to wind power industry increased. The consumption mandate would also cause sectoral outputs of other sectors, especially energy intensive sectors, to drop.

The analysis is carried out based on present (2012) data on electricity supply costs of various technologies to generate electricity. The capital costs of renewable energy technologies, including wind power technologies, have declined over time in the past. However, it is difficult to predict how far the cost reduction will go and when wind power technologies would be economically competitive with traditional sources of electricity generation. Even if they are competitive in terms of the levelized costs of electricity generation, utility planners still discount wind and solar because these are intermittent resources to generate electricity and do not provide a firm power or capacity guarantee, which is essential to have a reliable electricity supply system.

ENDNOTES

1 The Brazilian government's Decennial Energy Plan (PDE 2021) sets a goal of 16 GW of installed wind capacity by 2021, accounting for 9% of national electricity consumption (GWEC, 2014).

2 By the end of 2010, total wind power capacity was 927 MW, it increased to 5,900 MW by the end of 2014 (REN21, 2015).

3 In this study, a production subsidy refers to a premium required to lower the levelized cost of wind power generation to a level to make it competitive to other sources of electricity generation, such as hydro, natural gas etc. In other words, wind power producers can secure their expected rate of returns with the help of this premium which they receive in proportion to the amount of wind electricity they produce.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

[4] However, recognizing the role of power sector on climate change mitigation policies, CGE models developed for climate change mitigation polices started to represent different electricity generation technologies separately instead of lumping them in a single technology (see e.g., Rana, 2003; Paltsev et al., 2005; Timilsina and Shrestha, 2006).

[5] Please see to Timilsina and Landis (2014) for more information on the use of Logit model to represent investment behavior in the power sector.

[6] The subsidy policy averages the premium for wind power into a relatively large base of total consumptions of goods and services in the country whereas the mandate policy averages the premium into relatively smaller base of consumption of electricity only.

Chapter 30
Ensuring Environmental Sustainability Through Sustainable Entrepreneurship

Isaac Oluwajoba Abereijo
Obafemi Awolowo University – Ile-Ife, Nigeria

ABSTRACT

Sustainability has become an important issue worldwide because of great concerns about the unintended social, environmental, and economic effects of increasing population and economic growth, as well as consumption of natural resources. One recent concept arising from sustainability issue is sustainable entrepreneurship which integrates both the social and environmental aspects, and linking them with entrepreneurial activities. This chapter therefore suggests that efforts of developing countries at promoting entrepreneurship should go beyond engaging in business enterprises but include encouraging the use of entrepreneurial values and approaches to solve sustainability problems. Hence, this chapter is an effort at developing a framework that can be used to influence sustainable entrepreneurship behaviour of the students in developing countries.

INTRODUCTION

As far back as 1970s there has been a great concern about environment and development. This is because of the considerable negative effects that industrialisation is having on the natural environment in term of diminishing the vitality and sustainability of economic systems (World Resource Institute, 2004 cited by Dean and McMullen, 2007). Apart from the problems that are peculiar to local environment like air pollution, surface-water degradation, and toxic wastes in groundwater, there are negative impacts of industrialisation that are of global concern. These, according to the report of United Nations (2004), include ozone depletion, climate change, and the worldwide destruction of ocean fisheries.

The first major international gathering to discuss sustainability was the United Nations conference on the Human Environment held in Stockholm in 1972. The conference led to the establishment of the United Nations Environment Programme (UNEP) as well as the creation of numerous national envi-

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

ronmental protection agencies at country level. It was during this period that the concept of sustainable development became popular. The concept was further popularised by the report of the World Commission on Environment and Development in 1987, titled 'Our Common Future' (or Brundtland Report). This report gave the classic definition of sustainable development as development which meets the needs of the present without compromising the ability of future generations to meet their own needs (World Commission on Environment and Development, 1987). Since then, sustainable development is accepted as a convergence between the three pillars of economic development, social equity, and environmental protection (United Nations, 2010).

The concern about sustainability has also opened new opportunities for entrepreneurship and introduced a new dimension to its study. This is because entrepreneurship is believed to have potential of resolving problems of market failure inherent in the economic system, especially environmental issues. Hence, sustainable entrepreneurship, which is a spin-off concept from sustainability development, integrates both the social and environmental aspects, and linking them with entrepreneurial activities. The strategy of achieving this is the encouragement of green enterprises, which required firms to reconcile sustainability aspects with profitability.

Over the past decade, African economies have experienced rapid advancement towards integration into the global economy. This can be seen from the efforts of many of the countries undertaken significant economic reforms such as improving macroeconomic management, providing conducive private investment climate, liberalising markets as well as widening the space for entrepreneurship to drive strong and inclusive growth (Ahmed & Nwankwo, 2013). These authors however noted that there is much at stake in continuing this process of scaling up entrepreneurship as a dynamic process towards sustainable economic development. One of such is how to ensure that entrepreneurship is able to create value which is economic, social, or ecological in nature.
