While the efforts of various governments, especially in developing countries, at promoting entrepreneurship is laudable one, this should however go beyond encouraging business start up where people seek advantages only for themselves or unconsciously run their businesses in a destructive way that generates imbalances. Therefore, solution to unemployment must also consider sustainable entrepreneurship, which requires the use of entrepreneurial values and approaches to solve sustainability problems. That is, application of imagination to challenging problems by conceiving, prototyping and creating solutions that deliver environmental, social and economic value (Pascual, van Klink, & Grisales, 2011). Therefore, policies and programmes of African government on entrepreneurship should be long-term and take the future into account so as to be sustainable in nature.

Though the practice of sustainable entrepreneurship is not new in African countries when considering the waste-to-wealth initiative and recycling process, but a quick look at available literature shows that not many studies are addressing the concept of sustainability entrepreneurship in this continent. This chapter is therefore an effort to fill this gap by synthesising theories from the entrepreneurship, environmental and welfare economics literatures with the view to examine the potential of entrepreneurship to create value within the dimensions of sustainability in African countries. Moreover, the chapter develops a framework which is expected to provide direction for the development of entrepreneurship education that can create and develop sustainable entrepreneurial behaviour in students, especially those in tertiary institutions. The framework can also serve as input into the formulation of policies and programmes by the government of African countries to properly lay the foundation for effective delivery of education for sustainable entrepreneurship based on the best practices in developed countries.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Since sustainable entrepreneurship is an extension of entrepreneurship, the chapter begins with the concepts related to sustainable entrepreneurship and its definition. Next, the environmental and welfare economics theory is reviewed to conceptualise how entrepreneurial action can be used to address market imperfections so that environmental and natural resources can be efficiently utilised. The chapter then provides the theoretical and empirical background for the drivers or motivation for sustainable entrepreneurship as well as how entrepreneurship education can be used to develop sustainable entrepreneurial behaviours in nascent entrepreneurs. A framework for the development of sustainable entrepreneurial behaviour is then suggested. The chapter is concluded by considering the implication of developing sustainable entrepreneurial behaviour for the entrepreneurship educators and policy makers.

THEORETICAL BACKGROUND

Concept of Entrepreneurship and Sustainability Entrepreneurship

As early as 18th century, various definitions of entrepreneurship have been put forth but with no universally accepted one. According to Venkataraman (1997), entrepreneurship is defined as the process of how opportunities to bring into existence future goods and services are discovered, created, and exploited, by whom, and with what consequences. Recent definition put forth by Stokes, Wilson and Mador (2010) defined it by encompassing all the different definitions, based on what entrepreneurs do, who they are, and what they produced. While referring to Stokes, Wilson and Mador (2010) and synthesising from studies from previous researchers, Majid and Koe (2012) then put forth a definition which is adopted in this chapter. The definition focuses on behaviour, processes and outcomes of entrepreneurs. Entrepreneurship is therefore defined as a process of identifying, evaluating and pursuing opportunities through creativity, innovativeness and transformations to produce new products, processes and values that are beneficial. This definition takes into consideration the modern school of thought on entrepreneurship which is now playing emphasis on sustainability. That is, entrepreneurial thinking process should involve identifying, evaluating and pursuing business opportunities that will be economically viable as well as preserving the environment for the next generation.

The role of entrepreneurship in economic growth is also established in the literature. But the traditional entrepreneurship education usually prescribes to students a profit-driven mentality. This, in the word of Slater and Dixon-Fowler (2010), is termed 'profit-first' mentality, which has no regard for moral considerations or social responsibilities. Recently however, the concern for society gave rise to social entrepreneurship where profit motive is not the primary consideration but on societal problems. Inspite of its non-profit motive, various case studies have shown that there are social entrepreneurs who are able to make profit while creating the social values. Some of these cases include Jacqueline Novogratz (*Acumen Fund*), Bill Drayton (*Ashoka*), Sam Goldman and Ned Tozun (*d.light*), Rafael Alvarez (*genesys works*), and Jane Chen (*embrace*) among others (see http://www.forbes.com/impact-30/list.html for more information). The success story of these social entrepreneurs is what stirs interest in the direction of concern for the environment.

The consciousness towards the environment is therefore compelling the businesses already in existence to 'green' their products or services, processes and distribution. Likewise, the new start-ups are encouraged to start out with the intention of making environmental protection an integral part of the reasons for setting it up (Santiago, 2013; Walley & Taylor, 2002). The concern for the environment and the potential

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

of entrepreneurship to exploit the opportunities associated with environmental degradation has led to the concept of sustainable entrepreneurship. This is based on the concept of triple bottom line coined by Elkington (1994). That is, entrepreneurship that contributes equally to economy, ecology and society.

Sustainable entrepreneurship research has now emerged from the larger body of business and environment as well as corporate responsibility research. This is in response to the demand for modifications in business, social and environmental practices. Sustainable entrepreneurship, which is a concept linking development to entrepreneurship, is also variously defined in the literatures (for examples Elkington, 1998; Cohen & Winn, 2007; Dean & McMullen, 2007). But there is an agreement that the feature of sustainable entrepreneurship is based on certain fundamental aspects of entrepreneurial activities, which are personal initiative and skills, to create or discover business opportunities as well as realisation of market success. In addition to these activities, sustainable entrepreneurship also takes into account environmental and societal goals.

Therefore, the concept of sustainable entrepreneurship arises from the understanding that efforts at addressing environmental issues, such as ecosystem degradation and global climate change, requires a fundamental transformation in the way society consumes natural resources and produces energy. Hence, as put forth by Cohen and Winn (2007), sustainable entrepreneurship should result into entrepreneurial rents and also ensures social and environmental sustainability. Sustainable entrepreneurship therefore entails developing businesses which have positive relationships with the society in which it operates (Crnogaj, Rebernik, Hojnik, and Gomezelj, 2014). This means that business ventures arising from sustainable entrepreneurship must stand on the tripod of economic stability (profitability), social equity, and sustainable practice of reducing environmental degradation (Lumpkin & Katz, 2011). Hence, the principles of entrepreneurship can serve as means by which market failures such as environmental and social disruptions can be ameliorated (Crnogaj, Rebernik, Hojnik, & Gomezelj, 2014).

While synthesising the various definitions of sustainable entrepreneurship, Majid and Koe (2012) identified the main issues that sustainable entrepreneurship covers. These include what entrepreneurs can do in preserving economics, environment, social and culture in entrepreneurial ways. Hence, the authors put forth the definition of sustainable entrepreneurship as a process in which entrepreneurs exploit a business opportunity in an innovative manner for economic gains, society equity, environmental quality and cultural preservation on an equal manner. Unlike other definitions which focus on green or social domain only, the definition suggested by Majid and Koe (2012) covers the domains of economic, social, environmental and cultural. Hence, this definition is adopted for this chapter.

In conceptualising sustainable entrepreneurship, many researchers have used the triple bottom line (TBL) to describe sustainability development. The concept identified three main value creating aspects in sustainable business practices. These include economic prosperity, environmental quality, and social justice (Elkington (1997). Therefore, various models of sustainable entrepreneurship, based upon the concept of TBL, have been developed over the years. One of such models is based on the triune of social, environmental and economic to examine whether the entrepreneurs could operate an economically viable venture whilst retaining their environmental and social values (Dixon & Clifford, 2007 cited in Majid and Koe, 2012). Another is the value-based model developed by Tilley and Young (2009) which argue that sustainable entrepreneurship should be treated as the combined efforts of the 12 individual values that drive sustainability.

As it is argued in the definition of sustainable entrepreneurship, that its definition should cover the four domains of economic, social, environmental and cultural, likewise Majid and Koe (2012) proposed another model which included all these four domains in order to be regarded as true sustainable entre-

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

preneurship. The argument is based on the thought of Nurse (2006) that sustainability issues, especially in developing countries, should not rely heavily on western scientific knowledge. This is because over dependence on western scientific concepts in managing sustainability can lead to the loss of traditional or indigenous knowledge. This traditional wisdom can actually serves as solutions for sustainable development problems in developing countries. This explains the reason why culture is included as the fourth pillar in sustainable development.

Market Imperfections and Entrepreneurial Opportunities

Central to the environmental economics is the concept of market imperfections, which is the failure of markets to efficiently allocate limited resources in a way that benefits society most. These imperfections contribute to environmental degradation. Fortunately, these market imperfections have been discovered as avenue where opportunities for the creation of radical technologies and innovative business models can be developed (Dean and McMullen, 2007; Cohen and Winn, 2007). These opportunities form the foundations for an emerging model of sustainable entrepreneurship. Exploiting these opportunities can enable existing or would-be entrepreneurs to obtain entrepreneurial rents and, at the same time, improve the social and environmental conditions. Central to the need to understand how market failure may be used to explore sources of entrepreneurial opportunities is the question Venkataraman (1997) raised about 'where opportunities to create goods and services for the future will come from'. The answer is now emerging from the understanding of how market failures can serve as entrepreneurial opportunities.

There are four of these market imperfections identified in the literature and which are also seen as sources of entrepreneurial opportunity. They are: firms are not perfectly efficient, externalities exist, pricing mechanisms work imperfectly, and information is not perfectly distributed. The theoretical background for understanding how each of these market imperfections can create entrepreneurial opportunities is based on the theoretical views on entrepreneurial opportunity, which is synthesised by Sarasvathy, Dew, Velamuri and Venkataraman (2003). First is the allocative view (opportunity recognition) which suggests that opportunities exist when there is potential to redistribute resources to benefit others without adversely affecting others. Second, there is also the discovery view (opportunity discovery) where entrepreneurial opportunities arise from information asymmetries with respect to the true value of resources and the resulting value of the combination of those resources into outputs. Lastly, the creative view (opportunity creation), that is, when opportunities are identified ex-post when entrepreneurs is seeking to maximise the utility functions of multiple stakeholders. Each of these views of entrepreneurial opportunities is useful in establishing how entrepreneurial rents can be achieved through innovations which correct the existing unsustainable use of environment.

Based on the extensive review of literature on the concept of market imperfection by Cohen and Winn (2007), the authors are able to establish the role that each of the imperfections plays in environmental degradation as well as how it can lead to any of the generic types of opportunities stated above. The first imperfection indicates the inability of firms to be perfectly efficient in their resource allocation. The outcome is that both the firms and consumers can only achieve a fraction of the potential efficiencies available from natural resources. Efforts at bringing markets closer to equilibrium will therefore require that the efficiency of resource allocation be increased. This can be achieved through opportunity identification and exploitation using entrepreneurial process. These opportunities derive from the conversion to a cyclic economy (Kirchgeorg, 1999 cited in Cohen & Winn, 2007) in which improvements in efficiency of resource use depend on recycling and recovery at every stage of the process. That is, ability

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

to convert industrial and consumer waste into new products and services. From the above, innovating entrepreneurs who discover the potential to reduce that waste (through recycling) will be able to correct the imperfection due to inefficient resource allocation.

The second imperfection is about existence of externalities, which may be positive or negative. This imperfection suggests that the costs or benefits associated with the production or consumption activities of firms are not correctly reflected in the prices of products and services being offered by such firm. Positive externalities occur when the third party benefits without incurring the full cost associated with the value of benefit received. One example of positive externalities is when new good, resulting from research and development investment of a company, is purchased by the consumers at price below what would fully reflect the value of technological improvements (Abereijo & Ilori, 2012). On the other hand, it becomes negative when the third party suffers from the activities of a firm without receiving adequate compensations. Examples of this abound, which include impact of industrial smoke, water pollution, etc, on health and economic activities of surrounding communities. Therefore, if an entrepreneur can substitute current production processes, which results in externalities, with innovative ones, such entrepreneurs would have discovered an entrepreneurial opportunities for new business and also brought about positive environmental externalities. The types of opportunity identification that are most likely are opportunity discovery and creation. In the word of Cohen and Winn (2007), innovative firms that are able to recognise and create opportunities to reverse existing negative environmental externalities (for example, air pollution) can generate triple bottom line results. That is, their entrepreneurial actions can produce social benefits (through improvement in the quality of air within the communities) and environmental benefits (improved ecosystem functioning), and which is being done profitably. Apart from entrepreneurial opportunities resulting from improvement on production processes, there could also be an institutional entrepreneurship. This is type of entrepreneurship involves a process whereby the transaction costs associated with environmental-based externalities is reduced. Institutional entrepreneurship, as defined by Dean and McMullen (2007), is the process of reducing transactions costs through the development of economic institutions by profit-motivated economic actors. Example of institutional entrepreneurship is a legal firm who coordinates the interests of the parties that are being affected by negative externalities. By this effort, the right of the parties concerned can be enforced and the cost of bargaining and contracting with the producer of negative externalities can also be reduced (Dean & McMullen, 2007).

Moreover, the possibility of pricing mechanism working imperfectly is the third market imperfection. This imperfection arises because of the assumption of the conventional economics theory that natural resources are infinitely plentiful and that they have a market value that accurately reflect supply and demand. The reality, as put forth by Kurz and Salvadori (1997), is that many natural resources are exhaustible, undervalued and underpriced. Therefore, if the natural resources are valued more accurately and perfectly priced the demand for the use of non-renewable factors of production will decrease, while demands for more renewable factors will increase. Therefore, entrepreneurship principles can be applied whereby innovative entrepreneurs begin to discover opportunities in renewable factors of production. Example is disruptive technologies which are been sold in the market where consumers cannot buy high end products. The specific examples are Thin Film Technologies producing solar photovoltaic cell being marketed in third world countries without established power grids (Cohen & Winn, 2007).

The fourth market imperfection concerns the imperfect distribution of information. The assumption of neoclassical economics is that suppliers and buyers within free market have perfect information about prices, products and the market. But in reality, there is presence of information asymmetry, which some-

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

times is responsible for the unsustainable production and consumption patterns. The imperfect distribution of information are categorised into two by Dean and McMullen (2007). These are knowledge that producers have about supply and demand conditions, and knowledge that customers posses regarding the nature of product or service attributes. Some of the factors that may be responsible for imperfect information are changes in technology, tastes, and demographics. In relation to environment, imperfect information therefore exist when better channels of supply are not known or when markets for environmentally superior products are yet to be discovered. Entrepreneurial opportunities associated with this imperfect information could include the use of new product or process technologies or efficient means of supply which are not damaging to the environment. Also, identifying customers who prefer environmentally superior products or services could also serve as another source of entrepreneurial opportunities. In relation to the second category of imperfect distribution of information, opportunities can also exist for what Dean and McMullen (2007) referred to as customer-focused informational entrepreneurs. These entrepreneurs exploit opportunities by enhancing customer knowledge about the environmental attributes of products and services.

Drivers of Sustainable Entrepreneurship

The existence of numerous market imperfections, with regard to the environment and social conditions, suggests that it is not automatic that entrepreneurs will likely pursue those opportunities from which entrepreneurial rents exist. Hence, there are certain behaviours associated with individuals who prefer to pursue entrepreneurial opportunities based on market imperfections. The theoretical literatures identified certain drivers towards sustainability entrepreneurship orientation, which are categorised as being externally- or internally-driven (Kuckertz & Wagner, 2010; Gibbs, 2009; Masurel, 2007; Schlange, 2006). Government policies and or incentives as well as pressure groups constitute the external drivers, while the entrepreneurs' value system is the internal driver. Whether externally or internally driven, the response to sustainability issues also differs. Hence, Baumgartner (2009) posited that the approach could be introverted, or extroverted, or eco-efficient practices, or visionary strategy. The introverted approach involves responding to the pressures from stakeholders such as government regulation, while the extroverted approach involves highlighting the accomplishments in sustainability reports. The eco-efficient practices by firms involve adopting conservative approach of energy conservation and waste management. It is only the visionary strategy approach that actually integrates sustainability issues in business operations.

Empirically, Schick, Marven and Freimann (2002) discovered in their study that individuals categorised as eco-dedicated were influenced by their families in their childhood. Hence, some authors are of the opinion that subjects and courses that create environmental awareness, at all levels of education, could lead future entrepreneurs in the right direction (Dobson, 2007; Schaper, 2002). The findings of Schlange (2006) also confirmed that one major characteristic of sustainable entrepreneurs is a strong emphasis on ecological aspects in their business vision. It is also discovered that the main driver for a sustainable entrepreneurial motivation is structured along the social and ethical dimension. The results of study on the factors influencing propensity to sustainable entrepreneurship of SMEs in Malaysia revealed that attitudinal (attitude towards sustainability) and perceptual (perceived feasibility and desirability) factors positively and significantly influenced such propensity (Koe, Omar, Sa'ari, 2015; Koe, Omar & Majid (2014). The authors therefore concluded that effort at promoting sustainable entrepreneurship requires entrepreneurs developing sufficient sustainability capabilities, establishing a positive or

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

favourable sustainability attitude and creating attractive sustainable entrepreneurial practices. Moreover, prior knowledge and focused attention can also contribute significantly to opportunity recognition in sustainability-related market failure (Bell and Stellingwerf (2012). Another important driver, noted by these authors, is motivations to solve the sustainability-related market failures.

The Role of Entrepreneurship Education

There is recognition in the literature that entrepreneurship education can help promote sustainable entrepreneurship. For example, Shane (2003) postulates that opportunity is likely to be exploited if an individual is better educated. This is because the information and skills acquired through education can increase expected returns for opportunity exploitation. Hence, many universities, especially in developed countries like United States of America, are incorporating sustainability into the curricula of their undergraduate studies (see McEwen, 2013 for examples of sustainability entrepreneurship education activities at the university level). It is also noted in the literature that sustainable entrepreneurship requires a new educational approach. The education should specifically focus on sustainability and be delivered in a way to stimulate sustainable entrepreneurial behaviour in students. In the word of McDonough and Braungart (2002), the goal of sustainable entrepreneurship education should be to equip the students with knowledge and skill needed to operate on renewable energy and to eliminate the concept of waste by making every waste product a raw material or input for another activity or return it into the cycle of nature. Ultimately, students of sustainable entrepreneurship should be able to apply sustainability frameworks to design new products, services, and processes (McEwen, 2013).

Among the knowledge base and skills needed are awareness of local and global environmental problems and future trends, acquisition of environmental values, and engagement in ecological or systems thinking (Richardson, Irwin and Sherwin (2005). Other skills identified by SustainAbility (2008) are the ability to seek alternative and innovative ways of meeting present needs as well as developing new business models that support the resulting innovative products and services. Also the future sustainable entrepreneurs should be able to get inspiration from the solutions already provided by the nature. This is termed biomimicry, which is an approach to innovation that seeks sustainable solution to human challenges by emulating nature's time-tested patterns and strategies (Biomimicry Institute, 2014). It is therefore important to design curricula and pedagogy that can influence the attitudes and actions of existing and, especially, the would-be entrepreneurs. The pedagogy should emphasise active, experiential, inquiry-based learning and real world problem solving in the classroom, on the campus and in the local community (McEwen, 2013). Moreover, to ensure long-term retention of the knowledge, skills and values gained the author proposed that the curriculum should provide learning experiences on real-world problems prevailing within their immediate university environment, larger community, government and industry.

Beyond the pedagogy, there are certain factors identified in the literature that may likely make entrepreneurs to discover sustainable development opportunities. These include their knowledge of the natural and communal environments in which they live as well as their perception about the threats on these environments (Patzelt and Shepherd, 2011). Other, as posited by these authors, includes the extent of their altruism toward others within the community. This again underscores the importance of approach to sustainable entrepreneurship education, which must be appropriately designed to develop these attributes.

Various approaches on education for sustainable development identified in the literature include, first, normative and zero-sum perspectives which involve awareness-building, critical thinking and introduction of tools to support environmental protection (Springett, 2005). Second approach is instrumental

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

perspective that highlights the value of sustainability and corporate social responsibility initiatives to build competitive advantage (Kashyap et al., 2006). The more recent approach is the one that highlight the importance of entrepreneurship education to inspire and build awareness of the opportunities inherent in the sustainability arena for self-interest and to benefit diverse stakeholders (Kuckertz & Wagner, 2010). While the first and second approaches are reactive, the third is proactive in nature. That is, the third approach is meant to influence attitudes and intentions related to sustainable development. Drawing from the theory of planned behaviour, the present and future behaviour of an individual is strongly determined by behavioural intentions (Ajzen, 1991). This means that the behavioural intention of sustainable entrepreneurs will depend on attitudes, subjective norms and perceived behavioural control. The theory of planned behaviour is therefore providing the framework within which the link between education and sustainable entrepreneurship can be explored.

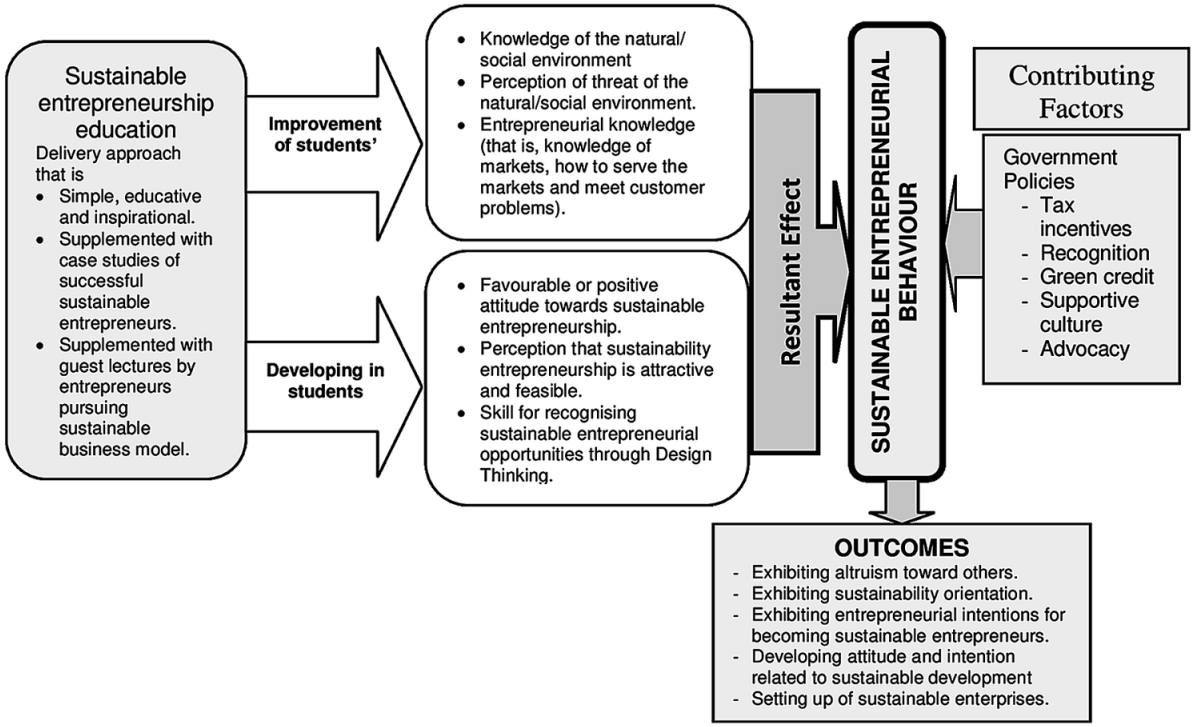
Relating this theory to sustainable entrepreneurship, Lourenço, Jones and Jayawarna (2013) posited that formation of sustainable entrepreneurial behaviour intention is dependent on learner's perceived benefits of learning about sustainable entrepreneurship, perceived behavioural control, and subjective norms formed through perceived ease of use of knowledge related to sustainable entrepreneurship. Therefore, it can be proposed that the intentions of would-be entrepreneurs to utilise their learning related to sustainability are influenced by their perception of learning, perception of benefits and the perceived ease with which the learning content can be applied. The empirical finding of Lourenço, Jones and Jayawarna (2013) also confirmed above theory. First, the author found that if prospective entrepreneurs perceive benefits from content related to sustainable entrepreneurship their intentions to exploit such learning will be enhanced. Second, if nascent entrepreneurs learn content related to sustainable entrepreneurship, the likelihood of exploiting such learning will also be enhanced. In summary, the major driver for would-be entrepreneurs to utilise learning is their understanding of the benefits of sustainable entrepreneurship and their perception of learning.

Another important motivation of prospective entrepreneurs to utilise learning about sustainable entrepreneurship is whether or not such entrepreneur has profit-mentality. This argument, proposed by Giacalone and Thompson (2006), is confirmed by the empirical finding of Lourenço, Jones and Jayawarna (2013). That is, profit-minded entrepreneurs will likely pursue those opportunities that promise higher entrepreneurial rents. However, Lourenço, Jones and Jayawarna (2013) discovered that, though a profit-first mentality will influence evaluation of sustainable entrepreneurship, but it is not a significant factor deterring the ability to learn material that could be in conflict with existing institutional logic of profit-first value. Hence, there is still value in introducing learning content related to sustainable entrepreneurship to would-be entrepreneurs with a profit-first mentality. It is then suggested by these authors that providing sustainability-related content in entrepreneurship education and business start-up is a valuable intervention.

The implication of the above, especially for the educators, is the need to develop competences for the delivery as well as the curriculum that can develop sustainable entrepreneurial behaviour in the students.

FRAMEWORK FOR SUSTAINABLE ENTREPRENEURSHIP

Based on the literature review, as discussed above, it is clear that the problem of environmental degradation, arising from the failure of markets, can be resolved through entrepreneurial action. That is, there are entrepreneurial opportunities associated with these market imperfections which can be exploited



EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

using entrepreneurial process. Both theoretical and empirical literatures are however suggesting that only entrepreneurs who are sustainability-oriented will likely support the idea of sustainability and exploit the opportunities associated with the market imperfections. This then indicates the importance of entrepreneurship education in fostering the entrepreneurial intentions targeted at opportunities related to sustainable development. The education will help fostering sustainable development-oriented entrepreneurial behaviour, as well as encouraging the nascent entrepreneurs to pursue business that can result in sustainable market offerings.

Considering the complexity inherent in opportunities for sustainable entrepreneurship, the contents and pedagogical input is very crucial, especially on how it can influence learners' attitudes and intentions towards sustainable development. Empirical results showed that when the techniques of delivering the education are simple and easy to learn, the perceptions of the learners about the benefits of learning sustainable entrepreneurship will be raised (Lourenco, Jones & Jayawarna, 2012). Therefore, the combined effect of understanding the benefits of sustainable entrepreneurship and perception of learning are major motivation for exploiting the learning by nascent entrepreneurs.

Figure 1 therefore shows the proposed framework for developing sustainable entrepreneurial behaviour of future entrepreneurs, especially in tertiary institutions in African countries. From this figure, the delivery approach for teaching sustainable entrepreneurship should be simple, educative (well grounded in entrepreneurship and environmental economics theories), and involves intensive hands-on experiences. This is because sustainable solutions require a lot of creativity, and as Schumpeter (1934) noted, the entrepreneurial process in sustainability involves creative destruction of conventional production methods and consumption patterns. To further stimulate the interest of students and make them appreciate the

Figure 1. Framework for the development of sustainable entrepreneurial behavior

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

benefits associated with green business ideas there is need for industrial visit to successful businesses with best-practices. Also, the education should be supplemented with case studies of successful sustainable entrepreneurs as well as guest lectures by entrepreneurs pursuing sustainable business model.

It is expected that the approach will achieve two major goals in the learners. First, it will improve students' knowledge and perception of threats in the natural and social environments, as well as improving their entrepreneurial knowledge about the market and how to serve it, and how to meet customers' problems. Secondly, the students will develop favourable or positive attitude towards sustainable entrepreneurship, thereby perceiving sustainability entrepreneurship as being attractive and feasible. The skill for recognising sustainable entrepreneurship will also be developed in the students.

Beyond the contribution of sustainable entrepreneurship education, government policies and programmes are also important. That is, policies and programmes that can encourage and support entrepreneurial actions towards addressing environmental challenges with innovative business solutions should be put in place. Though government might not be able to decide on which market imperfections to address; efforts should however be directed at formulating policies that can foster entrepreneurial behaviour that is oriented towards sustainability, which can be in form of tax incentives, recognition, green credit, and advocacy among others.

FUTURE RESEARCH DIRECTIONS

The framework developed in this chapter is based on the results of findings in developed countries. While these findings can provide direction for sustainable entrepreneurship education, yet it is important to carry out empirical studies on the motivation and attributes of indigenous entrepreneurs in Africa who are already engaging in sustainable entrepreneurship.

CONCLUSION AND POLICY IMPLICATIONS

Attempt has been made in this chapter to contribute to sustainable entrepreneurship literature by synthesised from the various thoughts and findings from the entrepreneurship, environmental and welfare economic literature in general as well as sustainable entrepreneurship in particular. The chapter establishes the need to change the orientation of the future entrepreneurs from being profit-minded alone to being environmental conscious. That is, maintain a balance between profit generation and sustainability development. As it is noted in the environmental and welfare economics literature, majority of environmental problems being experienced results from the failure of market. Fortunately, these market failures provide avenue for business opportunities which in turn can improve the efficient functioning of market. Therefore, instead of the nascent entrepreneurs contributing further to the degradation of the environment they can use entrepreneurial process to discover, evaluate and exploit opportunities inherent in these market failures. Therefore, developing sustainability capabilities and attitude of nascent entrepreneurs which is favourable to sustainability has implication for entrepreneurship educators and policy makers.

On the part of educators, entrepreneurship education should go beyond preparing the students to start small businesses, but also emphasise transformational entrepreneurship that can bring about a complete change in their values and behaviours. Hence, the pedagogy of sustainable entrepreneurship education should be able to stimulate sustainable entrepreneurial behaviour in the students, thereby encouraging

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

them to pursue 'green' business ideas rather than opportunistic ones that are driven by self-interest. The education should also be designed in a way that will achieve two major goals. Firstly, efforts should be geared at making the students understand and appreciate the contemporary sustainability challenges, such as climate change and depletion of non-renewable resources among others. Closely related to this is the knowledge of the potential business opportunities for sustainable entrepreneurship associated with these challenges. Consequent on the above, entrepreneurship education should be delivered in a way that will be able to develop the creative ability of students to respond to environmental and social problems as well as to discover opportunities embedded in these problems. Since one of the desired effects of entrepreneurial education is entrepreneurial inspiration, part of the delivery methodology should include case studies of successful sustainable entrepreneurs and guest lectures by entrepreneurs who are committed to pursuing sustainable business model.

Also, the policies and strategies of government should not be reactive alone, whereby established firms are made to be socially responsible, through corporate greening. It has even been found that these efforts have not meaningfully solved the environmental problems (York & Venkataraman, 2010). According to these authors, reactive policies will only bring about incremental reduction in the activities of the firms which have contributed to environmental problems. Such reduction might not be sufficient to achieve the desired economic, environmental and social sustainability. Moreover, reactive policies might not fully resolve existing market imperfections and will not encourage innovative drive necessary to discover opportunities associated with sustainability problems.

Therefore, the policies and programmes of government should support entrepreneurial actions that can encourage entrepreneurs to use entrepreneurial process to resolve environmental challenges with innovative business solutions. This could be in form of tax incentives, recognition, green credit, establishment of eco-business incubators, and patronage of green products and services from such businesses. Government should also create a platform where nascent sustainable entrepreneurs can have access to information about the existence of entrepreneurial opportunities within environmental degradation. Equally important is the effort of government to facilitate collaboration and networking with national and international organisations who can assist in the development of technologies required to solve the environmental problems.

Chapter 31
Sustainability Reporting in Transitional Economies

Marwa Hassaan
Mansoura University, Egypt

ABSTRACT

This chapter provides insights on some issues associated with the development of sustainability reporting in Egypt as a transitional economy that recently developed the S&P/EGX ESG index. In a dynamic world, and faced with a scientific proof that relates dangerous climatic changes to corporate activity, corporate financial reporting needs to be placed in perspective. Hence, as a social science, accounting should play a vital role in integrating corporate financial and non-financial measures. Semi-structured interviews were employed to investigate the extent to which sustainability reporting is appreciated in the Egyptian market by both business enterprises and the investors. Results indicate that sustainability information is of limited interest to markets except when it is identified as relevant in terms of risk or governance. On the investors' side, returns were seen as the main driver of portfolio selection. However, sustainability issues would be seriously considered when comparing among alternatives with similar returns.

INTRODUCTION

Sustainability reporting is a broad term that describes the disclosures to be made by firms on the positive or/and negative impacts of their activities on the environment, society and the economy. Hence, this mechanism has the potential to enable firms to set goals, measure performance, and manage change in order to make their operations more sustainable (KPMG, 2013: 10; GRI, 2013: 3). Globally, sustainability reporting enables the integration between financial and nonfinancial information, providing stakeholders with enhanced information to make more informed decisions.

Recently, there is an increasing trend among many organizations around the world to make their operations sustainable. Furthermore, the idea that long-term profitability should go hand in hand with social justice and environment protection is gaining ground. Hence, the quest to move to a truly sustainable economy is understood by organizations' financiers, customers and other stakeholders. This suggestion is supported by the findings of a recent KPMG's global reporting survey which highlights that more

than 50% of reporting companies worldwide include sustainability related information in their annual reports compared to 20% in 2011 (KPMG, 2013: 11).

As a promising exchange, recently the Egyptian market has taken a pivotal step towards fulfilling the innovation in international best practices. In this context, the S&P/EGX ESG index was planned and developed as the principal index in Egypt to address the investors' concern about environmental, social and governance issues. The S&P/EGX ESG raises the profile of listed companies that are the best performing in terms of three parameters; environmental, social, and corporate governance responsibility (ESG). The index employs a unique and innovative methodology that quantifies a company's ESG practices, and then uses a scoring system to rank listed companies based on the established criteria. Unlike previous indices of this kind that measure ESG parameters on a committee and internal consensus basis, the quantitative scoring system of the S&P/EGX ESG is very informative as it provides investors with sustainability related information in addition to financial information. In other words, recognizing the need for an investable index, the selection process requires that eligible companies not only have high ESG scores, but also meet a market capitalization and liquidity threshold.

Legitimacy theory highlights the extent to which corporate social and environmental disclosures are influenced by the boundaries established by the society in order to be appreciated and avoid being penalized by the community in which the company operates. However, this theory does not take into consideration that legitimacy is interpreted differently from one society to another according to societal values, political system and government ideology. On the Other hand, signaling theory suggests that markets react to good and bad signals, most likely these signals are perceived as indicators of potential returns.

Building on this, sustainability reporting that is a voluntary disclosure that releases negative impacts of company's activities on the environment, society and the economy may not be supported. Hence, markets particularly transitional ones may discourage sustainability reporting initiatives that is fundamental if sustainability agenda is to be a meaningful practice. Stemming from this viewpoint, financial accounting researchers should investigate the extent to which capital markets can contribute to sustainable development. As sustainability relating information is voluntary, companies may be selective in releasing such information. This viewpoint is supported by the fact that wealth maximization is the main goal for companies as well as for current and potential investors, even corporate governance codes continue to place shareholders as the main stakeholder.

Drawing from the contextual interplay among accounting, capital markets and sustainable development, qualitative approach has been chosen to best address the research question. To the best of the researcher's knowledge this study is the first to investigate how the Egyptian market perceives sustainability reporting.

SUSTAINABILITY REPORTING: AN OVERVIEW

Sustainability Development

In broad terms, sustainable development is defined as the ''development that meets the needs of the present without compromising the ability of future generations to meet their own needs'' (UNWCED, 1987: 8). From the researcher's point of view, this definition highlights a key theme of sustainable development that is 'needs', which reflects the issue of scarce resources and how current generations should consider the welfare of the future generations. This depicts the interactive relationship between

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

the environment and development. This also sends a message to rich societies that the needs of poorest societies should be given a priority as it's one world. In a similar vein, Goeminne (2011: 627) argues that sustainable development raise a need for a more integrated approach to deal with interrelated global environmental and development matters.

The Brundtland Commission highlighted the idea that while the "environment" was previously considered as a sphere separate from human emotion or action, and while "development" term was employed to describe political goals or economic progress, it is more comprehensive to understand the two terms in relation to each other. In other words, the introduction of sustainable development called for the development of an integrated approach to deal with complicated global environmental problems and development issues (Goeminne, 2011: 627).

The Brundtland Commission was developed by the United Nations in 1984, as a result of the rise of environmental concerns by various pressure groups in order to gather countries to work and pursue sustainable development together. *Silent Spring* (Carson, 1962) had raised popular consciousness about the dangers of excessive pesticide use and some progress had been made in improving air and water quality in industrialized areas through 'Clean Air' acts and the like. By the early 1970s Friends of the Earth and Greenpeace had been established as a result of the perceived dangers posed to the planet by new practices such as nuclear tests and dam building. Later on the calls for a UN conference on the environment originated from the Swedish Ambassador to the UN who was particularly concerned with the effects of acidic rains and the acidification of the water systems in Scandinavia. The conference was held in Stockholm in 1972, the issue of pollution widened to include the problems being experienced by developing countries. In 1971, a UN sponsored meeting of experts in pollution met in Founex, Switzerland, and for the first time, made the explicit connection between industrial development, which was a justified desire of developing countries, and environmental degradation, which was seen as the price that should be paid. Since then, environmental protection was seen as one of the barriers towards development (Grubb et al., 1993). However, surprisingly, this meeting concluded that there is no conflict between environment and development, and that these two concerns should be mutually supportive (Engfeldt, 2002). It ended with the *Stockholm Declaration on Human Environment* and the *Action Plan for the Human Environment.* It also led to the establishment of the United Nations Environment Program (UNEP) a year later.

Additionally, during the 1970s the rise of Third world debts and the oil supply crisis, all necessitated taking an action by world's leading countries. Ten years later, a special session of UNEP's governing Council was held to discuss the momentum affairs. It was clear that while the world economy achieved a substantial growth, the least developed are suffering and that many witnessed a fall in per-capita production during the 1980s (Tolba & El-Kholy, 1992). It was at this point that UN developed the World Commission on Environment and Development under Gro Harlem Brundtland. Its aim was to build a future more prosperous, more just, and more secure, resting on ecologically based policies and practices. At the beginning, there was an overwhelming belief that, in order to attain this goal, significant changes in current approaches, would have to be confronted, which would involve changes in individual attitudes and lifestyles and more crucially changes in certain critical policies… and the nature of co-operation between governments, business, science and people (UNWCED, 1987).

This Commission took appreciated steps in order to conceptualize the relationship between the environment and development, in light of the continuing disparity between levels of prosperity in the Northern hemisphere and the Southern, and the thoughts expressed at Founex in 1971. During the sitting of the Commission, which was to last two and a half years, a number of catastrophic events occurred

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

which provided a great challenge at that time like the discovery of the hole in the Ozone layer over Antarctica and the explosion of Chernobyl nuclear reactor in the USSR. Such events led the commission to take pivotal steps to place the environment at the core of strategic management (Grubb et al., 1993). It also highlighted notions of justice and fairness to the peoples of the developing world, in terms of fair shares of the world's resources and redistribution of wealth to improve the standards of living of poor populations. The Brundtland Commission officially dissolved in December 1987 after releasing the Brundtland Report entitled 'Our Common Future' in October 1987, a document which coined, and defined the meaning of the term 'Sustainable Development'. In 1988 the organization 'Center for Our Common Future' was established to take the place of the Commission. This report contributed to the development of 'Environmental Accounting'. In its early stages, environmental accounting was mainly influenced by science and economics of sustainable development disciplines (Grayand Laughlin, 2012).

The Need for Sustainability Reporting

sustainability reporting is an emerging form of reports that aims at integrating financial and nonfinancial information with the purpose of providing stakeholders with enhanced information to make more informed decisions. Hence, Sustainability reports provide information that describes the economic, environmental and social impacts of company activities. Accordingly, this adds to the responsibility of accountants who are required to develop their practices to recognize social, environmental and economic interactions between the company and its external environment. Sustainability accounting is seen as an extension of environmental accounting that is initially emerged from social accounting (Grayand Laughlin, 2012; Bebbibgton & Larinaga, 2014).

The motive for this type of reporting arises out of the realization that financial statements alone fail to provide satisfactory information to stakeholders who are looking for comprehensive quantitative and qualitative information that really depicts the overall corporate activities. This argument is supported by Modapothala and Issac (2009), who suggest that sustainability reporting provides a framework through which companies provide reasonable and credible corporate reporting to satisfy various stakeholders' needs for information and, consequently, increase their goodwill. Sustainability reports are more comprehensive than traditional selective reports that only target specific user group(s). Hence, nowadays releasing sustainability reports becomes a common practice among companies operating in developed countries particularly in North America, Japan and Europe as an extension of environmental reports (WBCSD, 2002; KPMG, 2008).

There are many recipients of sustainability related information like investors, legislators, local communities, environmental groups and employees. Enhancing corporate image particularly in the industrial sector which used to be subject to severe criticism from the media and society is becoming an obvious motive for sustainability reporting practice. The corporate scandals witnessed during the last two decades raised the need for many user groups to exert pressure on companies to improve their level of transparency to include in addition to financial performance related information, environmental and social responsibility related information (KPMG, 2008).Consequently, many countries like Japan, Netherlands and New Zealand have implemented statutory requirements to push companies towards carrying out their environmental and social responsibilities (Kolk, 2003). This in turn, can play a vital role in spreading the culture of environmental protection among the management of such companies.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Sustainability related information is published either in a separate report or presented as a separate section in the company annual report. It is also a common practice among companies to release sustainability information on their websites (Salama, 2009).

Recently sustainability related information concerning environmental, social and governance issues is becoming one of the most significant trends in financial markets. Many modern investors are aware about the importance of sustainable responsible investing (SRI), and corporate management's focus on corporate social responsibility (CSR). Furthermore, many international organizations have taken important steps in order to pave the way for incorporating sustainability related concerns among business organizations' priorities. For example the United Nations backed Principles for Responsible Investment (UN PRI). Additionally, the Global Reporting Initiative (GRI), the Carbon Disclosure Project (CDP) and the Sustainability Accounting Standards Board (SASB) are strongly supporting sustainability reporting (Clark, Feiner & Viehs, 2014: 6).

SASB is a registered non-profit organization in the United States (US), that was officially commenced its activity in 2012. SASB aims at developing and disseminating industry-specific accounting standards for material sustainability issues for the purposes of integrated reporting. The SASB standards are suitable for disclosure in standard filings. Additionally, they are applicable and relevant globally for companies looking to report on material environmental, social and governance issues.

SASB is developing standards for 88 industries in 10 sectors using a multi-stakeholder, transparent process. The standards describe both impacts as well as opportunities for innovation. Consequently, following such standards enable companies to create value for their future success in the business world.

SASB was conceived following research conducted by the Initiative for Responsible Investment at Harvard University on determining industry-specific material issues and associated key performance indicators. After an irresistible positive response by businesses, SASB development supported in order to set industry tailored performance integrated indicators (integrating ESG and financial aspects) that take into consideration the materiality of sustainable development concerns (Gilman & Schulschenk, 2013).

SASB developed a number of principles to guide the improvement of the sustainability accounting standards. Such standards should satisfy the following criteria (Gilman & Schulschenk, 2013: 16):

1. Being applicable to all investors on an evidence based approach.
2. Being pertinent and relevant across an industry, based on robust evidence.
3. Being focused on driving long term value creation and risk mitigation
4. The expected benefits exceed the perceived costs.
5. Being applicable by the companies.
6. Being easily verified such that they are measurable, quantifiable when possible, comparable, replicable and auditable.
7. Being objective and support decision making.
8. Being of the highest quality possible at any given time
9. They embody the minimum set of standard criteria which include relevance, usefulness, applicability, cost-effectiveness, comparability, completeness, directionality and auditability.
10. Being reflective of the views of stakeholders.
11. They support the shift to integrated reporting.
12. They support the convergence to international accounting Standards.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

SASB is committed to a transparent multi-stakeholder process in the development of its sustainability accounting standards. The process is well defined and consists of the following steps (Gilman & Schulschenk, 2013: 16-17):

1. SASB creation of the Sustainable Industry Classification System (SICS) to categorize industries according to their resource intensity and their sustainability innovation potential. The system is tied back to standard classification systems.
2. SASB development of a materiality map as the starting point for understanding the relative materiality of issues per industry.

The materiality map follows a three step process looking at:

1. Evidence of interest
2. Evidence of economic impact
3. Forward looking adjustment

Using these tests, the material issues are then ranked and a threshold is established by which material sustainability issues are determined for each industry. The SASB research team then reviews these material issues.

1. This is followed by an in-depth industry research to provide context within which the sustainability issues are analyzed, including industry trends, key environmental, social and governance issues. This research also includes the identification of existing metrics and practices used to quantify and articulate each material issue. Following this, the SASB research team selects those KPIs and disclosures that are of the highest quality from the existing population or creates new ones where none exist or those that do are not of sufficient quality.
2. Subsequently, Industry Working Groups (IWGs) are established to review the sustainability accounting standard developed by the SASB research team, providing comment and feedback to SASB.
3. The IWGs are comprised of members with a depth of industry knowledge and expertise and members from the following interest groups:
    a. Market participants (investors, research analysts, exchanges)
    b. Corporations
    c. Public interest and intermediaries (government, NGOs, academics, accountants, auditors, consultants).
4. The SASB research team then incorporates the IWG feedback and publishes the performance indicators publically and requests comments thereon. Public comment is open for 30 days.
5. The SASB research team then incorporates the public comments into the standard.
6. Afterwards the standard is reviewed by the SASB Standards Council to ensure consistency, completeness and accuracy and compliance with the standards setting process with American National Standards Institute guidance and SASB principles. Upon their approval, the sustainability accounting standard is deemed complete and will be published.

SASB standards provide companies with standardized sustainability metrics designed to communicate performance on sustainability topics. By supporting comparability, relevance, understandability, and

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

verifiability, SASB standards help companies ensure that their disclosures on sustainability are useful for decision making purposes.

SASB standards are intended to provide the basis for "suitable criteria" that meet the following attributes:

- **Objectivity**: Criteria should be free from bias.
- **Measurability:** Criteria should permit reasonably consistent measurements, qualitative or quantitative, of subject matter.
- **Completeness**: Criteria should be sufficiently complete so that those relevant factors that would alter a conclusion about subject matter are not omitted.
- **Relevance**: Criteria should be relevant to the subject matter. SASB identifies accounting metrics for each sustainability disclosure topic in the SASB standards.

SASB recommends that each company consider using these sustainability accounting metrics when preparing disclosures on the sustainability topics. As appropriate when disclosing a sustainability topic identified by this Standard, companies should consider including a narrative description of any material factors necessary to ensure completeness, accuracy, and comparability of the data reported.

Where not addressed by the specific accounting metrics, but relevant, the registrant should discuss the following, related to the topic:

- The registrant's strategic approach to managing performance on the topic;
- The registrant's relative performance with respect to its peers;
- The degree of control the registrant has;
- Any measures the registrant has undertaken or plans to undertake to improve performance; and
- Data for the registrant's last three completed fiscal years (when available).

SASB recommends that registrants use SASB standards specific to their primary industry as identified in the Sustainable Industry Classification system. If a registrant generates significant revenue from multiple industries, SASB recommends that it also consider sustainability topics that SASB has identified for those industries and disclose the associated SASB accounting metrics.

In disclosing to SASB standards, it is expected that registrants disclose with the same level of rigor, accuracy, and responsibility as they apply to all other information contained in their SEC filings.

The SASB standards are intended to provide guidance for companies that engage in public offerings of securities registered under the Securities Act of 1933 (the Securities Act) and those that issue securities registered under the Securities Exchange Act of 1934 (the Exchange Act). Disclosure with respect to the SASB standards is not required or endorsed by the SEC or other entities governing financial reporting, such as FASB, GASB, or IASB.

Unless otherwise specified, SASB recommends that:

- A registrant disclose on sustainability issues and metrics for itself and for entities that are consolidated for financial reporting purposes as defined by accounting principles generally accepted in the United States for consistency with other accompanying information within SEC filings.
- For consolidated entities, disclosures be made, and accounting metrics calculated, for the whole entity, regardless of the size of the minority interest; and

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Information from unconsolidated entities not be included in the computation of SASB accounting metrics. A registrant should disclose, however, information about unconsolidated entities to the extent that the registrant considers the information necessary for investors to understand the effect of sustainability topics on the company's financial condition or operating performance (typically, this disclosure would be limited to risks and opportunities associated with these entities).[1]

Sustainability Reporting: The Theoretical Foundation

Many scholars suggest that corporate disclosure behavior is influenced by the political and socio-economic environment within the country in which the company operates (e.g., Elnaby & Mosebach, 2005; Nobes, 2006; Qu & Leung, 2006; Hassaan, 2013). Consequently, managers' incentives may differ from one country to another and from one company to another due to the differences in societal values as well as company characteristics.

To date there is no single theory that can comprehensively interpret or predict corporate financial disclosure practices. However, legitimacy theory and signaling theory are the most commonly employed in interpreting sustainability disclosure practices.

Legitimacy theory highlights how management reacts to community expectations to avoid legitimacy costs and being penalized by the community (Brown & Deegan, 1998; Wilmshurst & Frost, 2000). Hence, this theory emphasizes the importance of societal acceptance for company continuity, on the grounds that, company actions affect the environment in which it operates (Ghazali, 2004; Hassaan, 2013). ''Legitimacy itself can be considered to be a condition or status. Legitimation, on the other hand, is a process which organizations can undertake (perhaps through particular disclosure strategies) to take them to this state'' (Brown & Deegan, 1998: 23). This theory is mainly used to explain social and environmental disclosures on the grounds that companies as members in the society are expected to carry out their activities within the boundaries established by the society within which the company operates (Wilmshurst & Frost, 2000; Ghazali, 2004). However, this theory is criticized on the grounds that, it does not take into consideration that legitimacy is interpreted differently from one society to another according to societal values, political system and government ideology (Ghazali, 2004; Hassaan, 2013). Additionally, in a transitional economy where sustainability reporting is an emerging application, it seems that gaining legitimacy is not a priority to companies operating in such economies. On the other hand, signaling theory suggests that markets react to good and bad signals, most likely these signals are perceived as indicators of potential returns.

Building on the above, sustainability reporting that is a voluntary disclosure that releases negative impacts of company's activities on the environment, society and the economy may not be supported. Hence, markets particularly transitional ones may discourage sustainability reporting initiatives that is fundamental if sustainability agenda is to be a meaningful practice. On the other hand, as long as sustainability related information is voluntary, companies may be selective in releasing such information. This viewpoint is supported by the fact that wealth maximization is still the main goal for companies as well as for current and potential investors particularly in transitional economies where environmental and social issues are not a major concern, even corporate governance codes continue to place shareholders as the main stakeholder.

Based on the above discussion it will be interesting to investigate the applicability of the legitimacy and signaling theories in the Egyptian context as one of the promising transitional economies.

LITERATURE REVIEW

The modern concern with human-environment interactions was highlighted since 1972 in Stockholm conference on human development. The following three decades have witnessed a widening of the debate concerning the relationship between human development and the environment and emerges against a background of concern about the environmental crisis, the under development of the majority of the world's population and social responsibility (e.g., Pirages, 1990; Bartelus, 1994; Esteva, 1992; Tolba & El-Kholy, 1992; Gray et al., 1995; Sachs, 1995; Gray, 2002; O'Donovan, 2002; Patten, 2002; Parker, 2005; Campbell, 2007; Pulver, 2007; Crane, Matten & Spence, 2008; Chen & Roberts, 2010).

Since the 1980s environmental accounting began to emerge as a distinct topic of research. During that time, some legal requirements addressed the necessity for disclosing environmental liabilities by business enterprises (Bebbington & Larinaga, 2014:397). Consequently, some researchers investigated the association between environmental disclosures and corporate characteristics (e.g., Trotman & Bradly, 1981). The focus of such studies was to shed light on the disclosure of environmental issues that were local in nature. However, after the issuance of the Brundtland Report (UNWCED, 1987), many research papers directed towards environmental accounting.

The Brundtland Report was a starting point that inspired many developed countries to take actions to protect the environment from abuse. For instance, in the UK, the Brundtland Report encouraged Department of the Environment to ask economist David Pearce to write a report on environmental economics ultimately giving rise to the influential Blueprint for a Green Economy (Pearce, Markandya & Barbier, 1989; Bebbington & Larinaga, 2014). Consequently, the Chartered Association of Certified Accountants commissioned Rob Gray to describe how accounting might contribute in the wake up of Pearce et al. (1989). This resulted in the publication of The Greening of Accountancy which helped in creating the base for environmental accounting (Bebbington & Larinaga, 2014: 397). Environmental accounting literature in the early nineties was strongly inspired by ideas imported from both the science and the economics of sustainable development (Gray and Laughlin, 2012). The emerging literature at that time, was mainly concerned with the interaction between accounting and environmental valuation (eg.,Hines,1991; Power, 1992).

Later on, environmental accounting began to attract researchers from different areas of accounting such as management accounting, financial accounting and auditing (Thomson, 2007; Bebbington & Larinaga, 2014).This literature provided the basis for the recognition of sustainability as a policy issue and also formed the starting point for many of the more recent research papers on sustainability and sustainable reporting(e.g., Adams, 2004; Ballou, Heitger & Landes, 2006; Aras & Crowther, 2008; Jackson, 2009; Milne, Tregidga & Walton, 2009; Gray, 2010; Bansal & Hoffman, 2012; Bebbington & Larrinaga, 2014; Bebbington & Larrinaga, 2014; Unerman & Chapman, 2014; Cho, Laine, Roberts & Rodregue, 2015).

Increasing organizational interest in sustainability reporting and accountability, along with increased academic investigation of these accounting issues, have resulted in greater evidence and public awareness of sustainability. The recognition of social and environmental issues by corporate board of directors is most likely reflected via corporate sustainability reporting practices, which have in recent years spread swiftly and perceived as a component of the information stream produced by business organizations. Moreover, currently many organizations are developing a growing array of accounting, accountability and assurance practices to enable identification and handling of sustainability related risks and opportunities (O'Dwyer, Owen & Unerman, 2011; Malsch, 2013; Cho et al., 2015). Moreover, the development of such practices have emerged critiques and debates, supported with insights from academic research,

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

regarding the degree to which such practices might be considered as applicable(Gray, 2010; Cho et al., 2015). The issue of corporate sustainability related assertions and practice has been investigated by many researchers who produced inconsistent results (e.g., Archel, Husilos & Spence, 2011; Dhaliwal, Radhakrishnan, Tsang & Yang, 2012; Malsch, 2013; Milne & Gray, 2013; Unerman & Chapman, 2014).

Opponents of sustainability reporting argue that voluntary sustainability reporting scope is limited (O'Dwyer et al., 2005) and that it is employed by businesses as a means to gain legitimacy and serve their own interests rather than signaling rational plans and commitments (Adams, 2004; Milne and Gray, 2007; Cho et al., 2012; Patten, 2012; Milne and Gray,2013). Hence, company reputation will be the main factor that governs its decision regarding what type of sustainability relating information to release, with corporate management being most concerned with bending, obscuring, or rationalizing their poor social and environmental performance (Cho et al., 2010; Cho et al., 2015). On the other side, proponents of sustainability reporting argue that it improves corporate accountability and transparency regarding social and environmental impacts of its activities (Bebbington, et al., 2014). Additionally, sustainability related assertions are to some extent considered as signals to the market that the company is proactively managing its social and environmental risks (Malsch, 2013).

Many researchers who investigate the emergence of corporate sustainability reporting practice (e.g., Ferguson, 2007; Llewellyn and Milne, 2007;Bebbington et al., 2008;Laine, 2009; Gray, 2010), argue that the information presented in such reports are just vague narratives of little value with respect to sustainable development. This may be attributed to the absence of a clear description of sustainability development on the level of organizations accompanied with the absence of credible sustainable development accounts in practice (Gray & Milne, 2004; Gray, 2010;Bebbington & Larinaga, 2014).

From the perspective of cost accounting studies, full cost accounting is performing well as it moves beyond the entity to detect external factors(Bent, 2006; Frame & Cavanagh, 2009; Fraser, 2012; Xing, Horner, El-Haram & Bebbington, 2009). Hence, such studies are appreciated as it recognizes the interactive relationship between the entity and its surrounding environment. However, still sustainability accounting needs further effort from accounting researchers in order to depict a competent accounting treatment for sustainability related issues within accounting paradigm. This requires opening the door for conscious discussions about social, environmental and economic issues associated with sustainable development, between accounting researchers from one side and stakeholders and researchers from other disciplines on the other side. From the point of view of some researchers (e.g. Gray, 2010; Bebbington & Larinaga, 2014), accounting for sustainable development calls for a research approach that is distinctively different from that of accounting, environmental accounting and social accounting by avoiding a purely narrative focus.

Building on the above, it can be said that, the development of corporate sustainability reporting oriented research requires careful consideration from accounting researchers. A clear definition of sustainability accounting should be wisely stated, issues associated with sustainable development should be determined and included into accounting paradigm and the criteria for analyzing managerial behavior and evaluating financial and non-financial indicators must be clear to all parties affecting and being affected by sustainability reporting. Grounded theories should be identified to illustrate all aspects associated with corporate sustainability reporting.

The review of the prior research that investigates sustainability reporting reveals the lack of consensus among earlier researchers regarding the issue of sustainability reporting. Hence, there is a need for further research particularly in transitional economies whereas sustainability reporting is considered as a newly imported practice.

EGYPT'S STOCK EXCHANGE AND SUSTAINABILITY REPORTING PRACTICES: AN OVERVIEW

The Arab Republic of Egypt has always been a regional leading reformer. In general terms, the Economic development in this country has gone through four significant phases: Pre-nationalisation (before 1956), Post-nationalisation (1956-1973), Open Door Policy (1974-1990), and the Extensive Economic Restructuring (1991 to date). Each reflects the political strategy adopted by the ruler. Additionally, the performance of the Egyptian Stock Exchange is always heavily influenced by government foreign policies which subsequently affect internal economic performance (Hassaan, 2013).

The Egyptian economy is unique as Egypt is one of the few developing countries that transformed from a capitalist economy to a planned economy, and then returned to a capitalist one. In other words, the move to a free market economy in the 1990s was challenging to the government, private sector institutions as well as the accounting profession. Consequently, to promote foreign direct investment, it was necessary to develop the financial reporting system and improve disclosure and transparency to comply with the international best practices.

The legislation regulating companies listed on the EGX includes: Firstly, the Capital Market Law No. 95 of 1992 and its Executive Regulations No. 135 of 1993 concerned with regulating the EGX by monitoring the market status in general and maintaining steadiness and growth. Secondly, the Central Depository Law No.93 of 2000 which maintains all registration, clearance and settlement procedures associated with trading transactions, the main purpose being to reduce risks associated with trading physical securities, to enhance market liquidity, and to assure fast securities exchange. Thirdly, Decree No. 30 of 2002 of the Capital Market Authority Board of Directors on Securities Listing and De-Listing Rules of the Cairo and Alexandria Stock Exchanges (ROSC, 2009).

As a promising exchange, since 2012 the Egyptian market has taken a further step towards fulfilling the innovation in international best practices. In this context, the S&P/EGX ESG index was planned and developed as the principal index in Egypt to address the investors' concern about environmental, social and governance issues. The S&P/EGX ESG includes listed companies that are the best performing in terms of three parameters; environmental, social, and corporate governance responsibility (ESG). The index employs a unique and innovative methodology that quantifies a company's ESG practices, and then uses a scoring system to rank listed companies based on the established criteria. Unlike previous indices of this kind that measure ESG parameters on a committee and internal consensus basis, the quantitative scoring system of the S&P/EGX ESG is very informative as it provides investors with sustainability related information in addition to financial information.

The population from which the S&P/EGX ESG Index constituents are derived is the top 100 Egyptian companies by ESG scores, listed on the Egyptian Stock Exchange (EGX). All 100 companies in the population were chosen after being subjected to a screening process which incorporates environmental, social and governance indicators against which the company's disclosure practices are evaluated.

There are two screens; one focusing on environment & social indicators that is based on output obtained from the mapping of Global Reporting Initiative (GRI), Global Compact (GC) and Millennium Development Goal (MDG), and the other one focusing on corporate governance indicators that is an adaptation of Standard & Poor's existing corporate governance methodology to suit the Egyptian market.

The screening process ultimately yields a score, or an evaluation, for each of the companies in the population. The evaluation process seeks information relating to companies' disclosure of the ES&G screen indicators available in the public domain, such as a company's annual report, Web site, bulletins

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

and/or the disclosure made on the stock exchange. The final aim is to determine whether a company has made transparent disclosure, in such documents, on any of the indicators that are part of the ES&G screening system.

In cases where a company discloses a well-known public indicator, it is awarded a score of one; and if it did not it is awarded a score of zero. Similarly, public disclosure of 'extra-point' indicators is awarded a score of three; non-disclosure is, again, given a zero.

The weight for each index constituent is set in the following manner (S&P EGX ESG Index Methodology, 2012: 6-8):

1. **Quantitative Score**: Each of the companies trading on the Egyptian Stock Exchange is assigned a quantitative ranking based on three factors – transparency and disclosure of:
   a. Corporate governance,
   b. Environmental practices and
   c. Social governance.
   d. Raw values for each factor are calculated for each company in the index. These values are, then, standardized. The three standardized values are summed up and the companies are ranked in a descending order.
2. **Qualitative Score**: Those companies with the highest scores under the transparency and disclosure (T&D) process are selected for the qualitative scoring. Independent sources of information, news stories, Web sites and CSR filings are used to evaluate the actual performance of the company on a scale of 5 to 1, with 1 being the lowest and 5 being the highest. Then a final qualitative score is assigned for each company.
3. **Composite Score**: A composite score is calculated for each company by summing up the quantitative and the qualitative scores. Based on this, the top 100 stocks are chosen as the eligible pool, from which the final 30 stocks will be derived.
4. Each company's weight in the index is determined as a function of its ESG score. The index is calculated by means of the divisor methodology used in most S&P Indices. On any given day, t, the index value is simply the index market value divided by the index divisor (Figure 1).

The SWF is set only once a year at the index rebalancing date (August, 1). Therefore, the stocks will be weighted in exact proportion to their ESG Scores only at the rebalancing date. The weights of stocks in a score-weighted index between rebalancing dates depend on their relative price performances. The SWF might be adjusted between rebalancing dates. Additionally, since the S&P/EGX ESG index is score-weighted, the weights of individual stocks are not affected by corporate actions such as stock splits, spin-offs and rights offerings. Consequently, from the researcher point of view, the S&P/EGX ESG index applicability is ideal given the unique nature of the Egyptian Capital Market.

RESEARCH METHODOLOGY

Given the complex nature of sustainable development, and the relative lack of knowledge about the mechanisms by which businesses undertake sustainability reporting, semi-structured interviews were undertaken. Building on the review of prior research and the S&P/EGX ESGindex a relatively standardized set of questions was created. The following themes were developed within the interviews:

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1.

$$\text{Index Value}_t = \text{Index Market Value}_t \Big/ \text{Index Divisor}_t$$

$$\text{Index Market Value}_t = \sum_{X=1}^{n} IWF_{X,t} * \text{Modified Index Shares}_{X,t} * Price_{X,t}$$

$IWF_{X,t}$ = Investable Weight Factor of stock X on date t

$Price_{X,t}$ = The price used for stock X in the S&P/EGX ESG Index computation on date t

n = The number of stocks in the S&P/EGX ESG Index on date t

$\text{Modified Index Shares}_{X,t}$ = Shares used for stock X on date t

This term is calculated in the following manner:

$$\text{Modified Index Shares}_{X,t} = \text{Index Shares}_{X,t} * SWF_{X,t}$$

$$\text{Index Shares}_{X,t} = \text{Shares Outstanding}_{X,t} * IWF_{X,t}$$

The Score Weight Factor (*SWF*) term ensures the index weights each stock with its ESG Score. This is accomplished by setting the SWF at the rebalancing date, d, as follows:

$$SWF_{X,d} = k * Score_X / (IWF_{X,d} * \text{Index Shares}_{X,d} * Price_{X,d})$$

The constant k is used as a multiplier since the quotient $Score_x / (IWF_{x,d} * \text{Index Shares}_{x,d} * Price_{x,d})$ results in a very small value.

1. The clarity of 'sustainable development' concept
2. How sustainability reporting is perceived by the interviewees

Sample Selection

The researcher planned to conduct 20 interviews; ten persons from each group (board of directors of companies listed on the EGX whether their companies are listed on the S&P/EGX ESG index or not and securities brokers as sustainability reporting users). However, despite the original intention, the researcher could only complete 15 interviews (75%), six from the first group (two of them are members in the Board of Directors of companies listed on theS&P/EGX ESG index, particularly participants 5 and 6)and eight from the second group.

Before conducting any of the interviews, the researcher contacted the potential interviewees to explain the purpose of the study and to obtain their permission to participate. People who agreed to be interviewed were asked to determine the suitable time and were informed of the themes to be covered during the interview to allow them to consider the information being requested.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Interview Questions and Ethical Considerations

The interviews were semi-structured and lasted between 30 and 40 minutes and were conducted between November 2014 and January 2015. The interview questions were open-ended to encourage free expression of participants' views, ideas, and perceptions. Firstly, Interviewees were asked if the concept 'sustainable development' is known by them. Then discussions moved to questions directly relating to sustainability reporting with respect to how it is valued by them.

Measures to ensure the trustworthiness of the study were also incorporated in the interviews. Each began by emphasizing that complete anonymity would be provided to interviewees. Notes were taken during the interviews, as the interviewees were not prepared to be tape-recorded. Interviewees were encouraged to speak freely, and for verification purposes, they were asked to read the notes taken by the researcher during the interview to make sure that their views were accurately reported. The questions were translated into Arabic, as this was the language used. The researcher then translated the transcripts from Arabic to English, and to further guarantee the validity of the texts, the researcher asked a linguistic specialist to review her translation.

In constructing the interview questions the researcher followed the recommendations of Collis and Hussey (2003) to keep questions simple, avoid using unnecessary jargon or specialist language, phrase questions to keep the meaning clear, avoid asking negative questions because they are easy to misinterpret and avoid leading or value-laden questions. The researcher decided to use a manual method as the number of interviews and the interview material were manageable. Also, as qualitative data analysis depends mainly on deep understanding of data by the researcher and as software programs do not analyze qualitative data in depth, it was decided that the use of software was inappropriate.

RESEARCH RESULTS

The Clarity of 'Sustainable Development' Concept

The interview data indicates that all participants are aware about the concept of sustainability. However, it is more recognized in relation to the environmental impact of organizational activities as reported by 11 interviewees. '' …it is a newly developed concept that is concerned with how to carry out your economic activity without polluting the environment or harming its natural balance'' Interviewee 3 (first group).''…it is an emerging culture among businesses worldwide that requires them to be environmentally responsible" Interviewee 10 (second group). The association between sustainability and economic, environmental and social endeavors is recognized by only four participants; three from the first group and 1 from the second group."…it is to achieve the economic, environmental and social objectives to improve the welfare of the current population without preventing the coming generations from that right'' Interviewee 5 (first group). ''…it is to be environmentally and socially accountable while achieving economic objectives'' Interviewee 15(second group).

How Sustainability Reporting is Valued

The interview data collected from the first group is contradictory with respect to the importance of sustainability reporting. Members of the board of directors of companies listed on the S&P/EGX ESG

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

index believe in the importance of sustainability reporting and perceive it as part of transparency and accountability '' …we used to support any recommended practice so we decided to take the initiative and release sustainability reports…our reputation and our image in the eyes of the community means a lot… we used to provide a role model in transparency and accountability to our competitors and to other businesses'' Interviewee 6(first group).However members of the Board of Directors of companies not listed on the index consider releasing sustainability reports as unreasonable cost.''…we believe in social and environmental responsibility of business organizations…we are already working on decreasing the harmful impacts of our activity on the environment and that costs us a lot of money… but we think releasing sustainability reports is an extra unneeded cost as the majority of people if not all do not consider such reports and it is not a mandatory requirement'' Interviewee 4(first group).

With respect to the perception of the first group participants regarding whether releasing negative impacts of their activities throughout sustainability reports may affect their financial performance, all interviewees agree that investors are initially looking for investment opportunities that provide them with the highest return regardless of the economic, social and environmental impacts of investee activities as long as the company is not violating laws that increase their risk.'' …our main responsibility is to achieve the highest return on capital invested… investors put their money in the company that provides them with the highest return…they do not think about the impact of its activity as long as it is not subject to governmental regulations that may increase the company risk'' Interviewee 2(first group).

With respect to the perceptions of the second group participants regarding the importance of sustainability reports, they all argue that it is a good practice that reflects company's accountability. However, they all mentioned that returns on investment is the main factor to be considered in deciding which company to invest in. ''sustainability reporting is an appreciated practice that reflects social and environmental responsibility of business organizations and improved transparency…when deciding which company to invest in, the returns on investment is the main aspect ''Interviewee 8(second group).''… of course sustainability reporting is a good thing but when we talk about investment decisions the best investment opportunity is the one that provides the highest return'' Interviewee 13(second group). Four interviewees mentioned that sustainability related information is most likely to be considered when comparing investment opportunities with similar returns.''…to be honest sustainability related information most likely to be considered when you choose among investment opportunities of similar returns'' Interviewee 12(second group).''…when comparing between two investment opportunities with similar returns, the optimum choice will be the one which is more socially and environmentally responsible'' Interviewee 15(second group).One participant argued that when the company reputation is affected due to its harmful activities it is better to avoid investing in such company even if it is the best available investment opportunity''…if the company reputation is affected due to irresponsible activities that harm the environment and the community it will not be a good decision to invest in this company even if it is currently paying the highest return because at any time its value will be at stake…it is a risky investment that you should avoid'' Interviewee 9(second group).

SUMMARY AND CONCLUSION

Based on the interview data, the following generalizations could be concluded:

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

1. All participants are aware about the concept of sustainability. However, it is more recognized in relation to the environmental impact of organizational activities.
2. The interview data collected from the first group is contradictory with respect to the importance of sustainability reporting. Members of the board of directors of companies listed on the S&P/EGX ESG index believe in the importance of sustainability reporting and perceive it as part of transparency and accountability. However, members of the Board of Directors of companies not listed on the index consider releasing sustainability reports as unreasonable cost.
3. With respect to the perception of the first group participants regarding whether releasing negative impacts of their activities throughout sustainability reports may affect their financial performance, all interviewees agree that investors are initially looking for investment opportunities that provide them with the highest return regardless of the economic, social and environmental impacts of investee activities as long as the company is not violating laws that increase their risk.
4. With respect to the perceptions of the second group participants regarding the importance of sustainability reports, they all argue that it is a good practice that reflects company's accountability. However, they all mentioned that returns on investment is the main factor to be considered in deciding which company to invest in.
5. Half of the interviewees from the second group mentioned that sustainability related information is most likely to be considered when comparing investment opportunities with similar returns and one participant argued that when the company reputation is affected due to its harmful activities it is better to avoid investing in such company even if it is currently the best available investment opportunity because at any time its value will be at stake.
6. The interviewees responses partially supported the use of both the legitimacy and signalling theories in interpreting sustainability reporting practices. To some extent, it seems that there is an emerging awareness among different parties affecting and being affected by sustainability reports regarding the importance of sustainability reports in shedding light on the economic, social and environmental consequences of corporate activities. However, in the meantime, interviewees responses indicate that sustainability information is not of high priority neither to investors or companies operating in the Egyptian market. This emphasizes the impact of socio-economic factors and cultural values on corporate transparency and disclosures.
7. As long as sustainability reporting is voluntary (i.e., not enforced by law), companies will be encouraged to be selective in releasing sustainability relating information. This viewpoint is supported by the fact that wealth maximization is still the main goal for companies as well as for current and potential investors particularly in transitional economies where environmental and social concerns are not yet part of decision making inputs and where the complementary relationship between corporate financial and non-financial performance is not considered.

KEY TERMS AND DEFINITIONS

EGX: The Egyptian Exchange previously referred to as Egypt's Stock Exchange. It encompasses two exchanges, Cairo and Alexandria, both governed by the same board of directors and sharing the same trading, clearing and settlement systems.

Legitimacy Theory: It highlights the extent to which corporate social and environmental disclosures are influenced by the boundaries established by the society in order to be appreciated and avoid being penalized by the community in which the company operates.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

S&P/EGX ESG Index: It was planned and developed as the principal index in Egypt to address the investors' concern about environmental, social and governance issues. This index raises the profile of listed companies that are the best performing in terms of three parameters; environmental, social, and corporate governance responsibility (ESG).

Signaling Theory: Suggests that markets react to good and bad signals, as such signals are perceived as indicators of potential returns.

Sustainability Reporting: It is a broad term that describes the disclosures to be made by firms on the positive or/and negative impacts of their activities on the environment, society and the economy.

Sustainable Development: Describes the development that satisfy the needs of the present generations without limiting the ability of future generations to meet their own needs.

The Brundtland Commission: The World Commission on Environment and Development developed by the United Nations in 1984 under Gro Harlem Brundtland, as a result of the rise of environmental concerns by various pressure groups in order to gather countries to work and pursue sustainable development together.

The Brundtland Report: Refers to 'Our Common Future'report, thatwas issued in 1987 by the UNWorld Commission on Environment and Development. This report placed environmental issues into political agenda by emphasising the necessity of dealing with environment and development as one single issue.

The Global Reporting Initiative (GRI): An international non-profit independent standards organization founded in 1997, that helps businesses, governments and other organizations understand and communicate their impacts on issues such as climate change, human rights and corruption.

Chapter 32
The Strategic Association Between Information and Communication Technologies and Sustainability:
A Country-Level Study

Sarah Jinhui Wu
Fordham University, USA

Wullianallur Raghupathi
Fordham University, USA

ABSTRACT

The authors investigate the strategic association between information and communication technologies (ICTs) and sustainability using empirical data. Their hypothesis is that ICTs can promote a country's sustainability. In their framework the authors include the ICT factors of access, quality, affordability, applications, and institutional efficiency & sustainability. Sustainability is represented by individual development indicators, grouped in the clusters of environment, transportation infrastructure, energy consumption efficiency, economic development, and education. Using secondary data on ICTs and sustainability development indicators for countries from the World Bank, meanwhile controlling for the wealth effect, our main multivariate result indicates that ICTs factors have a positive association with sustainability. ICTs, therefore, have the potential to promote sustainability. The authors' results are useful in shaping strategic policy decisions that involve the nature and extent of investment in ICT infrastructure at the country level.

1. INTRODUCTION

The purpose of this exploratory work is to examine the association between information and communication technologies (ICTs) and sustainability at the macro level. When we talk about the macro level, we are referring to the sustainability impact that arises out of the application of ICTs across society (Avgerou, 2010; Bengtsson & Agerfalk, 2011; Heeks, 2010; Mascarenhas, 2010; Melville, 2010; Millet & Estrin, 2012; Spence & Smith, 2010; Watson et al, 2010). Many of these papers have discussed the macro impacts of ICTs as net positive. Therefore, it is worth investigating the actual association between ICTs and sustainability. Although the greening of ICTs, for example, the reduction of electronic waste or of the energy consumed by computers – is an important goal of the information technology community, the focus of this research is "greening through ICTs," that is, the applications of ICTs to promote sustainability broadly (Millet & Estrin, 2012).

In this paper we develop a framework for conceptualizing and studying the association between ICTs factors and sustainability development indicators at the country level. Our research is motivated by various propositions that ICTs' factors such as access, affordability and applications, and the like — have the potential to improve country sustainability at the macro level. Once in place, these improvements may lead to improved environment, efficient transportation, efficient delivery of energy, increased economic development, and higher literacy.

This study addresses the relationship empirically. Although studies in past decades have examined and generally confirmed the positive role of ICTs in development, productivity and other macro level indicators (Avgerou, 2010; Bengtsson & Agerfalk, 2011), none have examined the quantitative role of ICTs in enabling sustainability. Despite the anecdotal evidence and the potential, the relationship between ICTs and the broader social goal of sustainability is not well understood (Berkhout & Hertin, 2004). Scant research has been conducted into whether and what types of ICT favorably influence sustainability (Jokinen et al., 1998). Unlike many of the others, our study provides empirical data on which country leaders can base decisions to allocate their limited resources to ICT infrastructure selection and development and thus derive maximum benefits.

In this study, sustainability is characterized by a number of world development indicators that collectively specify the sustainability level of a country (Carraro et al, 2009; Hueting & Reijinders, 2004; Pinter et al, 2005; Spangenberg, 2005; UN, 2007). The indicators are grouped into the broad research constructs of environment, transportation, energy, economic development and education (World Bank, 2010). The ICTs are represented as a group of factors in the global ICT index developed by the World Bank (2010) for each country (Minges & Qiang, 2006). This group of factors has been used in prior studies on ICTs and country-level public health delivery (Raghupathi & Wu, 2011a) and ICTs and country-level governance (Raghupathi & Wu, 2011b). The data for all the indicators and factors are derived from various country-level World Bank data sets. We believe that important insights can be derived from studying potential associations between ICTs and sustainability development indicators.

This study makes several contributions. First, we introduce the contemporary literature on sustainability and ICTs' role as a potential enabler to the information systems research community. Second, we develop an initial framework of the relationship between ICTs and sustainability. Third, we empirically examine the relationship with a large data set, so generalizability of the conclusions is possible. Fourth, by studying the macro effects, countries can make selective investments in ICTs to promote different aspects of sustainability.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

The balance of the paper is organized as follows: we first provide background information with respect to sustainability at the macro level and the potential of ICTs to enable sustainability at the country level. We then describe the conceptual framework of the association between ICTs and sustainability and develop the corresponding hypotheses. Third, we describe our methodology. Fourth, we discuss the results of our statistical analysis and implications. Finally, we discuss the scope and limitations of our study as well as the key contributions, and suggest directions for future research.

2. BACKGROUNG AND LITERATURE REVIEW

The World Summit for the Information Society (WSIS) is specific in its Declaration of Principles, "Building the Information Society: a Global Challenge in the New Millennium," that ICTs serve as powerful instruments for productivity and economic growth through job creation and employability, leading ultimately to improved quality of life overall (http://www.itu.int/wsis/docs/geneva/official/dop.html). The Global e-Sustainability Initiative (GeSI) considers extending the influence of ICT to all aspects of socio-economic development and applying these technologies to both rich and poor countries in order to achieve the strategic principle of sustainable development across the globe (http://www.gesi.org ; http://www.itu.int/wsis/basic/about.html). Likewise, the United Nations Development Program (UNDP) says, "ICT is an increasingly powerful tool for participating in global markets; promoting political accountability; improving the delivery of basic services; and enhancing local development opportunities (http://www.undp.org/)" as reported in GeSI (2005) (http://www.gesi.org). These macro effects are believed to be widespread and complex (Berthon & Donnellan, 2011).

The UN defines ICTs "as tools that facilitate communication and the processing and transmission of information and the sharing of knowledge by electronic means." The definition encompasses the full range of electronic digital and analog ICTs, from radio and television to fixed and mobile telephones, computers, and such electronic-based media as digital text, audio-video recording and the Internet (http://www.un-gaid.org/). More recently, the National Research Council has suggested that "the ultimate goal of much of ICTs in sustainability can be viewed as informing, supporting, facilitating and sometimes automating decision making that lead to actions with significant impacts on achieving sustainability objectives" (Millet & Estrin, 2012).

Today, globalization is characterized by an important shift to knowledge-based societies – mainly driven by ICTs – where knowledge and information increasingly represent new patterns of growth and wealth creation and open up possibilities for more effective poverty reduction and sustainable development (Griese et al., 2001). Knowledge has become a principle force of social transformation. Without the global ICT infrastructure, financial trading as well as global trade and travel would collapse. A recent study by Vodafone (2005) on the effect of mobile phones in Africa provides evidence that mobile telephony has improved economic growth significantly. Moreover, this impact was twice as large in developing countries as in mature economies, with developing countries averaging 20 phones per 100 people and increasing GDP growth by 0.6% (Vodafone, 2005).

In this global arena, the governments of nearly all countries have expressed the goal of transforming their countries into learning economies and knowledge societies. This 'knowledge-based' and 'knowledge-led development' has the potential to tackle many of the problems confronting societies. One could hypothesize that 'knowledge' and 'information,' deployed equitably and systemically, could alleviate key sustainability challenges. At the country level, ICTs have the potential to bridge the digital divide (Pee

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

et al, 2010). They can be used to "manage the boundaries between knowledge and action in ways that simultaneously enhance the salience, credibility and legitimacy of the information they produce (Cash et al., 2003)." At the company level, ICTs can help 'green the organization' as well as manage resources more effectively (Berthon & Donnellan, 2011; Dao et al, 2011; Des Autels & Berthon, 2011; Watson et al, 2011). This has a positive wholesale effect on investment and society.

Drawing on recent literature (Mathews, 2003), three primary groups of effects are identified in which ICTs have the potential to play a wide range of important roles in enabling sustainability across the various constructs (Berkhout & Hertin, 2004; Goehring, 2004; Jitsuzumi et al., 2000; Jokinen et al., 1998; Mitomo & Oniki, 1999). *First-order effects* or *direct effects* arise from the increased efficiency in manufacturing and other activities through the use of various types of ICTs. Examples include ICT control of air conditioning equipment to reduce energy consumption and energy savings in transport by the use of intelligent transport systems (ITS). This phenomenon is known as immaterialization. *Second-order effects* or *indirect effects* are changes in the behavior of individuals and organizations arising from lifestyle and work-pattern changes enabled by the use of ICT. For example, telework/tele-commuting (T/T) not only reduces an employee's daily commuting time but also the energy consumed in commuting. Other examples are the deployment of remote sensing devices to monitor the state of the global environment as well as the use of computerized bidding mechanisms for trading the right to emit carbon dioxide (CO_2). This role is termed amaterialization. The second-order effects are often labeled as enabling effects. *Third-order effects* are also indirect effects and reflect the *promotion of the overall decision-making capability of a society* refers to the implementation of sustainable public policies via information systems that gather, organize, and disseminate relevant information (Heinonen et al, 2001). Third-order effects are often called systematic effects. In addition, ICTs can be used very effectively to communicate accumulated knowledge on sustainable development. Our conceptual framework is based primarily on the second order of effects.

As documented in the literature, ICTs contribute to the overall productivity and economic growth of a country (Fors & Morens, 2002). In addition to preventing waste and generating savings through efficiency, knowledge systems assist with the coordination of sustainability efforts, both locally and globally. As the information economy expands and information societies are formed (Heinonen et al., 2001), developing countries— rural areas, in particular—can move toward parity (Greller & MacKay, 2002) in many of the indicators, such as education level, transportation, public health, and quality of the environment (Gholami et al, 2010; Loh et al, 1998; Techatassanasoontorn et al., 2011). Through ICT-enabled sustainable development, countries can envision improved growth and better quality of life overall (Hughes & Johnston, 2005). The literature review strongly suggests that empirical studies in the association between ICTs and sustainability development indicators will go a long way in eliciting key policy issues.

3. CONCEPTUAL FRAMEWORK AND HYPOTHESIS

Based on the background discussion above, we draw broadly from the literature in several disciplines, including the conceptual basis for sustainability (Komiyama & Takeuchi, 2006; Lane, 2011; Larson, 2011), ICTs & sustainability (see Bengtsson & Agerfalk, 2011; Berthon & Donnellan, 2011; GeSI, 2008(a); Melville, 2010; Millet & Estrin, 2012; Watson et al., 2011), global development (European Commission, 2005; Parikh, 2009; Shih et al., 2008; UNESCO, 2002; WEC, 2005; WWF, 2008), and

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

the substantive number of publications at NRC (2010, 2011) and the World Bank (2010), to develop the conceptual framework for this study. Many studies consider the several macro effects of ICTs, such as on development, growth and productivity and found them to be positive (e.g., Meso et al., 2006; Meso et al., 2009).

Specifically, we drew from the report SMART 2020: Enabling the Low Carbon Economy in the Information Age (http://www.theclimategroup.org/publications/2008/6/19/smart2020-enabling-the-low-carbon-economy-in-the-information-age/) to adapt and extend for our framework. This report by Millet & Estrin (2012) organizes the potential application of ICTs to sustainability in terms of three broad categories, namely, (1) infrastructure and systems (e.g., energy, transportation), (2) ecosystem services and the environment, and (3) socio-technical systems (e.g., economic development and education). As such, we capture sustainability from five dimensions – environment, transportation infrastructure, energy consumption, economic development, and education – in this study.

We adapt the framework from Raghupathi & Wu, (2011a, 2011b) which have served as the basis for studies on the relationship between ICTs and country-level public health delivery and ICTs and country-level governance. While first-order effects of ICTs on sustainability have been studied extensively in the literature (Berthon & Donnellan, 2011), Raghupathi & Wu (2011a, 2011b) studied the second-order of ICTs on country-level public health delivery and country-level governance. In particular, they explored the association or relationship between ICTs and public health delivery and ICTs and governance in the aggregate.

Take Raghupathi & Wu (2011a) work for example. They empirically investigated the relationship between ICTs and the delivery of country-level public health. The underlying hypotheses suggested that ICTs improve the efficiency and effectiveness of public health delivery mechanisms. They conceptualized ICTs as five factors – accessibility, quality, affordability, applications, and institutional efficiency, and sustainability. The public health delivery was represented by the changes in the indicators of immunization coverage, TB infection, sanitation, undernourishment, life expectancy, mortality rate, and health care expenses. Results indicated in most cases ICT factors had a significant contribution to a country's delivery of public health over and above a country's income level. ICT accessibility factor contributed to improved delivery for nearly all of the public health indicators followed by ICT applications factor. The findings were useful at the country level for informing policy decisions regarding the nature and extent of investment in ICT infrastructure for the delivery of public health.

In the second study (Raghupathi & Wu, 2011b), they investigated the relationship between ICTs and country-level governance. Again the five factors of ICTs were modeled as independent variables and their impacts on governance indicators were assessed. Using secondary data from the World Bank, and controlling for the wealth effect, the main multivariate result indicated that ICTs – with the exception of the institutional efficiency and sustainability factor – had a positive relationship with governance indicators. They also found that accessibility was the most important ICTs' factor to enhance governance.

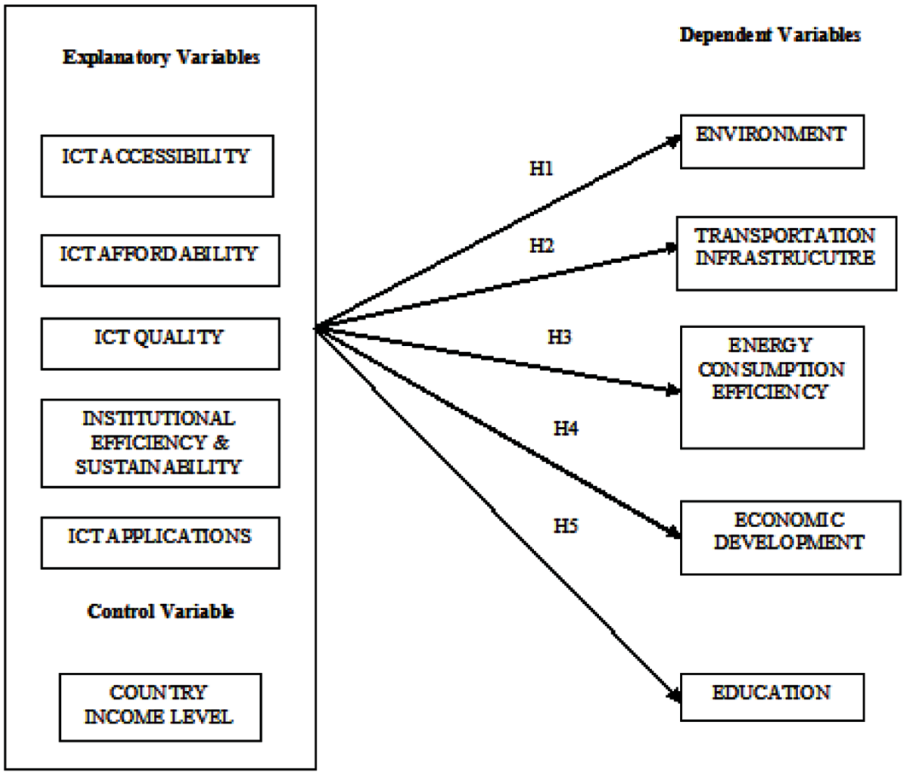
The three-order effects of ICTs are also the often-cited characterizations of the linkages between ICTs and sustainability (EITO, 2002; Hilty, 2008; Hilty et al, 2006; Kohler & Erdmann, 2004; Yi & Thomas, 2007). The macro models used for assessing the sustainability impacts of ICTs often differentiate between the orders of effects (Hilty, 2008; OECD, 2010). The first-order effects look at the impacts related directly to the life cycle of ICT hardware, including the production, use, recycling and disposal of ICTs (Ropke & Christensen, 2012). For example: how can hardware and software production and network architectures become greener (Servaes, 2012)? Apparently, the focus is on ICT sustainability itself, that is, green computing (Dao et al, 2011).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

The second-order (indirect) effects are the impacts and opportunities created by the ongoing use and application of ICTs. These effects, also called enabling effects, ask such questions as: how can ICTs reduce energy consumption in other sectors – video conferencing in lieu of traveling, home work place, intelligent traffic systems, smart buildings, and others (Servaes, 2012)? They address the impacts due to the application of ICTs that have the power to change the processes of production, transportation, consumption, etc. For instance, this category includes the energy savings achieved by ICT-enabled optimization of production processes or by replacing a physical product with a service (Ropke & Christensen, 2012).

The third-order effects are the impacts and opportunities created by the aggregated effects of large numbers of people using ICTs over the medium to long-term. Also called systematic effects, they look at green ICTs as a model for knowledge accumulation and innovation (Servaes, 2012). How can ICTs change the way we live and work resulting in a reorganization of production and consumption? For example, the third-order effects address the environmental impacts related to the medium or long-term adaptations of behavior and economic structures that follow from the availability of ICTs and the services they provide. Additionally, the rebound effects that emerge from efficiency gains can be included in these effects (Ropke & Christensen, 2012).

Most of the benefits of ICTs lie in the second-order effects via increased efficiency, transparency, and speed of transactions, rapid market-clearing, long-tail effects, and others (Yi & Thomas, 2007). For example, the average transatlantic business flights use 80,000 to 100,000 pounds of fossil fuel (Cohen, 2000), which could be easily avoided by the use of teleconferencing. The results from various studies differ – for instance, depending on the extent to which rebound effects are taken into account. Several recent studies addressing the second-order effects have reported positive results in the environmental sector (Erdmann & Hilty, 2010; The Climate Group, 2008). The current emphasis on the positive potential of ICTs is also reflected in the recent special issue of Journal of Industrial Ecology where the focus is on the "Benefits Side of the Equation" (Masanet & Matthews, 2010).



Based on all these works and the prior frameworks established in Raghupathi & Wu (2011a; 2011b) linking ICTs to second-order effects on health care delivery and governance, this framework is extended to characterize the association between ICTs and the second-order effects on country sustainability and presented in Figure 1.

- **Environment:** ICTs can have a positive impact on the environment for example, improving air quality, among other factors (Casal et al., 2005; Elliot, 2011; Melville, 2010). The ICTs are linked to the environment in the millennium development goal as well. They provide researchers with critical tools for the observation, simulation, and analysis of environmental processes such as in monitoring air quality and mitigating poor air quality (Climate Group, 2008; Millet & Estrin, 2012). ICTs play a key role in environmental management in activities ranging from optimizing clean production methods to decision making. The information gathered, processed and disseminated by ICTs can help ensure that natural resources are used efficiently and sustainably.

Additional research reports from Cisco (2008), McKinsey (Boccaletti et al. 2008), the Economic Intelligence Unit (EIU, 2008), The Climate Group (2008) and the European Union (Barroso, 2008) discuss the promise of ICTs to enable environmental sustainability. For example, greenhouse gas emissions (GHG) have been identified as a major driver of changes to the climate and human activity has been identified as the probable cause of rising GHG emissions particularly carbon dioxide (CO2) emissions. ICTs have the potential to make a positive contribution to reducing the levels of GHG. Broadband (Broadband

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Conceptual framework

Commission, 2012; Budde et al, 2011), one type of ICTs can help various sectors of a country to reduce GHGs through dematerialization of physical products and applications, for example substituting travel with collaborative tools of substituting need to produce physical products by delivering e-products and services (Qiang et al, 2009). The power of broadband also forms the basis for the collection, sharing and analysis of vital data on the environment gathered via satellite, for example, or by direct sensor technology. The information can be used to predict natural disasters such as floods or famines and take mitigating steps (Broadband Commission, 2012; Budde et al, 2011). Therefore, ICTs have the potential to mitigate GHG emissions and improve air quality. Based on the premise that ICTs lead to improved environment, the following hypothesis is tested:

H_1: Information and communication and technologies (ICTs) are positively associated with a country's environment.

- **Transportation Infrastructure:** Transportation infrastructure also provides important opportunities for more sustainable development, especially in cities. By using ICTs, the manufacturing of transportation systems itself can be changed. 'Smart transportation systems' involve the use of sophisticated ICTs including analytics, smart meters, sensors and toll systems. ICTs have a central role in these efforts (Millet & Estrin, 2012). By incorporating intelligence in the systems, one can reduce congestion and fuel use and even cut CO_2 emissions. Both air and rail infrastructures can be made more efficient and effective. As such,

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

ICTs can lead to improved air and railway infrastructure in the aggregate. Therefore, to test the association between ICTs and transportation, the following hypotheses is formulated:

H_2: Information and communication and technologies (ICTs) are positively associated with a country's transportation infrastructure.

- **Energy:** Energy is another important construct in sustainability. It's been suggested that the biggest role ICTs can play is in improving energy consumption efficiency in power transmission and distribution (T&D) and in transporting goods (GeSI, 2008b). The report estimates ICT-enabled energy efficiency translates, in economic terms, into approximately $950 billion in cost savings through such applications as smart motor systems in Chinese manufacturing, smart logistics in Europe, smart building in North America, and smart grids in India.

ICTs can foster sustainable development by enabling better resource and energy use and by dematerializing transactions (GeSI, 2008a; EIU, 2008; Harter et al., 2010; Jitsuzumi et al., 2001). For example, mobile technologies enable m-banking, eliminating the need for physical branches. Other smart ICT applications have the potential to contribute to higher energy efficiency by making offices, homes and transportation system more 'intelligent' with, say, smart thermostats. Moreover, the ICT based services and working methods, such as teleworking and videoconferences, can result in lowering carbon emissions from business activities. Smart grid projects are already helping consumers save 10% on their bills and reducing peak demand by 15%. Imagine the potential savings when scaled to include companies, government agencies and universities. The investment by the federal government could yield almost a quarter of a million jobs first in digitizing the grid and in related industries such as alternative energy and automotive. Such an investment could enable new forms of industrial innovation by creating exportable skills, resources and technology (Millet & Estrin, 2012). Broadband technologies, for example, can enable intelligent home networks that can assist in controlling indoor climates and monitoring energy (Broadband Commission, 2012; Budde et al, 2011). Overall, we would expect an improvement in consumption efficiency and a move to more efficient energy sources. Therefore, we formulate the following hypothesis with regards to ICTs and energy:

H_3: Information and communication and technologies (ICTs) are positively associated with a country's energy consumption efficiency.

- **Economic Development:** The rapid and ubiquitous use of ICTs in all aspects of economic development is transforming the way that people live and work. ICTs have been demonstrated to contribute to economic growth and development by stimulating the productivity of people, organizations and nations (Avgerou, 2010; Djiofack-Zebaze & Keck, 2009; Flor, 2001; Gigler, 2011; Heeks, 2008, 2010; Mascarenhas, 2010). ICTs can improve the infrastructure capacity and efficiency of the private sector; increase production efficiency; and promote greater competition in the marketplace for delivery of goods and services. For example, the poor can have better access to the market with micro-level and economic networks, for example, via the use of village pay phones and knowledge centers that improve agricultural practices through access to information on crop selection, irrigation, fertilizers, and fishing and livestock conditions, thereby raising yields and reducing poverty and hunger (Von Braun & Toreno, 2006). Therefore, overall, ICTs can play a critical role in economic development, in the agriculture, manufacturing, and service sectors. Accordingly, we formulate the following hypothesis:

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

H_4: Information and communication and technologies (ICTs) are positively associated with a country's economic development.

- **Education:** The role of ICTs in education is linked to the millennium development goal of all children receiving primary school education by 2015. ICTs can mitigate the chronic shortage of facilities and teachers by enabling distance learning and supplementing teaching with electronic resources. This in turn can lead to improved attendance and higher literacy rates. Furthermore, ICTs can enhance the learning process by enabling increased access to knowledge and more collaborative and interactive learning methods. Additionally, scientific research and educational networks can be established. Both mobile technologies and the Internet have the potential to play a critical role in the delivery of school education (Mascarenhas, 2010). Overall, with ICTs, enrollment has the potential to increase with improved education quality. Therefore, we formulate the following hypothesis with respect to education:

H_5: Information and communication and technologies (ICTs) are positively associated with a country's education coverage and education quality.

Given that the purpose of this study is to look at the association among ICTs and sustainability development indicators, ICTs are the key factors. But one could argue a country's income level is a common element with the potential to influence both ICTs and sustainability. That is, countries with a high-income level typically have more resources and therefore can invest more in sustainability initiatives. Thus, wealth effect must be considered in the research model. Accordingly, we include a country's income level in our research framework and control for the wealth effect in the assessment of the relationship between ICTs and sustainability. The findings then will be more convincing in terms of the importance of ICTs.

4. METHODOLOGY

4.1. ICTs Factors and Measurement

Several attempts have been made in the past few years to measure the relative levels of ICT development in individual countries. These efforts have highlighted the significance of ICTs as key factors contributing to a country's economic and social transformation, and as a cohesive force for integrating a country into the global economy (Cieslikowski, et al, 2009; Minges & Qiang, 2006; World Bank, 2010).

The World Bank ICT Index provides a holistic view of ICTs by incorporating 21 ICT sector specific variables reflecting five factors of ICTs: access, quality, affordability, application usage as well as efficiency and sustainability. Instead of using a single ICT index, we consider the five factors of ICTs so as to provide concrete and further understanding of the relationships between ICTs and country sustainability. We follow the work of Raghupathi & Wu (2011a, 2011b), whose measurement of ICTs is primarily based on World Bank ICT framework. Under this framework, the composition of each factor has been defined. As such, each ICT factor is viewed as formative construct where the indicators influence the construct. These indicators are often called 'causal' indicators and the construct is often termed as a combination variable (Maccallum et al. 1993) or composite variable (MacKenzie et al. 2005). Table 1 summarizes the scope of each factor and lists the component variables for each factor used in this study.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Scopes and measurement of ICT variables

ICT Factors	Scope	Variables
ACCESS	Variables that reflect the availability of ICTs, such as fixed and mobile telephones, computer, the Internet, and televisions.	Telephone mainlines (per 1,000 people)
		International voice traffic (minutes per person)
		Mobile phone subscribers (per 1,000 people)
		Population covered by mobile telephony (%)
		Internet users (per 1,000 people)
		Personal computers (per 1,000 people)
		Households with television (%)
QUALITY	Variables that reflect how well networks perform by measuring telephone faults, and also measuring their bandwidth and international Internet capability	Telephone faults (per 100 mainlines)
		Broadband subscribers (per 1,000 people)
		International Internet bandwidth (bits per person)
AFFORDABILITY	Variables that measure the price of ICT services and the capacity of citizens to pay for them.	Price basket for residential fixed line (US$ per month)
		Price basket for mobile (US$ per month)
		Price basket for Internet (US$ per month)
		Telephone average cost of call to US (US$ per three minutes)
ICT APPLICATIONS	Variables that reflect the viability of the sector in terms of revenue generation and labor productivity	Information and communication technology expenditure (% of GDP)
		Secure Internet servers (per 1 million people)
		Schools connected to the Internet (%)
		E-government readiness index (scale 0-1)
INSTITUTIONAL EFFICIENCY & SUSTAINABILITY	Variables that measure the extent to which ICTs are used in different sectors of the economy, such as government and business	Telecommunications revenue (% GDP)
		Telecommunications investment (% of revenue)
		Telephone subscribers per employee

Note: Dimensions and items came from *World Bank – ICT at a Glance* 2004.

All the ICT variables were screened for non-normality, and those with high skewness and/or kurtosis underwent log transformation. The variables used in the later analysis do not have significant non-normality problems. One *Affordability* item and one *ICT Applications* item were deleted from further analysis due to a high proportion of missing values.

As formative constructs, we created a factor score for each ICT factor that averages its measurement items: the average of *Access* variables was denoted as AVGAC; the average of *Quality* variables as AVGQU; the average of *Affordability* variables as AVGAF; the average of *ICT Applications* variables as AVGICT; and the average of *Institutional Efficiency & Sustainability* variables as AVGIES. Since the measurement items are in different metrics, each measurement item was first standardized to mean as zero and standard deviation as one to make them in the same metric scale before taking the average. The factor scores were used to explain the variance of sustainability development indicators across the countries.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

4.2. Sustainability Development Indicators

Indicators are not ends in themselves. They are purpose-driven tools to guide, support and monitor decision-making (Carraro et al., 2009; CGSDI, 2001; Grunfeld, 2007; Hueting & Reijinders, 2004; IISD, 2000). Sustainability is a very broad term. Based on the literature (Adelle et al, 2009; Hughes & Johnston, 2005) we characterize sustainability in terms of the five constructs discussed above (environment, transportation infrastructure, energy consumption efficiency, economic development, and education). Each construct is then represented by one or more factors. Each factor is further derived by one or more measurement items which are extracted from the World Bank's World Development Indicators – WDI database (http://data.worldbank.org/data-catalog/world-development-indicators/). This is justified by the fact that indicators that address social, economic, environmental and institutional dimensions, although not designed for the special requirements of the knowledge society, are appropriate starting points for sustainability (Pinter et al., 2005; Spangenberg et al., 2002; U.N., 2007; UNDSD, 2001a, 2001b, 2008).

For example, environment, though a complex construct covering air, water, natural forest, etc, is mainly represented by air quality because the high missing values in other aspects restrain us from developing a more comprehensive construct. Air quality in turn is characterized by carbon dioxide emission, a world development indicator. Transportation infrastructure sustainability was gauged by the capacity of freight and passengers in air and rail transportation. Energy sustainability was assessed by energy consumption efficiency. Economic development sustainability was reflected in the percentage of added value of agriculture, manufacture, and service sectors in the GDP. Education sustainability was indicated by coverage of education and quality of education. The detailed information on the sustainability constructs, factors, and measurement items is summarized in Table 2.

Several of the sustainability development indicator variables suffered from non-normality. They were corrected by log transformation to comply with the basic assumption for ordinary least square in order to obtain best linear unbiased estimates.

4.3. Data Source and Research Model

In order to estimate the degree of association between ICTs sustainability development indicators, we extracted data from two World Bank databases. The data for the individual ICT variables were pulled from The World Bank ICT At-a-Glance country database (http://go.worldbank.org/FDTYJVBR60) for the year 2004, the last year of a complete and public data set. The same data can also be found at the web site of the International Telecommunications Union (ITU) (http://www.itu.int/ITU-D/ict/publications/world/world.html).

The data for country income and sustainability development indicators were obtained from the World Development Indicators database (WDI) for 2009. The countries were then classified as high-, middle-, or low-income countries (http://go.worldbank.org/CWTURYIPS0).

The datasets of ICTs' factors and sustainability development indicators (WDI) were merged based on the unique identification information of country name. The final dataset contained data for 196 countries.

In the phase of research design, we consider that the effect of investment in ICT may take time to generate effect. Put alternatively, a time lag is needed to allow us to see the long-term association between ICTs and sustainability. Yet, there was no suggestion on how long the lag needs to be in the existing literature. In the data collection phase, we also want to use the most recent and complete data. The data for the individual ICT variables were pulled from The World Bank ICT At-a-Glance country database

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Sustainability Constructs, Factors, and Measurement Items

Constructs	Factors	Measurement Items	Index
Environment	Air quality	Carbon dioxide emission (metric tons per capita)	
Transportation Infrastructure	Air infrastructure	Air transport, freight (million tons per km) Air transport, passengers carried Air transport, registered carrier departure worldwide	The three items were standardized and averaged to form an index.
	Rail infrastructure	Rail lines (total route – km)	The three items were standardized and averaged to form an index.
		Railways, goods transported (million ton – km)	
		Railways, passengers carried (million passenger – km)	
Energy consumption efficiency	Energy consumption efficiency	Electric power transmission and distribution loss % of output)	
Economic development	Agriculture sector net output	Agriculture, value added (% of GDP)	
	Manufacturing sector net output	Manufacturing, value added (% of GDP)	
	Service sector net output	Service, value added (% of GDP)	
Education	Education coverage	School enrollment, preprimary (% of gross)	The mean value of the enrollment in four different categories
		School enrollment, primary (% of gross)	
		School enrollment, secondary (% of gross)	
		School enrollment, tertiary (% of gross)	
	Education quality	Pupil-teacher ratio, primary Pupil-teacher ratio, secondary	The mean value of pupil-teacher ratio in two categories.

for the year 2004, the last year of a complete and public data set. The data for sustainability development indicators were obtained from the World Development Indicators database (WDI) for 2009. Though data were available for the more recent years, but numerous values were missing. Overall, the five-year lag between ICTs data and the sustainability development indicators' data is a compromise between the conceptual consideration and the availability of the data.

Multiple linear regression analysis was conducted to test each hypothesis in SPSS, the statistical software. The five ICT factors served as explanatory variables and the sustainability development indicators (Y) were the outcome variables, as shown in the following regression function. The country income level (the categorical variables of high, medium, and low, denoted as *CT* in the equation) served as a proxy for a country's wealth in the regression analysis to control for the wealth effect.

5. RESULTS AND DISCUSSION

Table 3 reports the descriptive statistics for all the ICTs' and sustainability factors. None of them indicate severe kurtosis and skewness after transformation. Table 4 reports the correlation matrix among the key variables. Most of the independent variables are correlated at $p<0.05$. Therefore, we used graphical methods in SPSS to detect potential heteroscedasticity by plotting the residuals versus fitted (predicted)

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 3. Descriptive statistics of all constructs

Note: (1) The green area reports the correlations among the independent variables (ICT factors); the pink area reports the correlations among the dependent variables (sustainability dimensions); and the blue area summarizes the correlation between independent and dependent variables. (2) *: Correlation is significant at the 0.05 level (2-tailed); **: Correlation is significant at the 0.01 level (2-tailed).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

values. The plots indicated that heteroscedasticity was not a threatening issue in this study and should not cause much problem to ordinary least square (OLS) estimates of the variance (and, thus, standard errors) of the coefficients. Still, we called in HCREG macro to SPSS to estimate OLS regression models but with heteroscedasticity-consistent standard errors (Hayes and Cai, 2007). The *t*-test statistics of regression coefficients (*p*-value) in later regression analysis (Table 5) were calculated based upon the heteroscedasticity-consistent standard errors.

Table 5 summarizes the multivariate regression analysis results. Before we run the multiple linear regression for each dependent variable, we ran a simple linear regression with only the control variable in the model, and we found that it explained a big proportion of the variances already in most of the cases (Table 5). For example, a country's income level explains 67% of the variance of air quality, 24% of the variance of air transportation infrastructure, 27% of the variance of the energy consumption effi-

Table 5. Multivariate regression results

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

ciency; 31% of the variance of service output out of GDP; and 46% of the variance of education quality. Then we conducted the multiple linear regression analysis with the control variable and independent variables (five ICT factors). We reported the change of R^2 with the addition of ICT factors to reflect their own contributions. In all the cases, we found that the model explanatory power has been improved significantly at $p<0.05$ (mostly at $p<0.01$) except for education quality.

The multiple linear regression model to test H_1 has demonstrated a great explanatory power (adjusted $R^2 = 0.74$), indicating that major factors have been included in the model. Country income level has a strong positive association with carbon dioxide emission. That is, high-income countries have higher levels of carbon dioxide emission or lower air quality than low-income countries.

Higher emissions in the developed countries could be a result of large industrial infrastructure, thriving of e-business, and change of business models. For instance, many retailing giants strengthen online business on the top of traditional brick-and-mortar model. The business-to-customer model requires frequent fulfillment of individual orders, which makes it less environmental friendly. Similarly, manufacturing companies adopt Just-in-Time (JIT) production system so as to minimize the inventory investment, but unfortunately JIT requires more frequent delivery of goods, which increases the carbon footprint.

ICT factors too contribute to higher emission; however, their impact is less significant compared to income level. While country income level could explain 67% of variance of emission, ICTs factors all together could only explain 7%. We found three ICTs factors influence emission level substantially, quality ($b = -0.25$, $p<0.01$), applications ($b = 0.17$, $p<0.01$), and affordability ($b = -0.18$, $p<0.01$). Apparently, their impacts are mixed with the positive and negative effects canceling each other out, resulting in a small net impact, so H_1 is not well supported.

We note, only the factor of ICT quality is associated with a reduction in emission and improved air quality. For example, broadband underlies the gathering, dissemination and analysis of key environmental data gathered via satellite or by sensor technology. This information can be used to predict natural disasters such as floods or famines. Natural disasters typically pollute the environment (e.g., earthquake in Fukushima leading to tsunami and nuclear disaster). Also, improved supply chain management with quality ICT infrastructure could collect point-of-sale data and optimize replenishment for different locations through order consolidation. As a result, fewer trucks are needed on the roads and emission is lowered. Additionally, video conferencing means less travel for employees. Electronic media reduces the manufacture of physical products. All these indicate less pollution to the air.

Considered in aggregate, it is conceivable ICTs themselves have a rebound effect or reverse effect – that is, their production and usage could possibly lead to emission and lower air quality. This is the reason ICT application is found to enhance emission. An example is the likelihood that the reduction in vehicle usage resulting from telecommuting will be accompanied by increased use of vehicles for leisure activities and the growth of long distance travel. Another example is the increase in the increased manufacture and use of computers and other electronic devices as paper flows are replaced by e-flows; while there is a reduction in paper usage (and decrease in tree cutting) there is increased potential for e-toxic waste to be generated. Rebound effects are pervasive across different effects, and the role of ICTs must be examined carefully in the context of trade-offs. A rebound effect also occurs when efficiency gains (directly or indirectly) trigger new demand, thereby counter-balancing the positive environmental effects. For example, there appears to be a positive correlation between the use of email and business travel, one instigating the other. Replacement may occur in the economy with use of ICTs (e.g., replacement of printed books by e-books); however, it may be outweighed by the increased consumption of alternative energy resources.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Hypothesis 2 looked at the possible association between ICTs and the transportation infrastructure. The testing of H_2 required us to run two separate regression models, with air and rail transportation capacity as dependent variables respectively. These two regression models showed similar results: the wealth effect was insignificant or mildly significant yet ICT factors as a whole explained much of the variance in air and rail transportation capacity. Specifically, ICT applications contributed the most to the explanatory power of the regression model (b = 0.62 and 0.60 respectively, $p<0.01$). H_2 is, therefore, supported. From dynamic, computerized systems that monitor flights and trains to the processing of real-time data for optimization and efficient allocation of resources, ICTs can help improve the air and rail infrastructure. Widespread availability of ICTs, especially communication infrastructure results in more widespread use of ICTs in transportation. Passenger reservation and ticketing systems can result in improved infrastructure. Smart air and rail systems can monitor capacity and utilization more effectively. From smart cards to pay for fares, to advanced analytics applications for scheduling, ICTs have potential to improve operational efficiency and reduce greenhouse gases.

With regards to Hypothesis 3, a regression analyses was performed to examine association between ICTs and energy consumption efficiency. It evaluated the potential association between ICTs' reductions in a country's electricity transmission loss (this is a reverse measure of consumption efficiency). We found that while country income level influences electricity transmission loss, the accessibility of ICTs also did. That is, the accessibility was significant in the reduced electricity transmission loss (b = -0.39, $p<0.01$). This in turn improved consumption efficiency. As such, H_3 is well supported.

Three additional regression models were developed to test Hypothesis 4. This hypothesis addressed the relationship between ICTs and economic development. First, the results showed that agriculture value added is effectively determined by a country's income level type: high-income country had low value added. Indeed, the ICT applications factor is associated with a further reduction in the agriculture value added (b = -0.31, $p<0.01$). Anecdotally, the use of smart sensors and analytics in agriculture has potential to improve agricultural practices in the long-term. As for the manufacturing sector, affordable ICTs and increased usage of ICT applications are associated with an increased manufacturing industry value added on the top of the wealth effect (b = 0.43 and -0.22 respectively, $p<0.01$). For the service sector, while high-income countries appear to be associated with high value added, greater ICT access and increased usage of ICT applications are associated with improved service value added (b = 0.50 and 0.24 respectively, $p<0.01$). Interestingly, the more expensive the ICT applications, the higher value added percentage. This can be explained by the fact that the more expensive the technology, the higher the payoff. For example, sophisticated real-time applications and large, enterprise applications are costly, but implemented properly they can result in greater payoffs. Overall, ICTs are associated with an increase in a country's value added in all sectors (particularly, the manufacturing and service sectors) with or without the wealth effect. Therefore, H_4 is largely supported.

It is well established as cited in several articles above that ICTs have a positive effect on various aspects of development. This study confirms some of these findings. It is conceivable, in developed countries, the role of technology in agriculture has reached its full potential and therefore, there is not much value added. However, there is great opportunity for technology usage, such as electronic monitoring of crops, metering water usage, prediction and forecasting tools and analytics in agriculture in developing countries to optimize the production, storage and distribution systems (World Bank, 2010). With regards to manufacturing and service, overall, ICTs' access, affordability and applications are playing a critical role. Taking a holistic view this implies ICTs from mobile phones & computing to broadband and the Internet, have become pervasive across manufacturing and service industries as vast amounts of data

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

are collected, analyzed, and disseminated for decision making and insight. ICTs enable the key aspect of communication and facilitate the development of markets and financial institutions (Mascarenhas, 2010; Murray, 2008). They lead to the "efficient, scalable, affordable and pervasive delivery of goods, services, and information flows between people, government and firms".

The assessment of Hypothesis 5 required the conduct of two analyses — examination of the association between ICTs and education coverage, and that of ICTs and education quality. On the one hand, we see the wealth effect playing a strong role in education coverage and education quality. Essentially, in high-income countries a larger proportion of students attend school and each student receives more attention from the teacher. On the other hand, increased school enrollment is associated with ICT applications ($b = 0.24$, $p<0.01$). Also, improved education quality is associated with ICT affordability ($b = 0.15$, $p<0.01$). H5 is well supported. From academic records to information on student mobility and attendance, data mining is helping schools monitor student performance more effectively. Additionally, the use of various ICTs in the delivery of curriculum and e-learning and distance learning are having a major impact on the coverage and quality.

6. CONCLUSION

This study empirically confirms the positive association between ICT factors and various sustainability development indicators beyond the wealth effect. Our cross-country regressions document that sustainability is stronger in countries associated with better ICT infrastructure. Interestingly, the wealth effect is negative in some areas. For example, rich countries have higher carbon dioxide emissions and higher energy consumption from non-renewable sources. All the results have policy implications and provide clear strategic guidance for countries to be more sustainable via ICTs. The results are especially encouraging to developing countries with resource constraints. Our study indicates which ICT factors and sustainability development indicators to focus on and where the promise of improvement has the most potential. Strategically, the improvement of ICT infrastructure needs to become a priority. All ICT factors have an influence on some aspect of sustainability. Therefore, resource allocation to overall ICT infrastructure development is the key to enabling a country's sustainability. Additionally, the study also shows which ICT factors play a key role in each sustainability indicator. For example, ICT application was associated with education coverage while affordability was associated with education quality. Countries can therefore juggle their resources depending on their sustainability priority.

6.1. Scope and Limitations

It is important to recognize the limitations of this exploratory study from the perspective of the nature of the study, measurement of constructs, model specification, data availability and the nature of the available data. First, the study assesses the relationship of ICTs and sustainability indicators across countries. It is a cross-sectional study, though lagged data were used in the analysis. Given the nature of this study, it does not indicate a direct causal relationship between ICTs and sustainability. We only take a snapshot and conclude there is a strong association between ICTs and improved sustainability. Yet, sustainability might also influence the decision of ICTs investment. The more complicated relationship can be studied with longitudinal data.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Second, in order to test the proposed hypotheses, we have to operationalize the theoretical constructs using observable and objective measures. The measurement for ICT five factors has been defined by World Bank and established the face validity, and we simply adopted that in this study. The measurement for the sustainability variables were selected as a compromise of face validity of constructs in hypothesis and data availability.

Third, the data acquired from the World Bank and the International Telecommunications Union are secondary in nature. WB database is evolving, the variables it tracks also vary at different time periods, and it takes time to collect and compile the country level data. For instance, the number of ICT variables in the current database is far less than that in the older database. 2004 is the last year that WB provided a complete and public dataset in ICT At-a-Glance country database, which contains 21 variables for five sector performance for each country. We believe all these variables together paint a much comprehensive picture of a country's ICT sector performance. The five factors of ICTs also enrich the study by allowing us to explore which ICT dimension is more associated with a country's different sustainability indicators.

Fourth, the data is only as good as how it is reported by the countries. However, in the past several years, several researchers have used such country-level data in e-government studies (see for example, Krishnan et al. (2013) and Srivastava and Teo (2007)). We build on these and other articles to validate our study in the use of such data sets.

Fifth, a robustness test was not explicitly conducted; however, the findings of the study do show the robustness of the relationships. The data used in this study continue to evolve with frequent updates to the World Bank database. The regression models were run twice. In the first run, the relationship between ICTs in 2004 and sustainability indicators in 2007 was examined with a three-year time lag; in the second run the same test was conducted with sustainability indicators in 2009 (i.e. a five-year time lag). The results were similar indicating the relationships are robust. The plausible reason behind the robust results is that all the variables are stock variables measured up to a specific time point. In other words, they are not the change variables from one year to another. As all the variables provide macro level information there are only marginal value differences in the variables across years. So the analytics may not show dramatic difference in findings.

Lastly, the current research model contains only one control variable. Though it is a critical one, as can been seen from the results in Table 5 (the control variable captures a good proportion of the variation in all sustainability indicators), variables such as country characteristics and non-technological strategies to promote sustainability may add additional information into the study and should be considered in the future studies. Additional variables relating to technology transfer, innovation, R&D, export/import regulation, tax laws, intellectual property and others may impact the study.

6.2. Contributions

Despite some of the limitations discussed above, this study makes a number of important contributions to the literature and provides strategic direction to country-level policy makers in governmental and non-governmental organizations and in the private sector regarding the role of ICTs in enabling and promoting sustainability. First, it is only recently that case studies and anecdotal narratives have emerged regarding the use of ICTs in sustainability initiatives. There is a need for understanding the impact at the national as well as global level. By studying the association between ICT factors and country-level

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

sustainability development indicators, our study contributes to the sparse but emerging literature at the country level. The findings can help global policy makers strategize on sustainability resource allocation and invest to maximize the global sustainability benefits. Second, nearly all of the related studies have focused on 'green ICT,' which addresses how ICTs can become self-sustaining (e.g., green data center etc.) (Berthon & Donnellan, 2011). On the other hand, this study examines the strategic and transformation role of ICTs in enabling sustainability. We show that ICTs are not the only pathway to sustainability. A country's income level, to a large extent, explains the level of sustainability. It seemed obvious that poor countries faced greater challenges in natural resource utilization. Indeed poor sustainable practices would have negative effects on economic development. The flip side is high-income countries had greater carbon emissions. Donor countries, global institutions and nonprofit agencies and foundations can make better choices in terms of investments. In addition, while ICTs may make substantive contributions to sustainability beyond the wealth effect, some of the effects may take longer to be observed (e.g., reduced carbon emission, increased literacy rate, safer and smarter transportation). Some of the insignificant results should not be viewed as distress signals so much as encouragement that with continued investments over time, poor countries may realize greater benefits. From a methodological perspective, we make novel use of publicly-available fee and non-fee based databases to enhance our understanding of the association between ICTs and sustainability development indicators. This study is an incremental step in the direction of more robust quantitative studies.

For policy makers and stakeholders, this study does show ICTs have a favorable impact on various sustainability constructs. Decision makers in environment, transportation, energy, economic development and education can carefully develop policy and implementation strategies based on the findings. For example, providing access to ICTs is important; likewise, the ready availability of ICT applications and the assurance of their quality play critical roles. However, policy makers must be fully aware of the socio-technical nature of the role of ICTs in sustainability constructs. They have to be aware of unintended consequences and rebound effects, that is the positive application of a technology in one aspect may lead to negative consequences in another.

6.3. Future Research

Future research may focus on cross-country and regional as well as longitudinal studies. Best practices also need to be documented. What works in one region may not in another. Cultural, political and economic environments have to be considered. Other variables relating to health, urban planning (NRC, 2010), and water and sewerage planning may reveal additional associations and effects (e.g., smart city design). Others may research the diffusion of ICTs for effective sustainability practices in developing countries and the development of coordinated global strategic models of ICT integration and use. Additionally, the innovation, leap-frog effect, and globalization aspects have to be addressed. An important aspect to study in sustainability is the *rebound effect*, which occurs when efficiency gains stimulate new demand that counterbalances, or even outweighs positive environmental gains. For example, the efficiency improvements (time, fuel, energy), made possibly by technological advances, are counteracted by an increasing demand (growing consumption volumes) of energy, products, services, passenger and freight transport. Another rebound effect is rematerialization, e.g. virtual information products are accessed via the Internet and then printed out or burned onto a compact disc or DVD.

Chapter 33
Integration of Renewable Energy in Refrigerated Warehouses

Kostadin Fikiin
Technical University of Sofia, Bulgaria

Borislav Stankov
Technical University of Sofia, Bulgaria

ABSTRACT

Refrigerated warehouses are large energy consumers and account for a significant portion of the global energy demand. Nevertheless the opportunity for integration of renewable resources in the energy supply of large cold storage facilities is very often unjustifiably neglected, whereas the employment of renewable energy for many other industrial and comfort applications is actively promoted and explored. In that context, the purpose of this chapter is to bridge the existing gap by raising the public awareness of stakeholders, researchers, practicing engineers and policy makers about the availability of a number of smart engineering solutions and control strategies to exploit renewables of different nature (solar, wind, geothermal, biogas, etc.) in the food storage sector, as well as by calling the readers' attention to the specialised knowledge in the matter, which has been published so far.

INTRODUCTION

On 5 June 2014 the UN Secretary-General launched the "UN Decade of Sustainable Energy for All", urging leaders from around the world to "deliver new and expanded commitments and partnerships that will transform the global energy landscape" ("UN Secretary-General", 2014). Increasing the integration of renewable energy sources (RES) in the global energy supply chain is one of the key aspects of sustainable development. Hence, one of the goals of the Sustainable Energy for All (SE4ALL) initiative is doubling the share of renewable energy in the global energy mix by 2030. As the International Energy Agency (2007) states, renewable sources are "essential contributors to the energy supply portfolio as they contribute to world energy supply security, reducing dependency on fossil fuel resources, and provide opportunities for mitigating greenhouse gases".

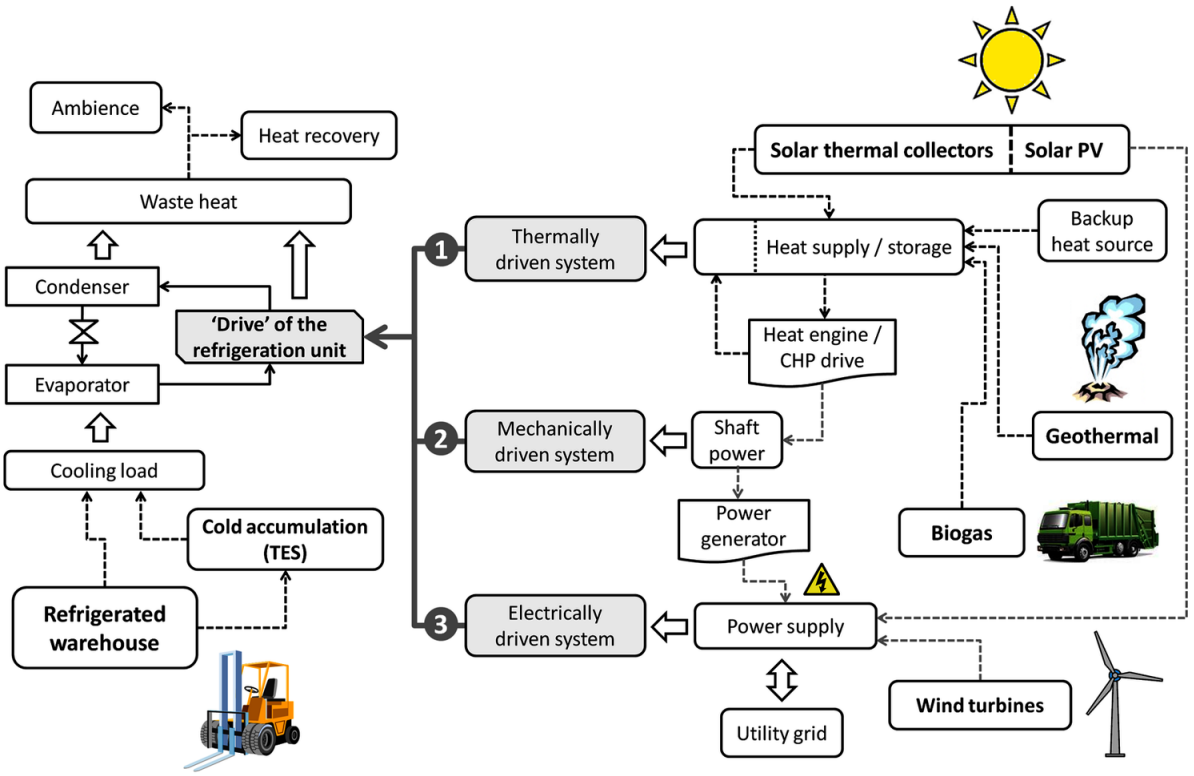
According to Coulomb (2006) and the International Institute of Refrigeration (2007, 2015), refrigeration (including air-conditioning) currently accounts for about 17% of worldwide electricity use, while over 80% of the global warming impact of refrigeration systems is due to this electricity use. Industrial refrigeration, comprising over 550 million m^3 of cold storage space worldwide (International Institute of Refrigeration, 2015), is a major consumer of about 8% of the electrical power on a global scale (consistent with the circumstance that approximately 40% of the global food output require refrigeration). In the context of sustainable development, designing or retrofitting of a cold store refrigeration plant should consider the possibility of using RES to provide at least a portion of the required energy input.

Although there are a number of RES-assisted technologies for different refrigeration applications, many of these tools are still at rudimentary stages of development, either not commercially viable or only applicable for relatively small-scale systems. However, integration of RES in refrigerated food storage facilities might provide a cost-efficient way of: (i) reducing electricity consumption from the grid, and/or (ii) shifting refrigeration loads from peak to low consumption periods, thereby contributing to the overall balance of the power supply system and minimizing the environmental footprint of the cold store. While many of the today's engineering solutions are not yet cost efficient by themselves, various governmental policies in support of renewable energy developments and integration are carried out around the world, which can substantially enhance the economic feasibility of RES-powered installations.



The objective of this chapter is to familiarise the readers with: (i) state-of-the-art RES-based technologies applicable to refrigeration systems, including their technical and economic performance, (ii) different strategies to integrate these technologies in the energy supply of refrigerated warehouses in an efficient way, (iii) practical examples, pilot projects and on-going research involving RES utilization for cold storage facilities, and (iv) government incentives which can facilitate investment in RES projects. The material is primarily intended to serve as guidance for cold store operators and refrigeration stakeholders, who are still unaware of the latest RES technologies and the opportunities to employ them in the food refrigeration industry. As the chapter has no ambition to analyse in-depth any of the concerned technologies, the readers are advised to examine additional literature in order to gain more comprehensive knowledge on the particular topics of interest (e.g., see the list of references as a starting point).

BACKGROUND

Integration of renewables in the energy supply of cold storage facilities can be accomplished in a variety of ways, as illustrated in Figure 1. Solar photovoltaic cells and wind turbines can be used for on-site power generation, while solar thermal collectors, geothermal sources and biogas combustion can serve as a heat source for thermally driven refrigeration systems. In addition, thermal sources can be used to drive cogeneration or trigeneration systems, thereby simultaneously producing electricity, heating and refrigerating output. Thermal energy storage for heat and cold accumulation can be integrated in the system to shift energy supply and/or demand as to permit better overall utilization of renewable energy. Provided that proper interaction is established between the cold store operator and the electric utility, on-site RES-generated power can be fed to the utility grid, which permits to sell excessive energy at attractive prices (especially in the presence of convenient government policies). The latter and the inclusion of thermal energy storage can overcome a major inconvenience of many RES technologies, i.e. the intermittent energy supply due to the fluctuating availability of the energy resource.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Various options to integrate renewable sources in the energy supply of refrigeration systems for cold storage facilities

Cold store operators can consider and evaluate different alternatives for RES integration in order to screen out the best option in terms of both technical and economic performance. Several metrics exist, which can be used to compare diverse alternatives. One of the main parameters, employed to evaluate the overall performance of refrigeration systems driven by renewable energy, is the overall system efficiency (*OSE*) defined as:

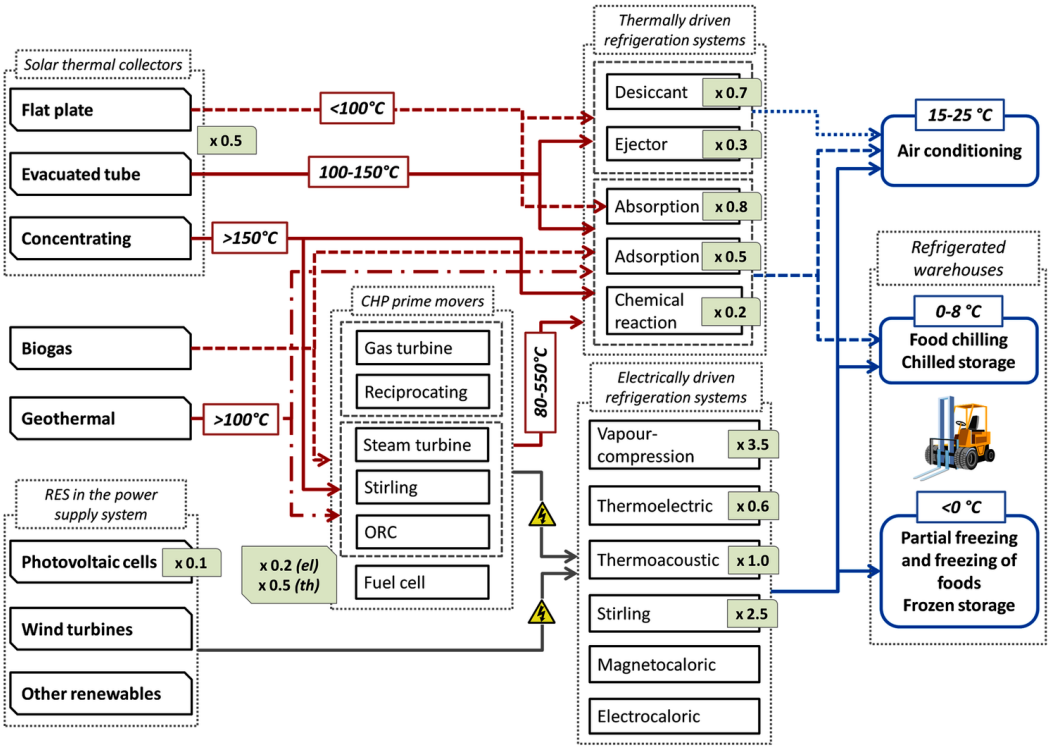
$$OSE = \frac{Refrigerating\,capacity}{Capacity\,of\,the\,renewable\,source} = \frac{Q_E}{E_R} = \frac{Q_E}{E_S} \cdot \frac{E_S}{E_R} = COP \cdot \eta_{es} \tag{1}$$

$$COP = \frac{Refrigerating\,capacity\left(useful\,output\right)}{Supplied\,input\,capacity\left(required\,input\right)} = \frac{Q_E}{E_S} \tag{2}$$

where *COP* is the coefficient of performance of the refrigeration system and $\eta_{es} = E_S/E_R$ is the energy conversion efficiency of the energy supply system utilizing RES (which is a product of the efficiencies of each consecutive stage of energy conversion prior to the refrigeration system, beginning from the device that captures the renewable resource).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

As a measure of performance, *COP* can be used not only to compare different refrigeration systems, but also to define system efficiency in comparison with the theoretically possible maximum. Thermodynamically the maximum possible efficiency of a refrigeration cycle operating between two temperatures (T_A – temperature of the heat sink, e.g. ambient temperature, and T_L – temperature of the refrigerated space, both in K) is the Carnot efficiency defined as:



$$\eta_{C,rc} = \frac{T_L}{T_A - T_L} \tag{3}$$

The actual efficiency of the real refrigeration cycle, i.e. *COP*, can be represented as a product of the Carnot efficiency and the anticipated fraction, α_r, of the Carnot efficiency that the cycle is expected to achieve:

$$COP = \alpha_r \cdot \eta_{C,rc} \tag{4}$$

Various possible configurations of RES-driven refrigeration systems based on different physical principles and indicative values of the respective efficiencies, for the consecutive stages of energy conversion, are shown in Figure 2.

Figure 2. Applications and indicative energy conversion efficiencies of refrigeration systems powered by renewable energy sources

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Many of the configurations shown in Figure 2 are commercially viable, while a number of these technologies (involving thermoelectric, thermoacoustic, magnetocaloric and electrocaloric principles of refrigeration) are still in an immature R&D phase of their elaboration. Part of the indicated configurations (e.g. those involving solar-driven desiccant and ejector refrigeration systems) are only feasible for air-conditioning applications and included just for completeness. Nevertheless, this chapter focusses on RES technologies and engineering solutions which are applicable for large-scale refrigeration systems suitable for cold storage facilities.

While technically feasible, some configurations may not be economically efficient. Several metrics can be used to assess the economic performance of different RES technologies. In some cases the installed cost per peak useful output is used, e.g. $/W or €/W. Depending on the context, useful output can be the refrigeration capacity or the output capacity of the energy supply system (which represents the required input capacity for the refrigeration system). Another relevant metric, used to evaluate the economic efficiency of RES, is the levelized cost of energy (*LCOE*), i.e. the ratio of the lifecycle cost of the system to the energy produced over its operational lifetime (Intergovernmental Panel on Climate Change, 2014):

$$LCOE = \frac{Present\,value\,of\,total\,costs\left(\$\right)}{Lifetime\,energy\,production\left(MWh\right)} = \frac{CRF \cdot I + OM + F}{E_S} \tag{5}$$

$$F = FC \cdot \frac{E_S \cdot FLH}{\eta_{es}} \tag{6}$$

where I is the total investment costs, including initial costs, construction costs and decommissioning costs, OM is the net annual operation and maintenance (O&M) costs, FC is the fuel costs per unit of energy input and FLH is the number of annual equivalent full-load hours. The capital recovery factor is calculated as:

$$CRF = \frac{r}{1-\left(1+r\right)^{-L_T}} \tag{7}$$

where r is the weighted average cost of capital (e.g. 5 or 10%) and L_T is the project duration, i.e. operational lifetime of the system (Intergovernmental Panel on Climate Change, 2014). *LCOE* is a particularly popular metric for RES power generation systems.

Opportunities for Integration of Renewables in Cold Stores

Various opportunities for RES integration in refrigerated warehouses are grouped and outlined hereafter in three sections of this chapter, entitled as follows: (i) *"Thermally Driven Refrigeration"* (which reviews the possibilities of using heat derived from RES to drive sorption refrigeration systems); (ii) *"Refrigeration through On-site Power Generation"* (which discusses distributed generation of electricity through RES technologies, including the use of cogeneration), and (iii) *"Integration of Renewables Involving*

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Thermal Energy Storage" (which examines engineering solutions for cold accumulation to utilize RES more efficiently in the context of the smart power grid).

THERMALLY DRIVEN REFRIGERATION

Solar Thermal Collectors

Solar thermal collectors are devices that capture solar radiation to heat a solid, liquid or gaseous substance. Collectors used for heating liquids (typically water or a glycol solution) are reviewed in this chapter.

While solar energy is an intuitive source for heating applications, its use for refrigeration is not so obvious, although there is usually a good match between the peaks of solar irradiation and cooling loads (in terms of both time and geographic location). In developing countries with no or unreliable power supply, where conventional fuels are difficult or too expensive to obtain, a number of solar refrigeration applications (e.g. vaccine storage or fish and milk preservation) have been known for decades. In industrialized countries, characterized with reliable supply of electricity from the grid, comparatively little interest has been shown in using solar energy as a driving source for refrigeration systems, because a number of technical and market barriers have led market actors to perceive these technologies as uneconomical.

The high initial cost of a solar system, whose largest portion is usually taken up by solar collectors, is one of the main obstacles. Solar radiation, however, is the primary source of energy for the planet and the potential of converting this energy for powering different processes, including refrigeration, is certainly huge. It is estimated that while 376,680,000 TWh of solar energy are dissipated into surface heating each year, only about 266 TWh are captured by solar collectors, of which 74% by thermal collectors, 24% by photovoltaic (PV) collectors and 2% by concentrated solar power (CSP) systems (Infante Ferreira & Kim, 2014). Since this energy is free whenever available, the only necessity is to find appropriate energy conversion technologies which can make utilization of this energy source technically and economically feasible.

One of the main inconveniences, common for all solar systems, is the fluctuating availability of solar radiation. Although this availability has more or less predictable annual and daily cycles, the solar energy to be captured is also determined by weather conditions, which are quite difficult to predict. Even in the presence of dedicated systems for thermal or electrical storage, it is very challenging to manage a system that relies solely on solar energy. Hence, efforts are to be concentrated on integrating the solar system with another energy source (primary or supplementary) in the most efficient manner, taking into account local climatic conditions and energy costs.

The design of a solar thermal system should be optimized to capture the largest possible amount of solar radiation through the smallest possible collector area in an economically efficient manner. Solar collectors can be installed at a fixed tilt, the optimum of which depends on location and season, e.g. for summer the optimal tilt is usually considered to be equal to the site latitude minus 10°. Alternatively, a movable sun tracking system can be used to automatically tilt the collector depending on the position of the sun – single-axis and two-axis trackers are available for this purpose. Tracking systems are necessary for concentrating solar collectors, but their involvement increases the complexity and cost of the system.

Flat plate and evacuated tube collectors are most common, because of the design simplicity and reasonable cost. Concentrating solar collectors use geometric optics to enhance collector efficiency, but this works effectively only for direct (i.e. beam) solar radiation and not for diffuse radiation, which in

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

some locations may represent the greater share of total solar radiation. Hence, concentrating collectors are beneficial mainly for sunny locations relatively closer to the equator, which receive high amounts of direct solar radiation. Table 1 summarises different types of solar collectors and the range of temperatures they are expected to provide to the circulating heat transfer fluid. Weiss and Rommel (2008) compiled a detailed survey of recent advances in the design and optimisation of solar thermal collectors for a wide range of operating temperatures between 80°C and 250°C.

The efficiency of a solar thermal collector is defined as the ratio between the heat supplied to the heated substance, Q_{sol}, and the total amount of solar radiation reaching the surface of the collector, i.e. the product of the solar irradiance I_β (W/m^2) and the surface area of the solar collector A_s (m^2):

$$\eta_{sc} = \frac{Q_{sol}}{I_\beta \cdot A_s} \tag{8}$$

This efficiency depends on operating temperatures (i.e. T_A – the ambient air temperature and T_M – the mean temperature of the heat transfer fluid) and can be defined as Lazzarin (2014):

$$\eta_{sc} = \eta_0 - a_1 \cdot x - a_2 \cdot x^2 \tag{9}$$

$$x = \frac{T_M - T_A}{I_\beta} \tag{10}$$

The three coefficients: a_1, a_2 and η_0 can vary significantly depending on collector types and constructions, and are normally determined by the manufacturer. Example values for four of the most commonly used solar collector types are shown in Table 2, along with indicative figures for the installed cost per unit area of the collector. The values given in Table 2 are derived from two different sources, i.e. the works of Infante Ferreira & Kim (2014), above, and Lazzarin (2014), below (shown in parentheses).

Table 1. Types of solar thermal collectors (Adapted from Kalogirou, 2009)

Collector Type	Sun Tracking	Absorber Geometry	Concentration Ratio	Indicative Temperature Range
Flat plate	No	Flat	1	30-80°C
Evacuated tube	No	Tubular	1	50-200°C
Compound parabolic	No	Tubular	1-5	60-240°C
	Single-axis	Tubular	5-15	60-300°C
Linear Fresnel	Single-axis	Tubular	10-40	60-250°C
Cylindrical trough	Single-axis	Tubular	15-50	60-300°C
Parabolic trough	Single-axis	Tubular	10-85	60-400°C
Parabolic dish	Two-axis	Point	600-2000	100-1500°C
Heliostat	Two-axis	Point	300-1500	150-2000°C

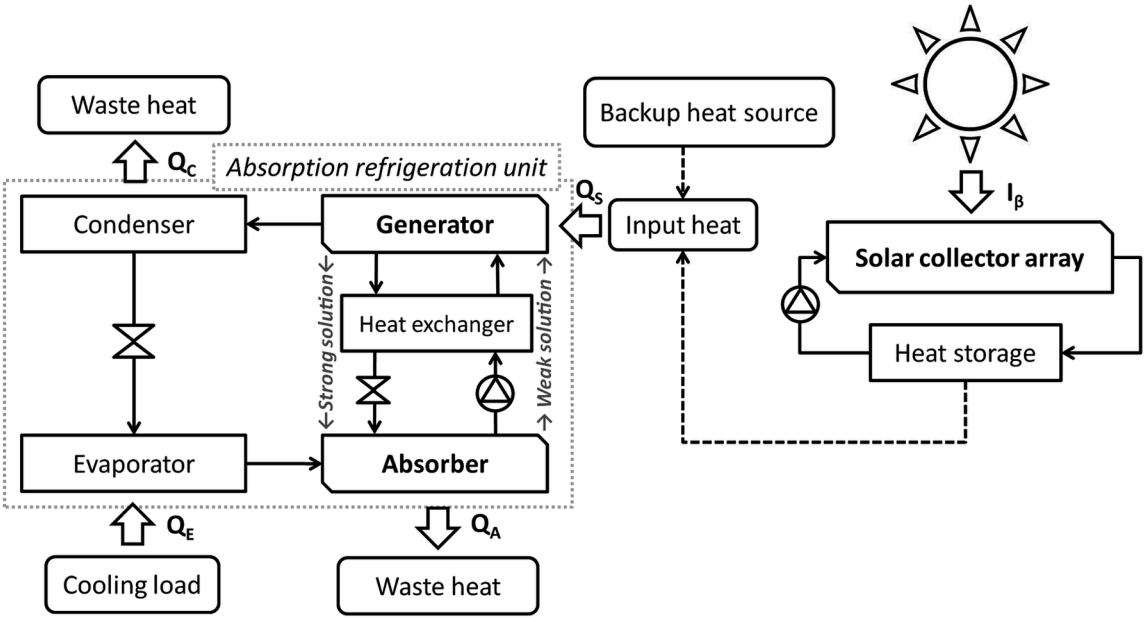
Table 2. Examples of zero-loss collector efficiency, heat loss coefficients and installed cost for different types of solar thermal collectors

Collector Type	η_0	a_1	a_2	Installed Cost
Flat plate	0.8 (0.79)	3.02 (3.94)	0.0113 (0.012)	€371/m^2 (€350/m^2)
Evacuated tube	0.84 (0.71)	2.02 (0.974)	0.0046 (0.005)	€750/m^2 (€650/m^2)
Parabolic trough	0.76 (0.52)	0.22 (0.475)	0 (0.0031)	€540/m^2 (€450/m^2)
Parabolic dish	0.82	0.22	0	€270/m^2

Solar Sorption Refrigeration

Sorption refrigeration machines are based on either the absorption or adsorption principle, which utilize physical or chemical attraction between a pair of substances to produce the required refrigeration output. In both cases heat, which can be supplied by solar thermal collectors, is used to regenerate the sorbent, while only small amounts of electricity are required to drive circulation pumps. The *COP* of sorption refrigeration systems is the ratio of the refrigerating capacity, Q_E, to the sum of the required input heat capacity, i.e. heat provided by the solar system, Q_S, and the power capacity of circulation pumps, P_P (which is usually negligible):

$$COP = \frac{Q_E}{Q_S + P_P} \approx \frac{Q_E}{Q_S} \tag{11}$$



In an absorption machine, the sorption effect takes place in an absorber and desorption occurs in a generator which utilizes heat, Q_S, to regenerate the sorbent. The refrigerant vapour generated in this process condenses in the condenser, rejecting heat, Q_C, to the ambience and flows back through the expansion valve to the evaporator. After evaporating and removing heat from the refrigeration load at the evaporator, Q_E, the refrigerant is absorbed by the substance used as sorbent, while sorption heat generated during this process is rejected to the ambience, Q_A. The process is illustrated in Figure 3.

Typically, the refrigerant-sorbent working pair of absorption refrigeration systems is either water-LiBr (lithium bromide) or ammonia-water. Ammonia-water systems require higher mass circulation rates and higher operating pressures than water-LiBr systems (ASHRAE, 2009). While water-LiBr absorption chillers are popular for air-conditioning applications, ammonia-water systems can operate at sufficiently low temperatures down to –60°C (Rutz, Mergner, & Janssen, 2012), which makes them suitable for food refrigeration purposes.

A solar-driven single-stage absorption refrigeration system is depicted in Figure 3. Multistage cycles are also available with one or more of the four basic heat exchangers (generator, absorber, condenser, evaporator) present at two or more places in the cycle, at different pressures or concentrations (ASHRAE, 2009). Several types of two-stage cycles have been developed, including double-effect and triple-effect cycles. These advanced configurations can provide better performance than single-stage systems, but also add complexity and increase unit costs. Typical *COPs* are in the range of 0.65-0.8 for single-effect

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Single-stage ammonia-water absorption refrigeration system powered by solar energy

and 0.9-1.2 for double-effect absorption systems (Rutz *et al.*, 2012). Advanced ammonia-water systems have comparable efficiencies with water-LiBr systems, e.g. the basic GAX (generator-absorber-heat exchanger) cycle has comparable performance with a single-effect water-LiBr system, the branched GAX cycle has comparable performance with a double-effect water-LiBr system and the vapour exchange GAX cycle would yield the same performance as a triple-effect water-LiBr system (ASHRAE, 2009).

Absorption refrigeration is in fact one of the oldest industrial refrigeration techniques, preceding vapour-compression refrigeration. Industrial absorption refrigeration units were developed in the mid 19th century by the Carre brothers in France and have been used during the American Civil War in the gunpowder production industry (ASHRAE, 2014). Another reported 19th century application is for ice production via wood-fired absorption systems (Briley, 2004). The concept of solar refrigeration is also not new. Augustin Mouchot demonstrated an absorption refrigeration machine driven by a concentrating solar collector at the Exposition Universelle of 1878 in Paris (Podesser *et al.,* 2010). The main reason for the modest market penetration in more recent years, as compared with the vapour-compression technology, is the high investment costs of absorption units. One of the causes is that while all components of vapour-compression systems are mass produced by different manufacturers, sorption refrigeration machines are usually manufactured as a whole unit by a single producer (Podesser *et al.*, 2010). Moreover the number of manufacturers of absorption refrigeration units is relatively small.

Solar-driven absorption refrigeration units have been applied and tested mainly for air-conditioning applications. Experience with cold storage facilities is limited and more research is needed to provide optimized solutions for larger scale systems. Experimental solar-driven absorption systems, which refrigerate small-scale cold storage compartments, have been investigated within the EU-funded SOLERA Project. In Freiburg, Germany, a linear Fresnel collector with a total aperture (mirror) area of 132 m^2 has been used to drive two ammonia-water absorption refrigeration units with a total refrigeration capacity of 24 kW. Weber *et al.* (2014) reported that such collectors have been operated at an efficiency

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

of 50-60%, providing heat at 100-205°C to the absorption units, whose *COP* has been in the range of 0.4-0.8 and refrigerating temperatures down to –12°C have been achieved (enough for storing ice with a thermal capacity of about 110 kWh). In a very similar configuration in Umkirch, Germany, a linear Fresnel collector with aperture area of 88 m^2 (Figure 4) is used to drive an ammonia-water absorption unit with nominal refrigerating capacity of 12 kW and *COP* of 0.6, which is tested for a 32 m^2 cold storage space. The absorption unit cools a water-glycol mixture to –5°C and charges an ice storage system with a thermal capacity of about 52 kWh (Döll, Bentaher, & Morgenstern, 2014).

Vasilescu & Infante Ferreira (2014) carried out a theoretical study of a large-scale system featuring a double-effect ammonia-lithium nitrate absorption unit with a refrigeration capacity of 343 kW (when cooling a fluid to –20°C, with input heat at 195°C and inlet cooling water temperature of 30°C), driven by a parabolic trough collector with an aperture area of 1,000 m^2. The study showed that for the climatic conditions of Naples, Italy the solar collectors can provide 50% of the heat required to cover the refrigeration demand of 600 kW in a food processing facility.

Instead of liquid absorbents, adsorption refrigeration systems utilize solid sorption materials with highly porous structure. Classical working pairs (refrigerant-adsorbent) for adsorption refrigeration are water-zeolite, water-silica gel and methanol-activated carbon (Podesser *et al.*, 2010). When saturated, the adsorbent can be regenerated with heat provided by a solar thermal system or another renewable source. Chemical adsorbents, e.g. metal hydrides, can also be used. Chemical adsorption is characterized with stronger bonds between the refrigerant and adsorbent, but it is more difficult to reverse and therefore more heat is required to drive the cycle (Pridasawas, 2006).

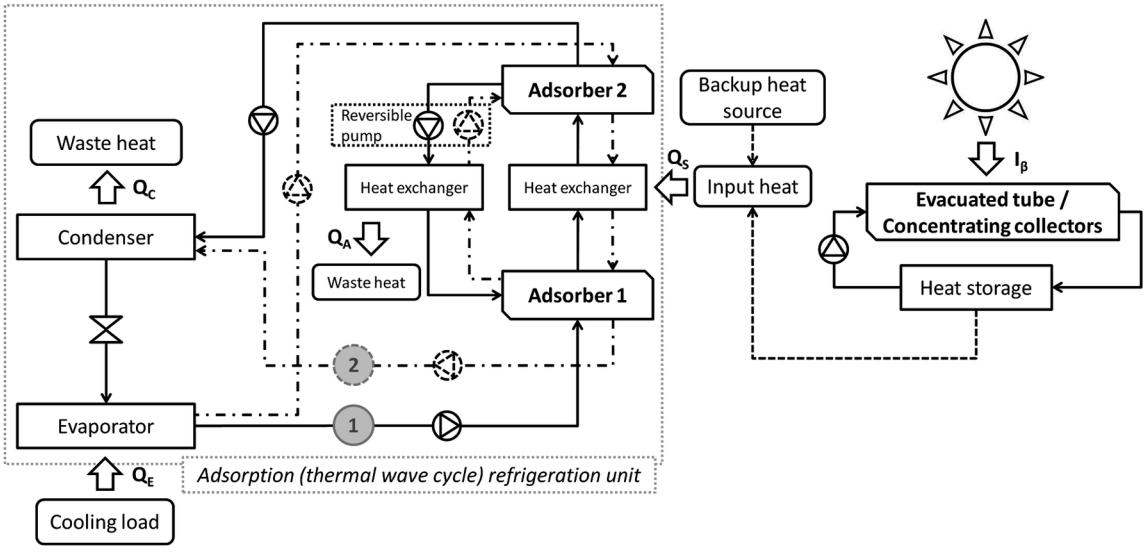
Unlike absorption systems, solid sorbents cannot be circulated and adsorption and desorption have to occur at the same solid adsorbent bed. The process is therefore intermittent and multiple adsorbent beds

Figure 4. Linear Fresnel collector used to drive an absorption refrigeration system at Umkirch, Germany. (© 2012, suncooling GmbH, a member of the KRAMER GROUP, Germany. Used with permission.)

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

are required to permit continuous operation of the system (Kim & Infante Ferreira, 2008). Advanced adsorption cycles (e.g. heat recovery cycle, mass recovery cycle and thermal wave adsorption cycle) have been developed to cope with this issue (Lewis, Chaer, & Tassou, 2007). Schematic of a thermal wave cycle adsorption system driven by solar energy is presented in Figure 5.

Adsorption refrigeration systems offer several advantages as compared with absorption systems, including less corrosion issues when working at higher temperatures and the possibility of being activated by lower temperatures – as low as 50°C, as compared with 90°C for absorption systems (Wang & Vineyard, 2011). Additional advantage of adsorption systems is that they involve few moving parts, which means reduced noise and vibrations. This can also decrease maintenance efforts, but the external hydraulic circuits have to be carefully designed (Podesser *et al.*, 2010). However, the *COP* of adsorption machines is typically lower, e.g. 0.2-0.5, with α_r in the range of 0.04-0.33 (Infante Ferreira & Kim, 2014). Chemical reaction systems have much lower *COPs* in the range of 0.1-0.2 (Pridasawas, 2006).



The number of manufacturers of adsorption systems is even lower than that of absorption systems. Commercially available large-scale units (larger than 100 kW) are manufactured by the Japanese company Mayekawa, while small-scale units (less than 15 kW) are produced by the German companies Invensor and SorTech (Podesser *et al.*, 2010). Commercial adsorption systems are still limited to mostly air-conditioning applications, while low-temperature adsorption refrigeration systems, potentially applicable to industrial facilities for cold storage, are still in a R&D stage (Lewis *et al.*, 2007).

The overall system efficiency of solar sorption refrigeration systems can be defined as:

$$OSE = \frac{Q_E}{I_\beta \cdot A_s} = \frac{Q_E}{Q_S} \cdot \frac{Q_S}{Q_{sol}} \cdot \frac{Q_{sol}}{I_\beta \cdot A_s} = COP \cdot \eta_{hd} \cdot \eta_{sc} \tag{12}$$

where η_{hd} is the efficiency of the heat distribution system and η_{hd} is the efficiency of the solar collector. *OSE* is typically low for solar refrigeration systems. Lazzarin (2014) estimated an *OSE* of 45% for a

Figure 5. Thermal wave cycle adsorption refrigeration system powered by solar energy

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

single-effect absorption system driven by evacuated tube collectors and 40% for a double-effect absorption system driven by a parabolic trough collector. Comparing the prices of sorption refrigeration units, Kim & Infante Ferreira (2008) showed that the investment cost per refrigerating capacity (€/kW) of adsorption systems is in the range of €500-855/kW, as compared with €210-400/kW for single-effect and €300-855/kW for double-effect absorption systems.

Other Renewables as a Heat Source

Thermally driven refrigeration systems can operate with heat acquired from other renewables (e.g. via combustion of biofuels or geothermal sources). Holdmann (2008) reported a geothermally driven absorption system with a refrigeration capacity of about 180,000 BTU per hour (or approx. 53 kW), developed for the Ice Museum of Chena Hot Springs Resort in Alaska. Small-scale biofuel-driven or geothermally driven sorption refrigeration systems are available, but for large-scale applications combined heat and power (CHP) generation can be a more feasible option. Such systems are discussed further in this chapter.

REFRIGERATION THROUGH ON-SITE POWER GENERATION

Solar Photovoltaic Systems

Photovoltaic (PV) modules are solid-state semiconductor devices which employ the photoelectric effect to convert solar radiation into direct current (DC). This DC power can subsequently be used directly or converted to alternating current (AC) to run electrically driven refrigeration systems. If an appropriate interaction is established between the cold store operator and the electric utility, PV-generated power can also be sold to the utility grid.

Due to the reduced prices and increased efficiencies of PV systems, whose use is continuously fostered by various government incentive programs, total global operating capacity of solar photovoltaic systems has grown rapidly since the beginning of the new millennium – from 1.8 GW in 2001 to 100 GW in 2012, with the top markets currently being Germany, Italy, China, the United States, and Japan (REN21, 2013). According to the U.S. Department of Energy (2012), prices of PV modules have declined by 95% between 1976 and 2010 and as of 2010 the installed cost of a commercial PV system (including the price of the modules, power electronics and BOS costs) per peak power capacity was roughly $5/W. According to Lazzarin (2014) the unit cost of a PV module on per area basis is on the average €650/m^2.

The most common types of PV cells are based on the monocrystalline and polycrystalline silicon technologies, which currently hold 85% of the PV market share. Another major type employs thin-film PV cells, which are about 100 times thinner than crystalline silicon cells. Thin-film cells most commonly use cadmium telluride (CdTe) as a semiconductor material, amorphous silicon and alloys of copper indium gallium diselenide (CIGS). Among thin-film technologies, CdTe-based PV modules have experienced the highest market growth during the last decade (U.S. Department of Energy, 2012). Concentrating PV systems are also available, but their market share is still small (REN21, 2013). Typical lifetime of solar PV modules is in the range of 20-25 years.

The efficiency of PV modules is defined as the ratio of generated electrical power to the product of solar panel surface area and incident solar radiation:

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$\eta_{PV} = \frac{P_G}{I_\beta \cdot A_s} \tag{13}$$

This efficiency depends on the module type and design. According to the U.S. Department of Energy (2012), crystalline silicon modules currently have efficiencies in the range of 14-16%, non-standard high-quality designs achieve module efficiencies of about 17-21%, while thin-film modules have lower efficiencies in the range of 6-14%. Manufacturers provide reference values for η_{PV} determined under standard conditions, but the actual efficiency of PV modules varies according to ambient conditions. Lazzarin (2014) proposes the following equation to calculate the operating efficiency of PV modules as a function of ambient air temperature and solar irradiation:

$$\eta_{PV} = \eta_{PV,R} \cdot \left[1 - \beta \cdot \left(T_A - T_{Ref}\right) - \frac{\beta \cdot \tau\alpha \cdot I_\beta}{U_L}\right] \tag{14}$$

where T_{Ref} is the reference temperature at which the reference efficiency $\eta_{PV,R}$ is evaluated (e.g. 25°C); β is a temperature coefficient of the PV cell (e.g. 0.004 K^{-1} for monocrystalline cells); $\tau\alpha$ is the product of glass transmissivity and cell absorptance (typical value is 0.95) and U_L is the overall heat loss coefficient of the PV cell (e.g. 20 $Wm^{-2}K^{-1}$). This equation shows that the operating efficiency decreases when ambient air temperature and solar irradiation are higher. Apart from the efficiency of the PV module itself, the efficiencies of the other components of the PV system have to be taken into account.

The overall efficiency of a refrigeration system driven by a PV system can be defined as:

$$OSE = \frac{Q_E}{I_\beta \cdot A_s} = \frac{Q_E}{P_S} \cdot \frac{P_S}{P_G} \cdot \frac{P_G}{I_\beta \cdot A_s} = COP \cdot \eta_{pd} \cdot \eta_{PV} \tag{15}$$

where P_S is the power supplied to the refrigeration system and η_{pd} is the efficiency of the power distribution system. A conservative estimate for *OSE* of a vapour-compression refrigeration unit driven by a photovoltaic system, using indicative values as shown in Figure 2 (η=0.1 and *EER*=3.5), would be 35%. If the system involves energy storage then this value would be somewhat lower. The *LCOE* of PV systems can vary significantly depending on local conditions. Comparing several situations, the U.S. Department of Energy (2012) estimated indicative values of *LCOE* for commercial systems in the range of $120-340/MWh.

PV systems can serve as a primary or supplementary energy source for any of the electrically driven refrigeration cycles, as depicted in Figure 2. Photovoltaics, among other solar systems, have varying energy production as a result of the varying availability of incident solar radiation. The power supply of the refrigeration system must therefore be designed to cope with this varying electricity production rate. For smaller scale systems DC power generated by the PV modules can be used to directly operate the DC motor of a compressor in a vapour-compression system. In that case a major consideration is to appropriately match the electrical characteristics of the motor driving the compressor with the available current and voltage being produced by the PV array (Klein & Reindl, 2005). Electric batteries can serve as a buffer between the PV system and the load, providing electrical storage. If the PV system

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

is connected to the utility grid, a proper energy management system (EMS) can provide the means for shifting power supply from/to the grid depending on the variation of the PV power supply and the power demand of the cold storage facility. The overall performance of the EMS can be enhanced through the thermal energy storage (TES) strategies described further in this chapter.

The relatively low energy conversion efficiencies, varying power production and high prices have traditionally been a barrier for wider implementation of solar PV systems. For many applications they are not economically viable or the associated payoff periods are too long, which often deters investments. Traditional cold storage applications of PV modules have been primarily for milk, fish and vaccine preservation in developing countries, especially in areas with no or unreliable power supply, but these are usually small-scale storage compartments with refrigeration capacities in the range of a few kilowatts. In developed countries with reliable power grids the use of PV systems for refrigerated warehousing has been limited until recently.

Large flat roofs of refrigerated warehouses are, however, a very convenient location for PV systems because of the presence of both a large unoccupied area for placing of PV modules and a substantial consumer of energy at the site of its generation. In addition, peak power demand in cold stores tends to coincide with the time when the intensity of solar radiation is at its highest, although higher temperatures and solar irradiation decrease the efficiency of PV modules. Similarly to all power generating systems, roof-mounted PV systems should be carefully designed and safely maintained in order to prevent fire hazards. Government incentives are among the most important drivers which enhance market penetration of PV-based technologies. Such measures are described in more detail in the section *"Policy instruments in support of renewable energy integration"*. The ease of demonstration, visibility and publicity of such PV projects promote public interest and stakeholders' confidence in renewable energy technologies as a whole.

Promising prospects are revealed today for a sound integration of PV systems in refrigerated warehouses. A number of state-of-the-art engineering solutions around the world employ large PV arrays (including some in the megawatt range) capable of meeting a significant portion of the power demand of the cold storage facilities they serve. Some of these recent developments are summarised in Table 3.

Top-view photographs of three of the facilities listed in Table 3 are shown in Figures 6, 7 and 8.

Solar Thermo-Mechanical Systems

Solar thermal collectors can provide energy to a heat engine for conversion of heat into mechanical work. This mechanical work can be used to drive the compressor of a vapour-compression refrigeration machine (Figure 9). In a basic configuration, the collector utilizes solar radiation incident on its surface to heat a fluid, which is usually water being converted to steam supplied to the heat engine, Q_S, which converts it to mechanical work, W, and rejects waste heat to the ambience, Q_A. The mechanical work, in turn, drives the compressor of the refrigeration machine, to remove heat from the evaporator, Q_E. Waste heat of the refrigeration cycle is rejected to the ambience at the condenser, Q_C. A storage tank can be included to provide some high temperature storage and serve as a buffer between the solar collectors and the heat engine.

The overall system efficiency of a solar thermo-mechanical refrigeration system can be defined as:

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 3. Some recent installations of large-scale solar PV systems at refrigerated warehouses

Location/Source	Technical Features	Cost / Economic Benefits
Refrigerated warehouse at the Gloucester Marine Terminal in New Jersey (Holt Logistics Corp., 2014)	• 27,528 roof-mounted modules (102,200 m^2) • 9 MW installed capacity • Capable of producing 11 GWh per year (meeting 80% of facility power demand) • 3-4 MW expansion is planned	• Investment of $42 million • $11 million in federal tax credit • Continued support of solar renewable energy credits (RECs) through the New Jersey renewable portfolio standards (RPS) scheme • Expected return on investment in 10 years or less
Cold storage facilities in La Mirada and Livermore, California, and Phoenix, Arizona ("DelSolar Completes", 2011; US Foods, 2011a, 2011b, 2011c)	• La Mirada: 4,998 modules with 1.15 MW installed capacity (annual production of approximately 1.65 GWh, 16% of power demand) • Livermore: 4,354 modules with 1.18 MW installed capacity (annual production of approximately 1.3 GWh, 40% of power demand during daylight hours) • Phoenix: 3,934 modules with 0.9 MW installed capacity (annual production of approximately 1.5 GWh, 15% of power demand)	• Facilities have earned Green Business Certification • The project in La Mirada has been partially funded through the California Solar Initiative program • Solar systems are leased from renewable energy providers
Seven cold stores at various locations in England (Yearsley Group, 2012)	• 8,997 roof-mounted modules • Capable of producing 1.753 GWh per year	• Investment of £3.5 million • The project is intended to meet carbon reduction commitments as part of ISO 14001 environmental certification
Refrigerated warehouse and distribution centre at Goldthorpe near Barnsley, England (Bennett, 2014)	• 6,000 roof-mounted modules (15,000 m^2) • 1.5 MW installed capacity • Estimated to provide 1.2 GWh per year	
Multi-purpose distribution center (including food storage facilities) in Heddesheim, Germany (Wirsol, 2013)	• 33,096 roof-mounted modules (110,000 m^2) • 8.1 MW installed capacity • Capable of producing 7.9 GWh per year	• Pre-certified by the German Sustainable Building Council (DGNB) with gold certificate
Three cold stores in New Jersey (EDF Renewable Energy, 2009; Milk, n.d.)	• 30,000 roof-mounted PV modules of different technologies with total capacity of 3.2 MW • 21% reduction in grid power consumption	Part of the solar system is owned by the cold stores operator: • Investment of $9 million • $4.6 million in state and federal incentives, including 30% federal tax credit, a New Jersey state subsidy, and accelerated depreciation Part of the solar system is owned by a renewable energy provider: • Electricity production is fed to the cold stores at a fixed price under a power purchasing agreement (PPA)
Cold storage facility in Wilmington, Los Angeles, California ("California Green Designs", 2011)	• 7,500 roof-mounted modules with installed capacity of 1.49 MW • Capable of meeting 75% percent of facility power demand	• Average savings of between $40,000 and $42,000 per month on electricity costs • Benefits from government and utility incentives, including 30 percent federal grant, one-year accelerated bonus depreciation and rebate from the Los Angeles Department of Water & Power
Cold storage facility in San Diego, California ("ICE Cold Storage", 2009; Milk, n.d.)	• Roof-mounted modules with 1.1 MW installed capacity • Capable of meeting 72% of facility power demand • Average production of 1,295 kWh per day during the winter months and 3,383 kWh per day in summer months	• Investors share renewable energy credits (RECs) Part of the solar system is owned by the power provider: • Part of San Diego Gas & Electric Sustainable Communities Program that supports renewable energy initiatives Part of the solar system is owned by the cold store operator: • Investment of $3.5 million before any subsidies • 40% reduction of the investment cost as a result of 30% federal tax credit and a five-year California refund (on a kWh basis)
Refrigerated warehouse in West Sacramento, California (Milk, n.d.; "Tony's Goes Green", n.d)	• 5,700 roof-mounted modules with installed capacity of 1.2 MW • About 43% reduction of grid power consumption	• Investment of $7.2 million before any subsidies • About 50% reduction of the investment cost as a result of federal tax credit and a $3.5 million rebate from Pacific Gas & Electric • In times of excessive production electricity is fed to the grid on a net metering basis • Average savings of $22,000 per month on energy costs

Table 3. Continued

Location/Source	Technical Features	Cost / Economic Benefits
Refrigerated warehouse at the Port of Baltimore, Maryland (HelioSage, n.d.)	• 3,136 roof-mounted modules with 736.9 kW installed capacity • Providing 824 MWh per year (capable of meeting 20% of facility power demand)	• Benefits from sale of solar renewable energy credits (SRECs) • Expected payback in less than six years
Cold storage facility in Portland, Oregon (Henningsen Cold Storage Co., 2010)	• 1,386 roof-mounted thin-film modules (3,017 m^2) • 200 kW installed capacity • Capable of meeting 20% of facility power demand	
Food Bank of Contra Costa & Solano, California (Food Bank of Contra Costa and Solano, n.d.)	• 516 roof-mounted modules	• Investment of $450,000 • California Energy Commission rebate
Cold storage and packing facility in San Joaquin Valley, California (REC Solar, 2014)	• Ground-mounted system on a four acre field adjacent to the cold storage facility • 1.07 MW installed capacity • Capable of meeting 75% of facility power demand	• Local rebates • 30% federal investment tax credit and other tax incentives • Expected payback in five years

Figure 6. Solar park on the roof of MTC Logistics' cold store at the Port of Baltimore. (© 2011, HelioSage. Used with permission)

$$OSE = \frac{Q_E}{I_\beta \cdot A_S} = \frac{Q_E}{W} \cdot \frac{W}{Q_S} \cdot \frac{Q_S}{Q_{sol}} \cdot \frac{Q_{sol}}{I_\beta \cdot A_S} = COP \cdot \eta_{he} \cdot \eta_{hd} \cdot \eta_{sc} \tag{16}$$

where η_{he} is the thermal efficiency (i.e. the ratio of the work output to the heat input) of the heat engine. The *OSE* of solar thermo-mechanical refrigeration is usually quite low (e.g. around 5%), which is unfavourable for the market penetration. According to Klein & Reindl (2005), such systems can be competitive if concentrating solar collectors with tracking systems are used to provide high temperatures for large-scale refrigeration applications (e.g. over approx. 3,500 kW).

Figure 9. Solar thermo-mechanical refrigeration system

Rankine and Stirling engines are the main options as far as the heat engine for a solar thermo-mechanical system is concerned. Stirling engines can be used at very high temperatures (e.g. above 750°C). These are therefore preferable when parabolic dish collectors are employed, while Rankine engines are applicable for lower temperatures and can be successfully combined with parabolic trough collectors (Infante Ferreira & Kim, 2014).

Applications of solar thermo-mechanical systems are limited and currently this technology is available only from a small number of large manufacturers (Podesser *et al.*, 2010). Another possibility is to use the heat engine for power generation. Aye *et al.* (2012) investigated the performance of a small-scale system with a solar-driven Organic Rankine cycle (ORC) engine, providing power for a vapour-compression refrigeration system, used for field storing of chilled blueberries at a storage temperature of 4°C. In addition, waste heat of the engine can be utilized for a thermally driven refrigeration system. Combined heat and power generation (CHP) systems using solar energy are discussed further in this chapter.

Wind Turbines

Wind turbines are devices that convert the kinetic energy of wind into electrical power. There are two main types of wind turbines – horizontal-axis wind turbine (HAWT) and vertical-axis wind turbine (VAWT). The Darrieus and Savonius wind turbines are recognizable VAWT types, but in general HAWTs are more common. Different designs are available, but the main components of a typical HAWT include blades, rotor, pitch system that turns the blades and controls rotor speed, low-speed and high speed shafts, gearbox that connects the low-speed shaft of the rotor with the high speed shaft which drives the generator (converting mechanical energy into 50-60 Hz AC current) and control system (including an anemometer, windvane, controller, and brake) which switches the machine *on* or *off* depending on wind speed. Upwind positioned HAWTs also include a yaw drive to keep the rotor facing into the wind

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

as the wind direction changes. Sizes and tower heights of wind turbines vary significantly. Some are available with small rotor diameters and capacity of only a few kilowatts, while the largest unit is 125 m tall, with a rotor diameter of 190 m and has a peak capacity of 10 MW. Like solar PV systems, wind turbines can be used as an off-grid energy source for electrically driven refrigeration systems or can be connected to the utility grid.

Wind has been used as an energy source since ancient times primarily for the purposes of grinding grain, pumping water and moving ships, while the use of wind turbines to generate electricity dates back to the late 19th century (Royal Academy of Engineering, 2014). Nowadays their use is growing rapidly and, according to REN21 (2013), global installed capacity of wind turbines reached 283 GW in 2012, up from 24 GW in 2001. Naturally, wind turbines are most beneficial in locations with steady winds, both onshore and offshore. The top markets of wind energy are currently the United States and China, followed by Germany, India and the United Kingdom (REN21, 2013).

Wind turbine prices reached their peak in 2008 and have been falling since then, before stabilizing in 2012, while the O&M costs have dropped significantly (REN21, 2013). A study by Tegen *et al.* (2013) on the economic performance of wind turbines in the United States indicates that as of 2011 the installed cost of onshore wind turbines varies in the range of $1.4-2.9/W and LCOE varies in the range of $60-100/MWh for operational lifetimes of 20-30 years. Both cost metrics have much higher values for offshore turbines (Tegen *et al.*, 2013). Comparison of the above metrics with those of solar PV systems indicates that wind turbines can be less expensive on a levelized basis, while the operational lifetime of both is similar. However wind turbines are usually more efficient for large-scale utility generation systems, while PV systems are more versatile and can be combined in smaller increments to produce varying capacities. The major consideration should be the availability of the energy resource, as wind and solar energy can have very diverging potentials in different locations.

Industrial examples for cold storage facilities featuring on-site wind turbines are already available. A landmark RES project is the Testa Produce's LEED Platinum-certified refrigerated food distribution facility in Chicago, Illinois, which features a 72 m high wind turbine with a capacity of 750 kW, along with PV modules and other sustainability oriented solutions, as visible in Figure 10 (Grover, 2011; Epstein, 2013). The wind turbine has an installed cost of $1.6 million and is capable of meeting up to 40% of the facility's energy demand (Podmolik, 2011). The Walmart distribution center in Red Bluff, California also features a wind turbine (80 m in height, with a rotor diameter of 76 m), which has an installed capacity of 1 MW. The turbine has an estimated production of 200 MWh annually and is capable of meeting 15-20% of the facility's electricity demand ("Walmart unveils", 2012). Furthermore, Walmart Corp. (2014) reports that the company has renewable electricity generation capacities (in operation or under development) amounting to a total of 2,200 GWh per year.

Combined Heat and Power Generation

Combined heat and power (CHP) generation, also known as cogeneration, is the simultaneous production of electricity and useful heat, whereas the heat is a by-product of the electricity generation process, i.e. waste heat, which would otherwise be discharged to the environment, is utilized as an energy source. Any system that simultaneously generates heat and electricity can be classified as a CHP system, but most commonly it involves a heat engine using the combustion of a carbon-based fuel to drive a power generator and the waste heat left is used as a thermal source for heating purposes or a thermally driven cycle. A thermally driven refrigeration system can be integrated with the CHP system to exploit this

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 10. Testa Produce's LEED Platinum-certified refrigerated food distribution facility in Chicago, featuring a 750 kW wind turbine. (© 2013, Epstein. Used with permission)

waste heat as an energy source for refrigeration. Such configurations are often referred to as trigeneration systems. CHP systems have traditionally been used for district heating power plants and more recently for district cooling systems. They have also been used in places without reliable power supply. With the development of smart grids and increasing share of distributed power sources, linked to the utility grids, CHP systems are becoming more common, although they are still not a customary feature.

Various RES configurations can provide the primary energy for a CHP system. Different operable combinations of prime movers (heat engines) and renewables for CHP generation are shown in Table 4.

Biogas-fuelled and solar-driven systems are two of the more promising options for RES-driven trigeneration systems of refrigerated warehouses. Geothermal systems are also an interesting opportunity where Earth heat is plentiful. The power provided by the CHP unit can drive any of the known electrically-driven refrigeration systems, while the residual heat can run a thermally driven refrigeration system, depending on the temperature and amount of heat available.

Solar-Driven CHP Systems

Solar energy can be used as a heat source for CHP systems when conditions are favourable for installing concentrating solar collectors that can provide sufficiently high temperatures for the heat engine (e.g. above 150°C). Stirling or Rankine cycle heat engines are most commonly used for solar-driven CHP systems. Rankine cycle systems using organic working fluids, i.e. organic Rankine cycle (ORC) systems,

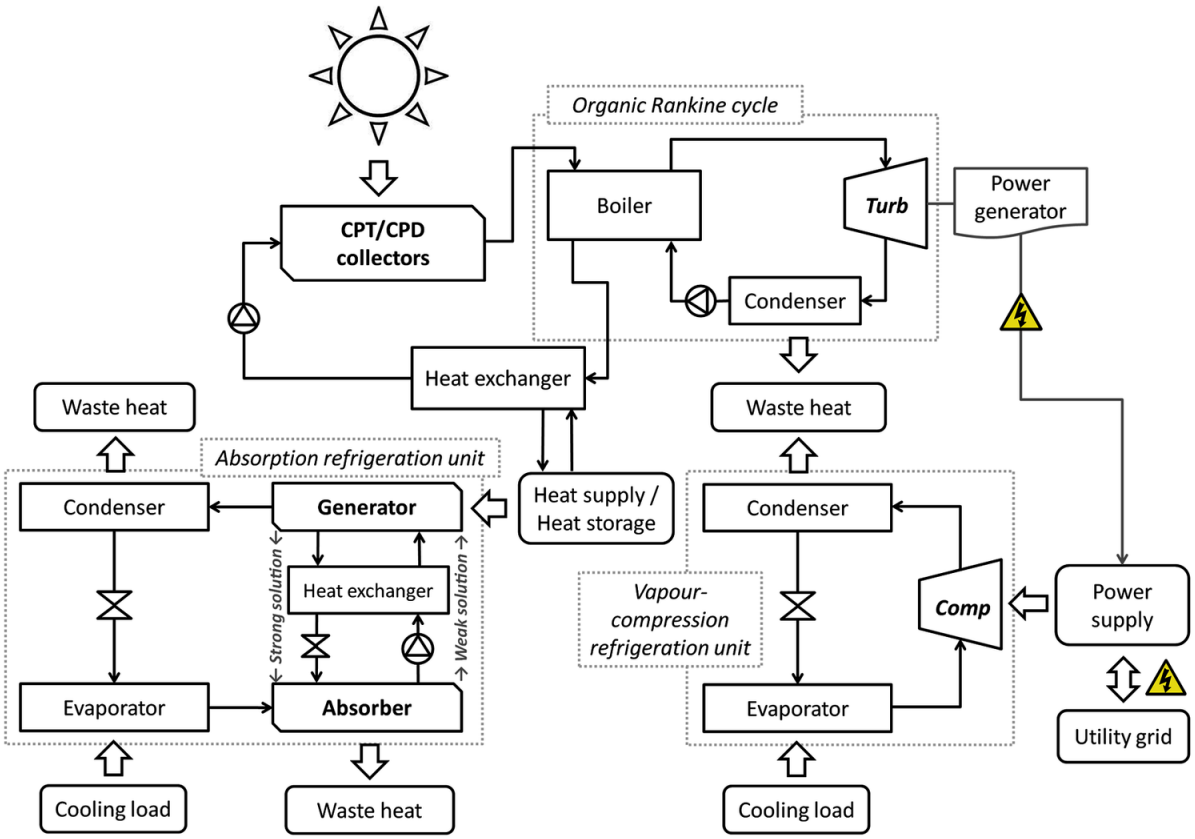
Organic Rankine cycle engine			✓	✓	✓

are arguably the most promising technology for solar-driven CHP systems, because they operate at lower temperatures, which can be achieved by concentrating solar collectors in smaller-scale systems. Stirling cycle engines typically require parabolic dish concentrating collectors, while ORC systems can also operate with parabolic trough collectors. Linear Fresnel concentrators are also a suitable choice for ORC systems (Quoilin, 2011). Both Sirling cycle and Rankine cycle heat engines, specifically designed for use with solar concentrating collectors, are available. Commercially available ORC systems with various capacities are reported to operate with heat source temperatures in the range of 74-350°C (Arvay, Muller, Ramdeen, & Cunningham, 2011). Figure 11 illustrates a commercially available 1 MW ORC module designed by Siemens (Siemens AG, 2014).



A possible configuration of trigeneration system with a solar-driven ORC engine, providing energy for both vapour-compression and absorption refrigeration units, is depicted in Figure 12.

Figure 11. A Siemens AG ORC module with a power output of up to 1 MW (© 2014, Siemens AG. Used with permission)

Figure 12. Single-stage absorption and vapour-compression refrigeration systems powered by a solar-driven ORC engine

The electrical, $\eta_{el,CHP}$, and thermal, $\eta_{th,CHP}$, efficiencies of a solar-driven CHP system can be defined as:

$$\eta_{el,CHP} = \frac{P_G}{I_\beta \cdot A_S} = \frac{P_G}{W} \cdot \frac{W}{Q_S} \cdot \frac{Q_S}{Q_{sol}} \cdot \frac{Q_{sol}}{I_\beta \cdot A_s} = \eta_{pg} \cdot \eta_{he} \cdot \eta_{hd} \cdot \eta_{sc} \tag{17}$$

$$\eta_{th,CHP} = \frac{Q_R}{I_\beta \cdot A_S} = \left(1 - \eta_{he}\right) \cdot \eta_t \cdot \eta_{hd} \cdot \eta_{sc} \tag{18}$$

where P_G is the generated power [W], Q_R is the recovered (utilized) residual heat [W], η_{pg} is the efficiency of the power generator, η_{he} is the thermal efficiency (i.e. the ratio of the work output to the heat input) of the heat engine, η_{sc} is the efficiency of the concentrating solar collector and η_t is the fraction of the waste heat utilized. The overall efficiency of the solar-driven CHP system is therefore:

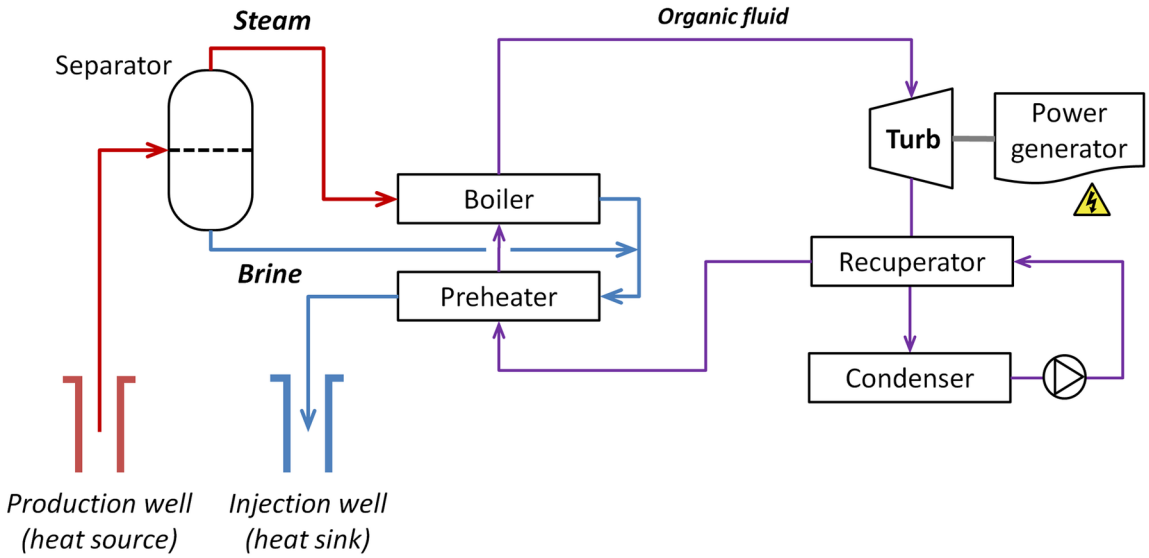
EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$\eta_{CHP} = \frac{P_G + Q_R}{I_\beta \cdot A_S} = \eta_{el,CHP} + \eta_{th,CHP} \tag{19}$$

This overall CHP system efficiency does not account for the individual efficiencies of the refrigeration systems which use the energy. According to Müller-Steinhagen & Trieb (2004), annual electrical efficiencies of solar-driven CHP systems can be expected in the range of 8-25% depending on technology (e.g. 10-15% for systems using parabolic trough collectors). For electrical efficiencies of over 20%, a solar tracking system is required, but this increases cost and decreases reliability, which is particularly undesirable for smaller-scale distributed generation systems (Norwood, 2011). The overall thermal efficiency of a Rankine cycle heat engine, driven by a variety of solar collector configurations, can be expected to reach more than 50% (Norwood, 2011). Thus, the overall efficiency of a solar-driven CHP system can reasonably be expected to exceed 60%, given the global average efficiency of CHP units is 58%, while state-of-the-art CHP systems can achieve overall efficiencies of over 85% (Intergovernmental Panel on Climate Change, 2014).

Indicative figures for the installed cost of a solar-driven ORC CHP system (per peak electrical and thermal capacities) are $\$3.2/W_{el}$ and $\$0.4/W_{th}$ (Norwood, 2011). According to the Intergovernmental Panel on Climate Change (2014), the *LCOE* of concentrated solar power systems is generally in the range of \$100-480/MWh (median of \$150-320/MWh) for plant lifetime of 20 years, but this does not account for the benefit from the recovered heat. Norwood & Kammen (2012) performed life-cycle analysis (LCA) of a solar-driven CHP system for air cooling in Oakland, California (which uses a single solar dish collector and a Rankine cycle) and predicted a levelized cost of \$250/MWh (electricity) and \$30/MWh (heat).

Geothermal CHP Systems



The comparatively lower heat source temperatures, needed to run the organic Rankine cycle engines, makes geothermal energy another viable option for implementing ORC-based CHP systems, wherever Earth heat is readily available. Geothermal sources are typically available with temperatures in the range of 110-180°C (Arvay *et al.*, 2011), but can also reach up to 300°C (Quoilin, 2011). As previously mentioned, this is within the operating range of commercially available ORC engines and geothermal sources with temperatures as low as 74°C can be utilized (although efficiency is low at such low temperatures).

A setback concerning geothermal systems is the high cost of drilling. In order to attain higher source temperatures, a geothermal system would generally require drilling of deep boreholes for the production and injection wells which, according Quoilin (2011), can reach up to 70% of the total investment for a geothermal ORC plant. Typically, a fluid (e.g. brine) is circulated through the production well (heat source) and injection well (heat sink), which in turn requires high pump power consumption. For low-temperature ORC plants this consumption can account for 30-50% and more of the system's electrical output (Quoilin, 2011).

ORC systems designed for geothermal applications have been developed by Ormat Technologies. In most cases, the fluid circulated through the production and injection wells is separated into a stream of steam, fed to the boiler of the ORC engine, and a stream of brine in a dedicated separator (Kaplan, 2007). The condensate is afterwards mixed with the separated brine to provide preheating of the organic fluid fed to the boiler in order to increase the thermodynamic efficiency of the cycle. Figure 13 shows

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 13. Configuration of a geothermally driven ORC engine (Adapted from Kaplan, 2007)

a configuration with an additional heat exchanger (recuperator) which is applicable when the expansion in the turbine is done in the dry superheated zone and the expanded vapour contains heat which has to be extracted prior to condensation (Kaplan, 2007).

Biogas-Fueled CHP Systems

The heat for driving a CHP system can be provided by combustion of biofuels (solid, liquid and gaseous), as shown in Table 4. In fact, most of the installed CHP systems employing ORC engines use biofuels as an energy source (Quoilin, 2011). An important advantage of biofuels over other renewables is reliability, as the resource is generally non-intermittent and energy production is easier to control. One of the most important considerations for efficient utilization of biofuels is the availability of biomass feedstock in close proximity to the CHP plant (U.S. Environmental Protection Agency, 2007).

Residual biomass, as opposed to biomass derived from energy crops, can be derived from various sources, among which wood wastes, crop residues, manure biogas, wastewater treatment biogas, municipal solid waste, food processing residues, etc. (U.S. Environmental Protection Agency, 2007). Combustion of biogas, derived via anaerobic digesters from biodegradable waste or from wastewater treatment facilities, is suitable for CHP systems of cold storage facilities. In particular, this can be beneficial for refrigerated warehouses of (or near) large food processing plants. Common food-processing wastes are fruit pits, cheese whey and meat processing residues, but these can be difficult to utilize as a fuel source because of the varying characteristics and properties of different waste streams. Hence, such wastes are most often disposed of as industrial wastewater and discharged to a local wastewater treatment plant (U.S. Environmental Protection Agency, 2007).

Food and other biodegradable wastes, composed of organic material, are subject to anaerobic decomposition of the organic matter and produce biogas with high methane (CH_4) content of 45-70% (Rasi, 2009). Methane yields of selected feedstock from the food and other industries are reported by Rutz *et*

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

al. (2009). Methane, which is the primary ingredient of natural gas, has high heat of combustion and substantial global warming potential (GWP). Thus, its capture and utilization in waste-to-energy systems is stimulated by many countries, some of which have put in place (or are planning to adopt) climate change mitigation policy instruments for that purpose. According to Eriksson (2010), the energy content of biogas can be expected in the range of 4.5-8.5 kWh/Nm^3, while pure methane has an energy content of 9.81 kWh/Nm^3. Through appropriate upgrade processes biogas can be converted to biomethane with methane content of about 90% (Rasi, 2009).

As indicated in Table 4, biofuels can be used as a heat source for various CHP prime movers. In the case of biogas, a gas turbine engine is especially suitable, as biogas can directly be fed to the combustion chamber of the engine. A disadvantage of biogas-driven CHP systems is the high capital and maintenance costs, along with the system complexity due to the need for involvement of appropriate equipment for conversion of biogas and pre-processing of the produced fuel in order to meet engine requirements. More information on biogas conversion is published by Hillen *et al.* (2010), Krich *et al.* (2005), Rutz *et al.* (2012) and the U.S. Environmental Protection Agency (2007).

The high capital and maintenance costs can lead to long payback periods if no government incentives are available. A feasibility study of biogas-fuelled CHP systems for meat processing facilities in Australia indicates a payback period in the range of 9.2-13.4 years. The financial benefits from savings of CO_2 emission permits to reduce the payback period for such systems to 7-9.2 years (McPhail & Rossington, 2010). Table 5 details typical performance parameters of biogas-fuelled CHP systems with different prime movers, while Table 6 shows estimates for the capital and operating costs associated with biomethane production, based on a study of Krich *et al.* (2005) about the production and use of biomethane from dairy waste.

The waste heat of the flue gases, which exit the CHP system at rather high temperatures of 80-550°C (Rutz *et al.*, 2012), can be utilized as heat source for a thermally driven refrigeration system. Suamir & Tassou (2011) evaluated the performance of an integrated system combining biogas-fuelled trigeneration and CO_2 refrigeration, designed to supply supermarkets with heating, cooling and electrical power. The today's technology level of such systems still requires relatively long payback periods. Waste heat of the primary system can also be used for additional power generation through a heat engine operating at lower temperatures (e.g. an ORC engine). Rutz *et al.* (2012) estimated that waste heat from a CHP plant with 1 MW electrical capacity can be used for an ORC engine to generate 7-10% (0.07-0.1 MW) additional power, thereby increasing the efficiency of the system by 45%. The CHP system can directly

Table 5. Prime movers for biogas-fuelled CHP systems (Adapted from U.S. Environmental Protection Agency, 2007)

	Gas Turbine	Microturbine	Reciprocating Engine	Steam Turbine	Stirling Engine	Fuel Cell
Capacity	0.5-40 MW	0.03-0.25 MW	< 5MW	0.05-250 MW	< 0.2 MW	< 1 MW

Table 6. Indicative cost ranges for biomethane production equipment (Adapted from Krich et al., 2005)

Equipment	Cost
Anaerobic digester	
Capital cost	\$88-164 per 1000 m^3
Operating cost	\$17-21 per 1000 m^3
Biomethane upgrading plant	
Capital cost	\$55-110 per 1000 m^3
Operating cost	\$130-240 per 1000 m^3
Biomethane storage	\$0-100 per 1000 m^3
Biomethane transport	\$0-32 per 1000 m^3

be used to mechanically drive the compressor of a vapour-compression refrigeration system, while the waste heat could drive a sorption refrigeration system (ASHRAE, 2008). Figure 14 shows simplified schematics of two possible configurations of trigeneration systems driven by a gas turbine.

A number of refrigerated warehouses around the world feature CHP systems fuelled by on-site produced biogas. For instance, the Cannington Cold Stores' Bridgwater site in the United Kingdom features a system with anaerobic digestion tanks and gas holders for on-site biogas production and storage (Figure 15). Biogas is produced from various food wastes originating from the 45,000 m^3 cold store, which provides ambient, chilled and frozen storage down to –25°C ("Cannington Cold Stores", n.d.). The produced biogas is used for heat and power generation via an on-site CHP system. Electricity generated by the CHP system is used to power the cold store and surplus electricity is fed to the utility grid under the Renewable Obligations scheme established in the United Kingdom. Waste heat from the CHP system is fed to the digesters to run the biogas generation process ("Cannington Cold Stores", n.d.). According to Kirk Group (2014), the total digestion volume of the facility is expected to reach 18,000 m^3, while the generating capacity is expected to exceed 3.3 MW. Another example of a biogas production plant, using food wastes in the United Kingdom, is the Premier Foods' RF Brookes ready-meal factory at Rogerstone, Wales. The plant is estimated to generate 1.4 million m^3 of biogas with an energy content

of about 8.4 MWh, which is fed to a CHP system, thereby displacing 10% of the factory's fossil-fuel consumption ("Serving up food-factory waste", 2011).

INTEGRATION OF RENEWABLES INVOLVING THERMAL ENERGY STORAGE

Integration of solar, wind and other distributed renewable energy sources in the power grid can be challenging, especially for traditional centralized grids with top-down structure. This is caused by the mismatch of supply and demand of energy, as total generation has to match total consumption in the grid at any moment. Grid balancing problems are common for both developed and developing economies worldwide. Peak summer loads because of the high energy demand for air-conditioning have become a typical problem for the U.S. power grid, while in Europe, which possesses a higher share of RES in its power supply system, the problem with the intermittency of renewable sources is even more pronounced.

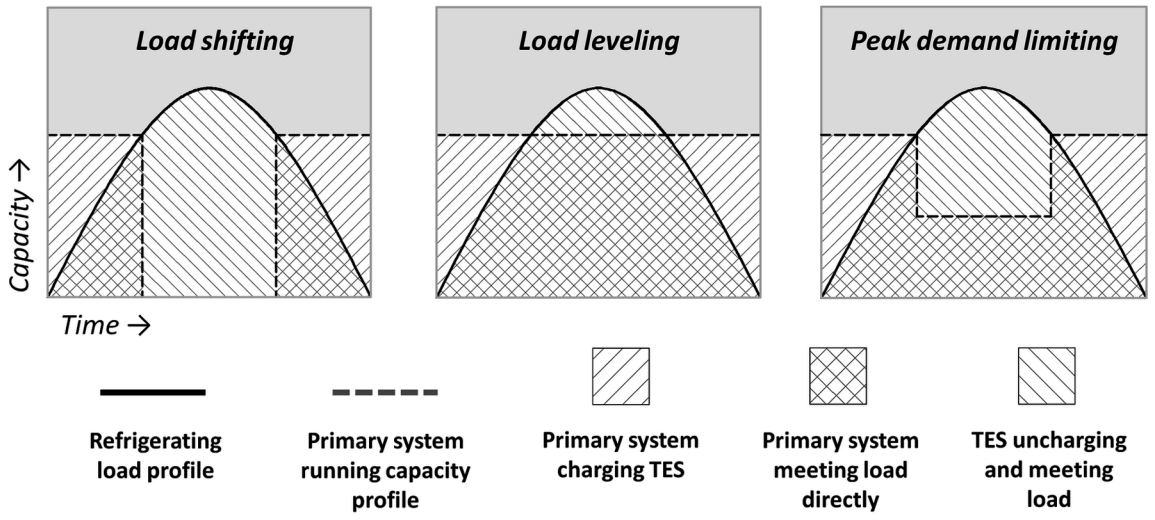
The development of "smart grids" involves transition from the traditional top-down approach of power supply to a more distributed and flexible electricity supply and distribution system. Within this framework, industrial cold storage facilities can become a more active player within the grid by either selling excessive on-site generated electricity or by improving the power grid balance through smart temperature control, involvement of TES and energy management, thereby providing substantial economic benefits to the cold store operator (Fikiin, 2012a).

Thermal Energy Storage for Cold Accumulation

Embedding TES systems as part of the cold-store refrigeration plants is a quite logical and intuitive measure, employed for years by the cold chain operators to profit from the cheaper electricity tariffs

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

at the low-consumption periods. Simultaneously, TES appears to be a powerful tool for increasing the RES share in the cold storage sector by accumulating the excessive renewable energy, generated on-site, unless it is sold to the electricity grid (Fikiin, 2012a, b).



In fact, TES does not reduce (and might even increase) the overall energy consumption, but it distributes the loads during time in a much more efficient way. The main benefits for the store operator can be summarised as follows (Fikiin, 2012b; ASHRAE, 2008):

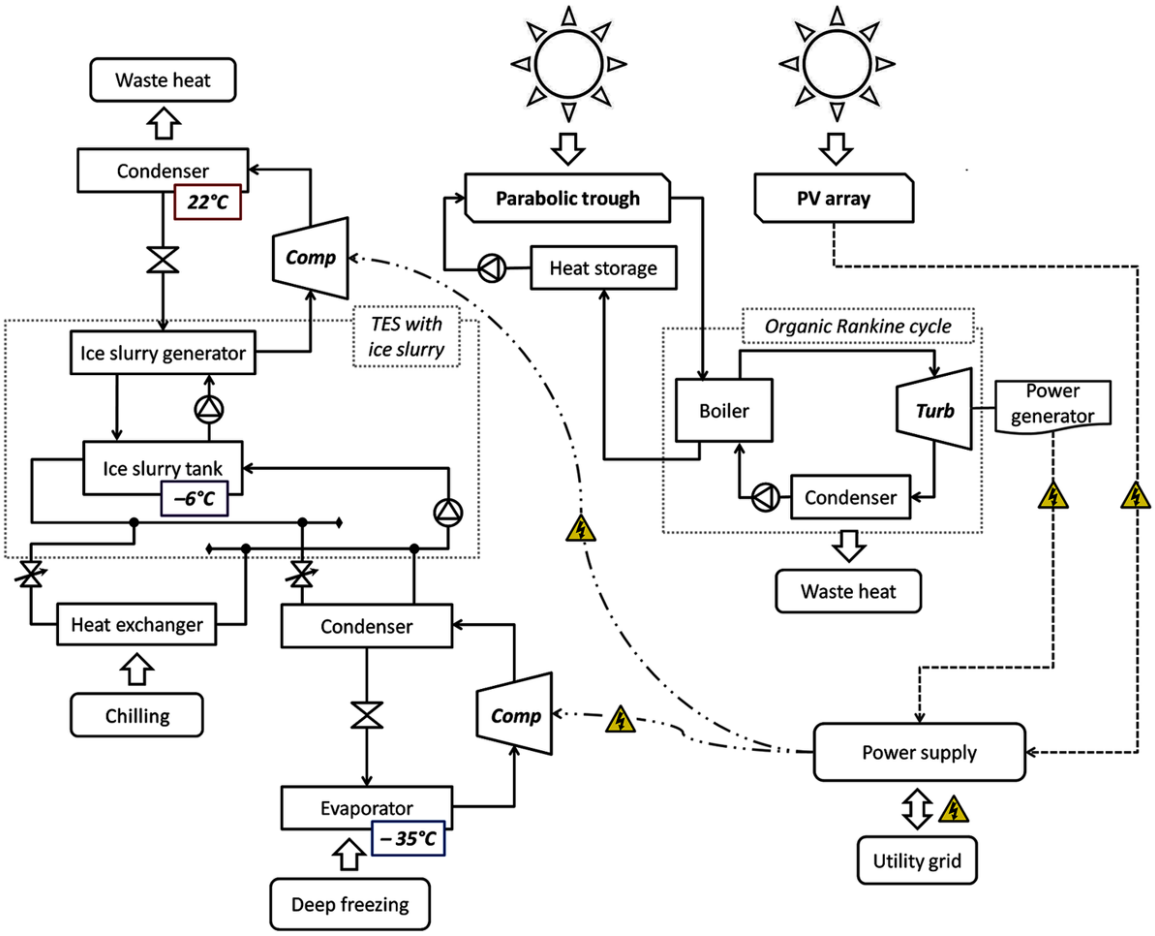
- Overall energy expenditures of the facility are lower;
- Peak capacity is reduced, which brings down the investment and the equipment size;
- Plant operation and maintenance are optimized, because when the refrigeration plant operates with large load variations, especially at capacities much lower than the designed maximum capacity (i) its efficiency drops substantially, (ii) control becomes more complicated, and (iii) some plant components may experience technical problems to cope with these variations.

Figure 16 gives a simplified example of peak demand reduction strategies when using TES. A TES system typically serves as a thermal buffer between the primary refrigeration circuit and a secondary circuit which supplies cold by pumping secondary refrigerant to air coolers placed in the refrigerated rooms of the store. The TES systems accumulate in tanks or special vessels the superfluous cold produced when running the primary circuit, thereby cooling the secondary refrigerant even when the compressors are switched off. This type of thermal storage is often referred to as "active" storage.

Comprehensive information on TES systems and their various benefits can be found in relevant literature (ASHRAE, 2008; Stoecker, 1998). TES systems can be classified in accordance with: (i) type of thermal storage medium, (ii) whether they store primarily sensible or latent heat, or (iii) the way the storage medium is used (ASHRAE, 2008). Thermal storage media may consist of water, aqueous solutions, pure or multicomponent liquids (e.g. containing glycols and alcohols), ice and phase-change materials (PCM),

Figure 16. Charging and discharging strategies for TES to meet peak refrigeration loads (Adapted from ASHRAE, 1993)

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use



along with microcrystalline ice slurries, PCM slurries, etc. For example, Fikiin, Kaloyanov, Filatova, & Sokolov (2002) analysed a number of refrigeration systems and technologies involving ice-slurry-based TES for different industrial scenarios. Another useful review has been published by Tassou *et al.* (2005).

There are practically unlimited opportunities and numerous engineering solutions for integrating renewable energy in TES systems and cold accumulating facilities of refrigerated warehouses. Figure 17 illustrates a possible arrangement of such a refrigeration plant employing ice-slurry and powered by a solar-driven ORC engine.

Temperature Control for Passive Thermal Energy Storage

Temperature is generally considered as the "single most important factor determining the food quality and safety". This definition means that a lot of other process parameters or storage conditions may more or less influence upon the food product in different industrial situations, but temperature is the

Figure 17. Possible arrangement of a solar powered refrigeration plant using ice slurry (Adapted from Van Bael, 1996; Fikiin et al., 2002)

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

only physical value whose importance is always enormous. Hence, proper temperature control is the prime simple receipt for the success of every food processor, store operator and retailer (Fikiin, 2003). The temperature-controlled cold supply chain for refrigerated processing, storage, distribution, retail and household handling of foods is therefore of paramount importance for guaranteeing safety, quality, wholesomeness and extended shelf-life of perishable commodities (Fikiin, 2003; Cleland, 2010).

From the viewpoint of product safety and quality, the "golden rule" is that storage temperature must be maintained as constant as possible. In that context, numerous product-specific data for the practical storage life of different chilled and frozen commodities kept at the well known constant storage temperatures are published in the specialized literature (ASHRAE, 2014; Fikiin, 2003). However, as Table 7 implies, the "golden rules" and strategies for energy savings might often contradict safety and quality related requirements. For instance, the so-called "passive" thermal energy storage involves artificial temperature fluctuations to accumulate cold in the refrigerated products, when excessive and cheap energy is available, and to release this energy at the time of peak loads, when the energy demand is higher (Altwies & Reindl, 1999; Van der Sluis, 2008). Such approaches are very intuitive and proven in real practice for many years. The need for additional investment to build up "active" TES systems is thus avoided.

Recent advancements in information technologies and automatics make it possible to implement sophisticated temperature control strategies for intelligent energy use. Such an intelligent approach could be illustrated by a comparatively simple strategy, called "Night Wind", investigated under EU's FP6 Project No. 020045 "Grid Architecture for Wind Power Production with Energy Storage through Load Shifting in Refrigerated Warehouses" (Van der Sluis, 2008). The "Night Wind" strategy combines the advantages of using a passive TES principle and a way to involve renewable wind energy when meeting the electricity demand of cold stores on a local, regional or Europe-wide level. As discussed further in this section, similar strategies have been applied outside of Europe as well.

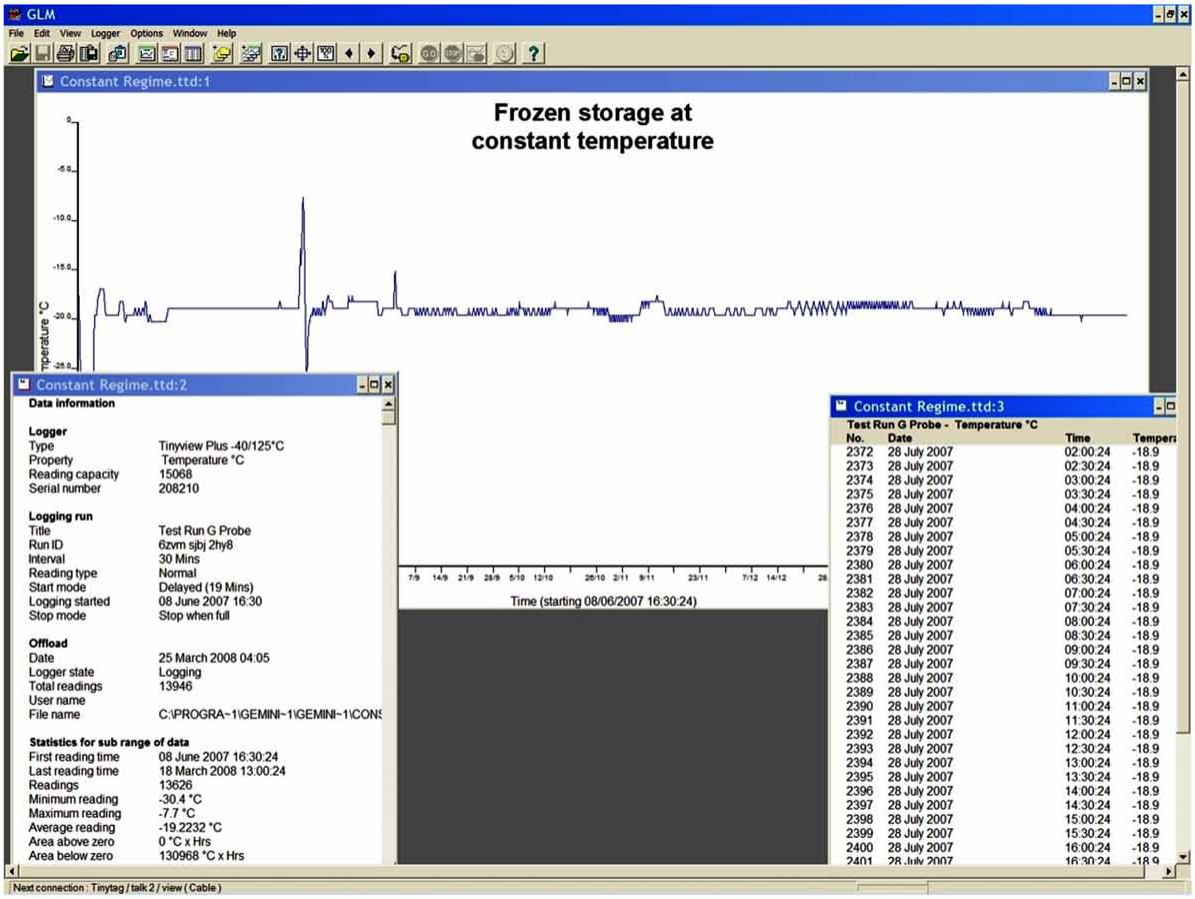
Table 7. Electricity saving strategies for refrigerated storage (Estrada-Flores, 2010)

Electricity Saving Strategies	Temperature-Related Heuristics For Quality Preservation
For Frozen Products	
• Peak avoidance techniques • Sub-cooling of the warehouse during weekends • Intelligent matching of load (variable and fixed compressor's capacity) • Adaptive defrost	• Peak avoidance and sub-cooling techniques should maintain product temperatures within –8 and –25°C
For Chilled Products (Dedicated Storage)	
• Peak avoidance techniques (see heuristics) • Intelligent matching of loads	• Sub-cooling to temperatures below 0°C is not recommended for horticultural products (or others susceptible to freezing damage) • Sub-cooling to –2°C can be well tolerated by some dairy products (e.g. milk, butter, cheddar cheese)
For Controlled Atmosphere storage	
• Increasing evaporation temperature above the recommended storage temperature is a possibility (see heuristics)	• Tolerance of commodities to temperatures above the recommended storage temperature needs to be investigated experimentally. No temperature tolerance guidelines have been fully established for controlled atmosphere storage

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

The "Night Wind" Concept

Distributed renewable energy resources (such as wind and solar energy) have a substantial potential for energy supplies and reducing CO_2 emissions but have been difficult to integrate so far because of their intermittent contribution. The integration of wind power into the nationwide and transnational energy supply systems becomes more complicated with increasing the production capacity of installed wind turbines, because of the mismatch of supply and demand of energy. The wind energy is generated at random times, whereas the energy use pattern shows distinct demand peaks during day time and office hours, and low consumption during the night. Refrigerated warehouses are constant power consumers (day and night), where electricity is converted by the refrigeration plant into thermal energy. The use of a refrigerated warehouse for storing renewable wind energy affords economic benefits resulting from the cost difference between low and peak-hour electricity tariffs and permits to offset undesirable demand peaks in the electrical grid (Van der Sluis, 2008; Fikiin, 2011; Fikiin, van der Sluis, Paraskova, Iserliyska, & Tsokov, 2009, 2010). Energy is stored by producing more cold than necessary (thereby refrigerating the products below the prescribed temperatures), while turning off the refrigeration plant releases virtual energy matching the difference between the average and the zero cold store demands, thus letting foods warm up back to the recommended temperatures of storage. For example, if the temperature of stored frozen products throughout the European Union is permitted to vary by 1 °C only, all refrigerated warehouses can act as a giant battery on the grid – they could store twice the EU's wind power production, as estimated for 2010 by Van der Sluis (2008). Refrigerated foods themselves are thereby used for passive TES as accumulators of cold (Fikiin *et al.*, 2009; Fikiin, 2012c). In particular, frozen foods are thus employed as a phase-change material (Fikiin, 2011, 2014). While balancing wind power production by fossil fuel power generation is inefficient, such balancing by refrigerated warehouse load management is a sustainable (environmentally friendly and cost effective) alternative with reduced running costs for the cold chain operators (Van der Sluis, 2008; Butler, 2007; Fikiin, 2011).



Quality Attributes of Frozen Foods Undergoing Temperature Fluctuations (Freeze-Thaw Cycles)

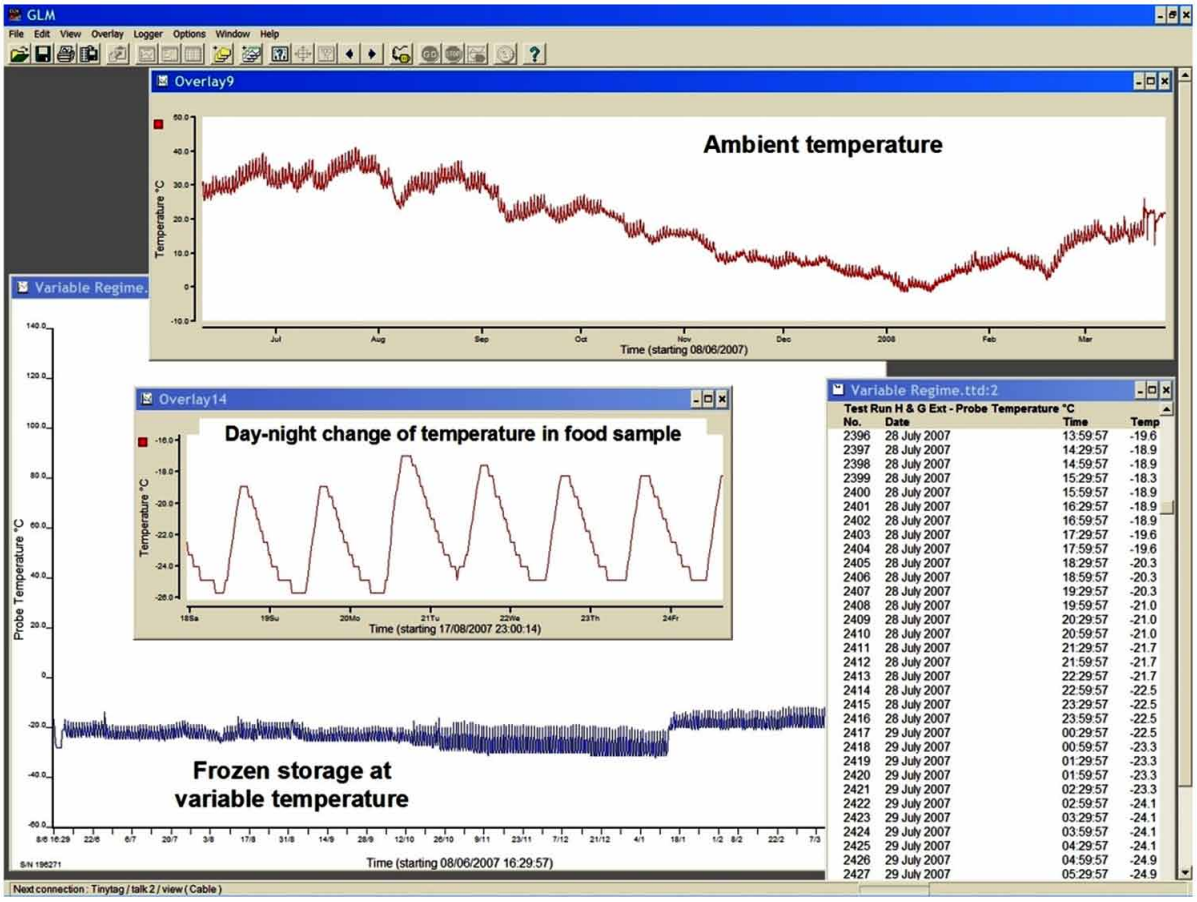
Special attention is to be paid to the refrigerated food quality as affected by the "Night Wind" technology. For that purpose, quality attributes of selected frozen foods undergoing temperature fluctuations (freeze-thaw cycles) have been investigated. Parallel tests have been conducted with 10 different food samples of identical type, shape and size, stored during 8 months at constant and variable temperature regimes (Fikiin, 2011; Fikiin *et al*., 2009, 2010). The samples – meat (bacon), fish (smoked Mackerel fillet), bakeries (fruit pie), fruit (strawberries), vegetables (tomatoes, melons and peppers), potatoes (blanched/semi-grilled French fries) and ice cream have been wrapped in plastic bags and boxes, evacuated and frozen at a constant air temperature of –19 °C as well as at a variable temperature (with day-night cycles) ranging from –16/–18 °C down to –26/–28 °C, as shown in Figure 18 and Figure 19 (Fikiin, 2011; Fikiin *et al.*, 2009, 2010).

After 3 days, and 2, 4, 6 and 8 months of frozen storage, the samples have been thawed in air ambience up to a temperature in the product centre of 20-22 °C. Thus, a number of quality attributes have periodically been evaluated – texture (by penetrometric measurements), colour (by the method of Gardner) and drip losses. Sensory evaluation has also been carried out (with the aid of a taste panel) to estimate the

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 18. Frozen storage at constant temperature (classical)

product appearance, colour, flavour and consistency. Data obtained have been summarized in the form of tables, graphs and predictive equations (Fikiin, 2011; Fikiin *et al.*, 2009, 2010).



This study revealed that the quality of frozen products, subject to fluctuations of storage temperature, is generally acceptable but, as expected, inferior in comparison with food maintained at a constant temperature (in compliance with the established food refrigeration standards and good practices). However, for many products this quality decay is rather negligible and can be offset by the obvious economic and sustainability-related advantages of the "Night Wind" technology (Fikiin, 2011; Fikiin *et al.*, 2009, 2010). In that context, potatoes (French fries) appeared to be the most robust "Night Wind friendly" product (Fikiin, 2011; Fikiin *et al.*, 2009, 2010).

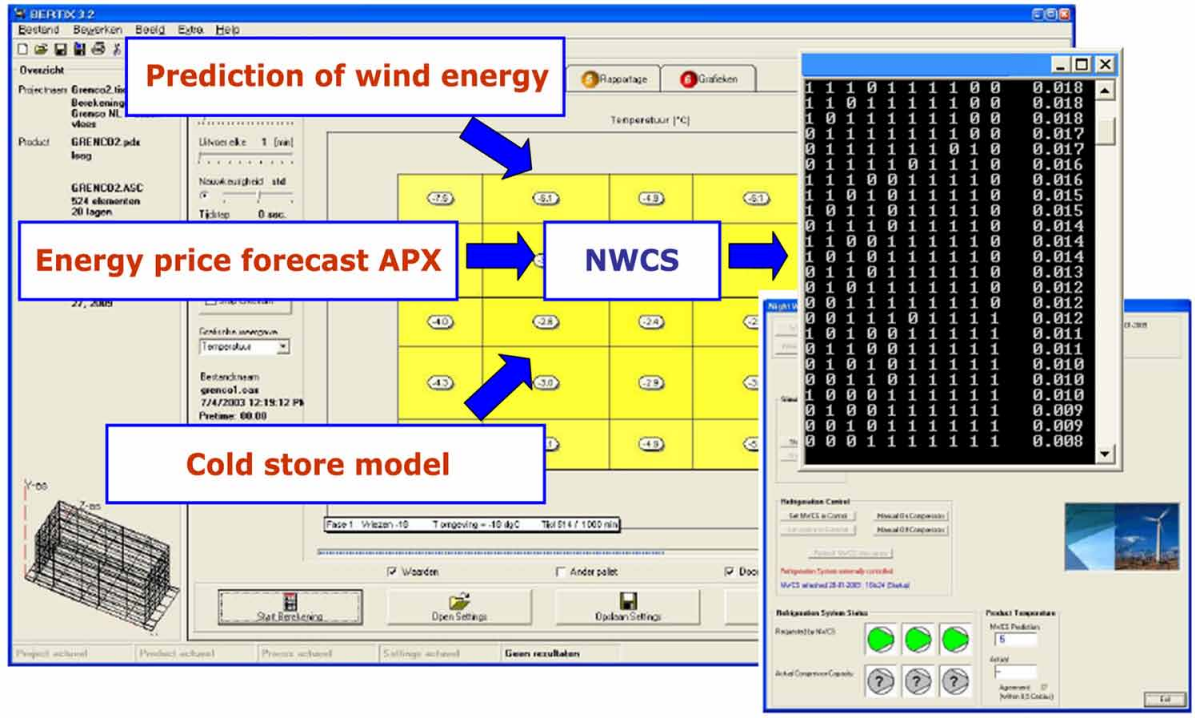
Decision Support and Automated Control

The "Night Wind" concept needs optimal strategies for fine control of the cold store operation, based on economic criteria, e.g. balance between the instantaneous wind energy production and actual electricity demand, predicted dynamic/stochastic variations of electricity tariffs on the stock market, etc., along with engineering and food quality requirements. For that purpose, a control system (Figure 20) has been

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 19. Frozen storage at variable temperature (Night Wind)

created to manage in real time wind power integration, depending on the store's refrigeration demand, the intermittent availability of wind energy, the variations of electricity prices as per a stepwise subscription plan or in a stochastic manner on the stock market, and other factors (Van der Sluis, 2008; Fikiin, 2011).



The control system can serve: (i) as a decision-support information system to assist the cold chain operator when taking decisions on the most profitable pattern of energy use, or (ii) as an expert system embedded in the hardware and software for fully automated control of the store.

Economic Benefit and Precautions

The "Night Wind" temperature control strategy has been demonstrated at the store of Partner Logistics BV at Bergen op Zoom, the Netherlands – one of the largest frozen food stores in Europe (for 680,000 pallets). This refrigerated warehouse stores basically French fries, whose quality remains almost the same after daily temperature fluctuations and freeze-thaw cycles. Van der Sluis (2008) reported a very substantial real profit from implementing the "Night Wind" technology at this facility. Other pilot projects following the concept behind "Night wind" have also been started. Curry (2010) reports application in a 155,742 m^3 refrigerated warehouse in Cuxhaven, Germany used to store frozen fish at –20°C.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 20. The "Night Wind" control system (Adapted from Van der Sluis, 2008)

Another example is the SnoTemp Cold Storage facility in Albany, Oregon used for storing blueberries (Scruggs, 2013). The EU-funded "e-harbours" project has also examined this strategy for cold stores in the Antwerp and Hamburg harbours. An interactive simulation which visualizes the concept is available online at: http://eharbours.eu/simulation/.

Implementing the "Night Wind" technology for passive TES should be made with extremely high attention, care, due diligence and compliance with the established food standards and regulations. Small inaccuracies might badly damage the stored produce. The best approach is to seek professional advice of competent food technologists, food refrigeration experts or to approach directly the "Night Wind" coordinator (http://www.nightwind.eu). Many delicate products are not at all suitable to endure temperature fluctuations, so that a careful and detailed in-situ examination of each specific product is needed before any dangerous industrial exercises with large quantities of expensive produce.

POLICY INSTRUMENTS IN SUPPORT OF RENEWABLE ENERGY INTEGRATION

Policy instruments are a type of leverage that governments and other public authorities often utilize to improve the competitiveness of renewable energy developments, as the latter are often capital intensive and require some form of support in order to become economically efficient. Cold store operators can benefit from such policy instruments when integrating renewable energy sources in their energy supply. The most common policies in support of renewable energy developments are described below, including examples of implementation of such policies in some countries. REN21 (2013) reports that, as of early

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

2013, policy instruments in support of renewable energy are in place in 127 countries worldwide. A summary of different types of policies enacted by some of the countries is given in Table 8 (where the acronyms in the headers denote different policy instruments described further in this section).

Detailed up-to-date information on active policies in different countries can be found online at: http://www.res-legal.eu/ (for the EU), http://www.dsireusa.org/ (for the USA), and http://www.iea.org/policiesandmeasures/renewableenergy/ (worldwide).

Regulatory Policies

Feed-In Tariffs

Feed-in tariff (FIT) schemes provide renewable energy producers with long-term agreements, usually with duration of 10-25 years, which typically involve guaranteed access to the power grid and oblige electric utilities to purchase electricity, generated by eligible renewable sources, at specified prices for every kilowatt-hour (kWh). The price can depend on type of technology, project location and size, among others, but can also be bound to decline over time, in track with expected reductions in the cost of renewable energy technologies. Feed-in tariff schemes may also be linked to streamlined administrative procedures, which reduce bureaucratic overhead, minimize project costs and accelerate the pace of project development (Couture, Cory, Kreycik, & Williams, 2010). FITs can be designed with a fixed tariff level or as a premium over the prevailing market price of electricity.

The feed-in tariff is the most widely adopted policy instrument for supporting renewable energy developments and, according to Couture *et al.* (2010), has promoted approximately 75% of global PV and 45% of global wind deployment. Historically feed-in tariffs are considered a German model and have been the driving force behind the sustained development of renewable energy projects in the European Union, where this mechanism has been applied for about two decades, but has more recently spread to other regions, including North America, Australia and Southeast Asia.

In Germany feed-in tariffs apply to various technologies, e.g. €48.7/MWh for onshore wind developments, €110.2-159.2/MWh for solar systems, €250/MWh for geothermal systems and €60-143/MWh for biomethane, with various degressions of tariffs and additional premiums applicable (KPMG International, 2013). In France feed-in tariffs for onshore wind developments amount to €82/MWh for the first 10 years and the same or a reduced rate for the next 5 years, while tariffs for solar PV systems vary in the range of €172.7-315.9/MWh, depending on the type and size of the power plant, €200/MWh for geothermal systems and €81.2-133.7/MWh for biogas (KPMG International, 2013). Feed-in tariff policies in the United States vary according to state. According to the U.S. Energy Information Administration (2013), state-level programs are established in California, Hawaii, Maine, Oregon, Rhode Island, Vermont and Washington, while various programs have been established independently by different utilities in some of the states, including Florida, Georgia, Indiana, Kentucky, Mississippi, New York, North Carolina, Texas, Virginia and others.

Net Metering

Net metering (NM) is a service to power consumers that are also power producers, under which electricity generated on-site and fed to the utility grid is used to offset electricity provided to the consumer by the utility during the applicable billing period. This is similar to the feed-in tariff mechanism, but the significant difference is that in a net metering program electricity fed to the utility grid is compensated at the regular retail rate at which the utility sells power to the consumer, i.e. the equivalent of subtracting the amount of electricity (kWh) generated on-site and fed to the grid from the amount (kWh) consumed from the grid and paying the remaining electricity to the utility at normal retail prices. The feed-in tariff scheme may therefore be more beneficial to a RES producer.

Renewable Portfolio Standards and Renewable Energy Certificates

Quota obligations, also referred to as renewable portfolio standards (RPS), require or encourage electricity producers within a given jurisdiction to supply a certain minimum share of their electricity from designated renewable resources (U.S. Energy Information Administration, 2012). This regulatory mechanism is typically imposed on electric utilities or producers, with a certain penalty being imposed in case of failure to comply. To facilitate compliance, often RPS schemes are accompanied by a renewable energy certificates (RECs) program.

RECs are tradable credits (usually in the form of electronic records) which represent the value of electricity produced from renewable sources not connected to the grid of the respective utility (Van der Linden *et al.*, 2005). Such programs permit electric utilities or producers, unable to meet their RPS obligations, to buy RECs from other suppliers, even when there is no physical connection (i.e. power grid) between the respective entities. Because the possession of RECs can serve for compliance and

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

avoidance of penalties, RECs attain monetary value and can be traded like other commodities, i.e. they can be purchased directly from the renewable energy producer or from intermediaries (Van der Linden *et al.*, 2005). The RPS and RECs systems are also related to the feed-in tariff system and these are sometimes used in combination.

REN21 (2013) reports that renewable portfolio standards are enacted at the national level in 22 countries, as well as in 54 states or provinces in the United States, Canada, and India. An RPS system, known as Renewable Obligations scheme, is established in the United Kingdom, whereby renewable power producers receive tradable renewable obligation certificates, i.e. RECs, the amount of which depends on technological maturity and *LCOE*. There is a penalty for non-compliance to the RPS scheme which amounted to £42.02/MWh as of 2013-2014 (KPMG International, 2013). In China a 15% renewable quota is imposed on utilities, while Norway and Sweden have established a common green certificate (i.e. RECs) market (REN21, 2013). According to the U.S. Energy Information Administration (2012), most of the states in the USA have renewable portfolio standards, among them California which requires electric utilities to derive 33% of their retail sales from eligible renewable energy resources by 2020, with an interim target of 25% by the end of 2016.

Fiscal Incentives

Governments often provide financial incentives, in the form of subsidies, grants, rebates and loans, in order to reduce or offset the installed cost incurred by the investor in a renewable energy project. Grant programs usually provide, on a competitive basis, one-time lump-sum payments that are not repayable and are often based on a percentage of the total investment costs. Rebates provide a refund or discount off the initial cost of the project, often based on the installed capacity of a system, e.g. $/kW, and are generally acquired through an application process (Lantz & Dorris, 2009). Another support mechanism is soft loans, involving below-market interest rates among other benefits, provided to RES developers. Most countries use at least some of the aforementioned mechanisms to promote renewable energy developments. For instance, in the United States various grant and loan programs are applied at the federal level, while many of the states have their own rebate program.

Tax incentives in the form of tax deductions or tax credits are another popular mechanism. Tax incentives can be based on the amount of investment or production and may include: exemption of investments in renewable energy projects from income or corporate taxes, exemption of RES from energy taxes, tax refunds or lower VAT rates for renewable electricity and other stimuli (Van der Linden *et al.*, 2005). Tax incentives are similar to rebate programs, but the main difference is that they only reduce tax liability and therefore have a less direct impact. Tax incentives are a widespread policy adopted by many governments. For instance, a number of tax incentives related to renewable energy are available in China, including reductions in corporate income taxes and VAT (KPMG International, 2013). In the USA investment and production tax credits are enacted at the federal level. According to the North Carolina State University (2014), as of 2013 renewable electricity production tax credits vary in the range of $11-23/MWh, depending on the renewable source and generally apply to the first ten years of operation, while investment tax credits amount to 30% of the investment costs for solar, fuel cell and small wind installations and 10% for geothermal, microturbine and CHP installations, with limitations on maximum amount and system size.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Another less common incentive mechanism is green marketing whereby individual power consumers voluntarily pay a premium on the electricity bill to promote renewable electricity, which is subsequently at least to some degree paid to the RES producer. The scope and effect of this policy has been until now much more limited.

Public Competitive Bidding

Public competitive bidding, also referred to as public tendering (PT) or pubic auction, is a procurement mechanism whereby public authorities solicit bids for a given amount of renewable energy supply or capacity and the contract is awarded to the most competitive bid, but typically at prices above standard market levels (REN21, 2013). Electric utilities are hence often obliged to purchase the electricity at the price proposed by the winning bids and are sometimes supported by a government fund (Van der Linden *et al.*, 2005). Separate auctions can be carried out for different RES technologies. This mechanism has been used in some countries, including the United States, United Kingdom, Ireland, France and China (Van der Linden *et al.*, 2005).

POLICY CONTEXT AND POTENTIAL FOR FUTURE RESEARCH

As stated by the UN Secretary-General "New and renewable sources of energy stand at the centre of global efforts to induce a paradigm shift towards green economies, poverty eradication and ultimately sustainable development" (Food and Agriculture Organization of the United Nations, 2011). Renewable energy can be used throughout the food sector either directly to generate energy on-site or indirectly by integrating this energy into the existing conventional energy supply system. Renewable energy sources tend to be widely dispersed throughout agricultural areas. Reliable and affordable energy supply is an essential component for sustainable development (Food and Agriculture Organization of the United Nations, 2011, 2012; United Nations, 2013; European Strategic Energy Technology Plan, 2010).

Wherever good renewable energy resources are available, farmers, fishermen, food processing and preservation businesses have various opportunities to install equipment for generating wind power, solar power, micro-hydropower, etc. In the future, it may also be possible to obtain electricity from sea and ocean resources. Solar thermal, biomass and geothermal resources generated from decentralized facilities can serve for both heating and cooling. The IPCC report *"Renewable Energy and Climate Change Mitigation"* (Intergovernmental Panel on Climate Change, 2011) assesses in more detail each of these technologies and analyses their integration into existing and future energy supply systems. Issues concerning sustainable development, costs and potential revenues and supporting policies are also considered in this report (Intergovernmental Panel on Climate Change, 2011; Food and Agriculture Organization of the United Nations, 2011).

The worldwide market for industrial refrigerated storage of food, beverages and pharmaceuticals is large and constantly growing. Conventional refrigeration plants deliver temperatures in the range of –50°C to 20°C, while the refrigeration capacity of most plants commonly varies in the range of hundreds of kWs to dozens of MWs. Large electrically-driven vapour-compression refrigeration machines supply cold to a distribution network and operate with a *COP* ranging, most often, from 3 to 6 as a function of the required refrigerating temperature and other working conditions. Large cooling towers are usually employed to dissipate condenser heat to the environment. Industrial installations, using heat from

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

waste processes and RES to operate thermally-driven refrigeration equipment, become competitive with the vapour-compression systems in areas where the electricity supply is unstable. For example, solar thermally-driven refrigeration systems might employ roof- or ground-mounted, low- and medium-temperature solar collectors but very few industrial systems have been implemented and studied so far. The rising price of electricity increases the interest in solar refrigeration whose capital cost is still relatively high and prevents a wider market uptake. Further research on equipment simplification, unification and cheapening is thus critically important (European Solar Thermal Technology Platform, 2008; European Technology Platform on Renewable Heating and Cooling, 2014).

Developing of knowledge-based energy and resource management systems for improved efficiency through sharing resources (e.g. plants, conventional and RES energy, water, residues and recycled materials) and integrating multiple production units of a single company or multiple companies on a single industrial production site also represents a rather challenging research trend of multidisciplinary and cross-sectional nature (Sustainable Process Industry through Resource and Energy Efficiency, 2013). Making the cold storage sector a key player in this cross-sectorial interaction and elaborating adequate expert systems for smart automated control of refrigerated warehouses in accordance with such criteria can thus revolutionise the sector, thereby contributing to building a resource-efficient and highly sustainable economy of the future.

CONCLUSION

The opportunity for RES integration in the energy supply of cold storage facilities has often been overlooked so far, because of credible concerns over technical and economic performance, but also due to the lack of sufficient knowledge on the various engineering solutions to the problem. Although extensive information on RES applications and research for heating and power generation is available and easily accessible, studies concerning refrigeration systems are still scarce, while relevant information is fragmentary and dispersed. In order to bridge this gap, the present chapter provides a broad, albeit not entirely exhaustive, review of recent developments and ongoing research on state-of-the-art technologies for RES utilization in industrial refrigeration plants, with a particular focus on refrigerated warehouses for storage of perishable food commodities.

Presently, the RES use for on-site power generation, especially through solar PV systems, appears to have gained more ground than RES-powered thermally driven refrigeration systems, as far as large refrigerated warehouses are concerned. There is significant progress in the application of roof-mounted PV systems, due to their easy implantation and substantial government incentives. Whilst on-site wind turbines and wind parks are still rare, in a smart grid context, the proposed "Night Wind" strategy can substantially benefit both cold store operators and electric utilities.

Solar, geothermal and biogas-driven CHP and trigeneration systems are still uncommon, but recent developments and research show promising trends. Solar-driven Stirling engines are actively investigated and developed by several companies, while development of the organic Rankine cycle technology affords encouraging prospects for low-temperature solar and geothermal applications. CHP and trigeneration systems driven by biogas present a valuable opportunity for food-processing factories which generate large amounts of food wastes. Thermally driven refrigeration systems need further improvements in order to become technically feasible and competitive for large refrigerated facilities, but the number of pilot and research projects is growing. In general, further research is required to make RES-powered systems

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

(which are currently viable for small-scale air-conditioning and cooling applications) competitive for larger refrigeration capacities as well. In the medium term, building up of experience and increased number of market actors should significantly enhance the technical and economic performance of the aforementioned technologies.

RES-related projects are often hardly plausible to cold store operators, because of the difficulties associated with technical implementation and high initial investments. In addition, such projects need a pro-active and/or interactive approach towards the energy supply system, require increased organizational efforts and thus demand greater resulting involvement of the cold store operator. Hence, it might appear to be more comfortable for the operator just to count on its traditional role of passive electricity consumer from the utility grid, especially in the short term. Nevertheless, RES integration is a paramount trend for sustainable growth of the cold storage sector around the globe. The RES attractiveness constantly increases because of the escalating costs of conventional energy resources. While the capital costs for initial investment in RES technologies are comparatively high, the renewable resources are practically free in most cases, i.e. the running costs are marginal. The selection of the most appropriate RES technology for a particular industrial scenario should be based on (i) a thorough evaluation of resource potential of the concrete site, (ii) dynamic modelling and simulation, along with a comprehensive life cycle analysis of the concerned RES system, and (iii) a survey of local government policies and incentives. Furthermore, knowledge-based optimisation and accurate energy management are indispensable to ensure that the RES system is operated in the most efficient manner.

ACKNOWLEDGMENT

Part of this survey has been performed within the EU Projects NIGHT WIND (*Grid Architecture for Wind Power Production with Energy Storage through Load Shifting in Refrigerated Warehouses*, No. SES6-020045) and ICE-E (*Improving Cold Storage Equipment in Europe*, No. IEE/09/849/SI2.558301) whose support is gratefully acknowledged. The authors would also like to thank Richard Tracy, Vice President of the Global Cold Chain Alliance, and Ron Vallort, ASHRAE President (2004-2005), for their kind assistance.

KEY TERMS AND DEFINITIONS

Cold Accumulation: Preliminary cooling or freezing of a thermal energy storage medium with the aim of shifting refrigeration loads and permitting more efficient operation of the refrigeration system and/or more beneficial energy consumption patterns.

Cold Storage: Storage of perishable commodities (e.g. food, pharmaceuticals and biomaterials) in a refrigerated environment, thereby preserving their natural qualities for extended periods of time.

Cold Store (Refrigerated Warehouse): Industrial facility for refrigerated storage of foods or other biomaterials in chilled or frozen state.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Distributed Generation: Decentralized generation of electricity, involving small-scale power generation systems located at the site of consumption, often allowing the consumer to act as a producer of electricity within the power supply system.

Passive Thermal Energy Storage: Strategy for shifting the energy demand of a refrigeration system by allowing temperature fluctuations in the refrigerated warehouse thereby accumulating cold in the stored products and/or the cold store construction.

Policy Instrument: Leverage mechanism used by public authorities to stimulate certain developments (e.g. investments in renewable energy projects) in order to overcome existing barriers and achieve predefined objectives, such as increased share of renewable energy in the energy supply mix.

Renewable Source: Energy resource which is non-depletable in a reasonable time frame, because it can be replenished in a relatively short period through naturally recurring processes.

Smart Grid: Electrical grid with advanced infrastructure, incorporating sophisticated information technology and control mechanisms, to balance the generation, distribution and consumption of electricity in the most sustainable, efficient, reliable and economic manner.

Sustainable Development: Societal development which provides the mankind with the capability of maintaining acceptable living standards without causing severe harm to the native environment and irreversible exhaustion of the natural resources available to the present and future generations.

Trigeneration: Simultaneous production of electricity, heating and refrigerating output, where residual heat of a cogeneration (CHP) plant is used to run a thermally driven refrigeration system.

APPENDIX

Table 9. Nomenclature

a_1, a_2	Temperature dependent heat loss coefficients of the solar collector
A_s	Surface area of the solar collector [m^2]
CRF	Capital recovery factor
E_R	Capacity of the renewable energy source [W]
E_S	Input capacity required by / supplied to the refrigeration unit [W]
FC	Fuel costs per unit of energy input
FLH	Number of annual equivalent full-load hours
I	Total investment costs, including initial costs, construction costs and decommissioning costs
I_β	Solar irradiance [$W.m^{-2}$]
L_T	Project duration / operational lifetime of the system [years]
OM	Net annual operation and maintenance costs
P_G	Generated electrical power [W]
P_P	Power capacity of circulation pumps [W]
P_S	Required input power capacity [W]
Q_A	Waste heat rejected to the heat sink / ambience [W]
Q_C	Waste heat of the refrigeration cycle rejected at the condenser [W]
Q_E	Refrigerating capacity [W]
Q_R	Utilized residual heat of the CHP system [W]
Q_S	Supplied input heat capacity [W]
Q_{sol}	Heat supplied to the heated substance by solar collectors [W]
r	Weighted average cost of capital
T_A	Ambient air temperature / heat sink temperature [K]
T_L	Temperature of the refrigerated space [K]
T_{Ref}	Reference temperature at which the reference efficiency ηPV,R is evaluated [K]
U_L	Overall heat loss coefficient of the PV cell [$W.m^{-2}.K^{-1}$]
W	Mechanical work output of the heat engine [W]
α_r	Anticipated fraction of the Carnot efficiency that a refrigeration cycle is expected to achieve
β	Temperature coefficient of the PV cell [K^{-1}]
η_0	Zero-loss efficiency of the solar collector
$\eta_{C,rc}$	Carnot efficiency of the refrigeration cycle
η_{CHP}	Overall efficiency of the CHP system
$\eta_{el,CHP}$	Electrical efficiency of the CHP system
η_{es}	Energy conversion efficiency of the energy supply system
η_{hd}	Efficiency of the heat distribution system
η_{he}	Thermal efficiency of the heat engine

Chapter 34
Green Development:
Case of Turkey, Norway, and China

Bülent Doğru
Gümüşhane University, Turkey

Hikmet Gülçin Beken
Gümüşhane University, Turkey

ABSTRACT

The focus of this chapter is to assess green or sustainable development concept because of its increased importance throughout the world. Droughts, environmental degradation, air pollution, greenhouse gas emissions are important problems that the humankind have been facing since the Industrial Revolution. Renewable energy sources can be used to overcome these problems. The general tendency of modern-day societies is to transform traditional production techniques and development models to new renewable energy sources and also move towards to sustainable development path. Therefore, this study tries to explain current status of Norway, China and Turkey in terms of their renewable energy sources and policy implementations.

ABSTRACT

The focus of this chapter is to assess green or sustainable development concept because of its increased importance throughout the world. Droughts, environmental degradation, air pollution, greenhouse gas emissions are important problems that the humankind have been facing since the Industrial Revolution. Renewable energy sources can be used to overcome these problems. The general tendency of modern-day societies is to transform traditional production techniques and development models to new renewable energy sources and also move towards to sustainable development path. Therefore, this study tries to explain current status of Norway, China and Turkey in terms of their renewable energy sources and policy implementations.

INTRODUCTION

Nowadays it's a well-known fact that since the First Industrial Revolution (FIR) we have pumped million tons of carbon dioxide and other harmful gases into the earth's atmospheric layer to which all the living things, human, animal and plants are dependent. The negative effects of the FIR and the climate change prove that we are living in a quite fragile earth. This fragile planet has been used as a huge garbage can for many years. Industrial pollution, global warming and climate and environmental changes have now an unpredicted economic, social, and political effects on 7 billion people throughout the world. However, recently there is a growing demand towards a more green, sustainable and environmentally sensitive way of life since the beginning of twenty-first century. This demand is being supported by renewable energy sources and technological improvements. In twenty-first century, may be in a very near future, it is expected that the fossil fuels have been dominating life of humankind for many years will be replaced by energy-saving way of life in terms of consumption and production.

In the last century, especially inability to avoid the use of fuel and the petroleum based energy sources and greenhouse gasses from carbon emissions have caused the drastic changes in weather patterns never witnessed. The World's being surrendered by fossil fuels since the FIR has made our planet extraordinarily hotter and polluted today.

In addition to these destructive weather changes, the World's poorest countries have had to face many problems such as drought and famine related to the more polluted plant from many aspects. These problems made these countries more fragile than the others.

Today, some developed and developing countries, especially Scandinavian countries in the north Europe, are trying to change their production methods from traditional and harmful techniques, mostly depending on fossil fuels, to the sustainable methods based on renewable energy sources without serious damage to the nature and our planet. Furthermore, the environmental damage that is a result of fossil fuels has been taxed in some industrialized countries. For instance, in Norway contemporary generation is paying a tax for using the next generation's share from nature and environment.

Despite some international environmental regulations such as the Kyoto Protocol, and despite the increasing importance of green and sustainable development in the twenty-first century, we have not yet reached to the desired levels for the sake of our planet in terms of a clean and habitable world. It is, however, potentially seen that in the future environmental pollution based on usage of fossil fuels will face various penalties for non-compliance to the environmental regulations. The Paris United Nation Conference in 2015 represents a powerful commitment to solve the problem of raising greenhouse gas emissions, with the contributions of the action plans of both developed and developing countries throughout the world.

The rest of this chapter is organized as follows: The first part of the chapter introduces the Green Industrial Revolution; the second part is on the innovative green development. After the explanation of the green development we handle some country examples in the third part of the chapter including Turkey, Norway and China. The chapter ends with the evaluation and suggestions as concluding remarks.

GREEN INDUSTRIAL REVOLUTION

The FIR, took place in England in the late eighteenth century, was both a turning point for human history and closure of a pre-industrial production age. Before this industrial revolution, people generally used

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

to use animals and some basic materials as their economic power source. In the late eighteenth century James Watt, an English mechanical engineer, changed human history by inventing steam engine. This invention led the way to the revolution in machine base manufacturing (Clark & Cooke, 2015), and improved productivity and production volume in textiles industry with the leading of Great Britain at the turn of the nineteenth century. By the invention of this machine, production evolved from hand-based manufacturing to machine-driven industrial production. We are defining this era in terms of industrial and hence economic and transition of production method from hand made to machinery in England in 1760s as FIR. This transition made drastic changes in industrial production with the development of new machine tools and factory systems. The steam power pave the way for new chemical manufacturing and iron production processes which improved efficiency of waterpower. The coal became one of the major sources in the industrial age instead of wood and other bio-fuels in pre-industrial age. These modern production methods were first used in textile industry (Landes, 1969) and made Great Britain the most powerful country in this factory based mass production.

The Second Industrial Revolution (SIR), took place in United States of America (USA) around the end of nineteenth century, was also a turning point for human history, because an unimaginable world of machines and oil industry with the inventions of electricity by Thomas Edison and the telephone by the Graham Bell in this era revolutionized daily lives of ordinary people. Improvements in transportation systems, telecommunication centers and electrical networks required huge amounts of energy as a natural consequence of this ease in daily life. Economic and technological progress continued during the SIR with an increasing acceleration. The steam power-driven transport systems like railways, boats and ships, the mass production tools and steam-powered factories were evolved to a new characteristic with the increasing adoption of steam power[1] in almost each level of industrial production, especially improvements in the USA in this era is noteworthy.

Both the first and second industrial revolutions have made our planet hotter and smokier, caused very severe environmental problems (Clark & Cooke, 2015). Besides these problems, now our planet is overcrowded and natural resources are getting scarcer day-by-day. If the world continues consuming natural resources at this fast pace as it did in FIR and SIR, in a very near future the planet will be running out of its fossil fuels. In this context, environmental problems and scarcity of energy sources will be the first issue in the future with the increase of extra population in the world. The UN estimates that there will be around 10 billion people by 2050. Most of these people will be from less developed or developing countries, which is meaning that demand to new clothes, homes, electro mechanic tools like televisions, cars, washing and dishing machines, refrigerators, cell phones and other non-durable goods in the daily life will be likely to increase geometrically. Already, developments and demands to industrial products coming from developing countries have been increasing greenhouse gas emissions and pollution for many years.

For the very reason, a new era driven by sustainable development, mostly adopted in Asia in the 1980s, in Nordic Countries in the 1990s as well as then with the leading of Germany at the turn of the 21st Century, is named as "Green Industrial Revolution" (GIR). Some other calls this new era "The Third Industrial Revolution" (TIR). Green energy-driven production methods, innovative smart green technologies and public sensitivity toward the environment (Clark & Cooke, 2015) are fundamental characteristics of this new era, and it is gathering steam across the globe. According to Rifkin (2011), "We are on the cusp of a new energy era and a new economic paradigm that will literally empower hundreds of millions of human beings to create their own energy and share their surpluses with neighbors across regions, nations and continents. The democratization of energy gives rise to a new 'Distributed Social Vision'

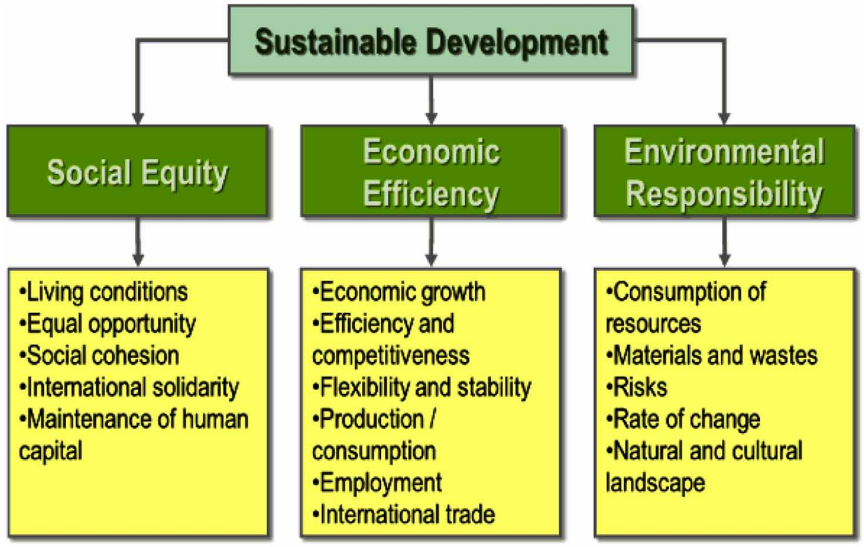
EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

in the twenty-first century that will change our economic, political and cultural institutions as dramatically as the enlightenment vision that accompanied the First Industrial Revolution two centuries ago."

It is a well-known fact and an indispensable reality that demand for clean energy, energy efficient products, buildings, homes, modes of transport and environmentally sustainable production processes will dominate our social and economic life over the coming decades. So that reason, each country has begun to develop a strategy to react to this new era that has already created a new market around the world. The countries leading this transformation from SIR to GIR will increase their benefit enormously in terms of both a healthier life and an economic return. Breathing a healthier air, drinking clean water, economic expansion in the forms of new markets, new jobs, value added products and huge profits are only some of these benefits that a leading country can own in a very near future. In addition to these benefits, the countries that lead this green revolution on the time will also dominate the second half (maybe the first) of the twenty-first century both economically and politically. On the other hand, countries ignore this transformation will be called Luddites[2]of this century (Gordon et al., 2013).

It has been predicted that a greener planet would stipulate sustainable development all around the world since the twenty-first century. Sustainable development depicted in Figure 1 is a complex concept and determined by three main and many sub-main issues. These important pillars are environmental responsibility, economic efficiency and social equity. Environmental responsibility is a key indicator showing capacity of environmental systems and conserving amount of recycling resources to be respected and amount of wastes to be reduced by generations. It is comprised of consumption of resources, materials and waste, risks, rate of change and natural and cultural landscape. Economic efficiency, the second component of sustainable development, is also a key parameter promoting significant improvements in the welfare populations, and is related to sustain economic growth, maximizing profits and expanding the markets. Economic growth, efficiency and competitiveness, flexibility and stability, production/consumption, employment and international trade are sub-titles of this component. The social equity, the third issue, is related to satisfying the diversified needs of population such as food, health and education that are among the essential requirements. Social equity involves living conditions, equal opportunity, social cohesion, international solidarity and maintenance of human capital. Besides these three issues, World Bank also suggest nearly 150 indicators to assess the sustainability, they fit them into five major categories:[3]

1. Energy and air quality,
2. Water, materials and waste,
3. Land and biodiversity,
4. Transportation and livability,
5. Human amenities and health.



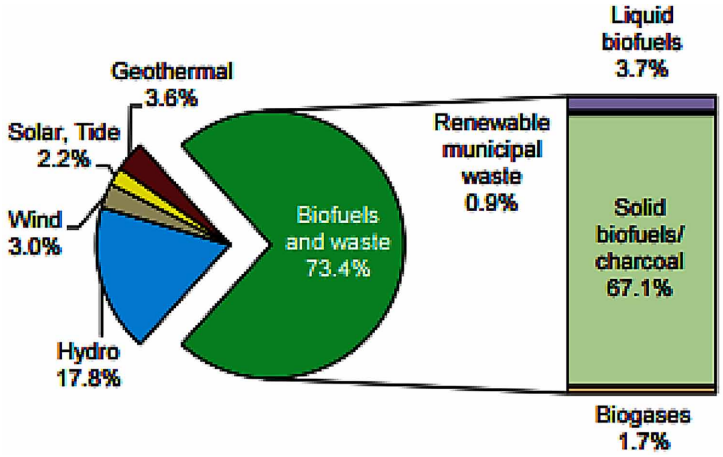
These indicators are also mentioned under the three main determinants of sustainable development in Figure 1 as mentioned before.

Recently, there has been a widespread support for the drastic increment in energy efficiency and change in energy use from fossil fuels to renewable sources (Flavvin & Lenssen, 1994). A renewable source is seen as a key and efficient solution to the environmental problems we face today. That is why it is believed that sustainable development will rise on the shoulder of renewable energy sources.

There is a cause and effect relationship between sustainable development and renewable energy, because renewable energy has been a key parameter in the long run life of a country since fossil fuels tend

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Determinants of sustainable development
Sources: https://people.hofstra.edu/geotrans/eng/ch8en/conc8en/3es.html; Swiss Statistics (2002), Measuring Sustainable Development, Insights into MONET, Neuchatel.



to exhaustion. For instance, the greenhouse gas emissions depending on fossil fuels have higher costs but no benefits for humankind and are related with the unsustainable development (Manso & Behmiri, 2013). Moreover, human beings have been aware of the severe consequences of the traditional energy sources including environmental problems, global warming and climate change that will give damage to their daily life in a near future if a switch to renewable energy is not made in a short time. This led humankind to use renewable energy sources like solar, wind, geothermal, hydropower and wave power[4]. Economic development depends on these alternative energy sources will also be sustainable, because we know that a long run growth is likely to be sustainable if it is not related to fossil fuels. Renewable energy sources mostly based on clean and safe sources, maintaining new resources for the next generations have been a fundamental determinant of sustainable development for nearly thirty years. Hence, exchanging fossil fuels with renewable energy sources or reducing fossil fuels' dependency in buildings, industrial and agricultural sector (Manso & Behmiri, 2013) may decrease growth rate of economy in the short run, but it will promote a healthy economic life to the residents in the long run. Nevertheless, renewable energy share of global final energy consumption in 2009 is only 16.2%. The remaining energy is provided from fossil fuels (81%) and nuclear energy resources (% 2.8) (Renewable Report, 2012). Figure 2 below represents the share of renewables in world energy supply. According to International Energy Agency (IEA:2015) report, biofuels represent the largest renewable energy source in the World renewables energy supply for the year 2013. Hydro-power energy ranks as the second largest energy source with the ratio of 17.8%. The share of other renewables, however, such as geothermal, solar and wind energy are still low in comparison with bio-fuels and hydro-power, so, they do not have equal share and weight in use and supply overall.

These numbers are significant to evaluate the place and importance of the renewable energy sources for societies and countries throughout the world. However, it should be kept in mind that there are important barriers in order to invest in renewable energy sources. Because investments in the energy sources

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Product shares in world renewable energy supply (in 2013)
Source: International Energy Agency, IEA Statistics, Key renewables Trends: Excerpt from renewables Information, 2015, p.3.

are always related with the competitiveness of the energy source, the price structure of renewable and traditional energy sources are significant. The tension between these two markets clearly affects the share and the intensity of each source considerably. Investments in renewable energy sector can also be seen as a new way in our modern societies to maintain energy security of the country. Also, this newly improving field will affect the job creation and increase the growth of country along with its local and national development path. Therefore, the government regulations and implementations both on prices and incentives will be decisive on the plans and investments of private business (GWEC:2014). It is obvious that there are some barriers coming from the government policies on price and incentives, and undeniable contributions to energy security and economy in general.

In this context, The Kyoto Protocol, agreed on in 1997 and seen as a key strategy for reducing greenhouse gas emissions, is accepted as a declaration of using renewable energy throughout the world (Kaygusuz & Kaygusuz, 2002). Renewable energy sources such as solar, hydroelectric, biomass, wind, ocean and geo-thermal energy have many environmental benefits but no cost to the nature when compared to the fossil fuels. The level of greenhouse gas emissions and amount of liquid pollutants of these renewable energy sources is near zero (Boyle, 1998). Energy provided from renewable sources constituted an estimated 19% of global final energy consumption in 2013. Table 1 presents world final consumption of both fossil fuels and renewable energy sources from 1970s to 2030s. What is seen clearly in table is that World's primary energy demand will raise about 60% from 2002 to 2030, meaning that yearly increase will reach to 1.7%. Nonetheless, this yearly growth rate is less than over the past three decades. Therefore, fossil fuels will continue to be the main energy supply source in the near future. The share of renewable energy resources will remain at around 14% (Bilen et al., 2008).

In order to emphasize the current tendency in the regions all over the world, Figure 3 represents the share of renewable energy in total energy supply based on the World regions. It is obvious that the share of renewables in total primary energy supply has increased in each region which is a clear sign of the importance of the renewables. By all means, there are significant differences between regions. For instance, the OECD area has 9% of renewables that indicates a relatively smaller share in comparison with the share of China such as 10.7%.

THE GREEN DEVELOPMENT IN TURKEY

The green development in Turkey is mostly related to renewable energy sources. The number of academic studies, however, concentrating on the issue of green or sustainable development is less than those in the developed countries. Of the remaining few studies on sustainable development focus on the long run equilibrium of saving and investment, and carry out their impact on GDP growth rate and foreign debt. Sancak and Demirci (2012), Çetinkaya and Türk (2014) and Şanlı and Aksöz (2014) are three of these studies investigating the effect of domestic savings on GDP growth rate and foreign debt for different

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

time periods. The results of these studies suggest that a sustainable development can be achieved with the help of higher domestic savings and less dependency on foreign debt. In this study, however, we are focusing only on some parameters of renewable energy sources in terms of green development in Turkey. In this part, we are firstly depicting a general situation of all renewable energy sources in Turkey, and then concentrating on solar, wind, hydro and geothermal energy sources.

Need to clean, domestic and renewable energy is commonly accepted and seen as a key parameter of long run economic life in Turkey as well as all over the world. Turkey is supposed to build its sustainable development on renewable energy sources because geographical location of Turkey brings many advantages for using renewable energy sources. Three seas, namely the Aegean Sea located to the west, the Mediterranean Sea located to the south and the Black Sea located at the north, surround the country. The average rainfall is about 650 mm, and the annual temperature varies between 18 and 22 degrees Celsius. At the coastal areas of Turkey a typical Mediterranean climate is predominant, whereas at the interior and particularly at high places from sea level show arid and conventional climate characteristics. Benefiting from renewable energy sources in Turkey to reduce greenhouse gas emissions and climate change mitigation should be a necessity not an option due to its geographical location (Bilen et al., 2008). Turkey possesses all kinds of energy sources but these resources are restricted and limited. That's why Turkey is an absolute energy importing country in the world (Kaygusuz & Kaygusuz, 2002).

A high dependency on fossil fuels and growing energy demand make it crucial for Turkey to invest in renewable energy resources. Hydro, wind, solar, geothermal and biomass and biogas are fundamental renewable energy resources of Turkey. The total share of renewable energy in primary energy supply in Turkey is only 6.3%. The economic potential, however, of installed capacity for hydropower, wind and geothermal is only 40%, 9% and 19%, respectively (see Table 2). It is clear that Turkey should expand this potential to a higher level (Bölük, 2013: 156-157).

Table 3 presents the production of fossil fuels and renewable energy sources of Turkey between 2002 and 2011. It is clearly seen that renewable energy supply increased to 7 million tep in 2011 from 3.7 million tep in 2002, and the share of renewable energy sources in total energy supply increased to 6.1 in 2011 from 4.8 in 2002, namely approximately an 87 percent increase took place in 9 years. Such an increase may be not underestimated but this amount of renewable energy production is not sufficient to mobilize the potential of the Turkey. This statistics shows that renewable energy production is still at a negligible level in Turkey (Aydoğuş, 2013).

Table 2. The situation of renewable energy in Turkey

Type of Energy	Technical Potential (MW)	Economical Potential (MW)	Installed Capacity (MW)
Hydropower	54,000	42,000	17,137

Table 4 indicates the consumption of fossil fuels and renewable energy sources (water, wind, solar geothermal) of Turkey in 2011. Renewable energy consumption is also at the negligible level as well as its production. Water based energy (hydraulic) consumption is at the first order among these renewable energy sources. Although Turkey has a big potential for producing renewable energy sources, it has not been yet realized. The production (Table 3) and consumption shares (Table 4) of the geothermal, solar and wind energy sources are near zero. Especially in industrial and in transportation sectors, Turkey has not yet benefited from solar, wind and geothermal energy sources (See Table 4).

Final energy consumption, estimated for Turkey up to 2030, is shown in Table 5. It is indicating that primarily energy need will continue to be provided from fossil fuels up to 2030 as well as the rest of the world. Total consumption will increase to 463 Mtoe in 2030 from 152 Mtoe in 2010. It is predicted that the share of fossil fuels will decrease to 86% in 2030 from 98% in 2010. Of the renewable energy resources, the hydropower has a share with 50%, which means that half of the total renewable energy consumption will be supplied from waterpower in Turkey in the future.

Solar and Wind Energy

Solar is the oldest and most efficient renewable energy source, and has been providing energy for the life on the earth for million years. It has been accepted that human beings had begun to control solar energy since 400 BC. At those times, Socrates argued that buildings might be constructed in the north- south directions and south side of the buildings should be covered with more windows to benefit from solar energy efficiently (Kolomoyets, 2010:19, Ulu, 2014: 14). On the other hand, wind energy that is the kinetic energy of moving air was firstly used as an energy source by Paul La Cour to produce electricity in 1891. Wind energy is an indefinite energy source as well as solar, because it needs no raw materials (Bayındır, 2010: 23).

Potential of solar energy is at its highest level at Equatorial belt countries, and it is also at an efficient level in Turkey. It is technically possible to benefit from potential of solar energy throughout the Turkey except north - east part of the Black Sea region. Table 6 shows annual sunshine duration and potential of solar energy of each region in Turkey. Especially southeastern Anatolia region and Mediterranean region have comparative advantages in terms of both solar energy potential and sunshine duration time. Table 6 indicates that the overall potential of solar energy resource of the Turkey is around 9121 kWh/m^2 per year.

In Turkey, June and December are the months that solar energy could be produced more and less, respectively. Turkey could benefit from this energy sources more than average 2000 hours per year depending on its geographical advantage (Ayhan, 2010: 171). There are 96 solar energy plants in Turkey (Ulu, 2014: 14), and according to the statistical data of the EIE-General Management of Renewable Energy board of Turkey- the average annual sunshine duration in Turkey is 2640 hours, i.e 7.2 hours in a day; the total intensity of radiation is 1311 kWh/m2-annual, i.e 3.6 kW/m2 a day (ITU Report, 2007: 93).

Wind power is also an important renewable energy resource in Turkey. Figure 4 presents cumulative installations for wind power plants in Turkey. It is clearly seen that there is an increasing trend on installation of new wind power plants.

The total wind power production of the Turkey has reached to 3 GW (gigawatt) in 2015, while it was only 131.5 MW in 2007. This production makes Turkey the 10th biggest country in Europe in terms

of wind power production (Hurriyet, 2015). However, this energy source cannot be stored yet so it is consumed via electricity grid. Wind energy is currently used to produce electricity in a limited number of wind turbines. The capacity usage ratio in these turbines is between 0.25-0.45. For instance, in USA even for the windiest places, this ratio is limited to 0.48 (İTÜ Report, 2007: 89-90).

When we compare the regions of the Turkey according to installed capacity for operational wind power plants (Figure 5), we see that Aegean region takes the first place with a share of 38.29 percent, and South East region is the last region with a share of 0.8 percent.

Waterpower and Geothermal Energy Sources

Waterpower is the commonly used renewable energy source, which uses the potential energy of the water, and transformed it to the kinetic energy to produce electricity. Waterpower was used to via watermill in the past, and after the technological improvements modern dams have been replaced by the watermills. The first dam constructed in Turkey is Çubuk 1 located near the capital of Turkey, Ankara (TMMOB-İMO, 2012; Ulu, 2014:20)

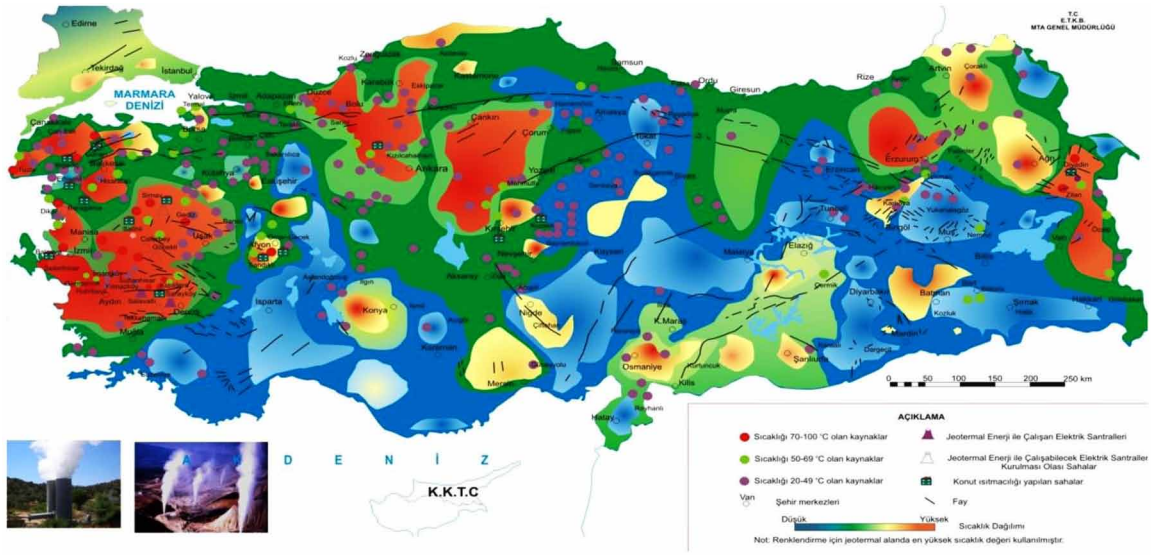
According to the report released by the Energy Market Regulatory Agency (EPDK) in 2012, 44 of the 78 installed power plants that involved in Turkey's Renewable Energy Support (YEK) mechanism are hydroelectricity power plants with a total capacity of 932.26 MWe. 22 of the rests are wind with a total capacity of 684 MWe, 8 are biomass with a total capacity of 73.4 MWe and 4 are geothermal power plants with a total capacity of 72.35 MWe. The Turkish Electricity Production Company (EUAS) owns 11,629 MW of the installed hydropower. The total MW distribution between these dams are as follow: Karakaya (1,800 MW), Ataturk (2,405 MW) and Keban (1,330 MW). In addition to the public investments, a few big private companies like Dogus Holding, Akenerji and Aksa are also active and have some investments in hydropower sector (PWC Report, 2012: 13-20).

The waterpower potential of the Turkey is around 1% of the world and 16% of the Europe. According to statistics released by Ministry of Energy in 2014, the total waterpower of Turkey is 433 billion kWh. However, only 140 billion kWh of this magnitude could be considered economically.

Another renewable energy source is the geothermal energy, stored between layers of the earth, and nowadays considered as a clean energy by almost the entire world. Geothermal energy exploration goes back to 1960s in Turkey. The first explorations focused on areas having a high enthalpy potential like Kızıldere and Germencik. Then, places having mid-enthalpy potential such as Seferihisar, Simav, Salavatlı, Tuzla, Dikili and Caferbeyli are also explored (ITU Report, 2012: 100).

On the other hand, Turkey is one of the leading countries in terms of geothermal energy source with approximately 1000 hot and mineral water sources. 95% of these sources are used for household heating

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use



(Ağaçbiçer, 2010: 125) and tourism intended thermal activities. Figure 6 depicts regional distribution of the geothermal sources of Turkey. Hot water sources are mostly located in Aegean, East and Central Anatolia. Exploration activities of new geothermal energy sources that previously only focused in west Anatolia have recently been continuing in a wide area of the rest Anatolia because of the energy demand of the household for heating. In this context, explorations in the last 7-8 years are focused and developed in Izmir-Aliaga, Ş.Urfa-Karaali, Agri-Diyadin, Kırşehir, Nevşehir-Kozaklı, Van-Ercis, Yozgat-Saraykent, Balıkesir-Bigadiç, Afyon- Gazlıgöl and Balıkesir-Havran (TMMOB-EMO, 2012; Ulu 2014: 18).

THE GREEN DEVELOPMENT IN NORWAY

Norway became one of the earliest countries following the way of sustainable development thanks to its prime minister Gro Harlem Brundtland. Although sustainable development has not been an explicit goal four country until 2003, when a National Action Plan for Sustainable Development put into forward, many government policy documents have included sustainable development as an issue should be overcame in the future. Then, an active policy has not been implemented within the framework of this national plan. Nonetheless, strategic sustainable development initiatives from 1989 to now are a phenomena in Norway. Influence of the petroleum economy on distributional politics in Norway has effected sustainable development goals negatively and prevented the implementation of the national plan. Noticing the fact of sustainable development in an early stage has made Norway one of the leading countries in the world in terms of sustainable production and consumption of renewable energy sources at home (Lafferty et al., 2007).

Figure 7 shows the results of technologies for renewable energy and some pictures taken from renewable energy sources produced in Norway. Today, solar energy, bioenergy, winds power, hydropower, ocean

energy, geothermal energy and technologies for renewable energy are critical parameters in Norwegian economy in terms of long run sustainable development.

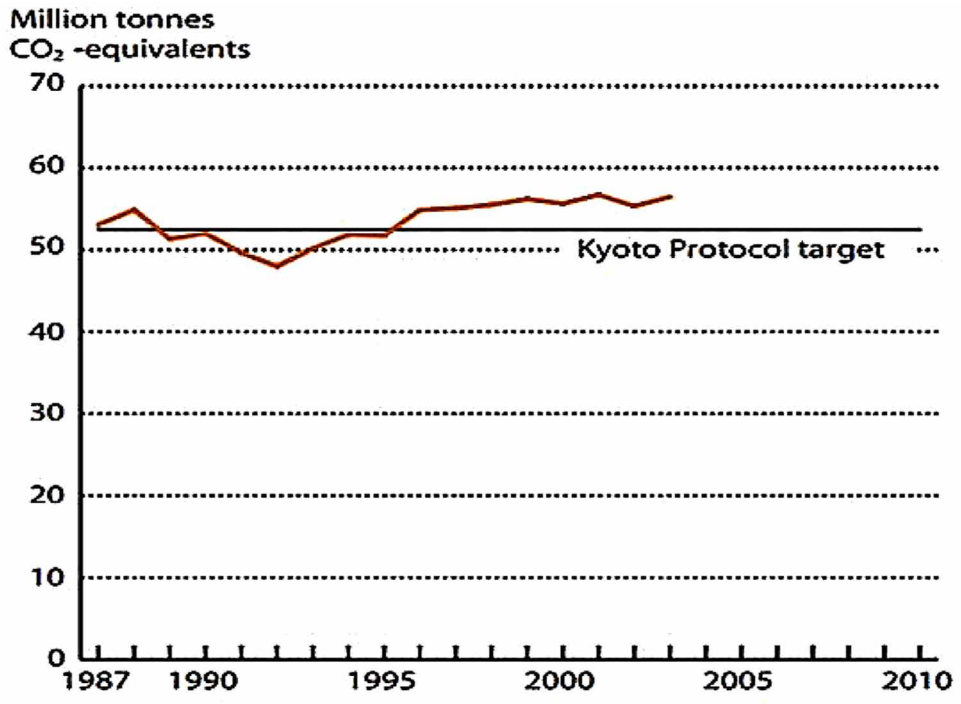
Norway is the member of European Economic Area, which tries to integrate European Union (EU) member states and European Free Trade Association (EFTA) countries.[5] The policy implementations of EU and common policy areas in EU should be considered significant when the current status and future prospects of Norway are taken into account. In this sense, the Directive 2009/28/EC or The Renewable Energy Directive of 2009[6], put forward the main targets to attain to the desired levels of renewable energy sources in share of total energy sources. By 2020, 20% of the total energy consumption of the European Community should be supplied from renewable energy sources. In general[7] the targets by 2020 indicate as of reduced greenhouse gases by 20%, getting 20% energy purely from renewable energy sources and also to increase the energy efficiency by 20%.

The main characteristics of Norway energy market is summarized as lowness in electricity price, wealth of hydro-power and finally large reserves of oil and gas (Scarlat et al., 2011: 3389). In the work of Gullberg (2013), the possibility of Norway to be a "green battery" of Europe is questioned based on renewable energy sources. What is expected to be a green battery is that the hydro-power resources and reservoirs of Norway can contribute to reach to the renewable energy targets of Europe but the findings based on different scenarios emphasize that this could happen only in the long term.

It should be kept in mind that Norway has already achieved to attain a low carbon electricity system by using hydro-electricity (Gullberg et.al.; 2014: 216).This condition might affect the policy implementation of the country and the decisions that will be given how to cooperate with other countries. For instance, there is a coordination between Sweden and Norway in order to support renewable electricity by using green certificates in this field (Blindheim; 2015:208). This cooperative action can be seen as a way to realize both the local targets and EU directives. With the cooperation of Norway and Sweden, it is expected to have 13 terrawatt hour (TWh) new renewable power product by year 2020 (Trømborg, 2015).

The shares of wind, hydro and biomass energy in total renewables can be seen as 1.3%, 88.7% and 10% respectively (EUROSTAT). This indicates that Norway has an advantage with its vast and rich renewable

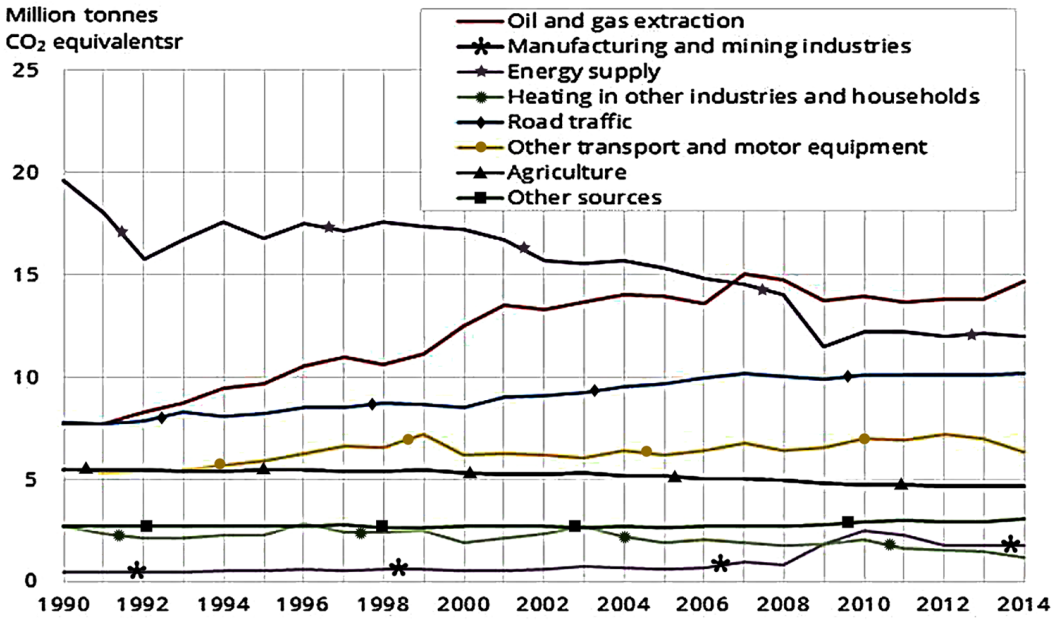
EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use



energy sources such as wind, solar, bio-energy, wave and tidal energy from the ocean (RENERGI, Work Programme 2014-2015, p. 13). As one of them, the offshore wind capacity of the country is 2 MW in 2013 and same for the end of 2014. In this context, the Joint Electricity System between Norway and Sweden can be seen as a way to strengthen the use of wind energy as a renewable source (GWEC, 2014).

Figure 8 shows the greenhouse gas emission (GHG) in Norway by comparing the level of GHG emissions with the Kyoto target. The adopted renewable energy sources have an impact on GHG emissions which is negatively related with the climate change. The emission of GHG is higher than the Kyoto Protocol target level since the middle of 1990's till 2005 (Ministry of Finance, 2005). In 2014, the GHG emission in Norway is 53.8 million tonnes of CO_2 equivalents. If the year 1990 is accepted as a reference year according to the Kyoto Protocol, annual GHG emissions were 52.0 million tonnes, and the increase in annual emission is around 3.5%. When the main contributors wanted to be found, the most contribution to the GHG emission is done from oil and gas extraction by 27% (14 million CO_2 equivalents) based on the preliminary results in 2014. Manufacturing industries and mining sectors are ranked as the second by 12 million CO_2 equivalents based on preliminary numbers. (Statistics Norway, n.d.)

Figure 9 shows the GHG emissions based on the source. Oil and gas extraction comes at first ranking and shows an increasing trend since 1990's. In comparison with oil and gas extraction, the contribution of heating and energy supply to GHG emission is relatively low. (Statistics Norway, https://www.ssb.no/, accessed 11.10.2015)



In the document titled "The Government's Environmental Policy and the State of the Environment in Norway (2004-2005)" (The Norwegian Ministry of the Environment, 2005) the problems of the environment across the world in general and particularly in Norway were emphasized as climate change,

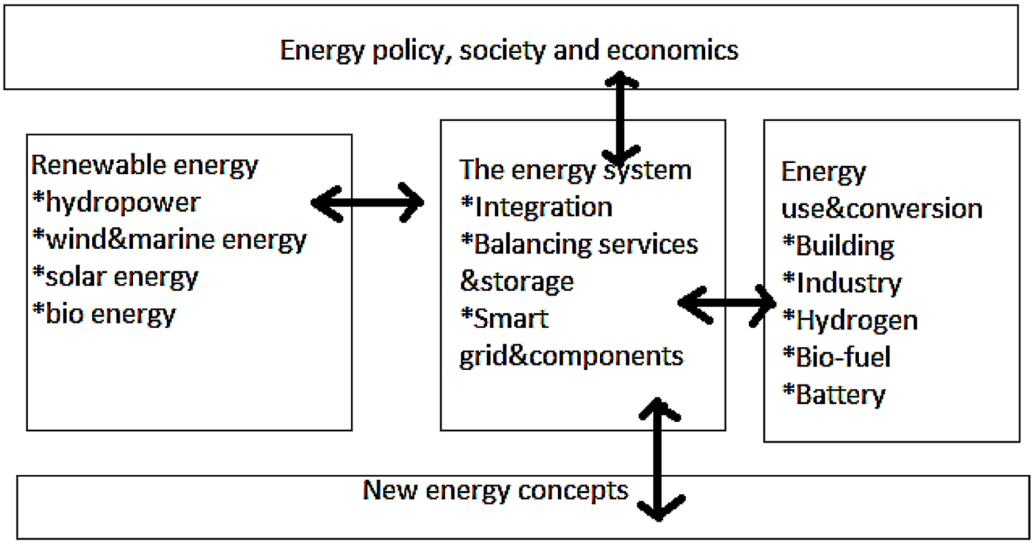
hazardous waste, emissions and the difficulty to come over the pressures on biodiversity. This document is a clear sign of the awareness in adopting policies to solve the environmental problems on the governmental level.

In this manner, National Strategy for Sustainable Development[8] and National Action Plan for Sustainable Development[9] are the examples of country's commitment to the sustainable development. Both of these documents and the following documents are adopted in order to represent the importance of sustainable development goal. The Rio Earth Summit and Johannesburg Summit in 1992 have all effect on these plans to be created as a part of global action. They both show the role and participation of public sector and the other actors to achieve this goal. The acceptance of inseparability of environmental policy and sustainability can be found in the plans. Also, using collective actions/measures are strongly recommended in the plans. The emphasis is to attain a development approach which is sustainable as economically, ecologically and continuously.

Norway implemented RENERGI (clean energy for the future) programme starting the year 2004 till 2012. RENERGI programme was replaced by ENERGIX programme in 2013. The main purpose of RENERGI programme was to manage the energy sources efficiently and conduct sound energy policies which were in harmony with environment on national level, and also to have a competitive energy sector without neglecting international cooperation (The Research Council of Norway, 2007). These programmes have both short and long term perspectives. Some research and innovation projects were supported in order to constitute energy efficiency within the concept of country's energy policy by increasing the public awareness (RENERGI, 2005).

In this context, ENERGIX programme can be seen as a way to continue to the clean energy strategy of the country. The main framework of the programme is to use and consume renewable energy sources



EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

efficiently; to have reliable energy supply; to reduce GHG emissions; to enhance and strengthen the knowledge and innovation of restructuring energy system of the country in the long run. The prioritized areas can be found in Figure 10 (The Research Council of Norway, 2013:1).

The efforts of each country as keeping rise in the temperature below a specified level or to use clean energy can be seen easily with the international agreements and conferences such as Kyoto and United Nations Conference on Climate Change. Each country has their own national action plans in compatible with global targets. A country can get benefit by coordinating or cooperating with another country in the field of energy and environment. As the case studies of this chapter, the collaboration between China and Norway are mentioned. The bilateral cooperation or collaboration between China and Norway have several undeniable opportunities for both countries. From Norwegian side, it is well known that the China has a big and growing potential of markets in the field of new renewable energy sector. Thus, it is an area to invest and to use the experience that have gained so far. This collaboration can be seen such as government to government cooperation, university/research institutes cooperation, technological research, and the financial and technical support to Research & Development (R&D) activities (Delman & Chen, 2008:ii). There are some challenges, however, that can be found in difference at scale and coordination. Norway can take the leading position but it should be kept in mind that standing alone, Norway has not the power and weight like international organizations or integrations such as European Union. Lastly, due to the numbers of actors that want to participate this process, a competition arises between national area of Norway (Vik & Smith, 2008).

The international cooperation of Norway regarding renewable energy sources is not with China but also with other countries such as India, Indonesia and South Africa in order to cut the greenhouse gas emissions. The role of Norway here is to transfer technology and make investments by using its expertise and experience (Norwegian Ministry of Environment; 2006-2007).

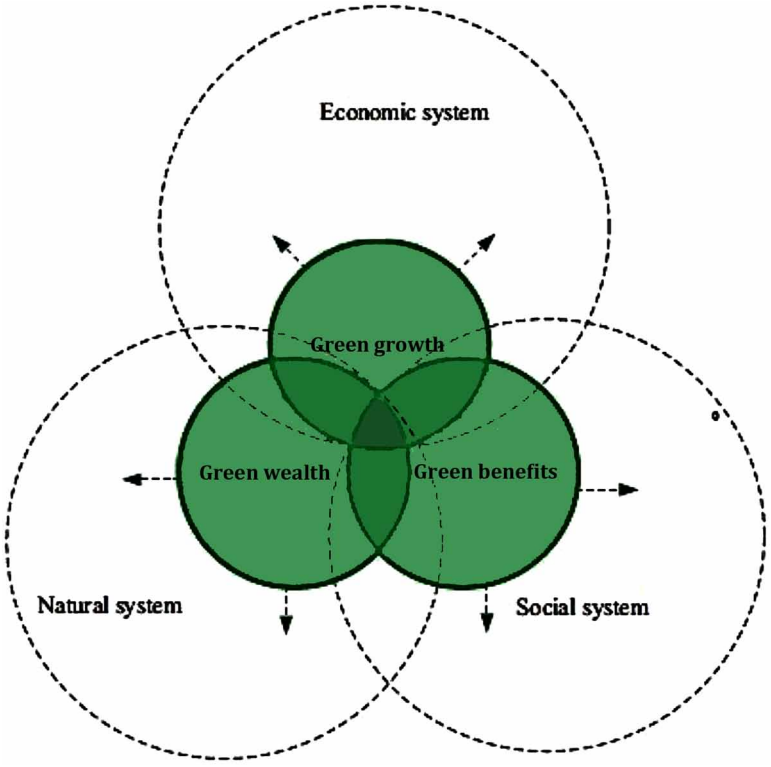
THE GREEN DEVELOPMENT IN CHINA



China deserves a special interest because of its leading position in the world economy in terms of industrial production. The growth trend of the country has been increasing and also is decisive for the performance of the global economy. The pressure to industrialize and to keep high scores of growth also affect the environment of the country and the world as well. The nature and the environment are accepted as our common property resources. Therefore, the policies taken by each country have an impact of our future. In this section, the past and current status of China will be evaluated based on environment and energy.

The concept and the theory of green development in China are considered from a perspective of three forces:

1. Harmony of nature and mankind,
2. Marxist approach to nature,
3. The existence of sustainable development reality (Hu, 2014:16).

This figure represents the systemic structure of green development. Green development is strictly and closely related with economic, natural and the social system of the related society. It also shows us that the concepts of green growth and green development are inseparable. These three dimensions affect each other and also are affected from each other. So, one policy implication in one dimension will

Figure 11. The relationship between three "green" concepts
Source: Hu, 2014:39.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

be decisive for the other dimensions. However, the meaning of green growth has expanded over time, it affects overall production. This effect comes from the adaptation of the production system to the environmental, resource-saving processes and structures (Jänicke, 2012:14).

The history of green development in China consists of four different stages:

1. Pre-1949 period was heavily dominated by an agricultural society characteristics and was also influenced by the Confucianism and Buddhist tradition.
2. 1949-1978 period with the increasing importance of economic growth, witnessed an important urbanization and industrialization process.
3. 1978-2004 period was also labeled not just its rapid urbanization and ongoing economic growth, but the negative outcomes such as environmental degradation.
4. After 2004, the new paradigm was adopted in order to harmonize the balance between nature and mankind (Hu, 2014).

It is impossible not to have any link between the actions of humankind and environment. Humankind intend to protect the environment but move towards an opposite way with a good and bad grace. Some kind of evidence can also be found in Chinese history. One of them is the result of being an agricultural society. In this intensively agricultural society, agricultural activities have an impact on soil erosion, water and environment pollution and deforestation (Ottley & Valauskas, 1983:85).

It can be easily said that what China has been through recently is a kind of transition from black/old/traditional development model to green/new/non-traditional development model (Hu, 2006). By adopting green development strategies, China has both a chance to protect environment and to meet the basic needs of the people. This issue is important not just for Chinese citizens but also for the world population. Therefore, all the efforts as green development embedded in the sustainable development strategy should be accepted as a way to transform the country into a modern society (Li & Obertheitmann, 2009:1412). Environment, energy and sustainable development are related with each other. Every energy source whether it is traditional or not has an environmental impact. If the energy efficiency is increased, the negative outcomes of an energy source will be removed. So, getting success in the efficient use and utilization of energy sources affect the aim of sustainable development positively (Dincer & Rosen, 1999:437).

OECD Review of Innovation Policy in China (OECD, 2008) emphasizes the pioneer position of China in science and technology and also for the research and development, but it is also mentioned that China still has some shortcomings and deficiencies regarding innovation capability and performance in comparison with OECD countries. Therefore, the country has to adopt national innovation systems in order to implement regulations and to increase the cooperation between all related actors. This innovative capacity is important in order to improve the technology that is used in the field of energy production and consumption which is vital for renewable energy.

Developed and developing countries- China is also included- has been trying to implement some plans and programmes on renewable energy because of its positive effect on sustainable development. Renewable energy can affect the whole economy to create new job opportunities and to protect environment in accordance with their sustainable development goals. In a world where countries such as Japan, UK, The Netherlands, US and Denmark are in a leading position in some of the renewable energy areas (electronic technology, wind turbine etc.), China has good reasons and incentives to support renewable energy. According to US energy Information Administration Report (IEA, 2015) by 2011, China was the largest energy consumer of the world. Coal, as a type of fossil-fuel, is a widely used energy source

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

in China. China can be labeled World's number one coal producer and importer. This intense and overwhelming use of coal has a negative effect that can be seen as increasing carbon-dioxide and sulfur dioxide emissions. It can be easily seen that there is an increasing trend in coal consumption since 1965. It was about 114.4 million tonnes of equivalent (Mtoe) in 1965; 524,7 Mtoe in 1990; 699,9 Mtoe in 2000 and 1.962,4 Mtoe in 2014. The numbers in 2014 corresponds to the 50.6% as a share of total (BP Statistics; 2015). This increasing amount of use has both economic (high healthcare costs, bias in public spending) and environmental (land degradation, air pollution) effects that are a major concern for citizens (Mattis).

In China, The Circular Economy Promotion Law was adopted in 2008. It is a commitment to create a regulatory framework to transform the development way of the country into sustainable development (OECD, 2009) and green economy (Zhu, 2014). It consists of three-layer approach (Yuan et.al., 2006:232):

- **1st Circle (Micro/Corporate Level):** The aim is to facilitate cleaner production by firms.
- **2nd Circle (Meso/Inter-Firm Level):** In order to maintain an eco-industrial network to protect environment.
- **3rd Circle (Macro/Social Level):** By developing eco-cities, eco-provinces to integrate all the efforts spent for environment protection and energy conservation.

Basically, this approach is related with the recycling, reusing, and reducing the waste capacity (China Circular Economy Promotion Law, n.d.) of economy whether it is the result of production or consumption. Although, circular economy triggers the decisions of local and domestic firms to increase investment and create job opportunities, still faces some challenges and barriers. These barriers are classified in the fields of policy, technology and public participation (Geng & Doberstein, 2008:234). Unawareness of citizens to participate and support this approach, not having an appropriate tools to measure the efficiency of the process, and lack of integrated regulation system in the country are the instance of the factors that affect the success of implementation (Geng & Doberstein, 2008: 234; Zhou et al., 2014:7-10).

By the awareness of the importance of renewable energy in the world, China has also planned some strategies for the renewable energy development from 2010 to 2100 based on four phases. It starts with the partially commercialization of renewable energy sources and the traditional energy sources will gradually be replaced by the renewable energies. By the 2100, the structure of energy use in the country will be completely changed (China National Energy Strategy and Policy 2020, 2013).

The government in China has been giving some subsidies to the renewable energy sector since 1950's. These subsidies vary from research and development activities, providing some low-interest loans to the sector and to tax incentives. It should be kept in mind that the country has not got any price-setting mechanism in this area. The coverage of government support and subsidies have been expanded considerably from 1950's to 1990's (NREL; 2004). It is also seen by tax incentives of the renewable energy producers. Overall the general value added tax (VAT) is around 17%, the kinds of renewable energy (wind 8.5% and small hydro-power 6%) have a level of much lower tax. This lower tax rates are positively related with the price of the renewable energy power (Junfeng et.al, 2006:14).

The trend in the growth rate can be seen in the both Figure 12 and Figure 13. The growth rate is 11% in 1995 and in the year of global financial crisis of 2008 it is around 9.6% and 7.4% in 2014. When the long run trend of the growth is analyzed (starting from 1965), the trend is fluctuated between in the range of 20% and minus 5% and mostly positive, with a few years of exemption (see Figure 13).

As a country with high growth rates, China is known with regional income distribution inequities (Ginting et al, 2013:24-31). These inequalities have also some unignorable effects on the nexus of en-

ergy and environment such as the concentration of emissions and energy use of different regions. Policy implications should be done by alleviating regional disparities in order to produce an integrated policy. As it is seen from Graph 2, country has been performing sound economic growth trend since 1970's. It should be kept in mind that these fast growth numbers have some negative side effects such as increased environmental degradation and social problems (Li & Obertheitmann, 2009:1421-1423).

Being a rapidly expanded and growing country, China has been facing great pressures in order to reconcile the necessities of economic development and environment protection. China was at the crossroads in this sense in order to find a way to meet the future energy needs without giving any harm to the environment. China's Agenda 21 was accepted as a statement of this effort. By applying this "Agenda" from the year 1994, China declared what kind of policies and implications will be taken or have been taken so far in order to maintain sustainable development (China's Agenda 21, n.d.). China's Agenda 21 shows medium and long-term plans on economic and social development (Li & Obertheitmann, 2009:1413). It contains both sector specific and general development measures and strategies of the country. Implementation of family planning, preventing the degradation of desertification, decreasing Sulphur dioxide emissions, developing cleaner energy sources are some targets of the Agenda in order to get success in the field of sustainable development (China's Agenda 21, n.d.). In their critical work, Bradbury and Kirkby (1996:106) emphasize that as a consequence of wide ranging implementations in the "Agenda", success can be measured only in certain elements. In addition to this, serious efforts and incentives should be performed by the government to reflect their commitment to sustainable development.

In order to improve sustainable development strategy, Chinese government published Program of "Action for Sustainable Development in China in the Early 21st Century" (n.d.) in 2004. This program clearly stated the successes and problems of the country in the context of sustainable development. Then the main objectives, principles and guidelines were given for maintaining sustainable development. For example, in relation with industrial restructuring, the main target is given as to raise efficiency in the utilization of both land and water resources in conjunction with the strengthened energy conservation and efficient energy utilization (Program of Action for Sustainable Development in China in the Early 21st Century, n.d.: 5-6). Graph 3 shows the CO_2 emissions for the selected regions of the world such as China, United States and European Union. The increasing trend in general is very common for these selected regions. From 2000's the average rate for China is higher than the rest of the regions.

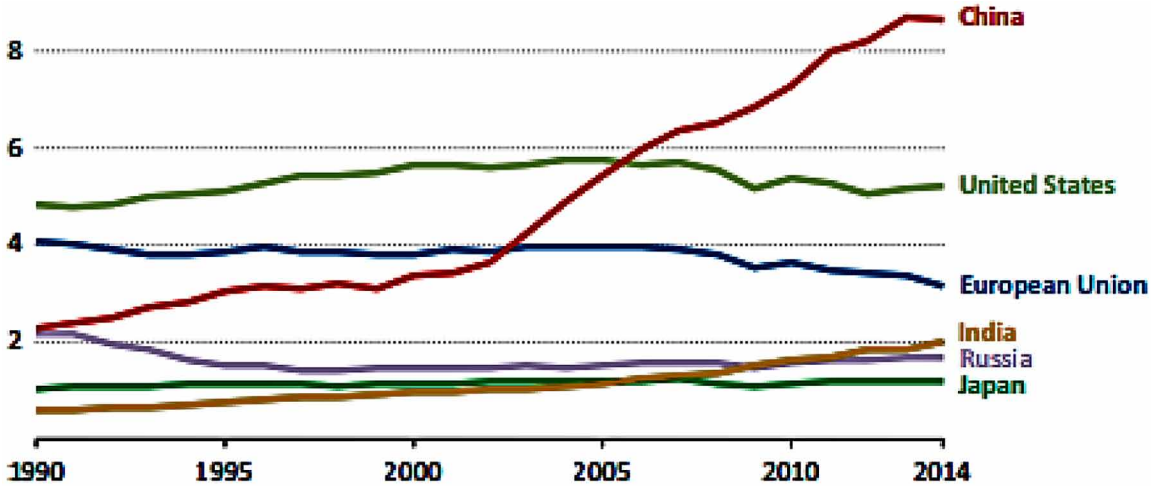

Table 7 shows the total energy consumption and its composition in China. The total energy consumption has been increasing since 1978. The share of coal as an energy source is decreasing but it is still high around 66%. In comparison with this traditional energy source, the renewables such as hydro, wind and nuclear can get only 9.8% share from the total energy consumption.

Global World Energy Council Report (GWEC;2014) emphasized the sign of increased wind industry capacity as for one single year in 2014. China is worth-mentioning due to the wind installations that took in place as of new wind power (23,196 Mega- Watt) all alone within this year. By the end of 2014, the total wind capacity of the country has reached 114,629 Mega-Watt, in which reflects the improving effect on the wind capacity of Asian region and the World. (GWEC;2014). These numbers can be seen in Table 8.

In China, the quota system was implemented to accelerate the pace of the transition to the low carbon economy by increasing the use of renewable energy sources. The responsibility of the provinces and regions in China is to use wind, solar and biomass energy sources for electricity consumption. Provinces that met their quota criteria will be rewarded, if not, they will be suspended from the new fossil fuel power generations projects (RE100, 2015:4). It should not be forgotten that each province has different

Figure 14. CO_2 emissions in selected regions
Source: IEA, World Energy Outlook, 2015, s.27.

quotas based on the type of renewable energy source of the specified region (Ng, 2014). Ziong et al. (2014:1190) emphasize the effect and significance of the Renewable Energy Quota System in China. It is clearly stated that this system can be used as a new policy instrument and a way to increase the generation of renewable energy. However, some researchers such as Zhou et al. (2010) also found the quota system beneficial to cut the energy use in the times of government tight control over the state-owned enterprises which dominated mostly the industry structure, nowadays the changing nature of the control and dominance cannot allow to use this system as efficient as it was in the past. Thus, the expected effect of promoting renewable energy sources cannot be obtained, quite the contrary a displacement or substitution effect can occur as claimed in the case of European Union (Eurosolar Info; 2006).

The decisions and implementations regarding energy and energy-infrastructure are crucial not just for China but for the whole world in terms of global warming and climate change. Also, the challenges in water resource are worth to mention. The clean water demand in China will be increasing due to the population increase and urbanization. Problems in water supply/resource security affect some policy areas such as environment, energy and health. The best way is to use new infrastructure services for giving opportunities in reducing carbon and water footprints, and saving the energy costs (Chen & Warren, 2011:90-92).

In history of China, the implementation of energy conservation policies by law can be found. For instance, as one of them, Law of the People's Republic of China on Energy Conservation (2015) was adopted in 1997. The main purpose of this law was to provide energy conservation in all sectors of the economy. The responsibility of the State was emphasized such as using new and renewable resources of energy, supporting research and development activities and also implementing policy and plans such as tax and pricing. Another example can be given as Law of the People's Republic of China on Promotion of Cleaner Production (2015) adopted in 2002. The aim of this law is basically to protect human health and environment, and to reduce pollutant factors and processes. Some measures have been taking in order to maintain building energy conservation by implementing building efficiency standards and regulations since 1960's in China (Yao et al., 2005:1979). When the high energy consumption of office

and residential buildings in China by the proportion of 16% of total energy use, new building projects have to meet the energy consumption criteria based on the Design Standard for Energy Efficiency of Public Buildings since 2005 (OECD;2009).

China's Eleventh Five-Year Plan was prepared for the years 2006-2010. In order to have a sustainable growth in the long run, all the main targets (about economic growth, natural development, human society) were maintained in the Plan. There were targets about economic growth to have an annual growth of GDP at 7.5% and GDP per capita 6.6% between 2006 and 2010. In relation to natural environment, the reduction of emission of major pollutants and reduction of energy consumption per unit of GDP targets are the examples of restricted (the responsibility of fulfilling these targets belongs to the state) targets. Lastly, the targets about human society vary from urbanization, population growth to health and education (Fan;2006).

Chinese government announced Twelfth Five Year Plan for the period of 2011-2015. The main emphasis of the Plan was the growth but an inclusive and higher quality growth. Therefore, the Plan was closely interested with the regional inequalities, well-being of citizens and the protection of the environment by improving energy efficiency. It's noteworthy that seven industries were selected to be developed for sustainable green development. Three of them are closely related with the aim of sustainable growth such as energy savings, new energy and clean energy methods and vehicles (KPMG; 2011).

Both Eleventh and Twelfth Five-Year Plans are a manifesto to follow the road to sustainable development. The targets and aims of the Plans were chosen for the best performance in the content of green growth. As well as having resemblances, there were some new implementations. What is new in the Twelfth Plan can be found in Table 9.

Regarding energy use and renewable energy source efforts of a country can be found both on local and global level. By having international collaboration both sides can get benefits. As an example of international cooperation, the U.S. and China declaration about climate change can be given. Both countries cooperate in a way to reduce GHG emissions and try to be the examples of low-carbon economies. In this manner, by 2030 the main target of China is to increase the share of non-fossil fuels in consumed energy to around 20%. The U.S. sets the target of reducing its GHG emissions by 28%. The success of these targets depend on the bilateral cooperation based on theoretical and practical level (The White House:2014). Their success or failure in pursuing this cooperation might also have effect on the global level.

Considering to move towards a green economy, China has been facing some challenges and barriers such as:

Table 9. Comparison of 12th five year plan to 11th five year plan

What's New in the 12th Five-Year Plan?
Two new pollution targets (10% reduction in nitrogen oxide and ammonia nitrogen)
Increase in average life expectancy by one year
Increase in patents (3.3 patents per 10.000 people)
Increase in high school enrollment rate from 82.5% to 87%
Development in affordable housing

Source: KPMG (2011).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

1. Institutional barriers which are related with the role and size of the government existence and intervention in the market,
2. Some deficiencies in implementation of regulations and coordination mechanisms, and
3. Pressures from international community and organizations because of the increased importance of China in global economy (CCICED; 2011:216-218).

The success of the future energy system of China depends on the struggle between traditional and new renewable energy sources. The competitive and the efficient one will be the decisive power of the country (The Guardian, 2015).

CONCLUSION

Nowadays it is a big reality that the big and indispensable fact we should overcome in future is fighting against droughts, heat waves, rising sea levels and concerns about catastrophic climate changes or la nina. These problems or today's mounting threats should be resolved by involvement of many countries within the framework of openness, participation, and science. Because of these reasons, the era of sustainable development or third industrial revolution must be built on water security, green industrial growth and intertemporal consumption, which requires making a fair share of total resources, one country have, between generations.

Sustainable development can be achieved by using renewable energy sources, because there is a long run relationship between sustainable development and renewable energy sources. The effect of renewable energy sources comes from their flexibility and low operational cost in comparison with traditional/old/black energy sources (Dinçer & Rosen, 1999:436). It is common for countries to adopt renewable energy policies and implementations due to its close relationship between environment protection and sustainable development.

Amount of renewable energy sources of Turkey are less than its long run potential level, although it has a good geographical and strategic position on the world within the context of renewable energy sources including wind, solar, geothermal or others. Therefore the share of renewable energy in total energy production and consumption is also at ignorable levels, near zero percent.

Norway, as a member of EFTA, but not a member of EU, has relevant energy policy strategies with EU. Especially with its position in renewable and clean energies, Norway cooperates with other European countries and also with China in order to help them to reach its targets.

China has shown high and sustainable growth rates almost a decade and this situation has been questioned whether it is possible to sustain these numbers or not. A continuous and sustainable growth is related with environment and use of natural resources. With an increase in factors of production either quantitatively or qualitatively, each country can grow. This brings on mind the question of what kind of growth strategy should be adopted from the countries. The short term growth should not prevent the future growth potential of the given country. Therefore, growth should be sustainable and environment-friendly. According to the latest numbers from Bloomberg New Energy Finance (2015), the total investment amount of clean energy was about $310 billion in 2014 in worldwide. One of the reason of this high score is the success of some countries and regions about clean energy investment such as China with a record of to 32% from previous year (Bloomberg New Energy Finance, 2015).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

The trend in modern societies is to realize the green growth strategies. Every country tries to stop or at least to decrease the negative consequences of rapid growth such as air pollution, environmental degradation and climate change. Individual measures are necessary but not sufficient. Based on cooperative actions or international decisions, countries are trying to reach sustainable development in long run. In this sense, the policy implementations, measures and tools used become more important.

Chapter 35
Transforming University Curricula Towards Sustainability:
A Euro-Mediterranean Initiative

Vassilios Makrakis
University of Crete, Greece

ABSTRACT

The UNESCO Chair ICT in Education for Sustainable Development in cooperation with the RCE Crete (Regional Centre of Expertise) on Education for Sustainable Development responding to the UN Decade of Education for Sustainable Development (DESD 2005-2014) took the initiative to establish a North-South Network for embedding sustainability in higher education institutions. A Consortium with 12 universities (six from Europe and six from Middle East) led by the UNESCO Chair and the RCE Crete at the University of Crete prepared a proposal submitted to the Tempus- European Commission programme for funding. The RUCAS (Reorient University Curricula to address Sustainability) project, studied in this chapter, has initiated various activities in the partner countries' institutions, which seem to exert significant curricular changes. The changes include the revision of courses, building the appropriate infrastructure, the development of an online community of practice and the RUCAS Toolkit that are being used as drivers for reorienting university curricula to address sustainability. As a result, a growing number of academics in the partner institutions are concerned with the current sustainability crisis and claim for a transformative shift in what they teach and how teaching is practiced.

ORGANIZATION BACKGROUND

The RUCAS project is initiated by the RUCAS Consortium of 12 Universities and three NGOs financially supported by the European Commission for a three-year period (2010-13) and it is coordinated by the University of Crete, Greece. More specifically, the project aims to:

1. Support the development of Education for Sustainable Development (ESD) in the Higher Education sector in Egypt, Jordan and Lebanon.
2. Build capacity amongst university staff to embed ESD in curricula and pedagogy.
3. Review and revise undergraduate curricula to address ESD in line with Bologna and Lisbon processes.
4. Assist the coordination and dissemination of ESD policy, research, curriculum reform and practice relating to ESD in the partner institutions that are expected to function as role models in the region.

It adopts a multi/inter-disciplinary and systemic approach contextualized in the three partner countries, namely Egypt, Jordan and Lebanon. The approach entails the following key outcomes:

- Establish continuous dialogue with university faculties regarding directions and means of education for sustainability.
- Develop ESD competences for university students contextualized to the European Union and Arab region.
- Evaluate ESD student competences in the participating Higher Education Institutions (HEIs).
- Establish and apply a Virtual Learning & Management System for running a community of practice in reorienting university curricula to address sustainability.
- Develop an ICT-based training Toolkit on ESD curriculum reform and innovation in Higher Education, reflecting the ESD student competences framework.
- Establish Virtual Training Centers in each partner university to support the process of reorienting university curricula to address sustainability.
- Build capacity amongst university staff to review, revise, infuse and embed ESD in undergraduate university curricula; and institutionalize and disseminate ESD curriculum reform.
- Apply and evaluate the revised university curricula with respect to the ESD student competences.
- Bridge the gap between HEIs and society through the placement of at least 100 students from each of the six partner institutions (600 in total) in the Arab partners in local stakeholders dealing with ESD local/regional issues.
- Promote reorienting HE towards ESD as a viable avenue for "whole institution" curriculum reform, research and teaching across all HEIs in the Arab region and the other member institutions.

Transforming university curricula towards sustainability is defined as a process that integrates ecological integrity, social and economic justice and human wellbeing into course content and instructional methodologies. This definition places faculty at the center in curriculum transformation. It has been argued that learning processes which can enable transformative changes largely depend on academic staff and their capabilities and willingness to support such processes (Hegarty, 2008; Ceulemans & De Prins, 2010; Barth & Rieckmann, 2012). Embedding sustainability in the university curricula is therefore seen as a process and praxis in transforming faculty perspectives and increasing their active global competence and sustainable citizenship. Sustainability does not simply require an 'add-on' to existing structures and curricula, but implies a change of fundamental epistemology in our culture and hence also in our educational thinking and practice. Seen in this light, sustainability is not just another issue to be added to an overcrowded curriculum, but a gateway to a different view of curriculum, of pedagogy, of organisational change, of policy and particularly of ethos (Sterling, 2004, p.50).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

SETTING THE STAGE

Who Is Involved in the RUCAS Initiative?

The RUCAS Consortium consists of 12 universities, six from European Union (EU), namely: University of Crete, Greece, Dublin City University, Ireland, University of Athens, Greece, University of BordeauxIII, France, University of Stockholm, Sweden & University of Padova, Italy and six from Egypt (Heliopolis University & Suez Canal University), Jordan (Hashemite University & University of Jordan) and Lebanon (Notre Dame University & La Sagesse University), as well as three NGOs (SEKEM, MIO/MEdIES & IndyACT). The University of Crete, as the leading University supported by the other EU Universities has the task to coordinate all the processes and practices to achieve the set objectives and outcomes in the six Middle Eastern Universities.

Challenges Identified for the RUCAS Initiative to Consider

- The great challenge of the 21st century for institutions of higher learning is to train professionals who are critical of, and capable of acting in transforming their frames of reference to achieve sustainable development goals and objectives.
- Although, interdisciplinary teaching and learning is highly prioritised in the participating institutions, in practice, there is lack of interdisciplinary perspective and motivation among teaching staff. Interdisciplinary collaboration is essential for modernizing higher education and it is a necessary condition for any transformation to meeting the challenges of climate change and sustainable development in the region.
- Reorienting university curricula to address sustainability (RUCAS) is very urgent and necessary to equip graduates with knowledge, skills, perspectives and values of sustainability so as to assume responsibility for creating a sustainable future and lifestyle.
- The greatest educational impediment to facilitating inquiry and asking critical questions may well be the linear way of viewing course content and pedagogy. Reflective inquiry is thus needed for engaging learners in dealing with complex sustainability issues and constructing meaning.
- A division of knowledge into fields of specialization continues to characterize modern educational systems, which challenge the RUCAS participating institutions.
- Lack of staff readiness to address sustainability issues from a transformative perspective is observed.
- Existing administrative and other infrastructures were not ready to respond to and support the transformation of university curricula to address sustainability.

The emphasis here is placed on the role of academic staff and staff capacity building programmes as one potential catalyst for transforming university curricula to address sustainability considering four main questions. The first main question is a "*What*" question, and focuses on which competences a student graduating from a university should have in relation to sustainable development. The second main question is a "*How*" question that focuses on how can the pedagogical processes make the sustainability competences achievable. The third main question is a "*Where*" question that looks at the perspective of the curriculum for promoting a 'transition from transmissive education to transformative education. The fourth and last question is a "Whom" question that focuses on the roles and readiness of academic staff

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

to implement curriculum and pedagogy transformation towards sustainability. In this context this paper describes the case of a Euro-Mediterranean initiative and analyses the extent to which this programme has contributed on transforming curricula changes in partner universities.

CASE DESCRIPTION

Defining Sustainability Competences: The "What" Question

The term "competency" or "competence" echoes everywhere and it has generated hot debates in terms of its definition and application (Barth et al., 2007; Rauch & Steiner, 2013). Drawing on the OECD DeSeCo work, Rychen and Salganik defined competence as

the ability to successfully meet complex demands in a particular context through the mobilisation of psychosocial prerequisites (including cognitive and non-cognitive aspects' and as the 'internal mental structures in the sense of abilities, dispositions or resources embedded in the individual' in interaction with a 'specific real world task or demand'. (Rychen and Salganik, 2003, p.43)

The concept of Gestaltungskompetenz in Germany is characterized in particular by key competencies that are required for forward-looking and autonomous participation in shaping sustainable development (Seitz & Schreiber, 2005; De Haan, 2006). The Gestaltungskompetenz concept can be viewed as a combination of the emancipatory and the instrumentalist approach to ESD, as it emphasizes both individual autonomy and active participation in societal transformation.

Measuring Sustainability Competences

A framework consisted of three levels has been developed to be used as a guide for the design and validation of ESD-related competences for students at the university level (Makrakis et al., 2012). The first level refers to the process of identifying the initial corpus of generic and disciplinary ESD competences (conceptualisation). The second level leads to the development of a consensus-based corpus of generic and disciplinary ESD competences and its refining through measuring construct validity and reliability analysis (validation). The third level goes further with the verification and possible refinement of competences (implementation). Implementation concerns the effort to verify the piloted scale in the previous step through re-testing its reliability with the target group (Makrakis, 2011a; 2011b). Through consensus reached by 32 panellists, sustainable development was defined as

to making informed, contextual and conscious decisions driven by the principles of solidarity, justice, accountability, equity and transparency for the good of present and future generations, locally and globally and to act upon those decisions for advancing social, economic and environmental wellbeing. (Makrakis, 2011b, p. 411)

Education for sustainable development was defined as

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

the learning needed to maintain and improve our quality of life and the quality of life of generations to come. It is about equipping individuals, communities, groups, businesses and government to live and act sustainably, as well as giving them an understanding of the environmental, social and economic issues involved. (Makrakis, 2011b, p. 411)

These definitions were important to panellists in order to generate sample competence items classified as generic (interdisciplinary) and discipline-specific competences. The first may be described as a combination of knowledge, understanding, skills and abilities that all graduates should have and the second related to a specific field of knowledge within a certain academic discipline. The clusters adopted for the generic competences were based on Jacques Delors' UNESCO report *'Learning: the treasure within'* (UNESCO, 1996), which recognizes four pillars for education of 21st Century: 1) learning to know, 2) learning to do, 3) learning to be and 4) learning to live together. We also added the fifth cluster of 'learning to transform oneself and society' that has been later introduced by UNESCO as the 5th pillar. These five pillars were conceptualised and contextualised to address sustainable development issues (Table 1).

Validation of the Sustainability Competences

Cronbach's alpha was computed to examine the internal consistency of the sustainability competence items composed in each of the five clusters that were piloted in one of the partners' institutions. The alpha values for the five clusters ranged from 0.77 (learning to be), to 0.74 (learning to live together), 0.77 (learning to know), 0.79 (learning to do) and 0.76 (learning to transform oneself and society). Reliability tests suggested that screening the data would improve reliability levels. We screened the collected data by discarding items that showed very low corrected item-total correlations, i.e. <0.25. The constructed sustainability competences implemented through a survey in 11 universities that participate in the RUCAS project (Makrakis et al., 2012). The aim of the survey was: 1) to further redefine the items included in each generic competence cluster and discipline-specific competence items and 2) to identify, among other things, the knowledge students get from their courses in relation to sustainable development, the sources of sustainability knowledge, the teaching methods, the attitudes towards learning to live sustainably, the sustainability actions and the perceived functions and roles of universities. The results of this survey would be used for developing the strategy and the capacity-building

Table 1. Clusters defined in the context of education for sustainability

Cluster	Definition
Learning to be	This type of learning concerns all the processes and practices that lead to human self-actualisation, self-regulation and cultivating a sense of being versus having.
Learning to live together	This type of learning concerns all the processes and practices that lead to a peaceful and non-discriminatory society and human co-existence with the natural world.
Learning to know	This type of learning concerns all the processes and practices that lead people to experience, construct and transform knowledge for making sustainability a mode of life and being.
Learning to do	This type of learning concerns all processes and practices that lead to merging knowledge with action for building a sustainable future.
Learning to transform oneself and society	This type of learning concerns all the processes and practices to transform their unsustainable values and behaviours and collectively engaged to change society towards sustainability.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

programme for reorienting university curricula to address sustainability. The study population was set to include all final year students of six academic disciplines, namely: educational sciences, social sciences, applied sciences, business/economics sciences, technical sciences and health sciences. In total, 3757 replies were collected among the 11 university partners: 54% females and 46% males. In terms of student geographic composition, 62% come from the three Middle East countries (Egypt, Jordan and Lebanon) and the remaining 38% from Europe (Greece, France, Ireland, Italy and Sweden). There were variations among the country samples, with the higher response from Jordan (39%) and the lowest from Ireland (1%). The variation is mainly due to the number of disciplines involved in each country and the size of institutions. After several screening attempts, 54 items remained in our final pool of items. Reliability levels for the reduced clusters of sustainability competences came as 0.86 (learning to be), to 0.85 learning to live together), 0.87 (learning to know), 0.88 (learning to do) and 0.86 (learning to transform oneself and society). Table 2 summarizes the correlation matrix along with variables' means and standard deviations. The five clusters of perceived sustainability competences correlated significantly with each other and with the overall index of perceived ESD competence. The highest correlation between the variables comprising the four dimensions perceived ESD competence quality was between learning to know and learning to live together (Pearson's $r= 0.90, p<0.01$), whereas the lowest correlations were those between learning to live together, learning to know, learning to transform oneself and society and learning to be (Pearson's $r= 0.58, p<0.1$). In addition, the five clusters of perceived sustainability competences correlated significantly with the total sustainability competence scale, ranging from $r= 0.80$ *to* $0.88,$ at $p<0.1$. Similarly, Table 3 summarises the correlation between the five generic clusters of education for sustainable development competences with the six discipline-specific competences for applied sciences, economics/business sciences, educational sciences, health sciences, social sciences and technical sciences. The correlations range from 0.45 to 0.71 at p< 0.01 level. The results clearly give further credence to the sound psychometric properties of the sustainability competence instrument.

The RUCAS Approach: The "How" Question

The RUCAS survey revealed that, 30% of the 3.757 students have taken courses directly related to sustainable development, 50% have taken courses including some aspects of sustainable development and 21%

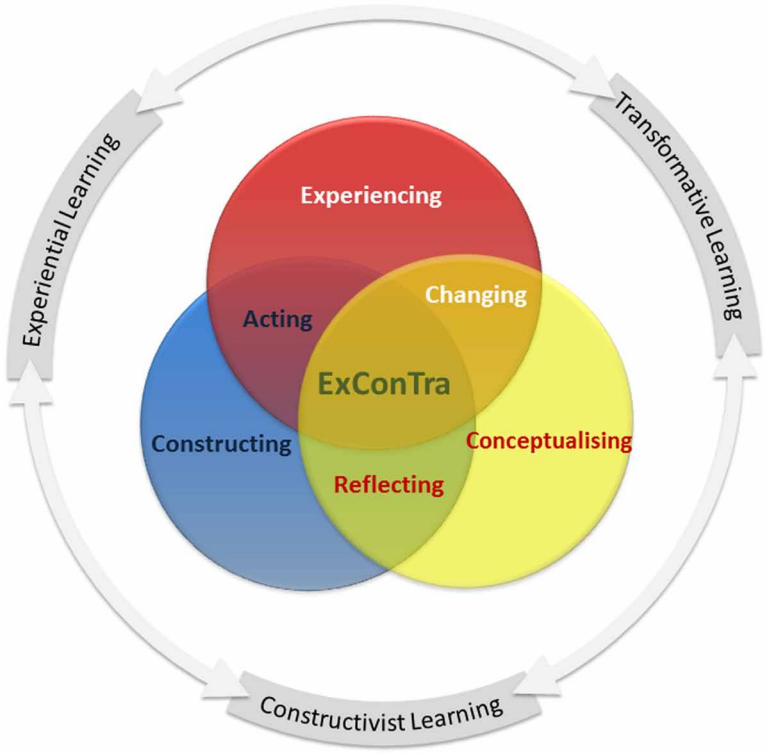
have done a course assignment or project that concerns sustainable development. Comparing European and Arab students, the corresponding results for Arab students are 20%, 48% and 12%, while for European students are 23%, 50% and 19% respectively. In terms of academic disciplines, the survey shows that the most active in embedding sustainable development in their curricula are the disciplines of Business/ economics followed up by Educational Sciences. The least active ones are those of Health Sciences and Technical Sciences. When students were asked to rank the key sources of information about sustainable development, the Internet was ranked first by 37% among EU students and 63% among Arab students and even higher than university courses (20% for EU students and 16% for Arab students). Surprisingly, Radio scored much higher (33%) than university courses (16%) and TV (16%) among Middle Eastern students. The average means of the generic ESD competences as depicted in Table 3 show a range from 3.9 to 4.2 on the six-point scale. Similarly, average means of the discipline-specific competences show a range from 3.6 to 4.0. The fact that some courses related to sustainability have been introduced cannot be seen as an adequate response to the current sustainability crisis. Things cannot be changed by just adding and/or embedding sustainability in one or two courses being taught with conventional pedagogical methods. It has been revealed that most of the students (62%) rated lecturing as the most dominant teaching method, while other teaching and learning methods such as place-based learning (15%), inquiry-based learning (16%), problem-based learning (17%), discovery learning (16%), inter-disciplinary teaching (20%), which are suitable with learning to live together sustainably, are much less evidenced in higher education pedagogies (Makrakis, 2012). These findings suggest there is need for a revised curriculum, not only in terms of content, but also in terms of teaching and learning methodology, including learning processes such as values clarification and critical reflection.

Accordingly, we have made two key decisions: first, to develop a strategy for reorienting university curricula to address sustainability that ended up to the RUCAS Model consisted of seven interactive and cyclical processes to respond to three critical questions: 1) what to teach and how to teach it; 2) how to design and implement a course and 3) how to ensure that students are learning what is being expected (Figure 1). The RUCAS model provided the guiding instrument in the course revision, implementation and evaluation process to address sustainability.

Second, we have adopted Makrakis and Kostoulas-Makrakis (2012a) ExConTra learning model depicted in Figure 2. This model is underpinned by experiential (Kolb & Kolb, 2005), constructivist

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. The RUCAS Seven Step Model



(Jonassen, 1999) and transformative (Mezirow, 2000; Marsick & Mezirow, 2002) theories of learning and is associated with educational approaches such as inquiry and discovery-based learning (Hai-Jew, 2008; Balım, 2009; Alfieri et al. 2011), case-based learning (Carroll & Borge, 2007; Lee et al., 2009), service learning (Shumer & Duckenfield, 2004; Simons & Cleary, 2005), place-based learning (Ault 2008; Gruenewald & Smith, 2008; Smith & Sobel, 2010) and reflective/reflexive learning (Kostoulas-Makrakis, 2010; Tilbury, 2011). All of these methods are based on the principle that students experience, construct and transform their own versions of reality rather than, simply absorbing versions presented by others. From a sustainability perspective, these methods help to transform unsustainable actions and reconnect people to the natural and cultural world of which they are an organic part.

In the following, three examples will be presented, one from Heliopolis University in Egypt, the other from the University of Jordan and the last from Notre Dame University in Lebanon focusing on an assessment of the extent to which the five pillars of sustainability competences were integrated into the revised course curricula to address sustainability. The assessment was based on peer-review carried out by a team of experts from three EU partner universities. More specifically, Dublin City University expert team was assigned to review courses revised in the Egyptian partners, an expert from Heliopolis University was assigned to review the Lebanese partners and another one from University of Padova was assigned to review the Jordanian partner universities. The methodology for peer-reviewing used an open-ended instrument that covered various dimensions of course curriculum revision for sustainable education substantiated by class observation and focus interviewing.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

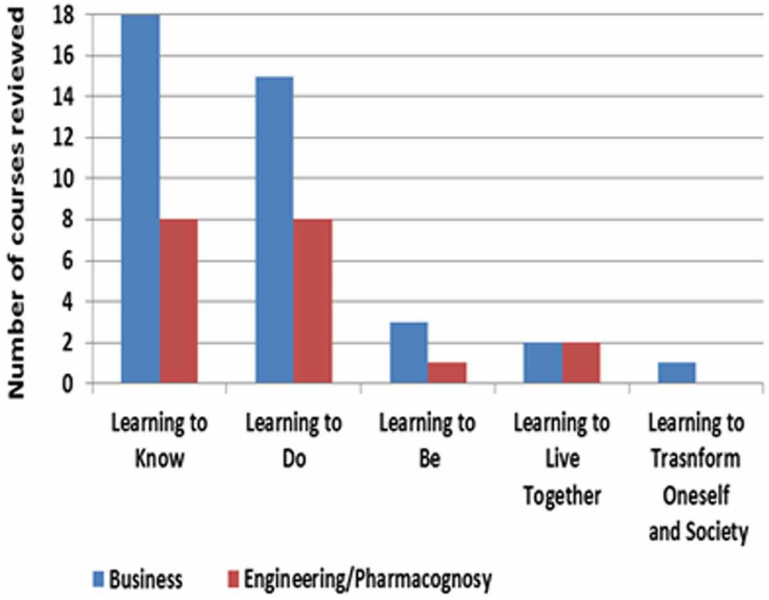
Figure 2. The ExConTra Learning Paradigm

In the case of Heliopolis University, 34 courses within the disciplines of Business, Engineering and Pharmacognosy were reviewed by the DCU team in April 2013. In general, all revised courses have infused sustainability, some to a greater extent, such as: Living Economics; Money & Accounting; Sustainable Development; and Pharmacognosy I, II. A number of innovative projects have been noticed, such as the 'Water is Life project' that straddles several different disciplines. Results summarised in Figure 3 show that there is an emphasis on sustainability aspects related to preparing learners to know and do, while there is less emphasis on sustainability aspects related to preparing learners to reflect on own values base (Learning to Be), or on how learners can contribute to peaceably "Live Together," or on how learners can act as Agents of Change (Learning to Transform Oneself and Society). It has been also observed that there is creative engagement between lecturers & students, especially through the student engagement in real-world project based learning. Examples of real-world projects are the ones on an Engineering project on hybrid cars and "IT and Sustainable Development". In discussions with management, it was also evident that there is a high degree of commitment to the infusion of sustainability in all aspects of University life. A Summer Internship programme was seen as an excellent initiative, providing practical experience in partner companies within SEKEM, as well as other institutions, factories, farms etc.

In the case of the University of Jordan, 11 courses within the disciplines of Math teaching, International Finance, Finance Analysis and Multimedia Programming, were reviewed by the University of Padova reviewer in June 2013. As Figure 4 shows, there is an emphasis on sustainability competence aspects for preparing learners to know and do, but less emphasis on preparing learners to reflect on own values base (Learning to Be), or on how learners can contribute to "Learning to Live Together," or on how

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Integration of the five pillars of sustainability competences in Heliopolis University



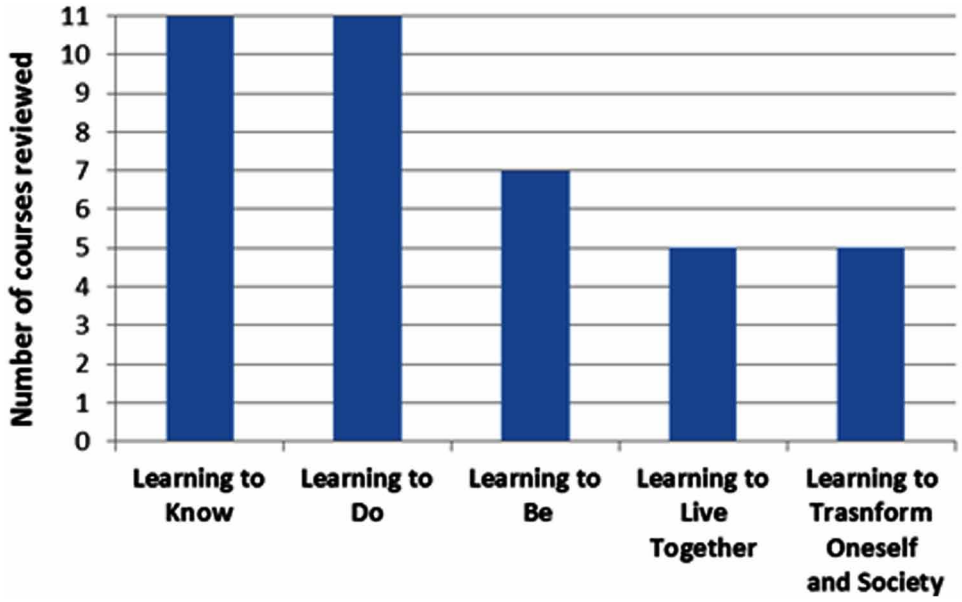


Figure 4. Integration of the five pillars of sustainability competences in University of Jordan

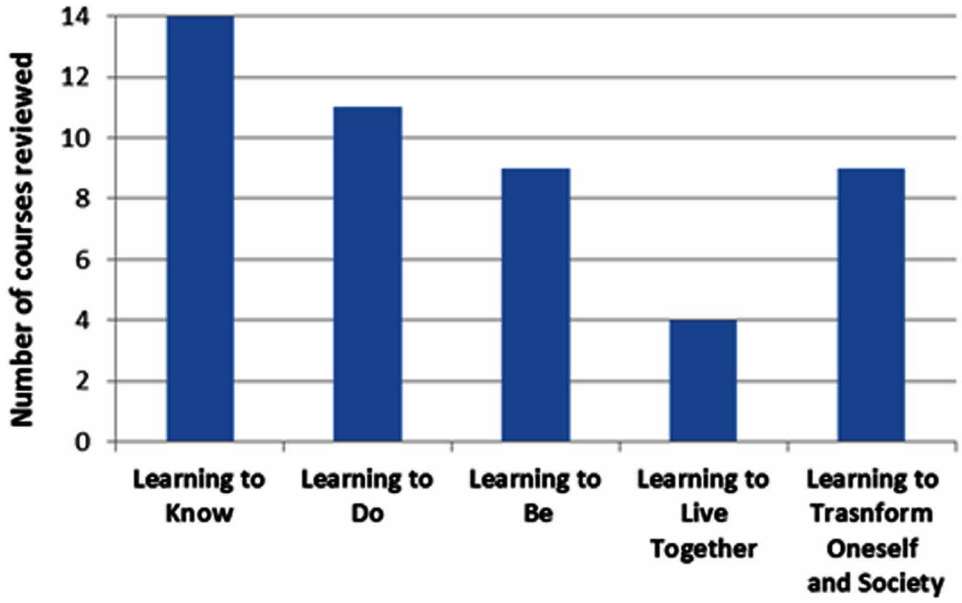
learners can act as "Agents of Change" (Learning to Transform). Various practicum assignments were developed placing students in relevant community sites. For example, a student practicum concerned 'Environmental education for the young child' that aimed to improve the physical environments at the College of Education in the University of Jordan. Another practicum focused on working with community institutions, such as orphanage and home for the elderly. Another practicum involved students in

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

working with children and teachers from public and private schools to improve their understanding of their environment, and the importance of sustainable development. Working as volunteers to help poor children by picking olive trees from a farm and taking 1/3 of the crops for poor children was another innovative practicum developed by students at the University of Jordan. Designing a Learning Center at the University of Jordan Kindergarten can be also counted as an innovative practicum assignment. The Learning Center includes: hand made puzzles to improve thinking skills; stories; thinking games and learning materials from recycled items. 'Designing a digital story' and 'Solve problems regarding international finance crisis' are other practicum assignments developed by students participating in the revised courses.



In the case of Notre Dame University-Louaize in Lebanon, a total of 14 revised courses within the Faculties of "Business Administration and Economics," "Engineering" "Nursing and Health Sciences," "Natural and Applied Sciences," "Engineering," and "Political Science, Public Administration and Diplomacy" were reviewed by the Heliopolis University team in May 2013. All of the courses reviewed had sustainability infused in them albeit to greater and lesser degrees. It was found that the courses that were most interesting were, "Economics of developing countries" and "Air Pollution Engineering". Practicum student assignment developed within the first course are 'Groundwater pollution and its impacts on development in Lebanon', involving stakeholders such as the Federal Institute for Geosciences and Natural Resources-Lebanon. Another practicum assignment focused on 'Child labor', involving among others the Ministry of Social Affairs-Lebanon. Other practicum assignments focused on reducing youth unemployment, involving various schools such as Jesus and Mary, Saint Joseph and Champville as well as the Lebanese American University; 'Agricultural development', involving the Ministry of Agriculture-Lebanon and Cenacle Libanais pour la protection de l'environnement; 'The effect of oil extraction on economic development in Lebanon', involving the Ministry of energy and water resources and the Ministry of economy; and 'Sports in Lebanon: A potential tool for development and peace', involving the Ministry of youth and sports and the Federation Libanaise du Basketball (FLB). In the context of the "Air Pollution" course, practicum assignment developed are 'Assessing Particulate Matter Pollution at a Construction Site in Keserwan' and the 'Air Pollution Impact of Private Generators in Sahel Alma and Haret Sakhr, involving the municipalities of Haret Sakhr & Sahel Alma; 'Noise Pollution of a Building Under Construction in Metn on the Surrounding Environment' and the 'Emission of Pollutants from cars at NDU-Louaize' and 'Measuring Indoor Air Pollution at Different Locations in NDU-Louaize. As Figure 5 shows, with the exception of the pillar "Learning to live together," that seemed to be neglected by most of the courses, all others are sufficiently represented in the courses reviewed. In particular, there is an emphasis on preparing learners to know and do, and a bit lower but equal emphasis on preparing learners to reflect on own values base (Learning to be) and on how learners can act as "Agents of Change" (Learning to Transform).

The RUCAS Curriculum Perspective: The "Where" Question

Considering curriculum perspectives, it is of particular importance to examine current curricula to identify where they are focused and to where should be directed in light of current trends and sustainability crises. In terms of academic disciplines, Table 4 shows that the most active in embedding sustainable development in their curricula are the disciplines of Business/economics followed up by Educational Sciences. The least active ones are those of Health Sciences and Technical Sciences. Interpreting the average means of the discipline-specific competences related to sustainability, ranging from 3.6 to 4.0 of

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 5. Integration of the five pillars of sustainability competences in Notre Dame University

the six-point scale together with the overwhelming dominance of lecture-based approaches to teaching, university curricula in the RUCAS participating higher education institutions needed a re-examination of their orientation.

It is often said that education plays a dual role. On the one hand, it reproduces certain aspects of current society and, on the other hand, it prepares students to transform oneself and society. Although, these roles are not necessarily mutually exclusive, curricula tended in the past to reproduce an unsustainable culture rather than empowering citizens to think and work towards a sustainable future (Makrakis & Kostoulas-Makrakis, 2012b). Sterling (2001) sets out what the role of education could/should be:

- To replicate society, culture and citizenship: A socialisation function.
- To train for employment: A vocational function.

Table 4. Sustainable development curriculum experiences by academic disciplines

Disciplines	SD courses taken		Relevant to SD		SD assignments		No
	No	Yes	No	Yes	No	Yes	
Education	65%	**35%**	38%	**62%**	76%	**24%**	800
Sciences	70	30	48	52	84	16	915
Technical Sciences	83	17	70	30	86	14	423
Health Sciences	86	14	62	38	94	6	325
Soc. Sciences	70	30	55	45	73	27	763
Business/Ec.	54	**46**	34	**66**	65	**35**	414
Total	70%	**30%**	50%	**50%**	79%	**21%**	3640

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

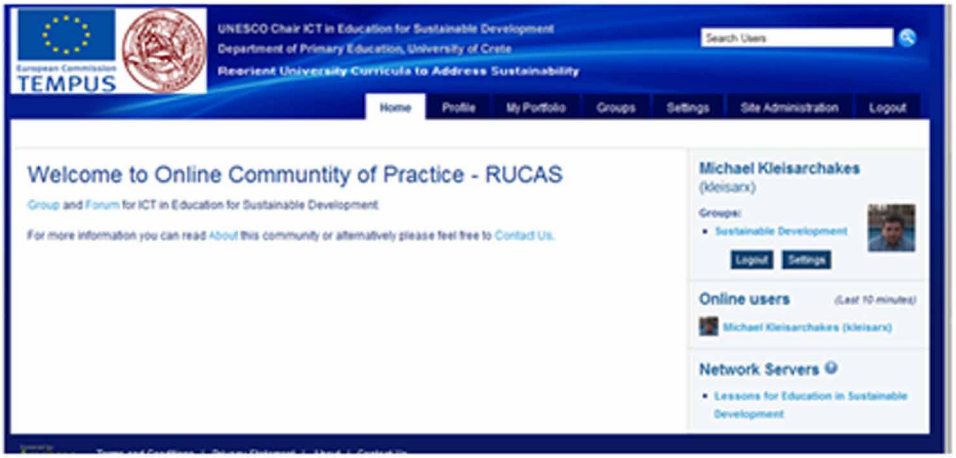
- To develop the individual: A liberal humanist function.
- To encourage a fairer society and a better world: A transformative function.

The last role is seen by Sterling as central to achieve a more sustainable educational system. The first two roles mirror ideologies adherent to curriculum as product, the third, curriculum as process and the fourth curriculum as praxis. Curriculum as product is principally based upon an objectivist approach – seeing knowledge as something stable that should be replicated in learners' minds, decontextualized from social reality and perceived as existing independently from learners' experiences. A division of knowledge into fields of specialization continues to characterize modern educational systems, including in the RUCAS participating institutions with some variation. Such a curriculum orientation functions as a bottleneck to turning these institutions into sustainable universities. This forces university teaching staff to view knowledge from a compartmentalised perspective that leads to serving and maintaining a culture of unsustainable production and consumption. In decontextualized learning, curricula and teaching methodology are mainly used in the context of instrumental rationality and technical interest in knowledge, which does little to develop human self-realization and critical discourse (Makrakis & Kostoulas-Makrakis, 2005; 2012). A curriculum as process is not a prescribed body of knowledge to be transferred, but rather an active process that links with the practical form of reasoning (Grundy, 1987). In this sense, the curriculum is being considered more open-ended than a prescribed body of knowledge, setting an emphasis on interpretation, judgment and meaning making. Curriculum as praxis moves beyond process, as it integrates in its conception an emancipatory knowledge interest, not just a practical one.

Assessing the students' preferences towards the roles universities can play and the curriculum that these roles support shows what values are dominant and what directions are needed to be taken as well as how to better understand the extent to which sustainability principles drive curriculum development. Taking into consideration the whole sample of the RUCAS survey, it is evidenced a clear trend towards the transformative function, that sees a university as an agent of change towards a fairer society and a better world. More specifically, 42% of students indicated that function compared to 6% that perceived the university's role to replicate society and culture and promote citizenship. When taking into consideration the country of students, perceptions are spread between the liberal and the transformative role. Italian and Irish students indicated a clear preference to the liberal role, in contrast to the Greek (56%) and Jordanian (46%) students who were oriented towards the transformative role. It is interesting to note, that the Egyptian students' preferences are situated between the socialisation (28%) and the transformative (37%) role. A more balanced preference between the liberal and transformative role was revealed among the French, Swedish and Lebanese students. Similarly, a more balanced preference is revealed between the vocational, liberal and transformative role among Lebanese students.

Although, the students' perspectives with respect to the role and function of higher education is directed towards the transformative function, the peer-review on the revised courses shows that the corresponding pillar or cluster of "Learning to transform oneself and society" competence was integrated in less than half of the courses peer-reviewed, with the exception of the Notre Dame University-Louaize. Students must not only acquire new skills and information through transmissive and constructivist approaches, but also critically reflect and radically transform their own perspectives, knowledge and approaches to thinking and learning.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use



Preparing Academic Staff for Transforming Curricula: The "Whom" Question

The great challenge of the 21st century for institutions of higher learning is to train professionals who are critical of, and capable of acting in transforming their frames of reference to achieve sustainable development goals and objectives. To facilitate and strengthen the transformation of university curricula towards sustainability in the partners' universities, an online community of practice (OCoP) has been developed that gives access to all academic staff in the partner institutions (http://community.cc.uoc.gr). The RUCAS OCoP (Figure 6) considers university instructors as part of a "critical community" of practitioners committed not only to improve the quality of teaching and learning in their institutions, but also to transform those structures, practices and behaviours that provide constraints to turning their universities into sustainable ones. It provides a virtual space in which university staff and other practitioners across its consortium members can come together, share stories and experiences, and solve problems pertaining to the RUCAS tasks and activities. Although, the OCoP is restricted to the academic staff involved in the RUCAS project, it is planned to be open to every interested university that wants to be associated with the RUCAS Sustainable Universities Network.

Two types of participation among members of the OCoP have been identified: 1) active participation and 2) peripheral participation. As depicted in Figure 7, university staff participating in the RUCAS project used the OCoP tool to formulate discussion groups/forums, upload revised course syllabi, use the space provided as a repository for teaching materials, guidelines, publications and so forth. About one third of the more than 100 members of the RUCAS OCoP can be considered as active participants. The rest can be considered as peripheral participators, who read and benefit from its tools and resources without contributing themselves.

The RUCAS OCoP played a critical role in the three regional workshops aimed to get the academic staff ready to transform their courses and pedagogies. The first regional workshop was held at the Notre Dame University-Louaize in Lebanon (October 2011) with the aim to introduce academic staff to the teaching methods, concepts, principles, processes and practices in ESD curriculum design and revision for Higher Education. The specific objectives were to: 1) build capacity amongst university staff in the partner universities of Egypt, Jordan and Lebanon to embed ESD in curricula and pedagogy and 2) review

Figure 6. The RUCAS OCoP

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 7. The RUCAS repository

and revise undergraduate curricula to address ESD in line with Bologna and Lisbon processes. Through this workshop, 52 participants discussed why there was a need to re-orient university curricula to address sustainability and identified ESD themes, teaching methods, goals and competencies to be addressed within their curriculum design and practice. A particular model for ESD curriculum re-orientation was also presented and discussed. The first regional workshop paved the way to the second that was held in Cairo January, 2012. In the second regional workshop 35 academic instructors were to review the produced revised course syllabi and present experiences from their practices. In particular, the emphasis was placed on reviewing existing courses and teaching methods to address issues that are pertinent to education for sustainability through the infusion approach.

All members of the group participated in a rich discussion and provided feedback and suggestions of how to infuse ESD and obstacles that partner universities might face. The keyword that members identified as the means to infusion was 'contextualizing' examples within ESD without undermining the main concepts of the original course. Results of this discussion were evident in the session that followed. In the 3rd Regional Workshop held in Amman April, 2012, 40 participants:

- Examined the implementation process of the revised courses during the spring semester.
- Discussed the process and outcomes of disseminating the ESD-student competence survey results through publications in international journals and conferences as well as the general dissemination activities for the project.
- Prepared suggestions and a catalogue for course revisions and new courses in the disciplines of educational sciences, technical sciences, health sciences, applied sciences, business/economic sciences and social sciences for the next academic year.
- Discussed the strategies for the institutionalisation of ESD in the partner institutions.

A particular emphasis was also placed on the student practicum placements in the community. In this context, community engagement work was perceived as an important dimension of ESD since engagement with communities helps to bridge the gap between theory and practice and between universities and

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

the broader community. The opportunities for students to engage in service learning programmes which provide them with 'real-life' experience were emphasised. It was widely shared among the participants that engaging students in situations identical with those they are expected to find after graduating and to equip them with the necessary hands-on experience to confront the real-life issues, is of paramount importance in curriculum transformation. Such activities help students to reflect upon their experiences in the real world and to gain a deeper understanding of their role as active local/global citizens and professionals in their respective academic areas and to develop practical skills to apply in real-life situations. To this end, emphasis was placed upon reflective and reflexive practice through the use of particularly developed self and peer-reviewing instruments that ensure quality and facilitate the monitoring and evaluation process of the RUCAS initiative.

CHALLENGES PAST AND PRESENT FACING THE ORGANIZATION

The great challenge of the 21st century for institutions of higher education in general and the RUCAS partner institutions, in particular is to educate students on learning to live together sustainably. This challenge implies that university curricula and teaching methods should be revised and improved upon in order to infuse sustainable development and translate knowledge and critical consciousness into action. Higher education institutions bear a profound, moral responsibility to increase the awareness, knowledge, skills and values needed to create a just and sustainable future. Indeed, higher education plays a critical but often overlooked role in making this vision a reality. Other challenges faced before the start of the RUCAS project were: 1) lack of staff readiness to address sustainability issues from a transformative perspective; 2) lack of understanding about why an interdisciplinary education for sustainability program is needed and 3) existing administrative and other infrastructures were not ready to respond to and support the transformation of university curricula to address sustainability. To this end, reorienting university curricula to address sustainability (RUCAS) was seen as a very urgent and necessary initiative to equip graduates with knowledge, skills, perspectives and values of sustainability so as to assume responsibility for creating a sustainable future and lifestyle. From experiences of RUCAS interventions in different contexts and situations, there are some specific challenges, which have come across.

Challenge 1: Creating a mechanism by which different stakeholders can work together is complex due to different perceptions, interests, experiences and understandings of what is needed and how issues and problems can be handled.

Challenge 2: Training university staff for course revision, especially from different educational and socio-cultural backgrounds is a real challenge. Some may think that they know best and not give due importance to the opinions or perspectives of the others. Some could also raise conflicting ideas and they may be intimidated by others due to different interests, perceptions, culture, and academic background.

Challenge 3: Develop local ownership and self-reliance. From a managerial perspective, issues identified were related to developing local and regional leadership that could sustain efforts to make major transformations at various domains and levels. Also, appropriate coordination among all the Consortium members and working teams for connected related activities was a critical issue.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Challenge 4: From an organisational perspective, there was an issue of communication, taking into consideration different perceptions of leadership, time, culture, political problems arising in the region, etc.

Challenge 5: From a technological point, one major challenge concerned the supporting infrastructure in terms of coordination and professional development that would foster the attempted transformative actions to change course content and instructional methodologies.

Challenge 6: Students must recognize the limitations of their current knowledge and perspectives. This means that university teaching staff cannot simply transmit knowledge on students. What is required is a true transformation of students' existing knowledge, especially through learning to clarify own values and critical reflection.

Challenge 7: Identifying important learning goals/objectives and outcomes aligned with appropriate feedback and assessment procedure is of critical importance in this process. Ensuring the alignment of learning outcomes, teaching methods and learning activities and assessment tasks is decisive to the course revision process.

Challenge 8: Embedding sustainability in the university curricula is emerging as a process and praxis in transforming faculty perspectives and increasing their active global competence and sustainable citizenship.

Challenge 9: Building of quality assurance systems supported by new information technologies is seen as a key development process.

Challenge 10: Keeping up to date academic staff with disciplinary and interdisciplinary knowledge and skills, especially through professional development and academic rewards is critical to any transformative change planned.

SOLUTIONS AND RECOMMENDATIONS

Referring to the above cited challenges, our experiences show that establishing a 'platform' where you can have an open and continuous discussion or dialogue with different stakeholders is of paramount importance. A face-to-face communication among participants has been proved difficult and costly. Thus, the use of online and offline discussions with key stakeholders and ensure that they are informed regularly and thoroughly is a decisive strategy to the success of any program. Developing local ownership and self-reliance is a managerial perspective that can generate changes and sustain efforts to make major transformations at various domains and levels. Another issue was the level of willingness to get involved in highly demanding tasks. This was tackled through incentives and rewards such as joint publications, certification and so forth. Development of a shared understanding and acceptance of managerial principles among all participants proved to be a critical driver to achieve expected outcomes. Setting-up an internal and external monitoring and quality assurance system is seen very critical. Indeed, distributed leadership is of critical importance together with encouragement for co-production of and sharing knowledge. The building of a supportive infrastructure in terms of coordination and professional development can foster the attempted transformative actions to change course content and instructional methodologies. The establishment of a Virtual Training Center in each partner university is expected to support the process of reorienting university curricula to address sustainability. Similarly, the online community of practice

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

(OCoP) and the development of an ICT-based training Toolkit on ESD curriculum reform and innovation in Higher Education can be considered among the key drivers for transformative change. Development of guidelines for strengthening stakeholders' inputs in the curriculum development and implementation has been considered as a critical solution to the demands for capacity-building.

Indeed, one critical move to support academic staff has been the development of a monitoring and evaluation framework to provide guidance about the core teaching and learning approaches used in transforming their courses and pedagogies towards sustainability. This covers basic pedagogic methods, approaches to curriculum design and various quality assurance instruments used across all stages from developing competences to integrating competences in the course revision process as well as self assessment and peer-reviewing. Through critical reflection of biases and assumptions, academic staff involved in the RUCAS project had the opportunity to critically reflect on their understandings, points of view and habits of mind, worldviews, and create transformative learning experiences to alter their frames of reference, teaching practices and course content. Summing-up, other solutions attempted are: obtaining constructive feedback and strengthening the inputs of the key stakeholders; monitoring visits by internal and external evaluators to verify adoption of quality assurance standards; contextualise sustainability taking into consideration local problems and issues; organize symbolic rewards to the most committed ones (e.g. certification, champion awards); identify the barriers and drivers related to their potential contribution; encourage and support strong distributed leadership and support for the change agenda; provide needed materials and resources in a timely manner and appropriate coordination among all working groups.

Our reflections on the processes and practices during these three years revealed a number of key strategic points that should be taken into consideration when implementing such fundamental change in higher education curricula and pedagogy. These include: a commitment for personal and institutional change; designated leadership at institutional and consortium level; a multi-stakeholder perspective; a risk analysis and a plan for change; development and dissemination of appropriate resources; and engagement in capacity-building. Replication and up-scaling are fundamental objectives of the RUCAS project as it provides the opportunity to build on best practices and lessons learned and expand the reach and impact not only within partner institutions, but within partner countries. The issue of up-scaling is inherent in the project itself as the RUCAS project provides a viable avenue for "whole institution" curriculum reform, research and teaching across all Higher Education Institutions in the Arab region.

FUTURE DIRECTIONS INCLUDING RESEARCH

Our experiences and studies with the participation of more than 3000 undergraduate students in European and Middle Eastern Universities indicate that it is very important to develop undergraduate students' sustainability competences and sustainable development issues than developing specialised post-graduate courses. Such an approach will have a greater impact on society, environment and economy besides the increased employability of graduates and the modernisation of universities. Also, the isolation in the partner countries' higher education institutions from the labour market and stakeholder guidance in course design and content has placed sustainable development courses in a marginal position. A multi-stakeholder-driven model for modernising higher education curricula is needed, taking into con-

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

sideration the evidence that current efforts to curricula take place within a framework of limited or not any stakeholder consultation. There is a critical need for Middle East universities in light of the climate change challenges their region is facing to cultivate interdisciplinary expertise among their future leaders across many of the societal sectors. Further research is needed to identify and analyse the barriers and drivers of stakeholders' inputs to interdisciplinary curriculum development. Research questions to be considered include the following: What and how much knowledge about sustainability is required in the course? Does the course already include the examination of and the development of perspectives and values that lead to the transition towards a healthy, just, equitable, secure and environmentally sustainable society? To what extent are students encouraged in this course to be aware of the connections between the environmental, social, cultural, political and economic aspects of sustainability? Are the teaching methods used consistent with the values, ethics and principles of education for sustainability? As most failed attempts to embed sustainability cite a lack of leadership, incentives, knowledge, and/or resources when trying to implement new programs or add them to existing curricula, further research is needed to explore barriers and drivers to embedding sustainability in higher education institutions.

CONCLUSION

The RUCAS Euro-Mediterranean initiative through the development of sustainability competences and capacity-building programs to train university teaching staff for embedding sustainability in their academic disciplines is considered a good example for reorienting university curricula to address sustainability. It provides the opportunity to build on best practices and lessons learned and expand the reach and impact not only within partner institutions, but beyond that. Within the three years of the RUCAS initiative, we have transferred expertise from European universities through the organization of three regional workshops in Beirut, Cairo and Amman, where university staff coming from six disciplines have been trained on revising course curricula to embed sustainability. An Online Community of Practice (OCoP) developed is being used as a resource, repository and forum (http://community.cc.uoc.gr/). Almost 250 university courses have been revised to address sustainability across the six prioritised academic disciplines (educational sciences, social sciences, applied sciences, technical sciences, business/economics sciences and health sciences). A pilot initiative for student placement and practicum has been carried out, through which more than 3000 students have been involved in producing collaborative projects dealing with local sustainability issues. The opportunities for students to engage in service learning programmes provided them with 'real-life' experiences. It was also widely shared among the participants that engaging students in situations identical with those they are expected to find after graduating become more equipped to confront with real-life issues.

The interventions carried out by the RUCAS project have contributed significantly in producing a corpus of university teaching staff in each partner university who in turn initiated course curriculum revisions to address sustainability. It has also resulted in shifting traditional approaches to teaching and learning towards alternative teaching and learning methods such as place-based learning, inquiry-based learning, problem-based learning, discovery learning, inter-disciplinary teaching, which are suitable to education for sustainability. It is of particular importance to note that students participated in a survey for mapping their competences related to education for sustainability. They were also actively involved,

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

especially through practicum assignments during the implementation of the revised courses. Teaching staff was also involved in developing the ESD-student competence framework that was applied. They also took part in professional development or capacity building workshops to get the needed readiness and involved in the curriculum revision process, the implementation and the assessment of the revised courses. Administrative staff has also taken part in facilitating the process and the local National Tempus Offices organised external monitoring field visits. The revised student courses and the institutional ESD framework policies and practices that are being developed are also expected to be the drivers of change within and among institutions in the partner countries and region.

ACKNOWLEDGMENT

This work has been developed within the framework of the RUCAS (Reorient University Curricula to address Sustainability) project that has been funded from the European Commission (European Commission, TEMPUS- No 511118-2010-GR-JPCR). The content of the paper reflects the views of the author, and the Commission cannot be held responsible for any use which may be made of the information contained therein.

Chapter 36
Transdisciplinary Methodology of an Architectural and Urban Discourse in Higher Education

Svetlana Perović
University of Montenegro, Montenegro

ABSTRACT

The chapter includes identification of the need for reconceptualization of architectural and urbanistic discourse in higher education and the definition of the transdisciplinary methodology for a sustainable development of the living environment. Architecture and urbanism as complex disciplines that start from the existential social needs and reach to the most complex challenges and aspirations involve complex approaches and complex relations. Professional educational environment from architecture and urbanism aspect is integral. It includes the study of forms and models of urban space planning to architectural structures, details, materials, environmental challenges, as well as new paradigms of shaping life and work in the community. This requires the involvement of various disciplines and forms of knowledge for forming a competent and productive response to modern challenges of the real world. With the development and adoption of transdisciplinary methodology in environmental higher education, a platform can be developed for sustainable urban development in a sustainable social community. Technological aspect has a central role in that process.

INTRODUCTION

Research in this paper is essentially motivated by a tendency to understand the complexity of an urban system, with an emphasis on architecture and urbanism, that is the built environment as a primarily product of activities of these fields. This paper examines the challenges posed by the diversity of opinions and attitudes in a monodisciplinarry action and also the articulation of the challenges of the integrated knowledge from different perspectives. A comprehensive response to the sustainability of the solution

cannot be provided by none of the standard, linear theories. This leads to the replacement of opinions with an integrated knowledge that promotes the sustainable development of the urban environment. In this context, the reconceptualization of educational methodology in higher education is essential.

Urban expansion policies, intensive urbanization and technical and technological possibilities have led to cities developing into power centers, which are adopting a global city character. On the other hand, questions of urban poverty, urban health, urban decay, brownfield sites, urban regeneration etc. are coming into focus, demanding a higher level of insight in the development and shaping of urban areas. Global approach to research and urban question-solving is an important part of sustainable development, where universities take central place in the process. In that context, collaborative educational architectural and urbanistic discourses with a high level of collaboration can develop an adequate platform for answers to complex questions of 21st century urbanism. Production of professionals with developed conscience for a comprehensive overview of problems and with transdisciplinary collaborative knowledge can strongly contribute to sustainable upgrading, controlling and managing of urban areas.

The aim of education is the production of competent professional intellectual elite for the specific requirements of space and time. This aim is attainable only if we are committed to continuous and integrated model of studying, for layered understanding of the urban environment and the humane and healthy view of social values. These are also the basis for the development of environment of permanent cultural paradigms.

Cultural environment is the most precious asset of the human society, the culture of spatial management has become an important measure of the cultural level of a society in the 21st Century, which can play a decisive role for the future of civilization (Kurtović-Folić & Perović, 2012). Cities are explicit indicators of knowledge, architectural and cultural strength and overall social development. Knowledge and skills are the pillars of development. United engaging discourse and practice and different professional competencies articulatesproductive management of the urban system, its control and improvement.

Architecture and urbanism as broad areas of action include the complexity of the educational system. Complexity involves multiple dimensions and contents of the study program, many layers and cooperation between all factors and levels of the educational process. Complexity of architecture and urbanism as disciplines, suggests and obliges their layered studying that is customized to dynamic social changes and modern conditions of life and work. An important direction in the professional educational environment is to promote the new forms of urban culture and society development, to promote the development of new forms of urban culture and society, through integral engagement, which has been embedded in strategic methodological framework oriented toward research line. Thereby,the educational process is not only the companion of social change, but its driver, and thisis possible to achieveonly by healthy thinking and acting.

The 21st Century involves flexibility and globalization of knowledge. The complexity of the urban system and the complexification of the needs of users of space, requires a complex analysis of various factors and influences that shape the developed environment and facilitate the process of design of architectural and urbanistic programs.

The aim of this paper is to define a new model-general transdisciplinary methodology of architectural and urbanistic discourse in higher education, which will enable the development of a platform for complex analysis of urban problems in purpose of sustainable development of the physical structure of cities. This methodology could be generally applied in other study programs of higher education.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

BACKGROUND

Higher education in the 21st century, in scientific research, is relying primarily on issues of sustainable development and pervasive emphasizing of the need for abandonment of the dominantly disciplinary methodology of education. The term sustainable development has emerged as a response to environmental degradation and an expressed need for global cooperation in order to achieve joint sustainable solutions. Sustainable development is an integrated economic, social, environmental, technological and cultural development directed towards the protection and improvement of the environment. The most cited definition of sustainable development is the Brundtland definition as follows:

Sustainable development is development that meets the needs of the present without compromising the ability of future generations to meet their own needs (Bruntland, 1987).

Issues and encouragement of sustainable development are a global task with diverse and complex challenges (Baker, 2006). In the context of the necessary changes, a more specific definition of sustainable development is as follows:

In essence, sustainable development is a process of change in which the exploitation of resources, the direction of investments, the orientation of technological development, and institutional change are all in harmony and enhance both current and future potential to meet human needs and aspiration (Brundtland, 1987).

Research shows the need for a new era of social, economic and environmental development that will be based on integrated knowledge.It is important to note that since 1990 there has been a series of declarations proclaimed on sustainability in higher education, which was investigated by various authors (Grindsted & Holm, 2012; Lozano at al., 2013; Wright, 2002).With the goal of sustainable development, declarations, charters, and other promoted documents, dominantly point to the central role of the universities in addressing the issues faced by the modern civilization, as well as to the need for integrated models and paradigms in the curricula of higher education, from the interdisciplinary to the transdisciplinary level.

The significance of the proclaimed declaration is shown by the fact that more than 440 universities in the world have signed the Talloires Declaration, the first Declaration on Sustainable Development in Higher Education (ULSF, 2012), which was created out of the need for urgent solving of problems in the living environment and articulating the directions of sustainability. In the world with most profound changes, environmental education has a leading role in the control and development of urban systems, and is formalized as a key in this process.

In the *Decade of Education for Sustainable Development* from 2005 to 2014, declared so by the United Nations in 2002, the universities have been recognized as important places for the contribution to sustainable development which implies "Reorienting educational programs" (UNESCO, 2005). Regarding architecture and urbanism education, it is important to consider the context of collaborative environmental education, as sustainable, including interdisciplinary collaboration and articulating new methodological challenges of transdisciplinary orientation. Transdisciplinary environmental education involves the production of integrated knowledge and presents the most realistic but also the most challenging methodological choice that can meet the global challenges of the new century.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

ENVIRONMENTAL EDUCATION AND SUSTAINABLE URBAN DEVELOPMENT

In the Declaration of the United Nations Conference on the Human Environment, held in Stockholm (UN Documents, 1972), there is a set of proclaimed principles and strategies for the conservation and development of a productive and healthy environment. Conference in Stockholm has, for the first time on a global level, pointed out the need to integrate environmental education into existing educational systems.

Research methodologies, paradigms, models of higher education by various authors, as well as a number of proclaimed declarations and charters on sustainable development in higher education, have had a significant impact on the transformation of architectural and urbanistic discourse in the world with the most profound changes in society. These changes have particularly been in the spotlight during the last decade that has officially started of the new millennium, which is quite clear an age of intensive transformations, and they are stimulated by the rapid development of technical and technological capabilities, global challenges, and complex environmental problems. However, there are more theoretical discussions and attitudes, while the practice of higher education takes place predominantly in the disciplinary context.

Modern environmental education includes integrity of architecture, urbanism, landscape and interior architecture, art, design and other disciplines, which is particularly evident in the 21st Century when the issues of environment and sustainable development have become more complex. The very description of the city cannot be displayed without analyzing the economy, public policy, civil engineering, history, literature, religion, art, with each discipline having its own domain of research. Architecture is well positioned to offer an adequate synthetic overview (Allen, 2012). Questions of the relations of humans and the environment, history and theory of architecture and urbanism, art, technology, social sciences, ecology, planning and design, cultural heritage, multiculturalism etc., reflect adequately through the integrated architectural and urbanistic activities.

Development of new domains, such as Ecological Urbanism (Mostafavi, 2010), Landscape Urbanism (Waldheim, 2006), Meteorological Architecture (Rahm, 2009), Transurbanism (Brouwer, Mulder, & Martz, 2002) Transarchitecture, cultural tourism etc. pander the need for integrated science and confirm the previous hypothesis. The revised Charter for Architectural Education, from 2011, which was initially approved in 1996, highlights the connection between architecture and other disciplines, "architecture is a discipline which draws knowledge from the humanities, the social and the physical sciences, technology, environmental sciences, the creative arts and the liberal arts" (UNESCO / UIA, 2011). Architecture and urbanism cannot be treated independently in the context of sustainable development, but there has to be a developed, "Awareness of responsibilities toward human, social, cultural, urban, architectural, and environmental values, as well as architectural heritage" (UNESCO / UIA, 2011). The objectives of the Charter for architectural education are

The creation of a global network of architectural education within which individual achievements can be shared by all and that it will enhance the understanding that architectural education constitutes some of the most significant environmental and professional challenges of the contemporary world (UNESCO / UIA, 2011).

Classification of environments on physical environment (natural and built environment) and non-physical environment (social, cultural, political, economical), indicates the importance of integrity of the disciplines, that the space is next to the physical dimensions also cultural and perceptual and ecological.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

It is not sustainable, in light of the global challenges of ecological crisis and climate changes, to study isolated natural and built environment, which places architecture and urbanism in the context of environmental research. "Eco-development, ecosystem planning, bioregional planning, and green and sustainable design are all new ideologies and concepts that place emphasis on resolving environmental problems caused by human activities" (Salama, 2008, p. 109) Urban sustainability is an essential component for the advancement of civilization. "The promotion of sustainability in the design of the built environment is a key-factor for addressing the challenges that mankind faces in response to finite resource availability, ecological deterioration and climate alteration" (Altomonte, 2009, p.12).

The high degree of responsibility in modern society in economic, social, and ecological sense, particularly issues of urban health, is placed on professionals who plan, design, build, manage the built environment. The impact of sustainability that is truly rooted in the program of higher education (Farren-Bradley, Sarah, & Amanda, 2010) allows the articulation of sustainable professional practice.

In theory and professional research there is increasing emphasizing of the role of architecture and urban planning in the process of sustainable development, through the creation of directives and methods that put green building in the focus in the domain of evaluation of property. The most common and most influential international environmental methods for assessing environmental impact are: Leadership in Energy and Environmental Design (LEED), developed in 2000 by the U.S. Green Building Council (US-GBC) and Building Research Establishment Environmental Assessment Method (BREEAM), founded in 1999 by the Building Research Establishment (BRE).

Architectural and urbanistic works with specific aesthetic and technical values and an environmentally sustainable design are the requirements in contemporary city shaping. Such courses of action cannot be developed without adequate professional training. Students should acquire adequate knowledge on the impact of environmental, structural and technological issues, planning, design and construction of space as well as artistic disciplines (The European Higher Education Area, 2010).

The last decade has significantly changed paradigms and architectural education reforms in Europe and in the world. It has caused the inadequacy of the application of certain directives in the context of rapid economic change and its reflections on the equally rapid changes in society (Spiridonidis, 2011). Architectural and urbanistic curricula include the production of professional elite that is prepared to meet the challenges in planning and shaping of the modern built environment and with a clear vision of sustainable development. Sustainability is a core issue of architecture, which needs to be integrated into the architectural program at the global level (Wright, 2003). Environmental education plays a central role in articulating and promoting of sustainable solutions in a time of intense technological and social changes.

RE-CONCEPTUALIZATION OF DISCIPLINARY METHODOLOGY IN ARCHITECTURAL AND URBANISTIC DISCOURSE

The key initiator of sustainable social development are the universities. Sustainable higher education involves a re-conceptualization of conventional methodology in higher education with study curricula of traditionally linear orientation. In order to develop sustainability in higher education, which is constituted by declarations, increasingly university programs are being directed to review and revise the current curriculum. It is certain that radical transformations are necessary in the methodology of higher education, which is designed, predominantly, on disciplinary grounds. Modern higher education implies sustainable curricula across all levels, which refers to the highest forms of cooperation. Integrated knowledge, that

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

involves intensive and integrated collaboration between disciplines and stakeholders, will have a more certain preparedness to face the challenges of sustainability, resilienceand vulnerability that dominate the contemporary study of the modern city. Urban expansion and global processes point to the importance of choosing the methodological approaches to the analysis, research, and specific interventions in urban space. Human activities on the one hand produce wealth in the cities, and in parallel, studies show that poverty and fragmentation occupy a significant position in the urban system. Understanding of architectural and urbanistic discourse as central to collaborative environmental educational process, creates space for the articulation of integrative educational methodological paradigm in the context of sustainable development of the built environment. It is unrealistic to encourage disciplinary methodological transformation and development in modern high education, in the context of the sustainability paradigm. Contemporary architecture and urbanism include planning and design of the built environment in the atmosphere of intense: social, economic, environmental, technical and technological changes, diverse opportunities and challenges. Global influences, environmental conditions, climate change, and global requirements, transportation systems and infrastructure with the technological possibilities point to the new position of architectural and urbanistic work with multidimensionality and multidisciplinarity emerging to the fore. It is getting more difficult to study architectural and urbanistic discourse fragmentary, especially due to a number of disciplines involved in the creation of environmental sustainability. Environmental sustainability requires an integrated system process in the development of the built environment and a high degree of collaboration between different disciplines, which must involve integrated knowledge. Re-conceptualization of conventional methodological paradigms of higher education transforms the disciplinary linearity into a transdisciplinary infrastructure network of innovative, productive learning methodologies. Limitations of conventional and conservative disciplinary educational methodology interpret the articulation of awareness through new challenges based on the principles of connectivity, holistic and collaborative levels of reality. Starting from the physical ambient in which the process of education is being conducted, architecture and urbanism are harder seen as specific and independent units: industrial design, parametric design, management, engineering, urban health, regional and local conditions cannot be partially investigated. The need for an integrated intellectual research has been formalized.

In the conventional framework of higher education, an innovative approach to sustainable education involves joint action learning, with Juisto, McCauley and Stephens (2013) state processes, opportunities and challenges of shared action learning through five stages:

(1) Project impetus, (2) Contextual research and project planning, (3) Community engagement and project refinement, (4) Action, and (5) Reflection and reporting. The key theory of urban sustainability for effective education is a holistic view through collective action, which is "critical thinking; holistic or systemic thinking; long-term orientation; engaged, participative learning (in contrast to passive or spectator sports-like behavior); collaborative learning; timely feedback; and learning in cyberspace-as-classroom. (Banai, 2012)

Out of different levels of reality, Disciplinarity, Multidisciplinarity, Puridisciplinarity, Crossdisciplinarity, Interdisciplinarity, Transdisciplinarity (Max-Neef, 2005; Georgescu & Georgescu, 2012), unlike others, the highest level of integrity - transdisciplinarity works between and beyond disciplines, with a unique methodology aimed to solve common problems. The focus is on the problem, and the autonomous action of disciplines is unacknowledged. Sustainability of autonomous action of disciplines, up to

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

interdisciplinary, it is not certain. Global urbanization, economic instability, as well as increased awareness of the environmental crisis has sparked a different way of thinking about the design methodology, one of interdisciplinary orientation (Allen, 2012). Interdisciplinarity, which is increasingly present in the curricula of higher education in the field of architecture and urbanism, has a tendency to develop relationships between social, economic and environmental factors that influence the development and transformation of the contemporary cultural landscapes. The bodies of knowledge originate from different disciplines and are necessary for the successful creation of the built environment, and the importance of awareness of the role of architecture and urban planning in order to improve the quality of life through sustainable cities is primary. Interdisciplinarity contains as an essential feature the identification of certain attitudes and issues that cannot be explained through the disciplinary methods and theories, as well as the diagnosis of complex and systemic problems in practice. Looking at educational engagement in a broader sense, it can be concluded that a productive development of general urban culture requires the integration of education through the convergence of natural and social sciences as well as the inclusion of new ones that have not yet strengthened their position in the current time. This, it seems, is at the same time an important pillar for the sustainability in the global ambient.

There are close-knit relations between interdisciplinarity and sustainability in education, where students are thinking beyond the frameworks of one discipline and effectively collaborate in the process of solving problems. Various approaches are possible in the promotion of interdisciplinarity that arise from the need to transform the standard curriculum. For example, landscape urbanism has appeared in schools in the 1990s, in order to encourage interdisciplinary research in the post-industrial city. It includes a variety of disciplines: architecture, urban planning, landscape architecture, ecology, hydrology, horticulture, construction, infrastructure. Also, climate change requires a review of the conventional paradigms of education. Visual and functional architecture should develop a sensitive relationship towards the context and local conditions. Global impacts in the local context, as well as the need for higher levels of integrity prompted the Graduate School of Architecture, Planning and Preservation-GSAPP, Columbia University, to develop Studio X, "the first truly networked global think-tank devoted to real-time engagement with the future of the world's built environment." Studio X was launched in 2008 (GSAPP, Columbia University, 2013) and is "a global network of advanced research laboratories for exploring the future of cities." StudioX " is a new kind of cultural space in the city" with the mission of "bringing together the worlds of architecture, design, art, planning, preservation, construction, media, business, education, and research" and it develops "a special relationship with local artists: visual, multi-media, installation, performance, music, literature networked truly global think tank devoted to real-time engagement with the future of the world's built environment" (GSAPP, Columbia University, 2013).

Intensive changes of the modern world induce vulnerability of urban systems, which is not easy to track, control and develop in accordance with the requirements and consequences of these changes. Interdisciplinary methodology has proved insufficient in solving complex issues of modern cities. In that sense, development of transdisciplinary methodology and integrated knowledge that involves a combination of research, education, and engagement of different stakeholders, can become a new paradigm in sustainable education. Students in transdisciplinary educative collaboration have the ability to approach the problem differently, to think globally and act locally, and to develop critical and creative thinking (Salama, 2008). Future architects will have the capacity to not only consume knowledge, but to create it as well (Salama, 2008).

The choice of methodology for studying and understanding of the city and its architecture and routing the flows of urban development opens the way towards a sustainable urban system. Research confirms

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

that the role of transdiciplinarity in the new century is essential. Modern practice indicates that there are certain levels of knowledge transformation and the tendency towards a collaborative methodology of education, but with insufficiently developed criteria and shows the need for a radical revision of the existing higher education system.

TRANSDISCIPLINARY METHODOLOGY IN ARCHITECTURAL AND URBANISTIC EDUCATION

The educational transdisciplinary action intends to avoid the fragmentation of knowledge for the benefit of communicativeness (Andalécio, 2009). Transdiciplinarity should be the strategy for development of educational engagement, but not exclusively based on the theoretical principles but as a way of thinking and acting. Diverse research and experience from other areas shows that in most universities, and even those who are profiled as the faculties for transdisciplinary studies, where transdisciplinarity, from the name of the faculty to the program itself, has been officially adopted as a model of studying in theory, teaching is carried out in the disciplinary framework (Andalécio, 2009). This confirms the complexity of application of this methodology. Transdisciplinarity as a concept, appeared in the 70s of the 20th Century, and gained in importance only two decades later, when the two streams appeared, treating this term by noting the importance of routing one-dimensional classical thinking towards multidimensional that transdisciplinarity accepts (Klein 2004). Transdisciplinarity is based on complexity, layering, compaction, communicativeness but also specifics that include different perspectives. The importance and actuality of the term indicates a need towards new, more productive studying models that follow the requirements of global time and dynamics of social changes. Transdisciplinarity involves deliberation of methodology in professional education on a higher level. Transdisciplinary metodhology is universal, it is applied in all areas of knowledge and represents a new "revolutionary" model of cogitation in the 21st century.

First World Congress of transdisciplinarity was implemented in 1994, where the statute of transdisciplinarity was adopted. The main goal of the congress was the implementation of transdisciplinarity in education. The greatest impact and the greatest achievement in this direction was achieved by the establishment of The International Center for Transdisciplinary Research CIRET, in 1987 in Paris. This triggered the development of new organizations and programs of transdisciplinary orientation. Transdisciplinarity has in time acquired international impact, particularly in the field of higher education, which became open to various experiments and the development of transdisciplinary curricula, particularly at the post-graduate studies level at universities. Transdisciplinary methodology has become primary in modern research of the development in practices of education for a sustainable future (UNESCO, 1998).

The need for transdisciplinary methodology stems from the global requirements, limitations of the disciplinary methodology, the search for knowledge that goes beyond disciplines and includes a variety of stekeholders. As other authors discuss "transdisciplinarity involves going between, across, and beyond different disciplines. While interdisciplinarity refers to the links between knowledge and models available in different disciplines, transdisciplinarity moves beyond this to develop both a new vision and a new experience of learning" (Morin, 1999). Integrated knowledge can address complex problems of modern urban systems. Sustainable development could initiate transdisciplinary thinking which is of a research, critical and creative nature. Burry (2012) points to the need for new models of practice, emphasizing transdisciplinary approach to the design of the built environment with the concept of ideas and practical applications that articulate the call for the integration of knowledge and research in design.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

The emergence of science is linked to a clear separation between scientific and practical knowledge, which changed over time. "The emergence of transdisciplinary orientations in the knowledge society at the end of the 20th century is the most recent step" (Hirsch Hadorn et al., 2008, p.19).

Adaptive, flexible, creative and integrated architectural-urbanistic design, as well as the transdisciplinary approach in fields of architecture, urbanism and landscape urbanism have resulted in the development of an entirely new understanding of the built environment, and, which are not constructed on traditional paradigms and patterns of planning and design, aesthetic and functional requirements, but is the new guidance as indicated by the developed relations: meteorological architecture, transarchitecture, transurbanism, ecological urbanism and others. Introducing a transdisciplinary understanding of the built environment articulates a whole new philosophy of relation towards space, which was known back in the history of the building of cities.

Notable names in the history of modern urbanism, who represented the integrated study of cities in the context of the living environment are Patrick Geddes, Lewis Mumford, and RadhakamalMukerjee. These 'trans-disciplinary' environmentalists' (Guha, 2000), have treated the city as an organic whole, an active stage for the performance of various philosophies of life, needed to be integrally researched.

Environmental crisis is largely related to the engineering crisis of planning and design of cities, which is why new methodological points are a significant contribution towards the development of sustainable cities. Drawing on previous research and viewpoints of the authors and the developed general methodology of transdisciplinarity, it can be concluded that the methodological basis of architectural and urbanistic discourse in the direction of sustainable development involves training in the context of environmental synthesis of disciplines. Disciplinary methodology of architectural and urbanistic education as multidisciplinary fields is not sustainable. Disciplinary methodology solves the problem in the short term, while interdisciplinary methodology that is selectively applied in practice in higher education, as it appears, is not sufficient to meet the various needs and impacts of the 21st Century, especially if committed to the development of sustainable cities of the future.

Transdisciplinary methodology is an integrated single methodology for different types of knowledge. It integrates different disciplines, theory and practice, universities, academic and non-academic structure, and others. Transdisciplinary methodology over time is reflected in the new language of paradigms and models that can be used as instruments for complex and global problems that are outside the realm of traditional scientific methodology. Research shows that in the transdisciplinary methodology of architectural and urbanistic discourse of higher education, the central place belongs to the environmental study, then communication, creative and critical thinking and technological aspects, in order to articulate the sustainable development of cities. In addition, ecological, socio -economic, political and cultural influences on architectural and urbanistic activities should especially be emphasized, as well as the unity of theoretical and practical experiences. Engineering sciences, as well as the arts are integral elements of architectural and urbanistic education.

Engaging students through critical thinking, decision making in problem solving, consolidation of ideas and skills through feedback information, and implementation of ideas in the implementation of innovative and productive solutions is of primary importance. The effectiveness of communication relations, effective strategic communication platform, communication as a strategic interactive long-term process, scientific research, intellectual, in-depth research practice, are essential in the practice of transdisciplinary methodological education of architects and urban planners. Given the complexity of the implementation of transdisciplinary methodology, Max-Neef (2005) notes two possibilities of transdisciplinarity "a weak and a strong transdisciplinarity" (p.5), in the context of the reorientation

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

of higher education. Since there are many challenges and the wider adoption and implementation of transdisciplinary methodology into the curriculum of higher education is a complex process and yet to come, from the aspect of architecture and urban planning every step forward is of great importance for sustainable planning and design of the cities.

TECHOLOGICAL ASPECTS OF THE TRANSDISCIPLINARY COLLABORATION IN EDUCATION

The technological aspect is central in contemporary design of urban space. Planning, research, experiments, alternative, new models of physical structures include adequate modeling and intensification of communication globally. It is no longer enough to be exclusively related to a certain space and intervene in it from the perspective of a particular discipline. The intensity and complexity of information technology and capabilities and their availability have allowed the connection, dialogue and mobility in the broadest sense.

Technological innovations developed in the last decade largely construct a platform for the new technological era, complexity of which will largely determine the complexity of the educational system. Digital technologies such as e.g. the Geographic information system -GIS enable transformation of the rational planning approach towards communicating. The complexity of the space planning involves a high level of professional competence and responsibility in the context of sustainable development. GIS could become an effective tool in planning and designing sustainable cities. Computer technologies such as "computer aided design (CAD), 3D object scanning, rapid prototyping (RP) and industrial rapid manufacturing (RM) technologies such as computer numerically controlled (CNC) cutting / milling technologies," are very incentive to overcoming disciplinary boundaries (Marshall & Pengelly, 2006). By means of appropriate computer technology it is possible to employ new forms of cultural, psychological, sociological, aesthetic, artistic domains in the design process. In this sense, it is necessary to develop also the technologically innovative solutions that cross disciplines and integrate different knowledge. Allen (2012) identifies three stages of digital design, the first stage is metaphorical, created during the 80s in the 20th century, the second phase, which occurred during the 90's is experimental, while the third, current phase, is the age of digital technology, robotics and parametric design.

Education should be developed in line with rapid technological changes, which requires extensive revision of the curriculum, international architectural and urbanistic education, the use of integrated models of technology hardware and software, telecommunications and multimedia technology. The last two decades are characterized by rapid technological and social changes and with it complex challenges in the architectural practice of education (Allen, 2012).

Education in the broadest sense, has a key role in achieving the required profound changes in contemporary society dominated by digital technology patterns. The specificity of disciplinary educational process is no longer a primary strategy, but above all, production of professionals who can respond to the global, ecological, climatic, geographical, regional circumstances in local conditions. Technological capabilities foster collaboration, transprofessionalism as a challenge with new forms of cooperation at all levels can be more dominantly positioned than the conventional differentiated practice of problem solving.

The synthesis of disciplines through modern effective technological models can promote and encourage the more productive processes of architectural and urbanistic education and professional practice in cultural contexts.

CHALLENGES OF TRANSDISCIPLINARY METHODOLOGY IN HIGHER EDUCATION

Limits to disciplinary thinking (Ramadier, 2004) have resulted in the development of higher levels of integrity, which in realization faces various challenges. Research of Evans and Marvin (2006) showed that interdisciplinary theoretical basis of researching the city as a complex combination of science, technology and society, and complex problems at the beginning of the decade, have not been finally realized in practice. Universities are constantly exposed to various external influences, external influences, and organizational influences (Hyun, 2011). This points to the complexity of the radical transformation of methodologies in higher education. Methodological innovations include a gradual and continuous process of revision of curricula, from interdisciplinary to the transdisciplinary level. On the other hand, the failure to develop educational programs related to sustainability at universities and institutes, present an impact on society as a whole (UNESCO, 1998). Contemporary methodological shift in architectural and urbanistic education shows that there is a strong need for changes, but that often transdisciplinary defined curricula are implemented in practice in an interdisciplinary framework. The main challenge is that the transdisciplinary methodology strongly advocates the development of a single integrated methodology for problem solving. Different disciplines develop their own research methodologies and actions and often with high levels of contradiction, which makes it difficult to create a unified language.

Also, if we talk about sustainable development, collective and individual interests are varied and often conflicting. The development of new paradigms and models of transdisciplinary orientation in pursuing the highest forms of cooperation on different levels, includes certain paradoxes that have to be overcome. "One of the challenges of higher education is to reconceptualize its relationship with the rest of society, both civic and corporate, so it can broaden its role to address the challenges of today's world – the polycrisis (McGregor & Volckmann, 2011, p. 2).

FUTURE TRENDS

We start from the position that the transdisciplinary methodology is a necessity of higher education in the 21st Century. The development of sustainable cities implies sustainable architectural and urbanistic education. It would be useful to direct future research towards the development of new models, paradigms, patterns that would more approximately determine the features and articulate the benefits of transdisciplinary methodology in architectural and urbanistic discourse in the context of environmental higher education. This would help encourage commitment to transdisciplinary methodology of the curricula at universities as primary drivers of sustainable development.

CONCLUSION

The academic environment is a particularly sensitive issue and it implies the inclusion of all forms of institutional infrastructure and researching diagnosing of the key issues and the cross section for its improvement. Academic study programs, personnel policy, transparency, universality and innovative visions of development are the basis of productive knowledge. Acquiring of skills and competence, creativity,

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

critical thinking, international cooperation, teamwork in the transcultural contexts contribute to a more complex approach of the problem.

The mission of modern higher education in the 21st Century includes orientation towards the development strategy of integrated knowledge, which, as such, can meet the challenges of the global process of urbanization, cultural and social transformation. Sustainable development of the physical structure of the city is the primary issue in response to the demands of the global time. Integrated urbanistic and architectural knowledge entails the inclusion of more autonomous disciplines in the system of collaborative work, as well as other forms of knowledge that with united action could provide the answers to the questions of the global world in the local context. Transdisciplinary methodology of architectural and urbanistic discourse in higher education can become a paradigm of the sustainable development of cities in the 21st Century.

Global processes are increasingly shaping the local built environments. Unified knowledge can meet the challenges of the third millennium for the goal of sustainable development. University knowledge implies the adoption of transdisciplinary methodology. Studying architecture and urbanism in a transdisciplinary environmental context is of particular importance for a sustainable future.

KEY TERMS AND DEFINITIONS

Architectural and Urbanistic Sustainable Higher Education: Environmental integrated education with architecture and urbanism as central disciplines.

Architectural and Urbanistic Sustainable Knowledge: Environmental integrated knowledge that includes academic and non-academic knowledge, with a purpose of developing a human-built environment in a dynamic time of technology.

Environmental Sustainable Higher Education: Integrated education of different disciplines and forms of knowledge.

Interdisciplinary Higher Education: Interconnected education of independent disciplinary methodologies.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Multidisciplinary Higher Education: Education of independent disciplinary methodologies.

Sustainable Higher Education: Education that is the product of integrated knowledge.

Transdisciplinary Higher Education: Education of a single integrated methodology, which is created by the transformation of different disciplinary methodologies.

Chapter 37
Sustainable Education: A Buzzword of Universiti Teknologi PETRONAS, Malaysia

Muhammad Zahid
Universiti Teknologi PETRONAS, Malaysia

Zulkipli Ghazali
Universiti Teknologi PETRONAS, Malaysia

Haseeb Ur Rahman
Universiti Teknologi PETRONAS, Malaysia

ABSTRACT

The sustainable development (hereafter, S.D.) aims a growth that could satisfy the wants and needs of present generation without affecting future generations. Accordingly, this study investigates the role of HEIs in S.D. by selecting the case of Universiti Teknologi PETRONAS, Malaysia. The study adapted the universities sustainable development initiatives checklist/index for qualitative analysis of the main website, operational documents, and practical initiatives of the university for S.D. The findings revealed that the university has good and meaningful contributions towards three dimensions of S.D. i.e. economic, social and environment. The study proposed an improvement in Education for Sustainable Development (ESD) and implementation of S.D. framework for universities. The findings have significance and practical implications for academia, regulatory bodies, policy makers, and HEIs. Also, the findings are significant in association with new economic model (NEM) and vision 2020 of Malaysia.

INTRODUCTION

It is the issue of everybody to concern with society and its welfare. The individuals, larger or smaller groups, formal or informal entities, public or private firms, governmental or non-governmental organizations considered as the key stakeholders of society must always have aspired to champion societal concerns (Amoako, Agbola, Dzogbenuku, & Sokro, 2013). Sustainability has a broad sense and can be viewed as the relationship of organizations with the society as a whole, and the need for organizations to

align their values with societal expectations (Dowling & Pfeffer, 1975; Elkington, 1997; Roca & Searcy, 2011). In reality, it is a standard that organizations can impact their environment with the potential to build a sustainable development (Helg, 2007). However, it is grave that society educates everyone to be responsible. As concerning to all societal actors, universities are considered are the ones educating the future leaders of a country. What these educational institutes teach and do not teach may make or break the nations' future and well-being (Amoako et al., 2013).

The most accepted definition of sustainable development (S.D.) was firstly coined by the Brundtland Report which claims for a development that "meets the needs of the present without compromising the ability of future generations to meet their own needs" (WCED, 1987). The main contribution of this pioneering concept highlighted that the human well-being depends on the health of the environment, in other words, on society, economy and environment are inextricably connected (Delai & Takahashi, 2013). Sustainable development is three nested and interrelated domains where the largest is the environment that provides ecosystem services and natural resources, in the middle is society and the smallest is economy (Baxter, Boisvert, Lindberg, & Mackrael, 2009). Hence, S.D. comprises of three main dimensions: environmental, social, and economic.

S.D. has become a globally accepted concept and become a guide to interacting with nature and society. In order to overcome the challenges of S.D., it calls for a paradigm change at all levels including education sector (Disterheft, Caeiro, & Azeiteiro, 2013). To support this argument universities have been charged with the key roles in promoting and implementing sustainable development (UNESCO, 1992). Moreover, many scholars see the impact of universities on S.D. has vastly greater than any other single sector of society because universities educate the coming generation of decision-makers, influencers, and leaders (Lozano, 2006). Due to societal impact universities are seen as multipliers for distributing S.D. principles with the ethical obligation to systematically integrate S.D. into their institutions (Cortese, 2003). Hence, a number of universities have responded and showing good progress in the implementation of S.D. in universities. "The emerging fields of sustainability in universities is Education for Sustainable Development (ESD) which can be seen as an evolving scientific foundation for the advancement of sustainability, including the transition to sustainable universities" (Disterheft et al., 2013). ESD is being part of the sustainability discourse and policy-making process since very the beginning, it has been influencing the debate on learning objectives, contents, pedagogies, and competencies necessary for the paradigm shift to S.D. (Disterheft et al., 2013). During the last decade, there is an increasing trend in higher education institutes to engage in incorporating and institutionalizing S.D. into their curriculum, operations, research, outreach, assessment and reporting (Lozano & Young, 2013).

However, in spite of many steps and policy making for S.D. number of universities are engaging with S.D., while, most of them are continued to be traditional. Consequently, they are still lagging behind to contribute in a holistic manner for a broad spectrum of stakeholders requirements (Lozano, Lukman, Lozano, & Huisingh, 2013). The current study has an objective to investigate S.D. initiatives of a university with a focus on three dimensions economic, social and environmental. The study will answer the research question that how a university could contribute for S.D. The study selects University Technology PETRONAS (official name as Universiti Teknologi PETRONAS - UTP) Malaysia as a case. The remaining sections of the paper consist of a brief literature review, a Malaysian perspective, a case study of UTP, conclusion and recommendations.

LITERATURE REVIEW

History

Generally, the literature evidenced that the origin of S.D. is associated with the publication of "Limits to Growth" by the Club of Rome in 1972 (Meadows, Meadows, Randers, & III, 1972) to the United Nations conference on the Human Environment, held in Stockholm in 1972. However, the concept itself can be traced back 300 years in the work of Hans Carl von Carlowitz published about sustainable forestry, and T.R Malthus (1766-1834) who reported the environmental limits to population growth (Mebratu, 1998). So, evidenced from this historical work that the emergence of S.D. concept is a post-industrial era, and it is much older (Disterheft et al., 2013). Nonetheless, there is a general consensus among the scholars that the WCED report "our common future" known as Brundtland Report considered as an evolution of S.D. The report coined the definition of S.D. as "S.D. is a development that meets the needs of the present without compromising the ability of future generations to meet their own needs" (WCED, 1987). The term S.D. sometimes applied to economic growth or as a development strategy. S.D. is being the process to achieve a growth. While the term sustainability would have more emphasis on the environment, stand for the final goal of human wellbeing (Lozano, 2008; Waas, Hugé, Verbruggen, & Wright, 2011). However, in the common practice and literature, these terms are not using as separate and in the usual approach of using these terms interchangeably.

Additionally, a consensus about the basic principles and ideas of S.D. and sustainability comprises normativity, intra and intergenerational equity, justice, gender equality and participation. These principles have been endorsed by the Rio Declaration at the UN Earth Summit in 1992 and are usually associated with both terms equally (Disterheft et al., 2013). Accordingly, during the 1970s and 1980s, many of educational institutions moved forward in establishing environmental sciences and environmental studies programs (Rowland, 2013). In the meantime, campus staff and administrators working in campus operations have started to address issues like utilization of resources. Moreover, such efforts often driven by economic forces, for example, an increase in energy prices encouraged energy managers to seek means for energy conservation. Water shortages and increased costs led the water conservation both in buildings, offices and landscaping as well. As a result, the introduction of the Talloires Declaration[1] by Jean Mayer of Tufts University in 1990 was an important turning point in the evolution of the campus-based sustainability movement in the USA and Canada. The declaration clearly recognized higher education role in sustainability education, and the signatories are committed to their institutions to ten actions, including fostering environmental literacy for all. This declaration was important because it explicitly linked ESD to campus operations in a section titled, "Practice Institutional Ecology". The signatories committed to setting an example of environmental responsibility. At that time only four US universities were present, however, by 2010, there were 350 total signatories around the world (Rowland, 2013).

Sustainable Universities

Cortese, (2003) identifies four dimensions for sustainable universities: education, research, university operations and external community. Lozano (2006) adds a fifth dimension of assessment and reporting. These dimensions are considered as interconnected and dealt with in a comprehensive, dynamic, horizontal in manner and considered crucial for implementing sustainable development in a holistic way. There are still some issues with less attention like the non-materialistic aspect of sustainability related

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

to social, cultural and ethical questions. However, some good progress has been made in curriculum greening, campus operations (environmental issues and their educational dimension) system transitions approach towards a large group of stakeholders, outreach programs and last but not the least assessment and reporting. Universities are also conducting specific conferences with the focus on S.D. implementation in universities (Disterheft et al., 2013; Lozano, 2011).

Education for Sustainable Development (ESD)

As discussed earlier the debate about S.D. has also initiated the concept, ESD which helps to achieve the goals of sustainability. It has been a field for international educational policy-maker since the beginning of the S.D. debate. The ESD concept started being institutionalized in 1992 with the international recognition of Agenda 21 and its specific chapter 36 about education at the UN Earth Summit in Rio de Janeiro (UNDES.D., 2009). ESD can be defined as ''Education for Sustainable Development (ESD) is a learning process (or approach to teaching) based on the ideas and principles that underlie sustainability and is concerned with all levels and types of learning to provide quality education and foster sustainable human development—learning to know, learning to be, learning to live together, learning to do and learning to transform oneself and society'' (UNDES.D., 2009). The UNESCO was assigned as manager for the implementation of Agenda 21's chapter 36, and ESD has received much attention worldwide. Further related achievements were the UNESCO report ''Education for a Sustainable Future'', in which the necessity of a reorientation of education in all sectors and the key principles of ES.D. are stressed, and the launch of the UN Decade on Education for Sustainable Development (2005–2014) that stimulated numerous projects on all educational levels.

Similar to the concept difficulty of S.D., ESD has also no single, uncontested definition, and often terms such as Education for Sustainability (EfS) or Sustainability Education (SE) are used interchangeably. Other terms which are used less frequently such as Earth Education; Environmental and Developmental Education; Environmental Education for Sustainability; Education for a Sustainable Future; Education as Sustainability; and Sustainable Development Education (Filho, Manolas, & Pace, 2009).

Some Milestones and Policy-Making for S.D. in Higher Education

To support the commitments towards sustainable development more than 20 declarations and policy documents are promulgated for education institutions (Disterheft et al., 2013). All of them are based on a moral obligation toward promoting and contributing to S.D. within universities: ''perhaps the unifying theme among all declarations and policies is the ethical and moral responsibility of universities to be leaders in promoting sustainability'' (Wright 2002). In 1972 at Stockholm Conference education was formally known on an international level to play an important role in fostering environmental protection and preservation (Lozano et al., 2014). Afterwards, more HEIs have engaged and embedded in environmental education and education for sustainable development (ESD) into their systems' elements (Lozano, 2006). Similarly, HEIs developed and signed a collection of declarations, charters, and initiatives to provide guidelines or frameworks for HEIs for showing their commitments and better embed sustainability into their system, Table 1 exhibited most widely recognized higher education for sustainable development (HESD) (Lozano et al., 2013).

1991	Halifax Declaration, Conference on University Action for Sustainable Development, Canada	Higher Education
1992	Report of the United Nations Conference on Environment and Development (Rio Conference); Agenda 21, Chapter 36: Promoting Education, Public Awareness and Training and Chapter 35; Science for Sustainable Development	Society
1992	Association of University Leaders for a Sustainable Future, founded, USA Kyoto	Higher Education
1993	Kyoto Declaration, International Association of Universities Ninth Round Table, Japan	Higher Education
1993	Swansea Declaration, Association of Commonwealth Universities' Fifteenth Quinquennial Conference, Wales	Higher Education
1993	COPERNICUS University Charter, Conference of European Rectors (CRE)	Higher Education
1996	Ball State University Greening of the Campus conferences were in 1997, 1999, 2001, 2003, 2005, 2007, and 2009	Higher Education
1997	Thessaloniki Declaration, International Conference on Environment and Society: Education and Public Awareness for Sustainability, Greece	Education
1999	Environmental Management for Sustainable Universities (EMSU) conference, first held in Sweden. Following conferences in 2002 (South Africa), 2004 (Mexico), 2006 (U.S.A.), 2008 (Spain), and in 2010 in The Netherlands	Higher Education
2000	Millennium Development Goals The Earth Charter Global Higher Education for Sustainability Partnership (GHESP)	Society Society Higher Education
2001	Lüneburg Declaration on Higher Education for Sustainable Development, Germany	Higher Education
2002	World Summit on Sustainable Development in Johannesburg, South Africa (Type 1 outcome: Decade of Education for Sustainable Development; Civil Society outcome: the Ubuntu Declaration)	Society
2004	Declaration of Barcelona	Higher Education
2005	Start of the UN Decade of Education for Sustainable Development (DES.D.) Graz Declaration on Committing Universities to Sustainable Development, Austria Abuja	Education Higher Education
2009	Abuja Declaration on Sustainable Development in Africa: The role of higher education in S.D., Nigeria Torino (Turin) Declaration on Education and Research for Sustainable and Responsible Development, Italy	Higher Education Higher Education

Nonetheless, signing a declaration has not yet ensured that the signatory institutions will implement S.D. within their systems. As a result, some universities accused of "greenwash" if they fail to implement S.D. thought out their system instead of signing a declaration (Bekessy, Samson, & Clarkson, 2007). Moreover, some universities without signed any declaration or belonging to any charter, are performing well for S.D. (Lozano et al., 2013) such as regional development (Dlouhá, Huisingh, & Barton, 2013), to reduce greenhouse gas emissions, academic leadership, commitment via inclusion of S.D. in their mission and vision statements (Lee, Barker, & Mouasher, 2013).

Sustainability Reporting in HEIs

Sustainability reporting has gained much importance in the last decade in both profit and non-profit organizations. In the corporate world this trend has increased over the last decade (Daub, 2007). When we see this increase, particularly in the corporate world looking at the world's 250 largest companies; in 1999, only 35% of them reported on their corporate social responsibility activities, in 2013, 93% of these organizations have compiled sustainability reports (KPMG, 2013). From the viewpoint of fairness that the private, public, and non-government sector should have a concern for increased disclosure of organizational activity. However, in the recent literature, only a few research papers (partly) address sustainability reporting by government and non-government organizations (Hahn & Kühnen, 2013). Following the increasing trends of sustainability reporting in the corporate world (Kolk & Perego, 2010; Lozano & Huisingh, 2011), some higher education institutions (HEIs) have started sustainability reporting (Ceulemans, Molderez, & Van Liedekerke, 2014). However, this trend of sustainability reporting is still in its early stages in HEIs, both because of the lack of a substantial number of reporting, and low quality of reporting outcomes (Ceulemans et al., 2014). In the Global Reporting Initiative (GRI) Database [2] the first sustainability report from the university sector was in reported in 2001, and by the end of 2012, this number gradually increased to 33 reports. Similar to the low number of HEIs publishing these reports, only a low number of research studies have been conducted to addressing the issues of sustainability reporting in HEIs, and in spite of the slowly progress of trend sustainability reporting in higher education, it is still unclear for certain players in this field what sustainability reports contain.

S.D. and Malaysia

The awareness towards the sustainable development in Malaysia was highlighted for the first time in the Third Malaysian Plan (1976-1980) published by the Economic Planning Unit (EPU)[3] from the Prime Minister's Department. The Plan designed a blueprint for the Government of Malaysia (GOM) for five years as a development strategy. From the fourth to presently the Tenth Malaysian Plan (2011-2015), the concept of sustainability gained much importance in line with global initiatives on sustainable development (Samuel, Agamuthu, & Hashim, 2013). The Eighth Malaysian Plan (2001-2005) focused on the incorporation of environmental considerations into development was intensified, which result in the integrated and holistic management of the environmental and natural resources. During these periods institutional capacity and regulatory frameworks were reinforced, new approaches and planning tools were established for environmental protections. As an end product, the National Environmental Policy (NEP) was formulated in 2002.

Under the ninth Malaysian Plan (2006-2010) environmental stewardship was promoted to ensure the balancing of development and environment. The Plan has strongly emphasized the need for R&D to enable the achievement of enhanced environmental quality in the century. Moreover, the efforts towards sustainability are further established under the Tenth Malaysian Plan (2011-2015) with the introduction of the AFFIRM (Framework for Awareness, Faculty, Finance, Infrastructure, Research and Marketing) to develop a complete ecosystem for environmental sustainability. Through this period, institutional capacity and regulatory frameworks were reinforced, new approaches and planning tools were established for environmental protection. Two focus areas have been identified for the next five years first developing a roadmap for climate resilient growth, and second, enhancing conservation of the nations' ecological assets. During 2010 the Government of Malaysia has taken several steps towards implementation of sus-

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

tainability e.g. Government announced an RM 100 million CSR fund, creating of a federal level ministry dedicated to Green Technology, and also allocated funds for RM 1.5 billion towards the development of environmental sustainability. The Malaysian government has also announced a commitment to reduce carbon emissions up to 40 percent by 2020. Sustainability declared as one of the three goals of New Economic Model 2010 (NEM, 2010).

Through National Key Economic Areas (NKEA) in the Tenth Malaysian Plan, the government would improve the quality of public higher learning institutions through performance-based funding by escalating the rating system for Malaysian Higher Education Institution (SETARA) in order to cover private universities and college universities, and its faculty level. It also introduced the central enrollment system for all students including international students with flexible credit accumulation framework. A conducive educational system would be provided to attract students and world leading faculties in niche areas to set up branches in Malaysia (NEM, 2010).

METHODOLOGY

The current study uses University Technology PETRONAS (official name as Universiti Teknologi PETRONAS - UTP) Malaysia as a case study by adapting universities sustainable development initiatives checklist/index from the previous literature (Lozano et al., 2014). For the grounding of S.D. initiatives the study uses qualitative content analysis procedure for the years 2011 to 2015 of UTP main website (http://www.utp.edu.my/), embedded website links, internal university operational documents and departmental initiatives those are directly linked to S.D.

Universiti Teknologi PETRONAS (UTP)

Universiti Teknologi PETRONAS (UTP) established as a university in the private sector of Malaysia in 1997. In the start university offered a variety of programs related to engineering and technology at graduate and post graduate level. Currently, UTP offers five (5) engineering programs namely Chemical, Civil, Electrical & Electronics, Mechanical and Petroleum, and three (3) technological programs namely Petroleum Geoscience, Information & Communication Technology and Business Information System, Applied Physics, and Applied Chemistry. However, the university later introduced the programs in management and humanities as well in order to produce graduates with excellent skills of leadership and communication. The University has a current strength of 6000 students from more than 50 countries around the world. It has produced more than 10000 graduates till date since its inception in 1997.

The Quacquarelli Symonds (QS) ranked UTP as 4-star institution (out of five-star rating) in five areas of employability, internationalization, innovation, facilities and access among eight. The UTP is the only university with this honor in the private sector of Malaysia. The university has also ranked in top 200 universities of the QS World University Ranking by subject for Chemical Engineering in 2015. Moreover, the departments of Electrical & Electronic Engineering, Mechanical Engineering and Computer Science & Information Systems of the university have also included in the world ranking. In addition, the university has a distinction to be the only university in the private sector of Malaysia ranked in the top 200 universities in QS rankings for Asia in 2014. The university stood 335 in the QS World University Rankings for Engineering and Technology Faculty. The University is a Tier 5 (Excellent) University

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

for SETARA (Rating System for the Malaysian Higher Education Institutions). It has also achieved the status of Tier 5 for D-SETARA (Discipline-Based Rating System) in engineering.

UTP has the vision to become A Leader in the education of engineering and Technology and recognized as a Centre of creativity and innovation.

The mission of the university is to produce well-rounded graduates who are creative and innovative with the potential to become leaders of the industry and the nation. Moreover, the university also aims to encourage creativity and innovativeness for the welfare of the society.

UTP Endeavors for Sustainable Growth

UTP focuses Research and Development activities in order to earn the name of a research university within and outside Malaysia. The university carries out extensive research projects in collaboration with PETRONAS (which is the parent company of the university) and other national and international institutions. Subsequently, the university focuses nine areas namely Enhanced Oil Recovery, Carbon Dioxide Management, Deepwater Technology, Nanotechnology, Green Technology, Biomedical Technology, Hybrid Energy Systems, Intelligent Cities and Sustainable Resources. This focus is considered to strengthen all the three dimensions of sustainability not only in university but in society and country as well. The university was, therefore, awarded a 5-star rating by Malaysian Research Assessment Instrument for research, development, and commercialization in the recent past.

The Centre of Excellence (COE) and Centre for Intelligent Signal and Imaging Research of the university focus biomedical image analysis with neurochemical imaging. Subsequently, these were recognized as the National Higher Institutions by the Ministry of Education in October 2014 to focus. Moreover, the Centre of Innovative Nanostructures and Nano devices were also recognized as a national COE by the Ministry of Science, Technology and Innovation, Malaysia in 2011.

Economic Sustainability

Department of Mission Oriented Research (MOR)

The R&D Master Plan of UTP focused on developing technological platforms in the Oil & Gas, Transportation and Intelligent System in the start. However, the university, later on, turned its attention on "Mission Oriented Research" in "Oil and Gas Industry" of the country. This shift triggered much by the current capabilities of the university and importance of the sector which have a great contribution in the GDP of the country. In addition, the university aimed to assist the core businesses of its parent company (PETRONAS) which enjoys the status of "leader" in the sector. Subsequently, a department of Mission Oriented Research established to focus Enhance Oil Recovery (EOR). EOR is a technique that increases oil production by injecting stored carbon into the mature oil fields. The department focusing research areas in the field of enhancement of Reservoir Rock and Fluid Characterization, EOR screening and modeling, New and Novel Technologies like Nano-enhanced EOR and EOR Agent Injection. The department prioritizes the enhancement of WAG applications by implementing modified chemicals synthesized from local sources and Nanomaterials developed by UTP researchers. The department undertakes research activities spanning from Geology through drilling and finally on EOR recovery methods as the method has a higher success rate. Following are mission and vision statements of the department. The department aims to develop and improve reservoir characterization and recovery methods in EOR to enhance

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

recovery. The department has the vision to be known as a leading R&D institution on advanced EOR Fluids and acknowledged as an expert in Reservoir Modeling and Characterization in EOR.

Following are the details of various projects carried out by the department.

1. Simulation of Injecting Characteristics During WAG Process.
2. Mathematical Modeling of Steam-Alkaline-Gas (SAG) Injection.
3. Synthesis and characterization of a polymeric smart surfactant for enhanced oil recovery purposes.
4. Development of a new alkaline smart surfactant acid flooding formulation for enhanced oil recovery.
5. Development of a graft polymer for enhanced oil recovery.
6. Development of biopolymers for enhanced oil recovery.
7. Development of new EOR methods with the application of EM waves and Nano particles.
8. Understanding the effects of Asphalting presence on multi-phase relative permeability characteristics.
9. Understanding the effects of different injection schemes and displacement efficiency during WAG injection.

Intelligent Cities

Undoubtedly, Good quality of living is the right of every human being on the earth. However, most of the human are deprived of it due to a number of reasons in developed as well as developing countries. Good living quality includes the basic necessities like food, air, water, shelter, electricity, transport, roads, sewerage, health care facilities and security with a reasonable cost and without tempering environment much. In a nutshell, good quality of life demands a well establish the infrastructure to efficiently deliver. The efficient infrastructure not only contributes to the good quality of life but also increase economic prosperity which further improves the quality of life. The issue of quality living is more highlighted in urban areas where the population density is higher than that of rural areas. Thus, the city governments, whether in developed or developing countries, face a number of problems to cope with in providing good quality of life. The MOR for Intelligent Cities of the UTP focuses these challenges to convert into opportunities so that to improve the quality of life in cities, local economy, and the environment. The MOR specifically focuses the following areas for developing and promoting intelligent cities.

To focus these areas, the MOR provides following facilities for improving the attainment of objectives. The MOR for intelligent cities has the vision to be known for social and technological innovation in modern cities by identifying and developing core research agenda and capabilities in the fundamental and advanced domains related to intelligent cities.

Figure 1. MOR specifically focuses areas for developing and promoting intelligent cities

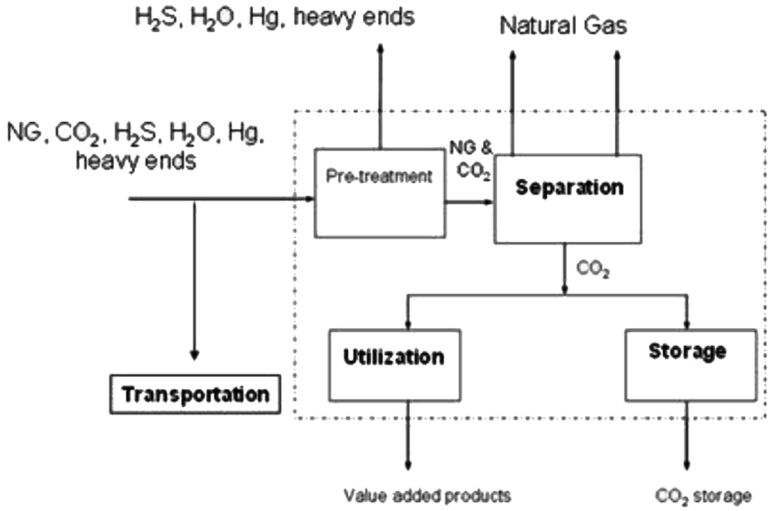
Commercialized Product: Math Quest

UTP by collaborating with Hezmedia Interactive S.D.n Bhd and MDeC has developed Math Quest. The idea behind developing this Math Quest was to help the students of primary school aged between 9 to 12 years. The quest has been developed for learning numbers by combining the learning and role playing game theories. The Eight mini games developed for the quest include Mailbox Mania, Nail the Jackpot, Rock in Room, Chaos Store, Sword Force, Chop the Chunk, Pearl Voyage and Baa… Baa Bad Sheep. Each of these games is different with a common objective of learning numbers. Due to the difference in nature, tutorials have been provided at the start of each educational game.

The achievements of this product are as follows:

1. Won Gold Award for Engineering Design Exhibition 24 (EDX24).
2. Silver award - Malaysia Technology Expo (MTE) 2011.
3. 1st Runner Up in the INTEL DST Asia Pacific Challenge 2011.
4. Gold Award – ITEX 2012.
5. Gold Award- INPEX 2012.

Environmental Sustainability



Carbon Dioxide Management

About 40% of the world gas reservoir which is approximately 2500 trillion cubic feet has a high volume of CO2 and H2S. Malaysia accounts for undeveloped CO2 –NG gas fields having a capacity of 13 trillion cubic feet of these two cases. The processing of high CO2 -NG requires an advanced technology in pretreatment, separation, utilization, transportation, and storage. The MOR of the university focuses on projects like CO2 which ensures the safety of the environment. The department currently focuses the technologies which separate CO2 particularly on adsorption, absorption, membrane, cryogenic, high gravitational separation and hybrid system including corrosion. The department is focusing selective removal of CO2 (Solvent Absorbent, Membrane, Adsorbent) in material handling activities. Moreover, the quality of NG pipeline (Absorption, Adsorption, Membrane, Cryogenic, and Supersonic Gas Separation) is focused in the separation and modeling activities. In addition, the management of material towards high CO2 handling (improved alloy steel and corrosion inhibitor are prioritized in corrosion. The separation technologies of CO2 –NG gas of the department will enable monetization of high CO2-NG gas fields in Malaysia. Moreover, the technology is expected to grant a competitive edged to PETRONAS which will help its penetration in domestic as well as international market. The following model explains this technological process.

The department has a mission to become a center of excellence in CO2-NG separation technology for oil and gas industries by expanding the frontiers of the technology for the betterment of society. The department has the vision to acquire a status of leader in Technology Research and Development of Separating High CO2- NG.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Carbon Dioxide Management Technological Process

Hybrid Energy Systems

The depletion of fossil fuels, global warming and focus on renewable energies has grabbed much of the attention these days. The MOR has a Hybrid Energy System which can be broadly categorized into three groups namely Alternative Energy, Power Systems, and Novel & Hybrid Systems. The Hybrid Energy System of MOR currently focuses hybrid energy systems by considering all the available local resources for renewable energy.

The Hybrid Energy System MOR is committed to enhancing its capabilities by equipping various labs. Currently, the department has the following facilities to support research.

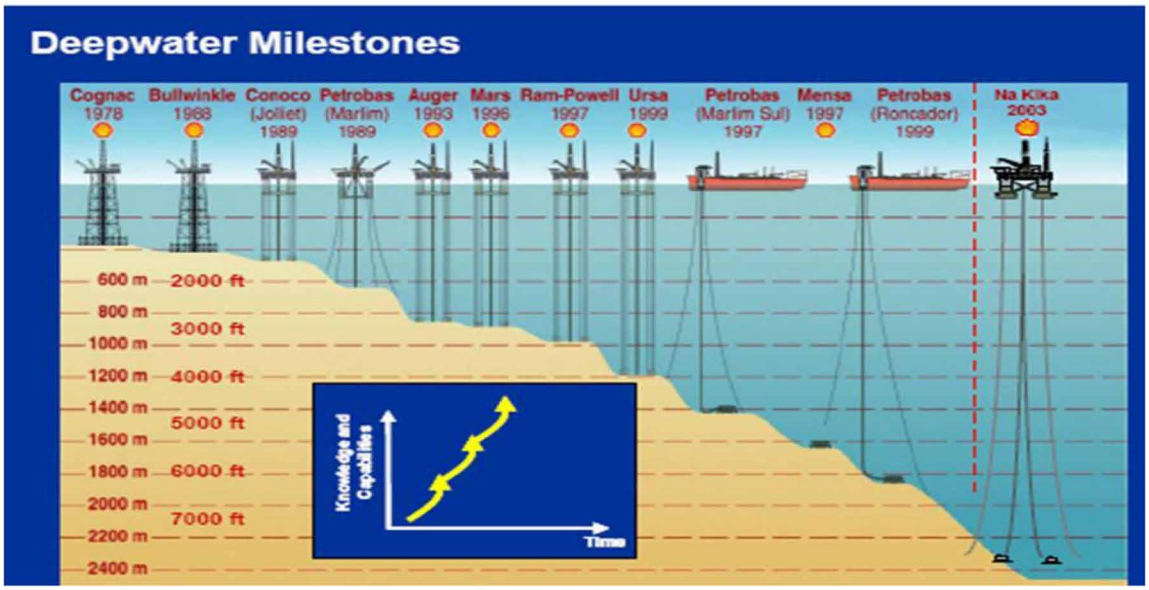
1. Centre for Automotive Research and Electric Mobility (CAREM): It is a state of the art laboratory equipped with optical research engines, high-speed imaging, planar laser induced fluorescence, particle image velocimetry, laser Doppler anemometry, phase Doppler anemometry, single and multi-cylinder test beds.
2. Gas District Cooling Plant: The plant is the ownership of the university where various projects are undertaken mainly in cogeneration systems.

Biomass Gasification Lab for Power Generation: This lab is equipped with custom built gasifiers which facilitate studies and research on how to convert the local biomass resources into gas. The lab is also equipped with diesel and petrol engines which are connected with dyno meters and emission measurement systems.

3. Solar Research Site (SRS): SRS facilitates five experimental research models to strengthen integrated techniques for improving the performance of the thermal solar systems.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

The department aims to earn a name in energy efficient technologies and integrated alternative energy systems so that sustainable energy solutions could be found for the welfare and betterment of the society. It concentrates on Electrical Power Generation Systems, Thermal Energy Systems, and Energy Management Systems to develop such Centers of Excellence that could fulfill the energy needs of the nation.



Deep-Water Technology

The term "deep water" means the water that has a depth between 500 to 1,499 meters. The water that has a depth more than 1500 meters is known as ultra-deep water. After a successful and easy access to offshore hydrocarbon deposits during last five decades, the industry is eager to explore more inaccessible locations for searching oil and gas reserves. Subsequently, the deep water technologies focused for the past ten years. The industry has been also focused much by the increasing price of the commodity and issues of energy crunch and shortages in future. It is expected that more and more research and investment will improve the technology, understanding and economic viability of the industry.

The department has the vision to be a preferred choice and deep water R&D center of excellence in Asia-Pacific by 2017. The department has the following deep-water technology projects:

1. Deep water structure integrity and reliability.
2. Pipeline flow assurance.
3. Sub-sea systems.
4. Geohazards and Geotechnic.
5. Knowledge management.

Figure 3. Deep water technology models

Nanotechnology

Nanomaterials have potentials to produce such new products which could energize the economy, overcome societal issues, rejuvenate existing industries, and create entirely new businesses. These opportunities arise as a result of the unique properties (physical, magnetic, optical, chemical, mechanical, electronic, and biological) of materials when they are at Nanoscale (< 100 nm). It is considered that a novel solution-oriented approach to materials and nanomaterials development should be carried out to realize its complete economic benefits. This approach requires a robust understanding of the fundamental scientific principles operated at the nanoscale, including interdependent structure-property relationships. This will enable cost-effective design, synthesis, and scale-up of materials that deliver selected properties, allowing for the focus on the requirements for specific applications as the primary drivers of the design process. These, in turn, will accelerate the development of nanomaterial which will result in a large number of diverse products to penetrate in markets so that solve the long awaited issues and stimulate economic growth. The MOR for nanotechnology has the vision to be the nation's premier center of excellence and provider of Nanotechnology. (See Figure 5).

Green Technology

The Green Technology of MOR concentrates on sustainable technologies in order to decrease environmental issues pertain to greenhouse gas emissions, water contamination, chemicals, toxic waste and heavy metals management. The mission deals these issues through channelizing activities to the main themes like wastage of wealth, clean technology, and cost effective solutions. The mission has two

Figure 4. Nanotechnology mission

Figure 5. Nanotechnology mission

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

research centers namely Center for Biofuel and Biochemical Research (CBBR) and PETRONAS Ionic Liquid Center (PILC). These centers focus the following areas:

1. **Bio-Fuel and Bio-Chemical:** This area covers the conversion of biomass to solid, liquid, gas, fuels and biochemical products.
2. **Ionic Liquid:** This area deals in developing new potential ionic liquid which supports oil & gas industries.
3. **Green Process System Engineering:** This area focuses green process modeling, simulation, integration and optimization in order to boost the efficiency of material and energy management in green processes.

It has a mission to develop such novel, sustainable and competitive technologies which could reduce environmental pollution and greenhouse emissions. The current projects are shown as follows:

1. Fatty acid alkyl ester from ceibapentandra, using the microwave-assisted technique.
2. Development of Agro-based activated carbon and modified carbon nanotubes (CNTs) for CO2 Capture.
3. Prototype development of integrated biodiesel blending system for mixtures of rubbers seed oil and crude palm oil.
4. Conversion of waste polyethylene and liqnocellosic materials to syngas using catalytic gasification process.
5. Conversion of paddy husk into silica ash, bio-gasoline, bio-char syngas using high-temperature microwave heating.
6. Synthesis, characterization and rheological study of novel biodegradable drilling polyol esters of jatropha.
7. Exploration of novel feedstock for the production of biodiesel.
8. Development of biomass catalytic gasification systems for sustainable bio hydrogen production.
9. Development of graphitic nano fiber and carbon nanotubes for hydrogen storage.
10. Thermodynamics of phase and chemical equilibria in the transesterification of triolein to methyloleate.
11. Investigation of the kinetics of carbon dioxide adsorption on amine functionalized MCM-41.
12. Synthesis and characterization of novel ionic liquids for toxic metal ions extraction.

Biomedical Technology

One of the MOR also works for Biomedical Technology (BMT) in UTP. It has a Centre for Intelligent Signal and Imaging Research (CISIR) which is one of the leading missions in Biomedical Engineering and Technology in Malaysia, which has more than 20 faculty members and 80 postgraduate students. It can broadly categorize into five main research groups of Intelligent Medical Imaging (IMI), Neuro-Signal Processing (NSP), Pervasive Computing & Embedded Systems (PCES), Health Informatics & Modeling (HIM) and Adaptive & Assistive Bio-Engineering (AABE).The five groups cover the topics of dermatology, ophthalmology, neuroscience, orthopedics, rehabilitation and disease modeling. The mission facilitate researchers with cutting-edge and state-of-the-art equipment like multispectral cameras, thermal cameras, 3D laser scanner, 3D optical scanner, 128-channel EEG machine (compatible with fMRI for simultaneous data acquisition), eye tracker, fNIR system, wireless EMG system, ECG

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

machine, 20 channel wireless EEG machine and customized sodium knee coil for FMRI. The MOR BMT has the vision to be a National Center of Excellence in Health Diagnostic Tools. The MOR BMT has a mission to provide solutions to different problems in the field of biomedical science and engineering by exploring the frontiers of knowledge.

Social Sustainability

University Internship Programs

Universiti Teknologi PETRONAS (UTP) established with the aim to produce graduates who are not only technically sound but also strong in critical thinking, communication, behavioral skills, business acumen, practical attitude and solution synthesis ability. UTP has a compulsory practical training for undergraduate students in the form of two internships. The internships namely Student Industrial Training (SIT) and Student Industrial Project (SIP) both have a duration of 14 weeks. This experience is considered to enhance the knowledge and understanding of students. The university keeps contact with different industries to facilitate students in placing them for internships. The Student Industrial Internship Programme (SIIP) is one of the examples of the University –Industry collaboration.

Sustainable Development

The Sustainable Resources Mission Oriented Research (SUREMOR) focuses the emerging discipline of "sustainability". The SUREMOR include the economic and environmental dimensions of sustainable development. It also focuses human capital development for a sustainable environment. SUREMOR in collaboration with university conducts activities of social responsibility and sustainability in the fields related to engineering, technology, and humanities.

The SUREMOR has the vision to be a Leading Regional Centre for Sustainable Resources in low carbon materials and environmental Engineering.

SUREMOR concentrates on THREE (3) areas relevant to global sustainability (see Figure 6).

Charity/Donation

UTP established Yayasan UTP (UTP Foundation) to further promote education in the country in 2007. Yayasan UTP has a key role in seeking donations and searching new partnerships with individuals and organizations to support university UTP its growth for becoming a leading educational institution for creativity and innovation. Yayasan grant scholarships for research and innovation in the field of arts, sports and culture. It also aims to extend philanthropic activities and financial support for the welfare of the society. Yayasan has also an important role in achieving the vision of the university to become a role model and leader in technology, education, innovation, and technology. In October 2013, UTP had organized a successful Golf tournament at Kelab Golf Sultan Abdul Aziz Shah (KGSAAS), Shah Alam Selangor. The tournament raised a fund of almost RM 0.5 million for Yayasan UTP fund (see Box 1).

Yayasan UTP (YUTP) provides non-repayable financial aid to deserving Malaysian students studying in UTP on a need basis. An amount of RM6, 000 granted to a successful applicant for assistance in tuition fee. Yayasan UTP provides 3 types of scholarship.

Figure 6.

1. LOW CARBON DESIGN AND CONSTRUCTION
   - ✓ High Performance Binders
   - ✓ High Performance Aggregates
   - ✓ Sustainable Structure (Repair, Maintenance & Durability)
2. RESOURCE EFFICIENCY
   - ✓ Formulation of 3R's and Waste Water Formulation
   - ✓ Recovery of Energy
   - ✓ Water Resources & Basin Management
3. WATER UTILISATION AND WASTEWATER MANAGEMENT
   - ✓ Pollution Management & Policy
   - ✓ New Treatment Materials
   - ✓ Novel Treatment Systems

Box 1.

Cultural Activities

Yayasan, Alumni UTP and Dewan Filharmonik PETRONAS (DFP) have jointly organized a Tapestry of Colours 2015 – a concert in 2015. The concert aimed to raise funds for Yayasan UTP (YUTP) and thus the revenue collected from tickets given to the foundation. The Yayasan grants scholarships to the deserving students of UTP to support research, creativity, and innovation in the fields of arts, sports, and culture. The foundation has granted total scholarship worth RM 3.5 million to more than 400 students till date, since its inception in 2010 (see Box 2).

Box 2.

UTP Performing Arts Group (UPAG) Shines at World Dance Festival

The university has a Performing Arts Group (UPAG) comprised of 19 members from the UTP Performing Arts Group (dancers) and 6 members from UTP Gamelan Group Sanggar Kirana (musicians). The UPAG has recently represented Malaysia for the third time in 10th Cheonan World Dance Festival at Cheonan Samgeori Park, Cheonan, Korea. The group achieved 3 awards namely Best Costume Award, Best International Street Parade Award and First Prize Award for Cheonan Folk Dance Competition International Category in this festival (see Box 3).

Box 3.

International Culture Night

The International Student Council (ISC) of Universiti Teknologi PETRONAS (UTP) has organizing 'International Culture Night (ICN) since, 2011.The first program in this connection was successfully organized on 1 April 2011 which aimed to showcase different cultures, dances, and costumes of different countries. It is one of the colorful events of the university which is liked much by the students as well as outside local community. The event is now supported by the State of Perak and Jabatan Kebudayaan Kesenian Negara Malaysia (JKKN) Negeri Perak. The event has following main objectives.

1. To introduce and promote the cultures of enrolled students from different countries of the world (around 60 countries).
2. To improve communication, coordination, integration and familiarity among the students from different cultures and between local and international students.
3. To promote respect, peace, understanding and harmony among different cultures.
4. To provide a platform for students in other universities to come and perform at the event for the sake of establishing good relations.

Meet UTP@F1 Showcase

The UTP has an event "Meet UTP@F1 Showcase" where an institution of higher learning with the collaboration of well-known Formula 1 PETRONAS Grand Prix exhibit different educational opportunities and renowned F1 grand prix events. The event promotes Universiti Teknologi PETRONAS (UTP) and this time Formula 1 PETRONAS Grand Prix 2015 as well. Visitors can see race cars on display along with educational opportunities in UTP. The prospect students and their parents can seek guidance for admission and career development from the staff, students, and alumni of the university. Students are also encouraged to walk in along with their educational credential to get admission and sponsorships on the spot. The university also organizes an exhibition to show its inventions and accomplishments which enhance the morale of students, faculty, and staff. The Computer and Science department of the university exhibit their robots in these exhibitions.

Other Initiatives

Consultancy

The university is also committed to becoming a preferred choice in providing multi-discipline consultancy services and products. The University has about 300 active in-house consultants in the various fields of specialization and they are well prepared to undertake any sectors from the consultancy services. The University has also established a knowledge-based partnership with other parties from within and outside of the country to undertake consultancy services according to market demand. Recently, the university has completed a feasibility study of deep water sea port in Lumut. This consultancy team also looked into the possible impact of the proposed project on the demand for labor and supply. In addition, the report analyzed the possible impact of the project on all other sectors (including the feasibility of electronic vehicles manufacturing plant) and the consequent.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Professional Chairs

UTP provides opportunity to industries to sponsor different Professorial Chairs for establishing a relation between academia and industry. This collaboration enables the university to gain knowledge and experience from its partners in the industry which ultimately contributes to students' development. At present, the university has following 4 professorial chairs namely:

1. Schlumberger Chair in Petroleum Engineering.
2. Shell Chair in Petroleum Geoscience.
3. Transocean Chair in Drilling Technology.
4. Mitsubishi Chair in Green Technology.

Academic and Research Conferences

Research provides a solution to the modern age problems which benefits society. UTP focuses research activities and innovation for sustainable knowledge. In conjunction, the university arranges a congress by the name Engineering, Science and Technology Congress (ESTCON) after every two years. The congress includes a number of conferences from different fields of engineering, technology, information technology along with humanities and management.

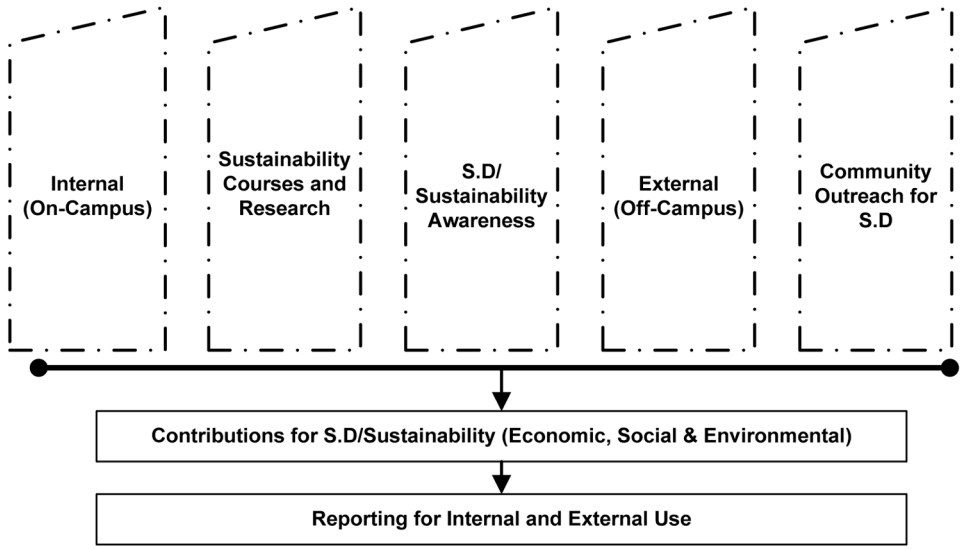
UTP Corporate Social Responsibility

Recently in Aug 2015, on the hands of Tun Dr. Mahathir launched UTP Corporate Social Responsibility (CSR) book "A Gift of Hope". "A Gift of Hope", is a book launched in conjunction with UTP's CSR approach, aligned with the university's overall vision and goals. The purpose of the book is to highlight the relationship between the university and the local society in which it resides.

CONCLUSION AND RECOMMENDATIONS

HEIs could become sustainability leaders and change drivers; they can ensure the needs of present and future generations by contributing through their institutional role, and they can educate future generations to make sustainable societies. In this regard, HEIs are required to empower and aware their employees to implement the S.D. paradigm in order to ensure S.D. throughout the university system including education research, campus operations, community outreach, assessment and reporting (Lozano et al., 2013). The debate of S.D. in HEIs has expanded over the past decades. It has been recognized that HEIs play a pivotal role in promoting S.D., sustainability principles, contributing to the paradigm shift for the better future of current and future generations. HEIs covers S.D. gamut by adopting two mainly focusing practices: on-campus and off-campus sustainability practices. These two are commonly considered as the best practices for S.D. adoption within universities. Campus sustainability covers inside the campus operations directly or indirectly link to S.D. including ES.D., sustainability research projects, S.D. related conferences, inside environmental and social contributions, while off campus covers all the outside contributions of HEIs for the S.D. domain. The current study finds that Universiti Teknologi PETRONAS, Malaysia has good and meaningful contributions for S.D. as shown in the above discussions.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use



However, despite some progress and good examples, only a few HEIs are engaged and follow an S.D. implementation process holistically. They just follow the one-sided trend of "going green" only for the purpose to fulfill market requirements, somehow marketing advantages, and economic benefits. As a result, it increases greenwashing and may lead to losing the original meaning and credibility of S.D. Despite the progress made and signs of transition, there is still a long way to go to mainstream sustainability in HEIs, and a paradigm shift from unsustainability to sustainability is still difficult to identify. Even institutions having many years of experiences in the field of campus sustainability are wedged in situations that hinder a full sustainability implementation.

Keep in view the case study of UTP we conclude the findings and proposed Table 2 and Figure 7 for avoiding the implementation barriers. Table 2 provides rigorous steps for S.D. implementation within the culture of any organization particularly a university. The study proposed these steps in following catego-

Table 2. Education for sustainable development priority areas

Commitment to S.D. and E.S.D.	Priority
1. Top Management Commitment	High
2. Vision and Strategy	High
3. Targets & Benchmarking	High
4. Stakeholders Identification	High
5. Stakeholder's Awareness & Empowerment	High
6. Research & Development for S.D.	High
7. Focus on Social, Environmental and Economic Sustainability	High
8. Reporting for Internal & External Use	High
9. Adhere National and International Policy(ies) (where applicable)	High

Figure 7. Proposed sustainability implementation framework for university

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

rization i.e. top management commitment, vision and strategy, targets and benchmarking, stakeholders identification, awareness and empowerment, R&D for S.D., focus on economic social and economic sustainability, reporting for internal and external usage and last but not the least follow a national and international policy where applicable. In Figure 7 the study proposed sustainability management system (SMS) for HEIs. The purpose behind the SMS for HEIs is to ensure the implementation of S.D. in line with the 9 priority area as defined earlier.

APPENDIX

Table 2.

Initiative for Sustainable Development	Reporting
S.D. included in the vision and mission, goals & objectives	Yes
Policy for implementing S.D.	Yes
Strategic plan for implementing sustainability	Yes
Staff dedicated to S.D.	Yes
S.D. working group	Yes
S.D. office	Yes
University leaders provide an S.D. budget or in-kind support	Yes
Plans to improve energy efficiency	Yes
Energy efficient equipment	Yes
Renewable energy usage	Yes
Plans to reduce GHG emission	Yes
Efforts to reduce GHG	Yes
Plans to improve prevention and management of waste	Yes
Waste bins to separate and recycle waste	Yes
Policies and activities to reduce paper consumption	Yes
Plans for water and wastewater management	Yes
Course on S.D. for all students	Yes
Optional courses on S.D. in the curriculum	Yes
Integrated sustainability courses throughout all curricula	Yes
Invited lecturers/professors on S.D.	Yes
Teaching across the natural sciences and social sciences faculties	Yes
Continuing education to the public on S.D.	Yes
S.D. institute research center	Yes
Funding for S.D. research	Yes
Promotion of holistic thinking in research	Yes
Use of research generated in S.D. teaching	Yes
A number of publications on S.D.	Yes
Patents in the field of S.D.	Yes
Creation of S.D. new knowledge and technologies	Yes
Research between the natural sciences and social sciences faculties	Yes
Exchange programs in S.D.	Yes
Joint S.D. degrees with other universities	Yes
Joint S.D. research with other universities	Yes
Collaboration in S.D. research projects with other universities	Yes
S.D. partnerships with other society stakeholders	Yes
Part of interdisciplinary S.D. expert networks	Yes
Academic staff involved in voluntary advisory activities in S.D.	Yes
S.D. events that are open to the public/community	Yes
S.D. working for group with members from different departments	Yes
Policies that promote S.D. for all students and staff	Yes
Sustainable practices for students	Yes
Student participation in S.D. activities	Yes
Employees and other stakeholders act sustainably	Yes
S.D. efforts are visible throughout the campus	Yes
Staff and researchers are aware of S.D.	Yes
Staff and researchers are engaged in S.D. research	Yes

Chapter 38
Integration of Education for Sustainable Development Into Formal Secondary Curricula of East Timor

Ana Capelo
University of Aveiro, Portugal

ABSTRACT

This chapter explores the relevance of Education for Sustainable Development (ESD) in formal education reform in East Timor. This chapter relied on relevant published documents and information published by various national and international agencies concerning East-Timor. It firstly reflects on the organization background of development of new secondary curriculum in East Timor; then it focuses on what protocols and principles form the basis of these new curricula. There is further description of the development and implementation of the new curricula inclusive of subject selection in consideration of ESD and Millennium Development Goals (MGDs) as illustrated with some examples of ESD integration in new textbooks for 10th year. Lastly, it highlights the challenges that team developers faced at the completion of curricular development and presents some solutions to overcome difficulties related to restructuring and implementation. Thus this chapter aims to provide an example of sustainable development integration into secondary curricula of a young country - East Timor – while illustrating the extent of curricular materials could contribute to developing skills, values and attitudes aligned with sustainable development perspectives.

ORGANIZATION BACKGROUND

Education for sustainable development (ESD) concerns educational processes to help achieve sustainable development (SD), based on three premises: environmental protection, economic development and social development, integrated in an inclusive and equitable manner (UNESCO, 2011a). Therefore, ESD is important for improving the living conditions of all citizens, promoting SD and achieving the

Millennium Development Goals (MDG), especially in young countries like East Timor. The government of East Timor has recognized the importance of secondary school curricula restructuring, including disciplinary programmes, along with the production of resources required for the various disciplines, as a priority (RDTL, 2011). In these circumstances, the Government, within the project *"Restructuring of secondary school curriculum of East Timor,"* together with Portuguese institutions (e.g. IPAD, 2010), has been developing new secondary curricular materials, with the general purpose to contribute to local MDGs (UNMIT, 2010) and sustainable development, (Capelo, 2013). Also, teacher-training courses were implemented (IPAD, 2010.

Many young countries that have undergone a post-war political transition present common patterns of development. Such a political transition may include internal conflicts, divergence over environmental and economic priorities, and a diverse ethno-cultural heritage. East Timor is no exception and presents many problems of resource degradation and deterioration, as well as local and regional diversity in the social, economic, cultural and environmental domains, reinforcing the need to respect and preserve national identity (Presidency of the Ministers' Office, 2007). All these concerns underscore the need to improve education in order to promote respect and a sense of responsibility for the sustainable development of the country. In other words, educational practices (formal, non-formal and informal) should be adjusted to local needs in order to encourage students to explore questions, issues and problems, especially in contexts relevant to SD (GC-UNESCO, 2009).

A main role of formal institutions is strengthening the preparation of students to face emerging local, national and global problems in an appropriate way, and to understand these problems and constructively participate in solving them. Moreover, the holistic perspective present in any educational program guided by ESD principles will help students develop multiple competences, e.g., technical, cognitive and emotional (UNESCO, 2011a, b).

East Timor is a country in Southeast Asia, comprising the eastern half of the island of Timor. During 400 years it was a Portuguese colony. In 1975, East Timor declared its independence but soon after it was invaded and occupied by Indonesia. In 1999, following the United Nations-sponsored act of self-determination, Indonesia relinquished control of the territory, and East Timor became the first new sovereign state of the 21st century on May 20, 2002. After independence, East Timor became a member of the United Nations and the Community of Portuguese Language Countries (Earnest, 2003). Since independence, Timor-Leste's social and economic policies have focused on alleviating poverty to address the immediate needs of our people, consolidating security and stability, and providing a foundation for nation through building institutions of State. As most education infrastructure in Timor-Leste was destroyed during the Indonesian period. East Timor's Government had invested in building and rehabilitating schools across the country, training teachers and innovating curriculum (RDTL, 2011).

Since this time, the government has invested in building and rehabilitating schools across the country, with modern and adequate classrooms, water and electricity. Also, the government invested in reform of education system, including development of a new curriculum that focused on "developing relevant knowledge, useful capacities and critical intellectual and social skills, and on promoting creativity and problem-solving skills, communication skills and critical thinking" (RDTL, 2011, p. 23). To achieve these goals, the Timorese Ministry of education has relied on the support of international experience of higher education institutions, many of which Portuguese. Portuguese institutions emerge not only because Portuguese is one of the two official languages, but also because it is the language selected for education (Albergaria-Almeida et al., 2012).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Actually, reform in at all levels of education is ongoing. Secondary school reform, in particular, is supported by the cooperation between East Timor and Portugal for the period of 2009 and 2012. The new secondary curriculum replaced the old curriculum and the respective curricular textbooks from Indonesia and Brazil. These old textbooks still exist, with extensive programs, written in a condensed form and with little diversified strategies. Though the introduction of the new textbooks reduced the shortage of textbooks, there were still not enough textbooks to teach and all the students – some students had to rely on copying notes from the board. Furthermore, most of the old textbooks did not focus on East Timor, and were not relevant to the East Timor context or case (Earnest, 2003). Their language is difficult for teachers because they have textbooks in Indonesian but the level of proficiency of Indonesian by the students is less than satisfactory so sometimes they had to explain in Tetum. Concerning the Portuguese language, the Government had made Portuguese the official language and in most schools there were teachers from Portugal that were teaching the students and East Timorese teachers Portuguese (Earnest, 2003).

In short, the work presented here, focuses on the process of design, acceptance and implementation of new secondary school curriculum materials developed during the course of specific protocol cooperation between East Timor and Portugal. Additionally, it focuses on some aspects guiding the new general curriculum which were behind its design, in particular ESD and MDGs approaches (IPAD, 2010), and its acceptance by government authorities, such as the Ministry of education, as well as, by the teachers.

SETTING THE STAGE

The Ministry of Education of East Timor within the framework of a Cooperation Protocol with Portuguese Institutions, specifically, *Portuguese Institute of Development* and *Calouste Gulbenkian Foundation*, followed by a Cooperation Agreement between *Calouste Gulbenkian Foundation* and one of Portuguese Universities, namely Aveiro University (AU) (Martins & Ferreira, 2012), prepared new secondary curriculum such as, *Programmes*, *Textbooks for Students* and the corresponding *Teacher's Guides* (IPAD, 2010). Specifically, a multidisciplinary team of approximately 60 specialists from AU supervised by two coordinators (Prof. Isabel Martins and Angelo Ferreira) are structured to produce new curricular materials for 14 disciplines, for the three years of schooling, 11th/10th/12th, respectively. In total, the team produced 42 *Textbooks for Students* (150-160 pages each), 42 *Teacher's Guides* (75-90 pages each) and 14 disciplinary *Programmes* (approx. 60-80 pages each) (Martins & Ferreira, 2012).

The need for suitable curricular materials is of particular importance, as the minister of presidency of East Timor highlighted in the official launch of the 'Education First Initiative': *"It is not good enough that many have to walk hours each day, to an overcrowded classroom, without appropriate books and curriculum"* (Prime Minister RDTL, 2012).

CASE DESCRIPTION

As is already well documented in numerous studies (e.g. Albergaria-Almeida et al., 2012; Shah, 2012), and official documents of the Government (RDTL, 2011), most schools and virtually all teaching equipment and materials in East Timor were destroyed or had disappeared (MECYS/SSLS, 2005), after the independence referendum in 1999. Most of remaining items were Indonesian and/or Brazilian textbooks.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

The recent protocol between East Timor and institutions in Portugal came to bridge the lack of specific secondary curriculum materials for East Timor.

Developmental of General Secondary Curriculum in East Timor

For the development of a general secondary curriculum, the Portuguese team took into consideration the necessity to overcome: "low enrollment ratios in secondary education;" "the large number of out-of-school secondary-school-aged youth;" difficulties in "adjustment of secondary education structures to accommodate ever increasing cohorts of students and their diversified learning needs and interests;" "low relevance, quality and efficiency in last secondary education programmes;" due to "out-dated information;" "discipline-based, college-bound curriculum;" "inadequate qualifications of many teachers and education managers and school principals;" "over-centralized administration of secondary education and lack of school autonomy, essential for improved efficiency;" and "inadequate and inappropriate use of new technology as subject, education resource and tool of delivery" among others problems [(Nan-zhao & Haw, 2002), p. 426-427]. Some of these purposes were still recognized by technical missions for monitoring the secondary curriculum restructuring in East Timor, e.g. Ferreira et al. (2011). These technical missions was performed during 2009 and 2011, five in total, where a Portuguese team is developing contacts with Timorese authorities in order to meet and work with educational leaders, schools and teachers, and with other entities that could provide relevant issues to curriculum development.

In addition to these contacts, the team consulted documents and reports from national and international agencies for the Asia-Pacific context, official documents of the East Timor Government, the recommendations of UNESCO and other UN organizations concerning ESD priorities for the second half of the Decade of Education for Sustainable Development (UNESCO, 2005), recommendations given by international bodies dedicated to ESD promotion and implementation (e.g. SEAMEO INNOTECH, 2010), as well as the East Timor work developed by researchers and educators that are important to link up (e.g. Jones, 2010; Leach, 2010; Nicolai, 2004, Taylor-Leech, 2008). IN consideration of all of these, the team designed a curriculum with a combination of content and competency-based approaches, where topics and contents were selected according to the:

1. Opinions and suggestions from local citizens about some issues that should be present in new curriculum (NIER, 1999),
2. Necessity of including new disciplines in secondary curriculum, such as, "Geology," "Citizenship and Social Development," "Themes of literature and culture" and "Multimedia technologies" (NIER, 1999),
3. Inclusion of thematic contents that reflected local characteristics, i.e. adaptation to cultural context (NIER, 1999),
4. Inclusion of MDGs-related issues (e.g. poverty, hunger health) (ESCAP/ADB/UNDP, 2007),
5. Inclusion of SD or ESD-related issues (SEAMEO INNOTECH, 2010),
6. Integration and promotion of learning goals and activities that take into account actual literature about science education (e.g. activities that encourage creative thinking, problem solving and promote greater autonomy) (e.g., NIER, 1999; Nan-Zhao & Haw, 2002), and
7. Awareness of Timorese Ministry of Education and AU for monitoring and evaluating the process of new curricular materials implementation (NIER, 1999).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

The intentions of the team are explicitly to develop secondary curriculum in an ESD perspective, in terms of specific learning characteristics and resources (see Table 1), as well as, of ESD subjects (see Table 2). The Timorese Government itself had already stated the interest of promoting a quality education towards sustainable development of the country (Capelo et al., in press).

Review of ESD experiences in the first half of the DESD (Wals, 2009) confirms that ESD can help mobilize people's participation in SD and their problem-solving capacity through processes which enable different learning contexts to flourish (e.g., collaboration, dialogue and participation). The term "process" used in this context refers to methodologies or pedagogical approaches, or teaching and learning styles adopted to implement ESD at different educational levels (Tilbury, 2011), while the term "learning context" comprises the use of different learning approaches and resources.

In science classrooms, these are linked to the concept of "Learning to Change" (UNESCO, 2011a, p. 101), which advocates "teaching science through interactive pedagogy, such as project-based learning, experiential learning and cooperative learning" (UNESCO, 2011a, p. 92). Taking this into account, Table 1 aims to suggest appropriate ESD learning approaches and resources (UNESCO, 2011a) for secondary school programmes in East Timor, whether in science or social disciplines.

The learning approaches mentioned above are based on a set of "learning characteristics" defined by UNESCO (2011a), some of which are "participatory" and others are "collaborative." According to Tilbury (2011), an internationally renowned researcher in the area of sustainability leadership, these characteristics are the most appropriate for supporting ESD learning. This researcher refers to them as, respectively, "processes of active and participatory learning" and "processes of collaboration and dialogue" (2011, p. 7). Also, states that the first, especially, encourage pupils to:

- *ask critical reflective questions;*
- *clarify values;*
- *envision more positive futures;*
- *think systemically;*
- *respond through applied learning; and*
- *explore the dialectic between tradition and innovation (p. 29)*

Concerning the set of specific ESD key themes that should be addressed in the curricula (see Table 2) the team took into consideration the specific literature concerning ESD-related issues (UNESCO, 2011a; Wals, 2009) and specific key themes recommended for the second half of the DESD for the Asia-Pacific region (UNESCO, 2010). These key these included "preventing the loss of biodiversity," "water management," "climate change adaptation," "disaster prevention," "rural development," and "cultural diversity" (UNESCO, 2011a, p. 94). Cultural diversity is relevant since respect and preservation of indigenous knowledge and traditional languages (e.g. Jones, 2010; Leach, 2010; Nicolai, 2004; Taylor-Leech, 2008) are paramount o true sustainability.

The team had also count some priority areas stated by ESD strategy for the Southeast Asia region (UNESCO, 2005a, p. 2) such as "natural resources" and "environmental education" and relevant targets from among the eight MDGs that have not been achieved in East Timor (UNMIT, 2010), such as "environmentally sustainable development" (see Table 2).

Table 1. Suggested appropriate ESD learning approaches and resources for secondary school programmes in East Timor

ESD learning approaches which could be addressed in secondary curriculum of East Timor
Cooperative and collaborative
Participatory
Student-centered
Experiential
Evidence or research based
Project and activity based
Interdisciplinary (inter-relationships across disciplines in dealing with problems)
Borderless (can take place regardless of time and location, and regardless of age)
Esd learning resources which could be addressed in secondary curriculum of East Timor
Science kits
Games
Research documentation
Information and communication technologies (ICT) articulation

Table 2. Appropriate ESD key subjects for secondary school curriculum East Timor

ESD key subjects which could be addressed in secondary school curriculum of East Timor
Health promotion, namely: HIV/AIDS Malaria Tuberculosis Others
Environmentally sustainable development, namely: Preventing the loss of biodiversity Water management Climate change adaptation Food security Disaster prevention Natural resources management and consumption Rural development
Environmental education
Cultural diversity (promotion of indigenous knowledge, recognition of traditional languages)

Examples of ESD Integration in New Curriculum

The following examples of ESD issues are related to the themes of *International Year of Water Cooperation* (WWAP, 2012) and the *International Year of Sustainable Energy for All* (UN, 2011; UNDP, 2011) as integrated into the new secondary textbooks of 10th schooling year. In consideration of the International Year of Water Cooperation, the new Biology and Chemistry textbooks integrate in an implicit way, subjects that help Timorese to become aware about the access, distribution and consumption of water (see Table 3).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 3. Examples of the integration of issues related with international year of water cooperation in East Timor secondary Chemistry and Biology textbooks

Chemistry	Biology
Unit A. Materials, Waste and Risk Management	Unit 1. Biodiversity and Dynamic Unit of Life
"Water is the most precious resource of the Earth, being a duty of each of us to preserve it and look after it. It serves for drinking, bathing, (....) and suspensions in medicines" (p.55) "How do I purify water in an emergency situation?" (p. 55)	"In East Timor, there are more than 100 rivers (...). Many of these rivers are not permanent, drying in the dry season. (…) the island of Timor is drier than the surrounding islands" (p.13) "In the Millennium development goals Report of, (...) (forecast of sanitation improvement and providing better water supply to the population in Timor-Leste" (p. 52)
"Off-shore platforms» petroleum exploration using desalination processes for drinking water" (p. 70)	"The solid remains (...). These remains can still release metals and ions that will contaminate water and soil" (p.48)
	"Reduce the use of natural resources will be a first step to consider. We can, for example, think about reducing the use of potable water to what is strictly necessary. "For example, we can reuse the water to wash the food to water" (p. 49)

Concerning the integration of subject issues or practices related to the *International Year of Sustainable Energy for All*, the analysis of new Biology and Chemistry curriculum materials of 10th school year, in particular, do not explicitly address matters relating to sustainable energy for all, which does not mean that they are not useful for teachers and students. From these books, Timorese acknowledged problems related to energy, were able to develop respect and values for energy resources and adopt attitudes and behaviors according to ESD perspective (Capelo et al., 2012).

Some practical activities suggested in these materials (e.g. Biology Programme, p. 18; Chemical Programme p. 24) can stimulate students to study matters relating with the *International Year of Sustainable Energy For All* (Mendes el al., 2012; Ferreira et al., 2012). Besides, regarding Chemistry, the *Programme* does not refer to matters that relate to Sustainable Energy for everyone, but refer to environmental consequences of waste disposal practices such as burning and incineration (p. 21). In the Chemistry *Textbook*, natural resources appear in the definition of sustainability in the *glossary* (Ferreira et al., 2012, p. 164) and in the *introduction* (p. 6), while the *Teacher's Guide* has the definition of environmental protection, in the *glossary* (p. 76), as well as a reference to energy utilization (p. 50). The term still arises in the context of integrated energy resources, oil exploration platforms and on issues proposed at the end of a subtopic (Ferreira et al., 2012, p. 70). Similarly, fossil fuels and alternative energy sources are integrated into a personal and socially relevant content, like desalination platforms, as well as issues proposed at the end of the same subthemes (Ferreira et al., 2012, p. 70).

In this perspective, the current curriculum gives relevance to certain aspects that the old curriculum did not give such as: i) contextualization to the reality of East Timor, ii) interdisciplinarity, iii) teaching centered on students, iv) promotion of practical activities, and v) promotion of ESD learning approaches and subjects. Overall, the *Programmes*, *Textbooks for Students* and *Teacher's Guides* of all disciplines under the responsibility of AU have been defined and prepared for specific curricular areas and for three years as mentioned earlier, namely, 4 for General Component (Portuguese; English; Citizenship and Social Development; Multimedia Technologies); 5 for Science – Physics (Technologies &; Chemistry; Biology; Geology; Mathematics); and 5 for Social Sciences Humanities (History; Geography; Sociology; Themes of literature and culture; Economics and Quantitative methods) (Capelo, 2013).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Approval of New Curriculum and Its Impact

The new general secondary curriculum has already been approved by National Parliament resolution No. 20/2011 and Government resolution No. 24/2011; Decree-Law No. 47/October 19, 2011 (published in Journal of Republic, series I, no. 38, pp. 5308-5314, October 19, 2011) (Capelo, 2013). The *Programmes* have been delivered to the Timorese Minister of Education. Moreover, *Textbooks for Students* and *Teacher's Guides* for all disciplines of 10th grade have already been edited and are actually being used in schools since 2012. On the other hand, *Textbooks for Students* and *Teacher's Guides* for 11th and 12th grades and for all disciplines have been prepared and delivered to the Timorese Minister of Education, for editing and use from 2013.

In consideration of the curricular reformation and development, the Timorese government always showed receptiveness with respect to the work performed by the Portuguese team. The Timorese government recognized the educational value of ESD promotion and MDG achievement in the curricula (information obtained in informal conversations between elements of Portuguese technical mission and Minister of Education, not published). Timorese teachers in conversations with the Portuguese team, revealed a huge motivation for using the new curriculum. However they recognized their own limitations and difficulties, such as:

1. resistance to change their traditional teaching habits, as well as, to change the curricular subjects, identified by the fear of the unknown,
2. discrepancy in learning opportunities between "urban" and "rural" teachers and between "genders,"
3. awareness of the relevance of new curriculum for achieving ESD purposes and then contributing to MDGs,
4. lack of pedagogical resources in classrooms,
5. high miscommunication risk due to language difficulties, and
6. risk of "educational culture shock" between trainees.

CURRENT CHALLENGES

To contribute to better performance by Timorese teachers, the Timorese Government approved an intensive course held in Portugal for Timorese teachers. Thus, the AU held an intensive six week course in October and November 2011 for 24 general secondary school Timorese teachers. These teachers were selected by the Timorese Ministry of Education, who come to Portugal to improve their training for teaching in the 10th year of schooling. This opportunity was later extended to their colleagues in East Timor. Specialists of disciplinary teams, trainers and guests teachers of secondary schools participated in the training, which allowed the Timorese teachers to experience aspirational functioning schools, and in some cases, participate in secondary school classrooms.

Also, the Timorese government supported a bachelor's course carried out in East Timor, designed and implemented with the collaboration between Portuguese teachers and the Timorese Ministry of Education. This bachelor´s course includes several modules that correspond to different subjects with an enrollment of 301 Timorese teachers. This course was held at the *National Institute for Teacher Training* (INFORDEPE), located in Díli, East Timor. During this course Timorese teachers revealed a great motivation and sense of responsibility for using the new curriculum. The implementation of

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

teaching strategies (e.g. formulation of thinking questions, collaborative construction of concepts maps, construction and presentation of posters, daily plans about ESD subjects) to replace the old strategies were welcomed (Albergaria Almeida et al., 2012).

The Timorese teachers also demonstrated awareness of their own limitations and difficulties, showing solidarity among each other in order to minimize and overcome obstacles related to the interpretation of new themes (e.g. ESD or MDGs issues), new methodologies implementation, e.g. laboratory activities; language difficulties and cultural shock between trainees, among others.

The bachelor's course does not explicitly address matters relating to ESD/MDGs issues integration in the new curriculum (which does not mean that they were not useful for teachers, in a collaborative way). It did assist to develop (i) awareness about issues or problems related with MDGs, (ii) respect and value of national heritage, and (iii) attitudes and behaviors towards sustainable development (Capelo et al., 2012). Future revisions or adjustments of new secondary school curriculum mean that every aspect of the process of curriculum implementation should be monitored and evaluated regularly.

SOLUTIONS AND RECOMMENDATIONS

In general terms and with regard to curricular implementation, it was recognized that there are some difficulties. The East Timor Government identified and made efforts to overcome them. For instance, the Government is aware of the poor training of teachers and stresses the importance of continuous teacher training (e.g. Ferreira et al., 2011; Afonso et al., 2011). Also, the East Timor Government now pays particular attention to the process of monitoring and evaluation of curricular implementation (ME-RDTL, 2012).

For contributing to this, the Portuguese team is developing contacts with Timorese authorities in order to meet and work with educational leaders, schools and teachers, and other entities that could provide relevant issues to monitor and evaluate curricular implementation. Several authors (e.g. Baker, 2000; Horton & MacKay, 1999) state that monitoring and evaluation should be prioritized in cases like this one, i.e., when the reform could benefit from the results of an evaluation, to provide feedback to policy-makers, for instance, providing guidelines about teacher training.

This training and follow-up should be provided by the teams that produced curricular materials. It is obvious that the need for a significant effort to provide the school park with the minimum conditions for a teaching quality and dignity that the Timorese deserve and need (properly equipped classrooms, laboratories, computer rooms, libraries, etc.). It is clear, however, that financial investment is not all that is needed. Improving the schools' organization and commitment of everyone in the creation and maintenance of a good working environment, especially with regard to maintenance and cleaning, is vitally important (Ferreira et al., 2011).

Other countries in Asia also followed guidelines towards the alignment of secondary school curriculum by ESD purposes (e.g. Malaysia, Laos, Cambodia), considering the priorities of an equitable education for all, and improving the quality of life for all. However, these countries are also going through the processes of monitoring and evaluation of the new curriculum to readjust some aspects to the necessities of each one. Last but not least, the proposed new curricular materials aligned with ESD key subjects and practices will enable students to develop relevant skills in terms of a better understanding of science subjects, for instances, climate change, loss of biodiversity, food security and rural development required for SD (UNESCO, 2011a).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

However, even though the selected subjects in each discipline may indicate that secondary school curricula are aligned with ESD principles, it is also important to assess if they then contribute effectively to SD. As Tilbury (2011) highlighted in a very clear way:

One critical question remains […], which relates to the extent and the depth of connection between the choice of processes in ESD initiatives and actual contributions to sustainable development. In other words, is there a direct relationship between processes and outcomes in ESD? (p. 8)

Thus, the complexity of a system-wide reform requires changes that imply various stakeholders' intervention, training and the monitoring and evaluating of the new curriculum in order to build a better future. Moreover, it is important not to underestimate the timeframe for a system-wide change to give time and to prevent the capacity to resist to centrally mandated changes (Hallinger, 2012).

ACKNOWLEDGMENT

This paper is a result of the FCT project "TIMOR – Evaluating the impact of restructuring the system of secondary education in East Timor – a study in the context of international cooperation" (PTDC/MHC-CED/5065/2012), funded under the Programa Operacional Temático Factores de Competitividade (COMPETE) and subsidized by the Fundo Comunitário Europeu FEDER. The author also acknowledges the support of Fundação para a Ciência e Tecnologia (FCT), Portugal, Scholarship SFRH/BPD/65032/2009.

Chapter 39
A Paradigm Shift: Empowering Farmers to Eliminate the Waste in the Form of Fresh Water and Energy Through the Implementation of 4R+T

Ozge Dolunay
OZ Solar Energy Irrigation Systems, Turkey

ABSTRACT

The growing population in Turkey as well as in the rest of world is focusing their attention on the availability of main resources for now and for future generations. As the clock ticks by, this focus is intensifying at an exponential rate. Depleting resources, dependency on fossil fuels, high costs of energy, water quality, food cultivation and food safety present themselves as expected issues of our generation. Waste in the form of electricity and fresh water in agricultural practices can be reduced by using Reduction, Recovery, Reuse, Recycle and efficient Technologies in order to come to a sustainable management of waste starting with small-scale farming implementations. This generation must act to implement these changes, and they must act now.

INTRODUCTION

The growing necessity of adequate waste management measures is an important area of sustainability. Waste management of not only solid and liquid wastes but also the wastes in the form of electricity, water and soil (through erosion) which complement the multidisciplinary approach of (4R+T) 4 R's consisting of Reduction, Reuse, Recycling, and Recovery with (T) the efficient Technologies in the rural development and agricultural practices.

The growing population and increasing demand of food bring more emphasis on the agricultural production and dairy industry. The current irrigation practices urgently need a shift from the massive flood irrigation in thousands of hectares to more environmental friendly, sustainable irrigation methods such as drip irrigation with renewable energy powered pumping systems. This shift in the irrigation method

would meet with the waste management pyramid at the Source Reduction & Reuse which is the most preferred action as a result; save the natural resources, conserve energy both water and electricity, save money for consumers and for governments as well as making farming more profitable.

Economically, the agricultural areas in Turkey are around 8.5 million hectares in total of which 69% is currently irrigated by all types of irrigation methods, although generally flood irrigation is the primary method. The development of the infrastructure of the remaining 31% in the coming years will not only increase the agricultural yield and create new jobs but will however put pressure on both the water resources and electrical infrastructures.

Because of the unreliability of the resource due to the effects of the climate change it is even more prudent to manage our resources more carefully.

This is where the importance of Technology wrapped around in the 4R's comes into play and creates the ability to make major shifts in farming methodologies against conventional practices.

Reduction in the consumption of water and the energy to provide this resource is the focus of this chapter.

BACKGROUND

The population of Turkey is estimated to be 100 million in 2030 by TUIK (Currently 75 million - Turkish Administration for Statistics). Turkey with its current water resources and changing water demand needs to sustain its water resources at least at current usage levels to be able to meet the demand in 2030 with 100 million people.

State Hydraulic Works (DSI) states the current yearly usable water quantity per capita is 1.519 m^3 approximately. With the growth rates provided by Turkish Statistic Administration (TUIK), only by conserving the water sources as they are at the moment, the usable water quantity per capita will decrease to 1.120 m^3 per year, which is very close to the definition of 'water poor' being less than 1.000m^3. This creates another pressure and importance at the same time for sustainable water and resultant energy management practices.

With the growing world population toward 2050, there is a challenge to produce 50% more food up to 2030 and to double the production by 2050. The conditions will make the world achieve these targets by using less water due to the growing industrialization, urbanization and climate change. Water efficiency, water management, especially in agriculture, being the major water user, reaching about 70% of the fresh water withdrawals and over 40% of OECD countries' total water withdrawals (OECD, 2010).

In Turkey, 75% of the total water consumption comes from the irrigation sector. As a result of a fast growing industrialization with the growing rate of population the availability of water per capita is decreasing. Most of the investments realized were on the irrigation infrastructure by transferring the water natural resources to the fields. Large capital investments are necessary in order to expand the irrigated area which results in difficulties in the allocation of the capital investment while putting pressure on the consumptive use of water resources (Cakmak, 2010).

The Turkish Government transferred the irrigation schemes to water user organizations and is one of the world leaders. However, the water price in these organizations is still based on operation and maintenance costs, and is charged per hectare depending on the crop. It does not include the Economic and Opportunity costs associated (Cakmak, 2010).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

State Hydraulic Works (DSI) declares new prices on a yearly basis. In 2015, depending on the irrigation type (free flow or pumping), the irrigation prices varies between 7.50 TL/da (1da=0.10 ha) to 103.50 TL/da. (DSI) In addition to these costs, operation and maintenance costs are also charged by the users, which are also declared annually. In comparison, urban water pricing differs between 3.93 TL/m^3 – 0.47 TL /m^3 excluding environmental tax and solid waste management fees (ISKI, 2015).

In some regions of Turkey, open irrigation canals from the dam to the field is causing inefficient irrigation, resulting in loss of water through evaporation (50%) and damages to the canals along the way (Adana TAYEM, 2013).

Electricity prices for pumping the water for irrigation are also resulting in very high expenses for the users in addition to their current water prices. Most of the water unions and farmers cannot pay and are in debt for their irrigation.

In addition to this price structure, all wells will have metering installed which will monitor the quantity of the water consumed by 2nd April 2016. This is actually a postponed date; the scheme was meant to be implemented by April 2013. (Official Gazette dated 4th April 2014, law no.167).

State Hydraulic Works (DSI), declares that the ground water reserves of Turkey is 21.54 billion m^3 (2013) of which the safe reserves are 16.95 billion m^3 (2013) of water. The irrigation consumption from ground water is up to 13.55 billion m^3 of which 25% is taken by registered well users, 45% is used for domestic use, and 30% is done by irrigation Cooperatives and by State. The number of registered wells in 2012 is recorded by DSI as 206.451, and it is estimated that the number of unregistered wells is approaching 200.000.

Therefore, it is very important for consumers to understand the value of water, prior to the irrigation, usage and processes. It is also very important that the costs associated with these processes is understood well by the users and that the introduction of sustainable water management systems can be easily offset against those costs.

MAIN FOCUS

In the year 2015, it is possible to have sustainable water and energy management in agricultural practice through the use of 4R's and efficient technologies. This will overcome the issues relating to waste creation from excess fresh water usage and the associated high costs of energy consumed in both the recovery and the reticulation.

By reducing the volumes of water consumed and eliminating electricity power bills, we improve the overall profitability of the farm. This then gives the farmer the opportunity to use these additional funds to focus on the balance of 4R's+T. This holistic approach to the waste management and operation of the farm complex will create a much more sustainable and profitable environment.

The field studies that we have carried out show that the majority of the farmers who have their own wells are either not aware of the quantity of water they consume to irrigate or the capacity of their submersible/surface pumps used to reticulate. Generally they are uninformed. Thus, they are unaware how much water they use for their crops. It is declared that 70% of natural water resource is consumed by agriculture. However if we could realign the unknown with the known parameters this percentage could be dramatically reduced. Through simple education methods, these unknown parameters could be monitored and reduced very easily.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

The groundwater law no.167 published in 2013, took measures on the metering systems for both electricity and water consumption in the wells, which caused a lot of controversies among the farmers. The implementation of the law was thus, postponed by the Board of the Ministers of Turkey stating that there was a short supply of equipment to implement the infrastructure required. This was a big setback for the proponents of the introduction of water consumption metering and control.

Decreasing water sources per capita in the coming years, increasing cost of electricity, importance of growing food to meet the demand of an increasing population, oblige the Government to initiate measures such as the water metering systems. Also, different methods of support mechanisms such as grants, low interest financing of renewable solutions to solve water management, all support the use of the resources focusing on the reduction, reuse, recycling and recovery in a sustainable and Technology smart way by the Government.

Typically flood irrigation is used to irrigate in most regions using large electrical pumps through canals and pipelines to provide mass volumes of water over short periods of time. Against this backdrop of flood irrigation, there is little research and even less knowledge of the amount of actual water particular crops do require and so this lack of knowledge results in over compensation of the amount of water that is used.

Therefore, if farmers could be educated to recover their water by pumping it in the storage tanks and using gravity to drip irrigate we not only reduce both volumes of water and energy consumption but create control over the volumes of water and the erosion of the soil. With a 'closed loop' drip irrigation, the water not used in the system can be returned to the storage for Reuse. Also, grey water from the farm domestic use can be Recycled and used for irrigation or farm domestic use further reducing the fresh water demand at the source. Furthermore, the recycling of washed down/cleaning water used in animal husbandry within farm complex can be used to break down manures to create fertilizer for the crops.

Then, by introducing either solar or wind power to run irrigation pumps off the electrical grid (off-grid) from either underground water tables to surface or from canals, dams and ponds to the fields, we not only reduce the energy consumption but we remove the enormous cost of bringing the electrical network to the area that requires irrigation and the dependency on the network utilities to provide a reliable electrical service. These irrigation pumps are often installed in 'end of line' situation, which results in not only voltage issues but high costs for the farmers. By using renewable resources, which are naturally available and are for free all day, every day of the year in varying volumes, we remove both these high infrastructure and operating costs, making the farm more profitable.

Through case studies, it is acknowledged that solar or wind powered pumps with half of the rating of conventional mains power pumps, can provide the volumes of the water required and are equal or even greater than the conventional methods (based on standard variables). As a result, the introduction of renewable energy powered pumps; farmers can have the independence of owning and controlling their own irrigation and even taking away the dependence on shared cooperative pumping systems.

It is a well-documented fact that flood irrigation loses 50% of the water flooded to evaporation. Spray irrigation (Sprinklers) loses 30% and drip irrigation loses only 10% to evaporation. Therefore it is implicit and imperative that farmers be educated in proper irrigation methods to reduce fresh water consumption.

One of the key focuses needs to be that the price of water charged by the relevant authorities needs to be based on actual kiloliter consumption rather than by the hectare depending on the crop, as is currently the case.

In this context, the use of good technological equipment comes into perspective when implementing such changes. The difficulty is that there is no one system that does all. Each farm has to be designed

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

specifically to the individual farm requirements. That is water tables can differ in depth, distances that the water needs to be pumped vary and the area to be irrigated is always different. The biggest challenge in this step is the introduction of good quality, environmental friendly, long lasting and efficient technologies to design the farms of the 21st century.

In an everyday developing world, certain measures can be taken on sight by Reduction, Reuse, Recycling, and Recovery with the efficient Technologies in the rural development and agricultural practices. This would not require very high investment costs but would be necessary to implement sound management and better understanding of nature, water, agriculture, environment and human beings.

SOLUTIONS AND RECOMMENDATIONS

There is not a single solution to tackle in addressing the water and energy wasted in the agricultural practices, animal husbandry, generally in farming. The solutions are multiple, combinable depending on the place that is going to be applied. The government, State Agencies, Universities, Research Centers and Companies who are already aware of this issue can play an important and big role.

The Government has already set the law on renewable energy, defined the feed-in-tariffs and enabled the citizens to implement renewable energy. However, as the bureaucratic layers of this implementation process is quite costly and lengthy especially for small capacity users, the growth of residential and/or agriculture sector small-scale business have not widely used yet. A further solution for this case would be the enhancement of the policies for agriculture, more precisely a wider policy comprising sustainable development, by providing the opportunity for future generations to have fresh water resources and good quality grown food etc.

Sustainable management of water resources in agriculture can be achieved through several solution implementations.

1. Educating the farmers, providing training on how valuable their environment is and how best to utilize their water and their energy needs to grow their crops.
2. Publishing new laws, regulations, communiqué and their implementation countrywide will broaden the sustainable development approaches in the farming.
3. Installing monitoring systems to better understand the actual usage and requirements.
4. Implementing the correct water pricing to stop wasting the fresh water.
5. Bringing subsidies, grants for the installation of renewable energy water pumping systems, smart equipment for reuse and recycle the water.
6. Structuring regional/crop-based sustainable farming models as guidelines to be implemented not only in Turkey but in different parts of the world as well.
7. Bridging agriculture with engineering designs and technology.
8. Supporting and subsidizing Public – Private – University Project applications for small scale projects and create competitions all around the country to promote these models as well as to raise awareness in every corner of Turkey.

Farming in Turkey has been carried out using traditional methods, which date back hundreds of years. This shift from traditional or conventional to sustainable farming can be implemented through both education and field trainings of individual farmers in an in-situ application which would involve all

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

stakeholders / interest groups in the end-to-end process. Eventually, a positive impact on both the quality of the products grown and the health of the consumers who consume them will be greatly enhanced.

FUTURE RESEARCH DIRECTIONS

There needs to be a paradigm shift from traditional farming methods towards proper business management practices in agriculture, the implementation of consumption control methods and the use of renewable energy resources.

New farming methods with the inclusion of renewable energy, environmentally friendly smart technologies can be implemented with joint projects between companies, universities and public represented by local authorities in the region of the projects. Implementation models of such partnerships can be further investigated.

There also needs to be a deeper understanding, through field-testing of the actual water requirements for each type of crop grown, monitoring the behavior of nature, the tendencies of the climate, the impact of the climate change, water tables and their forecast.

It would also be challenging to study the impact of small-scale sustainable farming into the rural economy as well as projecting it to the economic development of the country by bringing a green approach to the fossil fuel driven, waste intensive agriculture.

CONCLUSION

It is still possible to prevent 'water poor' status being labeled on Turkey. If action is taken now through the reeducation of farmers, our water resources can be preserved and managed well into the middle of this Century. The implementation of new methods, models of renewable energy technologies in the recovery, reduction, reuse, and recycling of water through efficient technologies would bring a breath of fresh air to both the farmers' side as well as the governments' side when both water and energy are putting a lot of pressure.

The education of farmers in Turkey is crucial in reaching 4R + T in sustainable agriculture practices but not limited to.

The holistic approach that comes with the paradigm shift of traditional farming will eventually bring better results starting from the family to the village, to the society and to the country as a whole.

KEY TERMS AND DEFINITIONS

4R + T: Reduction, Reuse, Recycling, Recovery and Technology.
Drip Irrigation: Controlled quantity and timing of the irrigation.
Flood Irrigation: Literally covering the surface of the ground with water to varying depths.
Off-Grid: Not connected to any local or national electrical power network.
Recovery: Extraction of water from water table (ground water), dam, rivers and canals.
Recycling: Collection of waste water, treatment and redistribution.
Reduction: To reduce the volume of water and energy consumed.
Registered Well: Wells that are identified and permitted by Turkish government.
Reuse: To capture excess or remaining volumes for redistribution.
Unregistered Well: Wells that are unknown to any authority.
Water Poor: Water consumption amounting less than 1000 m^3 per capita.

This research was previously published in the Handbook of Research on Waste Management Techniques for Sustainability edited by Ulas Akkucuk, pages 368-379, copyright year 2016 by Information Science Reference (an imprint of IGI Global).

Chapter 40
Employment Aspect of Energy Performance Practices in Buildings and Fiscal Policy Proposals for Turkey

Tülin Altun
Cumhuriyet University, Turkey

Hilal Görkem
Çanakkale Onsekiz Mart University, Turkey

ABSTRACT

Energy efficiency practices in buildings can be an important tool in fighting unemployment by creating many new jobs, besides increasing the economic, social and environmental levels of welfare. Therefore, energy-saving measures in buildings constitute a major aspect of energy policies in many developed countries. This study focuses on two main issues. The first of these is the evaluation of the increase in employment resulting from energy efficiency in building measures, and the second is the development of fiscal policy proposals for Turkey by comparing practices applied in Sweden and Greece.

INTRODUCTION

Increase in population, rapid growth, income increase and changes in consumption habits have resulted in the rapid growth of world's energy demand and the reserves in existing energy sources have approached critical levels. In the face of this increase in energy demand, the environmental and economic sustainability of fossil energy sources that have a large share in energy production and consumption have begun to be questioned. According to the 2015 report of the International Energy Agency-IEA (IEA, 2015, p. 25), more than 80% of primary energy consumption is derived from fossil fuels. More than 90% of the CO2 emissions that cause global warming stems from fossil fuel consumption. According to the predictions[1] that IEA has made based on three different scenarios, it seems possible to reduce the share of fossil fuels in energy consumption in the case of improving new energy efficiency policies and increasing

renewable energy investments. If the current policies are maintained, the security of countries' energy supply will be jeopardized and environmental degradation will increase. In this regard, as an alternative to fossil fuels energy production based on renewable sources such as solar, wind, hydro, biological and geothermal resources and one without risks unlike nuclear energy has been a significant current issue. Although the policies aimed at increasing renewable energy sources constitute a major step of measures to be taken with regards to energy supply, the use of these sources is yet limited. As for the efficient use of existing energy sources, it constitutes the demand aspect of measures. By increasing the efficiency of energy consumption it would be possible to reduce the environmental damage of fossil fuels[2] and to meet without interruption the energy needs of societies. In addition to this, energy saving would provide many economic and social benefits at the macro and micro levels such as the increase of countries' capacity for international competitiveness, the improvement of balance of payments for countries that import a large part of their energy since their external dependency would decrease and the reduction of energy costs for individuals as well as businesses. Besides, energy saving measures have the potential to generate a major employment. New jobs would be created by means of direct, indirect and induced effects. Direct effects would be triggered in the production, application and marketing processes of technologies that are to improve energy efficiency, indirect effects would be triggered in other sectors associated with the energy efficient sectors and induced effects would be triggered by spending the revenues obtained from energy expenses. Countries frequently bring up against global economic crises. The impact of these crises on individuals and social welfare often becomes destructive especially due to its unemployment outcomes. Governments' support for the implementation of renewable energy resources and energy efficiency through a sustainable development perspective will result in success in the struggle for both global economic crisis and global warming (Erdoğdu, 2012).

32% of total energy consumption worldwide takes place in buildings according to the IPCC's 5th evaluation report (IPCC, 2014, p. 675). On the other hand, in Turkey, 32.3% of the energy gets consumed in the industrial sector, 25.0% in the transportation sector and 37.5% in the housing and services sector (Eurostat), and energy saving in housing might be provided to a large extent only by simple measures and low-cost techniques. When this potential is taken into consideration, it is of great importance to develop strategies and policies that will ensure energy efficiency in buildings.

Factors such as the use of renewable energy sources in buildings, recycling of waste, arrangements in heating/cooling, electricity/lighting systems, adjustments made in consumption habits to use energy more efficiently, will minimize energy consumption in buildings. Moreover, buildings called passive, green or sustainable will minimize the damage to the environment in the construction process. They can also be designed to consume nearly almost zero energy during their lifetime.

According to TUİK data, the construction sector in Turkey accounts for 6% of GDP as of 2013 and the growth rate of the construction sector is 11%. 7% of the total labor force is employed in the construction sector. 121,049 new buildings were constructed in 2013 and nearly 85% of these buildings are residential buildings (TÜİK, 2014, p.134,135,395,404,676,678.). In Turkey there is a great opportunity for structuring to have a green transformation in the long term when the "Law of Transformation of Areas under Disaster Risks", that prescribes within the framework of urban transformation improvements and renovations in buildings under risk, is taken into account. Energy efficiency measures that would be taken in existing buildings include simple procedures that could be implemented and have effective return in a very short term. Returns created by these measures to be taken, are capable of quickly meeting their costs in terms of both the public sector, at the individual level and the business environment. In the long-term, social, economic and environmental welfare will increase.

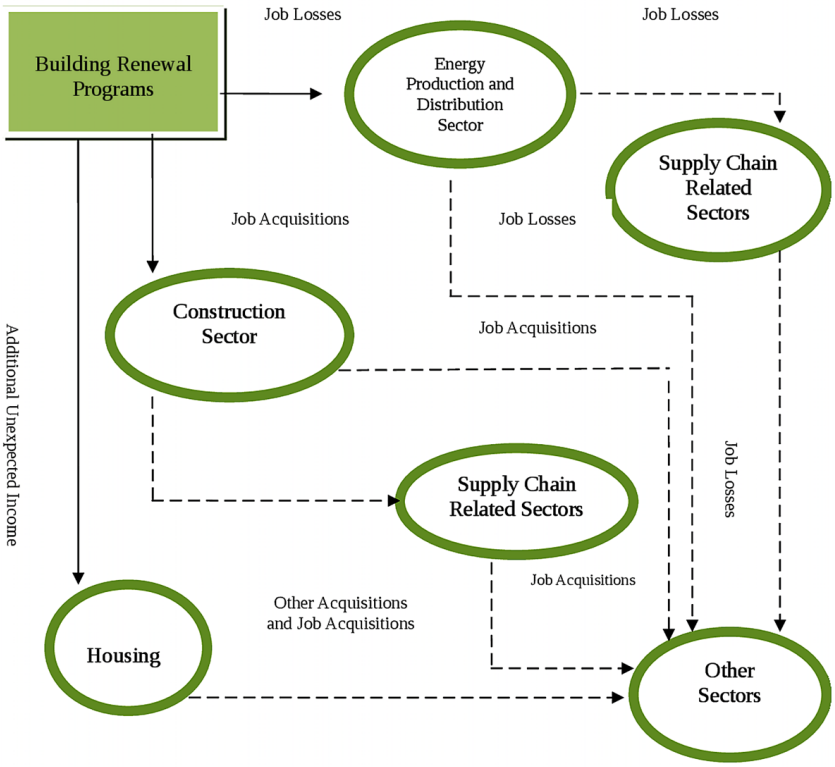
EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Energy efficiency measures in buildings provide many benefits and by emphasizing their impact on employment, fiscal policies that could be implemented in order to increase energy efficiency are evaluated in this study.

This study is grounded on two main issues. The first of these is the evaluation, at the theoretical and empirical levels, of the potential increase in employment generating from energy efficiency measures in buildings. The development of appropriate public policies taking into account the job opportunities that the energy efficient investments would generate in addition to their other advantages, is important for Turkey that is faced with high unemployment rates. Energy efficiency measures are considered to be among major possible solutions to the problem of unemployment in Turkey whose production is based on labor-intensive technology. The other issue on which this study is grounded is to develop policy recommendations with regards to the fiscal measures that may be taken in this direction considering all the benefits of these activities.

In this context, the second part of the study features theoretical and empirical literature that analyzes the impact of energy efficient projects on employment. There exists an extensive literature on how renewable and energy efficient projects would lead to new jobs in many sectors of the economy. The summary of the literature is limited to the studies that examine the effects on employment of energy efficiency measures in buildings.

Political measures developed to increase energy efficiency in buildings will be discussed in the third section. Financial and fiscal support for increasing energy efficiency in buildings offered in Greece, that has a financial setting similar to that of Turkey, and in Sweden, that is quite advanced in this matter, is being compared with the fiscal legislation and incentives in Turkey. In the fourth section, fiscal policy proposals for Turkey are developed by also evaluating fiscal practices offered worldwide but particularly in EU countries and in the United States in order to increase energy efficiency in buildings such as tax reductions and exemptions.



The fifth part consists of the conclusion.

THE EFFECT ON EMPLOYMENT OF ENERGY EFFICIENCY IN BUILDINGS: LITERATURE SUMMARY

Although there is no precise definition in literature on the energy efficiency measurement, energy efficiency is generally defined as the ability to produce with less energy without any decrease in the output or service quantity.[3] There exists a variety of methods for the improvement of energy efficiency in buildings. Technologies and procedures such as improving the old systems to prevent dissipation and unnecessary usage of energy, adapting new systems and making designs that would partially produce the energy need of buildings would save energy. The modification or renewal of lighting, heating, cooling, air conditioning and water heating systems, replacement of energy operated appliances with energy-efficient ones, making window, roof, floor and exterior insulations, improving the energy systems of buildings by new engines and mechanisms, and active energy management measures stand out among these. Changing consumer behavior is also among important factors in preventing energy waste. Many new jobs called clean or green jobs will emerge in the stages of energy efficient technique and technology production, their marketing, application and maintenance.

Figure 1. Chain effect of increasing energy efficiency in buildings on jobs
Source: Keskin, http:www.solar-academy.com/menuis/Yesil-Isler-ve-Istihdam.193310.pdf

Implementation of energy efficiency in buildings has four main effects on employment. These include the effects of investment, of operation and maintenance, of reducing activity and of increasing consumption (Mirasgedis et al., 2014, p.277-278).

- **Investment Effects:** Many new jobs will emerge in the stages of producing energy efficient measures, their marketing, implementation, pre-investment feasibility, design and etc. However, these jobs are periodic. After implementation these jobs will expire.
- **Operation and Maintenance Effects:** Processes related to maintenance and repair required to sustain energy efficient procedures also create new jobs. This kind of employment is permanent.
- **Reduced Activity Effects:** It will lead to job losses in the traditional energy sector since energy demand will decrease. This impact is permanent.
- **Increased Consumption Effects:** Energy expenses will decrease after energy efficiency investments and the revenues saved on this will be directed to the purchase of goods and services, previously not done, in other sectors. This increase in demand will lead to employment increase throughout the economy. This impact is permanent.

These impacts will affect the level of employment by generating direct, indirect and induced effects. Direct impacts on employment emerge as a result of expenses made to improve equipment or to install energy efficiency technologies and procedures. For example, expenses to be made for the transformation

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

of lighting systems into energy efficient ones, for the production and implementation of heat insulation materials, the production and modification of energy efficient tools and equipment directly affect employment.

Jobs related to energy efficiency in buildings are classified in Table 1.

New jobs will emerge in the areas listed above and have direct contribution to employment growth. Job losses will arise in the traditional energy sector though. Indirect effects occur in other sectors related with these equipment and services. For example, volume of work and employment will increase in sectors that provide intermediate goods to the energy efficient sectors. The fact that the supply chain of these goods and services are domestically available will increase the number of jobs created by bringing about a multiplier effect. There will be job losses in the sectors related to traditional energy sectors though. Induced effects emerge as a result of energy efficiency investments reducing the energy costs in the long term. Revenues obtained from energy savings will be redirected to the goods and services not consumed before. National employment will increase on the assumption that this demand will be directed to domestically produced goods and services in general.

Table 2 shows the direct, indirect and induced effects of energy efficiency procedures on employment according to investment, savings and the use of funds in economy.

Table 2. Energy efficiency employment impacts

Economic Effect	Direct	Indirect	Induced
Initial Investment in Energy Efficiency	"Energy Efficiency" jobs added as efficiency measures are implemented	Supply chain jobs added to support the investment	New jobs added as a result of spending from new incomes
Redirection of bill savings	Jobs added in the general economy from the spending of energy bill savings	Supply chain jobs added	New jobs added as a result of spending from direct and indirect impacts
Financing the initial and continued investment	Jobs offset in the general economy	Supply chain jobs ofset	Jobs offset by the offsetting income impacts

Source: Anderson et al., (2014), p.3.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Since energy efficiency procedures also cause job losses in other areas while creating new jobs, their gross effect on employment is more visible than their net effect. Although there are some difficulties in calculating the net effect, according to many empirical studies the net positive effect on employment is quite high despite the job losses in the traditional energy sectors.

Studies that analyze the effects on employment of energy efficiency procedures in buildings generally focus on the effects of energy efficiency investments on employment, on the employment effects created by the re-spending of revenues obtained from energy expenses and on the effects of the decreasing demand for traditional energy sectors on employment. The examples given are usually selected from the USA since the majority of the studies on this subject are conducted there.

Mirasgedis et al. (2014), have investigated the effects on employment, in Greece, of widespread measures taken in the building sector by making use of the input-output analysis and the adjusted earnings gain approach. These measures include the exterior and roof insulation of buildings constructed before 1980, installation of double or triple-glazed new window frames and the replacement of old diesel boilers used for heating by gas-fired boilers. According to the assumption that these measures are independently taken in 1000 households, direct, indirect and induced employment effects create gross 414 new jobs yearly. Exterior and roof insulation creates 155 new jobs, double or triple glazing of windows 88 new jobs and replacing old boilers 171 new jobs. But the net effect decreases due to the reduction of the activity in the traditional energy sector and net 275 new jobs are created.

Brookings Institution (2012), has emphasized some results of a study that shows the effects of PACE[4] program on the economic output level and on jobs in the USA. According to the results, 4 million dollar PACE fund can create a gross economic output of 10 million dollars on average. With this amount of fund, tax revenues can also increase by 1 million dollars at the federal, state and local levels and 60 new jobs can be created on average. Brookings Institution has made some calculations according to these results. Assuming that one percent of the 75 million owner-occupied homes in the U.S. are to invest in a PACE project that cost an average of 20,000 dollars each, it has been calculated that there will be a 15 billion dollar increase in the gross economic output, 4 million dollars tax revenue and 226,000 new jobs created.

Burr et al. (2012), have analyzed the results, in residential and commercial buildings in the USA, of national building energy ratings and disclosures that would reduce the potential energy costs and create employment, using the input-output model. Building energy ratings and disclosures include the annual energy rating of commercial buildings that are 25,000 feet square or bigger, the annual energy rating of residential buildings that have 20 or more units and the public disclosure of the building energy ratings. There are similar policy requirements in many cities and states in the USA. According to the results of the study, the amount of private investment will be more than 7.8 billion dollars until 2020 with this program and procedures that will ensure energy transparency in buildings and the energy cost saving for each 1 dollar invested would be 3 to 4 dollars. This program and procedures by causing direct, indirect and induced effects will create 23,713 net new jobs in total in 2015 and 59,620 in 2020. The energy costs of building owners, consumers and companies will be reduced by approximately 3.8 billion dollars through 2015 and by more than 18 billion dollars through 2020. More than 60% of the net jobs created will be generated by the effects induced due to the reduction of consumers' and companies' energy costs.

Garret-Peltier (2011), have analyzed, using the input-output model, the effect on employment and expenditures of incentives provided within the scope of Better Buildings Initiative[5] for retrofits in com-

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

mercial buildings in the USA such as improvement of energy efficiency-enhancing heating/cooling, electricity/lighting systems, insulation, new building energy systems and improvement of office equipment. According to their findings, the weighted average employment multiplier for each investment of a million dollars spent for the manufacture and installation of energy efficient technologies is 5.7 for direct effects, 4.1 for indirect effects and 3.9 for induced effects totaling up to 13.6. In addition to the energy efficient investments, new staff needs to be employed in order to monitor and operate the new energy systems in the buildings. The employment multiplier of such expenditures is 8.0 for direct effects, 4.4 for indirect effects and 5.0 for induced effects totaling up to 17.4. Energy efficient practices in buildings will reduce energy costs and contribute to employment by creating demand in other sectors. Employment multipliers created by the re-spending of the revenue saved from energy costs are 6.5 for direct effects, 3.4 for indirect effects and 4.0 for induced effects totaling up to 13.9. The contribution of 8, 692 million dollars of federal and private investments after the incentives provided by this program is 48, 633 direct full-time job years, 32, 969 indirect full-time job years and 32, 699 induced full-time job years totaling up to 114, 302 full-time job years.

Gold et al. (2011), have estimated the effect on the US economy and employment of many standards and legal regulations developed since 1987 until 2010 in order to improve the energy efficiency of lighting systems and equipment used in the commercial sector and the housing in the USA. 340,000 new jobs have been created in 2010 thanks to these standards and legal regulations. This figure corresponds to the 0.2% of USA's total employment. It is estimated that by improving these standards the number of jobs will rise to 387,000 annually in 2020 and to 380,000 annually in 2030. A savings of 34 billion dollars have been provided by the energy bills in 2010. It has been estimated that the level of savings will be 64 billion dollars annually in 2020 and 68 billion dollars annually in 2030.

Rhodium Group (2013) has estimated the amount of required investment in the event that the goals defined by Alliance Commission on National Energy Efficiency Policy[6]'s report, in order to improve energy efficiency in the USA, is realized and their effect on employment. The report aims at the reduction of energy efficiency in the USA by 18% until 2030. 166 billion dollars of annual investment is required for providing energy saving in the transportation sector, energy efficient industrial equipment and vehicles and the technology and design of buildings in line with these objectives. 48% of investments will be made in transportation, 43% for residential and commercial buildings, while the rest will be made in the industrial sector. It has been estimated that the net energy saving in 2030 will be 327 billion dollars. These investments will create net 1.3 million new jobs. It has been foreseen that the most significant increase will be in the service sector. The other sectors showing significant increase will be manufacturing and construction sectors, respectively.

The Rockefeller Foundation (2012), has calculated that taking the necessary measures[7] for providing energy saving in buildings in the US provides a 279 billion dollars of investment opportunity. It has been estimated that 3.30 million direct and indirect new jobs in total would be created by energy efficiency retrofits. Approximately 2.20 million of these jobs will be created by retrofits in residential buildings, 0.86 million by retrofits in commercial buildings and 0.30 million by retrofits in institutional buildings.

Anderson et al. (2014), have made estimations on the economic and employment effects of the application of Department of Energy's (DOE) energy efficiency programs in buildings in the US, according to the Energy Information Administration's (EIA) 2014 reference scenario. As a result of the actualization

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

of investments encouraging a reduction of electricity consumption by %15, 131,000 new jobs in 2020, 300,000 in 2025 and 320,000 new jobs in 2030 will be created including direct, indirect and induced ones.[8] If the electricity conservation is 10% then it is estimated that 70,000 new jobs in 2020, 198,000 in 2025 and 213,000 new jobs in 2030 will be created (according to %3 discount rate).

Markaki et al. (2013), have calculated the investments that Greece needs to make until 2020 in accordance with the energy and climate change package legislated by the European Commission in 2008 and the effects of these investments on employment. In order to achieve its renewable energy and energy efficiency goals, Greece needs to make, in the 2010-2020 period, a total investment of 47.9 billion Euros including 21.4 billion Euros in the power sector, 14.5 billion Euros in buildings, 10.9 billion Euros in the transportation sector and 1.1 billion Euros in the industry. The measures that need to be taken in the buildings are in general oriented to provide energy efficiency. 6800 million Euros need to be spent for the insulation of buildings cell in 1 million households, and 1257 million Euros for the replacement of old boilers in 700,000 households. In addition to this, 920 million Euros need to be spent for the installation of 7,500,000 smart metering systems, 360 million Euros for co-generation-district heating, 1179 million Euros for research in energy conservation, 459 million Euros for various pilot actions, 1493 million Euros for the installation of solar collectors for hot water and central heating in an area of 3,700,000 m2. 19,300 new direct jobs, 10,300 new indirect jobs and 5,100 induced new jobs totaling up to net 34,600 new jobs will be created annually during the period when expenditures for providing energy efficiency in buildings are made.

Young et al (2013), have analyzed the effects on energy saving and employment of the legalization and implementation of the Energy Savings and Industrial Competitiveness Act (S.1392)[9] that was submitted to the US Congress in 2013. Accordingly 66,000 net new jobs in 2020 and 164,000 in 2030 will be created and 2.1 billion dollars of net annual energy savings in 2020 and 13.7 billion dollars in 2030 will be achieved.[10]

Roland-Holst (2008), has examined, in terms of innovation and employment, the economic effects of energy efficiency policies practiced in the state of California. The study consists of two parts. The first part focuses on the economic effects of California's current energy efficiency policies. He concludes that the energy efficiency measures have provided $ 56 billion of household energy savings and that they have created approximately 1.5 million FTE (full-time equivalent) jobs with a payroll of $ 45 billion in total, between 1972 and 2006. He states that as a result of energy efficiency, California's dependence on importing energy has been reduced. It emphasizes that California has directed a larger share of its consumption to goods and services oriented at employment within the state, and that the supply chain of these goods and services are present within the state. He states that this creates a multiplier effect in job generation. The second part examines the economic effects that the implementation of "Draft Scoping Plan" issued in June 2006 by California Air Resources Board (CARB) would create. In order to evaluate the future economic effects of the policies proposed in the Draft Plan, Berkeley Energy and Resources (BEAR) model that is a statewide economic model developed by the Center for Energy, Resources, and Economic Sustainability (CERES) at the University of California Berkeley has been used. Roland-Holst concludes, by including the innovation potential, that the policies proposed by the Draft Scoping Plan will increase the Gross State Product up to approximately $76 billion and the real household incomes up to $48 billion and that it will create 403,000 efficiency and climate action driven jobs. He argues that the existing energy efficiency programs and standards will create 181,000 additional jobs until 2020 and that 22,000 more jobs will be created when innovation is taken into account.

ENERGY EFFICIENCY REGULATIONS IN BUILDINGS: SWEDEN, GREECE, AND TURKEY

This section examines the legal legislation and practices in Sweden, Greece and Turkey. Sweden and Greece have been selected as case studies, former for being one of the leading countries in energy efficiency and latter for having similar economic characteristics with Turkey.

To improve energy performance in buildings, legal regulations have been made since the 1950's in Sweden and since the 1970's in Greece. In addition, two EU member countries regulate their legal legislation in order to adapt to the directives of the European Commission. As well as defining legal obligations, they use financial and fiscal instruments such as subsidies, financial incentives, tax reductions and grants to increase energy efficiency and use of renewable energy sources in buildings. In Turkey relevant regulations have been made in the framework of Energy Efficiency Law issued in 2007 and Energy Performance of Buildings Directive issued in 2008 and some legal obligations especially for new buildings have been defined. However, there is no fiscal measures applied for energy efficiency in buildings except small financial incentives.

Regulations in Sweden

Total energy used per unit of heated area in residential and business buildings in Sweden is intended to be reduced by 20% in 2020 and 50% in 2050 compared to the usage in 1995. In addition, the increase of renewable energy's ratio displaying continuity and the disappearance of the dependence on fossil fuels for energy use in the building sector by 2020 is anticipated (2005/06:145 bill) (Sweden's Second National Energy Efficiency Action Plan, 2011, p.11).

Regulations related to energy efficiency in buildings have begun in the 1970's (Cialani & Perman, 2014, p.2). Various grants and tax reductions have been available for energy efficiency measures since the late 1970's. In the years 1985-1986 and 1986-1987 10% rated grant for thermal insulation in buildings has been given (Kiss et al., 2010). Although the first building regulations might be observed in 1956, requirements for energy efficiency have taken place in building regulations from 1975 (McCormick and Neij, 2009, p. 5). Accordingly, some k-values have been determined concerning building components. Various changes have been made about energy efficiency in code in 1984, 1988, 2002, 2006, and in 2008. The average U-Value requirements of buildings have been introduced in 1988. The building code in 2006 has set the energy demand levels for residences according to two climate zones. By adopting three climate zones in 2008, maximum power levels have been set (McCormick & Neij, 2009, p.6.).

Various laws have been issued in the 2000s to comply with EU directives and to transfer them into national law. At the same time, new regulations about energy efficiency measures have been made by issuing new laws and regulations about buildings and by making changes in the existing legislation, and various financial supports[11] have been offered.

Between the years 2000-2007 a grant program targeting investments in heating by solar energy was implemented in order to encourage the use of solar heating technology in residences and certain business buildings (Sweden's Second National Energy Efficiency Action Plan 2011, p. 31).

Energy incentives as grants between the dates of 2007-2009, and as tax deduction (in the 30% ratio of material and labor costs) between the dates of 2004-2006 have been given to single-dwelling residence owners for the installation of energy efficient windows and biofuel plants (Sweden's Second National Energy efficiency Action Plan 2011, p. 29).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

An incentive that covers the labor, material and planning costs for the installation of solar cells in public buildings has been given between 2005 and 2008 within the scope of the support whose abbreviation in Swedish is "OFFrot" (Sweden's Second National Energy Efficiency Action Plan 2011, p. 30, p. 32). A new grant program has been launched on July 1 2009 for the installation of solar cells. The grant program from which individuals, businesses and public organizations could benefit has supported installations that began and was completed between the dates of July 1 2009 and December 31 2011. Grants support at maximum 60% of investment costs with the exception of large companies (maximum 55%). In addition, the upper limit per solar cell is SEK 2 million and peak electric power installation per kilowatt is SEK 75000 plus VAT at maximum. During 2009-2011, a total of SEK 212 million has been allocated to support the installation of solar cells, within the scope of this grant program (Sweden's Second National Energy Efficiency Action Plan 2011, p. 30-31).

In accordance with the 2002/91 / EC Directive, an Act (2006: 985) has been issued on energy certification for buildings (Sweden's Second National Energy Efficiency Action Plan 2011, p. 28). This Act has made it mandatory since 2009 for rental buildings, cooperative buildings and some non-residential buildings to have energy performance certificates issued by certified experts (Wahlström and Hårsman, 2015, p.58).

A grant has been given, between 2006 and 2010, to single-dwelling and multiple-dwelling home owners and to owners of business premises with associated residences so that they convert from direct electricity heating to district/central heating or to individual heating with biofuels, heat pumps or solar energy (Sweden's Second National Energy Efficiency Action Plan, 2011, p. 30).

In accordance with the 2006/32/EC Directive and with the 93/76/EEC (Energy Services Directive) that has been legislated away, the Bill 2008/09:163 (A coherent energy and climate policy - Energy) has been drafted (Sweden's Second National Energy Efficiency Action Plan 2011, p. 5). It has set the targets of 6.5% energy saving by 2010 and of 9% by 2016 in comparison to the average final energy consumption of the period 2001-2005 (Sweden's Second National Energy Efficiency Action Plan 2011, p. 1). In the 3rd National Energy Efficiency Action Plan (2014, p. 1), it has been emphasized that Sweden has by far met its savings target under Sweden's Energy Services Directive.

The Swedish Government has initiated, in 8 December 2008, a tax reduction for repair, maintenance or conversion and extension works, whose abbreviation in Swedish is "ROT," in order to promote labor supply and to reduce black market labour. According to this regulation, a tax reduction is applied to the 50% of building work costs in residences or holiday houses. Maximum amount of reduction per person per year is SEK 50000 while new builds are excluded from it (Sweden's Second National Energy Efficiency Action Plan 2011, p. 29; Sweden's Third National Energy Efficiency Action Plan 2014, p. 39).

Since 2009, incentives for the installation of solar panels have been available to individuals, enterprises and organizations. Support meets 35% of investment costs. The amount of support is a maximum of SEK 1.2 million. SEK 210 million has been allocated for the period of 2013-2016 within this scope (Sweden's Third National Energy Efficiency Action Plan 2014, p. 39).

More strict requirements have been applicable as of February 2009 for new buildings that use electricity for heating or air conditioning (Sweden's Second National Energy Efficiency Action Plan, 2011, p. 27). Energy requirements have also been made stricter on January 1, 2012 for new buildings that are not electrically heated. Energy requirements have been hardened by 20% more on average (Sweden's Third National Energy Efficiency Action Plan, 2011, p. 86).

In 2014, the Swedish Government has given authority and responsibility to the Swedish National Board of Housing, Building and Planning for proposing, no later than June 15, 2015, quantitative guidelines

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

for energy management requirements in nearly-zero energy buildings (Sweden's Third National Energy Efficiency Action Plan 2014, p. 39).

Swedish Construction Federation has received a five year help for promoting energy-efficient new buildings and conversions. (Low Energy Buildings Program (LÅGAN)) In order to get support within this context, new buildings must achieve at least 50% better energy performance than Building Code (BBR). The conditions for conversions are 40% less energy consumption than the BBR requirement and that the energy consumption reduces by at least 50% (Sweden's Third National Energy Efficiency Action Plan, 2014, p. 40).

A new Planning and Construction Act has gone in effect as of 2 May 2011 replacing the Act (1994:847) about technical functional requirements for structural works, etc. and the 1987 Planning and Construction Act (1987:10) (Sweden's Second National Energy Efficiency Action Plan, 2011, p. 27). The Act determines the minimum requirements about energy management. Energy requirements have been made stricter by 20% on average (Sweden's Third National Energy Efficiency Action Plan, 2014, p. 38).

The new version of the Energy Performance of Buildings Directive 2002/91/EC has entered into force on 18 June 2010 (2010/31/EU) (Sweden's Second National Energy Efficiency Action Plan, 2011, p.7, 28). A bill has been presented in the spring of 2012 for transferring this directive into Swedish law. When the Energy Performance of Buildings Directive has been transferred to Swedish law in 2012, a new Act has also been agreed upon on Energy Declaration (Sweden's Third National Energy Efficiency Action Plan, 2014, p. 37).

The 2012/27 / EU Energy Efficiency Directive (EED) on energy efficiency must be applied as of June 2014 (Sweden's Third National Energy Efficiency Action Plan, 2014, p. 4). The Bill 2013/14: 174 (Implementation of the Energy Efficiency Directive) prepared for the implementation of the 2012/27/EU Directive in Sweden was passed in the Parliament on April 2014. Along with it, new laws on energy efficiency and changes in the existing law have come to the fore (Sweden's National Reform Programme 2015, p.41): the Act on Energy Measurement in Buildings (2014: 367), the Act on Energy Surveys in Large Companies (2014: 266), the Act on Certain Energy Cost-Benefit Analyses (2014: 268), the Ordinance on the Purchase of Energy Efficient Goods, Services and Buildings by Government Agencies (2014: 480).

2013/14: 174 Bill proposes regulations related to energy audits and energy management systems in accordance with the Article 8 (4) - Article 8 (7) of 2012/27/EU Directive. Accordingly, energy audits must be fulfilled by December 5, 2015 by major enterprises. Afterwards, the audits must be repeated at least once in four years (Sweden's Third National Energy Efficiency Action Plan 2014, p. 22).

Regulations in Greece

In Greece 25.5% of total energy is consumed in the residential sector, %41.4 in the transportation sector, 18.5% in industry, 1.9% in agriculture, 11.9% in the service sector and 1.7% in other sectors. The building sector in Greece is energy intensive and approximately 36.4% of total energy consumption takes place in the buildings as of 2015 (Eurostat). Since the 1970's, Greece has been making legal regulations for improving energy performance in buildings. The 1st Thermal Insulation Regulation (Hellenic Ministry of Environment, Planning and Public Works, 1979) in 1979 has attempted to reduce the redundant energy consumption of buildings. The use of solar thermal systems in buildings was among the measures taken for the promotion of Renewable Energy Sources (RES) in the 1990s. Until 2002, tax deductions have been applied to 75% of the taxable income obtained from RES systems in heating and cooling with the act L2364/1995 (Hellenic National Renewable Energy Action Plan, 2010, p. 69, 80). Regulations on

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

energy efficiency in buildings known as KOXEE have been introduced in 1998 with the 21475/4707 Ministerial Decision. Energy labeling of buildings has been initiated with this act. In 2005, KOXEE has been renamed to KENAK (Dascalaki et al., 2012, p.470). In general, the legal regulations have been issued in order to adapt to the Directive 2002/91/EC of the European Parliament and of the Council of 16 December 2002 on the energy performance of buildings. The act of L3661/2008 "Measures to reduce energy consumption in buildings and other provisions" has been issued and liabilities for improving the energy efficiency of buildings, providing energy saving and for protecting the environment have been determined within this context. This act focuses on energy efficiency in the building sector with the implementation of the Regulation on the energy performance of buildings (KENAK). (Hellenic 2nd National Energy Efficiency Action Plan 2008-2016, 2011, p.14-15).

KENAK sets two key requirements (Hellenic 2nd National Energy Efficiency Action Plan 2008-2016, 2011, p. 29-30):

- Submission of a study on the energy performance of buildings for issue of a building permit,
- Performance of energy inspections to buildings, boilers, heating and air conditioning systems.

5825/2010 "Endorsement of Energy Performance Buildings Regulation"" (M. D. D6/B/OIK, 09.04.2010) has been issued in April 2010. This Ministerial Decision has included measures such as issuing certificates for public and private buildings, improving the minimum energy standards in new buildings and existing buildings exceeding 1000 m^2 undergoing major renovation and making regular inspections of hot water and heating systems. Determining procedures such as the classification of buildings according to energy performance, the scope of energy performance certificates and their format, the improvement of energy performance measurement methods, etc. have been aimed at (IEA, 17.07.2012, http://www.iea.org/policiesandmeasures/pams/greece/name-22966-en.php).

2009/28/EC Directive has been issued in order to generalize the use of renewable energy sources (RES) EU-wide. Greece has issued L3851/2010 "Acceleration of the development of renewable energy sources for the confrontation of climate change" act in order to comply with this Directive. Article 13 of the Directive contains measures about buildings. Greece has expanded Article 10 of the act L3851/2010 according to the scope of L3661/2008. Reduction of VAT rates in natural gas and electricity markets, giving low interest-rate loans, financial incentives and grants for energy efficiency measures have been agreed upon. After the date of 01.01.2011, in order to issue building license for buildings 60% of their annual hot water needs must be met by solar thermal systems. All new buildings, latest by 31.12.2019, need to use renewable energy sources, electricity and heat cogeneration, district or block heating systems, and heat pumps with seasonal performance factor in their primary energy consumption. The deadline for new public buildings is 31.12.2014 (Hellenic 2nd National Energy Efficiency Action Plan 2008-2016, 2011, p.30,71; Hellenic National Renewable Energy Action Plan, 2010, p. 44, 46).

EU 2006/32/EC directive was adapted to the Greek legislation by means of the Law L3855/2010. "L3855/2010 on the improvement of the energy end-use efficiency have set the grounds for the transition to low energy consumption in buildings and identify a set of measures and mechanisms for this transition". Energy saving of 9% has been intended by the end of 2016 within the scope of this Law, compared with the period 2001-2005. (Hellenic 2nd National Energy Efficiency Action Plan 2008-2016, 2011, p.4, 29). The EU Energy Performance Building Directive has been recast in 2010 and Greece has issued L4122/2013 in order to adapt its legislation to this directive. The Law "updates the minimum energy performance requirements for buildings adopted by KENAK and provides that from 1of January 2021

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

all new buildings shall be nearly zero-energy buildings, whereas with regard to new buildings owned by the public and the wider public sector this obligation shall be implemented from 1 January 2019" (Kokkaliaris, Maria, 2015, p.63).

Many financial incentives have been defined within the scope of KENAK to provide energy saving in homes. Subsidies up to 35% have been applied on the marketing price of air conditioners in 2009 with the purpose of replacing old air conditioners. 141,323 air conditioners have been replaced within its extent. (Three times the target figure of 45,000). Financial incentives have been available since 2012 for the replacement of electricity or traditional heating systems with solar systems either by 50% or 100% depending on the climatic conditions of regions. With the "Energy Saving at Home" program that targets all housing built before 1990 in Greece, various supports are available to the households that have taken the measures of thermal insulation of roofs and exteriors, improvement of heating and hot water systems. 100% interest-free loans and 35% grants are offered to the people with an annual income of less than 40,000 or 60,000 Euros. 100% interest-free loans and 15% grants are offered to the people whose incomes range between 40,000-60,000 or 60,000-80,000 Euros. The program is financed by the EU European Regional Development Fund (ERDF) and national resources. A budget of 396 million Euros has been allocated. (Hellenic 2nd National Energy Efficiency Action Plan 2008-2016, 2011, p. 60, 69,70, 71, 74). With the incentives granted within the scope of this program, 40,000 buildings have been included within the program's scope until the end of 2013 and 400 million Euros have been fund-raised (Papamanolis, 2015, p4).

Regulations in Turkey

Turkey is number 21 in the world rankings in primary energy consumption and its share of world energy consumption is 1% (T.C. Enerji ve Tabii Kaynaklar Bakanlığı, 2015, p. 7-8). Approximately 32.3% of the consumed energy is consumed in the industry sector, 37.5% in the residential and services sector, 25.0% in the transportation sector (Eurostat). Turkey that has limited natural gas and oil reserves imports a large part of its energy. According to the foreign trade data in 2013, 49.2 billion of the 99.9 billion dollar foreign trade deficit in Turkey is originated from net energy imports (T.C. Gümrük ve Ticaret Bakanlığı RYKGM-Ekonomik Analiz ve Değerlendirme Dairesi, 2015, p.21). The amount of total primary energy supply in 2013 is 120,290 thousand toe. While 96,001 thousand toe is imported, domestic production meets 26.6% of energy supply with 31,944 thousand toe (T.C. Enerji ve Tabii Kaynaklar Bakanlığı, EİGM, 2013).

Legal regulations and practices for efficient use of energy and for benefiting from renewable energy sources are very limited. The most important initiative in this regard has been issuing of the 2007 L5627 (OG, 02.05.2007) "Energy Efficiency" law. This law includes procedures about increasing the efficiency of energy in production, transmission and distribution stages, in industrial enterprises, buildings, power generation facilities and transportation as well as principles and procedures for the utilization of renewable energy sources. Based on this law "Energy Performance of Buildings Directive" (OG, 05.12.2008) has been issued in 2008. This directive specifies the principles and procedures related to energy performance of buildings including control procedures, information gathering, and minimum performance criteria, standards and norms about architectural design, heating, cooling, insulation, hot water, electrical installation and lighting in buildings. Additionally, this directive regulates the measures of issuing energy identification certificate in existing and new buildings, meeting energy needs by renewable energy sources (RES), creating a nationwide building inventory, conducting activities in order

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

to increase awareness of energy culture and efficiency. The directive has decreed that new buildings built after 2011[12] must get an energy identification certificate that includes information on buildings' minimum energy needs and energy consumption classification, on their insulation properties and/or the efficiency of their cooling systems. In addition to this, the directive has made it mandatory that newly constructed buildings meet the improved standards in their thermal insulation, mechanical facilities, ventilation/air conditioning systems, hot water systems, electrical and lighting systems.[13] In the case that there are major renovations in existing buildings that include project changes about energy efficiency (in the case that the renovation cost exceeds the 25% of the property tax value of the building), the provisions of this directive are implemented.

"Energy Efficiency Strategy Paper 2012-2023" (http://www.eie.gov.tr/verimlilik/document/Energy_Efficiency_Strategy_Paper.pdf) has been published in 2012. It targets the reduction of Turkey's energy density (amount) consumed per GDP capita in 2011 by 20% in 2023.One of the strategic objectives set for the realization of this goal is to reduce energy demand and carbon emissions of buildings and to promote sustainable environmentally friendly buildings that use renewable energy sources. "In year 2023 the heat insulation and energy efficient heating systems providing current standards shall exist in all commercial and service buildings having total usage area of more than 10,000 m2 with the dwellings having building group class 3 or more from the defined building groups in the Communiqué About Approximate Unit Costs of the Buildings, which put into force annually, in metropolis contiguous areas from the buildings having usable attribute in the scope of Urban Transformation Law and Earthquake Regulation". The reduction by 10% of annual energy consumption in public buildings by 2015 and by 20% by 2023 has been targeted (Energy Efficient Strategy paper, 2012).

Measures to be taken in the buildings are also included among the strategic objectives of the 2011-2023 Climate Change Action Plan. Objectives have been identified for increasing energy efficiency and the use of renewable energy in buildings. These objectives are; the creation of thermal insulation and energy efficiency systems that meet the standards in commercial and public buildings that have a total area of use larger than 10 thousand square meters and in at least 1 million homes by 2023, effective implementation of Energy Performance of Buildings (BEP) Directive and of other energy efficiency directives in all buildings by 2017, development of means that will provide the necessary financial support for energy efficiency, renewable energy and BEP in buildings until the end of 2013, giving "Energy Performance Certificate" to all buildings by 2017, reduction of annual energy consumption of public institutions' buildings and facilities by 10% until 2015 and by 20% until 2023, providing at least 20% of the annual energy needs of new buildings by renewable energy sources as of 2017 (T.C. Çevre ve Şehircilik Bakanlığı, 2012, p. 11).

In addition to these, "The Directive on Certification of Sustainable Settlements and Sustainable Green Buildings" (OG, 08.12.2014) has been issued. The Directive regulates the principles and procedures for creating assessment and certification systems of sustainable settlements and sustainable green buildings in order to reduce a building's environmental impact by using its natural resources and energy efficiently, and it also regulates the principles and procedures for identifying the mission, qualifications and responsibilities of those who will take part in the certification process.

Besides these, communiqués and directives have been issued since 2002 for increasing the efficiency of central heating boilers and energy labeling the white appliances.[14] In addition to the legal regulations, credit and grant mechanisms have been developed to support high cost, high energy yield projects especially in industrial enterprises.[15] Most of this support is funded by international organizations. "Turkey Sustainable Energy Financing Program" (TurSEFF, n.d.) can also provide loans to homeowners for

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

efficiency-enhancing projects in addition to the credits it provides to industrial and commercial companies by means of partner banks. Projects need to provide energy savings of more than 30% in order to get support. However, most of the banks partnering in the program, keep the term for loan repayment short.

FISCAL POLICY PROPOSALS FOR TURKEY

The most important legal regulation in order to increase the energy performance of buildings in Turkey has been the issuing of "Energy Performance of Buildings Directive" in 2008. With this directive, issuing energy identification certificates for new buildings, that is a regulation practiced in many EU countries, has been introduced. The energy performance criteria for buildings during their construction have been determined by relevant Turkish Standards. However, it is not possible to talk about an important legislation aimed at improving the energy performance of existing buildings. There exists no incentive mechanism for this such as tax reductions and grants. Compared to the EU member states, Turkey has fallen fairly behind in this regard. According to the survey conducted by Building Performance Institute Europe (BPIE) (Maio et al., 2012) in 2011, grants and subsidies, preferential loans and fiscal instruments are widely used in energy-efficiency improving activities of EU member states.

Table 3[16] shows tax reduction supports used in some EU member states for energy efficiency activities in buildings. In Bulgaria a 100% tax reduction from the property tax is practiced both for Class A

Table 3. Level of support for tax reduction

	Level of Support	On Individual/ Households Income	On Property Tax	On Taxable Profit
Austria	25% (envelope, equipment)	X		
Belgium (Federal)	40% (envelope, equipment, other)	X		
Belgium	• 20% (new) E-level of E60 • 40% (new) E-level of E40 or less		X	
Bulgaria	• 100% for 7/10 year Class A • 3/5 y Class B • Building commissioned after January 1st 2005		X	
Spain	Up to 10% (envelope, equipment)	X		
Finland	60% of labour costs (envelope, equipment)	X		
Greece	Up to €700 (equipment)	X		
Ireland	Write off 100% of the purchase value in the year of purchase (equipment)			X
The Netherlands	41.5% (of annual investment costs) (equipment)			X
Portugal	• 25/50% property tax (Class A/A+)(equipment) • 10% increase in the deduction related to house loans in the individual tax (Class A/A+) • 30% (investment in RES)	X	X	
Sweden	€5 000 /y/building (labour costs)	X		
United Kingdom	n/a (equipment) n/a (envelope)		X	X

Source: Maio et al., 2012, p. 22.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

buildings that are 7/10 years old and for Class B buildings that are 3/5 years old. 60% of the labor costs of measures related envelope and equipment of buildings in Finland are subject to tax reduction deducted from the individual/household income. In Ireland 100% of the purchase value of equipment measures is written off in the year of purchase from the taxable profit. Some examples of tax credits and reduced VAT rates for energy efficiency activities in buildings are shown in the Table 4[16] and Table 5[16], respectively.

The public sector in Turkey needs also to make fiscal arrangements in this regard taking into account the social, economic and environmental benefits that improving energy efficiency in existing buildings will provide. Energy consumption has many externalities ranging from the health of living beings to their quality of life, to agricultural production and economic crisis risks. These externalities cannot be priced. Since positive externalities generated by energy efficiency measures cannot be measured it is deviated from the social optimum in the allocation of resources. Neither end consumers nor enterprises are willing to do by themselves the necessary renovation work for improving the energy efficiency of buildings. The failure of the market mechanism in this matter necessitates the intervention of the government (Erdoğdu et al., 2015). It is important that, besides legal regulations for the improvement of energy efficiency standards of buildings, activities that will motivate the households and enterprises about this begin. It is not well known by enterprises that energy efficient businesses offer profitable investment opportunities or by households that energy efficiency-enhancing activities meet their costs in a short time and that they provide significant energy savings in the long run. According to Sardinaou (2008), in general, there are two main obstacles to energy-saving investments: financial market obstacles and human factor obstacles. The fact that the future of energy prices is unclear (likely to fall), result in, in particular, low

Table 4. Level of support for tax credit

	Level of Support
France	40% on the interest of the home for 7 years (complements the zero interest rate loan) (envelope, equipment)
Italy	36/55% (envelope, equipment)
United Kingdom	• 100% tax relief on the cost (equipment) • €1 860 /y (£1 500/y) (envelope, equipment)

Source: Maio et al., 2012, p. 23.

Table 5. Level of support for reduced VAT rate

	Level of Ambition
Belgium	6% (envelope, equipment) instead of normal rate of 21%
Spain	8% (envelope, equipment) instead of normal rate of 18%
France	5.5% (7% from 1°of January) (envelope, equipment) instead of normal rate of 19.60%
Italy	10% (envelope, equipment) instead of normal rate of 21%
Netherlands	6% (envelope) instead of normal rate of 19%
Poland	8% (envelope, other) instead of normal rate of 23%
Portugal	13% (equipment) instead of normal rate of 23%
United Kingdom	5% (envelope, equipment) instead of normal rate of 20%

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

returns in energy-saving investments in the short term and the perception of these investments as risky. Even if the company managers have enough information about the profitability of energy saving, they are faced with capital rationing (Sardianou, 2008). Therefore, if governments accelerate their informing activities in this matter, facilitate access to financial markets, create demand by informing consumers, this will increase the private sector's motivation.

The results of the survey carried by YEGM (n.d.) in 2010 also point at the consumers' lack of motivation about activities to increase energy efficiency. 2531 people selected from 26 provinces of Turkey's seven geographical regions have been surveyed for this poll. It has researched how aware the public is of activities taking place within the framework of Energy and Natural Resources Ministry's energy efficiency project (ENVER) and how much they implement these activities. According to the survey, households are majorly (82.2%) not aware of the energy efficiency practices carried out by the Ministry. However, when the answers given to the report's questions on energy efficiency measures are considered, one can conclude that the households are willing to implement energy-efficient practices as they are better informed about these. For example, almost half of the refrigerator (51.5%) and washing machine (47.4%) preferences mentioned in the survey are energy-efficient (class A) ones. Ads by white appliance manufacturers ensure that households are informed on this to a great extent. More and better information provides a shift of consumption preferences for energy efficient ones. However, preferences for energy efficient ones in other white appliances such as dishwasher (27.5%) and air conditioning (9.2%) is quite low. Most of those who do not prefer Class A white appliances are not informed about the energy class of such goods. It can be argued that as the level of knowledge on lighting and thermal insulation increases so does energy-efficient practices. According to the answers given in the survey to questions about thermal insulation, 74.8% of the buildings do not have thermal insulation. However, according to the other findings individuals are informed about thermal insulation and are willing to get it done. For example, 47.2% of respondents' energy efficiency priority is to make thermal insulation. However, 55.7% of households (who have not insulated their homes) think that the cost of thermal insulation is high. Window glass insulation is better than the level of exterior and roof insulation. 60% of the windows are double-glazed, 0.9% have coated glass, while 39.2% are single glazed. Only 44.4% of lamps used for lighting in houses are energy efficient. The percentage of using both normal and energy-saving lamps is 42.1%.

Supporting the energy efficiency-enhancing projects of companies producing energy-powered equipment such as home appliances, lighting equipment etc. with low interest loans, grants and profit tax reductions, by increasing investments in energy efficient sectors, would both provide employment growth and increase demand as energy efficient products get cheaper. Since discounts made in VAT rates of these products would directly affect the end consumers, consumer preferences will shift towards energy efficient ones.

The majority of energy consumption in buildings is used for heating. Insulating the exteriors, roofing, flooring and windows of buildings would create a huge energy savings. According to a study conducted by IZODER (Garanti Bankası), an insulated building provides an average of 50% savings in heating costs. This study calculates the fuel costs of an exemplary 5-storey building with 4 apartments and a total living area of 500 square meters in Antalya, Istanbul, Ankara and Erzurum, respectively from warm to cold, with no insulation and insulated according to the insulation standard, and it concludes that insulation provides more than 60 per cent energy saving. Since thermal insulation procedures will significantly reduce household energy costs, households' motivations can easily be triggered. The share of a family's average energy consumption costs within the minimum wage is 30.8% as of 2014 (T.C. Enerji ve Tabii

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Kaynaklar Bakanlığı, 2015, p.30-33). Households spend a large portion of their income on heating costs. But many people, as also proven by the research of YEGM, think that the cost of thermal insulation is high. Therefore, offering financial and fiscal supports such as grants, low interest loans, subsidies and tax reductions, would encourage these practices. Given the that the income per capita in Turkey is quite low, subsidies and grants on thermal insulation for low income people should be applied, and local governments should take financial responsibility for it. According to the modern theory of public finance, public goods that benefit the local area should be provided by local governments. Energy efficiency practices in buildings are also a kind of local public service. However, the budgets of local governments may not be enough. The central government's support for local authorities by unconditional transfer payments would be an effective policy (Dongyan, 2009). In addition to this, the central government might encourage the private sector for the establishment of energy efficiency programs, and these programs might work in cooperation with local authorities.

For example, the PACE program (Brookings Institution, 2012) that supports practices that will provide energy efficiency in buildings in the United States might be taken as an example. PACE program supports renewable energy and energy efficiency practices such as solar panels and thermal insulation. PACE mechanism establishes a link between the homeowners and local governments. Local governments give specific loans to households that will make such investments and these loans are paid in up to 20 years through annual property taxes (PACE, http://www.pacenow.org/). A pilot program in Turkey under the leadership of companies that carry out energy efficiency activities might be launched and this program's cooperation with local governments might be facilitated. Property taxes might be determined based on the energy performance of buildings.

Additionally, fiscal policies such as pre-tax reductions for companies that carry out insulation practices and produce energy-efficient boilers, accelerated depreciation for energy efficiency equipment, tax refunds, tax concessions and abolition of tax exemptions for businesses that do not fulfill the energy saving criteria (Dongyan, 2009) might be launched. Making VAT reductions in energy efficient products would also help to reduce the cost of the final consumer. The tax reduction practice initiated in Sweden in late 2008 called ROT, aimed at maintenance or conversion and extension works in buildings might be taken as an example. With reference to ROT, the cost of maintenance and conversion works to be done in buildings for energy efficiency might be deducted from tax. In addition, grants might be given to individuals converting their heating systems to a system of biofuels, heat pumps or solar energy. Low-energy building projects might be supported as in the example of LAGAN.

Environmental taxes might be used by local governments. While high environmental taxes might have a deterrent effect for buildings that have high pollution impact and low energy efficiency, the other way around, implementing of low environmental taxes for buildings that have high energy efficiency with less environmental waste, would have an incentive effect (Erdoğdu et al., 2015).

Establishing appropriate financial support for low-income households is important both in terms of social justice and the effectiveness of the measures. In most cases, individuals from low-income groups live in buildings with low energy efficiency. The buildings inhabited by these income groups do not have thermal insulation measures as well as renewable energy sources like solar systems. The white appliances and other electrical equipment used in the homes as well lighting systems are old-tech products. Grants and low-interest loans for low income groups might be implemented modeled on the "Energy Saving at Home" program in Greece.

In order to take all these fiscal measures, it is necessary to make a building inventory in Turkey. The latest building count by TÜİK was done in 2000 (DIE, 2000). The updating of these data and to determine

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

the energy performance of existing buildings will give information about needed investments. Different practices should be recommended and developed considering that.

Turkey with its large surface area has a different climate and geographical structure. For example, while in the Mediterranean region one should focus on system and equipment adjustments that will improve energy efficiency of air conditioning systems, policies that will support thermal insulation practices in the regions of Eastern Anatolia and Central Anatolia should be implemented.

As a result of the fiscal measures that governments will take, energy efficiency investments will increase and new jobs will be created since there will be direct, indirect and induced effects on all the sectors of the economy. Energy efficiency improvements, as well as being a solution to the unemployment problem, will result in many acquisitions such as increasing Turkey's international competitiveness, improving the balance of payments and increasing environmental welfare.

CONCLUSION

Although the energy efficiency practices in buildings have huge advantages for individuals and enterprises, market mechanisms are not functioning well in this respect and supply and demand for energy efficiency is insufficient. Externalities are neglected altogether. In addition to the individual advantages of energy efficiency practices, they also have significant effects on the economic and social welfare of countries that cannot be ignored such as the reduction of environmental degradation, increased employment, increased national competitiveness and reduction of dependency on external energy. At this point, government intervention is needed. Many countries, bearing these benefits in mind, pay special attention to energy efficiency policies for buildings. Regulations on the energy performance of buildings constitute an important part of the environmental and economic policies. They also take into account the employment opportunities created by energy efficiency practices. Many countries, in particular US and EU countries, make legislative regulations in this area and develop standards. They operate incentive, grant, loan, subsidy mechanisms in order to implement these practices.

Energy efficiency practices in buildings will create new job opportunities and indirectly increase the volume of business in related sectors. In addition, this share, resulting from the reduction of energy costs, will be directed to new expenditures and will create induced employment effects. While there may be job losses in the traditional energy sector, these are negligible effects. Since Turkey imports a large part of its fossil energy sources, job losses in the traditional energy sector in Turkey will be less. Since demand will be directed mostly to domestic goods and services, its multiplier effect on employment will be much more.

This study examines the legal legislation and practices in Sweden that is one of the leading countries for energy efficiency and in Greece that has similar economic characteristics with Turkey, and these have been compared with those of Turkey. Sweden and Greece have amended their legislation in accord with EU's energy efficiency policies and goals. In addition, they also apply to a number of incentive mechanisms for energy efficiency. Greece is ahead of Turkey on energy efficiency in buildings. Works on this matter in Sweden go back to the 1950s. Although there is a legal legislation on the subject in Turkey, actual measures are inadequate. Energy Performance of Buildings Directive has been issued. However, although certain standards have been developed for new buildings, regulations for existing buildings are very inadequate. In this context, several fiscal measures have been proposed for encouraging energy efficiency in buildings in the light of practices in Sweden and Greece.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Supporting the energy efficiency-enhancing projects of companies producing energy-powered equipment such as home appliances, lighting equipment etc. with low interest loans, grants and profit tax reductions, by increasing investments in energy efficient sectors, would both provide employment growth and increase demand in Turkey as energy efficient products get cheaper. Since discounts made in VAT rates of these products would directly affect the end consumers, consumer preferences will shift towards energy efficient ones.

The central government's encouragement of the private sector for the establishment of energy efficiency programs, and these programs' working in cooperation with local authorities should be ensured. A pilot program in Turkey under the leadership of companies that carry out energy efficiency activities might be launched and this program's cooperation with local governments might be facilitated. Property taxes might be determined based on the energy performance of buildings. In addition to this, environmental taxes might be used by local governments. Tax rates should be determined in inverse proportion to the energy performance of buildings in a way to promote energy saving and to deter energy consumption.

In addition, central government might encourage the establishment of energy efficiency programs by the private sector and it might be ensured that these programs work in cooperation with local authorities.

The cost of maintenance and conversion work to be done for energy saving in buildings might be deducted from tax. Grants might be given to individuals to promote the use of renewable energy sources. Special financial supports might be provided to low-income households. Additionally, fiscal policies such as pre-tax reductions for companies that carry out insulation practices and produce energy-efficient boilers, accelerated depreciation for energy efficiency equipment, tax refunds, tax concessions and abolition of tax exemptions for businesses that do not fulfill the energy saving criteria might be launched by the central government.

In order to take all the measures listed here, first of all an inventory of buildings in Turkey should be taken and the scope and types of incentives should be determined according to geo-climatic zones and according to these zones' income levels.

KEY TERMS AND DEFINITIONS

Direct Employment Effects: The employment effects emerging in the stages of production, marketing and implementation of energy efficiency practices.

Energy Efficiency: Reducing the amount of energy consumed without sacrificing the amount and quality of output.

Energy Identification Certificate: A document showing energy needs and energy consumption characteristics of buildings.

Fiscal Incentives: The instruments such as tax reduction, incentives, grants and subsidies applied by the governments to support various activities of individuals and organizations.

Green Jobs: Jobs emerging in the stages of production, marketing, implementation and use of renewable energy sources or technology and activities providing energy efficiency.

Indirect Employment Effects: The employment effects emerging in the sectors related to energy efficient sectors.

Induced Employment Effects: The employment effects emerging by redirecting the savings stemming from energy efficiency practices to new expenditures.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

ENDNOTES

1 Bridge Scenario (has been drafted based on taking the four key political precautions that has been focused on during the 21st The United Nations Climate Change Conference (COP21)), 450 Scenario (450 parts-per-million C02 equivalent), Intended Nationally Determined Contributions (INDC) (has been drafted based on the commitments made by countries during the 21st The United States Climate Change Conference).

2 There are opinions that the increase in energy efficiency will reduce energy prices and will increase energy consumption by creating the rebound / take back effect (consumption growth effect that results from the fall in consumer costs). This approach that focuses on energy competence rather than energy efficiency advocates that CO2 emissions might be reduced by replacing fossil fuel based sources with renewable sources financed by the carbon tax. See: Herring (2006), Greening, Greene & Difiglio (2000), Brookes (1993), Grubb, Chapuis & Duong (1995).

3 Indicators used in energy efficiency measures can be classified in four main categories; these are thermodynamic indicators, physical thermodynamics indicators, economic thermodynamics indicators and economic indicators. The economic indicator among them measures the changes in energy input and service delivery according to the market value while measuring energy efficiency. See: Patterson, M. G. (1996). What is Energy Efficiency? Concepts, Indicators and Methodological Issues. *Energy Policy*, Vol. 24, No. 5, 377-390. The concept of energy efficiency based on economic approach is evaluated in this study.

4 The PACE program is a program that offers an innovative funding mechanism on how to improve the energy efficiency of buildings in the United States. This program supports renewable energy and energy efficiency practices such as solar panels and thermal insulation. The program, authorized by 29 states and District of Columbia, provides funding for states and local governments and payments are covered by property tax. See: Brookings Institution (2012) and PACE, http://www.pacenow.org.

5 It is a program of The Office of Energy Efficiency and Renewable Energy – EERE that is responsible of energy safety in the United States.

6 It is an NGO in the United States. The drafted report has been presented to the United States Congress so that it becomes law.

7 Action is taken based on the assumption that retrofits made in four key categories (new kit, new control systems, active energy management and integrated designs) will increase energy efficiency in buildings by 30% on average.

8 Estimates are made according to the 7%, no discount, 3% discount rates. The figures above show calculations made according to the 3% discount rate. The rate in 2030 of no discount is 327,000 and of 7% discount is 319,000 jobs.

9 Energy Savings and Industrial Competitiveness Act (S.1000) in the United States has been presented to the Congress for the first time in 2011. In 2013, the Act (S.761) has been improved and presented to the Senate Committee on Energy and Natural Resources. In 2013, the Act (S.1392) has been revised and re-presented to the Congress. It has not yet become law.

10 Calculations based on three different scenarios have been made in this study. The first scenario is created according to the obligations contained in the Core Bill S.1392. The second scenario is created according to Group A and the third according to Group A+. 2nd and 3rd scenarios are created according to some additional law amendments.

Chapter 41
Different Resources Consumption of Renewable Energy

Soobia Saeed
Institute of Business and Technology, Pakistan

ABSTRACT

Electricity consumption will encompass a large converse about connected with international electricity demand while in the next 2 decades. Newly, this improving rate connected with fossil fuels and also issues about the environmentally friendly consequences connected with gas emissions get renewed the attention in the progress connected with alternative electricity resources. Renewable Energy Sources and Climate Change Modify Minimization offers a good estimation on the chapter for the technological, scientific, environmentally friendly, financial and also societal aspects of this factor connected with six renewable energy (RE) options for the minimization connected with weather adjust. This functioning chapter on environmentally friendly Energy Solutions and Local climate Change Minimization presents an assessment on the literature for the scientific chemical, technological, environment, economic in addition to social areas of the contribution connected with six environmentally friendly energy (RE) sources on the mitigation connected with climate alter. This chapter is definitely an overview of presentation of the Local climate Change Minimization expansion on the essential results. Considering this significant component of Renewable Energy Sources can be reduce carbon dioxide, there is an international relating to reducing carbon emissions. Due to the fact most of the United Nations wanted to greenhouse gas (GHG) emissions is carbon dioxide, there is a can be a global concern on minimizing carbon emissions. Emissions of greenhouse gases (GHGs) resulting from the provision of the services of one have contributed significantly to improve the historical concentrations of greenhouse gases to the atmosphere of MIT. The IPCC (AR4) concluded that "most of the observed global climate improving as it is very likely that as a result of the improvement observed in the concentrations of anthropogenic gases mit techniques this mid of 20th century confirms Recent Files the use of fossil power accounts for most of the international anthropogenic GHG emissions". Emissions always grow, in addition to CO2 concentrations of it had

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

increased to more than 390 ppm, or perhaps 39% above pre-industrial levels, by holding from 2014-5. There are many options for reducing GHG emissions from energy system while satisfying the desire for global energy services. Some of these possible alternatives, such as energy conservation and competition, switching fossil fuel, RE, nuclear, plus carbon capture and hard drive (CCS) was evaluated from the AR4. A full assessment related to any profile minimization options will likely involve an evaluation of respective potential alongside minimization with his bargain with sustainable development as well as all associated risks, and costs. This phase will focus on the role that this display technology related to RE can participate in within the portfolio related to mitigation alternatives. In this sense, the only policies can be given to reduce emissions of carbon dioxide, to improve the implementation of green energy, and such encouraging technological innovation. At inclusion, supporting components, such as feed-in tariffs, rules Renewable side view in addition to tax insurance policies are used by governments to help develop green energy generation in addition to the implementation of the efficiency of energy use save energy. In this chapter, the various insurance policies could possibly be placed on reducing carbon emissions, for instance improving green energy deployment and also significant technologies. A pair of main clarifications may be realizing to scale back carbon emissions and also overcome the issue connected with weather adjust: exchange fossil fuel having green electricity options wherever possible and also enhancing energy proficiency. In this chapter, many of us discuss most up-to-date performance connected with technology intended for improving green electricity deployment and also electricity work with proficiency.

1. INTRODUCTION

Electrical energy usage can comprise an increasing reveal involving international energy demand above the subsequent two full decades. Recently, soaring energy price ranges and concerns regarding the environment effects involving emissions involving greenhouse gas fossils include renewed involvement in the particular development involving alternate energy sources. Renewable energy is already regarded a more appealing energy resource with regard to nuclear energy due to the absence of hazards and problems. The primary part of greenhouse gas is actually carbon dioxide; there may be international issue in relation to cutting down carbon dioxide emissions. With this impression, the different plans may be put on the particular decrease involving carbon dioxide emissions, including increasing the particular rendering involving environmentally friendly energy and the advertising involving technologies. A couple of key solutions may be carried out to cut back laser emissions and conquer the situation involving climate adjust: exchanging fossil heats up having environmentally friendly energy sources wherever possible and strengthen energy productivity. This chapter discuss with regards to innovative distinct alternatives for enhance the effective use of renewable energy and also productivity in energy use. Moderately a couple of nations have begun to introduce offices by which utilize renewable good quality hotspots for energy era. The significance associated with option energy sources all meets upward with environmental change difficulties of the exorbitant make use of fossil powers. You'll locate a few essential sparks by which invigorate the off shoot of renewable good quality advancements: energy solidity, monetary effects and also co2 partial lazer outflow decrease (Rask, 2009). The expression "elective vitality" portrays any kind of vitality other than the customary wellsprings associated with quality, including hydropower. Of late the center will keep on being in renewable quality sources. As indicated by simply Global Energy Firm

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

portrays two critical worldwide patterns that may describe the design of renewable innovations in the medium term. Firstly, as renewable drive advancements scale upwards, from an aggregate worldwide cause of 1, 454 giga-watts (GW) inside 2011 to simply just two, 167 GW inside 2017, they additionally should spread out topographically. Second, the more the past number of years of high fossil quality asset vitality utilization has driven renewable advancements in the event that you are progressively aggressive more than an expense premise for their options in a few countries around the globe and circumstance. Agreeing with a specific end goal to Worldwide Energy Agency reckonings, wind is a standout amongst the most aggressive sort related together with renewable vitality innovation one of numerous different choices, if nearby conditions like financing, CO outflow amounts and fossil quality asset costs demonstrate viable (Organization for Financial Co-operation notwithstanding Development, 2010). Indeed, even through since you that have two essential ideas inside of your advances: vitality gives building, which consider option sources connected with renewable vitality like wind and sun oriented force and vitality capability designing. It ought to be noticed that changing the capacity division and redesigning customary vitality having renewable vitality is transformative connected to mechanical change along together with shaping markets. The changing procedure for a few types of earth inviting vitality, for example, the wind and sun oriented may happen after 2020, paying little heed to in the event that they development cost of utilization is typically firmly expanding on your one decade from now. Similarly, renewable vitality markets are not effectively shaped in view of expense inconveniences furthermore the financing of fossil gets more sultry (Muneer, 2007).

2. RENEWABLE ENERGY AND CLIMATE CHANGE

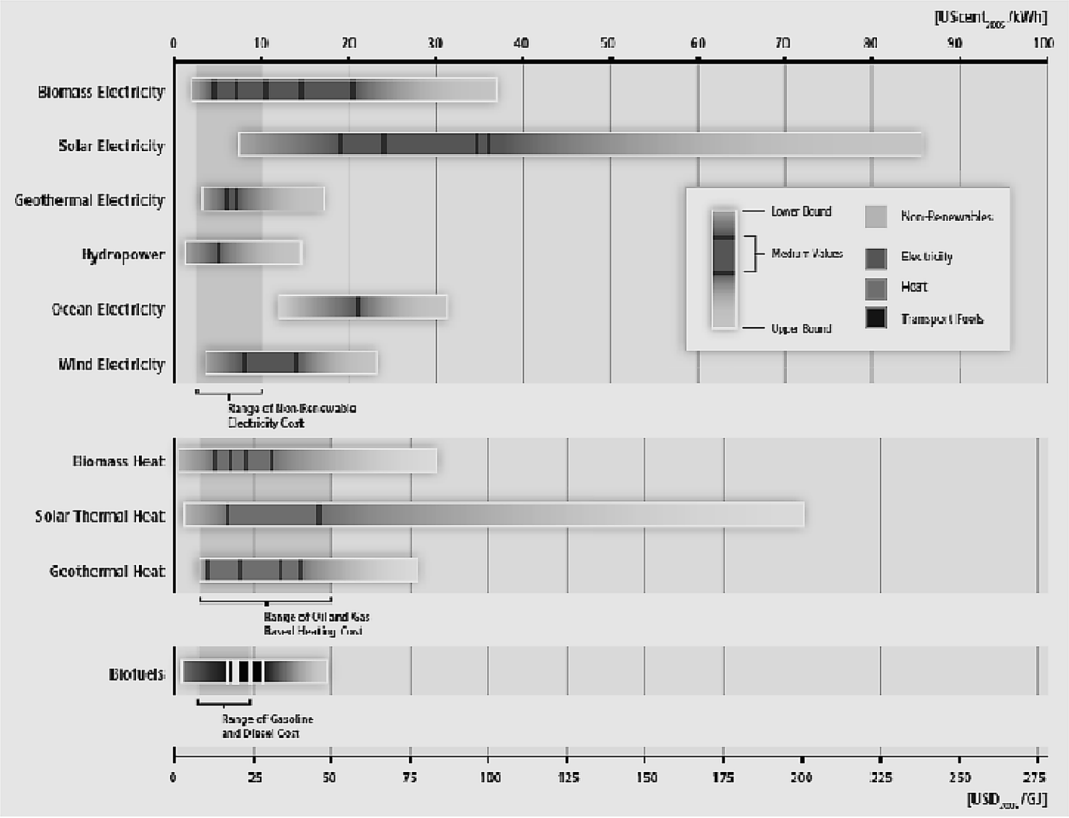
Aspiration for energy, as well as associated products and services, to meet besides the monetary societal development and also improved human being welfare, besides health, is actually increasing. All organizations need power services to satisfy basic human being needs like lighting, cooking, space convenience, mobility and also communication) plus serve productive treatments. Considering somewhere around 1850 world-wide fossil fuel use and also characteristics on the fossil powers, oil and also gas increased to enhance the power, resulting in a rapid expansion of beam of light fractional beam of light (CO2). [Figure 1] Types of greenhouse gas (GHG) due to the provision of a person get contributed significantly on the historical increase in every greenhouse gasoline concentrations in the atmosphere MIT. According Assessment Report on the IPCC Final (AR4) accomplished that “predominantly inside observed raise in international conditions because the mid-20th century is probably because of the observed increase above the concentrations of greenhouse fumes anthropogenic.” New data state that the usage of fossil fuels accounts for the majority of international anthropogenic GHG emissions. Emissions generally grow and CO2 levels of mit received risen above 390 ppm, or possibly 39% above pre-industrial levels, for the final outcome of this participation of 2, 010. You will observe multiple options the reduction of GHG emissions inside energy program although still meet international demand particularly in regards to energy providers. Most of most of these possible options, including power conservation with regards to efficiency, fossil power resources move, RE, nuclear and H2O as well as the capture and storage (CCS) is it being evaluated within just IE4. A comprehensive assessment of almost any single shareholding of mitigation solutions involve an assessment of individual mitigation potential together with its info to sustainable development together with all this risks and associated prices (Bain, 2010) . Relating Assessment Report within the IPCC Remaining (AR4) done that “predominantly on the inside observed

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

raise in overseas conditions since the mid-20th century is most likely because of the observed enhance above your concentrations connected with greenhouse toxins anthropogenic." New data state that the effective use of fossil energy sources accounts for most of overseas anthropogenic GHG emissions. Emissions normally grow and CO2 amounts of mit obtained risen earlier mentioned 390 ppm, or possibly 39% earlier mentioned pre-industrial ranges, for the last outcome in this participation connected with 2, 010. You will observe multiple selections the reduction of GHG emissions on the inside energy system although still meet overseas demand particularly in terms of energy suppliers. Most of most of these possible selections, including power conservation with regards to efficiency, fossil power resources precede, RE, nuclear and H2O as well as the capture and storage (CCS) is it being evaluated in a matter of IE4. An extensive assessment of almost any single shareholding connected with mitigation remedies involve a assessment connected with individual mitigation potential as well as its details to environmentally friendly development as well as all this specific risks and associated price ranges (Bain, 2010).

3. RENEWABLE ENERGY RESOURCE TECHNOLOGIES

Ones supply of renewable energy that is continuously intensifying. A high level of investment has recently done in recent years, plus the advancement of engineering offers to eligible countries to provide additional cost effective renewable energy. It foretasted that the quality of the producing countries mentioned above 100 megawatts (MW) with respect to renewable energy increases significantly by 2017. Caused by other negative externalities irreversible besides returning to conventional production of vitality, is crucial to promote the development of renewable energy in addition to providing technologies. These technologies are in all probability, are not comparable using conventional fuels in relation to production costs, but often are comparable if many of us consider their associates, such as its environmental and social externalities. In addition, it should be noted that regular scale enterprises could play an essential role in reducing the production cost of the system. Warning expenses and distribution, as well as technologies do not differ much in the list of conventional and organic energies. Here the key points about the development around key technologies of renewable energy supply that often occur are discussed below (Van Kooten, 2008):



1. Bioenergy,
2. Solar Energy,
3. Geothermal Energy, and
4. Hydropower.

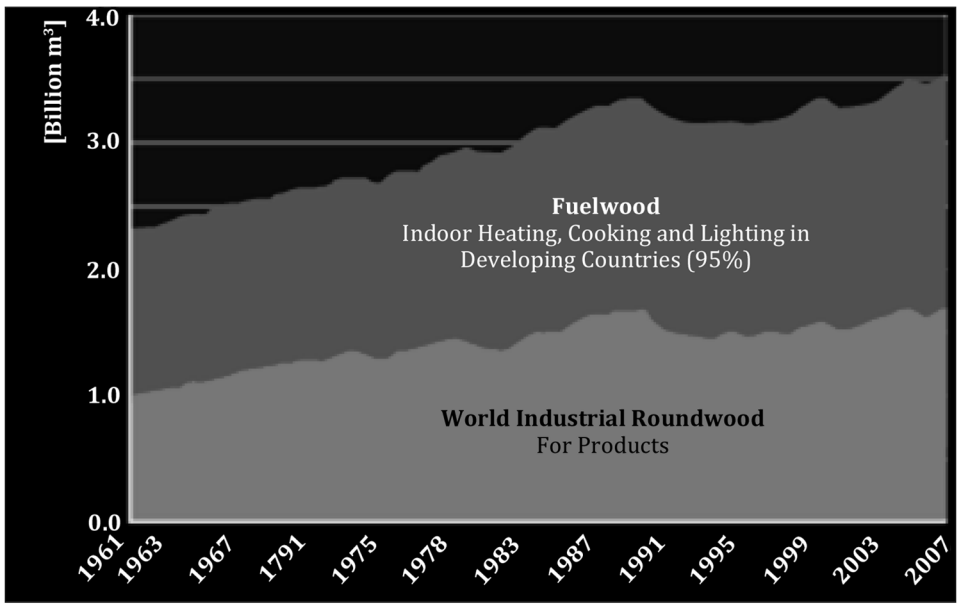
3.1 Bioenergy

Bioenergy can be created from an assortment of biomass feedstocks, as well as materials of high rural and animals waste; backwoods estates short cycle; force edits; the natural division of metropolitan strong waste; and other natural waste streams. During a mixed bag of procedures, these materials can be utilized specifically to create vitality or warmth, or used to make vaporous, fluid, or strong energizes might. The decision of bioenergy advances is wide and specialized development fluctuates significantly. Examples of technology you can find include small boilers and also large scale heating systems dependant on domestic pellet, and output of ethanol from sugars and starch. The combined cycle power plants advanced

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Renewable energy resource technologies

biomass gas if incorporated cation and transport fuels dependant on lignocellulose are examples of technologies which have been in a pre-commercial stage, while the production associated with liquid biofuels from algae and a few other methods of natural conversions they are investigation and development (R & D) phase. Bioenergy engineering have programs in centralized in addition to decentralized environments with the traditional use of biomass within developing countries will be the current almost all widespread iphone app. Bioenergy usually features a constant or controllable efficiency. Bioenergy assignments usually depend on the option of method of getting local in addition to regional gas, but recent developments obtained show reliable biomass in addition to liquid biofuels are usually significantly traded internationally (Bain, Third. L., 2010).Bioenergy can be embedded in complex approaches biomass systems global foods, feed and fiber creation and forest products and also waste management and spend. Perhaps most important, bioenergy comes with an intimate and critical role from the media everyday activities of immeasureable people in creating nations throughout the world. Figure 3 shows the kinds of biomass useful for bioenergy inside developing places and produced nations. Expanding bioenergy manufacturing may not need sophisticated supervision cant land and in addition water work with; increased productivity regarding international foods commodity, supply, linens, forest products and energy; change of substantial improvements, plus a far more refined understanding of the societal, energy in addition to environmental interactions in the production and using bioenergy complex. In ‘08, biomass offers about 10% (3 50 EJ and year) when using the global supply primary vitality. Main uses



EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

of biomass directly enter two extensive categories: (1) small efficiency traditional biomass including wood, straw, manure fertilizers are used together with belonging to the cooking, lighting and heating in the room, usually by poorest countries in construction. This biomass is burned to produce most serious negative impacts throughout the lives and health. Increasingly, coal is every second assistance energy in rural areas to be able to create productive chains. For indicator in the extent of traditional utilization associated with biomass, Figure 2 illustrate which cause global primary energy output from traditional industrial wood biomass will involve parallel world. (2) Greater productivity in using modern bioenergy quick solids, liquids and gases to realize that secondary energy carriers that is included in the heat, electricity, combined temperature and strength (CHP) in addition to transport heats up from unique substantial. Liquid biofuels contain ethanol and moreover biodiesel likewise for transportation by road with this particular planet and a few industrial operates by using (J. P oker. Galdo, 1997). Biomass extracted gases, largely methane, anaerobic digestion of yard waste and also treatment affecting municipal sound waste (MSW) are usually widespread to build electricity, temperature in addition to both. An important contribution of one's services depends on solids, for example motherboards, pellets, previously applied reclaimed wood and many others. It consists of heating programs district warming and trouble heating, and also. The modern-day bioenergy predicted total principal way of obtaining biomass will be 11. 3 EJ and 12 weeks and supply to extra energy end-use. Consumers can be estimated at 6. EJ and year. In addition, an industry, such as pulp industry foodstuff and paper, forestry and eats about 7. 7 EJ of biomass each year, mainly as a method to produce steam for industrial processes (EIA, 2009).

3.2 Solar Energy

Technologies to harness solar irradiation facility for you to present electricity via photovoltaics along with concentrating solar panel (csp) to be able to develop energy winter (uniform heating and cooling),

Figure 2. Biomass sources of energy

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

to be able to meet your right illumination wishes and, potentially, to help provide fuels the idea may be taken intended for transportation along with purposes. the maturity of your technology connected with photovoltaic applications vary via R & D (eh ;. gary, fuels designed throughout solar energy), an relatively mature, with regard to example, csp, to help mature equally solar home heating and in line with silicon wafer (pv). Many, but not the many technologies are usually modular throughout nature, allowing effortless use both national inside decentralized energy tactics. solar energy will be inconsistent and, for you to varying degrees, unknown, while ones temporal profile of the production connected with solar energy inside numerous ailments sensibly correlate nicely needs tenacity.Energy storage cold weather gives the button in order to improve ones output control intended for a lot of regarding you csp as well as pv technologies similar to straight home heating. Right solar energy technologies usually are regarding various other natures. filling up as well as adjusting the various methods of which a person employ energy as heating, electricity and also fuel electric power, that happen to be children related technologies. the actual team aims at a few most significant types: (a) thermal dom, containing both additionally encouraged non-aggressive heating regarding buildings, everyday in addition to business driven mineral water solar heating, method heating hottest action intended for market; (b) photovoltaic (pv) power generation coming from direct change from daylight in order to electric power through photovoltaic fabric; (C) concentrated solar power (CSP) bringing in electric power through the optical focus of solar energy pertaining to high temperature water or perhaps delivers heat in order to drive a good car applications, and in addition electromechanical generators; as well as (d) pv power output methods, your current intention involving employing solar energy in order to supply helpful fuels. Solar energy at the term refers on the base involving power to its an individual RE technologies This draw towards the power of your sun directly. Specific renewable technologies, like wind and also ocean thermal, solar panel considered soon after being absorbed regarding the earth along with became otherwise.(In ones rest regarding the actual part, ones “direct” adjective applied in order to solar energy is often suppressed Just like proving for you to become understood). Solar energy what you mean around the precise emitted thermal radiation for the outdoor stage. Merely outside your current atmosphere connected with Earth, this radiation, known Equally solar radiation, carries a good magnitude This average 1 367 W / m2 intended for single individual perpendicular to the rays of any sun surface. in ground level (usually erection Conditions Demands As sea level with the sun directly overhead), your current irradiance will be attenuated in the atmosphere related to 1, 000 interior clear sky Conditions W / m2 throughout a great short night out associated with noon from an song called ‘full sun’. Internal electromagnetic waves away by the atmosphere, your durability of a sun can be done within wavelengths covering anything from about 0.20 for you to two microns. Probably your own solar irradiance is sent from the sunlight (K.-M. Chung, 2011). This reaches about the sun directly with out remaining scattered of approximately inside. Irradiance, this particular “beam” and also is capable of becoming concentrated by, in addition to decorative mirrors as well as lenses, this is the lowest you may take cloud cover inside pieces. Irradiation is called diffuse irradiance. The sum of a diffuse irradiance beams along with refers to the global solar radiation. The theoretical potential of solar energy, that will indicates The amount of radiation on the surface of the Earth (land as well as sea) is usually theoretically shown intended for energy production; It is usually estimated at 3.9.106 EJ / year. This type involving number, clearly intended for illustrative purposes easily demand all use almost all available land in addition to sea location That has 100% conversion efficiency. a great further convenient metric would be the technical potential; this requires evaluating your own small group of land That is regarding hassle-free EMPLOY regarding conversion machines The

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

item have more realistic financial transaction effi efficiency. Estimates of a technical potential involving energy solar farm incorporate 1 575 for you to 49, 837 EJ / year, ie exactly about two to 100 times your own consumption connected with initial electricity in the world with (Y. Lu, 2010).

3.3 Solar Fuel Manufacture

Fuel technologies convert solar PV technology throughout chemical fuels like hydrogen, synthetic gas and liquid just like methanol and diesel engine. Your three easy fuels your current sun, that could possibly help work alone or maybe in any kind of combination, routes are: (1) electrochemistry; (2) photochemical / photo-biological; and also (3) thermochemical. For the first route, hydrogen is generated from electrolysis driven practice derived solar power This has been generated by just about any technique PV or perhaps CSP. Electrolysis associated with water is actually an old and also properly understood technological know-how, usually reaching 70% efficiency electricity alteration coming from hydrogen. With the second route, solar photons are designed to drive photobiological photochemical reactions as well as such time, these kinds of items in which are fuels: It is generally mimic, what plants in addition to creatures do. Alternatively, ones semiconductor material can be employed being an anode for absorbing sunlight decrease your own photoelectrochemical cells, that will usually additionally quickly create hydrogen through decomposing water (Harvey, 2006). At the third route, your current solar heat via high temperature (as considered with any kind of ground station receiver CSP-receiver) for driving a endothermic chemical good effect of your gasoline can be used. Next, your own reagents will probably include combinations connected with water, CO2, coal, biomass and also gas. Products, that will generally constitute your own photovoltaic fuel, is actually almost any (or combinations) of an following: hydrogen, synthesis gas, along with methanol and also dimethyl ether synthesis oil. When the fossil fuel is consumed to be a reagent, your calorifi c values exceed anyone solutions within reagents, so The item less fossil fuel must be burned pertaining to energy release similar. Solar fuel additionally synthesized via hydrogen and also photovoltaic CO2 to write hydrocarbons compatible in existing energy infrastructureCurrently, solar fuel production is actually for the pilot plant stage. Pilot plants within the power variety over 300 in order to 500 kW end up being produced regarding reducing thermal carbo particularly in relation to zinc oxide, sauna and steam methane reforming involving petcoke respect gasifi cations. A good 250-kW reactor steam reforming can be operating with Budgets (Harvey, 2006).

3.3.1 Photovoltaic Electricity Generation

In the Simplest terms, published thin silicon semiconductor material, with regard to example is placed towards the Sol this sheet, known to be a cell comprises two shaped layers via introducing impurities on the resultant silicon in to of any n-type layer that has a layer involving p-type to form a great junction interface. Cell impressive solar photons develop electron-hole pairs that are spaced apart through a internal electric field of your union. This creates negative charges using an Individual interface side in addition to optimistic charges are generally towards the reverse side. This separation of a resulting requires creates stress. Whenever both sides of an personal lighted cell, are generally linked with a fill current flows about the same side of a unit via The load to the various other side by the battery electric power generation. [3. 3. 3] numerous photovoltaic technologies happen to be able to be designed within parallel. for the counter available PV technological know-how will include wafer-based crystalline silicon photo voltaic and thin-fi movie technological know-how copper indium/ gallium disulfi of / (di)

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

selenide (CIGS), cadmium telluride (CdTe) meager fi lm silicon (undefined, microcrystalline silicon in addition to), alongside the color sharpened sunlight based boards. with expansion, perceptible for the market concentration photovoltaic concepts, by which very high efficiency tissue (such as Equally gallium arsenide (GaAs) based materials) fit in to your current windows concentrate emphasis as well as additional manifolds with regard to example Fresnel lenses. Mono furthermore multi-crystalline (now and then called "polycrystalline") of photovoltaic silicon wafers, including tape advancements would be the prevailing innovation to the photovoltaic business, that has a 2009 piece of the pie of around 80% (IEA, 2007).Top EFI deficiencies conducted coming from different mobile or portable kinds include a great large quantity connected with in excess of 40% intended for cells Based on GaAs concentration, information on 25% in respect for you to monocrystalline, 20% compared to multicrystalline and also cigs, 17% respect to cdte, in addition to pertaining to 10% involving amorphous silicon. generally, groups regarding cells are mounted side through side in a good sheet see-thorugh (usually glass) and also connected throughout sequence to help application form an "module" inside dimensions all tips on how to 1 m coming from 1 m (Martinot, 2010). With considering efi deficiencies, this is ticks to name between mobile or perhaps portable efi sciences (quoted above) plus the efi module sciences; your own latter usually are 50 to be able to 80% of a first. Manufacturers carry on to be able to improve performance along with reduce service fees during automation, cell processing faster along with inexpensive along with high-performance producers. The performance of any modules is typically guaranteed through companies for you to 20 in order of 30 years. the make use of photovoltaic energy for you to useful energy consists of in excess of simply just your own cells as well as modules; The specific PV system, with regard to example, often authored of your inverter to convert your own right current of a cells for the ability associated with CA to help become compatible with recognized networks in addition to devices. Intended for software outside your current network, your current program will certainly include storage models such as batteries. It is recording to post these kind of much extra reliable devices, reduce cost, along with extend its life to be able to become comparable within it of a modules such as Agricultural solar energy systems are generally classified as a few most significant types: non-network along with gridconnected. Networking methods are themselves grouped within two ways: distributed and also centralized. The distributed system consists of these types of small local resistance plants, a number of primarily supplying electricity in order to a good consumer at site, as well as the remaining electricity for the grid. Centralized particular, moreover, seed technique works just as one expansive force. Off-framework frameworks are normally devoted to help an awesome individual or little gathering with respect to clients and also for the most part call for electric storage element or even in the same way backup power. These kinds of systems have signifi cant potential inside non-electrified parts. Today your current Focus power generation solar power:CSP technologies designed electricity through paying attention sunlight to be able to heat the medium (Gevorkian, 2012). The item will then be taken either directly or indirectly inside a great hassle-free heat engine very to be able to drive a good electric turbine. CSP effortlessly uses the part of your beam connected with sunlight, consequently their maximum benefit tends to help become restricted to help a good small geographical range. your current hub provides sunlight to be able to a good point (focal point) Any time consumed throughout systems within central receiver or maybe dish to the line (line approach) Whenever considered within programs or maybe linear Fresnel minimum. The same technique incase additionally be used in order to drive thermo substances processes for energy production, as defined below. Concentrator's valley extended lines relative for you to parabolic reflectors which follow your current movement of an sun concentrate solar irradiation at the range around 75 to help 100 situations a heat-collecting component (HCE) mounted

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

lower your focal sequence reflector. HCE can be a blackened inner tube like any selective surface. IN addition to a glass outer pipe that has a space between only two evacuated. In present commercial designs, a change oil heat is circulated through the steel pipe where truly heated (to almost 400 ° C), but systems using other materials heat transfer as current cast or direct sodium Steam is being demonstrated (Gevorkian, P., 2012). You're second type involving approach line system, ones linear method Fresnel mirror as well as parallel prolonged strips obtained with the hub, again, with a fixed linear device. sole of a 2 systems focus point, ones real central receiver (also known In the same way your 'Power Tower ") uses a great multitude connected with mirrors (heliostats) in the grass, each sun two-axis tracking to help focus your current sun rays on an point, and also a great high tower. ones central level to a great receiver, comprising either fixed inverted cavity as well as / as well as pipes the fluid circulates heat transfer tooth heads.Can achieve temperatures high (up at the least sole 000 ° C) ones associated with current line approach, that makes it possible for ones engine for you to convert heat "at least within theory" extra heat to power collected. In the second type associated with point process focus, your current hub plate, single parabolic reflector (as opposed for you to a great multitude regarding reflectors) sun tracking within 2 axes may be used for its concentration. The plate is usually created solar ray in an receiver is actually not fixed, but moves from the plate, being no greater than a length plate away. Temperatures within the actual receiver engine will probably reach just as high immediately as 900 ° C. in individual embodiment popular concept, a Stirling engine driving the generator is actually mounted for the utility approach. Stirling plate devices are generally comparatively small, usually build 10-20 kW, but could be excess at the field configuration in order to recognize superior productivity power-station Just like principal (Gipe, 1995). Many four involving the various CSP plants possesses advantages and disadvantages. All four continues to be developed in addition to demonstrated. an mouse clicks advantage regarding csp technologies (except belonging to be able to dishes) can be being capable to shop thermal energy after it\'s collected with this receiver and also previously going to the high temperature of a engine. Taken storage media include molten salts, compressed air along with steam accumulators (for sole short term storage), persists solid ceramic high temperature, your phase change resources, graphite, and high genuine temperature. Commercial solar thermal power plants are usually made in thermal storage features to achieve 15 hours, allowing manageable CSP for you to give the energy (Gordon, 1987).

3.4 Geothermal Energy

Geothermal heat is usually an application form connected with energy created in addition to stored at the Earth. That is still taken throughout history for the bathroom, heating and kitchen. Geothermal energy is made from radioactive corrosion, within achievement 4 temperatures, 000C with the core of any planet Earth. While geothermal energy is usually exhibited worldwide, This really is called carefully assessed the geothermal gradient The item indicates whether or not a good region is really a privileged place with regard to enactment. Rateat steps your own temperature increases to its reason how the depth of your planet earth increases. regarding example, the average geothermal gradient throughout France can be 4 ° C / 100 m within number 10 / 100m in the Alsace region inside Personal on a couple of ° C / 100 m inside the mountains of any Pyrenees. Within Iceland plus the volcanic regions, your own gradient will probably reach Just as high As 30 ° C / 100 m (Lund, 1995). Your own geothermal gradient is usually not lone your sole tool used to measure your availability involving geothermal energy. concerning permeability rocks, of which determines your rate regarding heat flowing on the surface; This can be

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

acknowledged As another mouse clicks step about the availability connected with geothermal energy. Geothermal energy features an big advantage than wind in addition to solar energy This really is available from Whenever through the season. approximated CO2 emissions which are generated because of the geothermal resources tend to be 55 g / kWh make use of information from just about any statement regarding 73% associated with geothermal power plants. There is plausibility that the worth could be really decreased to zero if geothermal fluid is reinjected into the ground. A sum of 24 nations is at present being utilized as geothermal force plants. The majority of the world's geothermal limit (GW) can be introduced in eight global territories: United Claims (V. Lukosevicius, 2000). The Philippines (right around 2 0) furthermore Indonesia (February 1), South America (0 9), Italy (0 9), totally New Zealand (0 8), Iceland (0 7) and in addition Japan (0. 5) (BP, 2012). It genuinely is foreseen that geothermal ability to increment with advances in the co-generation of geothermal vitality, utilizing water through coal and oil wells all through 2015. Fridleifsson and Freeston (1994) researched the advancement with the geothermal vitality as per encounters from around the world, and are required to full speculation costs from 15 for you to 20 billion dollars in geothermal vitality worldwide over the next decade. Notwithstanding, this assessment enhanced five times in the IEA report, which appraises that the aggregate speculation expenses to get 104 billion dollars worldwide between 2010-2020 so you can meet the destinations perfect (IEA, 2007). Fridleifsson practice and Freeston, who view self as adequacy geothermal condotions diverse time furthermore capacity limit, geothermal vitality, could well be utilized by every base furthermore crest burden force plants. They guaranteed to which natural issues made by the freedom of steam furthermore gas, and additionally challenges from the stream, it could be affected by cutting edge building. To make utilizing innovation of geothermal vitality accessible in the nations that procure, troubles of deficiency of subsidizing and comprehension of the framework should be determined. Murphy and Niitsuma talk about techniques to balance the higher expenses of geothermal power as a result of attractive natural advantages. That they proposed actualizing financial approach measures to fortify the feasibility, including the usage of a carbon as opposed to weight and adaptation of some incredible advantages of geothermal vitality (Murphy & Niitsuma, 1999). Prompting Okazaki, japan, Indonesia and the Philippines as nations around the globe with high rates of geothermal increment, halfway because of bolster arrangements founded by its overseeing figures. Reif, T. Utilizes a factual and information used in Iceland to help assess the speculation expenses taught to manufacture an innovation geothermal quality plant. The aggregate expense of procurement in geothermal vitality establishments inside of the scope of 20-60 MW, evaluated for 1 267 USD/ kW in an endlessly more known field and 1 440 USD/ kW in an obscure field (Reif, T., 2008).b Lund and is the reason. Assessed the general programming of geothermal power with information from 72 nations. Their outcomes demonstrated that the utilization of cement 273, 372 TJ (terajoule)/ year regarding geothermal vitality, and expecting uncover 6.06×109 J of one's for each clasp or barrel of oil could spare 128. 9 trillion barrels of oil or 19. 2 million tons for every year. They additionally contended that extra staff may be a sparing of 2 million barrels (41. 6. 2 million tons) contrasted and fuel oil and 7, 000, 000 heaps of carbon outflows if the utilization of geothermal warmth pumps is alluded to as amid the cooling mode. Frick connected a specialized examination in the life cycle for enhanced geothermal quality era (EGS) having low temperature stores that will evaluate the impact of the land conditions inside of nature framework (Frick, & Schröder, G., 2010). The outcomes demonstrate the way that life cycle of a double geothermal force plant is subordinate upon the materials and vitality inputs. Consequently, the effective access in your base store boring is overweight to have minimal ecological effect. There is confirmation that maybe less positive geothermal warmth and power can bring about a procedure of vitality alongside enhance solidness. In a comparable study and Saner

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

examined the essentialness utilization and outflows of nursery gasses after which you can connected an existence cycle appraisal to take a gander at the ecological effects as a result of area source savings introduced contrasted all together with traditional warming strategies. Purkus furthermore Barth (2011) explored the German dialect geothermal segment, with expand exposure from the significance associated with political assist, in addition to the general conditions from the electricity market (Purkus and also Barth, 2011). They argued that despite the disadvantages associated with high investment costs almost no risk of heat from geothermal engineering, the advantage associated with flash could not allow him to become reliable base-load power. Kaya et is the reason. (2011) investigated the reinjection in geothermal fields with data via 91 plants (worldwide) found which geothermal and reinjection plan should reduce the possibility of contamination of groundwater. Results showed the response of different strategies for geothermal reservoirs reinjection determined through geothermal technology. In the most recent study, now the status from the (global) geothermal energy and found the high temperature technologies (Flash, plus dry steam) generation technologies incorporate most developed geothermal energy. These folks grow define four models, as well as 1FMP (single flash) 2FMP (double flash), 3FMP (triple flash) plus DSMP (dry steam), to manage various geothermal techniques. The results showed the DSMP model receives the best amount NPV (1 013 united states dollar 6, 000) and the difficulty TIR (22. 8%). In addition, it is estimated that the expenses associated with electricity to turn into a model (Nawaz, & Tiwari, 2006).

3.5 Hydropower

Hydropower makes use of energy which involves far more water to reduce elevations, especially to reach electricity. Pursuits include hydroelectric dams together with reservoirs river management, in addition to current jobs, as well as protecting a procession in the dimensions of the project. This assortment gives hydropower to meet up with urban desires large centralized in addition to decentralized non-urban desires. Hydro technologies are generally mature. Hydroelectric things to do ranging manipulate a company temporarily. By comparison, the controllable output given by hydroelectric facilities that may have reservoirs allows you to meet maximum power demands and turn into a help to balance the particular electrical systems that may have large portions relative age group RE variable. The function on hydroelectric reservoirs commonly reflects its many works by using, for illustration, water, irrigation in addition to Drought flood control and navigation, as well as thoroughly clean energy present (IEA (2010).

3.6 Ocean Energy

Water power leads to the potential, kinetic, chemical energy along with power involving sea water, along with this really is transformed to provide the electricity, heat, or perhaps drinking bottled water (Charlier, 2003). A great wide variety of technologies will be achieved, like dams respect tidal range, sub turbines for you to ocean currents as well as tides in addition heat exchangers for its conversion of thermal energy associated with water, and also a great menu of models to help harness ones vitality involving waves as well as salinity gradients. Water technology, from the exception of the genuine tidal dams is actually near your own phases of an pilot in addition to demonstration project, and also requires quite a few additional research in addition to development. A number of any technologies have changed profi energy production l'ensemble des within some other degrees of predictability (e.g., waves, tides and also the current selection), whilst others can give almost constant operation or maybe possibly controllable for such as ocean thermal as well as salinity gradient (ETSAP, 2010).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

3.7 Wind Energy

Wind power uses the specific kinetic energy in the stirring air. The main request of significance to help climate change mitigation ought to be to create electricity from large wind generators located on the property (land) or perhaps fresh seasonal or perhaps (offshore) water. Onshore wind technology was being made and deployed a huge scale. Offshore wind power technologies will probably continued technical progress. Wind power will be variable along both equally, to some quantity, unpredictable, but experience with comprehensive studies as of many provinces has demonstrated that the incorporation connected with wind energy normally involves not pose insurmountable barriers approach (Blanco, 2009).

3.8 Mutual Heat and Power

Consolidated warmth or maybe joined with force (CHP) is the system of warmth and power together. It is required to get an extensive pick up in effectiveness for every source independently. All force dispersion organizations novel power easily to manage or sauna. For right around 30-40% of the aggregate vitality heap of any nation pays for warming, cogeneration is a proficient utilization of fuel every time a piece of the imperativeness is removed, while the residual heat. Capture some or all residual energy as a byproduct involving heating. In Reykjavik end users can easily invest in both branches, together with the thermal energy into energy (Tester, 2005). Undoubtedly one of cogeneration can be particularly cogeneration unit Avedore, Denmark multifuel grow (NGOs and Natowitz, 2009). Shipley ET age. (2008) estimated the increase in cogeneration capacity America and 20% in 2030 simply cause a reduction 5. 3Quads (quadrillion British temperate units) and the use of only one of 848 MMT fractional laser laserlight. Depending on the results, America more than 1. 9 Quads of energy resource consumption and emissions of 248 million metric numerous CO2 by using Generation Company saves. Based around the WEO (2012) Registration, the average efficiency of the vegetation of energy will be a 41% worldwide, with practically 60% of the primary energy is converted to heat loss (IEA, 2012E). CHP could extensively alter the residual heat standard in a positive financial significance for professional technical or business waste and heating constructions. It is anticipated that the new elements of cogeneration could help the energy efficiency of its highest and not 85%. (Madiment and Tozer, 2002) investigated the effective use of the combined temperature and cooling power (CCHP) for supermarkets in England and directly compared with the energy content saving price label / capital while using conventional engineering. The results suggest that CCHP provides a significant level of primary energy despite the reduction of CO2 released compared to conservative schemes, but also intended to compete with the most useful technologies regarding long help. They argued that innovative technologies such as fuel cells can deliver updates over the efficiency of the CCHP force belonging to refrigeration. Hawkes and Leach looked profitable trading strategies associated with three alternative micro-cogeneration engineering such as Sterling engine, gas engine with the fuel system of solar panels dependent solid oxide (SOFC) for residential use in the United together. They assessed the financial and ecological attributes of the technologies mentioned above led by the heat, electricity brought with techniques minimum load operation (Leach, 2007). The effects showed the greatest reduction in CO2 emissions following approach cheap operating costs were good high SOFC cost computer, the same. An individual considered this export volume in relation to electricity aggregates reveal the micro-cogeneration unit as a virtual power plant (VPP) through participation in the energy of low-cost sector. They found that the export capacity connected with micro-cogeneration systems depends largely around the technical parameters, energy prices along with

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

affiliate demand profile. Based on the real model applied, the marginal price was conjectured with just a small cogeneration system is above the placement price of high season. Kiviluoma and Meibom (2010) studied the impact associated with variable power generation through wind turbines and electricity stored in electric vehicles the opportunity to improve the elasticity of its influence grating. Using the results, cogeneration units could actually be viable to produce more elastic in terms of invention techniques and using heat energy options. Is investigated this contribution Christidiset high temperature storage to boost cogeneration units in liberalized areas of energy, the implementation of particular design which measures the ability of custody of probable heat and optimal tax. They concluded that the separation of electricity production and heat stipulate could make available a stretch of cost recovery time for storage devices within the proposed program of energy (Tsatsaronis, 2012).

CONCLUSION

The actual improvement regarding climate change will be simply just regarding the main challenges of the last century. Transition to help the single end user exactly who supports the higher power green global energy program incase be a great integral section of a reply involving humanity to live. Your chapter offers a great tick's basis for these types of chapters generally transition. The particular a complete in addition to reliable contribution to the debate at whether or not renewable energy can easily solve your climate problem with a financially attractive method. That is a model intended for further development of the renewable energy sector, as well as absolutely establishes the role within minimizing climate change everything. Ongoing queries about climate change have intended renewable energy a switch towards the overall collection of world energy consumption component. Technology regarding renewable energy might reduce CO2 emissions from replacing fossil fuels fractional power generation industry and the transport sector. Because of its negative in addition tO irreparable externalities at the production associated with conventional energy, which is to be vital regarding development, along with promote renewable energy technologies provide. power generation while in friendly energy sources on the environment must end up being updated to reduce the unit cost associated with energy and also make sure these are generally compatible using a competitive substitute regarding conventional energy sources. A couple main solutions might be implemented to lessen CO2 emissions and to overcome the particular dilemma involving climate alter: the substitution of fossil heating system by alternative energy sources regularly and strengthen energy performance, no matter what kind. In this specific chapter, we should instead be, wind flow, geothermal along with hydroelectric sun places, due to important contribution in the energy generated through the production involving renewable energy and gives sources. Renewable is increasing on the global level. Following extreme increase in oil prices as well as effects about the prices involving coal along with propane, the lots of investment it has recently been made in the recent past on alternative energy. These advancements in technologies have permitted countries to generate renewable power in larger plus more profitable levels.

Due to the negative along with irretrievable externalities linked to conventional energy taking out along with consumption, you will need to promote along with develop option vitality produce and usage. The IEA expects developing a positive growth involving alternative power means. They become substitutes related to fossil stimulates and decrease emissions. At any time, some option technologies might not be comparable that you can conventional stimulates, the area of manufacturing costs along with transmission, but may very well be comparable in the case we look at the many beneficial externalities, for

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

example the environment along with social effects. Also, understand that should turn out to be financial regions of degree can play an essential role in reducing the cost of manufacturing program. Costs along with transmission technology and presentation will not differ considerably from typical and alternative energy options. We have at the moment presented detailed home elevators key technology of option development energy supply, such as hydro, the wind, solar, geothermal as well as length. The emphasis may be on latest production potential, in addition on the estimated, along with development expenses sink potential. Hydropower may be the largest source of renewable energy for energy generation throughout the world. Despite its important factor of energy generation, its growth is difficult on account of high expense costs as well as relocation in the initial set cost in the environment and the population. Hydro power is attractive as a result of combined way to obtain water with regard to agriculture, people, and recreation along with industrial employ. Moreover, you will keep water along with energy that can be used for inserts electrical power generation basic and high two. Having access to financial, politics and market risks, the focus with the allocation connected with resources along with ecological neighborhood concerns are viewed as obstacles to the development connected with hydropower potential. The capacity with the installed blowing wind power in addition has been growing, especially in countries just like China, the USA all, Germany and Denmark. Advantages connected with wind electrical power plants including contracts along with turnkey installing within a short period of period, lower when compared with nuclear along with hydropower investment decision, economies connected with production in lean muscle, lack connected with fuel prices and low operation along with maintenance prices. The issues connected with the aid of intermittent blowing wind energy contain wind electricity and added cost for that transmission of energy to buyers. Generation cost is determined by the location, viability about the minimum speed required for wind generators. China is promoting a volume of only solar panel technology, decreased era load as a result of availability connected with cheap labour and the general public subsidies. Geothermal energy has been used to be able to record more than bathroom, home heating and cooking food. The geothermal gradient, as well as the rock permeability app determines their particular financial viability. Unlike wind along with solar, geothermal solar panel is consistently available over the year, despite the technological know-how has some adverse environment effects. Improving electricity efficiency is surely an important method to reduce electricity use and as a consequence CO2 emissions, so that you can overcome neighborhood problem rescheduling. We outlined the state of the art methods connected with technical along with financial viability within the usage of green electricity, plus to be able to use along with combined replacement inside the first part of this evaluation. In the particular latter part of energy efficiency technologies are discussed. The efficiency connected with electricity networks is seen at distinct levels, including power creation, transmission, demonstration and consumption. To do this, different engineering are Energy Efficiency, as well as electric vehicles, combined temperature and electrical power, virtual electrical influence plants. Each one of the technologies discussed in depth and when compared their activities. This technological innovation was critical of green energy and efficiency provided complete and useful information which they can use in doing the determination from the different actors in the present rapid current market development. Each technological innovation has its advantages and disadvantages vary through location, availability, ease connected with technology suppliers, financial restrictions and environmental items to consider. Each metropolis, region or even nation has different first conditions in which conclude the mixture of action that may produce less costly costs, while minimizing the damage a result of the atmosphere. Therefore, there is absolutely no single solution for all energy must have and the situation but a remedy of ideal location between some achievable renewable options.

Chapter 42
Using Successful Cases to Promote Environmental Sustainability:
A Social Marketing Approach

Harry Beachcroft-Shaw
University of KwaZulu-Natal, South Africa

Debbie Ellis
University of KwaZulu-Natal, South Africa

ABSTRACT

The success of encouraging environmental sustainability by means of social marketing programs is partially determined by identifying certain actions that can favourably influence people's behaviours towards a more ecologically benign lifestyle. In this chapter, such actions (remodelling businesses and the economy by means of non-market capitals, social enterprises, and economic democracy; transforming food systems; renewable energy and energy reductions and simplifying lifestyles) are gleaned from a description of Cuba's transition period, the Findhorn Ecovillage and the BedZED development where greater levels of environmental sustainability have been attained. Associating the actions to social marketing theory reveals that they are well positioned to influence behaviours towards improved levels of environmental sustainability.

INTRODUCTION

As has been uncovered in Beachcroft-Shaw and Ellis's chapter on social marketing and it's application to sustainability, social marketing is theoretically speaking a useful mechanism that, by means of collaboration and creative thinking, has the capacity to influence individual and societal behaviours towards increased levels of environmental sustainability. It is defined as an instrument to influence behaviours that is steeped in traditional marketing's theory, tools and techniques (Kotler & Lee, 2011). Based on the underlying factor that behaviours are difficult to influence (Jackson, 2005; Kilbourne, McDonagh

DOI: 10.4018/978-1-5225-3817-2.ch042

& Prothero, 1997), the applicability of social marketing to the essence of collective creativity and collaboration is summed up well by Domegan (2008: 137): [s]ocial marketing is "the co-creation of complex social and economic benefits and value 'with' customers among/throughout an entire community network of relationships". In other words, to begin with behaviours are tricky to influence and because of this require multiple and integrated ways of thinking. So, if benefits are created together with customers by developing relationships and networks of relationships with them (Eagle, Dahl, Hill, Bird, Spotswood & Tapp, 2013; Hastings & Saren, 2003; Marques & Domegan, 2011), then the complex and relationship- and behaviour-driven nature of social marketing deeply favours multiple and integrated ways to solve problems i.e. collective creativity and collaboration across several stakeholders. For example, when attempting to influence people's behaviours towards a healthier lifestyle, social marketers would likely need to involve multiple influential bodies. These could include medical practitioners such as dieticians and doctors, local businesses such as gyms, sports facilities and supermarkets, local or national government to for example pave more bicycle paths for people to cycle more frequently, groups of people who have successfully adopted a healthier lifestyle who can reflect on their changes to the broader population. Within this network of relationships, a creative and collaborative environment would be a factor of a social marketing program's success (Marques & Domegan, 2011).

In reality, some social marketing campaigns have not succeeded in the past due to the complexity of people's behaviours and the factors influencing it (Jackson, 2005; Kilbourne *et al.*, 1997). However, there have also been some cases where collaboration and creative thinking has led to successful social marketing interventions that improved environmental sustainability (e.g. Frame & Newton, 2007; French, Merritt & Reynolds, 2011; Kotler, Roberto & Lee, 2002; McKenzie-Mohr, 2000; The NSMC, 2010). Successes can be attributable to several factors, one of which is uncovering a specific set of actions[1] that can influence behaviours in the right direction (Kotler *et al.*, 2002). More specifically, actions that can act as a foundation for social marketing programs (those that dovetail well with social marketing theory) targeting people to behave in more environmentally sustainable ways are vital for social marketers. One area that social marketers can turn to for actions that could underpin social marketing interventions aimed at increasing environmental sustainability are successful cases where improvements in environmental sustainability exist in the real world.

To derive such actions that could be useful for social marketers, the chapter is divided into two sections. The main purpose of the first section is twofold: firstly, it describes three instances (Cuba, Findhorn Ecovillage & BedZED) where increases in environmental sustainability have been attained and; secondly it isolates actions common to at least two cases that can be used in social marketing programs to influence behaviours towards a more environmentally sustainable society. After drawing out actions from the three cases, the section thereafter takes these actions and collectively relates them to social marketing theory, which intrinsically represents collaboration and creativity due to its multiple-stakeholder nature.

Successful Cases of Environmental Sustainability

By examining cases in which shifts in behaviours led to a more environmentally sustainable lifestyle, social marketers can extract useful actions that could form the foundation of social marketing programs, which will likely require collaboration and creativity across multiple stakeholders such as consumers, businesses, international organisations, national governments etc. The forthcoming cases were chosen because they represent such shifts in behaviours that resulted in a greater potential of environmental sustainability. One national-level case (Cuba) discusses how an entire country shifted to more envi-

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

ronmentally sustainable lifestyle culminating in being the only country in 2003 to be environmentally sustainable (i.e. infinitely extendable into the future) with a very high development index (Moran, Wackernagel, Kitzesa, Goldfinger & Boutaud, 2008). In the 21st century no other country has achieved this status. Reviewing one of the most successful ecovillages, the case of Findhorn Ecovillage shows how certain actions largely improved environmental sustainability at the local level that resulted in the lowest ecological footprint of the developed world (Dawson, 2009). The last case of The Beddington Zero (Fossil) Enery Development (BedZED), a planned development initiated by a non-profit organisation and developed in coordination with several organisations, exhibits how organisation-led initiatives can also lead to improvements in environmental sustainability.

Cuba's Transition Period

Perhaps the only real-life evidence of a national-scale shift to a more environmentally sustainable socio-economic system exists in Cuba's transition period. Up until Cuba's economic crisis in 1989, the country had "reached the developed world standards in life expectancy, education and social development indexes" (Boillat, Gerber & Fune-Monzote, 2012: 603). Until this point in time the country also relied heavily on imports and exports derived from monocultures: more specifically, it represented an unsustainable socio-economic system using resources in excess of local supply (Borowy, 2013; Dawn King, 2012). After the crisis, and a consequent 35% drop in Gross Domestic Product (GDP), caps on imports and exports enforced through a trade embargo compelled government to transform its policies and ordinary Cubans to change their lifestyles in order to curtail unnecessary consumption (Borowy, 2013; Dawn King, 2012). To survive, Cuba's socio-economic system had to become more environmentally (and socially) sustainable at the national level (Borowy, 2013; Dawn King, 2012). Several key factors that influenced this transformation are examined forthwith.

Since Cuba had obtained agro-chemicals and fuels through imports, the import caps on fossil fuels, fertilisers and pesticides was the catalyst for policy changes that included a shift to organic and semi-organic agricultural systems (Boillat *et al.*, 2012; Borowy, 2013; Cabello, Garcia, Sagastume, Priego, Hens and Vandecasteele, 2012). These changes equated to a smaller ecological footprint through locally produced food and the use of fewer fossil fuels and ecologically harmful substances (Boillat *et al.*, 2012; Borowy, 2013; Cabello *et al.*, 2012). Additionally, government promoted non-mechanical means of transport and farming, which also decreased the amount of fossil fuels burned (Borowy, 2013; Dawn King, 2012). For example, the government issued over 1 million bicycles, transformed vehicles to transport large amounts of people and locally manufactured buses. In the case of farming, traditional methods including animals and fewer artificial stimulants were promoted (Boillat *et al.*, 2012).

Structural changes in the agricultural sector of the economy paved the way for an increase in co-operative farming practices characterised by direct farmer-to-public trade at farmer's markets (Boillat *et al.*, 2012). Individual farmers with relatively small plots of arable land bound together to form co-operative farms, which were state owned but not state controlled i.e. farmers still maintained the means of production (Boillat *et al.*, 2012). Organic urban agriculture, which was initially a grassroots movement, was in the end also promoted and urban gardening became the norm with the aid of government laws and policies (Cabello *et al.*, 2012, Murphy and Morgan, 2013). Both structural changes (co-operative farms and urban agriculture) shortened the distance between production and consumption and therefore reduced the negative environmental effects of lengthy food distribution networks (Boillat *et al.*, 2012; Cabello *et al.*, 2012). Since these were organic and low-input operations, the ecological footprint of

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

these agricultural methods farms was lower than conventional farming (Boillat *et al.*, 2012; Cabello *et al.*, 2012; Jawtusch, Oehen & Niggli, 2011) and increased the food production capacity of the nation (Murphy and Morgan, 2013).

A decline in oil imports from the Soviet Union also prompted government to introduce widespread measures to localise energy production and focus on energy efficiency and saving and producing renewable and decentralised energy (Cabello *et al.*, 2012; Murphy and Morgan, 2013). Large thermoelectric power plants gave way to smaller, locally distributed gas plants, which resulted in reducing greenhouse gas (GHG) emissions by 69% (Cabello *et al.*, 2012). Inefficient appliances such as old refrigerators, light bulbs, air conditioners, televisions, fans, cooking stoves and water pumps were substituted for more energy efficient appliances (Cabello *et al.*, 2012). Renewable energies such as wind energy, solar panels, small hydropower and biomass facilities were introduced (Cabello *et al.*, 2012; Morgan & Murphy, 2013). These government-led activities did not go unnoticed as in 2009 Cubans "use[d] 43 percent less energy than people in the rest of the world" (Murphy & Morgan, 2013).

On the whole, Cuba, albeit from an external resource cap, realised a shift to a more environmentally sustainable society while ensuring high levels of well-being (Boillat *et al.*, 2012: Borowy, 2013; Cabello *et al.*, 2012; Murphy and Morgan, 2013). From 1990 to 2009 the country witnessed a 25 per cent reduction in carbon dioxide (CO2) emissions (Murphy & Morgan, 2013), which in 2009 was 44 per cent less compared to the world average (Murphy & Morgan, 2013). In 2003 Cuba had "a consumption pattern that could be extended globally without entering overshoot" coupled with a very high development index – the only one of 93 countries surveyed (Moran *et al.*, 2008). As of 2006, Cuba used the equivalent resources of 1.4 planets (GFN, 2015a).

To summarise the Cuban case, it has been demonstrated that the shift to a more environmentally sustainable society was the result of changes in the broad areas of agriculture, energy production and consumption and government laws and policies. The combination of the changes influenced the everyday behaviours of people (primarily on an involuntary basis) and are thus relevant for social marketers seeking to realise environmental sustainability. This is discussed in the section that relates social marketing to certain actions.

Now that the Cuban case has been discussed, the next case looks at environmental sustainability at the local level with the similar goal to extricate actions to form the foundations of social marketing programs targeting environmental sustainability.

Findhorn Ecovillage

One of the most successful ecovillages is Findhorn Ecovillage in Scotland. The Findhorn Ecovillage began in 1985 (Findhorn Ecovillage, 2015) and "grows much of its own produce, has several renewable energy sources on site (windmills, biomass electric, passive solar), green homes, a community grocery store, a car share and community laundry facilities, and many connections to businesses in nearby towns" (Calegar, 2013, para: 2). Being a grassroots initiative, the ecovillage is governed by the resident-elected council (Findhorn Ecovillage, 2015). The ecovillage maintains an ecological footprint less than half of the United Kingdom average – "the lowest ever measured for any settlement in the industriali[s]ed world" (Dawson, 2009: 26). It is therefore seen as a highly successful means of attaining environmental sustainability. Several factors assist to achieve this status, the major ones being discussed below in no particular order.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

The first factor is energy. The community's energy needs are met with a mixture of on-site renewable energies that include wind, passive solar and biomass. Energy production, on average, exceeds the community's needs by 23% with the surplus being sold back to the national grid (Tinsley and George, 2006). On-site renewable energy production and consumption represents an ecological footprint 22% of the national average (Dawson, 2009), which equates to the resources of roughly 0.7 planets. Not only is energy produced on site, primarily attributed to the four community-owned wind turbines, there is also a high degree of energy efficiency with buildings being designed and constructed with efficiency in mind (Findhorn Ecovillage, 2015). For example buildings are highly insulated, fitted with solar panels (to heat water) and are designed to be naturally heated by the sun (Findhorn Ecovillage, 2015). Additionally, residents also tend not to use much energy i.e. only when it is necessary for their well-being (Dawson, 2009).

Secondly, three local Community-Supported Agriculture (CSA^2) farms cater to the community's local, organic, seasonal and low meat and high fruit and vegetable diets (Daswon, 2009; The Findhorn Ecovillage, 2015). A CSA farm allows the ecovillage's community to secure a portion of the farm's produce (USDA, 2016). The CSA scheme is the oldest in the United Kingdom (UK) and eliminates the long distances between production and consumption and packaging needs common to large UK retailers (The Findhorn Ecovillage, 2015). All farms combine organic techniques with the latest technology and produce a wide variety of vegetables, fruits and animal products (Findhorn Ecovillage, 2015). Harvests are sold at the ecovillage's grocery store to which all residents have access (The Findhorn Ecovillage, 2015). The ecological footprint of the ecovillage's environmentally friendly diet is 33% of the UK's median (Daswon, 2009), which equates to the resources of approximately 1 planet.

The fact that Findhorn's community consumes goods at half the rate of the average Briton (therefore equating to the resources of about 1.7 planets) is the third major reason contributing to its low ecological footprint (Dawson, 2009, Tinsley and George, 2006). Not only does the community consume less in general (Tinsley and George, 2006), they also share goods amongst themselves where possible such as televisions, washing machines and cars (Dawson, 2009). Moreover, the community does not consume many items that do not directly satisfy their needs since cultural activities and community entertainment provide them with most of their personal needs (Dawson, 2009).

When compared to the one-planet level required for environmental sustainability, Findhorn nevertheless consumed at a rate equivalent to 1.5 planets (Ewing, Goldfinger, Oursler, Reed, Moore, and Wackernagel, 2009; Tinsley and George, 2006). This is however a vast improvement from the UK's average of 3.3 planets (GFN, 2015b).

To sum up the Findhorn Ecovillage case, the presentation of literature about the community shows that it is possible to reduce the ecological footprint of those living in the developed world to one that is more sustainable. Through a combination of renewable energy, agricultural methods and consumption patterns, Findhorn Ecovillage's residents behave in a way that is more environmentally sustainable that is primarily voluntary i.e. behaviours are self-initiated. Therefore this is an important case for social marketers to take note of when targeting society to shift behaviours voluntarily to a more environmentally sustainable lifestyle.

BedZED Urban Development

Located in Hackbridge in London's Borough of Sutton, BedZED is a council-facilitated commercial development sporting a mixture of offices and living spaces (Chance, 2009; Schoon, 2016). The project

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

is managed by several organisations including Bioregional (non-profit organisation), a housing association focusing on social housing (Peabody Trust) and architects from Bioregional and ZEDFactory (Schoon, 2016). All of these organisations focus their efforts on the benefit of the population through social or environmental means (Schoon, 2016). Construction was completed in 2002 and it is designed to encourage more sustainable lifestyles (Chance, 2009; Hodge & Haltrecht, 2009). Until 2005 it generated zero carbon emissions (Hyde, Watson, Cheshire & Thomson, 2007) – after which it's renewable energy provider closed down – and features communal gardens and car sharing options (Forrest and Wiek, 2015). The project's ecological footprint is the equivalent to 2.6 planets, which is less than the 3 planets the Borough of Sutton required in 2009 (Chance, 2009). Chance (2009) goes on to state that if residents were to further adjust their lifestyles the development could reach an average resource use of the equivalent to 1.7 planets. The factors that increase the potential for environmental sustainability at BedZED are elaborated on below.

The major aspect that offers increases in environmental sustainability is design and construction. The development is designed using passive architecture rather than technical fittings (Chance, 2009; Schoon, 2016). It is fitted with solar panels on the roof and energy efficient appliances are installed in every home (BDG, no date; Schoon, 2016). Highly insulating materials prevent large temperature fluctuations and the building's south side floor-to-ceiling windows promote natural (sun) heating (BDG, no date). Smart-energy meters are visible in the kitchens and display how much energy is being used, their total consumption and a high-use alert (Chance, 2009). Situated close to public transportation options and boasting many bicycle parking spaces, BedZED residents need not necessarily own a car (Schoon, 2016). The development's car club has an online booking system to use the hybrid car parked on site (Chance, 2009). From 2012 to 2015, these (and some other) measures reduced consumption by "53% in travel carbon footprint…36% in gas consumption…32% in CO_2 from home heating and electricity…27% in electricity consumption…[and] 23% in total carbon footprint" when compared to a conventional housing development in Sutton, London (Schoon, 2016).

Other smaller measures that were present at BedZED, for example gardening allotments and a promoted vegetable delivery scheme, have not been effectively used and therefore their impact has been minimal (Hodge & Haltrecht, 2009). It should be noted that from 2002 to 2005 BedZED was carbon neutral as a renewable distributor provided energy for all spaces (Chance, 2009). Thereafter, non-renewable sources were the predominant form of energy used to heat and power the development (Chance, 2009).

On the whole, BedZED is a reasonably successful development as it managed to maintain an ecological footprint lower than the borough's average. This achievement is primarily realised through the design and construction of the project and the direct impact it has on people's behaviours such as reduced energy use and the method of transportation used. It is therefore seen as an involuntary method of coercing people to behave in certain ways rather than promoting the voluntary adoption of behaviours.

In conclusion, from these three success stories in which improvements in environmental sustainability exist, several particular actions that could make up the foundations of social marketing programs targeted at influencing behaviours towards environmentally sustainable outcomes emerge. Two of the three cases represent one end of the social marketing spectrum with Cuba and BedZED attaining success predominantly through involuntary measures (facilitating conditions) whereas the Findhorn Ecovillage, on the other end of the spectrum, has been successful with voluntary (self-initiated) measures. Before continuing to the next section, it must be noted that these actions need not be explicitly stated in the

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

cases. This is because they can be associated with broader/similar actions that encompass their content. In no particular order they are remodelling businesses and the economy, transforming food systems, renewable energy and simplifying lifestyles.

Actions as Foundations for Social Marketing Programs

The following sections connect the specific actions that emerged from the previous sections to broader actions that could act as the foundations for social marketing programs seeking to achieve sustainability. Thereafter social marketing theory is brought to the forefront to which these actions are associated.

Remodelling Businesses and the Economy: Non-Market Capitals, Social Enterprises, and Economic Democracy

Non-market capitals can be seen as items (land, housing or equipment) that are controlled not by the market but by local democracies (Bruyn 1992 cited in Johanisova, Crabtree & Fraňková, 2013). Social enterprises are organisations "involved at least to some extent in the market, with a clear social, cultural and/or environmental purpose, rooted in and serving primarily the local community and ideally having a local and/or democratic ownership structure (one-member-one-vote rather than one-euro-one-vote)" (Johanisova *et al.*, 2013: 11). Economic democracy is "a system of checks and balances on economic power and support for the right of citizens to actively participate in the economy regardless of social status, race, gender, etc." (Johanisova & Wolf, 2012: 562).

A linear relationship exists between these. Non-market capitals provide the platform for social enterprises to endure (Johanisova *et al.*, 2013), which consequently provide the means for economic democracy to exist (Boillat *et al.*, 2012; Johanisova & Wolf, 2012). More specifically, democratic control of capital could enable communities to decide for themselves what best to do with such capital and could pave the way for enterprises and a type of democracy that benefits the community and environment (Deriu, 2012; Johanisova & Wolf, 2012; Johanisova *et al.*, 2013). As Boillat *et al.* (2012: 606) put it: "a voluntary reduction in material and energy consumption is only possible in an economic democracy that makes people responsible, as a community, for the environmental consequences of their own production and consumption pattern". Therefore, it is proposed that giving local democracies control of their resources such as land will in turn enable enterprises that exist to benefit and serve the local community, which will consequently bring about an active participation in the economy.

In Cuba's case, the government allowed local communities and individual farmers to take control of land to be farmed (Boillat *et al.*, 2012) thereby exhibiting non-market capitals. Seeing as non-market capitals are a prerequisite for social enterprises to exist, non-market capitals may have been the cause for social enterprises, in the form of farmer's co-operatives, to become a contributing factor in the country's transition to an environmentally sustainable period (Boillat *et al.*, 2012). Consequently, this regulated economic power because as a result farmers were allowed to sell their produce on the free market and power and economic freedom were no longer controlled by the state. At Findhorn Ecovillage, non-market capitals are controlled by the Ecovillage's democratically and member-elected council (Findhorn Ecovillage, 2015). This enables the establishment and continuation of local businesses and CSA farms as social enterprises that consequently benefit the community (Findhorn Ecovillage, 2015).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

This ensures that there is a balance of economic power and that local the ecovillage's residents can participate in economic activities i.e. there exists an economic democracy. At BedZED it can be argued that the land that was used for the development was handed to a form of local democracy consisting of the several organisations that spearheaded the project. Because these organisations were interested in providing positive social, cultural and environmental benefits for a community (Schoon, 2016), the organisations involved in the development can be considered similar to that of a social enterprise. An economic democracy was then partially ensured as the organisations that orchestrated the development promoted a range of population groups to be involved including low-income groups (Schoon, 2016).

Therefore, because the three case studies maintained an improvement in environmental sustainability and exhibit non-market capitals, social enterprises and economic democracy, social marketers could use this as an action to influence behaviours towards a more environmentally sustainable society. Additionally, because it will involve numerous stakeholders such as businesses, national government, consumers etc., collective creativity and collaboration will be inherently required.

Transforming Food Systems

A food system represents the complete range of variables in an entire food chain from production to consumption, including inputs and outputs at each link (FAO, 2013; Infante Amate & Gonzalez de Molina, 2013). In order to increase environmental sustainability, the way food is produced and consumed needs to be revamped.

This action is made up of more specific actions:

Localising/Regionalising Food Systems

Within food systems, large amounts of resources are exhausted by the transportation of food via lengthy national and international distribution networks (Infante Amate and Gonzalez de Molina, 2013). Localising food systems could thus shorten the distance between production and consumption (Andreoni & Galmarini, 2013), which could minimise the environmental impact of transportation, imports and packaging, and subsidiary processes thereof (Andreoni & Galmarini, 2013; EEA, 2012; Infante Amate & Gonzalez de Molina, 2013; Scherr, Uphoff & Herren, 2012; UN, 1992). Furthermore, localising/regionalising food systems would mean more seasonal and small-scale production (Infante Amate & Gonzalez de Molina, 2013; Latouche, 2010), which also maintains positive environmental outcomes (Barling, Lang & Lele, 2012).

Organic Food

"We think that only a shift towards organic farming (and corresponding changes in consumption patterns) can contribute to substantial reductions of resource use in the food system" (Infante Amate & Gonzalez de Molina, 2013: 32). Not only does organic farming promote biodiversity, provide environmental benefits and use less toxic compounds and energy (Infante Amate & Gonzalez de Molina, 2013; Jawtusch *et al.*, 2011), it can also sequester huge amounts of carbon (from fossil fuels and GHG emissions) – about 4,118 kilograms per hectare per year according to Hepperly (2003 cited in Bates & Hemenway, 2010: 51). Per acre, carbon sequestering of this magnitude equates to the GHG emissions of driving 16,000 km (EPA, 2015).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Low Meat and Dairy, High Vegetable and Fruit Diet

Due to its ecological burden, it has been said that the consumption patterns of developed nations should shift to a more vegetarian diet constituting less meat and dairy products and more vegetables and fruit – a diet that is better for the environment because it is less resource intense (Barling *et al*., 2012; EEA, 2012; Infante Amate & Gonzalez de Molina, 2013). To illustrate this, studies from Finland and Switzerland present data indicating that households eating less meat and more (organic) vegetables have an overall lower environmental impact (EEA, 2012). This comes as no surprise considering that within the food sector meat and meat products have the highest environmental impact (Tukker, Huppes, Guinée, Heijungs, de Koning, van Oers, Suh, Geerken, Van Holderbeke, Jansen & Nielson, 2006). Additionally, according to Infante Amate and Gonzalez de Molina (2013), cooking vegetables uses up to 70 times less energy than cooking meat products.

Highlighted in the previous section, empirical evidence from research done in Cuba and at the Findhorn Ecovillage demonstrate that organic and localised food systems had a direct impact on increases in environmental sustainability. In Cuba's case, localising food production reduced imports and exports, large-scale monocultures and the extensive distribution networks previously used to transport food around the country, all of which placed a strain on natural resources (Boillat *et al.*, 2012; Borowy, 2013, Murphy and Morgan, 2013). Furthermore, the organic and semi-organic farming techniques that were used throughout the country required fewer ecologically harmful inputs (Boillat *et al.*, 2012; Borowy, 2013; Cabello *et al.*, 2012) and in return offered better yields (Murphy and Morgan, 2013). Looking at Findhorn Ecovillage, the combination of a local and organic food system and low meat and dairy and high vegetable and fruit diet directly contributed to the very low ecological footprint the ecovillage maintained (33% of national average, roughly 1 planet), and in general the ecovillage's high level of environmental sustainability (Dawson, 2009). Such a food system virtually eliminates the distance between production and consumption and reduces the amount of resources required to produce food. At the BedZED project, although gardening beds were made available and a vegetable delivery box scheme was promoted, most residents did not make use of either. Instead most residents sourced their groceries from conventional shops in the area.

Thus, because localising/regionalising food systems has in two of three cases been connected to improvements in environmental sustainability, social marketers could use this action in interventions targeting behaviours that reduce environmental harm. Special attention needs to be paid to BedZED where changes to the food system did not work. Forrest and Wiek (2015) propose the core problem was that the actual residents did not introduce organise the gardening and organic box scheme, or any other changes to the food system for that matter, and therefore the motivation to take up this initiative was difficult to create and sustain once certain driving forces had been eliminated. Keeping all three cases in mind, social marketers will need to collaborate across several territories (production, retail, consumption etc.) and creatively deliver value with customers throughout a network of relationships in order for their interventions to succeed.

Renewable Energy and Energy Reduction

Renewable energy is defined as sources of energy that quickly regenerate and do not diminish over time (EPA, 2014). "Such fuel sources include the sun, wind, moving water, organic plant and waste material (eligible biomass), and the earth's heat (geothermal)" (EPA, 2014). Non-renewable energy sources

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

possess many negative side effects (Andreoni & Galmarini, 2013; Jackson, 2009; Moriarty & Honnery, 2012; WWF, 2014). Therefore, shifting to renewable energy sources will likely improve the chance of realising an environmentally sustainable method of energy production (Demaria, Schneider, Sekulova & Martínez-Alier, 2013; Latouche, 2010; UN, 1992). Additionally, while phasing in renewable energies, further positive effects for the environment could be obtained if (developed) nations reduce their energy consumption to only what is needed to maintain a high standard of living (R&D, 2010). This is because such actions would produce a double dividend in which both increasing renewable energy and reducing energy consumption as a whole would benefit the environment.

In all three instances described above, increasing renewable energy and decreasing energy use in general was a positive contributor to increases in environmental sustainability. Through a mixture of methods such as wind energy, solar panels, small hydropower and biomass facilities (Cabello *et al.*, 2012; Morgan & Murphy, 2013), renewable energy production in Cuba resulted in decreased fossil fuel use and thus enabled a higher level of environmental sustainability (Murphy and Morgan, 2013). Albeit out of necessity, further environmental benefits came from reducing electricity consumption as a whole (Boillat *et al.*, 2012) and exchanging inefficient appliances (televisions, refrigerators, etc.) for more efficient ones (Cabello *et al.*, 2012). Moreover, larger, inefficient plants were replaced with smaller, more efficient plants culminating in a gas reduction of 69% (Cabello *et al.*, 2012). At Findhorn Ecovillage all of the energy used is 100% renewable (predominantly wind) and comes from their community-owned wind farm (Findhorn Ecovillage, 2015). Buildings are designed and constructed to minimise energy use and are therefore oriented to make use of passive solar heating, fixed with solar panels to heat water and use extremely insulating materials. Furthermore, the district heating system is designed to be highly efficient (Findhorn Ecovillage, 2015). These were seen as essential reasons why the ecovillage preserved a high level of environmental sustainability (Dawson, 2009). The community's frugal use of energy is also seen as a contributing factor to the low level of energy use (Dawson, 2009). At BedZED, zero carbon emissions were recorded during the three years when the development's energy needs were met with renewable energy (Chance, 2009). In terms of reducing energy consumption at BedZED, its design and construction played a large role in reducing tenants' energy use, resulting in a decrease of 36% and 27% for gas and electricity consumption respectively (Schoon, 2016). Interestingly for social marketers, the installation of built-in smart-energy meters that are visible in the kitchens and display how much energy is being used, their total consumption and a high-use alert seemingly caused a 22% decrease in energy use (Chance, 2009).

Since renewable energy and reducing energy consumption will require collaboration and creative thinking across various sectors (national governments, businesses etc.) and it can increase environmental sustainability, it is seen as a promising action for social marketers to make use of when the intention is to improve environmental sustainability by influencing people's behaviours. Although wind energy was the largest producer of renewable energy at Findhorn Ecovillage, primary research will eventually determine the most appropriate renewable energy form.

Simplifying Lifestyles

Simplifying lifestyles is seen as a means to decrease material consumption by shifting away from high-consumption lifestyles (Alexander, 2011; Andrews & Urbanska, 2010). Since lower consumption means less resources used (Demaria *et al.*, 2013; Hamilton and Mail, 2003), simplifying lifestyles could benefit

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

the environment and help achieve environmental sustainability (Videira, Schneider, Sekulova & Kallis, 2014). The three cases are discussed in relation to this action.

In Cuba's case, the lifestyle shift to a simpler one the population had to endure was not voluntary but involuntary, as the shift was forcefully imposed. The state distributed bicycles and transformed the transportation sector to reduce fuel consumption and resource use (Borowy, 2013). High-consumption lifestyles were not even possible, for example, when electricity was available only 8 hours a day, incomes were low and consumer goods were not readily available (Murphy & Morgan, 2013). In general, Cubans have smaller living spaces and as much as 90% of the population don't own a car (Morgan & Murphy, 2013). Therefore, because the ecological footprint of the country was largely reduced, Cubans make it obvious that a simpler lifestyle, albeit involuntarily, has a positive impact on environmental sustainability (Borowy, 2013; Dawn King, 2012, Morgan & Murphy, 2013). Findhorn's population decreased resource use to half the amount of the average British person (Dawson, 2009, Tinsley and George, 2006) by simplifying their lifestyle (on a voluntary basis) through purchasing less consumer goods and living a simpler life disconnected to high-consumption lifestyle (Dawson, 2009). Instead of participating in high-consumption activities the community is involved in different social and cultural activities (Dawson, 2009). Additionally, because many of the residents work on site, car travel is just 6% of the national average and is said to be even less after the introduced car pool (Dawson, 2009). Thus, without being prompted by an external source, the community at Findhorn Ecovillage demonstrates the potentially positive environmental impact of simplifying lifestyles on a voluntary basis. One feature of the BedZED development – inherent in its design – is to encourage residents to reduce the carbon dioxide emissions from personal transport (Chance, 2009; School, 2016). Its car club, close proximity to public transportation and many bicycle parking spaces, for example, are ways that BedZED's design promotes a simplified lifestyle by not having to own a car (School, 2016). Such a method to simplify lifestyles plays a large role in the 53% decrease in resident's travel carbon footprint (Schoon, 2016). Compared to Sutton's residents of which 49% travel by car to work, only 17% of BedZED residents travel to work by car (Schoon, 2016).

To promote simplifying lifestyles as an action, social marketers will likely need to collaborate with different stakeholders (e.g. businesses, consumers, etc.) and creatively attend to delivering value to all stakeholders involved with the ultimate outcome resting on decreasing consumption as it can provide environmental benefits.

The previous section has insofar described three societies that have exhibited improvements in environmental sustainability and from these extracted specific actions that could provide the means to increase environmental sustainability via creativity and collaboration fostered through social marketing programs. The forthcoming section relates these actions to elements of social marketing theory, after which the chapter is concluded.

RECOMMENDATIONS

Utilising the important theories underlying social marketing (described in more depth in Chapter 16), the actions identified and outlined above should adhere to the basic social marketing theory. In short these are that in social marketing exchanges benefits should outweigh costs, benefits and costs should be exchanged within networks of relationships and the actions should operate within a critical marketing framework. The following sections elaborate on these three important tenets of social marketing theory.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Naturally, all of these theoretical insights will need to be justified by primary research to uncover the types of benefits and costs useful in exchanges, the kinds of relationships and networks the social marketer should use the way programs should be promoted to safeguard society (Eagle *et al*., 2013; French *et al.*, 2011; Grier and Bryant, 2005; Weinreich, 2011).

Actions as Exchanges

Exchange theory refers to the basic human trait that people behave to acquire the largest benefit in exchange for the lowest cost (Grier and Bryant, 2005; Hastings and Domegan, 2014). Therefore, because social marketing programs seek to influence people's behaviours, successful programs are underwritten by exchanges that offer greater benefits than costs that fulfil real needs and wants (Hastings & Domegan, 2014; Hastings and Saren, 2003; Kotler and Lee, 2008; MacFadyen, Stead & Hastings, 2003). From a social marketing perspective, environmental sustainability is a major benefit because it has been linked to human well-being since humans depend on the planet for their prosperity (Andreoni & Galmarini, 2013; Bonaiuti, 2011; Common & Stagl, 2005; Constanza, Alperovitz, Daly, Farley, Franco, Jackson, Kubiszewski, Schor & Victor, 2013). Any costs that compete against the basic necessity humans require to exist would be seen as inferior to the benefit that would ensue. Therefore, because the actions discussed above maintain the ability to improve the chances of attaining environmental sustainability, each action maintains, as a basic premise, greater benefits than costs. Social marketers would nevertheless need to translate the benefit of environmental sustainability into target audience related benefits. For example, instead of exchanging the environmental benefits with a target audience, it might be more relevant to the target audience if exchanges focused on saving them money or their children or grandchildren's well-being.

Actions within Networks of Relationships

"Social marketing is the co-creation of complex social and economic benefits and value 'with' customers among/throughout an entire community network of relationships" (Domegan, 2008: 137). Therefore, because relationships and networks are where social marketing exchanges take place, exchanges and relationships and networks are highly interrelated. To this end, social marketers design programs to facilitate exchanges that occur within certain relationships and networks that benefit individuals, groups and/or society (Marques & Domegan, 2011). Successful social marketing interventions should thus understand how exchanges could be incorporated into different relationships and networks (Marques & Domegan, 2011). Concerning relationships and networks in which exchanges of benefits and costs occur, all actions have the capacity to be promoted via upstream and downstream measures. This is because all actions can influence behaviours via voluntary and involuntary methods respectively. For example, social marketers could target policy developers, law-makers etc. at the macro level (upstream) and the voluntary behaviours of target audiences at the micro level (downstream) when promoting simplified lifestyles for instance. When influencing behaviours at different levels using the identified actions, social marketers should develop benefits and costs for each target audience.

Actions and a Critical Marketing Framework

State of the World reports (2010, 2012, 2013) indicate that the earth's population is living at unsustainable levels and suggest that large-scale shifts are necessary. The lack of sustainability can be seen as

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

the broad reason for actions to right the environmental degradation the world currently faces. Thus, actions that can in theory maintain large-scale environmental benefits, and therefore benefits to society, are crucial for building a critical marketing framework within which social marketing programs can successfully operate. All of the abovementioned actions could offer widespread environmental benefits and can therefore be used as the basic foundation for a critical marketing framework. Social marketers would need to explore each action in more depth to obtain a more precise critical marketing perspective i.e. to ensure that the specific action contributes positively to the population's prosperity (Andreasen, 1994; Hastings & Saren, 2003; Marques & Domegan, 2011) keeping in mind that society's well-being includes the well-being of the planet as society is dependent on the planet's well-being (Andreoni & Galmarini, 2013; Bonaiuti, 2011; Common and Stagl, 2005; Constanza *et al.*, 2013). For example, the relationship between social marketers and a network of government departments that are in charge of laws and policies to influence behaviours towards producing renewable energy should ensure that these laws and policies do not, for example, marginalise certain sections of society or provide exorbitant profits for a few companies.

To summarise this section, successful social marketing programs firstly require a set of actions that could influence behaviours towards the intended outcome (Kotler *et al.*, 2002). Secondly, successful interventions are underwritten by exchanges of benefits and costs that occur within networks of relationships that should safeguard society's well-being. Using the cases that were previously discussed, the section showed how actions could be used to establish exchanges of benefits and costs that are facilitated by networks of relationships and operate within a boundary that safeguards society. And since social marketing programs can operate at many levels i.e. between national governments, NGOs, individuals, businesses etc. and require innovative ways to address issued, it is a well-poised mechanism that intrinsically requires collective creativity and collaboration between stakeholders.

FUTURE RESEARCH DIRECTIONS

Ecovillages contain within it all the actions identified in this chapter such as renewable energy and energy reduction, transforming food systems, remodelling business and economy and simplifying lifestyles and, when combined, can have a powerful effect on environmental sustainability as witnessed in the case above. Thus, because ecovillages are a prominent candidate for realising a more environmentally sustainable future, social marketers should place emphasis on researching ecovillages and how to use them to influence behaviours to achieve more promising levels of environmental sustainability.

CONCLUSION

Behaviours are complex and therefore social marketing as a tool for influencing behaviours towards environmental sustainability demands collective creativity and collaboration across multiple sectors. Based on the idea that social marketing programs require a set of actions that can influence behaviours towards a more environmentally sustainable society, Cuba's transition period, Findhorn Ecovillage and the BedZED development, where increases in environmental sustainability have taken place, were analysed with the aim of unearthing such actions. Specific actions that could increase the chances of realising environmental sustainability indeed surfaced: relocalising businesses and the economy, transforming

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

food systems, renewable energy and energy reduction and simplifying lifestyles. To check whether these actions could be useful for social marketers to influence behaviours towards environmental sustainability, they were related to important theories underlying social marketing. Since the actions could be applied to social marketing theory, all actions emerged as highly favourable possibilities for social marketers targeting adherence to the resources of one planet earth. In particular, ecovillages transpired as being a highly opportune method to engender environmental sustainability as it contained within it all of the actions identified in the chapter.

KEY TERMS AND DEFINITIONS

Economic Democracy: An economic system in which citizens are supported to actively participate regardless of their characteristics.

Food System: A food system represents the complete range of variables in an entire food chain from production to consumption, including inputs and outputs at each link (FAO, 2013; Infante Amate & Gonzalez de Molina, 2013).

Non-Market Capitals: Non-market capitals can be seen as items (land, housing or equipment) that are controlled not by the market but by local democracies (Bruyn 1992 cited in Johanisova, Crabtree & Fraňková, 2013).

Renewable Energy: Renewable energy is defined as sources of energy that quickly regenerate and do not diminish over time (EPA, 2014).

Simplifying Lifestyles: Simplifying lifestyles is seen as a means to decrease material consumption by shifting away from high-consumption lifestyles (Alexander, 2011; Andrews & Urbanska, 2010).

Social Enterprises: Social enterprises are organisations that maintain a democratic structure and aim to benefit the local community and its relationship to the environment (Johanisova *et al.*, 2013: 11).

Social Marketing: Using traditional marketing techniques and practices, social marketing is basically a means to influence a target audience's behaviours in order to benefit them and/or society (Andreasen, 1994: 111; Kotler & Lee, 2011: 26).

Social Marketing Actions: These are actions that refer to proposed activities to achieve environmental sustainability.

ENDNOTES

1 Actions refer to proposed activities to achieve environmental sustainability.

2 CSA is defined as a relationship between a farmer and a community of shareholders who invest in the farm in return produce for a share of the farm's produce (USDA, 2016).

Chapter 43
Sustainable Development and the Sustainability of Socioeconomic Systems:
Some Reflections on Crises and Corporate Systemogenesis

Tikhomirova Olga
Saint Petersburg National Research University of Information Technologies, Mechanics and Optics, Russia

ABSTRACT

In the current global scenario, it is essential to ensure the stability and sustainable development of the socioeconomic system. The literature shows that there is so far no clear understanding of the nature of the sustainability and development of socioeconomic system. Systems thinking may be the right approach for the transition to sustainable development, supplying a way to understand the universality of the laws of development. This theoretical paper shows how the management of firms can be based on the universal laws of evolution and development

INTRODUCTION

This theoretical paper shows how the management of firms can be based on the universal laws of evolution and development. It aims to discuss and create a framework for better understanding the theory of development, sustainability, and the sustainable development of socioeconomic system, with a particular reference to business systems.

To this end, the paper will:

1. Study the main theories of development.
2. Discuss the essence of evolution and the development of the socioeconomic system.

3. Describe the main structural transformations over the last 100 years, considering the evolutionary change of socioeconomic systems on the global scale (highly complex nonlinear systems), structural transformations, and their implications in the global context.
4. Construct a holistic model of evolutionary dynamics of socioeconomic systems, allowing a better understanding of the systems as a whole, in interaction and interdependence with their elements over time. This model will be based on the coherent interaction and coevolution of the system's elements and subsystems.
5. Show how holism (systems thinking) in management and in corporate government can be an effective approach to sustainable development.

This study refers to several theoretical approaches from which we alter the terminology and some relevant methodological aspects: *General Theory of System* (Bertalanffy, 1968); *Synergetics* (Buckminster Fuller, 1975), Schumpeter's entrepreneurship theory (1949); the theory of social dynamics (Sorokin, 1937); the theory of social action (Parsons, 1949); Durkheim's theories of sociology and labor (1983 and 1900); Spengler's theory; the theories of economic cycles by Kuznets, Mensch and Elliott (1971–1973); theories of development of nonlinear system by Haken (2000) and Prigogine (1989–1994); and chaos theory as popularized by Gleick (1987). Furthermore, this study is based on a postulate concerning the transition of socioeconomic systems from unorganized to self-organizing systems.

We can find a similar direction and approach to management in the works of Beck & Cowan (2006) and of Warnecke (1993).

The paper provides an analytical overview of the financial and economic crises from 1900 to 2013. The data was analyzed using the system-synergetic approach of Kindleberger and Aliber (2005).

The contribution and implications of this research are to expand the existing theories of development in order to create the scientific basis for future studies. The study demonstrates the laws and tendencies of development and attempts to define the stage of development, shedding light on a new way to manage systems more effectively, helping to foresee future scenarios, and to prevent the negative circumstances the result from crises. Moreover, the proposed approach may facilitate focusing on the future and on innovation, instead of on vain attempts to preserve an imaginary stability. To this end, we consider the financial, economic, social, and technical elements of the enterprise as a connected holistic system.

ON THE UNDERSTANDING OF THE UNIVERSAL LAWS OF EVOLUTION

First, we consider the dialectical theories of the classical German philosophers (Hegel, 1807; Marx, 1894; Fichte, 1792–1810; Kant, 1770–1780s). Friedrich Engels systematized the three laws of dialectics: the transformation of quantity into quality; the negation of the negation (thesis, antithesis, synthesis); and the unity of opposites. According to the first law, within any period of development of society, changes gradually accumulate until further change cannot be accepted, triggering the leap of revolutionary transformation. According to the second law, within any stage of development, mutually antagonistic forces interact as a system. The third law states that any stage of development is the result of the negation and synthesis of the previous stage; development thus has the character of a spiral, and could be characterized as a three-step process.

Auguste Comte's "social physics" divides society into two components: social statics and social dynamics. The social system requires a more "intimate harmony of the component elements and more

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

complete subordination to the external world" (Comte, 1856, p. 353). According to Comte, "Humanity cannot herself act otherwise than by her separable members; but the efficiency of these members depends upon their working in co-operation" (Comte, 1856, pp. 354–355). In other words, social progress (that is, development) depends on the cooperation of the separate system elements (individuals). Social progress and development are the quintessence of positive knowledge. Comte states that "systematic study of the Past is necessary in order to determine the future" (Comte, 1856 p. 357).

Herbert Spenser's theory postulates the unity of the decomposition and creation of the system: "evolution is the transition from an incoherent undefined state to determined organized state; complex systems are formed from a combination of simple ones" (Spenser, 1852, p. 237). Evolution is the transition from an unconnected homogeneous number of elements to interconnected heterogeneous elements (the system). So, the process of social evolution is the process of social differentiation and the emergence of social strata: "at that time as parts of mass are integrated, they are differentiated" (Spencer, 1897, p.277).

The social evolution of Émile Durkheim depicts the evolution of societies from the mechanical solidarity of preindustrial society to the organic solidarity of industrial society. In simpler societies, people are associated by personal charisma and traditions, but in complex industrial societies, they are united due to interdependence, diversification, more specialized tasks, and the division of labor. The organic society is considered democratic, because it is based on freedom of choice and diversification of elements. On the contrary, the mechanical society tends towards totalitarianism (Durkheim, 1893, 1900).

Pitirim Sorokin's "Social dynamic" defines the dynamics of social systems as "any kind of motion, modification, conversion, alteration or 'evolution', in short, any change this logical entity in time, whether it changes its place in space, or are we talking about the modification of its quantitative or qualitative aspects" (Sorokin, 1937–41, p. 98). The most important element of the development is the "unit", which undergoes changes while concurrently maintaining its identity. The system may "change itself without losing its identity" (Sorokin, 1937–41, p. 99). Sorokin believed that the main causes of social change are immanent factors: "systems' changes are the result of their own resources and properties". External factors may have an influence on the system, up to the destruction of the system, but they do not have any impact on the preset path of development. The system has a built-in mechanism of development: "socio-cultural systems choose the way of existence by itself" (Sorokin, 1937–41, p. 807).

The *structural functionalism* of Talcott Parsons (along with his Structure of Social Action) and Robert Merton states that the social system is made up of the actions of individuals (Parsons, Shills, 1976). In the process of interaction, individuals are faced with a variety of choices about how they might act, given that their choices are limited by a set of physical and social constraints.

Oswald Spengler (1918) considered evolution as a changing of cultural–historical types. He distinguished the concepts of *culture* and *civilization*: culture is focused inward and on development, while civilization is focused outward and on mere expansion. Yet civilization is the destiny of every culture. Whereas culture is "things-becoming", civilization is the "thing-become"—that is, the transition from culture to civilization is the transition from dynamics (development) to stagnation (Spengler, 1918, 1922).

Another important theory of evolution in terms of economic dynamics was proposed by Joseph Schumpeter. The basis of Schumpeter's theory is "creative destruction", which indicated that development ("economic mutation") destroys the old and creates the new. "This process of 'creative destruction' is the very essence of capitalism" (Schumpeter, 1942). Thus, we must destroy our present to gain the future, and ordinary things to gain innovation; we must create chaos from order, in order to develop.

Other relevant theories of development in this period are the theory of long waves of Kondratiev (1935), the wave theory of Elliott (1938), and, more recently, the theory of spiral dynamics of Beck and

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Cowan (2006). These theories are based on the cyclical dynamic—on repeatability, the return to the past—where cycles can be determined and predicted.

These traditional paradigms are carried out by the need to avoid the nonequilibrium state and instability. The positivist sciences are based on laws that are limited in their possibility of explaining and describing reality: for example, it is impossible to find an appropriate geometrical function to describe mountains, rivers, trees.

In the 1970s, scientists began to examine the causes and patterns behind the chaotic behavior of various systems, finding that the apparent disorder has a logic and organization—that this "organization" differs from the traditional positivist understanding of order.

Questions of nonlinear dynamics and the development of nonlinear systems were investigated by various new theories, such as synergetics, chaos theory, and dissipative systems (Haken, 1996; Prigogine & Nicolis, 1989; Prigogine & Stengers, 1994; Gleick, 1987).

A relevant contribution was given by synergetics, which holds that:

- evolution is a process of formation of order from chaos;
- development occurs through self-organization;
- instability—the nonequilibrium state of the system—is the basic, initial state of every system; the state of equilibrium and orderliness is the stage of evolution;
- the development of the system is carried out through the sequence of nonequilibrium and equilibrium states (chaos and order);
- chaos is the creative force, not the destructive force;
- a complex system has a number of possible alternative ways of development;
- the creation of a whole by simple addition of initial structures is impossible.

Thus, according to the synergetics theory, the development process requires an increased complexity in space (e.g., geographic expansion, regional expansion, acquisition of material assets) and an expanding of areas of influence and interests. At the same time, development requires the differentiation of elements and parts of system and transitions from a state of disorder and homogeneity to a state of order and diversity. Development could follow two paths: the smooth evolutionary path or the revolutionary leap. Therefore, development can be considered as movement: through time (the transition from the past to the future); through space (the creation of new structures); and in terms of qualitative changes (innovations).

Considering all these theories of development, we can conceptually classify them into two groups:

1. *The cyclic-wave theories*, where cyclical development is reversible:
    - The theory of economic cycles (Kondratiev waves; the Grand Supercycle theory of Ralph Elliott (Elliott, 1938, 1946; The "Kuznets swing" of Simon Kuznets, 1930; and others);
    - The theory of cycles of innovation (e.g., of Joseph Schumpeter (Schumpeter, 1942), and spiral dynamics (Beck, Cowan, 2006)).
2. *The theories of the dialectical evolution of the system and self-organization*,

where dialectical development is irreversible. These theories are based on the well-defined dialectics of development, competition, and competitive evolution: Hegelian dialectic; Karl Popper (the competitive development of scientific knowledge); Comte's "social physics"; Ilya Prigogine (competition of the tra-

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

jectories of the development ("attractors") and the elements themselves (the process of self-organization); the systems approach and others.

DEVELOPMENT AND TRANSFORMATION OF THE GLOBAL SOCIOECONOMIC SYSTEM

In this section, we analyze the transformation and structural changes in business systems from the 1900s to the present.

By *structural transformation*, we refer to the various actions of businesses that lead to changes in size, ownership, assets, activities, etc. It includes investments, mergers and acquisitions, and diversification of business. Table 1 summarizes the transformations of business regimes.

Table 1. Summary of the organizational and structural transformation of business regimes

Period	Main characteristic of the business context	Priority of industry sectors	Priority of energy resource	Main factors which caused the crisis
End of the 18th century to the 1830s	Separate enterprises in developed countries were scattered	Textile industry	Water (the water mill and engines)	1790s, the beginning of the 19th century: terror in France, the Napoleonic wars, the boom in canal company shares, prices of raw materials in the US and Europe; the rapid development of construction and railways
Second half of the 18th century			Coal for melting cast iron (coke)	The rapid development in the construction of canals and railways, which became objects of speculation
19th century	The spread of the steam engine	Railways, the production of steam locomotives, shipping, the production of steam ships. steam engineering and technology	Coal begun to be used in transport	Heavy industry became an object of speculation
End of the 19th to the beginning of the 20th century	Horizontal mergers, the emergence of monopolies, cartels, trusts, and syndicates. The production of material-intensive products and services	Heavy industry, steel, chemistry, transport (railway, water), concentration of financial markets,	Coal, oil	1856–1857 crisis: end of the Crimean campaign, speculation in heavy industries, agricultural economic society, railway construction
1848		The gradual shift to the electrical power industry and electrical technology	The first production of oil from a drilling hole	
1920–1950	Vertical integration, businesses united within a single production process	Heavy industry, steel, chemistry, transport, electric power industry and electrical technology	Coal, oil. The role of coal was reduced gradually	1929–1933: overproduction and financial crisis. Crises of the 1950s and 1960s: the currency and financial crises.
1960–1970	The creation of conglomerates	Oil and oil products, oil refining, communications, transport	Oil	Energy crisis of 1974–1975.

continued on following page

Table 1. Continued

Period	Main characteristic of the business context	Priority of industry sectors	Priority of energy resource	Main factors which caused the crisis
1980s	Sectoral concentration of the businesses, the reshuffling of assets			Crisis of 1979–1982: oil prices increase, speculation on real estate and agricultural lands in the USA
1990s	Horizontal megamergers, creation of transnational corporations and global companies		Oil, the search for alternative energy sources. The share of coal in the energy sector was about 20%	Crisis of 1997–1998: a wave of bankruptcies of the world's largest companies, speculation on the capital market
2000s – present	Megamergers, the involvement of the developing markets in M&A. Production of innovation.	Microelectronics, computer science, biotechnology, genetic engineering	Oil, the intensification of the search for new environmentally friendly energy (natural, bio-fuels, etc.) and shale gas.	2008–2009: the global economic recession, financial crisis
The future	Business as innovation networks is based on information and knowledge. Clusters – the most effective form of business because of synergy.	Biotechnology, robotics nanotechnology, the global informational network	Ecofriendly, renewable sources of energy	?

Source: official, business and historical information; analysis and calculations by the author

Table 1 shows that the development of businesses and of entrepreneurship involved:

1. Only two human-invented production technologies: the steam engine and the electrical engine.
2. Only three types of energy source: water, coal, and oil (natural gas).
3. Innovations that changed the world include steam engines, electric motors, aircraft, computers, and microelectronics.

We now consider the statistical data on investment and on mergers and acquisitions for the largest deals of the second half of the twentieth century. We being with FDI and M&A (see Figures 1 and 2).

We can see that, as FDI as M&A are steadily increasing, the result of these transactions is a high concentration of assets and the creation of monopolies and oligopolies. We can also see that the activity of M&A increases just before and immediately after the years of a crisis.

Hence, economic and financial crises show drastic fluctuations of parameters and violations of the equilibrium state. If we compare the development of businesses with the evolution of biological systems, we find that, in periods of crisis, most systems increase their size (this recalls the giants of biological evolution). In business, these processes are equivalent to mergers and acquisitions—business consolidation as an attempt to survive the crisis situation. However, we find that the opposite process is also true: the size of systems can decrease in order to take the low competitive niche (e.g., the market niche) and to get rid of noncore assets. Statistics regarding the worldwide transactions of mergers and acquisitions and foreign direct investment shows stable growth, especially over the past decades.

We can thus point out that evolutionary processes are irreversible. Indeed, we believe that the increasing consolidation of businesses, and the interdependence and reliance on industrial production,

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

will inevitably lead to a deep crisis. This is because the process will persist so long as businesses do not change to a new business model of functioning and development. We judge that, to avoid this future crisis, firms should consider a new business model based on innovative energy saving or the adoption of alternative energy technologies; the international division of labor; and the cooperation and synergy of knowledge, not based only on production synergies.

A HOLISTIC MODEL OF CORPORATE SYSTEMOGENESIS

In this section we define our idea of a universal algorithm for the development of socioeconomic systems: the *algorithm of corporate systemogenesis*, presented in Figure 3. By *systemogenesis* we mean the sustainable development of socioeconomic systems as nonlinear systems in accordance with evolutionary laws.

We consider this development as an irreversible wave, where the complex system grows by itself and absorbs its own properties, which already existed on a lower level.

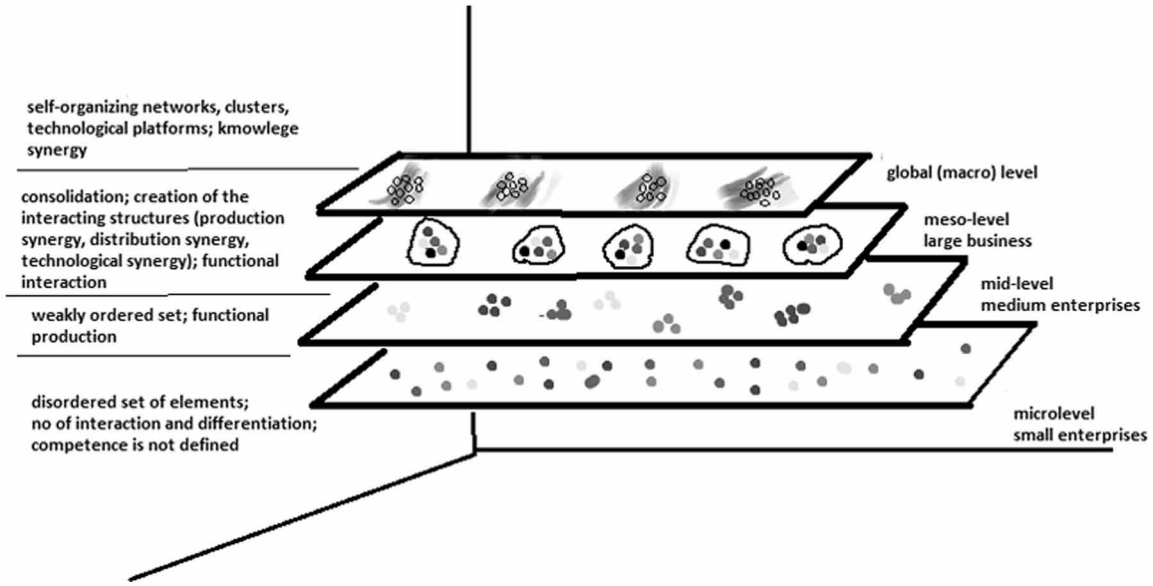
Figure 3. The proposed algorithm for corporate systemogenesis
Source: Author's work

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

The whole process of evolution is illustrated in Figure 4.

The development of socioeconomic systems is accompanied by the growth of interactions between its elements (people or departments). Interaction takes shape in various forms of cooperation, such as different unions, strategic alliances and partnerships, joint ventures, mergers and acquisitions, and clusters.

Evolutionary processes are accompanied by synergistic effects (Baker & Sinkula, 1999). This is because it is not possible to create the integrity of the system by simple additions to the original elements, which would inevitably lead to interference of their localization and functions.



All of the above mentioned stages of development can coexist and coevolve. In other words, we can simultaneously observe microenterprises at the unorganized spontaneous level of development, mesoenterprises with higher level of organization, and self-organizing business systems. We consider all the levels of development not to be mutually exclusive, but to be complementary; the development is a transition from one stage—micro, meso, or macro—to the next. Even if we can provide effectiveness at each stage of development, we consider the real essence of development to be the sequential change of states of the system.

But what happens within socioeconomic systems? How does the process of development occur?

The complex behavior of the socioeconomic system is formed by the interaction of a number of simple behaviors between its main elements—such as its people and workers. These elements of social groups operate independently right up to point of instability and crisis. At that moment, they begin to interact and cooperate (a similar behavior is observed in physical systems by Prigogine & Nicolis 1989, pp. 15–18).

The transition from one state to another and the leap forward to the new level of development are the results of the competition between two processes of interaction and random action. These processes have different directions of impact: interaction between the elements makes the system ordered, while the chaotic random actions of the elements lead to disorder.

Figure 4. The scheme of the model of corporate systemogenesis
Source: Author's work

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 5 shows an example of the elements of a system in a certain spatial localization.

The elements are uniformly distributed in space, with no interaction among them. The state of the system is characterized by complete disorder, with each element behaving randomly and chaotically. Examples of such a system include small enterprises that do not interact. Figure 6 shows a different situation.

In Figure 6, we can see the process of clustering. The elements of the system are spatially closer to other similar elements (e.g., the typical industry clusters). We can observe interactions between the elements within each cluster, while there is no interaction among the clusters.

Changes in the external environment cause two different reactions: if the elements interact, this can lead to the creation of clusters, or to a contrary reaction where they move away from each other, leading to a broader geographical distribution, as in the search for new market niches, or the expansion throughout regions.

Furthermore, the formation of clusters requires a change in the external environment, with favorable conditions that force businesses to unite and cooperate.

The development of socioeconomic systems is initiated by the actual or expected global regime shifts (systemic transformations)—namely, by functional and structural changes in the global system. These regime shifts include abrupt and irreversible transformations (e.g., changes in state regulation of an industry, fundamental technological changes, financial, economic, and sectorial crises, the development of new high-tech products, and the development of new sectors of the economy or business diversification). Thus, the impetus for development may counterbalance a crisis, forming a protection from its consequences, and even the expectation of increased profits in some industries.

The path towards development depends on the location of businesses, both in industry and in the global business system. If similar companies prevail in the industry, they will try to preserve their integrity, independence, and efficiency growth. A problem can be represented by managers trying to maintain the independence of the managed company, in order to protect their salaries. They are then not interested in cooperating or coordinating with other enterprises or competitors to create of unions, alliances, joint ventures, mergers, acquisitions, or other forms of interaction, as this may cost them their working place and salaries, or reduce their level of management control. For this reason, managers will be interested in increasing the value and size of their firms in order to protect it, following the logic that the larger

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

and more expensive the firm is, the less attractive it will look for acquisitions or other forms of external attack. However, the effect of such managerial behavior could be the opposite: buying larger companies leads to a more profitable synergy effect, and this makes the enterprise more attractive for acquisition.

SUSTAINABILITY AND THE SUSTAINABLE DEVELOPMENT OF THE BUSINESS SYSTEM: CONCEPT AND NATURE

In this section, we attempt to explain the concepts of sustainable development and sustainability, according to general systems theory and synergetic theory.

According to general systems theory, sustainability is the ability of the system to keep its movement on the given trajectory, or the ability of the systems to support the given mode of functioning, in spite of external and internal disturbances (Gigch, 1978). The main types of sustainability are equilibrium, homeostasis, and the stationary mode.

Equilibrium is the condition of a system in which all competing forces are balanced. The balance of a business system is not always the optimum from the social justice point of view. The equilibrium should be considered in two aspects: the static (point of equilibrium, such as equilibrium prices, or the equilibrium of supply and demand) and the dynamic, or growth, which means the balanced process of development.

Homeostasis is the stable state of a system in its interaction with the external environment.

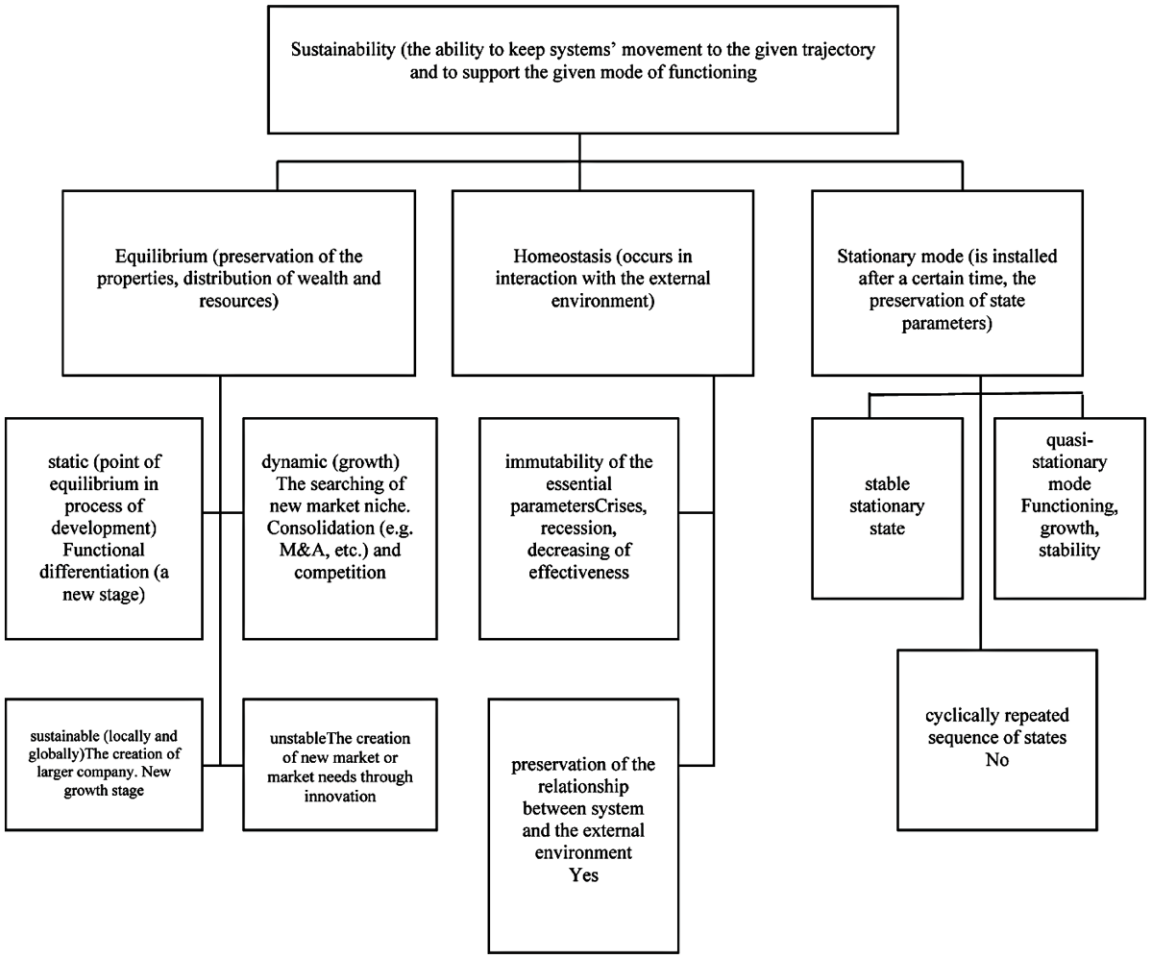
The stationary mode is the mode of functioning of the system in which the basic system parameters remain unchanged. The opposite form of functioning of the system is the period of transformation. We can see the transition from one state of the system to a qualitatively new state. In the transition period, transformational effects are observed—structural shifts and transition recession.

The generalized scheme of the concept of sustainability is showed in Figure 7.

What, so, is sustainable development and sustainability of a system? The question is whether we will be able to achieve sustainability of the system, increasing its effectiveness and sustainability.

The UN's concept of sustainable development involves a balancing of economic growth, environmental protection, and inexhaustible resources. In the Report of the International Commission for the United Nations Environment and Development Program, sustainable development is considered as development that meets the needs of the present generation, but without threatening the rights of future generations to such opportunities. Sustainable development means building an effective One-Planet Economy, a new understanding of the "good life" (a higher quality of life), and environment protection, and all this requires cultural changes. Much of the progress in sustainable development is being achieved by the business sector and local governments (Adams W.M., Jeanrenaud S.J., 2008).

Generally, all concepts of sustainable development are based on three hazy terms: economic growth, environmental protection, and inexhaustible resources.



But what do we have to do? How should we manage our businesses for sustainable development?

Sustainable development and sustainability are different concepts: sustainability refers to the state of the system, whereas sustainable development is a dynamic concept referring to movement, change, evolution, and innovative development. Thus, it is not easy to achieve sustainability and development at the same time.

However, in this case, it raises the question of whether the nature of sustainable development and sustainability is compatible with the UN declaration. Sustainability is achievable on the local level

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 7. The generalized scheme of the concept of sustainability of business systems
Source: Author's work

(financial, economic, social stability). But on the global level, the social systems could only achieve a state of dynamic equilibrium, which is not sustainability in a long term.

However, we must also understand that sustainable development and economic growth are different. Growth is just one of the stages of development; hence, we need to restrain growth and seek development. Because the main goal of economic growth is increase of effectiveness and income, it does not consider the natural environment. In contrast, the main goal of development is to create innovations to cope with the natural system's integrity and to save energy. Economic growth is therefore just one stage of the development towards the more advanced concept of sustainable development. For sustainable development, we have to learn how to manage all the stages of development, including the stages of growth, stability (dynamic equilibrium), transition, recession, and crisis. If we try to safeguard a single stage of development, we will not be able to move on to the next stage.

In this framework, crises are inevitable, and they give an opportunity to update and to produce further development. This is connected with the nature of development: development is carried out by transformation, but transformation means unsustainability. Sustainability is possible within some stages, but

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

not at every stage of development. Sustainable development is the understanding the whole process of development. We must achieve development, but not every aspect (economic, ecological, social) of it separately. Only by acting in this way can the consequences of the crises be creative, rather than destructive; crises will then provide growth, environmental protection, and human well-being.

A NEW APPROACH TO ECONOMIC EVOLUTION AND CRISIS: CRISIS AND INNOVATION

In this section, we analyze the relationship between development and economic crises. As we stated above, development means movement and change, while sustainability means the state of the system. We thus need unsustainability for development. What is unsustainability in social and economic systems? We consider unsustainability to be *crisis*. Table 2 shows the most important economic crises and the impact they had on the development of business.

As Table 2 points out, during the second half of the nineteenth century, and during the whole twentieth century, the global socioeconomic system experienced several major crises (1847–1848; 1857; in the 1950s and 1960s; 1974–1975; 1979–1980; 1997–1998; 2008–2009). Each of these had its own causes and its own consequences. However, each crisis led to a significant regime shift on the global level: the transition to new technologies (the steam engine was replaced by the electrical engine), or to new energy (water, coal, oil), etc. So, we can assume that the crises are not only an objective reality, but also constitute the need for a search for new opportunities. Crisis (or chaos) is a constructive beginning that provides new opportunities and conditions for innovation and sustainable development. Therefore, we can assume that crises are not only an objective reality, but precisely the need to search for new opportunities.

How exactly does a crisis offer new opportunities for business?

During a crisis, we have to find the most effective methods for working, to optimize the business processes, to reduce the production costs, and to search for new market niches and opportunities. Production needs to become more flexible and effective. In the period of stability, managers try to save the results that have been achieved and to ensure the growth of profitability, while in the period of crises, they are forced to invest in development and innovation. Stability often becomes stagnation, and stability must be disrupted if progress is to be achieved.

If we look at the most important innovations of the second half of the nineteenth century and of the whole 20th century, it becomes evident that the most important inventions and advances in science and technology were the driving forces for economic and social development only if they were accepted and propagated in a global environment (cf. the "institutionalization" of J. Schumpeter). But how do innovations become an engine of economic progress?

As an example, the steam engine was invented in 1780s. The global industrialization and boom in the railroad, metallurgical, and construction sectors led to the crisis of 1847–1848 in the industrialized countries of Europe and the United States. In 1834, the electric engine was invented, and this innovation started to work up the market. In 1903, the first airplane laid the foundations of a new era. The increased demand for oil as a fuel source caused price increases. And in 1970s and 1980s we faced an oil crisis.

The invention of atomic weapons during the Second World War, and the distribution of nuclear energy, including the environmental disaster in Japan in 2011, set us the task of reducing our energy dependence and energy use and searching for alternatives to oil. Next, from the invention of the computer to col-

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. The most important economic crises and their impact on the development of business

Period	Changes that led to the development of business systems
1900s	Increasing concentration of businesses, mergers and acquisitions, monopolization and consolidation of companies
1929–1933 (The Great Depression)	A gradual abandonment of the concept of the free market as a self-regulating system. Transition to a partial state intervention in the market relations (USA, UK, France, Sweden, Denmark, Norway), as well as full centralization and the direct intervention of the state as far as nationalization; the creation of close relationships between state and large private corporations (Germany, Italy, Spain)
Crisis after II World War	A third scientific and technical revolution, with radical changes in technology and production in developed countries. Development and intensification of the international division of labor, international expansion. The growth of international interdependence and the concentration of businesses. The consumption of energy resources increased; the transition from coal to oil could be observed in developed countries. State support of the modernization of production capacity and investment in the technical development of businesses. Rapid development and growth of production and economy in Japan, Germany, and Italy. Obtaining of independence of former colonies and the "decolonization" of economy.
Economic crisis 1974–1975	A deep economic crisis in all sectors of the US economy, which spread to all developed countries. The growth of energy dependence and, as a result, the intensification of the search for alternative energy sources. The share of own production and processing in developed countries increased, intensifying scientific research into energy and resource-saving approaches. Development and introduction of innovative technologies and equipment. Liberalization of the market, the opening of the customs borders in the EU countries in the post-crisis period; the intensification of consolidation of businesses. Business activity was restored at the expense of stimulation of demand. Communication technologies and computers were developed. Globalization and the active expansion of businesses from developed to developing countries.
1979–1982	The creation of favorable conditions for the development of production (the reduction of taxes, the increased availability of credit resources). The focus was shifted from the demand to the supply. The activation and rapid development of information technologies, telecommunications, and communication technologies. Globalization spreads around the world.
1990s	A new industrialization and restructuring of the economy, accompanied by the growth of the financial sector in most developed countries (e.g., the economic policy of Margaret Thatcher in the UK). The growing consolidation of the western European countries leads to a restructuring of industry and a strengthening of the need for a single currency in the European area.
2005	The rapid development of China and the transfer of production to developing markets (Russia, China, India, etc.) lead to the deindustrialization of the USA and western Europe.
Crisis 2008–2009	Transfer to innovative processes and technologies. The search for alternatives to oil and traditional energy resources. Real changes in the economy and business do not occur, but there is a global understanding of the need for a change in management and development.
2010–2013	A process of reindustrialization, restructuring, and diversification of the economy from the nonproduction and financial sectors to real production industry with high added value and knowledge (aircraft industry, pharmaceuticals, machine building, power engineering). There is a process of deglobalization, a crisis of the euro and the focus on the domestic market. We can observe increasing problems of European identity, unity, and economic interdependence between developed and developing countries.

Source: Author's work

lapse of the so-called dot-com bubble, only about 70 years passed. But social networks have seized the initiative, so that the boom of the computer company has not yet fully come.

Hence, we can assert that many years pass from an idea to its commercialization and wide distribution; the boom takes place cyclically—on average, every 70 years.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

The last crisis of 2008–2009 did not lead to any structural or ideological changes in management, development or functioning of businesses. It did not become the cause of innovation and did not force us to search for radically new solutions. Therefore, we believe that a new wave of deterioration is inevitable in the near future, until the coming of a quality change and the development of business and the world economy as a whole. The crisis is an opportunity of which no one has yet taken advantage.

In addition, an invention itself does not guarantee development—for example, the steam engine itself did not have such a large-scale impact on the markets as did the construction of railways and steam vehicles. Innovations, therefore, accumulate: each innovation absorbs previous ones and is based on them.

We believe that the basis of development of socioeconomic systems is the sequential change of states from chaos to order, from instability to sustainability. Evolution is like a snowball: it starts at an original point (an idea or invention), and as the evolution progresses, it covers more and more systems: companies, industries, markets and countries.

CONCLUSION

The analysis of some theories of development allowed us to describe our view of the universal laws of development, such the increase in complexity, the differentiation, the transition from instability to sustainability, the accumulation of changes and the transition from quality to quantity, and abrupt character of development.

The twentieth century socioeconomic systems experienced several abrupt regime shifts. Each period of transformation was connected with global changes, innovations, and economic crises. We could see that inventions gradually spread, becoming object of speculation that cause other crisis. The threat of crisis forces businesses to interact and to unite with each other, in the belief that a larger company is more sustainable. Our analysis of the statistical data on FDI and M&A showed the dynamics of the processes of concentration of assets and consolidation of businesses.

On these, assumptions we constructed a holistic model of the development of socioeconomic systems, based on holism and the systems approach. The algorithm of development is based on the gradual transition from an unorganized set of small and medium enterprises to self-organized clusters and unions.

Through the analysis of the theories of sustainability and sustainable development, we pointed out how sustainability and sustainable development are different concepts.

The synergetic methodology helped us to draw the conclusion that the crisis has a constructive essence and that development is possible through refusal from past, transition from stagnation to innovation.

Systems and holistic management thinking are necessary if the concept of competition is to be changed. The purpose of competition should not be to a win a war with competitors, but to co-create a unique product.

We should change our attitude to crises, considering them as creative instead of destructive. Life without crises is no utopia, as crises are necessary to focus on constant innovation as new opportunities for the firms.

The right kind of development on the global level is possible only by creating a win–win scenario.

In further research, we will make use of Herbert Spenser's theory, Sorokin's "social dynamic", the theory of Schumpeter, the three laws of the dialectic, and synergetic methodology.

Chapter 44
Renewable Energy Technologies, Sustainable Development, and Environment

Abdeen Mustafa Omer
Energy Research Institute (ERI), UK

ABSTRACT

The move towards a low-carbon world, driven partly by climate science and partly by the business opportunities it offers, will need the promotion of environmentally friendly alternatives, if an acceptable stabilisation level of atmospheric carbon dioxide is to be achieved. This chapter presents a comprehensive review of energy sources, and the development of sustainable technologies to explore these energy sources. It also includes potential renewable energy technologies, efficient energy systems, energy savings techniques and other mitigation measures necessary to reduce climate changes. The chapter concludes with the technical status of the ground source heat pumps (GSHP) technologies. The purpose of this study, however, is to examine the means of reduction of energy consumption in buildings, identify GSHPs as an environmental friendly technology able to provide efficient utilisation of energy in the buildings sector.

INTRODUCTION

Over millions of years ago, plants have covered the earth converting the energy of sunlight into living plants and animals, some of which was buried in the depths of the earth to produce deposits of coal, oil and natural gas (Lin & Chang, 2013; Glaas & Juhola, 2013; Gerald, 2012). The past few decades, however, have experienced many valuable uses for these complex chemical substances and manufacturing from them plastics, textiles, fertiliser and the various end products of the petrochemical industry. Indeed, each decade sees increasing uses for these products. Coal, oil and gas, which will certainly be of great value to future generations, as they are to ours, are however non-renewable natural resources. The rapid depletion of these non-renewable fossil resources need not continue. This is particularly true now as it is, or soon will be, technically and economically feasible to supply all of man's needs from the most abundant energy source of all, the sun. The sunlight is not only inexhaustible, but, moreover, it is

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

the only energy source, which is completely non-polluting (Bendewald & Zhai, 2013). This requires the harnessing and use of natural resources that produce no air pollution or greenhouse gases and provides comfortable coexistence of human, livestock, and plants.

Industry's use of fossil fuels has been largely blamed for warming the climate. When coal, gas and oil are burnt, they release harmful gases, which trap heat in the atmosphere and cause global warming. However, there had been an ongoing debate on this subject, as scientists have struggled to distinguish between changes, which are human induced, and those, which could be put down to natural climate variability. Notably, human activities that emit carbon dioxide (CO_2), the most significant contributor to potential climate change, occur primarily from fossil fuel production. Consequently, efforts to control CO_2 emissions could have serious, negative consequences for economic growth, employment, investment, trade and the standard of living of individuals everywhere.

ENERGY SOURCES AND USE

Scientifically, it is difficult to predict the relationship between global temperature and greenhouse gas (GHG) concentrations. The climate system contains many processes that will change if warming occurs. Critical processes include heat transfer by winds and tides, the hydrological cycle involving evaporation, precipitation, runoff and groundwater and the formation of clouds, snow, and ice, all of which display enormous natural variability. The equipment and infrastructure for energy supply and use are designed with long lifetimes, and the premature turnover of capital stock involves significant costs. Economic benefits occur if capital stock is replaced with more efficient equipment in step with its normal replacement cycle. Likewise, if opportunities to reduce future emissions are taken in a timely manner, they should be less costly. Such a flexible approach would allow society to take account of evolving scientific and technological knowledge, while gaining experience in designing policies to address climate change (Morrow, 2012).

The World Summit on Sustainable Development in Johannesburg in 2002 (Morrow, 2012) committed itself to ''encourage and promote the development of renewable energy sources to accelerate the shift towards sustainable consumption and production''. Accordingly, it aimed at breaking the link between resource use and productivity. This can be achieved by the following:

- Trying to ensure economic growth does not cause environmental pollution.
- Improving resource efficiency.
- Examining the whole life-cycle of a product.
- Enabling consumers to receive more information on products and services.
- Examining how taxes, voluntary agreements, subsidies, regulation and information campaigns, can best stimulate innovation and investment to provide cleaner technology.

The energy conservation scenarios include rational use of energy policies in all economy sectors and the use of combined heat and power systems, which are able to add to energy savings from the autonomous power plants. Electricity from renewable energy sources is by definition the environmental green product. Hence, a renewable energy certificate system, as recommended by the World Summit,

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

is an essential basis for all policy systems, independent of the renewable energy support scheme. It is, therefore, important that all parties involved support the renewable energy certificate system in place if it is to work as planned. Moreover, existing renewable energy technologies (RETs) could play a significant mitigating role, but the economic and political climate will have to change first. It is now universally accepted that climate change is real. It is happening now, and GHGs produced by human activities are significantly contributing to it. The predicted global temperature increase of between 1.5 and 4.5°C could lead to potentially catastrophic environmental impacts (Cantrell & Wepfer, 1984). These include sea level rise, increased frequency of extreme weather events, floods, droughts, disease migration from various places and possible stalling of the Gulf Stream. This has led scientists to argue that climate change issues are not ones that politicians can afford to ignore, and policy makers tend to agree (ASHRAE, 2005). However, reaching international agreements on climate change policies is no trivial task as the difficulty in ratifying the Kyoto Protocol and reaching agreement at Copenhagen have proved.

Therefore, the use of renewable energy sources and the rational use of energy, in general, are the fundamental inputs for any responsible energy policy. However, the energy sector is encountering difficulties because increased production and consumption levels entail higher levels of pollution and eventually climate change, with possibly disastrous consequences. At the same time, it is important to secure energy at an acceptable cost in order to avoid negative impacts on economic growth. To date, renewable energy contributes only as much as 20% of the global energy supplies worldwide (ASHRAE, 2005). Over two thirds of this comes from biomass use, mostly in developing countries, and some of this is unsustainable. However, the potential for energy from sustainable technologies is huge. On the technological side, renewables have an obvious role to play. In general, there is no problem in terms of the technical potential of renewables to deliver energy. Moreover, there are very good opportunities for the RETs to play an important role in reducing emissions of the GHGs into the atmosphere, certainly far more than have been exploited so far. However, there are still some technical issues to address in order to cope with the intermittency of some renewables, particularly wind and solar. Nevertheless, the biggest problem with relying on renewables to deliver the necessary cuts in the GHG emissions is more to do with politics and policy issues than with technical ones (Kavanaugh & Rafferty, 1997). For example, the single most important step governments could take to promote and increase the use of renewables is to improve access for renewables to the energy market. This access to the market needs to be under favourable conditions and, possibly, under favourable economic rates as well. One move that could help, or at least justify, better market access would be to acknowledge that there are environmental costs associated with other energy supply options and that these costs are not currently internalised within the market price of electricity or fuels. This could make a significant difference, particularly if appropriate subsidies were applied to renewable energy in recognition of the environmental benefits it offers. Similarly, cutting energy consumption through end-use efficiency is absolutely essential. This suggests that issues of end-use consumption of energy will have to come into the discussion in the foreseeable future (UN, 2003).

However, the RETs have the benefit of being environmentally benign when developed in a sensitive and appropriate way with the full involvement of local communities. In addition, they are diverse, secure, locally based and abundant. In spite of the enormous potential and the multiple benefits, the contribution from renewable energy still lags behind the ambitious claims for it due to the initially high development costs, concerns about local impacts, lack of research funding and poor institutional and economic arrangements (UNFCCC, 2009). Hence, an approach is needed to integrate renewable energies in a way that meets the rising demand in a cost-effective way.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

ROLE OF ENERGY EFFICIENCY SYSTEM

The prospects for development in power engineering are, at present, closely related to ecological problems. Power engineering has harmful effects on the environment, as it discharges toxic gases into atmosphere and also oil-contaminated and saline waters into rivers, as well as polluting the soil with ash and slag and having adverse effects on living things on account of electromagnetic fields and so on. Thus there is an urgent need for new approaches to provide an ecologically safe strategy. Substantial economic and ecological effects for thermal power projects (TPPs) can be achieved by improvement, upgrading the efficiency of the existing equipment, reduction of electricity loss, saving of fuel, and optimisation of its operating conditions and service life leading to improved access for rural and urban low-income areas in developing countries through energy efficiency and renewable energies.

Sustainable energy is a prerequisite for development. Energy-based living standards in developing countries, however, are clearly below standards in developed countries. Low levels of access to affordable and environmentally sound energy in both rural and urban low-income areas are therefore a predominant issue in developing countries. In recent years many programmes for development aid or technical assistance have been focusing on improving access to sustainable energy, many of them with impressive results. Apart from success stories, however, experience also shows that positive appraisals of many projects evaporate after completion and vanishing of the implementation expert team. Altogether, the diffusion of sustainable technologies such as energy efficiency and renewable energy for cooking, heating, lighting, electrical appliances and building insulation in developing countries has been slow. Energy efficiency and renewable energy programmes could be more sustainable and pilot studies more effective and pulse releasing if the entire policy and implementation process was considered and redesigned from the outset (Rees, 1999). New financing and implementation processes, which allow reallocating financial resources and thus enabling countries themselves to achieve a sustainable energy infrastructure, are also needed. The links between the energy policy framework, financing and implementation of renewable energy and energy efficiency projects have to be strengthened and as well as efforts made to increase people's knowledge through training. . The purpose of this study, however, is to examine the means of reduction of energy consumption in buildings, identify GSHPs as an environmental friendly technology able to provide efficient utilisation of energy in the buildings sector, promote using GSHPs applications as an optimum means of heating and cooling, and to present typical applications and recent advances of the DX GSHPs.

Energy Use in Buildings

Buildings consume energy mainly for cooling, heating and lighting. The energy consumption was based on the assumption that the building operates within ASHRAE-thermal comfort zone during the cooling and heating periods (Bos, My, Vu, & Bulatao, 1994). Most of the buildings incorporate energy efficient passive cooling, solar control, photovoltaic, lighting and day lighting, and integrated energy systems. It is well known that thermal mass with night ventilation can reduce the maximum indoor temperature in buildings in summer (Duchin, 1995). Hence, comfort temperatures may be achieved by proper application of passive cooling systems. However, energy can also be saved if an air conditioning unit is used (Givoni, 1998). The reason for this is that in summer, heavy external walls delay the heat transfer from the outside into the inside spaces. Moreover, if the building has a lot of internal mass the increase in the air temperature is slow. This is because the penetrating heat raises the air temperature as well as

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

the temperature of the heavy thermal mass. The result is a slow heating of the building in summer as the maximal inside temperature is reached only during the late hours when the outside air temperature is already low. The heat flowing from the inside heavy walls could be reduced with good ventilation in the evening and night. The capacity to store energy also helps in winter, since energy can be stored in walls from one sunny winter day to the next cloudy one. However, the admission of daylight into buildings alone does not guarantee that the design will be energy efficient in terms of lighting. In fact, the design for increased daylight can often raise concerns relating to visual comfort (glare) and thermal comfort (increased solar gain in the summer and heat losses in the winter from larger apertures). Such issues will clearly need to be addressed in the design of the window openings, blinds, shading devices, heating system, etc. In order for a building to benefit from daylight energy terms, it is a prerequisite that lights are switched off when sufficient daylight is available. The nature of the switching regime; manual or automated, centralised or local, switched, stepped or dimmed, will determine the energy performance. Simple techniques can be implemented to increase the probability that lights are switched off (ASHRAE, 2003). These include:

- Making switches conspicuous and switching banks of lights independently.
- Loading switches appropriately in relation to the lights.
- Switching banks of lights parallel to the main window wall.

There are also a number of methods, which help reduce the lighting energy use, which, in turn, relate to the type of occupancy pattern of the building (UN, 2003). The light switching options include:

- Centralised timed off (or stepped)/manual on;
- Photoelectric off (or stepped)/manual on;
- Photoelectric and on (or stepped), photoelectric dimming; or
- Occupant sensor (stepped) on/off (movement or noise sensor).

Energy Conservation

Likewise, energy savings from the avoidance of air conditioning can be very substantial. Whilst day-lighting strategies need to be integrated with artificial lighting systems in order to become beneficial in terms of energy use, reductions in overall energy consumption levels by employment of a sustained programme of energy consumption strategies and measures would have considerable benefits within the buildings sector. It would perhaps be better to support a climate sensitive design approach that encompasses some elements of the pure conservation strategy together with strategies, which work with the local ambient conditions making use of energy technology systems, such as solar energy, where feasible. In practice, low energy environments are achieved through a combination of measures that include:

- The application of environmental regulations and policy;
- The application of environmental science and best practice;
- Mathematical modelling and simulation;
- Environmental design and engineering;
- Construction and commissioning; and
- Management and modifications of environments in use.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

While the overriding intention of passive solar energy design of buildings is to achieve a reduction in purchased energy consumption, the attainment of significant savings is in doubt. The non-realisation of potential energy benefits is mainly due to the neglect of the consideration of post-occupancy user and management behaviour by energy scientists and designers alike. Calculating energy inputs in agricultural production is more difficult in comparison to the industry sector due to the high number of factors affecting agricultural production, as Table 1 shows. However, considerable studies have been conducted in different countries on energy use in agriculture (Kammerud, Ceballos, Curtis, Place, & Anderson, 1984; Shaviv, 1989; Singh, 2000; CAEEDAC, 2000; Yaldiz, Ozturk, & Zeren, 1995; Dutt, 1982) in order to quantify the influence of these factors.

RENEWABLE ENERGY TECHNOLOGIES

Sustainable energy is the energy that, in its production or consumption, has minimal negative impacts on human health and the healthy functioning of vital ecological systems, including the global environment (Baruah, 1995). It is an accepted fact that renewable energy is a sustainable form of energy, which has attracted more attention during recent years. Increasing environmental interest, as well as economic consideration of fossil fuel consumption and high emphasis of sustainable development for the future helped to bring the great potential of renewable energy into focus. Nearly a fifth of all global power is generated by renewable energy sources, according to a book published by the OECD/IEA (Baruah, 1995). "Renewables for power generation: status and prospects" claims that, at approximately 20%, renewables are the second largest power source after coal (39%) and ahead of nuclear (17%), natural gas (17%) and oil (8%) respectively. From 1973-2000 renewables grew at 9.3% a year and it is predicted that this will increase by 10.4% a year to 2010. Wind power grew fastest at 52% and will multiply seven times by 2020, overtaking biopower and hence help reducing greenhouse gases, GHGs, emissions to the environment.

Table 2 shows some applications of different renewable energy sources. The challenge is to match leadership in the GHG reduction and production of renewable energy with developing a major research and manufacturing capacity in environmental technologies (wind, solar, fuel cells, etc.). More than 50% of the world's area is classified as arid, representing the rural and desert part, which lack electricity and water networks. The inhabitants of such areas obtain water from borehole wells by means of water pumps, which are mostly driven by diesel engines. The diesel motors are associated with maintenance problems, high running cost, and environmental pollution. Alternative methods are pumping by photovoltaic (PV) or wind systems. At present, renewable sources of energy are regional and site specific. It has to be integrated in the regional development plans.

Solar Energy

The availability of data on solar radiation is a critical problem. Even in developed countries, very few weather stations have been recording detailed solar radiation data for a period of time long enough to have statistical significance. Solar radiation arriving on earth is the most fundamental renewable energy source in nature. It powers the bio-system, the ocean and atmospheric current system and affects the global climate. Reliable radiation information is needed to provide input data in modelling solar energy devices and a good database is required in the work of energy planners, engineers, and agricultural scientists. In general, it is not easy to design solar energy conversion systems when they have to

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

be installed in remote locations. First, in most cases, solar radiation measurements are not available for these sites. Second, the radiation nature of solar radiation makes the computation of the size of such systems difficult. While solar energy data are recognised as very important, their acquisition is by no means straightforward. The measurement of solar radiation requires the use of costly equipment such as pyrheliometers and pyranometers. Consequently, adequate facilities are often not available in developing countries to mount viable monitoring programmes. This is partly due to the equipment cost as well as the cost of technical manpower. Several attempts have, however, been made to estimate solar radiation through the use of meteorological and other physical parameter in order to avoid the use of expensive network of measuring instruments (Thakur & Mistra, 1993; Wu & Boggess, 1999; OECD/IEA, 2004; Duffie & Beckman, 1980; Sivkov, 1964).

Two of the most essential natural resources for all life on the earth and for man's survival are sunlight and water. Sunlight is the driving force behind many of the RETs. The worldwide potential for utilising this resource, both directly by means of the solar technologies and indirectly by means of biofuels, wind and hydro technologies, is vast. During the last decade interest has been refocused on renewable energy sources due to the increasing prices and fore-seeable exhaustion of presently used commercial energy sources. The most promising solar energy technology are related to thermal systems; industrial solar water heaters, solar cookers, solar dryers for peanut crops, solar stills, solar driven cold stores to store fruits and vegetables, solar collectors, solar water desalination, solar ovens, and solar commercial bakers. Solar PV system: solar PV for lighting, solar refrigeration to store vaccines for human and animal use, solar PV for water pumping, solar PV for battery chargers, solar PV for communication network, microwave, receiver stations, radio systems in airports, VHF and beacon radio systems in airports, and educational solar TV posts in villages. Solar pumps are most cost effective for low power requirement (up to 5 kW) in remote places. Applications include domestic and livestock drinking water supplies, for which the demand is constant throughout the year, and irrigation. However, the suitability of solar pumping for irrigation, though possible, is uncertain because the demand may vary greatly with seasons. Solar systems may be able to provide trickle irrigation for fruit farming, but not usually the large volumes of water needed for wheat growing.

The hydraulic energy required to deliver a volume of water is given by the formula:

$$E_w = \rho_w g V H \tag{1}$$

where E_w is the required hydraulic energy (kWh day^{-1}); ρ_w is the water density (kg m^{-3}); g is the gravitational acceleration (ms^{-2}); V is the required volume of water (m^3 day^{-1}); and H is the head of water (m).

The solar array power required is given by:

$$P_{sa} = \frac{E_w}{E_{sr}\eta F} \tag{2}$$

where: P_{sa} is the solar array power (kW_p); E_{sr} is the average daily solar radiation (kWhm^{-2} day^{-1}); F is the array mismatch factor; and η is the daily subsystem efficiency.

Substituting Equation 1 in Equation 2, the following equation is obtained for the amount of water that can be pumped:

$$V = \frac{P_{sa} E_{sr} \eta F}{\rho_w g H} \tag{3}$$

$P_{sa} = 1.6\ kW_p$, $F = 0.85$, $\eta = 40\%$.

A further increase of *PV* depends on the ability to improve the durability, performance and the local manufacturing capabilities of *PV*.

Biomass Utilisation

The data required to perform the trade-off analysis simulation of bio-energy resources can be classified according to the divisions given in Table 3, namely the overall system or individual plants, and the existing situation or future development. The effective economical utilisations of these resources are shown in Table 4, but their use is hindered by many problems such as those related to harvesting, collection, and transportation, besides the photo-sanitary control regulations. Biomass energy is experiencing a surge in interest stemming from a combination of factors, e.g., greater recognition of its current role and future potential contribution as a modern fuel, global environmental benefits, its development and entrepreneurial opportunities, etc. Possible routes of biomass energy development are shown in Table 5. However, biomass usage and application can generally be divided into the following three categories.

1. Biomass energy for petroleum substitution driven by the following factors:
    a. Oil price increase.
    b. Balance of payment problems, and economic crisis.
    c. Fuel-wood plantations and residue utilisation.
    d. Wood based heat and electricity.
    e. Liquid fuels from biomass.
    f. Producer gas technology.

   d. Fuel-wood crisis.
   e. Ecological crisis.
   f. Fuel-wood plantations, agro-forestry.
   g. Community forestry, and residue utilisation.
   h. Improved stoves, and improved charcoal production.
3. Biomass energy for development driven by:
   a. Electrification.
   b. Irrigation and water supply.
   c. Economic and social development.
   d. Fuel-wood plantations.
   e. Community forestry.
   f. Agro-forestry.
   g. Briquettes.
   h. Producer gas technology.

The use of biomass through direct combustion has long been, and still is, the most common mode of biomass utilisation (Table 5). Examples for dry (thermo-chemical) conversion processes are charcoal making from wood (slow pyrolysis), gasification of forest and agricultural residues (fast pyrolysis – this is still in demonstration phase), and of course, direct combustion in stoves, furnaces, etc. Wet processes require substantial amount of water to be mixed with the biomass. Biomass technologies include:

- Carbonisation and briquetting.
- Improved stoves.
- Biogas.
- Improved charcoal.
- Gasification.

Briquetting and Carbonisation

Briquetting is the formation of a charcoal (an energy-dense solid fuel source) from otherwise wasted agricultural and forestry residues. One of the disadvantages of wood fuel is that it is bulky with a low energy density and therefore requires transport. Briquette formation allows for a more energy-dense fuel to be delivered, thus reducing the transportation cost and making the resource more competitive. It also adds some uniformity, which makes the fuel more compatible with systems that are sensitive to the specific fuel input. Charcoal stoves are very familiar to African societies. As for the stove technology, the present charcoal stove can be used, and can be improved upon for better efficiency. This energy term will be of particular interest to both urban and rural households and all the income groups due to its simplicity, convenience, and lower air polluting characteristics. However, the market price of the fuel together with that of its end-use technology may not enhance its early high market penetration especially in the urban low income and rural households.

Charcoal is produced by slow heating wood (carbonisation) in airtight ovens or retorts, in chambers with various gases, or in kilns supplied with limited and controlled amounts of air. The charcoal yield decreased gradually from 42.6 to 30.7% for the hazelnut shell and from 35.6 to 22.7% for the beech wood with an increase of temperature from 550 to 1,150 K while the charcoal yield from the lignin

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

content decreases sharply from 42.5 to 21.7% until it was at 850 K during the carbonisation procedures (Sivkov, 1964). The charcoal yield decreases as the temperature increases, while the ignition temperature of charcoal increases as the carbonisation temperature increases. The charcoal briquettes that are sold on the commercial market are typically made from a binder and filler.

Improved Cook Stoves

Traditional wood stoves are commonly used in many rural areas. These can be classified into four types: three stone, metal cylindrical shaped, metal tripod and clay type. Indeed, improvements of traditional cookers and ovens to raise the efficiency of fuel saving can secure rural energy availability, where woody fuels have become scarce. However, planting fast growing trees to provide a constant fuel supply should also be considered. The rural development is essential and economically important since it will eventually lead to a better standard of living, people's settlement, and self-sufficiency.

Biogas Technology

Biogas technology cannot only provide fuel, but is also important for comprehensive utilisation of biomass forestry, animal husbandry, fishery, agricultural economy, protecting the environment, realising agricultural recycling as well as improving the sanitary conditions, in rural areas. However, the introduction of biogas technology on a wide scale has implications for macro planning such as the allocation of government investment and effects on the balance of payments. Hence, factors that determine the rate of acceptance of biogas plants, such as credit facilities and technical backup services, are likely to have to be planned as part of general macro-policy, as do the allocation of research and development funds (Barabaro, Coppolino, Leone, & Sinagra, 1978).

Improved Charcoal

Dry cell batteries are a practical but expensive form of mobile fuel that is used by rural people when moving around at night and for powering radios and other small appliances. The high cost of dry cell batteries is financially constraining for rural households, but their popularity gives a good indication of how valuable a versatile fuel like electricity is in rural areas (Table 6). However, dry cell batteries can constitute an environmental hazard unless they are recycled in a proper fashion. Tables 6 & 7 further show that direct burning of fuel-wood and crop residues constitute the main usage of biomass, as is the case with many developing countries. In fact, biomass resources play a significant role in energy supply in all developing countries. However, the direct burning of biomass in an inefficient manner causes economic loss and adversely affects human health. In order to address the problem of inefficiency, research centres around the world, e.g., Hall & Scrase (1998) have investigated the viability of converting the resource to a more useful form of improved charcoal, namely solid briquettes and fuel gas. Accordingly, biomass resources should be divided into residues or dedicated resources, the latter including firewood and charcoal can also be produced from forest residues (Table 7). Whichever form of biomass resource used, its sustainability would primarily depend on improved forest and tree management.

Table 6. Energy carrier and energy services in rural areas

Energy Carrier	Energy End-Use
Fuel-wood	Cooking Water heating Building materials Animal fodder preparation
Kerosene	Lighting Ignition fires
Dry cell batteries	Lighting Small appliances
Animal power	Transport Land preparation for farming Food preparation (threshing)
Human power	Transport Land preparation for farming Food preparation (threshing)

Table 7. Biomass residues and current use

Type of Residue	Current Use
Wood industry waste	Residues available
Vegetable crop residues	Animal feed
Food processing residue	Energy needs
Sorghum, millet, and wheat residues	Fodder, and building materials
Groundnut shells	Fodder, brick making, and direct fining oil mills
Cotton stalks	Domestic fuel considerable amounts available for short period
Sugar, bagasse, and molasses	Fodder, energy need, and ethanol production (surplus available)
Manure	Fertiliser, brick making, and plastering

Gasification

Gasification is based on the formation of a fuel gas (mostly CO and H_2) by partially oxidising raw solid fuel at high temperatures in the presence of steam or air. The technology can use wood chips, groundnut shells, sugarcane bagasse, and other similar fuels to generate capacities from 3 kW to 100 kW. Many types of gasifier designs have been developed to make use of the diversity of fuel inputs and to meet the requirements of the product gas output (degree of cleanliness, composition, heating value, etc.) (Pernille, 2004).

Biomass and Sustainability

A sustainable energy system includes energy efficiency, energy reliability, energy flexibility, fuel poverty, and environmental impacts. A sustainable biofuel has two favourable properties, which are availability from renewable raw material, and its lower negative environmental impact than that of fossil fuels. Global warming, caused by CO_2 and other substances, has become an international concern

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

in recent years. To protect forestry resources, which act as major absorbers of CO_2, by controlling the ever-increasing deforestation and the increase in the consumption of wood fuels, such as firewood and charcoal, is therefore an urgent issue. Given this, the development of a substitute fuel for charcoal is necessary. Briquette production technology, a type of clean coal technology, can help prevent flooding and serve as a global warming countermeasure by conserving forestry resources through the provision of a stable supply of briquettes as a substitute for charcoal and firewood.

There are many emerging biomass technologies with large and immediate potential applications, e.g., biomass gasifier/gas turbine (BGST) systems for power generation with pilot plants, improved techniques for biomass harvesting, transportation and storage. Gasification of crop residues such as rice husks, groundnut shells, etc., with plants already operating in China, India, and Thailand. Treatment of cellulosic materials by steam explosion which may be followed by biological or chemical hydrolysis to produce ethanol or other fuels, cogeneration technologies, hydrogen from biomass, striling energies capable of using biomass fuels efficiently, etc. Table 8 gives a view of the use of biomass and its projection worldwide.

However, a major gap with biomass energy is that research has usually been aimed at obtaining supply and consumption data, with insufficient attention and resources being allocated to basic research, to production, harvesting and conservation processes. Biomass has not been closely examined in terms of a substitute for fossil fuels compared to carbon sequestration and overall environmental benefits related to these different approaches. To achieve the full potential of biomass as a feedstock for energy, food, or any other use, requires the application of considerable scientific and technological inputs (D'Apote, 1998). However, the aim of any modern biomass energy systems must be:

1. To maximise yields with minimum inputs;
2. Utilise and select adequate plant materials and processes;
3. Optimise use of land, water, and fertiliser; and
4. Create an adequate infrastructure and strong research and development (R&D) base.

An afforestation programme appears an attractive option for any country to pursue in order to reduce the level of atmospheric carbon by enhancing carbon sequestration in the nation's forests, which would consequently mitigate climate change. However, it is acknowledged that certain barriers need to be overcome if the objectives are to be fully achieved. These include the followings.

- Low level of public awareness of the economic/environmental benefits of forestry.
- The generally low levels of individuals' income.
- Pressures from population growth.
- The land tenural system, which makes it difficult (if at all possible) for individuals to own or establish forest plantations.
- Poor pricing of forest products especially in the local market.
- Inadequate financial support on the part of governments.
- Weak institutional capabilities of the various Forestry Departments as regards technical manpower to effectively manage tree plantations.

However, social policy conditions are also critical. This is still very much lacking particularly under developing countries conditions. During the 1970s and 1980s different biomass energy technologies

were perceived in sub-Saharan Africa as a panacea for solving acute problems. On the account of these expectations, a wide range of activities and projects were initiated. However, despite considerable financial and human efforts, most of these initiatives have unfortunately been a failure.

Therefore, future research efforts should concentrate on the following areas:

- Directed R and D in the most promising areas of biomass to increase energy supply and to improve the technological base.
- Formulate a policy framework to encourage entrepreneurial and integrated process.
- Pay more attention to sustainable production and use of biomass energy feedstocks, methodology of conservation and efficient energy flows.
- More research aimed at pollution abatement.
- Greater attentions to interrelated socio-economic aspects.
- Support R and D on energy efficiency in production and use.
- Improve energy management skills and take maximum advantage of existing local knowledge.
- Closely examine past successes and failures to assist policy makers with well-informed recommendations.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Combined Heat and Power (CHP)

District Heating (DH), also known as community heating can be a key factor to achieve energy savings, reduce CO_2 emissions and at the same time provide consumers with a high quality heat supply at a competitive price. Generally, DH should only be considered for areas where the heat density is sufficiently high to make DH economical. In countries like Denmark for example, DH may today be economical even to new developments with lower density areas, due to the high level of taxation on oil and gas fuels combined with the efficient production of DH.

Most of the heat used for DH can be produced by large CHP plants (gas-fired combined cycle plants using natural gas, biomass, waste or biogas) as shown in Table 2. DH is energy efficient because of the way the heat is produced and the required temperature level is an important factor. Buildings can be heated to a temperature of 21°C and domestic hot water (DHW) can be supplied at a temperature of 55°C using energy sources other than DH that are most efficient when producing low temperature levels (<95°C) for the DH water (David, 2000). Most of these heat sources are CO_2 neutral or emit low levels. However, only a few of these sources are available to small individual systems at a reasonable cost, whereas DH schemes because of the plant's size and location can have access to most of the heat sources and at a low cost. Low temperature DH, with return temperatures of around 30-40°C can utilise the following heat sources:

- Efficient use of CHP by extracting heat at low calorific value (CV).
- Efficient use of biomass or gas boilers by condensing heat in economisers.
- Efficient utilisation of geothermal energy.
- Direct utilisation of excess low temperature heat from industrial processes.
- Efficient use of large-scale solar heating plants.

Heat tariffs may include a number of components such as a connection charge, a fixed charge and a variable energy charge. Also, consumers may be incentivised to lower the return temperature. Hence, it is difficult to generalise but the heat practice for any DH company, no matter what the ownership structure is, can be highlighted as follows:

- To develop and maintain a development plan for the connection of new consumers.
- To evaluate the options for least cost production of heat.
- To implement the most competitive solutions by signing agreements with other companies or by implementing own investment projects.
- To monitor all internal costs and with the help of benchmarking, improve the efficiency of the company.
- To maintain a good relationship with the consumer and deliver heat supply services at a sufficient quality.

Also, installing DH should be pursued to meet the objectives for improving the environment through the improvement of energy efficiency in the heating sector. At the same time DH can serve the consumer with a reasonable quality of heat at the lowest possible cost. The variety of possible solutions combined with the collaboration between individual companies, the district heating association, the suppliers and consultants can, as it has been in Denmark, be the way forward for developing DH in the United Kingdom.

Fuel Cells

Platinum is a catalyst for fuel cells and hydrogen-fuelled cars presently use about two ounces of the metal. There is currently no practicable alternative. Reserves are in South Africa (70%), and Russia (22%). Although there are sufficient accessible reserves in South Africa to increase supply by up to 5% per year for the next 50 years, there are significant environmental impacts associated with its mining and refining, such as groundwater pollution and atmospheric emissions of sulphur dioxide ammonia, chlorine and hydrogen chloride. The carbon cost of platinum use equates to 360 kg for a current fuel cell car, or 36 kg for a future car, with the target platinum loading of 0.2 oz, which is negligible compared to the CO_2 currently emitted by vehicles (IHA, 2003). Furthermore, Platinum is almost completely recyclable. At current prices and loading, platinum would cost 3% of the total cost of a fuel cell engine. Also, the likely resource costs of hydrogen as a transport fuel are apparently cheapest if it is reformed from natural gas with pipeline distribution, with or without carbon sequestration. However, this is not as sustainable as using renewable energy sources. Substituting hydrogen for fossils fuels will have a positive environmental impact in reducing both photochemical smog and climate change. There could also be an adverse impact on the ozone layer but this is likely to be small, though potentially more significant if hydrogen was to be used as aviation fuel.

Hydrogen Production

Hydrogen is now beginning to be accepted as a useful form for storing energy for reuse on, or for export off, the grid. Clean electrical power harvested from wind and wave power projects can be used to produce hydrogen by electrolysis of water. Electrolysers split water molecules into its constituent parts: hydrogen and oxygen. These are collected as gases; hydrogen at the cathode and oxygen at the anode. The process is quite simple. Direct current is applied to the electrodes to initiate the electrolysis process. Production of hydrogen is an elegant environmental solution. Hydrogen is the most abundant element on the planet, it cannot be destroyed (unlike hydrocarbons) it simply changes state (water to hydrogen and back to water) during consumption. There is no CO or CO_2 generation in its production and consumption and, depending upon methods of consumption, even the production of oxides of nitrogen can be avoided too. However, the transition will be very messy, and will take many technological paths to convert fossil fuels and methanol to hydrogen, building hybrid engines and so on. Nevertheless, the future of hydrogen fuel cells is promising. Hydrogen can be used in internal combustion engines, fuel cells, turbines, cookers gas boilers, road-side emergency lighting, traffic lights or signalling where noise and pollution can be a considerable nuisance, but where traffic and pedestrian safety cannot be compromised.

Hydrogen is already produced in huge volumes and used in a variety of industries. Current worldwide production is around 500 billion Nm^3 per year (EWEA, 2003). Most of the hydrogen produced today is consumed on-site, such as at oil refineries, at a cost of around $0.70/kg and is not sold on the market (Steele, 1997). When hydrogen is sold on the market, the cost of liquefying the hydrogen and transporting it to the user adds considerably to the production cost. The energy required to produce hydrogen via electrolysis (assuming 1.23 V) is about 33 (kWh/kg). For 1 mole (2 g) of hydrogen the energy is about 0.066 (kWh/mole) (Sitarz, 1992). The achieved efficiencies are over 80% and on this basis electrolytic hydrogen can be regarded as a storable form of electricity. Hydrogen can be stored in a variety of forms:

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Cryogenic; this has the highest gravimetric energy density.
- High-pressure cylinders; pressures of 10,000 psi are quite normal.
- Metal hydride absorbs hydrogen, providing a very low pressure and extremely safe mechanism, but is heavy and more expensive than cylinders, and
- Chemical carriers offer an alternative, with anhydrous ammonia offering similar gravimetric and volumetric energy densities to ethanol and methanol.

Hydropower

Hydropower has a valuable role as a clean and renewable source of energy in meeting a variety of vital human needs. Water is a basic requirement for survival: for drinking, for food, energy production and for good health. As water is a commodity, which is finite and cannot be created, and in view of the increasing requirements as the world population grows, there is no alternative but to store water for use when it is needed. However, the major challenges are to feed the increasing world population, to improve the standards of living in rural areas and to develop and manage land and water in a sustainable way. Hydropower plants are classified by their rated capacity into one of four regimes: micro (<50kW), mini (50-500 kW), small (500 kW-5 MW), and large (>5 MW) (Agnew & Duncan, 1989).

The total world installed hydro capacity today is around 1000 Giga Watts (GW) and a lot more are currently planned, principally in developing countries in Asia, Africa and South America as shown in Table 9, which is reproduced from (Okkan, 1993). However, the present production of hydroelectricity is only about 18 per cent of the technically feasible potential (and 32 per cent of the economically feasible potential); there is no doubt that a large amount of hydropower development lies ahead (Okkan, 1993).

Wind Energy

Water is the most natural commodity for the existence of life in the remote desert areas. However, as a condition for settling and growing, the supply of energy is the close second priority. The high cost and

Table 9. World hydro potential and development

Continent	Africa	Asia	Australia and Oceania	Europe	North and Central America	South America
Gross theoretical hydropower potential ($GWhy^{-1}$)	$4x10^6$	$19.4x10^6$	$59.4x10^6$	$3.2x10^6$	$6x10^6$	$6.2x10^6$
Technically feasible hydropower potential ($GWhy^{-1}$)	$1.75x10^6$	$6.8x10^6$	$2x10^6$	10^6	$1.66x10^6$	$2.7x10^6$

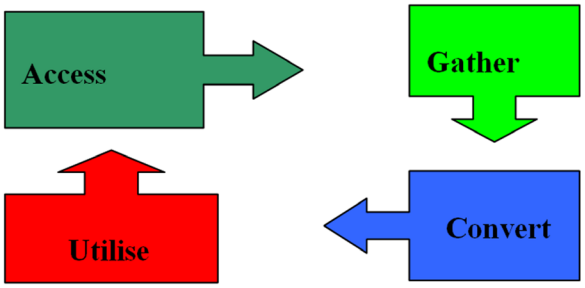
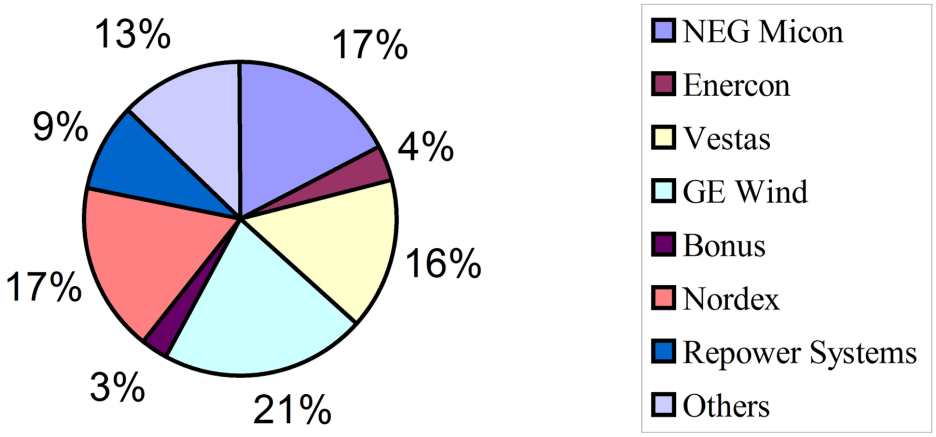
the difficulties of mains power line extensions, especially to a low populated region can focus attention on the utilisation of different and more reliable and independent sources of energy like renewable wind energy. Accordingly, the utilisation of wind energy, as a form of energy, is becoming increasingly attractive and is being widely used for the substitution of oil-produced energy, and eventually to minimise atmospheric degradation, particularly in remote areas. Indeed, utilisation of renewables, such as wind energy, has gained considerable momentum since the oil crises of the 1970s. Wind energy, though site-dependent, is non-depleting, non-polluting, and a potential option of the alternative energy source. Wind power could supply 12% of global electricity demand by 2020, according to a report by the European Wind Energy Association and Greenpeace (Njeru, 2013).

Wind energy can and will constitute a significant energy resource when converted into a usable form. As Figure 1 illustrates, information sharing is a four-stage process and effective collaboration must also provide ways in which the other three stages of the 'renewable' cycle: gather, convert and utilise, can be integrated. Efficiency in the renewable energy sector translates into lower gathering, conversion and utilisation (electricity) costs. A great level of installed capacity has already been achieved. Figure 2 clearly shows that the offshore wind sector is developing fast, and this indicates that wind is becoming a major factor in electricity supply with a range of significant technical, commercial and financial hurdles to be overcome. The offshore wind industry has the potential for a very bright future and to emerge as a new industrial sector, as Figure 3 implies.

Figure 1. The renewable cycle





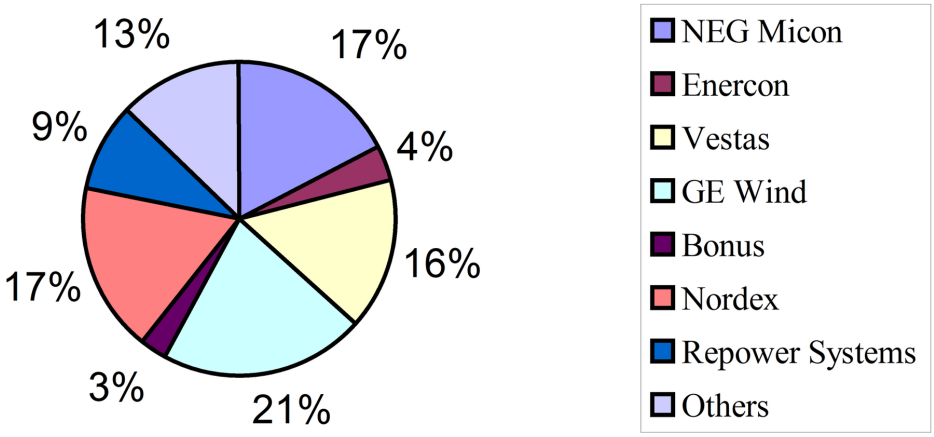


Figure 2. Global prospects of wind energy utilisation by 2003-2010

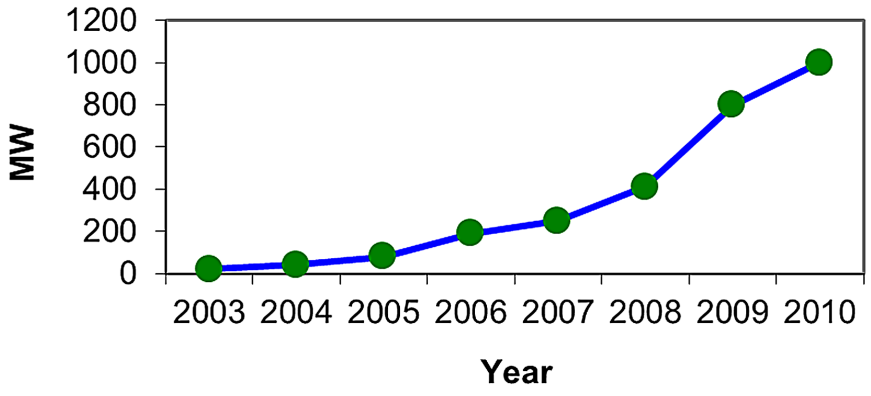
Figure 3. Prospect turbines share for 2003-2010



The speed of turbine development is such that more powerful models would supersede the original specification turbines in the time from concept to turbine order. Levels of activities are growing at a phenomenal rate (Figure 4), new prospects developing, new players entering, existing players growing in experience; technology evolving and, quite significantly, politics appear to support the sector.

ENERGY AND SUSTAINABLE DEVELOPMENT

Sustainability is defined as the extent to which progress and development should meet the need of the present without compromising the ability of the future generations to meet their own needs (Odeku, Maveneka, & Konanani, 2013). This encompasses a variety of levels and scales ranging from economic development and agriculture, to the management of human settlements and building practices. Tables 10, 11 & 12 indicate the relationship between energy conservation, sustainable development and environment.

The following issues were addressed during the Rio Earth Summit in 1992 (Abdeen, 2009):

Figure 4. Average windfarm capacity 2003-2010

Table 10. Energy and sustainable environment

Technological Criteria	Energy and Environment Criteria	Social and Economic Criteria
Primary energy saving in regional scale	Sustainability according to greenhouse gas pollutant emissions	Labour impact
Technical maturity, and reliability	Sustainable according to other pollutant emissions	Market maturity
Consistence of installation and maintenance requirements with local technical known-how	Land requirement	Compatibility with political, legislative and administrative situation
Continuity and predictability of performance	Sustainability according to other environmental impacts	Cost of saved primary energy

Table 11. Classification of key variables defining facility sustainability

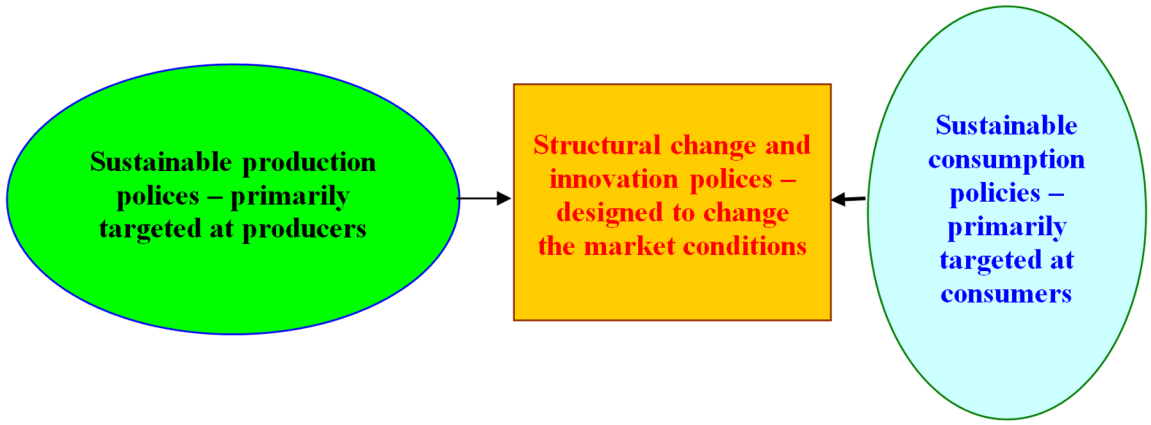
Criteria	Intra-System Impacts	Extra-System Impacts
Stakeholder satisfaction	• Standard expectations met • Relative importance of standard expectations	Covered by attending to extra-system resource base and ecosystem impacts
Resource base impacts	• Change in intra-system resource bases • Significance of change	• Resource flow into/out of facility system • Unit impact exerted by flow on source/sink system • Significance of unit impact
Ecosystem impacts	• Change in intra-system ecosystems • Significance of change	• Resource flows into/out of facility system • Unit impact exerted by how on source/sink system • Significance of unit impact

Table 12. Positive impact of durability, adaptability, and energy conservation on economic, social, and environment systems

Economic System	Social System	Environmental System
Durability	Preservation of cultural values	Preservation of resources
Meeting changing needs of economic development	Meeting changing needs of individuals and society	Reuse, recycling and preservation of resources
Energy conservation and saving	Savings directed to meet other social needs	Preservation of resources, reduction of pollution and global warming

- The use of local materials and indigenous building sources.
- Incentive to promote the continuation of traditional techniques, with regional resources and self-help strategies.
- Regulation of energy-efficient design principles.
- International information exchange on all aspects of construction related to the environment, among architects and contractors, particularly non-conventional resources.
- Exploration of methods to encourage and facilitate the recycling and reuse of building materials, especially those requiring intensive energy use during manufacturing, and the use of clean technologies.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use



And, the following action areas for producers were recommended:

- **Management and Measurement Tools:** Adopting environmental management systems appropriate for the business.
- **Performance Assessment Tools:** Making use of benchmarking to identify scope for impact reduction and greater eco-efficiency in all aspects of the business.
- **Best Practice Tools:** Making use of free help and advice from government best practice programmes (energy efficiency, environmental technology, resource savings).
- **Innovation and Eco-Design:** Rethinking the delivery of 'value added' by the business, so that impact reduction and resource efficiency are firmly built in at the design stage.
- **Cleaner, Leaner Production Processes:** Pursuing improvements and savings in waste minimisation, energy and water consumption, transport and distribution, as well as reduced emissions.
- **Supply Chain Management:** Specifying more demanding standards of sustainability from 'upstream' suppliers, while supporting smaller firms to meet those higher standards.
- **Product Stewardship:** Taking the broadest view of 'producer responsibility' and working to reduce all the 'downstream' effects of products after they have been sold on to customers.
- **Openness and Transparency:** Publicly reporting on environmental performance against meaningful targets; actively using clear labels and declarations so that customers are fully informed; building stakeholder confidence by communicating sustainability aims to the workforce, the shareholders and the local community (Figure 5).

This is the step in a long journey to encourage progressive economy, which continues to provide people with high living standards, but, at the same time helps reduce pollution, waste mountains, other environmental degradation, and environmental rationale for future policy-making and intervention to improve market mechanisms. This vision will be accomplished by:

- 'Decoupling' economic growth and environmental degradation. The basket of indicators illustrated in Table 13 shows the progress being made. Decoupling air and water pollution from growth, making good headway with CO_2 emissions from energy, and transport. The environmental im-

Figure 5. Link between resources and productivity

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

pact of our own individual behaviour is more closely linked to consumption expenditure than the economy as a whole.
- Focusing policy on the most important environmental impacts associated with the use of particular resources, rather than on the total level of all resource use.
- Increasing the productivity of material and energy use that are economically efficient by encouraging patterns of supply and demand, which are more efficient in the use of natural resources. The aim is to promote innovation and competitiveness. Investment in areas like energy efficiency, water efficiency and waste minimisation.
- Encouraging and enabling active and informed individual and corporate consumers.

Chemicals

Humans and wildlife are being contaminated by a host of commonly used chemicals in food packaging and furniture, according to the World Wildlife Federation (WWF) and European Union (Abdeen, 2008). Currently, the chemical industry has been under no obligation to make the information public. However, the new proposed rules would change this. Future dangers will only be averted if the effects of chemicals are exposed and then the dangerous ones are never used. Indeed, chemicals used for jacket waterproofing, food packaging and non-stick coatings have been found in dolphins, whales, cormorants, seals, sea eagles and polar bears from the Mediterranean to the Baltic. The European Commission has adopted an ambitious action plan to improve the development and wider use of environmental technologies such as recycling systems for wastewater in industrial processes, energy-saving car engines and soil remediation techniques, using hydrogen and fuel cells (Abdeen, 2012). The legislation, which has not been implemented in time, concerns the incineration of waste, air quality limit, values for benzene and carbon monoxide, national emission ceilings for sulphur dioxide, nitrogen oxides, volatile organic compounds and ammonia and large combustion plants.

Wastes

Waste is defined as an unwanted material that is being discarded. Waste includes items being taken for further use, recycling or reclamation. Waste produced at household, commercial and industrial premises are control waste and come under the waste regulations. Waste Incineration Directive (WID) emissions limit values will favour efficient, inherently cleaner technologies that do not rely heavily on abatement. For existing plant, the requirements are likely to lead to improved control of:

- NO_x emissions, by the adoption of infurnace combustion control and abatement techniques.
- Acid gases, by the adoption of abatement techniques and optimisation of their control.
- Particulate control techniques, and their optimisation, e.g., of bag filters and electrostatic precipitators.

The waste and resources action programme has been working hard to reduce demand for virgin aggregates and market uptake of recycled and secondary alternatives. The programme targets are:

8. Emissions from electricity generation 9. Motor vehicle kilometres and related emissions 10. Agricultural output, fertiliser use, methane emissions and farmland bird populations 11. Manufacturing output, energy consumption and related emissions 12. Household consumption, expenditure energy, water consumption and waste generated

- To deliver training and information on the role of recycling and secondary aggregates in sustainable construction for influences in the supply chain, and
- To develop a promotional programme to highlight the new information on websites.

Global Warming

This results in the following requirements:

- Relevant climate variables should be generated (solar radiation: global, diffuse, direct solar direction, temperature, humidity, wind speed and direction) according to the statistics of the real climate.
- The average behaviour should be in accordance with the real climate.
- Extremes should occur in the generated series in the way it will happen in a real warm period. This means that the generated series should be long enough to capture these extremes, and series based on average values from nearby stations.

On some climate change issues (such as global warming), there is no disagreement among the scientists. The greenhouse effect is unquestionably real; it is essential for life on earth. Water vapour is the most important GHG; followed by carbon dioxide (CO_2). Without a natural greenhouse effect, scientists estimate that the earth's average temperature would be –18°C instead of its present 14°C (Raphael, 2012). There is also no scientific debate over the fact that human activity has increased the concentration of the GHGs in the atmosphere (especially CO_2 from combustion of coal, oil and gas). The greenhouse effect is also being amplified by increased concentrations of other gases, such as methane, nitrous oxide, and CFCs as a result of human emissions. Most scientists predict that rising global temperatures will raise the sea level and increase the frequency of intense rain or snowstorms. Climate change scenarios sources of uncertainty and factors influencing the future climate are:

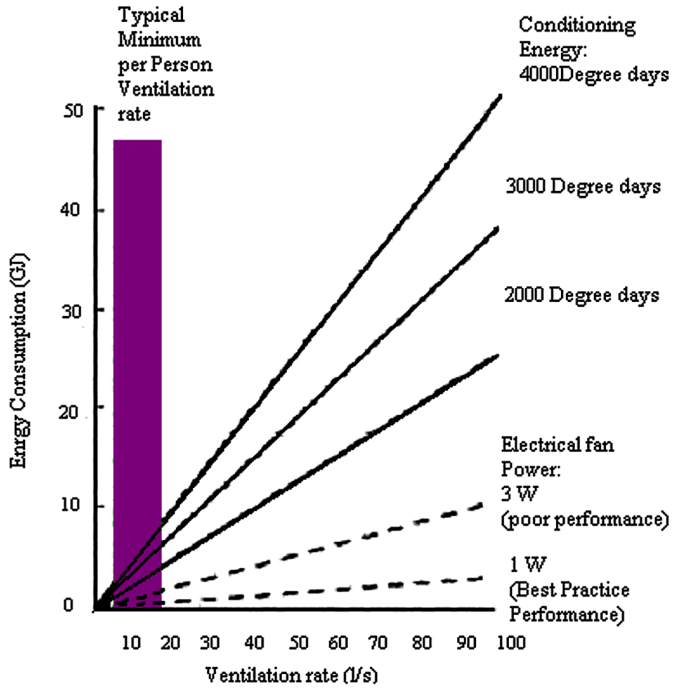
EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

- The future emission rates of the GHGs (Table 14).
- The effect of this increase in concentration on the energy balance of the atmosphere.
- The effect of these emissions on GHGs concentrations in the atmosphere, and
- The effect of this change in energy balance on global and regional climate.

It has been known for a long time that urban centres have mean temperatures higher than their less developed surroundings. The urban heat increases the average and peak air temperatures, which in turn affect the demand for heating and cooling. Higher temperatures can be beneficial in the heating season, lowering fuel use, but they exacerbate the energy demand for cooling in the summer times.

Neither heating nor cooling may dominate the fuel use in a building in temperate climates, and the balance of the effect of the heat is less. As the provision of cooling is expensive with higher environmental cost, ways of using innovative alternative systems, like the mop fan will be appreciated. The solar gains would affect energy consumption. Therefore, lower or higher percentages of glazing, or shading devices might affect the balance between annual heating and cooling loads. In addition to conditioning energy, the fan energy needed to provide mechanical ventilation can make a significant further contribution to energy demand. Much depends on the efficiency of design, both in relation to the performance of fans themselves and to the resistance to flow arising from the associated ductwork. Figure 6 illustrates the typical fan and thermal conditioning needs for a variety of ventilation rates and climate conditions.

Ground Source Heat Pumps



The term "ground source heat pump" has become an all-inclusive term to describe a heat pump system that uses the earth, ground water, or surface water as a heat source and/or sink. Some of the most common types of ground source ground-loop heat exchangers configurations are classified in Figure 7. The GSHP systems consist of three loops or cycles as shown. The first loop is on the load side and is either an air/water loop or a water/water loop, depending on the application. The second loop is the refrigerant loop inside a water source heat pump. Thermodynamically, there is no difference between the well-known vapour-compression refrigeration cycle and the heat pump cycle; both systems absorb heat

Table 14. West European states GHG emissions

Country	1990	1999	Change 1990-99	Reduction Target
Austria	76.9	79.2	2.6%	-13%

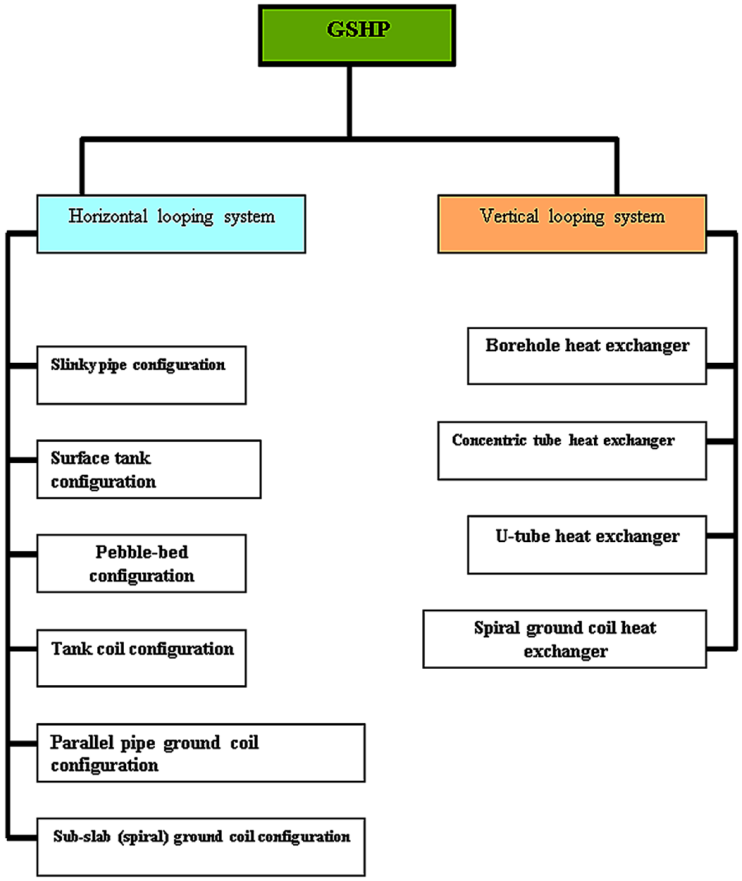
Figure 6. Energy impact of ventilation



at a low temperature level and reject it to a higher temperature level. However, the difference between the two systems is that a refrigeration application is only concerned with the low temperature effect produced at the evaporator, while a heat pump may be concerned with both the cooling effect produced at the evaporator and the heating effect produced at the condenser. In these dual-mode GSHP systems, a reversing valve is used to switch between heating and cooling modes by reversing the refrigerant flow direction. The third loop in the system is the ground loop in which water or an antifreeze solution exchanges heat with the refrigerant and the earth.

The GSHPs utilise the thermal energy stored in the earth through either vertical or horizontal closed loop heat exchange systems buried in the ground. Many geological factors impact directly on site characterisation and subsequently the design and cost of the system. The solid geology of the United Kingdom varies significantly. Furthermore there is an extensive and variable rock head cover. The geological prognosis for a site and its anticipated rock properties influence the drilling methods and therefore system costs. Other factors important to system design include predicted subsurface temperatures and the thermal and hydrological properties of strata. The GSHP technology is well established in Sweden, Germany and North America, but has had minimal impact in the United Kingdom space heating and cooling market. Perceived barriers to uptake include geological uncertainty, concerns regarding performance and reliability, high capital costs and lack of infrastructure. System performance concerns relate mostly to uncertainty in design input parameters, especially the temperature and thermal properties of the source. These in turn can impact on the capital cost, much of which is associated with the installation of the external loop in horizontal trenches or vertical boreholes. The climate in the United Kingdom makes the potential for heating in winter and cooling in summer from a ground source less certain owing to the temperature ranges being narrower than those encountered in continental climates. This project will

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 7. Common types of ground-loop heat exchangers

develop an impartial GSHP function on the site to make available information and data on site-specific temperatures and key geotechnical characteristics.

The GSHPs are receiving increasing interest because of their potential to reduce primary energy consumption and thus reduce emissions of greenhouse gases. The technology is well established in North Americas and parts of Europe, but is at the demonstration stage in the United Kingdom. The information will be delivered from digital geoscience's themes that have been developed from observed data held in corporate records. This data will be available to the GSHP installers and designers to assist the design process, therefore reducing uncertainties. The research will also be used to help inform the public as to the potential benefits of this technology.

The GSHPs play a key role in geothermal development in Central and Northern Europe. With borehole heat exchangers as heat source, they offer de-central geothermal heating with great flexibility to meet given demands at virtually any location. No space cooling is included in the vast majority of systems, leaving ground-source heat pumps with some economic constraints. Nevertheless, a promising market development first occurred in Switzerland and Sweden, and now also in Austria and Germany. Approximately 20 years of R and D focusing on borehole heat exchangers resulted in a well-established concept of sustainability for this technology, as well as in sound design and installation criteria. The market success brought Switzerland to the third rank worldwide in geothermal direct use. The future prospects

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

are good, with an increasing range of applications including large systems with thermal energy storage for heating and cooling, ground-source heat pumps in densely populated development areas, borehole heat exchangers for cooling of telecommunication equipment, etc.

Loops can be installed in three ways: horizontally, vertically or in a pond or lake. The type chosen depends on the available land area, soil and rock type at the installation site. These factors help to determine the most economical choice for installation of the ground loop. The GSHP delivers 3-4 times as much energy as it consumes when heating, and cools and dehumidifies for a lower cost than conventional air conditioning. It can cut homes or business heating and cooling costs by 50% and provide hot water free or with substantial savings. The GSHPs can reduce the energy required for space heating, cooling and service water heating in commercial/institutional buildings by as much as 50%.

Efficiencies of the GSHP systems are much greater than conventional air-source heat pump systems. A higher COP (coefficient of performance) can be achieved by a GSHP because the source/sink earth temperature is relatively constant compared to air temperatures. Additionally, heat is absorbed and rejected through water, which is a more desirable heat transfer medium because of its relatively high heat capacity. The GSHP systems rely on the fact that, under normal geothermal gradients of about 0.5°F/100 ft (30°C/km), the earth temperature is roughly constant in a zone extending from about 20 ft (6.1 m) deep to about 150 ft (45.7 m) deep. This constant temperature interval within the earth is the result of a complex interaction of heat fluxes from above (the sun and the atmosphere) and from below (the earth interior). As a result, the temperature of this interval within the earth is approximately equal to the average annual air temperature (Roriz, 2001). Above this zone (less than about 20 feet (6.1 m) deep), the earth temperature is a damped version of the air temperature at the earth's surface. Below this zone (greater than about 150 ft (45.7 m) deep), the earth temperature begins to rise according to the natural geothermal gradient. The storage concept is based on a modular design that will facilitate active control and optimisation of thermal input/output, and it can be adapted for simultaneous heating and cooling often needed in large service and institutional buildings (Strauss, 2013). Loading of the core is done by diverting warm and cold air from the heat pump through the core during periods with excess capacity compared to the current need of the building (Tukahirwa, 2013; Valkila & Saari, 2012; Vargas-Parra, 2013). The cool section of the core can also be loaded directly with air during the night, especially in spring and fall when nights are cold and days may be warm.

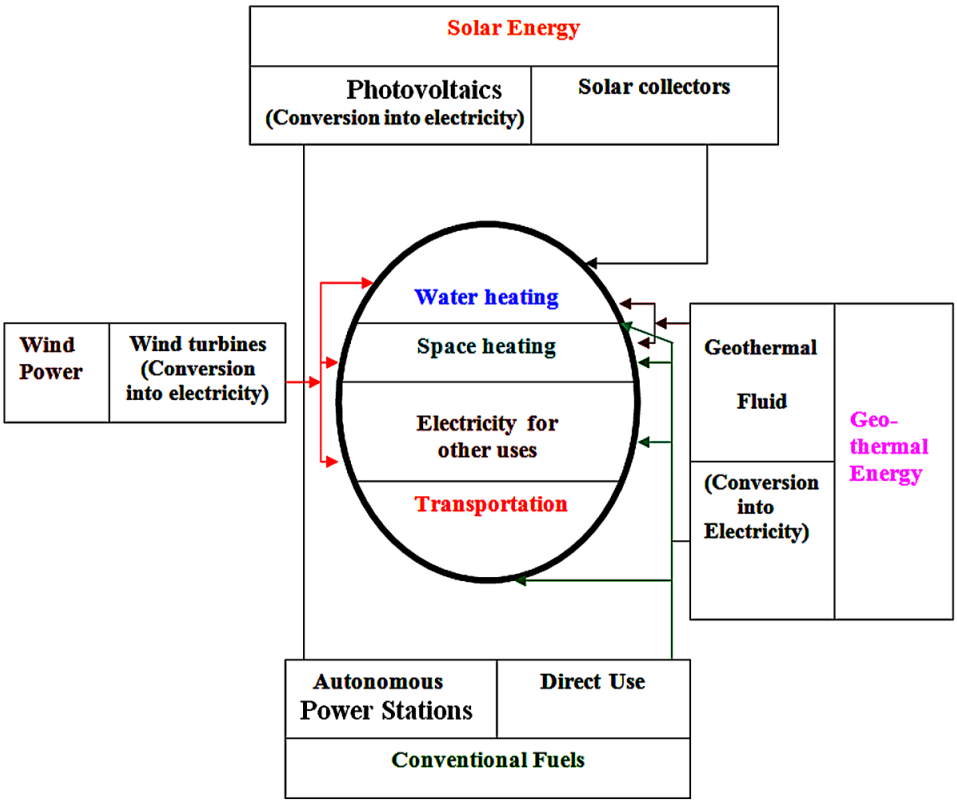
DISCUSSION

Peoples rely upon oil for primary energy and this for a few more decades. Other conventional sources may be more enduring, but are not without serious disadvantages (Vargas-Parra, 2013). The renewable energy resources are particularly suited for the provision of rural power supplies and a major advantage is that equipment such as flat plate solar driers, wind machines, etc., can be constructed using local resources and without the advantage results from the feasibility of local maintenance and the general encouragement such local manufacture gives to the build up of small-scale rural based industry. This communication comprises a comprehensive review of energy sources, the environment and sustainable development. It includes the renewable energy technologies, energy efficiency systems, energy conservation scenarios, energy savings in greenhouses environment and other mitigation measures necessary to reduce climate change. This study gives some examples of small-scale energy converters, nevertheless it should be noted that small conventional, i.e., engines are currently the major source of power in rural

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

areas and will continue to be so for a long time to come. There is a need for some further development to suit local conditions, to minimise spares holdings, to maximise interchangeability both of engine parts and of the engine application. Emphasis should be placed on full local manufacture. It is concluded that renewable environmentally friendly energy must be encouraged, promoted, implemented and demonstrated by full-scale plant (device) especially for use in remote rural areas.

The communication reviews various options of renewable energy sources that are possibly be applied to rural based energy needs which may wholly or partly replace the conventional sources of energy. Sustainable energy is a prerequisite for development. Energy-based living standards in developing countries, however, are clearly below standards in developed countries. Low levels of access to affordable and environmentally sound energy in both rural and urban low-income areas are therefore a predominant issue in developing countries. In recent years many programmes for development aid or technical assistance have been focusing on improving access to sustainable energy, many of them with impressive results. Apart from success stories, however, experience also shows that positive appraisals of many projects evaporate after completion and vanishing of the implementation expert team. Altogether, the diffusion of sustainable technologies such as energy efficiency and renewable energy for cooking, heating, lighting, electrical appliances and building insulation in developing countries has been slow. Energy efficiency and renewable energy programmes could be more sustainable and pilot studies more effective and pulse releasing if the entire policy and implementation process was considered and redesigned from the outset. New financing and implementation processes, which allow reallocating financial resources and thus enabling countries themselves to achieve a sustainable energy infrastructure, are also needed. The links between the energy policy framework, financing and implementation of renewable energy and energy efficiency projects have to be strengthened and as well as efforts made to increase people's knowledge through training. Different sources of energy, which can be used for different final uses. Those sources are wind power, solar energy, geothermal energy, the existing electricity production system and the conventional fuels with direct use (Figure 8). The main categories of final uses are: transportation, space heating, water heating and electricity for other uses.



CONCLUSION

There is strong scientific evidence that the average temperature of the earth's surface is rising. This is a result of the increased concentration of carbon dioxide and other GHGs in the atmosphere as released by burning fossil fuels. This global warming will eventually lead to substantial changes in the world's climate, which will, in turn, have a major impact on human life and the built environment. Therefore, effort has to be made to reduce fossil energy use and to promote green energy, particularly in the building sector. Energy use reductions can be achieved by minimising the energy demand, rational energy use, recovering heat and the use of more green energy. This study was a step towards achieving this goal.

The adoption of green or sustainable approaches to the way in which society is run is seen as an important strategy in finding a solution to the energy problem. The key factors to reducing and controlling CO_2, which is the major contributor to global warming, are the use of alternative approaches to energy generation and the exploration of how these alternatives are used today and may be used in the future as green energy sources. Even with modest assumptions about the availability of land, comprehensive fuel-wood farming programmes offer significant energy, economic and environmental benefits. These

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 8. Energy sources their final uses

benefits would be dispersed in rural areas where they are greatly needed and can serve as linkages for further rural economic development.

However, by adopting coherent strategy for alternative clean sustainable energy sources, the world as a whole would benefit from savings in foreign exchange, improved energy security, and socio-economic improvements. With a nine-fold increase in forest – plantation cover, every nation's resource base would be greatly improved while the international community would benefit from pollution reduction, climate mitigation, and the increased trading opportunities that arise from new income sources.

The non-technical issues related to clean energy, which have recently gained attention, include:

1. Environmental and ecological factors, e.g., carbon sequestration, reforestation and revegetation;
2. Renewables as a CO_2 neutral replacement for fossil fuels;
3. Greater recognition of the importance of renewable energy, particularly modern biomass energy carriers, at the policy and planning levels;
4. Greater recognition of the difficulties of gathering good and reliable renewable energy data, and efforts to improve it; and
5. Studies on the detrimental health efforts of biomass energy particularly from traditional energy users.

The chapter is one effort in touching all these aspects.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

RECOMMENDATIONS

- Launching of public awareness campaigns among local investors particularly small-scale entrepreneurs and end users of the RET to highlight the importance and benefits of renewable, particularly solar, wind, and biomass energies.
- Amendment of the encouragement of investment act, to include furthers concessions, facilities, tax holidays, and preferential treatment to attract national and foreign capital investment.
- Allocation of a specific percentage of soft loans and grants obtained by governments to augment budgets of the (R&D) related to manufacturing and commercialisation of the RET.
- Governments should give incentives to encourage the household sector to use renewable energy instead of conventional energy. Execute joint investments between the private sector and the financing entities to disseminate the renewable information and literature with technical support from the research and development entities.
- Availing of training opportunities to personnel at different levels in donor countries and other developing countries to make use of their wide experience in application and commercialisation of the RET particularly renewable energy.
- The governments should play a leading role in adopting renewable energy devices in public institutions, e.g., schools, hospitals, government departments, police stations, etc., for lighting, water pumping, water heating, communication and refrigeration.
- Encouraging the private sector to assemble, install, repair and manufacture renewable energy devices via investment encouragement and more flexible licensing procedures.

ACKNOWLEDGMENT

The financial support for this research work is from the Energy Research Institute (ERI). Thanks to my wife Kawthar Abdelhai Ali for her warmth and love. Her unwavering faith in me, her intelligence, humour, spontaneity, curiosity and wisdom added to this article and to my life.

KEY TERMS AND DEFINITIONS

Biomass Energy: The energy embodied in organic matter ("biomass") that is released when chemical bonds are broken by microbial digestion, combustion, or decomposition. Biofuels are a wide range of fuels, which are in some way derived from biomass. The term covers solid biomass, liquid fuels and various biogases. Biofuels are gaining increased public and scientific attention, driven by factors such as oil price spikes and the need for increased energy security.

Environment: The natural environment, commonly referred to simply as the environment, encompasses all living and non-living things occurring naturally on Earth or some region thereof. The biophysical environment is the symbiosis between the physical environment and the biological life forms within the environment, and includes all variables that comprise the Earth's biosphere.

Geothermal Energy: Geothermal power (from the Greek roots geo, meaning earth, and thermos, meaning heat) is power extracted from heat stored in the earth. This geothermal energy originates from the original formation of the planet, from radioactive decay of minerals, and from solar energy absorbed at the surface. Heat transferred from the earth's molten core to under-ground deposits of dry steam (steam with no water droplets), wet steam (a mixture of steam and water droplets), hot water, or rocks lying fairly close to the earth's surface.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Greenhouse Gases: Greenhouse gases are gases in an atmosphere that absorb and emit radiation within the thermal infrared range. This process is the fundamental cause of the greenhouse effect. The main greenhouse gases in the Earth's atmosphere are water vapour, carbon dioxide, methane, nitrous oxide, and ozone. Changes in the concentration of certain greenhouse gases, due to human activity such as fossil fuel burning, increase the risk of global climate change.

Hydropower: Hydropower, hydraulic power or waterpower is power that is derived from the force or energy of moving water, which may be harnessed for useful purposes. Hydropower is using water to power machinery or make electricity. Water constantly moves through a vast global cycle, evaporating from lakes and oceans, forming clouds, precipitating as rain or snow, and then flowing back down to the ocean.

Renewable Energy: Renewable energy is energy generated from natural resources such as sunlight, wind, rain, tides, and geothermal heat, which are renewable (naturally replenished). Energy obtained from sources that are essentially inexhaustible (unlike, for example the fossil fuels, of which there is a finite supply). Energy sources that are, within a short time frame relative to the Earth's natural cycles, sustainable, and include non-carbon technologies such as solar energy, hydropower, and wind, as well as carbon-neutral technologies.

Resource Management: Efficient incident management requires a system for identifying available resources at all jurisdictional levels to enable timely and unimpeded access to resources needed to prepare for, respond to, or recover from an incident. Resource management is the efficient and effective deployment for an organisation's resources when they are needed. Such resources may include financial resources, inventory, human skills, production resources, or information technology (IT).

Solar Energy: Energy from the sun that is converted into thermal or electrical energy; "the amount of energy falling on the earth is given by the solar constant, but very little use has been made of solar energy". Energy derived ultimately from the sun. It can be divided into direct and indirect categories. Most energy sources on Earth are forms of indirect solar energy, although we usually do not think of them in that way. Solar energy uses semiconductor material to convert sunlight into electric currents. Although solar energy only provides 0.15% of the world's power and less than 1% of USA energy, experts believe that sunlight has the potential to supply 5,000 times, as much energy as the world currently consumes.

Sustainable Development: Development, which seeks to produce sustainable economic growth, while ensuring future generations' ability to do the same by not exceeding the regenerative capacity of the nature. In other words, it is trying to protect the environment. A process of change in which the resources consumed (both social and ecological) are not depleted to the extent that they cannot be replicated. Environmentally friendly forms of economic growth activities (agriculture, logging, manufacturing, etc.) that allow the continued production of a commodity without damage to the ecosystem (soil, water supplies, biodiversity or other surrounding resources).

Wind Energy: Kinetic energy present in wind motion that can be converted to mechanical energy for driving pumps, mills, and electric power generators. Wind power is the conversion of wind energy into a useful form of energy, such as using wind turbines to make electricity, wind mills for mechanical power, wind pumps for pumping water or drainage, or sails to propel ships.

Chapter 45
Environmental Accounting for Industrial Growth and Sustainable Development in India:
An Overview and Theoretical Framework

Archana Singh
Symbiosis International University, India

Nehajoan Panackal
Symbiosis International University, India

Bhama Venkataramani
Symbiosis International University, India

ABSTRACT

Environmental accounting is an important function that provides industry with a means to incorporate information with business decision making and business operations. This chapter evaluates the extent to which the process of environmental accounting can be applied as a solid foundation for industrial growth and sustainability. Having an environmental accounting system in place allows the industry to better manage environmental costs and to discover new opportunities to minimize environmental costs through environmental thinking to the industrial sector. Researchers have adopted systematic literature review as a methodology to generate strong knowledge base for the study. In this paper, the theoretical foundation of environmental accounting and reporting is discussed with reference to India. The insights gained will shed light on positive outcomes of adopting environmental accounting for sustainability and manufacturing management in the industrial sector of India.

1. INTRODUCTION

There is a growing concern towards lack of adequate measures to ensure sustainability in our society. Environmental business management has focused its attention on how and why existing firms can become greener. The field of green management has begun to broaden its arena and recently there has been a growing recognition of the importance of several factors impacting green management such as linking sustainability and innovation, the role of small and medium enterprises in innovating products and processes keeping sustainability in mind. The importance of sustainability in strategic business development and green practices in industries is must. For an industry to have a positive environmental influence, real improvement can be created only if the production processes, products and services are environment friendly. Environment is the aggregation of the eco system of living organisms and the non living components like air, water, soil, etc. around us which together affects the livelihood of men and animals on earth. Natural Capital Accounting (NCA) is the measurement and valuation of natures benefits in terms of ecosystems, goods and services-like fresh water, flood control and forest products-to be incorporated into a general standard format consistent with conventional national accounts. (http://www.conservation.org/projects/pages/valuing-and Accounting-for-Natural-Capital)

Natural capital accounting (NCA) gives insights on how economic development depends on natural resources both for production as well as for absorption of effluents and pollution. This information will help policy makers while charting the development plan.

A native American proverb states that, "Only when the last tree is cut, only when the last river is polluted, only when the last fish is caught only then they will realize that we cannot eat money." In this background, it is not only imperative that we are aware of the importance of and need for sustainable development but it is also a requirement to bring on record and report to the stakeholders the extent of environment friendly measures or otherwise adopted and practiced by the organisation. Environmental accounting thus plays an important role in this regard and is now gaining importance in the reporting function of an organisation.

In the early 1970's, Norway's ministry of environment initiated the first natural resource accounting system which was later followed by other countries. In India environmental accounting is optional. Since the 1990's, Europe has been focusing on sustainable accounting indicating that the accounting profession has a significant role to play through environment sustainability reporting. Accounting for social economic and environmental aspects and reporting the same for decision making of internal and external stakeholders is facilitated through financial statements A customized format for identifying and recording environment related data can be created for disclosure. Business is an integral part of society and such disclosure shows the responsibility and commitment of the entities. Many researchers have discussed environmental accounting with reference to India and it is noted that awareness and adoption of environmental accounting is not a choice but a necessity. Since the new economic policy 1991 was implemented in India, the intensity of global competition has increased. Eco auditing is essentially related to Green accounting (Jasch, 2001). Green accounting is concerned with the appropriate analysis and reporting of environmental issues of an organization.

The present civilization is involved in various economic and non-economic activities which generates waste with potential constituents. Responsibility towards the environment is one of the crucial areas of social responsibility. Environmental pollution is a worldwide phenomenon and we must not forget that the earth's environment has been handed to us by the previous generations and nature. Wealth is enough to satisfy everyone's need but not their greed. Therefore environment protection is a critical issue in the

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

present day context. The indiscriminate disposal of such wastes contributes towards the environmental pollution and hazards. At present, the magnitude of environmental pollution is increasing at a very alarming magnitude in different parts of the globe.

Environmental issues are currently receiving due attention from the public and private sector. It has become crucial especially for manufacturing industries, to carefully monitor the effects of their activities on the environment. There exists a correlation between manufacturing industries and cost and challenges these industries need to face in the process of implementing environmental management accounting. Some of the companies adopt internally developed environment policies but they also face challenges in defining, separating, identifying, classifying, measuring and controlling the environmental protection cost. Namakonzi & Inanga. (2014).

The importance of environmental accounting information for management supports the prevalence of decision making usefulness theory in the implementation of environmental management systems. Nowadays members of the society appreciates the ill effects of exploitation of the environmental resources and are therefore concerned about the same. Environmental awareness is the new value emerging in our society and the same values need to be incorporated in the industrial sector. Every organisation needs to articulate its environmental management policy through an information system that helps to analyze the interaction between firms and environment. Being a corporate citizen, an entity is evaluated by its financial as well as environmental performance. The Indian corporate sector needs to improve as far as environmental performance. Laws have been laid down and amended for them to fulfill corporate social responsibility for the economic development of the Indian Economy. In the global and Indian context, environmental responsibility is of vital importance and a very crucial area. India being a developing country whose focus is on growth and development must ascertain the benefits and costs of environmental damages and degradation. The gross domestic product is highly impacted due to the environmental cost. Accounting is a language of business and it is very important that through accounting, the government and entities should fulfill the responsibilities towards the environment by measuring and reporting the costs of used or misuse of natural resources. Thus the need of environmental accounting has emerged. At the global level, the environment movement has grown giving birth to the United Nations Environment Programme (UNEP). When environment issues became a worldwide problem in the 1980's the world commission on environment and development (WCED) known as Bruntland commission was established by the United Nations. It published a report on sustainability called "Our common future."

Green economy has become the language at the global level to develop the environment. There are different social dimensions of sustainability and many concerns in the emerging framework for sustainable development. It is very important for the industry to raise general questions about measuring sustainability and to focus on sustainable economic renewal. Davies & Mullin (2011).

1.1 Environment Accounting: A Conceptual Analysis

Industries utilize natural resources for their production process. Consequently, it leads to environment pollution and degradation. Environmental consciousness is increasing day by day at the global level. The role of sustainable development is major and central as an organizing principle in industry as human activity and its impact on environment has become more evident. The two major concerns emerging out of it is to address innovation in our mode of thinking and policy in practice settings to explore knowledge. One outcome is development of different disciplines progressing sustainable development like sustainability science. Bebbington & Larrinaga (2014).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Corporate stakeholders need to pay attention on environmental accounting for reducing and avoiding costs and to improve the quality of the environment. Environmental accounting can be supported at the micro and macro level in relation to financial accounting, cost accounting and managerial accounting. Industrial, commercial and service industry at different levels must measure and evaluate the actual environmental impacts of various projects for development decisions which are economically and environmentally sound. Issuance of environmental regulations for new solutions needs to be updated for which accounting can play a vital role.

The consequences of environmental accounting are on the economic, social and legal status of a nation. Undoubtedly, the industry enjoys the competitive advantage by following proper environmental management. Government policies have not come out with great outcomes in this regard. It is very important for a developing nation like India to come up with incentives and rewards for quality environmental reporting. Stakeholders expect the business entities to meet environmental standards. Smith (2002) and companies need to provide environmental management system to support the same. Fortis (2002).Accountants that are responsible for the communication of business need to open their eyes to the impact of environmental issues on accounting, auditing and disclosure. Globally accountants are expected to be proactive and show their concern for the environment protection process. Liberalization and globalization has made environment accounting of vital importance today.

Environmental accounting is a growing field. Industries are taking serious attempts to identify the environment issues by the business houses. There is no single definition encompassing the scope of Environmental accounting. Data that have been included in the environmental accounts of different countries includes pollutant eminents in physical terms by economic sector, actual environmental protection expenditures by economic sector and hypothetical expenditures that would be required to further reduce pollution(sometimes called "maintenance cost"), by economic sector.

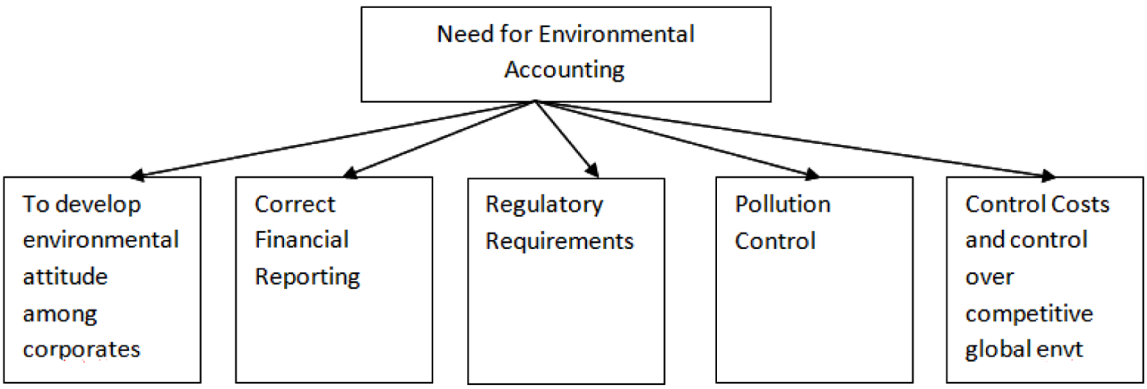
It assesses the costs and benefits to an enterprise due to environment preservation activities that are undertaken. Environmental accounting involves the identification, measurement and allocation of environmental costs, the integration of these costs into business, identifying environmental liabilities if any and finally communicating this information to the company's stakeholders.

The three main aspects of environmental accounting are—economic, social, and environment (Ball 2005; Milne 1996). Studies have been conducted for evaluating the financial and sustainable impact on financial management (Lamberton, 2005; Schaltegger & Wagner, 2006; Taplin, Bent & Aeron-Thomas, 2006). Gray (2006) was concerned that sustainability accounting must include revealing the right information to stakeholders for a sustainable organization. As a consequence, sustainability accounting needs to take care of environmental and social accounting issues. Environmental accounting and its disclosure is not mandatory. In the current era environmental problems are vital issues which makes environment accounting a strong branch of accounting. Legal authorities and standard setting bodies have made a conceptual framework of environmental accounting and its disclosures. Pramanik et al (2007).

Major functions of environmental accounting are to minimize the negative environmental effects of old accounting practices, to know environment related costs and to take active steps to set up initiatives in order to ameliorate the existing environmental effects of conventional accounting practices. Published sources of ACCA acknowledge full environmental costing to be adopted by business. Bebbington, Gray, Hibbit & Kirk (2001).

The forms of environmental accounting are environmental management accounting (EMA), environmental financial accounting (EFA) and environmental national accounting (ENA).EMA is an internal environmental accounting tool to support sustainable environmental management activities and environ-

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use



mental reporting. It includes segment environmental accounting, eco balance environmental accounting and corporate environmental accounting. EMA emphasis on energy and material flow information and environmental cost information. Economic performance is evaluated through environment management accounting theoretically, the concern remains rare. Christ & Burritt.(2013). It's an internal environmental accounting tool to select a project or investment activity. It consists of segment environmental accounting, eco balance environmental accounting and corporate environmental accounting. Segment environmental accounting includes environmental accounting tool to select an investment activity, eco balance environmental accounting talks about sustainable environmental management activities and corporate environmental accounting is concerned with informing proper financial reporting in accordance with environmental accounting. EFA focuses on environmental liability cost and other environmental costs. EFA is a method of reporting environmental liability cost and other significant environmental cost through financial accounting. ENA focuses on natural resources and environment cost at the national level. The specific focus of ENA is natural resources, stocks and flows, environmental cost and externality costs, etc.

The need for environmental accounting includes the factor show in Figure 1.

Environmental accounting is required to fulfill the responsibility of different stakeholders. The objectives include increasing environmental transparency, to determine positive relation between the company and society. The environmental accounting consumerism movement launched by the environmental lobby groups encourages the consumers to purchase environmental friendly products. Industries producing green products enjoy marketing advantage by doing so. Through this method of accounting, industries can show commitments by making environmental disclosures. Industries that are not focused on environment friendliness may use green accounting to overcome negative public opinions.

Due to environmental accounting, environmental awareness is enhanced and environmental commitment becomes a shared responsibility amongst the stakeholders. Environmental costs can be offset by generating higher revenues through sale of by-products or recycling. It helps in deciding cost of the product and helps in focusing perpetually on natural resource asset. Sustainability at the ecological level enhances national wealth and national economic accounts to find an economy's total wealth. It is important to know the physical flow accounts to determine the right policies by taking into consideration data on pollution and waste along with designing and evaluating environmental taxes. To asses economic progress there is a need to meet regulatory requirements of the industrial sector, to operate in an environmental friendly manner with an environmental attitude controlling operational efficiency and optimize cost and

Figure 1. Need for environmental accounting

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

waste. The important aspects of environmental accounting involves both internal and external factors. Internally they are the business and the investment made by the industry for minimizing losses to environment. This includes environment saving equipment and measurement in monetary terms is possible. Externally it constitutes costs of de gradation and destruction of soil, coastal and marine pollution and exploitation of non renewable sources like minerals, gas etc along with deforestation and land use. This step of accounting is very challenging and complicated. It is difficult to measure the loss accurately.

2. ENVIRONMENTAL ACCOUNTING IN INDIA: AN OVERVIEW

The developing countries like India are currently facing the challenge of promoting economic development without causing any negligence to the environment. A tradeoff between environmental protection and development is a major concern today. The concern of environmental responsibility and the sustainable industrial development has given rise to a novel branch of accounting known as environmental accounting.

Accounting is defined by the AICPA as "The art of recording, classifying, and summarizing in a significant manner and in terms of money, transactions and events which are, in part at least, of financial character, and interpreting the results thereof."

Following the end of the British rule, India plunged into serious troubles of communal riots. Initially India did not pay much attention towards the environment. The five year plans were implemented with a view to the economic development of the country. The second five year plan focused on industrial development. But the plans remained unconcerned about protecting nature. The public awareness on environmental issues grew after the beginning of the seventies when a law for protection of environment was passed. As there was requirement of environment related information from business on a periodic basis, the ministry of environment and forests has proposed that every company shall in the report, in the report of its board of directors disclose briefly the measures taken towards the adoption of clean technologies for the prevention of pollution, waste minimization, waste recycling and utilization, pollution control measures, investment on environmental protection and its impact.

Countries like India have to focus on environmental problems as well as make sure that the pace of economic development is high. Therefore it is must to have a tradeoff between the two. Proper evaluation of cost and damages to the environment should be studied to know the impact of major problems in terms of monetary costs. Environmental accounting will work as a tool to enumerate economic efficiency and environmental efficiency as a whole. In India disclosures related to environment in the corporate annual reports both financial and non-financial is not an encouraging level. Neither company law nor the accounting standards issued by ICAI prescribes disclosing norms for environment related matter in the corporate financial statements. There is a lack of environment awareness, poor enforcement of the of the environment protection acts is also partly responsible for freeing the companies from disclosure of such information. In the absence of standardized environmental accounting practices and disclosure techniques at both national and global level along with legal enforcement to advocate environmental accounting practices from a global perspective.

In the past, issues related to the environment were ignored by, large companies and small medium enterprises to a great extent. However, due to increasing concerns and awareness environmental accounting is receiving increased attention in the recent times. Many companies now consider it important to be green and follow green practices, as many investors place a high value on environmental responsibility. Environmental costs can be significantly reduced and eliminated due to business decisions, ranging

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

from operational to investment in greener process technology to redesign processes or products. Better natural resource and green accounts would provide valuable insights into the interaction between the environment and the economy. Industrialization is the main cause for environment degradation. Though it is vital for economic growth, but it drastically damages the environment. Optimum utilization of resources is the prime responsibility of every industry which has given birth to a new branch of accounting called environmental accounting. It is a must for organizations to implement the concept of sustainable development for balancing ecological activities and to measure the organization in an economic manner.

In the early 1990's Indian companies faced cut throat international competition wherein International firms disclosed non-financial information including environmental information to meet the expectation from Indian companies and to improvise their corporate image showing socially responsible behavior. Thus it was expected that Indian companies should report their environmental performance. But the disappointing part is that in the developing countries very little attention has been given to the state of environmental accounting. (Ahmed & Sulaiman, 2004; Thompson & Zakaria, 2004; Nafez & Kamal, 2000). Pahuja (2009) concluded that companies which have better environmental performance provide more environmental information in the annual reports as compared to poor performers. Her study also indicated the existence of statistically significant ''size'' and ''profitability'' effect. Hence, larger and more profitable companies disclose more information on environment as compared to smaller and less profitable companies. Environmental reporting by the public sector is higher than the private sector. Jaffar et al (2002) measured environmental performance on the basis of legal action taken on companies for noncompliance of environmental regulations by the department of environment. Companies having better environmental performance disclose more on the environment.

Rapid industrialization growth has great effect on the environment and is of major concern to the economy. The government has been supporting small enterprise sectors and they are tended to be the worst polluters. It is very important to pay attention to environmental issues as a part of their operations. Although existing environmental legislations serve some purpose of protecting the environment, the small scale and large enterprises have significant differences in the way they approach environmental issues (D'Souza & Peretiatko, 2002)

2.1 Environmental Accounting in Indian Industry: The Road Ahead

Eresi (1996) in his study disclosed that companies gave only positive information about the practices adopted by them in the context of environment conservation. Kumar (2002), examined the Indian Scenario and stated that accounting and reporting aspects of environmental protection is a must for policy statements in an annual report and emphasized that the environmental reporting in India was limited to little more than a sentence or two each in the annual report. Vasal (1998) administered a study on 144 companies found that the practice of preparing stand-alone environmental reports was yet to rake roots in India. Roy (2000) observed that companies giving environment disclosure in the public sector was more than in the private sector. Pradhan & Bal (2002) agreed that a company must reveal information environmental policy, environmental audit report, future targets. Shah analyzed 50 annual reports of large and medium sized companies and found that hardly any company report on failure regarding environmental protection or damage caused by the company to the environment and society. Environmental issues are of low priority for some companies who consider environmental protection as a trustee duty. Industries who consider environmental goals are supplementary to the business attempt to pilot and

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

control environmental impacts in an efficient manner, industries located in the upper right hand treat environmental issues as central to their core business

Environmental accounting can be implemented by industries of large, medium and small scale sizes. Whether administered by a global corporation or a small business, elements need to be in place for success. The business entities management must support these practices. These leaders need to focus in setting a positive tone when communicating the benefits of environmental accounting practices to the employee population and implementing it. Consisting of employees across all business lines, including finance, sales, manufacturing and procurement, these teams ensure that all environmental accounting policies and procedures are communicated and followed. The green entrepreneurs activities have an overall positive impact on the natural environment and moves towards a more sustainable future. All their business is structured and operated in such a way that every component has a neutral or positive impact on the environment. Environmental and social entrepreneurs, or ecopreneurs, lead socially committed, break-through ventures that are driven by environmental, social and economic goals. There exists a strong link between youth entrepreneurialism and environmentalism. A model called as Green-Works business model has been developed for attaining sustainability of the environment and social objectives of the organization. Sarah E.A. Dixon et al. Entrepreneurship can be driven by moral attitudes. Anderson (1998).

It has become important to give ecopreneurship a serious consideration as we are rapidly losing our natural resources which are the true capital of any nation. Unlike past decades where economic gains were the only measure of a nation's progress, now a day's sustainability is given high importance. Joshi, TOI. Environmental awareness and reporting in India is a wide road ahead to understand the reasons for environmental disclosure by taking into consideration the global scenario. Due to the depletion rate there is a contradiction in the growth of renewable resources and growing demand. Industries need to realize and make a genuine attempt on the optimum use of resources and curtail environmental damage. Initially GNP was considered growing with the growth of industrialization and technological advancement, but in reality industrialization has resulted in heavily polluted environments having a negative impact on the quality of life. Therefore industries must realize the prime responsibility for clean technologies which would contribute to the nation in the long run. Cost volume profit (CVP) analysis, standard costing and variance analysis cannot be adequately used as a measure of control in the present manufacturing system. (Bromwich and Bhimani, 1994; Kaplan, 1983; Lucas, 1997). Production process and less labor usage consequently may lead to non-existence of above tools (Drury et al, 1993; Hilton, 2002).

Economic, social and ecological systems of environment integrate to sustainability. Thus companies need to acquire sustainable development. Dixon & Fallon (1989).A sustainability management accounting system (SMAS) refers to sustainability and management accounting concepts and practices that deal with environmental and social issues. Development areas are related to human, social, economic and environmental aspects. Goodland (2002).

Environmental accounting seeks to better measure sustainability by expanding gross measures of national welfare (product, investment, etc.) to include non-market values, in particular ones associated with environmental goods and services. In addition, it also seeks to incorporate costs and benefits of environmental protection and depletion of natural capital – two measurements not typically included in national accounting systems such as gross domestic product. While opinions vary on how to perform green accounting, the technique is used worldwide and is well-established in the US.

Indian industry needs to have accounting practices which are conservative and innovative. It is very important to develop future accountants who can measure environmental degradation in quantitative

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

terms. It is a challenge and duty for India to understand the importance of the implementation of environmental accounting in the curriculum. Business should take care of social environmental liabilities.

Since 1991, the liberalization of the Indian economy has increased the pressure for international competition and changed the information needs of Indian companies. The future emphasis in India is on traditional practices and less on the new techniques, because higher benefits were derived from such techniques. Size (total assets) has an influential factor in the adoption of the newly developed practices. Most of the differences could be attributed to the differences in cultural values. Indian management generally avoids risk, is quite conservative, and less innovative in adopting new management accounting techniques. Since, Indians have a long history of their heritage; it takes them longer time to change their societal values and practices, which also seems true in the case of adopting new management accounting practices. Due to cost pressures, customer awareness, supply chain relations and activities of environmental campaigners encourage the companies to go for environmental initiatives Perry & Sheng(1999). Developed countries are highly concerned with the quality of their lives due to the arising alarm of pollution. The same concern is shared by developing countries hence; many laws pertaining to environmental protection are enacted. Industries need to integrate environmental issues into their strategic planning process. Banerjee (2001).

3. ENVIRONMENTAL ACCOUNTING: THE REGULATORY FRAMEWORK COST AND BENEFITS

Environmental accounting and reporting practices are in the evolution stage in India. Even though Indian industries comply with the rules and regulations with regard to environmental protection, till now no clear cut policies are formulated at the National, State or even at the industry level, for ensuring the level of compliance to environmental norms. Indian practice, voluntary environmental reporting with regard to the environmental parameters identified.

There has been an increased trend towards environment management and disclosure in annual reports, but meaningful disclosure has not been achieved in socially related company activities such as pollution control. So, reporting is yet to attain the desired shape in terms of both the quantity and the quality. This shortcoming may be because of the absence of any standard specifying the kind of information required to be disclosed, and the absence of any compulsion on the firms regarding such disclosures. Regular attempts have been made in this regard in the different countries to streamline the environmental reporting practices for industry. They are yet to come up with form of legislations; a comprehensive accounting standard. In India, a few such legislations require submission of different environment statements to be respective regulatory bodies. But nothing exists by now, which requires disclosure of environmental information through annual reports. In such situations it is quite encouraging to note that industries are voluntarily disclosing environmental (howsoever inadequate that may be) through their annual reports. Data on environmental accounting plays an important role to different users at different levels for different reasons. Now a days there is a huge demand on financial and economic data on environmental and natural resources for civilizing environmental performance and for the own self interest of the industry. Singh & Joshi. (2009).

Industry environment reporting is an important tool for developed countries driven by legal compliance. Green economic development aims at reducing environmental damage and government regulations along with voluntary self regulatory measures to curtail the impact on local environment is a must.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Such environmental management practices should be synchronized in different sectors of the society to promote green economic development. Gibson &Collins.

In the constitution under the directive principle of state policy‟ it is expressly mentioned that it is the duty of the state to protect and improve the environment and to safeguard the forest and wildlife of the country.” It is the fundamental duty of every citizen of India to protect and improve the natural environment including forest, lakes, rivers and wildlife.‟ Government of India enacted numbers of laws which can directly and indirectly help the protection of environment and natural resources. In addition to that union ministry of environment and forest and corresponding state governments have made a provision for environmental clearance before any industrial unit actually set up. However, there is no any specific guideline regarding accounting and disclosure of environmental cost and liabilities except provisions of company about disclosure of conservation of energy, technology absorption in director's report under sec 217(1). Recently ministry of corporate affairs laid more emphasis on corporate social responsibility and accordingly issued national voluntary guidelines on social environmental and economic responsibility of the business in 2011. In such guidelines, it also mentions that business should provide goods and service that are safe and contribute to sustainability throughout their lifecycle. It is explicitly mentioned that business should respect, protect and make efforts to restore environment. In pursuance of that a business should report:

Percentage of materials used that are recycled input materials, total energy consumed by the business entity for its operations, statement on use of energy saving processes and the total energy saved due to use of such processes, use of renewable energy as percentage of total energy consumption, Total water consumed and the percentage of water that is recycled and reused, statement on quantum of emissions of greenhouse gases and efforts made to reduce the same, statement on discharge of water and effluents indicating the treatment done before discharge and the destination of disposal, details of efforts made for reconstruction of bio-diversity.

The disclosures of above mentioned information are voluntary and there are no specific guidelines on format of reporting. On the other hand accounting standard board and Ministry of Corporate Affairs is till silent on environmental accounting and disclosure issue in corporate accounting and reporting. Environmental conservation benefit is measured in physical units and is the benefit obtained from the prevention, reduction, and/or avoidance of environmental impact, removal of such impact, restoration following the occurrence of a disaster, and other activities. By assessing the economic value of environmental conservation benefits which are measured in physical units, results are described in monetary values by some cases. Currently, in the field of environmental economics, a number of valuation methods are being developed for the purpose of determining the environment's economic value.

At the global level, environmental protection concern has increased; countries like India also had to set up a union ministry of environment along with essential legislations for coordination among the states and various industries. Although licensing for industry is abolished in India but environmental clearance is of vital importance.

The various laws relevant to environmental protection are as under: (a) Directly related to environment protection: i. Water (Prevention and Control of Pollution) Act, 1974. ii Water (Prevention and Control of Pollution) Cess Act, 1977. iii. The Air (Prevention and Control of Pollution) Act, 1981. iv. The Forest (Conservation) Act, 1980. v. The Environment (Protection) Act, 1986. (b) Indirectly related to environment protection: vi. Constitutional provision (Article 51A). vii. The Factories Act, 1948. viii. Hazardous Waste (Management & Handling) Rules, 1989. ix. Public Liability Insurance Act, 1991. x. Motor Vehicle Act, 1991. xi. Indian Fisheries Act, 1987. xii. Merchant of shipping Act, 1958. xiii. Indian Port

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Act. xiv. Indian Penal Code. xv. The National Environment Tribunal Act, 1995. It is important to note that all new projects require environment clearance. This clearance concerns both the Union Ministry of Environment and Forests and the corresponding State Govt. department of environment. Guidelines have been issued and all such projects are expected to obtain environmental and antipollution clearance before they are actually set up. A Central Pollution Control Board (CPCB) has also been set up. Wherever cases of violating of standards of water or air pollution have been detected, show cause notices have been issued to industrial units and all such units are being kept under regular inspection. (A report on environmental accounting: a general overview and Indian perspective social statistics division central statistics office ministry of statistics & programme implementation New Delhi).

System of integrated environmental and economic accounting (SEEA) is concerned with integrating different methodologies into an organised framework. It comprises of pure physical data relating to flow of material and energy, it takes those elements that are relevant to good management of the environmental and has environment related transactions and accounts of environmental assets measured in physical and monetary terms. It emphasis on depletion, defensive expenditures relating to environmental degradation.(Green National Accounts in India A Framework A Report by an Expert Group Convened by the National Statistical Organization Ministry of Statistics and Programme Implementation Government of India March 2013). It is vital to implement environmental accounting system for accurate information on environmental analysis, Mein-chin (2002), as it will ensure environment friendly management decisions. The usage of environmental accounting has changed over the past 2 decades. Now it is an important source of information for a company's manager. Schaltegger et al (1996).International accounting standards address the general principles for the measurement and disclosure of environmental matters in the financial report. (IAS 37). Any industry failing to comply with legal compliance requirements concerning environmental matters may face fines and penalties. It is important that some entities must recognize environmental obligations as liabilities in the financial statement. For example: obligations related to solid waste. The industry in which the entity operates must focus on environmental issues and should have accounting treatment adopted for environmental cost and environmental restoration liabilities (Pinckard & Wendy, 2000).

Environmental accounting techniques and the incomplete efforts of accountants and their allies to overcome environmental issues makes it mandatory to explore cost–benefit analysis. The identification and allocation of environmental costs requires accounting and book keeping knowledge. There is no universally accepted definition of environmental cost. It depends on the industry and its entity how the information will be used. Bouma (1998). According to the United Nations division for sustainable development, "the main problem of environmental management accounting is that we lack a standard definition of environmental costs". Environment cost that has been incurred by an entity with no return or benefit like damages done which cannot be recovered is environmental loss. The Canadian Institute of Chartered Accountants (CICA) (1993)Environmental cost can be listed as atmospheric emissions waste, energy consumption, material usage, oil & gas consumption, packaging, transportation costs, waste and waste resource use. By integrating social and ecological costs and benefits resulting from the natural environment into traditional economic accounting systems, green accounting aims to capture the interdependency and dynamic interactions between the three pillars of sustainability (economy, society, and environment). More accurately valuing natural resources costs and benefits may contribute to the development of more appropriate and sustainable economic, trade, and development policies.

Product related cost and research and development expenditure incurred can be categorized as capital investment, operating costs, research and development cost, environment administration and planning,

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

expenditures for remedial measures and recovery measures (Pramanik, 2002). From the time of acquisition to the cost incurred for capitalization of environment expenditure needs to be justifiable to mitigate environmental contamination. Contingent environment liability may or may not occur but to compensate a third party suffered is an obligation to pay future expenditure for environmental damage. Quantifiable environmental liabilities are shown with the accurate balance in the balance sheet and unquantifiable one are shown as foot notes explaining the nature. All natural assets are environmental assets but not vice versa (Mohamed, 2003).

4. HOW CAN ENVIRONMENTAL ACCOUNTING CONTRIBUTE TO THE SUSTAINABLE INDUSTRY GROWTH?

Sustainability is recognised the world over as the litmus test for any new project to be launched. The process of sustainability is uninterrupted and has forms diversity Rizkallah & Bone (1998). Mebratu (1998).The World Commission on Environment and Development was asked to formulate a global agenda for change. The General Assembly of the United Nations was called upon to propose long-term environmental strategies in order to achieve sustainable development. The term sustainable development was discussed by the World commission on environment and development in 1987 in their report which was titled as "Our Common Future". Sustainable development that "meets the needs of the present without compromising the ability of future generations to meet their own needs." (World Commission on Environment and Development (1987). Our Common Future. Oxford: Oxford University Press, p.43.) is supposed to be the global mission, necessity and hopefully, reality. Awareness of this problem1 leads to the fact that "all the world is in the same boat", that everyone should somehow contribute to the sustainable development and to communicate about problems, activities and accomplishments in this threatening area. Sustainability needs to pay attention to the poor of the present and future generation as they are the wealth of the nation. Sen (2013). Kordestani et al. (2015) have summarized the area of research towards developing sustainability. Manners in 2014 proposed sustainability economics as subservient to society. The concept of sustainability is important for all stakeholders, who take and implement the concept of sustainability in different stakes. Felix et al (2015). HR policies and interventions are pivotal to the success of sustainability (Dubey & Gunasekaran, 2015).

The heart of sustainable development is accountability of socio-economic policies for their environmental impacts. Development analysis comprises of non-economic objectives that do not lend themselves to monetary valuation. Integrating environmental concerns into economic policies is accounting for economic performance. Social evaluation of these objectives by means of norms, standards, and targets is required for integrated development.

Long term sustainability can be achieved through environmental instruments to decrease environmental footprint and for the betterment of relationship with the stakeholders. It is very important for an industry to comply all their operations with the principles of sustainable development as far as environmental responsibilities are concerned. They must inculcate more and greener environment practices in their business strategies for which developing and implementing environmentally sustainable practices and assessment of the same through environmental accounting and reporting need to be emphasized. Sandra & Dubravka (2014).Environment problem impacts every area globally and it is very important to study and explore the roots of environmental accounting (Moorthy, Yacob) 'Green procurement' practices and conceptualizes a strategic framework is required to further strengthen the linkage between the business

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

entity and industry. Dubey, Bag, Ali & Venkatesh (2013). The need for consistent, decisive environmental accounting principles is pervasive. A loss of nature's carrying capacity entails damage from an accounting perspective. Generally accepted accounting principles illustrate the need for environmental accounting. Environmental accounting entails a subset of GAAP and gives a holistic picture of both financial activity and associated risks. It would require additional disclosure to cover environmental contingencies; thus creating better awareness of a firm's overall financial position, and better educating management.

Accounting is a product of environment and it is shaped by the environment. (Choi & Mueller, 1992; Perera, 1989; Radebaugh & Gray, 1993). Core sectoral company's disclosure covering informational needs of stakeholders supports suitable framework for environmental disclosure. Environmental accounting is an emerging issue required to support the Indian industry. Incorporating environmental accounting into national economic accounts could provide a measure of sustainability; however, considerable advances in methods of measurement and valuation are needed. From a purely accounting perspective, particular forms of capital could be diminished or, in an extreme case, wholly eliminated without decreasing overall welfare if other forms can be substituted for it. There are, of course, no substitutes for the life-sustaining services of nature and the question of when and how to account for this fact is the source of many ongoing debates in green accounting.

To progress from an economic and social angle without endangering the natural equilibrium of the planet is a primary condition for sustainable development. Citizens as well as industries as their true stake of the future must avoid environment degradation. Environmental accounting is the expression of a new ethics that answers to the human worries for planetary development and progress. Letiţia & Dănuleţiu (2010).The progress and welfare of an economy is measured by the per capita income. Per capita income is calculated by dividing population with the national income. National income accounting is a tool for economic analysis reflecting changes in investment, savings, structure of industry, etc. Environmental degradation and scarcity of natural resources has a negative impact on development. Deterioration of environment and scarce natural resources add to the cost of development. Increase in the cost can hamper the future development of an economy. Some of the overarching methods currently in use for green accounting include natural resource accounts; emissions accounting; disaggregation of conventional national accounts; value of non-marketed environmental goods and services; and, green gross domestic product.

Identifying such costs promotes better decision making and better utilization of resources. In addition, it gives an incentive to management to save on environmental protection costs such as pollution reduction, fines, waste management, legal fees, monitoring, insurance, and regulatory reporting and consequently improve the environment. This calls for accountants to adopt and understand better environment management and accounting systems that can aid in identification, classification, allocation and control of environmental costs for better decision making and better environmental management among other benefits. Roger Adams, (2002) affirms that much of the interest surrounding environmental issues has been directed at external reporting and financial accounting and less in EMA which is intended for internal decision making. Environment accounting might also avoid huge, but predictable swings in revenue and expenses. Environmental economists are, in fact, already attempting to place a value on nature's services, something that a generation or two ago might have been considered unquantifiable, or worse, limitless. Many critical environmental valuations and estimates, accountants are the natural leaders for a team of professionals necessary to incorporate all of this valuable environmental data into a financial reporting package.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Industrial sustainability is a great challenge and accounting as a source of information can meet the criteria of sustainability. The 'going concern' principle outlines the accounting point of view of sustainability. Pollution control, equitable distribution of wealth poses challenges to industry. Sustainability is a concept understood at the global level and applied at the organizational level (Gray & Milne, 2002). Industrial sustainability is a situation of achieving economic, social and environmental performance.

Raising awareness of environmental issues and developing guidelines to assist identification of environmental issues and evaluation and reporting is required to provide education programs across disciplines focused on environmental issues and their accounting treatment. Indian civilization has a long tradition of taking care of the environment.

It includes Environmental conservation benefit associated with the inputs of resources into business operations, Environmental conservation benefit associated with environmental impact and waste emissions from business operations,

Environmental conservation benefit associated with the goods and services produced by business operations and Environmental conservation benefit associated with transports and other operations.

New methodologies and concepts for the successful implementation of environmentally sound and sustainable socio-economic development has increased its attention globally and has been emphasized in the report of world commission on environment and development.

5. LIMITATIONS OF ENVIRONMENT ACCOUNTING

Environmental accounting has various limitations which include difficulty in measuring cost and also measuring the benefits of environmental accounting. It is very critical to evaluate the right environmental cost and benefits in a systematic quantitative manner. Another paradox is consideration of internal cost and exclusion of cost to society. As of now, there are no standard accounting methods for environmental accounting. It is very difficult to do an intra firm comparison analysis between two firms and two countries. It is almost impossible to track the use of energy and material.

The limits of the accounting regulations to distinguish the environmental cost are an obstacle to the internalization of environmental externalities and do not support the main issue of a proactive environmental system. Bracci & Maran.(2013)

Valuation techniques for environmental goods and services are imperfect and shadow prices depict only partial valuations. The change in values for environmental goods and services are uncertain. Economic values are marginal and incremental, not absolute and total reliable industry data are not readily available. Environmental accounting is an ongoing and a long process, it needs to be integrated with financial accounting which in turn makes it complicated. Environmental accounting is a longitudinal process. Therefore, to draw a conclusion with help of it is not easy. Integration of environmental accounting with financial accounting, cost accounting and management accounting is a difficult task. User of environmental accounting needs to have adequate knowledge about rules and regulations and environmental aspects. In India, environmental accounting is still in the developing phase. It is a must for the corporate to formulate firm environmental policies for sustainable development.

Costs and benefits relevant to the environment are not easily available and measurable. Proper tracking of the use of energy and material or the cost of inefficient materials use, waste management and related issue is not done by many business and the Government organizations and they underestimate the environmental cost. It mainly considers the cost internal to the company and excludes cost to society.

The user of information contained in the environmental accounting needs adequate knowledge of the process of environmental accounting as well as rules and regulations prevailing in that country either directly or indirectly related to environmental aspects.

6. CONCLUSION

The primary challenge of environmental accounting is the absence of standards in identifying all that needs to be measured and deciding how it is to be measured. A number of initiatives have been undertaken to address the issues including the one undertaken by the United Nations. Experimental ecosystems accounting (EEA). An accounting framework for ecosystem is attempted to be developed by using a consistent set of principles to document information on ecosystem benefits as well changes to ecosystems over time. Wealth Accounting and Valuation of Ecosystems Services(WAVES), a World Bank let global partnership is also working in this area to promote sustainable development through implementation of NCA in several countries. However, the sheer intangibility of many of the resources does not lend itself for quantification and it is here that the concept of environmental accounting as a whole has not received the seriousness and commitment that it deserves.

One of the challenges of the reporting community at large in India is to improve comparability among environmental reports. Reviewed reports currently do not address issues on environmental reporting. It can be interpreted in any manner. Environmental accounting is a must for understanding the role played by natural environment in the development of an economy. It consists of data that contains the contribution of natural resources to the economic well-being and emphasizes on the costs imposed by environmental pollution and resource degradation. Reporters must give careful consideration to, how they identify issues for reporting. Even if researchers have propounded theories of environmental accounting, there is a need to investigate the feasibility and dependability of such studies by studying the longitudinal data. Involvement and commitment of corporate accountants in environmental management appears to be limited due to lack of regional reporting guidelines. Inviting inputs from stakeholders, while formulating guidelines, will be a valuable means of engaging stakeholders and enhancing mutual interests and priorities (Sustainability Ltd and UNEP, 1999). Such a bold and participative approach would ensure benefits of enduring value both to the industry and its stakeholders. Environmental awareness provides a transparent and dynamic way of reporting environmental performance for the business. It provides the internal and external users with reports which helps in capital decisions and pricing decisions. Environmental management accounting is more for the internal use of the business. Bartolomeo et al (2000).

Efficiency of the Indian economy is dependent to a great extent on business environmental efficiency. Environmental accounting reporting is concerned with cost and benefits arising due to the process and product of firms which also have environmental impact. It is very difficult to state whether corporate enterprises are environmentally sustainable ones. It is a must for the corporate enterprise to consider the impact on environment and then determine their profit level to assure that they leave the planet same at the start and end of the accounting period. Environmental accounting is vital and mandatory for a green economy. Developing countries like India may have to choose various possible approaches as per their needs, level of development and environmental management problems. Hence, a country wise analysis should be done based on a simple accounting framework with practical recommendations to comprehensively cover the needs of an economy for a successful planning process.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Moreover, the relationship between the business entity and the environment is receiving high attention. Environmental reporting is yet to find a permanent position in the financial sections of the annual report. Positive relationship exists between the profitability, size of the company. It indicates that the companies in India are becoming more enlightened as to the corporate environmental disclosures and social responsibility in this regard. At present, a debate on global climatic change and biodiversity is becoming more commonplace in corporate world, together with concern over water, air and soil pollution. Although the sustainability of economic development is a shared responsibility of organization and stakeholders, but business entities can play a vital role in slowing down the environmental degradation. A business entity has all the resources, technological knowledge, institutional capability and long-term vision to find out various environmental solutions. Effectiveness, efficiency and innovation can improve and streamline the manufacturing process, products with optimum use of raw materials along with decrease in the waste generated from production. Waste disposal methods and activities to keep pollution under control should be designed for quality environment management. Consequently environmental performance, customers' satisfaction and company performance will improve.

Environmental disclosure practices by Indian companies are of casual nature quantitative information and proper accounting pronouncements from regulatory authorities needs to be mentioned in the annual reports. The annual reports must disclose all information related to the environment. The lack of awareness and commitment on the part of company management about the social responsibility of the firm also keeps the firm away from reporting environmental costs and benefits. Thus, it can be concluded that the absence of a standardized environmental accounting practice and disclosure norms at national as well as international levels spur the corporate to be away from the environmental accounting practices and to shut their eyes towards the deterioration in the environment. In India, currently environmental accounting and reporting is at a preliminary stage and limited to demonstrating compliance to regulations and rules in the act to some extent.

Environment related disclosures in the corporate annual reports require due consideration. There are no latest company law and accounting standards; even ICAI does not prescribe the disclosure norms for environmental related aspects in the corporate financial reports. For few industries environmental accounting is mandatory such as oil and petroleum, natural gas, cement, steel, etc. For the rest environmental disclosures are voluntary in nature. The poor environmental performance of the company may also bind them to no-disclosure.

ACKNOWLEDGMENT

We are extremely grateful to Dr Rameshwar Dubey and his editorial team members for their high cooperation during the publication process.

Chapter 46
Development of the Green Economy in Romania:
Dimensions, Strengths and Weaknesses

Carmen Nadia Ciocoiu
Bucharest University of Economic Studies, Romania

Claudiu Cicea
Bucharest University of Economic Studies, Romania

ABSTRACT

The socio-economic context and globally discouraging trends observed in recent years regarding resource conservation and regeneration, control of climate change, technical, technological and informational inequality, progress gaps among nations and locally among citizens of the same country, have led to the need for developing policies, reforms and programs to support sustainable development. In this chapter the authors analyze some important issues regarding the Romanian experience in developing the green economy. They start with the background analysis of the concept, emphasizing several European Union documents regarding green economy and sustainable development. Then, the authors analyze the social and economic profile of Romania, in relation with some suggestive indicators of welfare, sustainability, equity and economic opportunities etc. Special attention is given to the environmental Performance Index (EPI) and Human Development Index (HDI). In the last part of the research, the authors present a short SWOT analysis for the green economy in Romania and several future research directions.

INTRODUCTION

In response to the environmental impact of current economic development, a new type of economy is promoted by the world countries, especially the developed ones. Although the concepts of "green products", "green investment" and "green energy" have been used in recent decades, the concept of green economy has been placed on the international agenda due to financial and economic crisis triggered in 2008. Green economy is seen as a framework for restoring economic growth, while addressing climate change and other issues of environmental sustainability and economic development.

It is obvious that there are many perspectives from which the concept of "green economy" can be analyzed. There are many economic schools with common ideas, but there are also schools with divergent views. Many of these ideas have been weak in showing that it can lead to a living standard at least equivalent to the current one. Often economic and social benefits of "green economy" were either poorly treated or incorrectly communicated.

Romania is among the countries that have rapidly adopted the concept of green economy; it has natural resources for its development, but has not yet recorded notable performances compared to other European countries.

The aim of this study is to provide an exploratory review of the extent to which the natural, social and economic profile of Romania is suitable for development of a green economy.

The first part presents some theories and practical issues related to the concept, and the last part discusses the threats and opportunities that arise through the development of green economy in Romania.

In this research we used a secondary data analysis conducted with national and European statistical data to highlight trends of indicators characterizing the natural, social and economic profile for Romania during 2004-2012 (www.insse.ro, eurostat.eu). Was also used the SWOT analysis to obtain a qualitative diagnosis of green economy stage of development. This study was conducted using various sources of information, such as national strategies, European and world reports of the various competent authorities in the field.

BACKGROUND

Simply said, the concept of "green economy" can be considered a synonym of the term "sustainable economy". However, the concept of "green economy" is often understood in a more distinctive sense that specifically focuses on the fundamental changes necessary to ensure sustainability of economic systems.

Ecological, industrial and environmental economic sciences are the three disciplines closely related to the "green economy" term (Huberman, 2010).

The term "green economy" was first introduced in a report to the Government of the United Kingdom in 1989 by Pearce, Markandya and Barbier, a group of environmental economists, in their work "Blueprint for a green economy". They aimed to advise the government on the existence of a single definition for "sustainable development" and on its implications for measuring economic progress and evaluating policies and projects. The term was not, however, defined; it was only mentioned in the title. Afterwards it followed another series of papers on the same subject: *Blueprint 2: Greening the world economy*, *Blueprint 6: For a sustainable economy*, and among the most recent: *New Blueprint for a green economy*, in 2012.

Measures to adopt green economy policies were initially discussed in international negotiations in 1992 at UNCED in Rio. The Rio Declaration included principles that promote eliminating unsustainable consumption and production (Principle 8), internalization of environmental costs and the use of economic instruments (Principle 16). 21 Agenda further elaborated these principles, integrating national expansion strategies, legal framework and regulations, as well as systems for integrated environmental and economic accounting. It was then when the United Nations Framework Convention on Climate Change (UNFCCC) was developed; it aimed economic, regulatory and market measures to control climate change by reducing carbon emissions.

In 2002, through Johannesburg Implementation Plan (JPol) the need to change production and consumption has been identified; a 10-year framework for sustainable consumption and production programs was designed. In 2003 and 2005 the International Meetings of Experts marked the need to promote social and economic expansion within the environmental capacity limits.

With the new context of 2007-2008, there have been attempts to simultaneously face economic crisis and to build a new system for attempting a transition to protect the environment and resources. So they developed "green incentive packages" and focused on specific areas where large-scale public investment could start a "green economy" (Atkisson, 2012).

Goals that characterize the "green economy" are the welfare of mankind and reduction of long term environmental risks. Many national economic stimulus plans were proposed or adopted in late 2008 and early 2009 and had a "green" part, such as in the U.S., Japan and South Korea, New Zealand and Australia.

The aspiration to sustainable economy is supported by the European Union's 2020 strategy (European Commission, 2010) which aims to develop: a smart growth (which involves education, knowledge and innovation); sustainable growth (promoting a more efficient economy in terms of resource use, greener and more competitive); inclusive growth (employment at the highest level, economic, social and territorial cohesion).

European Commission (2011) considers the green economy as one that "generates growth, creates jobs and eliminates poverty by investing in and preserving the natural capital on which depends long-term survival of our planet."

In 2008, the United Nations Environment Programme (UNEP) has launched an initiative called Green Economy, which culminated in 2010, with the publication of a report on the Green Economy. In this report, United Nations Environment Programme (2010) defines a green economy as the process of reconfiguring businesses and infrastructure to get a better return on natural capital investments, human and economic investments, while reducing emissions of greenhouse gas emissions, extracting and use of fewer natural resources, creating less waste and reducing social disparities.

The green economy has rapidly evolved from the theoretical and global side to the national and practical level. According to Barbier (2009) global recession requires a global initiative and vision. He believes that Global Green New Deal is the necessary response to these challenges.

Also in 2008, the Organisation for Economic Co-Operation and Development began working on an ambitious green growth strategy, defined as a way to continue economic growth and development, while preventing environmental degradation, biodiversity loss and unsustainable use of natural resources (Organisation for Economic Co-Operation and Development, 2011, p 9).

The world is in transition to a "green economy". It is understood that this is a long-term change, since today till in 2050, that will have different levels of intensity for different countries according to their motivation to develop in general and specifically at a social level and according to trade revitalization plans and poverty solving (DeLacy & Lipman, 2010).

Green economy aims investment in natural capital, economy decarbonisation and creating green jobs. According to United Nations Environment Programme (2010), this concept can be applied in various sectors such as agriculture, tourism, forestry, fisheries, industry, construction, transport, urban planning, renewable energy, water and waste management. The UNEP (2011) demonstrates that the transition to a green economy is possible by investing 2% of GDP (1.3 trillion $) per year from now until 2050 to greening sectors mentioned above; these investments must be supported by national and global policy reforms (Schmalensee, 2012).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

From this perspective, there are various ways in which green economy can favor both developed countries and developing ones. This type of economy should maintain, and also intensify the value derived from agriculture, fisheries and forestry, and all activities that depend on a protected environment, for underdeveloped countries. In the same time it should also reduce limits on energy quantities by providing renewable energy distribution systems at low cost; it should minimize their vulnerability to the impact of climate change, desertification, water degradation and biodiversity loss before as well as local impact of water, air and soil pollution. Green economy should generate both in the developed and developing countries, new innovative activities, and activities that create more jobs than traditional sectors, and increase industrial efficiency and energy security (Cosbey, 2011).

Although this concept is defined globally, it has a specific application: priorities and actions taken to facilitate the transition to a green economy can vary from sector to sector, from a value chain to another and according to individual national conditions (International Chamber of Commerce, 2011).

The transition to a green economy will considerably vary from one nation to another, as it depends on the specific of natural and human capital of each country and on its relative level of expansion. To achieve this goal a number of applicable conditions will be needed; these will consist of national legislation, policies, subsidies and incentives, international protocols for trade and assistance, market and legal infrastructure. Currently these conditions are oriented towards and encourage "brown economy" or "black economy" (United Nations Environment Programme, 2011). This black type of economy means that economic growth depends on petrochemicals such as coal, oil and gas and that production is realized with large amounts of carbon dioxide that are released into the atmosphere, resulting in air pollution and depletion of natural resources.

In the United Nations Environment Programme (2011) report *Towards a Green Economy. Pathways to Sustainable Development and Poverty Eradication*, is stated that a green economy grows faster than a brown economy, maintaining and restoring natural capital. Now, we live in a world where the pursuit of economic growth - defined as the real rate of gross domestic product growth - is one of the priorities of governments, private sector and even some segments of civil society, many of them dependent on the increase for financial support and overall stability. Therefore, the transition to a green economy without undermining economic growth would be a positive thing.

The green economy aims both the public and private sector. The difficulties that communities from developing countries are facing, as a result of climate change, raise problems for the business sector. Communities' risks are also business' risks. Local and global companies depend on community members as suppliers, customers, labor and resources, services and local infrastructure in order to operate. Companies that connect the community's welfare and their viability and that adapt to climate change having customers as a main concern, can gain competitive advantage, or the opposite may lose their reputation. To make the transition to green practices, companies must connect climate adaptation and resistance to organizational culture, to start from existing initiatives, to integrate climate adaptation to central processes of strategic business planning, to align goals with the priorities of adjustment, to build a portfolio of climate-specific goods and services, to build mutually beneficial relationships with stakeholders, to have partnerships with internal and external decision makers (World Resources Institute, 2011). So far, companies have been the ones that have achieved significant results in the fight against pollution, extraction and resource depletion (Kohr, 2011).

Green entrepreneurship is seen as the engine for the establishment of an economic - social - environmental holistic and sustainable system (Gibbs & O'Neill, 2012). For this it is necessary to establish a link among education, training, employment and environmental policies. Availability of skills for green

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

jobs has a crucial role in triggering change and facilitating a smooth and timely transition. Green sectors will require new types of jobs, while re-qualifying the existing ones. A well trained human resource and environmental conscious will also be more innovative in resource efficiency. Green technologies offer the possibility of new jobs for those who will quickly respond to the new paradigm (Pop, Dina & Martin, 2011).

Many of the costs required to start business in the green economy are high, especially those that are related to energy production. Research, development and investment in green energy are very expensive and still in an early stage. This aspect is not perceived as entirely economically viable for public.

Although green economy opportunities have been extensively discussed, the threats arising from the transition to a green economy have been treated within the holistic framework provided by UNCED, Rio Principles and Agenda 21, as shown in a few major works, among which: „Report by Panel of Experts on The Transition to a Green Economy: Benefits, Challenges and Risks from a Sustainable Development Perspective" (UN-DESA, UNEP &UNCTAD), „A Brief for Policymakers on the Green Economy and Millennium Development Goals" (United Nations Environment Programme, 2010).

The main risks that can be generated by switching to green economy are: its application in an unidimensional form, the "single size" approach, the adoption of protectionist trade policies, handling grants and financial aids, deepening social tensions, increase of population migration, the introduction of overly rigid standards for products marketed by developing countries, and others.

Moreover, countries of the world develop national policies and strategies to ensure the development of green economy and mitigation of risks arising from.

Although aspects of sustainable development in Romania are treated in numerous papers and from different perspectives, the same cannot be said about the green economy issue. Romania's situation regarding the dimension of green economy is briefly presented, among other countries, in some global and regional studies drawn up by international organizations.

A recent study by Deichmann and Fan (2013) includes Romania (among other countries) as a case study to analyze the economic benefits of implementing green economy. This report shows that rapid progress in energy efficiency, a shift to cleaner energy systems and a better management of green natural resources will bring benefits in climate action in Romania.

The employment dimension of green economy is treated extensively in the reports of project *New skills for green jobs: the case for a more gender inclusive labour market?* (2012), co-funded by the European Commission, DG Employment, Social Affairs and Inclusion in the framework of the PROGRESS programme. According to the final report (2012) in Romania there is a wider policy concern with building the capacity of the education and training system in order to develop occupational standards for green jobs.

The main national document that includes items related to policies and strategies to develop the green economy is the *National Sustainable Development Strategy Romania 2013-2020-2030* realized by the Government of Romania and United Nations Development Program (2008).

GREEN ECONOMY DEVELOPMENT POTENTIAL IN ROMANIA

The Romanian economy has been marked over the years by many transformations, mainly generated by the political regime and the vision regarding economic and financial resources' destination. Lack of stability at micro and macro-economic level and the consistency in the application of clear stratagems

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

of economy expansion led to a delay in our country development, despite the potential of natural capital and favorable geographical position at the crossroads of many trade exchange centers.

Despite the progress made in recent years is a fact that Romania still has an economy based on intensive use of resources, a society and a government still in search of a single vision and a natural capital affected by the risk of damages that may become irreversible.

In the second decade of XXI century after a difficult transition to a market economy, Romania has recovered significant differences compared to the other Member States of European Union, together with learning and putting into practice the principles and practices of sustainable development in the context of globalization.

Economic and financial crisis that covered the globe after 2008 emphasized the confusion state of the economy and halted for the moment the favorable situation that characterized our country once with the influx of investors who were operating in various areas of Romania.

Camasoiu, Caragea and Cristea (2013) present the importance of the green economy for Romania in the context of sustainable development and conclude that the sectors as agriculture, forestry, fisheries, food, as well as parts of chemical, biotechnological and energy industries have a large innovation potential based on sciences (life sciences, agronomy, food science, social sciences) enabling and industrial technologies (biotechnology, information and communication technologies) and local knowledge.

According Costache (2012), bio-agriculture, renewable energies, research and development, waste management are the sectors with the main potential for green growth and green jobs. Between obstacles facing green growth the author includes: lack of financial resources and funding, insufficient human resources at the institutional level responsible for formulating and implementing policies, lack of specialised staff, and a lack of implementation of strategies.

Natural Profile of Romania: Indicators of Natural Capital and Environmental Efficiency

The natural capital as well as the extent to which a country effectively uses it and protects its environmental assets is one of the green economy's dimensions that should be considered in the analysis.

Romania, a medium-sized country in the European Union, presents a variety of natural resources and geo-climatic conditions extremely important. These include: 94 habitats (out of 198 in Europe), 13 national parks, 14 natural parks, more than 20 billion tonnes of untapped mineral resources (nonferrous minerals, iron, salt, etc.), 150 types of forest ecosystems, 227 types of forests, 3,480 rivers, 246 alpine lakes, 105 species of mammals, 216 species of fish, 3,630 species of plants, etc. (NIS, 2011).

As shown in Table 1, water resources had a fluctuating trend, the total area covered by forests remained relatively constant between 6,233 to 6,354 thousands ha. The harvested wood slightly increased, while net annual wood growth parameters remained around the same value.

Similar to the EU-27, In Romania there is a general downward trend in emissions of greenhouse gases (including CO_2) a trend that should be encouraged in accordance with the objectives set in the National Strategy for Sustainable Development; it foresees for a reduction of greenhouse gas emission with 20% by 2020. The largest amount of emission is found in the energy sector, followed by industry and agriculture, 16776 tons, representing a situation valid for most of European countries. According to Eurostat, Romania has a low level of acidifying substances emissions (SO_2, NO_x şi NH3) and consistently decreasing; it also has the lowest amount of nitrogen fertilizer in Europe, less than 30 kg per hectare (Table 2).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

NIS data on total and per capita domestic material consumption, exhibit a yearly increase of this indicator, the most significant increase occurring in minerals consumption and for waste level. The upward trend is interrupted in 2009 due to the financial crisis effects. Also for this chapter, Romania has a relatively low level of collected waste per capita and an extremely small recycling rate, but with real growth tendencies.

These indicators show the potential of Romanian natural capital which supports the development of green economy relying on reducing greenhouse gases emissions and acidifying substances, as well as on natural resources that are superior to many other European countries.

Social Profile of Romania: Indicators of Welfare, Sustainability, Equity, and Sustainable Transportation

The United Nations Conference on Sustainable Development (or Rio +20) held in 2012 in Rio de Janeiro had the theme "Green Economy for Sustainable Development and Poverty Eradication". By explicitly linking the green economy with sustainable development objectives and poverty eradication, the Rio +20 process emphasized the importance of the social dimension of development.

A series of indicators of welfare, sustainability, equity and sustainable transport reflects the social dimension of the green economy in Romania.

It can be observed that the percentage of population connected to wastewater treatment plants increased from year to year, while the number of people aimed by those benefits evolved from 6,068,655 persons in 2006 to 6,582,104 in 2010; between 2009 and 2010, an increase of 345,579 persons was registered. An increase was experienced in the period under review for life expectancy at birth from 71.01 years to 73.43 years in 2010; in the gender wage gap level, from a share of 6.5% in 2006 to 11.6% in 2010; in green areas, from 20,098 ha in 2005 to 22,005 ha in 2010; in energy consumption for road transport, from 3,847 toe in 2003 to 4,734 toe in 2011; in air transport from 119 toe to 227 toe in 2011 (Table 3).

Energy consumption in both rail and waterway transport fluctuated in recent years due to fluctuations in the economy's evolution.

A slight increase was perceived in public expenditure on education as percentage of GDP, from 3.6% to 4.3% by 2011, but insufficient for current needs of the Romanian society.

Economic Profile of Romania: Indicators Regarding Response Policies and Economic Opportunities

A series of economic data such as investments for environment protection, expenditure on research and development (R & D) and renewable energy production, allow the characterization of a country economic potential to develop green economy.

Measures taken by national and local authorities in Romania to manage environment problems include investments oriented towards preventing and fighting pollution, natural resources protection and biodiversity conservation and other fields.

The largest investments for environment, in 2010, headed to first category reaching a total value of 3,598,479 lei; the highest percentage was recorded for fighting pollution in production and supply of electricity and for water supply and sanitation (Table 4).

According to the latest National Institute of Statistics data, the total expenditure for R&D in 2010 were 2,045,132 lei (as we can see in the Table 5), of which the largest share of the fields included in the

green economy was held by agriculture, with 170,729 lei, a relatively low value for the ordinary needs of a European country; ranked last is education, where there were spent 40,568 lei (National Institute of Statistics, 2011).

As it can be seen in Table 6 - Environmental taxes, Romania has a low level for revenues from environmental taxes share in the GDP, reaching a peak of 3.9% in 1999 and a minimum in 2008 of only 1.8% (EU average is 2.6% in 2010). From the total revenues from environmental taxes obtained by our country, the most significant share is held by taxes imposed in the energy field, fluctuating between 1.4 and 2.1% in recent years. Transportation tax imposed by local authorities had an upward trend, rising from 0.07% in 2001 to 0.36% in 2008, and later on descending. In the opposite direction, the share of taxes on pollution in GDP has decreased considerably from year to year, currently having an insignificant level. According to a study undertaken by the Center for Sustainable Policies Ecopolis (2011), our country recorded one of the lowest revenues from environmental taxes as a percentage of GDP; this translates into a total national inefficiency in terms of energy, low taxes and minimum excise adopted for electricity and fuels having negative effects on environment protection and on the effort to reduce the human intervention on it.

Table 5. R&D expenditure (2010)

The green certificates market registered considerable growth in Romania. A green certificate is a document confirming the 1MWh use of electricity from renewable sources, specifically non-fossil, such as solar, wind, geothermal, aerothermal, hydrothermal, hydropower, biomass, waste fermentation gas and sludge (from wastewater treatment plants) fermentation gas and biogas. According OPCOM (Romanian gas and electricity market operator), the national body responsible for supervising and trading green certificates in Romania, those are subject to a national mechanism which promotes the production of electricity from renewable sources by a quota system imposed by the acquisition of such certificates. Their value represents a supplement for producers received for "greening" the delivered energy; the price is set on the centralized market of green certificates (PCCV). Data in Table 7 shows that both the number and value of transactions with green certificates have increased considerably over the years, starting from 7841 certificates traded at a price of 155 RON / certificate to 410,628 certificates sold at a price of 241 RON / certificate.

Green energy has a critical potential for the economic development of our country. Currently, the Romanian electricity market has producers from all sectors of renewable energy, some achieving remarkable results. In Table 8 one can observe the fluctuating evolution of RES share in total electricity produced, the values being still high.

According to the study by Ernst & Young (November 2012), Romania is the main actor of Eastern Europe in the renewable energy chapter. In their ranking, our country ranks 13 in the index for all forms of renewable energy, ahead of countries like Poland, South Korea, Spain, etc.; it also ranks 10th for wind energy and 24th for solar energy, from 40 analyzed countries. The favorable situation of Romania is mainly due to substantial investments in RES-E programs (especially wind energy) from recent years. Solar energy is still underdeveloped, but announces a capacity for future growth due to improving the legal framework of authorization.

Romania has a great and diversified potential for renewable energy, estimated at 1.2 TW for solar energy, 23 TW for wind energy, 36 TW for hydropower (NIS, 2013).

Environmental Performance Index (EPI) and Human Development Index (HDI)

In addition to data characterizing natural, social and economic profile of a country there are a number of indicators that complete the performance analysis on sustainable development and green economy.

Table 7. Evolution of green certificates in Romania

Transactions	2006	2007	2008	2009	2010	2011
Number	7,841	37,703	95,593	141,607	248,694	410,628
Value (euro)	269,143.82	1,293,939.97	3,355,240.88	6,825,921.12	13,029,068.18	22,761,359.77

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Among these, Environmental Performance Index (EPI) by Yale University designed and Human Development Index (HDI) calculated by the United Nations Development Programme (UNDP); they are relevant as they measure how countries act to protect human health from the damage caused by environment and how they act to ensure ecosystems' protection, increase life expectancy, literacy, education and standard of living.

Environmental Performance Index (EPI) for 2012 compares and ranks 132 countries (30 in Europe, including Romania, 24 from America, 21 from sub-Saharan Africa, 18 in the Middle East and North Africa, 18 in Eastern Europe and Central Asia, 21 in the Asia Pacific region) worldwide, according to 22 indicators grouped into ten categories: environmental impact on diseases, the impact of water on health, the air pollution effects on health, air pollution effects on ecosystems, water resource effects on ecosystem, biodiversity and habitat, forestry, fisheries, agriculture and climate change.

These categories, and implicitly the indicators, track progress and performance of each country based on two objectives: environmental health and ecosystem vitality. For each indicator there is a target, which helps to achieve the final score along with weights and scores associated to each.

This index also outlines trends in the environmental performance of each country in the last decade, and the authorities' commitment for the future.

Romania ranks 88 of 132 countries in the EPI ranking, with an overall score of 48.3 (see Table 9), a similar performance to that of other countries, such as Ukraine, Cuba, Mexico, Azerbaijan and the Dominican Republic. Regarding the two major objectives of EPI, environmental status and ecosystem vitality, our country has achieved a score of 60.7, respectively 43, ranking 78 and 84.

Our country has achieved a high score of 51.6 for agriculture (through subsidies and regulation of pesticides), a score of 93.2 for forests (loss, covered areas and regeneration) and a score of 77.5 for diseases caused by the environment. Favorable positions are occupied by Romania in the categories: fisheries - rank 14, forests - rank 32, illnesses caused by environment - rank 55, and agriculture - rank 66.

In terms of trend analysis, our country occupies a very good position, 3rd, after Latvia and Azerbaijan, showing improvements for agricultural subsidies, fisheries and climate change. As a trend, Romania has a performance level similar to France, Belgium, Italy, Albania and Great Britain.

Switzerland, leader of Environmental Performance Index in 2012, achieved an overall score of EPI of 76.7, with 28.3 points more compared to our country, similar to France, Great Britain, Lithuania, Germany and Latvia. For the first objective of the EPI, the environmental status, Switzerland has gained 93.2 points, with 32.5 points more than Romania. In this category, Switzerland excels in air effects on health, which aims to minimize the use of solid fuels with serious repercussions on human health, for which it has a maximum number of points. 100 points are recorded also for water effects on health, and public access to sanitation.

Regarding ecosystem vitality, Switzerland is ranked first with a score of 69.6, with 26.6 points more than Romania. In this section, Switzerland stands out at biodiversity and habitat, with 98.1 points, at air effects on the ecosystem with 72.6 points, compared to only 21.4 points for our country, and at water resources with 50.8 points compared to only 25.7 points for Romania. Instead, our country succeeds in obtaining better results as regards forests and agriculture, where Switzerland is ranked 109. In trend level, Switzerland is ranked 89 with a score of only 2.4 for EPI trend, similar to countries like Japan, Venezuela, Togo, Canada and Colombia.

Bulgaria holds 53 the position of 132 countries with a score of 56.3 points, with 8 points more than Romania. For the two objectives, Bulgaria has achieved a better score of 92.2 than our country in the environmental status, but less than Romania (rank 43) in the ecosystem vitality level of 40.9 points.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Bulgaria's performance is similar to Cyprus, Israel, Malta, Greece and Canada. This country has a better score than Romania in agriculture, 60.1 compared to 51.6, in biodiversity and habitat, fisheries and forests, in the latter being a leader. Bulgaria performs bad in air effects on the ecosystem, climate change and water resources; at trend level it occupies the 16th position.

Human Development Index (HDI), is globally applied at the level of 187 countries by the United Nations Development Programme to measure social development based on combining several relevant indicators, life expectancy at birth, educational stock (average number of years spent in an education institution and schooling expected value) and gross national product per capita; they are grouped into three dimensions: health, education and living standards. HDI requires a minimum and a maximum for each dimension (frame) and measures the performance of each country in relation to them by providing values between 0 and 1.

In this ranking, Romania ranks 56, with an HDI of 0.786 (as we can see in Table 10), above the regional average value of 0.771, an increase of 11 percent over 1990. According to this indicator, Switzerland ranks ninth with a score of 0.913, and Bulgaria is situated after our country, 57th with a close value for HDI of 0.782. In terms of health index, Romania allocates a percentage of 4.4% of GDP for public health, less by 2.4% compared with Switzerland and with 0.7% more than Bulgaria. Life expectancy in our country has grown in recent years from 69.6 to 74.2 years, an average quite low compared

Table 9. Environmental Performance Index (2012)

Category (2012)	Romania				Switzerland				Bulgaria			
	Performance		Trend		Performance		Trend		Performance		Trend	
	Score	Rank	Scor	Rank	Score	Rank	Score	Rank	Score	Rank	Score	Rank

Population living with less than 1.25$ / day (%)	0.4	-	0.05
Gender inequality - index	0.327	0.057	0.219
Participation in the labor market	0.749	0.808	0.806
Innovation and Technology	-	-	-
Fixed and mobile subscribers per 100 people	135.9	177.7	164.9
Income - index	0.694	0.886	0.700
GDP per capita ($)	10905	37979	11799

Source: United Nations Development Programme (2013).

to Switzerland which has seen an increase from 75.7 to 82.5 years. In the education index, Romania has an average of 10.4 years of schooling, close to the values of the other two countries. In the other aspects, the (income) inequality index, poverty, gender inequality, innovation and technological development, our country has unfavorable values. GDP per capita shows that Romania is behind both countries with which the comparison is made.

THREATS AND OPPORTUNITIES REGARDING GREEN ECONOMY DEVELOPMENT IN ROMANIA

Based on the above presented elements, strengths and weaknesses, threats and opportunities of the green economy development in Romania were identified and presented in the Table 11.

FUTURE RESEARCH DIRECTIONS

Given the importance of the topic and its novelty, green economy development in Romania will remain on the agenda of various national and international institutions and many authors.

The main directions of future research include, but are not limited to, the following:

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 11. Strengths and weaknesses, threats and opportunities of the green economy development in Romania

Strengths	• The increase in the renewable energy resources use for electricity and heat production by improving the green certificate market; promoting mechanisms to support renewable energy resources usage in energy production. • Solving energy-intensive buildings problem, which account for 40% of carbon dioxide emissions through energy auditors certification activities, a program for thermal rehabilitation of buildings, development of a calculation methodology, interest subsidy on loans requested by buildings owners. • Well-trained human resources for various fields applicable to the introduction and development of green economy. • IT and technological potential for developing green technologies. • Annual investments in R&D activities in areas related to green economy. • increasing the number of green certificates sold in recent years to entrepreneurs. • Low level of acidifying substances in our country (SO_2, NO_x and NH_3) and the lowest amount of nitrogen fertilizers in Europe, less than 30 kg per hectare. • Downward trend in greenhouse gases emissions. • Increasing tendency for using waste to produce electricity. • Significant natural capital of our country. • Increases in the number of people connected to wastewater treatment plants, in the life expectancy, in green areas and in public spending on education as a share of GDP. • Agriculture potential of "greening", by reusing traditional methods of growing plants and by applying for grants.
Weaknesses	• Lack of a vision and a clear strategy on adopting measures for the introduction of green economy in all economic and social sectors. • Confusion among citizens regarding the existence and application of a unitary national policy for regulating green economy (national sustainable development strategies, government spending directed towards green sector, taxes on pollution, limiting carbon emissions, waste management policies). • Lack of publicity for this phenomenon. • Perceived impact of chemicals on health. • Urban problems (pollution, noise, traffic, etc.). • Uncertainty regarding policies for currently granting green certificates. • Small level of investment for natural resources protection and biodiversity conservation in recent years. • A low level of revenues from environmental taxes, below the European average.
Opportunities	• Measures to improve the environment in rural areas and biodiversity through sustainable management of agricultural lands, investments financed by the National Rural Development Programme. The environmental investments contribute to creating new jobs specific to green economy; we mention services in the environmental field, including development and maintenance of the necessary infrastructure (for instance: waste management, pollution control, maintenance of protected areas, the production of energy from renewable resources, prevention of natural risks, even activities from outside the environmental sector such as protecting natural heritage) offers an important prerequisite. • Continuous expansion of wind energy sector by developing new wind parks. • Solar energy market development through foreign investment (for instance Lukoil). • The entry on the "low-carbon" product market (solar panels, green materials, green supplies, etc.). • Improving transport efficiency through the introduction of alternative fuels. • Restructuring all interest systems (education, health, tourism, agriculture, forestry, etc.) and the achievement of necessary performance for our country's progress. • Promoting eco-tourism. • Reducing dependence on fossil fuels. • Creating new jobs through related areas that include green economy. • Innovation by creating sustainable products. • Increase economic competitiveness by raising the efficiency of resources use in production. • Accessing new markets for organic products, and increase of exports. • Designing a new sustainable development strategy that focuses on actions and not on objectives.
Threats	• Negative perceptions of citizens on issues that will affect community in the next five years: the need for economic development, creating jobs, clean water, waste management. • Reducing subsidies to photovoltaic energy sector and therefore stopping the advance in this area. • Lack of cooperation from authorities and citizens. • Demographic decline. • Lack of unity in development strategies. • High costs for green investments. • Extending economic and financial crisis. • Reluctance of consumers to change their consumption habits. • High prices associated with green products.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

1. Study on the competitiveness of the Romanian eco-industry, especially of small and innovative companies acting in the field of renewable energy, waste recycling, environmental auditing and consultancy.
2. Study of the synergy between digital economy and green economy in Romania and the place of innovation. Innovation in the green economy is in the form of a mix of green innovation, industries, and regions. It is important to realize the potential of ICT-based innovations for a greener economy.
3. The barriers and opportunities for green investment in Romania. Beyond the known infrastructure investment barriers and constraints, the challenge will be to identify the premises for green investment in Romania and what actions are needed to effectively increase green investment. In the same context must be examined the gap between business-as-usual investment levels and the amounts needed to address climate change and other environmental challenges.

CONCLUSION

Changes in investment patterns, technology, production and consumption associated with sustainability, often referred to as green economy are central in international circles. Economic and social development, in terms of sustainability, represented in recent years a major goal of many countries in Europe and beyond. To achieve this goal, the forms of government in different countries have developed national strategies, including both country-specific policies and general methods recommended to be worldwide adopted by specialized institutions, under Agenda 21 and the Rio Declaration.

There are many different assessments of the opportunities, costs and benefits of the transition to green economy for different social groups, countries and regions and also divergent views on the various approaches to achieving social, environmental and economic goals, inherent in the concept of sustainable development.

Romania, in the National Strategy for Sustainable Development 2013-2020-2030 Horizons, developed by the Ministry of Environment and Sustainable Development, analyzes the challenges in its attempt to make the transition to a green economy in relation to the objectives imposed at European level, and considers the following:

- **Climate Change and Clean Energy:** Romania's strategy aims at an optimal level of energy in the short, medium and long term and the prerequisites establishment for achieving energy security, the fulfillment of obligations to reduce emissions of greenhouse gases by 8%, and ensuring the energy system functioning and the development of measures to manage climate change.
    - **Actions:** Continuing the process of 35% energetic rehabilitation of residential and commercial buildings, connecting new electricity generation units, two new reactors and increasing awareness of the importance of climate change effects.
- **Sustainable Transport:** Continuous change of transport infrastructure, reducing the amount of used resources and the achievement of sustainability parameters as required by EU average level, by providing financial and technical conditions for infrastructure modernization projects, ensuring funds and completion of projects from the Operational Programme 2007-2013, extending the traffic management system.
- **Sustainable Production and Consumption:** The control of sustainable resource consumption by adopting a model of sustainable consumption and production to increase sustainable performance;

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

decoupling economic advance from environmental degradation by changing the ratio between resource consumption and added value creation;
    - **Actions:** Analysis of products impact on environment throughout their life cycle; supporting R&D activities; promoting digital technologies; reducing specific consumption of materials, etc.
- **Natural Resources Management and Conservation:** Reducing the current gap on environmental infrastructure compared to other EU member states;
- **Public Health:** Improving the structure of health system the quality of medical act and patient care through national programs implementation.

The transition to a green economy is a complex process, which raises difficulties for both developed and developing countries. To simplify the adoption of this phenomenon is important to design a national strategy based on the specific characteristics of Romania, on natural capital, human resources and the actual technological potential.

Through this study we aimed to identify threats and opportunities for the introduction of the green economy in Romania. As it can be seen from the analysis, there are currently a number of significant threats that can pose obstacles to the introduction of green economy, such as halting the advance in solar energy by reducing subsidies, lack of clear implementation tactics, the prices associated with green products, current crisis, etc.; there is also a number of opportunities, such as continuous expansion of wind energy sector and the favorable position of Romania among countries with claims in this area, entering the low carbon products market, etc.

The conclusion of this research is that Romania's transition to a green economy and its subsequent expansion will be a difficult process, given that our country is still in a poor stage of development in all sectors of interest, which require a complete restructuring as a preparation for full implementation of this concept; however, there is natural potential for its development.

KEY TERMS AND DEFINITIONS

Energy Efficiency: A very broad term that refers to the many ways in which we can achieve the same benefit (light, heat, motion, etc.) using less energy. The field covers efficient cars, light bulbs, improved industry practices, better insulation of houses and a range of other technologies. Because saving energy means saving money, energy efficiency is very profitable.

Environmental Investment: Investment for researching, proposing and implementing solutions to climate change which seeks to consider both financial return and social good.

Green Certificate: A document confirming the 1MWh use of electricity from renewable sources, specifically non-fossil such as solar, wind, geothermal, aerothermal, hydrothermal, hydropower, biomass, waste fermentation gas and sludge (from wastewater treatment plants) fermentation gas and biogas.

Green Energy: Also referred as clean energy or renewable energy. Energy from sources that either regenerates itself in a short time or are practically inexhaustible sources (solar energy, the wind, flowing water, biological processes, geothermal heat).

Natural Capital: Capital stock derived from natural resources such as biodiversity, ecosystems and the services they provide. Natural capital of a geographical or political-administrative area consists of ecological systems that function in natural or semi-natural regime and anthropological systems resulting from transformation and simplification of the above category.

Sustainable Consumption: The consumption which is looking at how the goods and services improve quality of life by keeping the energy, material and pollution intensity of all consumption functions within the carrying capacities of natural ecosystems.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Sustainable Production: The production of goods and services that respond to basic needs and bring a better quality of life, while minimizing the use of natural resources, toxic materials and emissions of pollutants and waste over the life cycle, so as not to jeopardize the needs of future generations. The sustainable production is focusing on improving environmental performance in key economic sectors, such as industry, agriculture, energy, tourism and transport.

Chapter 47
Exploring Landscapes in Regional Convergence:
Environment and Sustainable Development in South Asia

Srinivasan Rajamanickam
Pondicherry University, India

ABSTRACT

The South Asian region is a key economic zone, as seen from the global perspective. In the past two decades, it has witnessed a healthy growth in GDP terms. Globalization has propelled the countries in the region towards regional cooperation as a means to address common growth concerns. Along with geo-political compulsions that have fostered this convergence, we find that there are also socio-cultural and historical factors present that could serve as binding stones. However environment and climate change pose a huge challenge to the economic integration and growth in this region. While a number of institutional and policy regional cooperative measures have been put in place, there are certain bottlenecks in the region, which are again a product of its history, that need to be addressed. We feel that reassessment of national interests and priorities through strong political will are essential to mitigate these bottlenecks to realize the true potential of convergence in this region.

This is not just a technical issue. Everybody's actions are motivated by their inner life, their moral, spiritual and ethical values. Global agreements will be effective when they are rooted in the individual commitment of people, which arises from their own inner life. -Maurice Strong, Chair, Rio Earth Summit, 1992

INTRODUCTION

Sustainable development has emerged as a core theme of government policies, international cooperation, aid agency norms and civil society concern. Developing countries of the world have increasingly attuned their policies striving to balance developmental programs with conservation of natural resources that

sustain large rural populations depending on agriculture, forestry and related vocations. South Asian countries in particular have unique circumstances influencing their programs in this regard. The Himalayas, from where the major rivers of the region originate, straddle across five of the region's countries viz., Afghanistan, Bhutan, India, Nepal and Pakistan. Barring Sri Lanka, all the countries share waters of these rivers and exploit the ecological resources that the Himalayas and river systems offer. The seas surrounding the region are a major source of livelihood and the forests in the region are home to nearly a fourth of the region's population. The statistics published by the Asian Development Bank (ADB) indicate that the region has about 23% of the world's population and 15% of the world's arable land, but receives less than 1% of global foreign investment and tourism revenues, only 2% of global GDP, and 1.2% of world trade. Furthermore, South Asia is still home to about 410 million of the 720 million poor living in the Asia-Pacific region despite the rapid economic growth in India and, to a lesser extent, other countries. Of the 1.4 billion people in South Asia, 42% or 488 million live on less than a dollar a day (World Bank, 2008). In addition, key indicators suggest that social development still remains relatively low when compared to other Asian regions (ADB, 2006). Occupying about 5 per cent of the world's land mass, its population is expected to rise to about 25 per cent of world's population by 2025. Three-quarters of South Asia's population lives in rural areas. UNEP concludes that South Asia is very vulnerable to climate change. Impacts of climate change have been observed in the form of glacier retreat in the Himalayan region, where the approximately 15,000 glaciers will likely shrink from the present total area of 500,000 km^2 to 100,000 km^2 by 2035. These glaciers form a unique reservoir, which support perennial rivers such as the Indus, Ganges and Brahmaputra, which, in turn, are the lifeline of millions of people in South Asian countries (Bangladesh, Bhutan, India, Nepal, and Pakistan). This will exacerbate the challenges of poverty reduction and improving access to safe drinking waters, two of the Millennium Development Goals (UNEP, 2009). The region is considered to be the least economically developed as a geographical sub-region and their biggest as yet challenge seems to emanate from environment. Bindu Lohani (2014), ADB Vice-President for Knowledge Management and Sustainable Development says, "South Asia's economy is under serious threat and the lives and livelihoods of millions of South Asians inhabiting the region's many mountains, deltas, and atolls are on a knife edge. Countries must respond individually and collectively to cope with rising sea levels, disrupted water, food, and energy supply and increased disease".

While it is so, the region suffers from overt to subtle political imbalances that prevent convergence of energies towards addressing the issue of sustainable development. External conflicts and internal security challenges, partly from inherited colonial legacies and partly from perceived assertion for regional supremacy, have ridden the region through the past seven decades. These have created stalemates in regional dialogues towards convergence. It is evident that these obstacles can only be surmounted through constructive political will which is prepared to set aside narrowly defined 'national interests' for achieving common regional good. While the question of settling boundaries and defining maritime limits may take prolonged timeline, the issue of convergence on environmental challenges merits immediate attention as it has the potential to add to economic growth agenda and directly contribute to improving the livelihoods of millions in the region. Their economic stability, in turn, may perceivably contribute to mitigating the security challenges in the region leading to a more viable environment for resolving other major issues. The hypothesis therefore is that the environmental challenge to the economic prosperity of South Asia enjoins an urgent note to the indispensability of regional cooperation.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

This proposition arises not out of the niceties, if it may be politely said, of the global trend towards regionalism as a political tool for negotiating the delicacies of international politics. It arises out of the geological fact that the Himalayas, Bay of Bengal and Arabian Sea determine how the climatic conditions in the region will prevail and that what affects these features, like global warming for example, will affect the delicate balance between nature and livelihood of nearly a fifth of humanity.

OBJECTIVE

A large number studies have been undertaken by aid agencies such as the World Bank (WB), ADB and academics on environment, poverty alleviation and sustainable development. While a review of such works may be of interest to the reader, since this chapter attempts to evolve a perspective of the factors that mutate into the causes of environmental issues in South Asia in general and, India in particular, a conscious omission is made on this account. Also, the chapter explores environment and sustainability paradigm not just as a livelihood issue. It rather attempts to see whether the commonality of challenges on these fronts can form a platform for dialogue among South Asian countries and whether it can aid as a foreign policy tool strengthening regional convergence. Such an exploration is uncommon in the studies concerning sustainable development, foreign policy or regional cooperation and is also unique since the studies on environment and sustainable development generally tend to limit themselves to scientific aspect of environmental degradation or the econometrics of environmental impact and studies on foreign policy or regional cooperation tend to focus on geopolitical issues. The attempt to evolve a perspective of sustainability initiatives as a foreign policy option therefore, it is felt, may provoke thought process that may contribute to strengthening regional convergence from the environmental dimension.

METHODOLOGY AND OUTLINE

Keeping these perspectives in mind, this chapter, in seven parts, explores the landscape of regional cooperation through the prism of environmental economics in South Asia. Part I examines socio-cultural factors, colonial economics, global and regional geopolitical factors. The historical perspective is essential since the policies and practices which emerged out of these factors in the region have largely remained in place and continue to influence the institutions that are concerned with management of natural resources like forestry for example. Part II considers environmental economics vis-à-vis livelihood by looking at forestry, land use and rural-urban migration prompted by environmental issues. Part III considers certain case studies to assess how grassroots environmental sustainability practices and initiatives impact rural livelihoods. The purpose is to consider whether there is a case for regional cooperation for obtaining larger good. Part IV outlines how donor agencies have come to view development assistance in the context of sustainability. Part V explores existing policies and institutional measures in regional cooperation. It infers the emergence of conscious policy outlook on development through sustainable practices as essential in the context of South Asia and that sustainable management of natural resources necessitates cooperation due to peculiar geographical factors in the region. Part VI looks at civil society activism that has emerged as an influential factor in defining institutional programs and practices for

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

sustainable development as civil society activism plays an important role in shaping the contours of cooperation. Part VII attempts to evaluate regional convergence underlining the need for deliberate steps towards cooperation and de-bureaucratization of endeavors for larger public good. In conclusion, the study draws upon the example of European Union (EU)to suggest setting aside of politically weighted resistance to strengthen regional cooperation initiatives in order to meaningfully share environmental resources, thereby promoting sustainable livelihood in the region.

PART I: THELANDSCAPE OF CONVERGENCE

Socio-Cultural Factors

Geopolitical birth of South Asia as a regional cluster of nations can be dated to the late 1940s, except Afghanistan, Bangladesh and Nepal. Afghanistan and Nepal had existed as independent nations for centuries before and had umbilical relations with the rest of the subcontinent through the history and culture of their people. Nepal is intrinsically connected to the Hindu culture since for millennia Hindus of the subcontinent have considered the pilgrimage to Mansarovar and Mt Kailash through Nepal as one their holiest undertakings. The Pashupathinath temple at Kathmandu is considered as one of the holiest Shiv temples in the region, believed to have been constructed around 400 AD. The sub-continental appeal of the temple can be judged by the fact that Namboothiri Brahman priest from Kerala (at the southern tip of India) have been priests in the temple for over 350 years (Parameshwaranand, 2004; Shrestha & Singh, 1972). Afghanistan, on the other hand, is the land from which Babur the founder of the Mughal Empire in India hailed from. Through the course of Mughal rule of three centuries and subsequently through the follies of East India Company's adventures for installing puppet regimes in Kabul by undertaking three colossal Afghan Wars, in the late 19th century, the societies of both the regions remained entwined (Dalrymple, 2012). British colonial obsession with 'the Great Game', a term popularized by Rudyard Kipling's 1901 novel *Kim*, of Russian sphere of influence over Central Asia continues to influence the policies of western powers concerning Afghanistan (Bilgrami, 1972; Warikoo, 1989; Allworth, 1994). Afghanistan remains one of the central reasons for the rivalry between India and Pakistan for dominant status in South Asia (Warikoo, 2002; Cooley, 2012).

Bhutan on the central Himalayas had preserved its sovereignty and its historical relations with people of the subcontinent are not exactly dated. However, in AD 747, in the form of Padmasambhava, Buddhism arrived in Bhutan from India ((Bandopadhyay, 2009). Throughout the Mughal, Colonial and early independent period of India, Bhutan maintained cordial relations with the governments of the day. Sri Lanka, the largest island in the region, has had very deep cultural and historical relations with the subcontinent. To give an example, there are 16 sites related to the great epic Ramayana located in Sri Lanka. Kandy and Kadirgamam in Sri Lanka are home to important Hindu temples dedicated to Kartikey, the mythological son of Lord Shiv of the Hindu trinity. Buddhism was brought to Sri Lanka by Sanghamitra and Mahindra, both children of the great Mauryan emperor Ashoka, from India. Ashoka also presented the tooth of Buddha which is a national relic of Sri Lanka kept at Sri Dalada Maligawa, Kandy. The Tamils of northern Sri Lanka have familial connections in Tamil Nadu, India. Issues affecting the Lankan Tamils are at the forefront of Tamil Nadu politics and greatly influence coalition partnerships in New Delhi (de Silva, 1981; Perera, 1988).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Maldives came into being in 1965, transiting to independence from Britain. Historically, it had enjoyed trade relations with the subcontinent and African-Arab merchants for over two thousand years. India is a critical partner in development of Maldives. In 1988, India helped preserve peace from a coup attempt by militant groups by deploying 1600 Indian troops. Since then, Maldives has transformed into a stable democracy, though essentially remaining Islamic. From environmental perspective, Maldives is the most critically affected country in the world due to global warming. More than 80 percent of the nation's islands are just about a meter high above the ocean and increasing salinity is threatening livelihoods and occupations (GCCA-EC, 2009).

Bangladesh is the youngest nation in the region, becoming independent from Pakistan in 1971. The partition of Bengal during colonial rule in the subcontinent was ominous. Notwithstanding the separate nationality and predominant Islamic outlook, people of Bangladesh have the same cultural, linguistic and historical antecedents as the Bengali population in India. As the lower riparian, Bangladesh receives the waters of two of India's major river systems – the Ganges and the Brahmaputra. Sharing of these waters remains at the heart of Indo-Bangladesh relations.

The brief socio-cultural history presented above, forged by a variety of factors and actors, and is evidence of mutual influence and cooperation that has existed in the region for millennia. The strength of the socio-cultural bond predating present political boundaries augurs well with political cooperation necessitated by the process of globalization.

Colonial Economic Undertakings

In the political sense, the bulk of the subcontinent was unified by the Mughals and their administration developed a unique blend of local kingdoms superimposed by a central regal authority. The decentralized administrative structure left large areas of the region autonomous enough to deal with local resources as per priorities of local populations. Urbanization that began with the arrival of the British was conspicuously absent during the Mughal period. British Rule per se commenced when the Crown took over the rule of the subcontinent after the 'Sepoy Mutiny of 1857'. In the succeeding nine decades, Britain embarked upon the most successful commercial exploitation in history of its 'jewel in the crown'[1]. Four factors during the British Rule came to affect the environment and ecology of the subcontinent, though their impact on environmental economics of the region remains yet to be understood in its entirety. These are: the introduction of German forestry in the garb of scientific forestry, the making of the Indian Railways, the economic-ecological demand on the subcontinent for WW I & II by the Empire and the successive droughts that plagued the region between 1860 and 1900. Brief appreciation of these factors is essential to appreciate how environment is intricately and delicately linked to the economic lives of people in the subcontinent and therefore must remain at the heart of regional cooperation.

German Forestry and British India

Political consolidation of the subcontinent by the British in India was completed after the Sepoy Mutiny of 1857. Stung by their setbacks in quelling rebellion in their Bengal Army, British went about consolidating their rule with vehement fervor primarily for economic reasons. A tip-of-the-iceberg example is the report of the House of Commons Commission that examined the affairs of the East India Company (House of Commons Report, 1832). The report observed:

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

The following statement for the year 1828-29 will show the proportion in which the revenue is derived from different sources….Land Revenue £ 12895366[2]*…Opium trade £ 1930891…making a total £ 22691721.*

The report in page viii, noted with satisfaction that the Revenues from India have progressively increased from £ 16764700 in the three year term ending 1814 to £ 22987472 in the three year term ending 1828-29. The figures are annual averages, making a staggering 37.12 percentile growth. The phase of consolidation also witnessed a huge demand for forest produce, particularly timber for ship building and military use(Bowen, Lincoln, & Rigby, 2002). Since the loss of America, Britain was under pressure to find alternate sources of supply in the subcontinent since 'the forests that used to supply Bombay and Calcutta docks have fallen off from extreme exhaustion' (Gov of UK, 1832). India offered in the British calculation unlimited supply, though later it was explicitly accepted that such exploitation would force the natives to turn their attention to other natural resources for sustenance(House of Commons Minutes, 1832).

The 'extreme exhaustion' that was noticed in the forests of western India turned the British attention to the Himalayas. Guha (2010) studying the steady intrusion of state into the forests observes that their attention that was limited to Saal forests in the foothills between 1815 to 1850, culminated in the declaration of all forests as state property under the Act of 1878. By 1911, their economic interest resulted in the carving of extensive areas out of 'District Protected Forests' into protected forests where the state had the exclusive prerogative for commercial exploitation. In 1874, in an address to the Royal Scottish Arboricultural Society, Hugh Cleghorn (1875), the Inspector General of Forests in India, told his audience that "the government in India began to be seriously embarrassed by the scarcity of timber; its attention was directed to the management of the indigenous forests". Timber resources in India were declining rapidly under the pressures of the high timber demand in the British Empire, local use and above all the rapid expansion of colonial agriculture and the associated loss of forestry cover in India during the first half of the 19th century (Stebbing, 1922). At the heart of the transition from need-based requisition to large scale commercial exploitation of forests was one man named Dietrich Brandis and his implacable faith in German Forestry. Dietrich Brandis introduced scientific forestry in British India 1n 1856 and served as the first Inspector General of Forests. The history of German forestry and its influence on the management of natural resources, particularly forests, must be recognized as holding sway over the forest policies of the sub-continental nations even today (Saldanha, 1996).

Railways in the Subcontinent

The subject of railways and its impact on ecology and environment has received considerable academic attention. While the saga of railways is intrinsic to the consolidation of the Empire in the subcontinent, its introduction and expansion were primarily prompted by two factors. In 1839, the textile mills of Manchester ran into severe crisis due to the failure of cotton crop in America. India offered exceptional alternate source for cotton but the logistics in transporting cotton to the ports of Bombay, Madras and Calcutta were astronomical. This commercial compulsion was at the heart of introduction of railways in India in 1854. The Mutiny of 1857 with the attendant need to transport troops gave the project further fillip.

An important watershed in the environmental economic history of the subcontinent was the construction of a railway network after 1850. The network of tracks increased from only 32 kilometers in 1853 to over 51,650 kilometers in 1910. The construction of the railways required an enormous amount of timber because to build two kilometers of track almost 900 sleepers were needed. Indian trees, particu-

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

lar sal (*Shorearobusta*), deodar cedar (*Cedrusdeodara*), and teak (*Tectonagrandis*) were much used as sleepers, because of their strength and perceived resistance against rotting. Already severely depleted by the clearance of forests for commercial purposes earlier in the century, India experienced a resource crunch, and the authorities realized that the intensive extraction of timber could not be sustained indefinitely. In order to secure a continuous flow of timber the forests had to be brought under control using a management regime that would protect the forests and perpetuate the production of timber (Guha, 1983; Poffenberger, McGean, &Khare, 1996; Buckles, 1999; Oosthoek, 2001).

The Draughts and Floods

The United Nations Environment Program (UNEP, 2009) made a summative finding on the draughts and floods in the subcontinent in the following words:"during the period between 1871 and 2000 there were 22 drought years and 19 flood years. There had been three cases of prolonged drought conditions in 1904-05, 1965-66 and 1985-87, which caused great anguish. Similarly, there had been two cases of prolonged flood conditions in 1892-94 and 1916-17. Studies indicate a clear relationship between the occurrence of droughts and floods in South Asia with El Niño (La Niña) events in the East Pacific Ocean. It has been observed that, during the period 1856-1997, there were 30 El Niño years in which the average monsoon rainfall over India was seven per cent below normal; and in 10 of these 30 cases, drought conditions prevailed over India. During the same period there were 16 La Niña years, nine of which featured flood conditions over India, particularly in 1878 and 1983. However, it appears from some of the recent studies that this relationship has been weakening in recent years, possibly due to global warming". It is imperative to note that the cause of draughts and floods are more important than the aftereffects including relief and rehabilitation. The ecological degradation that occurred due to unrestricted exploitation of natural resources had a huge contribution in the causation of these natural disasters.

The Two World Wars

It would perhaps appear as a gross injustice to the men who divined Allied victories in both the great wars to say that their victory would not have been possible but for the resources of British India. In all fairness, it must be acknowledged that the natural resources of the subcontinent played a huge role in Allied victory owing to the following:

- With the outbreak of the First World War the work of the forest department began to suffer for two reasons. Firstly, the young officers of the forest department were called to serve the Army and secondly, the department had to deal with the enormous demands for timber and other forest produce from the Army. The conditions of war also warranted the increased supply of timber for military, railways and other government departments. During the First World War, much of the forests were destroyed for fuel and timber (Janaki, 1990, p. 24).
- In 1935, Burma was separated from India and with it went the huge tracts of as yet unexploited forests in Burma. The undivided sub-continental India till then had 24% of forest cover. With the separation of Burma, the total forest cover in India (including present day Pakistan, Bangladesh regions) came to 11%(Karve, 1961, p. 123)
- A greater testimony to the level of deforestation in India is hardly needed. Then the Second World Warcame. The Minister for Railways while presenting the Railway Budget in 1948 observed that

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

over 400 miles of railway tracks were uprooted lock, stock and barrel for the war efforts elsewhere in the world[3]. Carriages and sleepers and other infrastructure of the railways were extensively used by the Allied Forces in Africa and West Asia. He expressed his confidence that these would be built back for domestic needs of the country in the following years. The needs of the department of Defense for timber and forest products were larger than that of Railways with over 2.3 million Indians serving in the Allied Armies. Coal being prime commodity, wood was used extensively from Indian forests for railways and the Army throughout the war. The quantities of wood cut down for these requirements were colossal – for instance, over a million tons from the forests of United Provinces alone. The crushing demands of war often led to measures which worked against the basic principles of conservation and sustained yield. The war produced severe pressures on India's productivity and weakened the basis of forest based industries. It reduced the potentialities of production of timbers for various national requirements (Trivedi, 2011).

Global and Regional Geopolitical Factors

The nations of South Asia took their respective paths towards nation building after their independence. Each nation attempted to forge its own plans and methods to address issues of development. After experiencing sluggish growth in the initial three decades after independence, they attempted to align their economies in tune with the global trends in the late 1980's. However, their enthusiasm to adapt to the market economy of the west collectively created a dichotomous situation. Ahmad, Kelegama and Ghani (2010) observe that, "there are two faces of South Asia. The first South Asia is dynamic, growing rapidly, highly urbanized, and is benefiting from global integration. The second South Asia is largely agricultural, land-locked, exhibits high poverty, suffers from many conflicts, and is lagging. The divergence between the two faces of South Asia is on the rise. Many policy and institutional constraints contribute to this dichotomy. One important constraint is regional conflict that has made South Asia one of the least integrated regions of the world".

The geopolitical compulsions of the Cold war period resulted in alliances such as NATO, the Warsaw Pact, SEATO and CENTO. These emerged essentially as political alliances based on ideologies. However, the combined effect of the disintegration of USSR and globalization driven by market economy in the 1990's levied certain compulsions on nations to look for regional arrangements for mutual economic development. Regional groupings such as EU that emerged initially as political alliances based on common interest slowly transformed into economic alliances. Regionalism as a means to achieving common goals gained credence after the 1980's. The vibrancy seen in forging such alliances can be estimated by the fact that there are over 126 Regional Trading Alliances (RTAs) in the world of 198 nations. Apparently, the eagerness to find common grounds with neighbors and allies is driven both by geopolitics and market economics. The presence of highly industrialized countries on the one hand and the comparatively newly established countries with limited economic might on the other; the differences in ideologies and level of democracy; ability to build credible institutions to translate objectives of cooperation into development and challenges to internal stability in a vast number of countries pose serious challenges to successful regional cooperation. Hettne and Solderbaum (2006) observe that the new regionalism is characterized by its multidimensionality and complexity. It involves a rich variety of state and non-state actors, which often come together in informal networks and multi-actor coalitions operating at different levels of the world system. The feasibility to share technology, facilitate trade and therefore attain wider distribution of wealth between the alliance partners became a motivator for other

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

regions of the world such as South Asia and Central Asia, etc. to develop regional mechanisms such as ASEAN, SAARC, BIMSTEC, SCO, and CAREC. While the progressively enlightened leadership in the Third World realizes the potential of such alliances to address common challenges like poverty, they are also plagued by notions of 'national interest' that undermine cooperation on multi-sectoral platforms, particularly related to environment.

Having been born in the throes and aftermath of the Great Wars and influenced by the Cold War that prevailed till late 1980's, South Asian cooperation, when it emerged in the form of SAARC, understandably riveted its emphasis on peace building. The SAARC Charter of 1985[4] declares:

Desirous of promoting peace, stability, amity and progress in the region through strict adherence to the principles of the UNITED NATIONS CHARTER and NON-ALIGNMENT, particularly respect for the principles of sovereign equality, territorial integrity, national independence, non-use of force and non-interference in the internal affairs of other States and peaceful settlement of all disputes. (Emphasis added)

There are strong arguments in favor of regional cooperation in South Asia. In an increasingly interdependent world, countries of the Third World are at particular disadvantage. Unlike the developed West, across Asia (with the exception of China), Asia-Pacific and Africa native economies are at best developing and are inadequate to generate knowledge, skilled man power and technology to facilitate social development. This handicap compels countries to seek global and regional alliances to fill the gaps in their capacity deficits. Neoliberalism or economic development that has come to be seen as the key to social development is being evaluated through the narrow prism of trade liberalization and opening of economy. However, liberalization alone is not a necessary condition for countries to turn to 'regional integration arrangements' (RIA). The pressures of globalization are compelling countries towards greater economic efficiency, larger markets, acute competition, access (and the need for) superior technology and greater opportunities for investment through RIAs. In addition, there is also a desire to extend assistance to neighboring countries for mutual benefit and to prevent the spillover of unrest or large scale economic migration. These compulsions, along with the near catastrophic East Asian crisis of 1997 contributed to the formation of BIMSTEC. To its credit, the founding philosophy of BIMSTEC focused towards two highly promising aspects of cooperation and expansion: one, it focused on those sectors of the economy and cooperation that were generally outside SAARC purview and secondly, it presented an opportunity to connect South and Southeast Asia by partnering with Thailand. Thus, BIMSTEC essentially was born due to policy induced changes warranted by perceived economic gains suited to all member countries. It is also noteworthy that the BIMSTEC Charter (the First Summit Declaration) (BIMSTEC, 1997) is focused on economic cooperation and development:

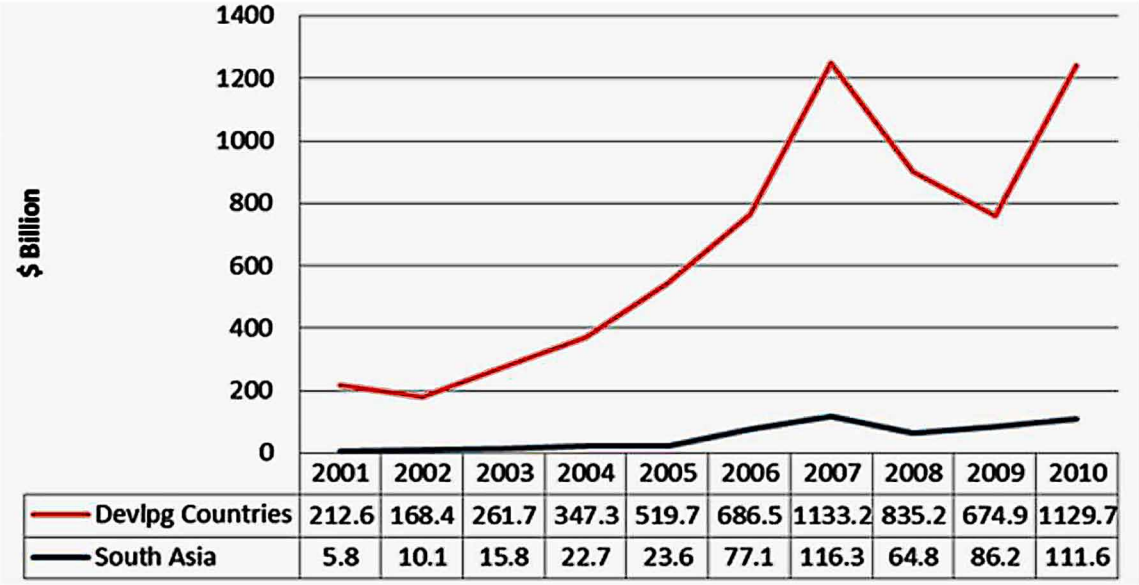
- Convinced that regional and sub-regional economic cooperation such as ours contribute to efforts towards global free and fair trade being pursued under the multilateral trading regime;
- Affirming that the above realities provide a firm foundation on which to build our partnership and overall cooperation;
- Resolving to foster a sense of community that will lead to the economic and social development of the entire region;

The initial areas identified by BIMSTEC for cooperation through 'lead' country initiatives were: trade and investment (Bangladesh), technology (Sri Lanka), transport and communications (India),

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

energy (Myanmar), tourism (India), and fisheries (Thailand). Implementation of a free trade agreement (FTA) for trade in goods by July 2006 and another FTA accord for services and investment by July 2007 were two of its most significant goalposts. Even though the formation of SAARC and BIMSTEC issued forth a promise for greater cooperation in the region, the challenges in front are equally compelling. Bhaskar (2006) made an important observation: "A comparison with established regional blocs reveals the daunting challenge BIMSTEC faces. In 2004, exports among the Association of Southeast Asian Nations (ASEAN) countries were at the level of USD 123.7 billion. As pioneers of regional economic cooperation, the countries that make up the European Economic Community (EEC) traded extensively among themselves, even in the absence of a preferential trading arrangement. Before any liberalization, intra-EEC imports made up 25 per cent of total imports. Current intra-BIMSTEC trade, for its part, stands at just 4 percent of total trade". In contrast Nag and De (2007) state that "In case of EU, there has been harmony among France Germany, Italy and UK who played a major role in institutions building highlighting the loss of national sovereignty to be accompanied by strong compensation mechanism including provision of public goods from integration".

While economics became an important incentive for cooperation, it is necessary to examine the extent to which environmental economics is important to the collective prosperity of South Asia. We undertook this examination from two perspectives: the contribution of agriculture, forestry and fishery to the gross national income in the region and the impact of environmental economics on livelihoods using case studies from academia.



PART II: SOUTH ASIA ENVIRONMENTAL ECONOMICS: A BACKGROUNDER

The South Asian region is a key economic zone, as seen from the global perspective. It assumes prime importance due to two fundamental reasons. Firstly, its huge population makes it a lucrative market for all kinds of products and the fact that this region is growing fast, adds weightage to this prospect. Secondly, the countries of this region, with the exception of Maldives and possibly Sri Lanka, are all major debtor countries and unable to break free from the 'low-level equilibrium trap' - created by low rates of capital formation, that compounds the need to secure resources from other sources, to build up a capital base. Following the East Asian meltdown, there has been a diversion of global funds towards this region (Figure 1- Net Capital Flows to South Asia 2001-2010) and therefore, this is a very crucial stage for the region, as a whole. As the global economy tends to become smaller, international trade assumes far greater importance. Today, the world market is much more complex and developing countries are increasingly being marginalized by larger economic blocs such as the European Union. Political leaders have understood the need for co-operation at the regional level to ensure better terms of trade in the global marketplace. All of the above means that the region for its survival has to perform at higher qualitative levels and yet manage to produce the quantities that would be able to feed its rapidly growing population.

Over the last few years, South Asia has been one of the fastest growing regions in the world. Between 2000 and 2008, the region registered an annual GDP growth rate of 6.6 per cent, which was higher than the average annual growth rate of Southeast Asia (4.8 per cent) but slightly below East Asia's (the fastest growing region) 7.4 per cent. In 2010, GDP growth in South Asia slowed down to 5.5 per cent per annum, still higher than Southeast Asia's 3.8 per cent but falling behind East Asia's 6.7 per cent. Although such a high average GDP growth rate of South Asia was dominated by India, other South Asian countries also experienced relatively higher GDP growth, exceeding 5.0 per cent between 2002 and 2007, except for

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Net capital inflows developing countries 2001-2010
Source: By Author, based on data from World Bank Global Development Finance 2012

Nepal: and the Maldives in 2005 (Table 1- Growth Rate of GDP 2001-2010). The lower growth rates of Nepal were due to the civil conflict and in the case of Maldives was caused by the heavy damage from tsunami in 2005. South Asia's robust economic performance, supported by sustained growth in industry and service sectors, is expected to continue in 2006, with an average growth rate at 6.6 per cent. This projected GDP growth rate is higher than Southeast Asia's projected 5.4 per cent and comparable with East Asia's 6.9 per cent (ADB, 2005, 2005; NEC, 2008; World Bank, 2006).

The data above brings out two important factors: First, South Asian growth is competitive and even with all the challenges in cooperation; the region displays positive potential as compared to Southeast Asia or East Asia (minus China). Second, Indian economy is critical to collective growth and therefore lends a stronger case for intra-regional cooperation.

While the prospects for higher growth through regional cooperation are evident, how do environmental factors contribute to economy in the region? Are protection, conservation and sharing of environmental resources a necessary condition for sustainable development? In order to appreciate the relation between

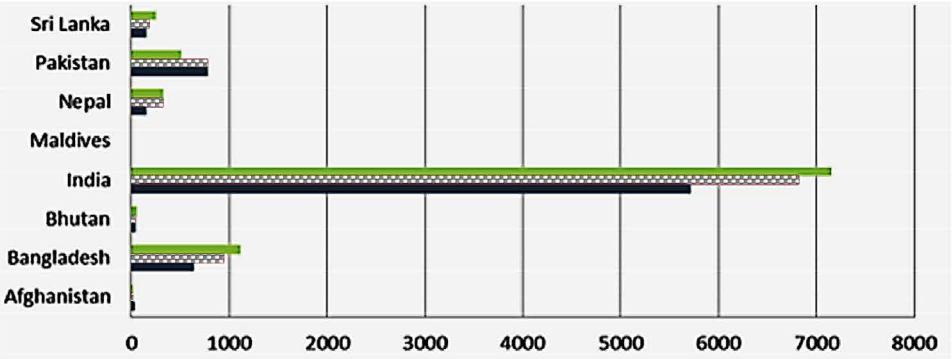
growth and environment in South Asian context, we compared the employment potential of forestry and the contribution of forest revenues to the GDP in South Asia as a test case. The data in comparative charts are appended as Figure 2, 3 and 4 respectively. The statistical information was collected from FAO and UN databanks accessible publicly on the internet.



The data shows that the combined employment potential of forest sector has registered an increase from 592000 to 620000persons (4.73 percent) in the ten years taken. It also shows that the cumulative

contribution to national incomes has increased from 7535 to 9422in US$ million (25.04 percent). If we take a combined regional GDP average, it is seen that revenue from forests contributes over 2% to GDP. In the case of countries like Bhutan and Nepal, it is in excess of 6.9 and 4 percent respectively. This data supports the premise that in the case of South Asia, a strong mechanism for cooperation on environment and forests will accrue employment and income generation and contribute substantially to the GDP growth rates.

When seen from the perspective that agriculture and related activities, a source of sustenance for over 60 percent of the population, depend on environmental and ecological factors and contribute to over 20 percent of GDP, the argument for regional cooperation appears to get fortified. Accordingly, we examined the land use practices and found that the region has four major farming systems on which nearly 87 percent of the population depends for their livelihoods directly or directly.

LAND USE PRACTICES

The number of people in South Asia is increasing at a rate of about 1.8 per cent per year and this increases the demand on food production to meet their requirements, without importing. However, a comparative increase in the amount of agricultural land is not seen and there is a slight decrease in some parts of South Asia. Around 60 per cent of the South Asian labor force is still involved in agriculture, while in Nepal more than 90 per cent of the populations are involved in this sector and 37 per cent of the Sri Lankan population is dependent on agriculture. The sector contributes to about 25 per cent of the GDP in the region. Between 1960 and 2000, the share of agriculture in national GDPs, in the region, has

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

decreased by 20 per cent, and yet the population dependent on agriculture has remained the same. This has led to unemployment, underemployment and migration to urban areas. The region's agriculture is characterized by small landholdings in the alluvial lowlands, where too many people depend on too little land and production is largely for subsistence. The high rates of tenancy and lack of new technologies compound the problem. Rice is the staple food crop and is usually grown under wet conditions. The four most important agricultural systems used in the region are below (Table 2 Major Farming Systems in South Asia).

Ecological degradation and its effect on the river systems that are important to agriculture in the region need no substantiation. Table 2 demonstrates that 33 percent of the land under irrigation is directly depends on rivers and the 29 percent rainfed will get affected by environmental factors that will affect the monsoon pattern in the region.

RURAL VERSUS URBAN MIGRATION DUE TO ENVIRONMENT

The rural-urban migration induced by land use practices which are in turn affected by a combination of environmental factors and agro-economic policies are also important to understand the impact of environmental economics on sustainable development.

Within Asia and the Pacific, the Pacific sub-region is the most urbanized, with 71% of the population living in cities and towns. Micronesia (Federated States of), Papua New Guinea, Samoa, Solomon Islands, and Tonga are exceptions, each having less than 25% of their population living in urban areas. In contrast, *South and South-West Asia is the least urbanized with only 33% of the population living in urban areas.* Exceptions in this sub-region are Islamic Republic of Iran and Turkey, where approximately 70% of the population lives in urban areas. (Emphasis added)

Post 1990, however, South and South-West Asia have witnessed the fastest urban population growth rate of all the Asian and Pacific sub-regions at an average of 2.4% per year during 2005-2010. The South-East Asia urban population growth was somewhat slower at 2.2% per year, followed by East and North-East Asia at 2.0% and the Pacific at 1.8%. In North and Central Asia the urban population growth rate has hovered close to zero over the last two decades (0.3% for 2005-2010). The rural population of the world has grown slowly since 1950 and is expected to reach its peak in a few years. The global rural population is now close to 3.4 billion and is expected to decline to 3.2 billion by 2050 (Figure 5:

Urban Rural Population, Asia Pacific Sub-regions 1990-2050). Africa and Asia are home to nearly 90 per cent of the world's rural population. India has the largest rural population (857 million), followed by China (635 million) (UN, 2014). The table (Table 3: Rural Population in South Asia 1990-2050) below illustrates possible decline in rural population across the most populous countries in South Asia (population in '000).

Rural-Urban migration has been traditionally apportioned to individual characteristics based on age, sex or education that may or may not predispose them to migrate (Sjaastad, 1962). However, this view underwent a gradual change from individual decision to household decision in which the household decides whether a member migrates away for economic reasons or the entire household migrates with him (Mincer, 1978; Haug, 2008; Bodvarsson & Van der Berg, 2013). Migration theory has also recognized that the community or context of the household also plays a role. It also recognizes that the local community-contextual factors may themselves be seen as affected by higher level provincial and

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

national policies and the latter by international factors (Woods, 1982; Bilsborrow, 2002). According to Todaro and Smith (2009) about two thirds of the poor in rural areas get by and sustain their lives with subsistence farming either as small farmers or working on land owned by other people. The other third are engaged in small scale activities. Poverty profiles for developing countries characterize the poor as being agricultural households with little arable land. In an agricultural based economy, where poor residents lack access to resources and there is a high level of inequality and an inequitable distribution of assets, non-farm labor becomes an important source of income for the poor. Environmental economists have come to recognize that environmental factors have considerable implications for rural-urban migration. As Bilsborrow (2002) observes:

This… migration also has significant environmental implications when directed predominantly to marginal, fragile areas that have often been made accessible recently through extensions of road networks. Through clearing of forests or other vegetation to establish croplands or pasture, the extensification process may: (a) damage watersheds; (b) reduce water retention and replenishment of underground aquifers; (c) increase surface runoff, flooding, soil erosion, and siltation of dams downstream; and (d) decrease soil fertility. While appropriate policies can control or moderate many of these consequences, most developing countries do not have the necessary resources and technology to implement such policies.

The effects of the environment on migration have received less attention than those of migrants on the environment; but these effects are now also attracting research interest (Reuveny, 2007). Today, interest in environmentally induced migration has focused on the issues of: (a) "environmental refugees"(international migrants compelled by environmental conditions to seek temporary asylum in another, usually neighboring, country); (b) "displaced persons" (people forced to migrate within their country by environmental disasters or civil strife); and (c) other persons who migrate from rural areas within their own country at least partly for reasons of environmental deterioration. The latter, not referred to as environmental refugees except in the sensationalistic literature, account for the largest number but have received little attention, both because the international funding community has generally neglected internal migration in low-income countries and because the issue does not usually involve persons in desperate need of assistance (Bilsborrow, 2002).

Considering the size of the population in South Asia that is dependent on environmental factors for supporting their sustenance, degradation of environment portends serious consequences. Though research interests in developing countries have not yet come to grapple with environmental factors as a moot point of sustainable livelihoods in a substantial manner, following case studies demonstrate that such a trend is evolving and environmental conservation will remain at the heart of environmental economics in the region.

PART III: CASE STUDIES ON ENVIRONMENT AND LIVELIHOODS

In the previous segments, we examined the indispensability of environmental economics to South Asian collective progress. Economists have traditionally felt that the externalities (such as products of nature) did not affect economics since in the first place the products of nature were taken for granted and, secondly, they were not available in the market with a price tag on them. As Panayotou (1997) observed,

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

"the prevailing configuration of markets and policies leaves many resources outside the domain of markets, unowned, unpriced and unaccounted for. More often than not, it subsidizes their excessive use and destruction, despite their growing scarcity and rising social cost. The result is an incentive structure that induces people to maximize their profits not by being efficient and innovative but by appropriating other people's resources and shifting their own costs onto others". The 1972 Stockholm Summit made the first attempt to forge world opinion on preservation and the interrelations between man and nature. The Rio 1992 Earth Summit can truly be said to be the commencement of serious research into the dimensions of environmental economics, particularly the emergence of the concept called sustainable development. Even at that time, Maurice Strong, Chair of the 1992 Earth Summit prophesized, "The battle for sustainable development will be won or lost in Asia." He was not being dramatic. Asia is home to 4.4 billion of 7.2 billion humans on earth. Without relying on any statistics, we can imagine the need for resources to house, feed and clothe this population. A step further, it would also help to remember that two thirds of Asians depend on agriculture and forestry for sustenance and sustainable livelihood for them cannot be realized without sustaining the resources of nature. In order to explore the relevance of this approach, we examined a cross section of published case studies from across Asia and elsewhere. It was also felt that such an exploration would validate our belief that sustainable development is possible only on a strong foundation of environmental protection/conservation. The hypothesis was to see whether South Asian cooperation must stand on the stilt of environment owing to its relevance on sustainable livelihood or are we merely exploring environmental concerns to satisfy our urge to sound appropriate in the international forum.

Chittagong Hill Tracts, Bangladesh

Kar and Jacobson (2012) found that households in the Chittagong Hill Tracts, Bangladesh, use different types of NTFP[5]s for subsistence and cash income, suggesting that some NTFPs are more market oriented while others are more important for subsistence. The Chittagong Hill Tracts are a heavily degraded area, with informants saying that forest resources have declined by about 50% from levels about ten years ago; however, the region still provides the largest forest-based contribution of any region to Bangladesh's economy. The majority of NTFP use is subsistence based, with about 65% of collected NTFP-related household income being used for subsistence, while approximately one-third of surveyed households also sold NTFPs for cash income. The three most important NTFPs for cash income were bamboo, wild vegetables, and broom grass followed by sun grass, bamboo shoots, medicinal plants and menda.

Sinharaja World Heritage Site, Sri Lanka

Senaratne, Abeygunawardena and Jayatilake (2003) illustrate how the relative importance of NTFPs for household subsistence and cash income has changed over time among households living adjacent to the Sinharaja World Heritage site in Sri Lanka. Overall, 82 NTFP species help to meet household nutrition requirements, generally as side dishes or snacks rather than as a staple food (except for yams). However, it was found that the new concepts in forest management have adversely impacted the contribution of NTFPs to household subsistence and cash income. Senaratne, Abeygunawardena and Jayatilake (2003) listed two reasons for the same: First, forest management restricted villagers' access to forest resources. With timber extraction, hunting wild animals, shifting cultivation, and gem mining prohibited, some of

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

the more lucrative NTFPs, such as wild game, are no longer an option for households. Second, changing socio-economic factors, such as decreased shifting cultivation and the growing importance of tea industry in Sri Lanka, have reduced household incomes. As a consequence, households now depend on this income to purchase foods and medicine rather than collecting them from the forests.

Pwo Karen Villages, Western Thailand

In Southeast Asia, research found that NTFPs make an important contribution to the livelihood of the households who gather and consume them. In particular, the consumption of NTFPs allows gatherers to live with lower amounts of cash than if they had to buy in the market what they can obtain from the forest for free. Understanding the economic value of non-marketed NTFPs helps determine the true income of the gatherers, and the amount of extra cash that they would need if they could no longer gather NTFPs. It also helps ascertain the true value of the standing forest, leading to more rational decisions about its alternative uses. Yet, the NTFPs that are not marketed are often ignored when estimates are made of the economic importance of NTFPs to rural populations. Data from one month of fieldwork in two Pwo Karen villages in ThungYaiNaresuan Wildlife Sanctuary in western Thailand concludes that wild food plants remain a preferred alternative to commercial food crops because gathering wild food plants is a much more efficient use of time than engaging in the market economy in order to purchase commercial food crops (Delang, 2006). The forest remains important for fuel wood, with 75% of households reporting gathering fuel wood from the forest and 49% of total fuel wood coming from the forest. Similarly, dependence on the forest for construction materials remains high, with 90% of households extracting construction materials for poles, pillars, and other purposes. They point out that these materials are durable and do not require regular collection, which means that the utilization of these forest resources conflicts less with tea cultivation because of the relatively lower time input compared with collecting NTFPs for food or medicine that is more time intensive(Agarwal, et al., 2012).

Kendrapada, Orissa, India

David Clover (2010) cites a case from the work of an Indian researcher. In October 1999, the state of Orissa in India was battered by a super cyclone that killed almost 10,000 people and caused a massive loss of livestock and property. Controversy ensued over whether the impact of the cyclone had been made worse by years of destruction of mangrove forests in the area. Many argued that a healthy barrier of mangroves might have buffered the effects of the storm and minimized the damages it caused. Saudamini Das, a researcher from SANDEE, assessed the factors that affected the impact of the storm. She found that mangroves do provide important storm protection to people, livestock, and buildings. Her study also found that, had the mangrove forests been intact, more than 90% of the deaths due to the 1999 cyclone would have been avoided (See Table 4: Effect of Mangroves on Mortality during 1999 cyclone in Kendrapada, India).

To put an economic value on the protective role that mangroves play, Das looked at the mitigating effects of standing mangroves in the area, at government compensation payments, and auto-compensated losses. She calculated that a hectare of mangrove forest land stopped damage worth $43,000 in the district during the super cyclone.[4] Of course, such severe storms do not occur every year. But even allowing for

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 4. The effect of Mangroves on mortality during 1999 cyclone in Kendrapada, India

Number of deaths caused by 1999 cyclone	392
With no mangroves: predicted mortality	603
With mangroves at 1950 level: predicted mortality	31

Source: Das, 2007

the fact that mangroves have no storm protection value during non-storm years, Das found a long-term protection value of about $8,700. At the time, a hectare of cleared land was fetching $5,000. Thus, Das showed that leaving mangroves as storm buffers generates more value to society than clearing them for development. It is not surprising that Das's work attracted widespread interest. A workshop convened in Orissa to discuss her research drew 175 officials, parliamentarians, media representatives, and NGOs. Her study was distributed by the Food and Agriculture Organization at a meeting about Cyclone Nargis, which struck Myanmar in 2008, and has been used in many other deliberations on coastal conservation issues.

The Forests in Chamoli, Uttarakhand

Guha (2010) finds that in Tribal India even today (the Tribal population constitutes over 8.6 percent of the country's population), "it is striking to see how in many of the myths and legends the deep sense of identity with the forest is emphasized" (p. 33). In such forest areas not only did the forests have a tremendous influence in molding religious and spiritual life, the inhabitants also exhibited a deep love of vegetation, often acting 'entirely from a sense of responsibility towards future generations' by planning species whose span of maturity exceeded a human lifetime. Guha's work on the link between people, nature and history of state control over the forests of Uttarakhand state in India retains monumental influence in discussions on sustainable livelihoods across the world. Guha's compelling evidence highlights the lesson that the world has gradually come to accept as important - native knowledge balances nature and livelihoods better that scientific knowledge imported from entirely different contexts. The case of German forestry in Colonial India is a telling example. This finding is also amply supported by a number of works related to Traditional Ecological Knowledge, (TEK) including but not limited to, as cited in Inglis (1993): Studies in the transmission of Traditional Ecological Knowledge (Ruddle & Chesterfield 1977); community-based Traditional Ecological Knowledge research approaches (Johnson, 1992); application of Traditional Ecological Knowledge to development (Brokensha, Warren & Werner, 1980) and to resource management (Klee 1980); detailed biological/ecological evaluation of fisheries Traditional Ecological Knowledge systems in Oceania (Johannes 1981); traditional conservation (Moruata, Pernetta & Heaney, 1982; McNeely & Pitt 1985); traditional coastal resource management systems (Lasserre & Ruddle 1983); Traditional Ecological Knowledge of northern ecosystems (Freeman & Carbyn 1988), dry land ecosystems (Niamir, 1990) and tropical forest ecosystems (Posey & Balee 1989); environmental philosophy and indigenous knowledge (Knutdson & Suzuki 1992); volumes of selected topics (Johannes 1989) and studies of traditional marine resource management systems in Asia and the Pacific (Ruddle & Johannes 1989).

Jodha (1986) while investigating the relationship between the rural poor and common property resources found that a large part of the consumption of the rural poor came from environmental resources. Their dependence on these resources for livelihood generation was unambiguously underlined in these

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

studies. Such a premise dispels the myth maintained implicitly in policy circles that the rural poor contribute to environmental degradation by over-extraction. Jodha offers a number of explanations for the apparent contradiction:

- The poor have a high rate of discount for the future due to low levels of income.
- Population pressure constitutes the major reason for degradation of natural resources.
- A large part of the degradation of the environment is the consequence of the failure of the market and the state to provide appropriate modes of management of natural resources.

Amazon Forests, Brazil

A poorly designed land ownership policy, combined with a macroeconomic problem, were driving people's behavior in ways that were rational from the individuals' point of view but harmful to the environment and wasteful of society's resources. When environmental economists showed that these failures of economic policy were a major cause of rainforest destruction, many of the subsidies and incentives for land clearing were removed (Binswanger 1991). Even macroeconomic policies that, at first glance, have little relationship to the environment can have powerful environmental effects, as the Brazil example shows(Clover, 2010).

The above cases have two major implications, as per Clover (2010): First, environmental degradation has a massive impact on people, making environmental protection vital. Second, rural people need to be involved in the environmental management of the land they use and live on. This means that good environmental policy must take into account not only the well-being of the poor, but also their participation[6].

The critical understanding of the links between economic activity, livelihood generation and incentives for and against conservation centered management of natural resources comes from inter-disciplinary studies of scholars like Wade (1987), Chopra, Kadekodi and Murty (1990), Ostram(1990), and Bardhan (1993) with their groundings in economics, anthropology and sociology. A substantial number of these studies in South Asia aimed at exploring the relationship between poverty and environmental degradation. While poverty and over population were postulated as the largest polluters, the studies found that the poor had more close livelihood and consumption linkages with environmental resources. A natural question that arises, therefore, is: Could these links be expropriated positively to yield sustainable patterns of development?

The above case studies make it concrete that the biggest challenge facing South Asia – eradication of poverty – is not possible unless environmentally sustainable development in consultation with local populations is adopted by governments.

PART IV: DONOR PERSPECTIVE ON ENVIRONMENT AND SUSTAINABLE DEVELOPMENT

Development as well as environmental projects is capital intensive. Cash strapped developing nations rely on donor agencies like World Bank (WB) and Asian Development Bank (ADB) to bridge the gap between their development objectives and national capacities. With the global awareness on climate change and its impact on poverty alleviation, hunger and disease, these donor agencies have also devel-

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

oped mechanisms that squarely attempt to raise funds as well as support developing nations in tackling these issues. World Bank (2013) for example states:

Climate change affects all of us. But it is expected to hit developing countries the hardest. Its potential effects on temperatures, precipitation patterns, sea levels, and frequency of weather-related disasters pose risks for agriculture, food, and water supplies. At stake are recent gains in the fight against poverty, hunger and disease, and the lives and livelihoods of people in developing countries. Tackling this immense challenge must involve both mitigation—to avoid the unmanageable—and adaptation—to manage the unavoidable—all while maintaining a focus on its social dimensions. Addressing climate change requires unprecedented global cooperation across borders. The World Bank Group is helping support developing countries and contributing to a global solution, while tailoring our approach to the differing needs of developing country partners. We are strengthening and building climate change partnerships with our member governments and a wide array of organizations.

ADB that works closely with South Asian governments has a clear appraisal of environment in the economic development of South Asia. Ahmad and Suphachalasai (2014) in their study for ADB "synthesizes the results of country and sector studies on the economic costs and benefits of unilateral and regional actions on climate change in ADB's six South Asia developing members, namely Bangladesh, Bhutan, India, the Maldives, Nepal, and Sri Lanka. The study takes into account the different scenarios and impacts projected across vulnerable sectors and estimates the total economic loss throughout the 21st century and amount of funding required for adaptation measures to avert such potential losses. It is envisioned to strengthen decision-making capacities and improve understanding of the economics of climate change for the countries in South Asia". The criticality attached to environment for the collective growth of South Asia is evident when we examine their report that states:

According to the report's findings the total climate change cost in South Asia will increase over time and will be prohibitively high in the long term. Without global deviation from a fossil-fuel-intensive path, South Asia could lose an equivalent 1.8% of its annual gross domestic product (GDP) by 2050, which will progressively increase to 8.8% by 2100. The model suggests that the Maldives will be hardest hit in GDP loss, while Bangladesh, Bhutan, India, Nepal, and Sri Lanka are projected to face 2.0%, 1.4%, 1.8%, 2.2%, and 1.2%, respectively, loss of annual GDP by 2050.

However, should the global community take actions along the Copenhagen–Cancun agreements to keep the global mean temperature rise below or within 2 degrees Centigrade, the region would only lose an average of 1.3% of GDP by 2050 and roughly 2.5% by 2100. Impacts on vulnerable sectors include:

Agriculture

Higher temperatures eventually reduce yields of desirable crops while encouraging weed and pest proliferation. Changes in precipitation pattern (timing and amount) increase the likelihood of short-run crop failures and long-run production declines, posing a serious threat to food security. Although there will be gain in some crops in some regions, the overall impacts of climate change on agriculture are expected to be negative and need to be much better understood.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Energy

A rise in average warming will increase energy requirements for space cooling (but reduce energy needed for warming), while increasing energy demand for irrigation. On the supply side, there is a direct influence on hydropower and thermal power generation through availability of water and the temperature of cooling water, respectively. Increases in intensity and frequency of extreme events like storms and sea level rise may cause more electrical system failures. Forest and other ecosystems Climate change will affect forest carbon pools in some countries of the region.

Health

The modeling results suggest that the mortality rate for the region caused by dengue, malaria, and diarrhea would increase over time as a consequence of climate change. Morbidity and deaths from such diseases could increase in the future under all scenarios.

Water

Although the monsoon-dominated annual precipitation cycle is expected to remain unchanged over South Asia, future decades are predicted to have drier and warmer winter months with reduced snow cover, while the summer/monsoon months are predicted to become wetter and warmer. The seasonal pattern of flows over the year could become more erratic, as rainfall is immediately converted to runoff instead of being stored as ice.

Adaptation Options, Policies and Strategies

The region's adaptation response need not be confined to symptomatic treatment of threats to traditional patterns of economic activity. More efficient regional economic diversification can create entirely new patterns and supporting infrastructure to take their place. In other words, policy makers need to take early action to adapt to climate risks, and this action needs to be informed by rigorous and timely evidence.

The South Asia developing member countries have by now developed their adaptation strategy. In some countries, such as India, state and sub national action plans have also been developed, allowing for integrating climate change adaption options in local project and facilities development. Building resilience to the impacts of climate change requires identifying the risks and vulnerabilities of sector and area development projects and programs, followed by developing the options for adaptation and mitigation measures that are socially, environmentally, and economically sound.

PART V: INSTITUTIONAL AND POLICY MEASURES IN COOPERATION

Globally viewing environment and cooperation on climate related issues as essential for economic progress has gained considerable momentum since the 1960s. Earlier, the word environment itself was usually associated with domestic or work environment and did not translate to the ecological and climatic context in which it is used today (Dauvergne, 2009). Environmental and ecological inputs into

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

production were assumed to be free of cost as well as inexhaustible. In the process they tended to be omitted in any explorations of economic theories. As Pigou (1932) and others observed, "Traditional microeconomics treats environmental effects as externalities of production or consumption" (Ayres & Kneese, 1969; de Bryun, 2000; Hussen, 2013). The transition of 'environment' by the 1980's from being mere 'externalities' to being the inherent modulator was persuasive. We may note with some satisfaction that South Asian Region did not lag behind the emerging universal consensus on the inseparability of environment to economics and sustainable development. The awakening in South Asia was propelled by the following factors:

- The compelling political reason to find solution to the biggest challenge they face – poverty and the realization that poverty alleviation across the region has its roots in common cultural practices and traditional economic interactions.
- Emerging global activism in the wake of Stockholm 1972 and the run up to Rio 1992.
- Huge civil society activation in response to the development agenda of regional governments. For example, protests against Tehri Dam, Narmada river projects, agitations in Bangladesh against Farakka and Teesta projects, Indian objections to Chinese plans over hydroelectric projects across Brahmaputra in Tibet and the issue of Indus water sharing between India and Pakistan.
- Globalization and regional integration mechanisms in other parts of the world that are being tempered by donor insistence on sustainable growth agenda.

Recognizing that countries in the sub-region also need to pursue measures that reduce production and trading costs through sharing of basic resources, the South Asia Cooperative Environment Programme (SACEP) was established in 1982. The SAARC committee on environment was set up in 1992. In 1997, SAARC environment ministers agreed to an Environment Action Plan and a common SAARC position on climate change. In the Islamabad Declaration of January 2004, the Heads of State agreed to "undertake and reinforce regional cooperation for the conservation of water resources and environment, pollution prevention, control of, as well as preparedness to deal with natural calamities". They also expressed strong support for the "early and effective implementation of the SAARC Environment Action Plan and the preparation of a SAARC state of environment report, as well as the commissioning of the work on drafting a Regional Environment Treaty. The SAARC Environment Ministers meeting in Dhaka in July 2008 adopted the Dhaka declaration on Climate Change and an action plan on Climate Change.

Meetings of the SAARC Environment Ministers

The meetings of the SAARC Environment Ministers and the Technical Committee on Environment and Forestry provide key mechanisms to guide and facilitate the agenda of cooperation. Since 1992, SAARC Environment Ministers have met nine times. In addition, a Special Session of the Environment Ministers in the aftermath of the Indian Ocean Tsunami was held in Malé in July 2005. Regional Centers have also been established and constitute an important framework of SAARC Institutions to address diverse aspects of environment, climate change and natural disasters. These measures include:

1. SAARC Coastal Zone Management Center (SCZMC) -Established in 2004 to promote cooperation in planning, management and sustainable development of coastal zones, including research, training and awareness

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

2. SAARC Forestry Center (SFC) - Established in 2007 for the protection, conservation and prudent use of forest resources by adopting sustainable forest management practices through research, education and coordination among Member States
3. SAARC Disaster Management Centre (SDMC) - Established in October 2006 to provide policy advice and facilitate capacity building including strategic learning, research, training, system development, expertise promotion and exchange of information for effective disaster risk reduction and management – the mandate of the Centre was expanded to include the development of a Natural Disaster Rapid Response Mechanism (Fifteenth SAARC Summit, Colombo, 2-3 August 2008)
4. SAARC Meteorological Research Centre in 1995 to carry out research on weather prediction and better understanding of monsoon.

Important Initiatives/Milestones

The Third SAARC Summit (Kathmandu, 2-4 November 1987) commissioned a Regional Study on the "Consequences of Natural Disasters and the Protection and Preservation of the Environment". The Study was completed in 1991.The Fourth SAARC Summit (Islamabad, 29-31 December 1988) directed that a joint study on the "Greenhouse Effect and its Impact on the Region" be undertaken. This study was initiated to provide a basis for an action plan for meaningful cooperation among Member States. The study was completed in 1992. The above two studies provided a comprehensive assessment of the state of the environment in the Member States of SAARC. The milestones of SAARC on the issue of Environment may be listed as below:

- SAARC Environment Action Plan (1997)
- Disaster Management in South Asia: A Comprehensive Regional Framework for Action 2006-2015
- Dhaka Declaration and SAARC Action Plan on Climate Change (2008)
- Delhi Statement on Cooperation in Environment (2009)
- Thimphu Statement on Climate Change (2010)
- SAARC Convention on Cooperation on Environment (2010)
- SAARC Agreement on Rapid Response to Natural Disasters (2011)

A Technical Committee on Environment was established in 1992 to monitor the progress made in the implementation of the abovementioned regional studies. The mandate of the committee has since been expanded to include meteorology and forestry. I additionally coordinates and monitors the progress of 1992 SAARC Environment Action Plan and 2008 SAARC Action Plan on Climate Change.

COLLABORATION WITH INTER-GOVERNMENTAL ORGANIZATIONS

SAARC also collaborates with many regional and international organizations on environmental issues. The initiatives include a Memorandum of Understanding (MOU) with the South Asia Cooperative Environment Programme (SACEP) in July 2004; United Nations Environment Programme (UNEP) in June 2007; the United Nations International Strategy on Disaster Reduction (UNISDR) in September 2008 and Asia Disaster Preparedness Centre (ADPC). SAARC avails technical and financial support in implementing regional programs through these MoU. SAARC is also an accredited Observer of the

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

United Nations Framework Convention on Climate Change (UNFCCC) since COP 16 (Cancun, Mexico, 29 November-10 December 2010) and has presented common SAARC positions on climate change.

Donor Initiatives

Individually and through collaborative network, SAARC nations avail donor assistance for ecologically important projects. Agencies like ADB that extend financial assistance to South Asian governments have evolved and/or supported development of legal and institutional frameworks in these countries concerning environment. Few prominent examples of ADB support for various law-related environmental programs in South Asian region are (Davis, 2014):

- In Pakistan, ADB supported the Supreme Court in establishing green benches, extending assistance to institutionalize environmental law training in judicial academies, and strengthening environmental adjudication.
- In Bhutan, ADB has commenced initial work to support the creation of a Bench Book comprising all environmental policies, laws, regulations, and case law. This will be an invaluable resource for the judiciary in adjudicating environmental disputes.
- At the same time, ADB, together with other development partners, convened the Colloquium on Biodiversity in Hyderabad, India. The Colloquium was a first opportunity for judges to work with a multi-lateral environmental agreement, aiming to emphasize the importance of law and law enforcement, particularly in relation to crimes of illegal logging trade and destruction of habitat and biodiversity in both land and oceans.

Country Specific Initiatives

A number of scholars believe that as contrasted to the western parts of the world, in South Asia there exists a dilemma between how the world perceives environment on the macro level (as a developmental issue) and how people perceive environment (as a livelihood issue) at the micro level. The situation in the countries of South Asia appears then to be characterized best by a dilemma. The macro picture relegates resource and environment linked issues to the background, often to be brought into the forefront only at the behest of international agencies or in the course of political negotiations centered on the management of the global commons such as the climate change and WTO negotiations. At the local levels, natural resources constitute a significant issue, both from the consumption and livelihood viewpoints and the emergence of non-governmental organizations has drawn the attention of civil society to it (Jodha, 1986; Chopra, Kadekodi, & Murty, 1990; Dasgupta, 2010). This dilemma rises largely due to the realization in government level that two thirds of the population of these countries depends on the earth and its resources for their sustenance. Apart from economic considerations, the awareness of the link between man, environment and religious-cultural orientation of the societies have resulted in governments undertaking certain initiatives that promote man-nature harmony. Some of the examples that could be gainfully looked into are as below:

- **Bhutan:** The government of Bhutan has evolved a strict conservation policy that places greater emphasis on maintaining at least 60 percent of land area as closed forests in order to maintain climatic equilibrium and prevent soil erosion. In South Asia, Bhutan has the largest forest cover

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

at 72.5 percent out of which 39.5 percent are closed. This policy orientation is rooted as much in economic and livelihood dependence on forests as much as it is rooted in Buddhist theological belief. In fact, as UNEP observes, Bhutan has even evolved its own standards in lieu of GDP called Gross National Happiness (GNH). *GNH,* as UNEP (2009) rightly observes is "the unique development philosophy adopted by Bhutan, is an attempt to define quality of life in more holistic and psychological terms than the conventional Gross National Product. The four pillars of GNH are the promotion of equitable and sustainable socio-economic development, preservation and promotion of cultural values, conservation of the natural environment, and establishment of good governance".

- **Maldives:** Maldives is the most threatened nation in the world due to global warming. *The National Environment Action Plan of the Maldives* outlines actions, policies and measures to protect and conserve the fragile biological diversity, particularly the marine ecosystem through integrated sustainable reef resources management since the entire population and economy of the country depend on local as well as global environmental factors.
- **India:** India has developed a National Policy and a Macro-level Action Strategy on Biodiversity, aimed at providing the framework for preparing detailed action programs at the macro level for conservation and sustainable use of the biological diversity that exists in the country.
- **Sri Lanka:** The *Biodiversity Conservation Action Plan (BCAP)* of Sri Lanka forms a broad framework for biodiversity conservation at the national level. It was prepared through wide stakeholder participation by the government and NGOs. A biodiversity secretariat has been set up by the Ministry of Environment and Natural Resources for implementation of BCAP. Its initiatives include development of measures for valuation of biodiversity, conservation of medicinal plants, establishment of a legal task force to identify gaps and recommendations in national legislation. Similarly, "WanaSenasuna" forest hermitage programme is another initiative by government of Sri Lanka to involve the Buddhist clergy and devotees for protecting the forests with cultural values. It integrates religious and cultural aspects into forest conservation to enhance to protection afforded to these areas.

PART VI: CIVIL SOCIETY ACTIVISM

People remain the reason why governments must exist. South Asia people, as has been amply pointed out above, have had close cultural and religious relationship with nature. The elements and resources of nature have not merely been deified by them; they have also taken upon themselves to usurp legal tools to safeguard their essential connection with nature and to preserve the resources of their environment. India, occupying more than 70 percent of South Asia and home to nearly 80 percent of its population takes the lead in environmental activism that has set standards for the region. We look briefly at civil society activism in India that has a huge influence on regional perspective on environmental cooperation.

The Constitution of India under part III guarantees fundamental rights which are essential for the development of every individual and to which a person is inherently entitled by virtue of being human alone. Right to environment is also a right without which development of individual and realization of his or her full potential shall not be possible. Articles 14, 19 and 21 of this part have been effectively usurped by the Judiciary as well as activists:

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

- **Right to Life and Right to Environment:** According to Article 21 of the constitution, "no person shall be deprived of his life or personal liberty except according to procedure established by law". Article 21 has received liberal interpretation from time to time after the decision of the Supreme Court in Menaka Gandhi vs. Union of India[7]. Article 21 guarantees fundamental right to life. Right to environment, free of danger of disease and infection is inherent in it. Right to healthy environment is important attribute of right to live with human dignity. The right to live in a healthy environment as part of Article 21 of the Constitution was first recognized in the case of Rural Litigation and Entitlement Kendra vs. State[8] (Popularly known as Dehradun Quarrying Case). It is the first case of this kind in India, involving issues relating to environment and ecological balance in which Supreme Court directed to stop the excavation (illegal mining) under the Environment (Protection) Act, 1986. In M.C. Mehta vs. Union of India[9], the Supreme Court treated the right to live in environment free of pollution as a part of fundamental right to life under Article 21 of the Constitution.
- **Noise Pollution:** The constitution of India under Article 19 (1) (a) read with Article 21 of the constitution guarantees right to decent environment and right to live peacefully. In PA Jacob vs. The Superintendent of Police Kottayam[10], the Kerala High Court held that freedom of speech under article 19 (1)(a) does not include freedom to use loud speakers or sound amplifiers. Thus, noise pollution caused by the loud speakers can be controlled under article 19 (1) (a) of the constitution.
- **Profession and Health hazards:** Article 19 (1) (g) of the Indian constitution confers fundamental right on every citizen to practice any profession or to carry on any occupation, trade or business. This is subject to reasonable restrictions. A citizen cannot carry on business activity, if it is a health hazard to the society or general public. Thus safeguards for environment protection are inherent in this. The Supreme Court, while deciding the matter relating to carrying on trade of liquor in Cooverjee B. Bharucha vs. Excise commissioner, Ajmer[11] observed that, if there is clash between environmental protection and right to freedom of trade and occupation, the courts have to balance environmental interests with the fundamental rights to carry on any occupations.
- **Public Interest Litigation:** Interpretation of the Supreme Court under Article 32 and 226 of the constitution of India favoring litigation by unconnected persons on matters of public interest resulted in a wave of environmental litigation. The leading environmental cases decided by the Supreme Court include case of closure of limestone quarries in the Dehradun region[12] (Dehradun Quarrying case,), the installation of safeguard at a chlorine plant in Delhi[13] (M.C. Mehta V. Union of India,) etc. In Vellore Citizens Welfare Forum vs. Union of India[14], the Court observed that "the Precautionary Principle" and "the Polluter Pays Principle" as an essential feature of "Sustainable Development."
- **Local Government and Environment:** At local and village level also, after the 73rd Amendment, Panchayat (Local Governance body at village level in India) have been empowered under the constitution to take measures such as soil conservation, water management, forestry and protection of the environment and promotion of ecological aspect. While this devolution is a matter of precedence in developing countries, whether Panchayati Raj Institutions have been able to achieve these objectives is outside the purview of this chapter.

PART VII: EVALUATING CONVERGENCE

Globalization as an inevitable process has huge impact on South Asian convergence. Historically the countries in the region came into being through political divisions during and in the aftermath of British colonial rule. The region continues to be dominated by the uneasy relationship between the two largest nations viz India and Pakistan. The course and quality of convergence of South Asian endeavors as a regional group as well as an economic entity will be defined by the quality of relations that these two countries will enjoy. Elsewhere in the world also, the course of the past two decades, as Pirages (2011) states "have been punctuated by increasing numbers of terrorist attacks, state failures, deadly epidemics, rapidly fluctuating world energy and food prices, a global economic meltdown, and intense storms and flooding that are very likely early effects of global warming. These and similar events have given impetus to the development of an alternative paradigm in international relations theory" focused on the intricate relations between man, his environment and sustainable development. This paradigm is not merely exploring the latent dimensions of economic theory that have grown out of the classical wealth generation oriented approach of the previous centuries; it explores an important link between development and human security or in the words of Pirages, 'ecological paradigm'. "An assumption inherent in this ecological or nontraditional paradigm is that significant threats to societies are just as likely to come from changes in human relationships with nature as they are from well-armed troops crossing borders" (Pirages, 2011).

South Asia like some other regions of the world remains a potentially violent region. Given its lengthy historical legacy of military and ethnic conflict, it is not surprising that security across South Asia is still narrowly defined in realist terms like absence of conflict. According to Geoffrey Dabelko and David Dabelko (1995), "at its most fundamental level, the term security has meant the effort to protect a population and territory against organized force while advancing state interests through competitive behavior." Given the effort that has been associated with this historical quest for wealth and power, limiting security concerns to mostly military matters is understandable, if not completely logical. Defense budgets, for the most part, are still used to purchase tanks and planes and not to fight infectious disease or stem global warming. But while troops massed on borders raise fears of impending destruction and death in some parts of the world, in other parts concerns over various kinds of environmental threats have been growing (Barnett, 2001; Kahl, 2006). Additionally, in an era of deepening globalization, infectious diseases can now cross borders more easily and are increasingly being recognized as very serious security threats.

In beginning of the chapter, we noted how regional cooperation that evolved from the political necessity for peace and stability slowly evolved into economic cooperation for sustainable growth. We also noted that through BIMSTEC, South Asia has extended its reach to integrate its economic progress with that of Southeast Asia. The traditional historical and cultural factors that have bound the societies of South Asia (as outlined earlier) provide the fundamentals for peace and stability that are important for regional integration to succeed in its objective. It is also important to recognize that ecological and environmental resources of the region are implicitly interdependent. For example, the Himalayas that are home to all the rivers that water the region are spread across five of the regions eight countries. Any action by an individual country that would adversely affect the ecology of Himalayas or the course of the flow of its rivers will adversely affect all the five in the long run. The sharing of the waters of Indus and Ganges are already at the heart of differences between India, Pakistan and Bangladesh.

Environmental economics of South Asia highlights an important factor that is unique to this region. The environmental resources of the region directly support the livelihoods of at least two thirds of

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

its population. This one single factor is the most powerful argument in favor of regional convergence for sustainable development. Further through our discussion, we found that the forest resource alone contributes to more than one percent of the region's GDP and direct employment to over half a million people. The case studies indicate that the livelihoods and sustainable incomes of vast majority of non-agricultural rural households and indigenous forest dependent populations are intricately enmeshed with natural resources.

Except India which has registered vibrant growth and in the process built substantial foreign exchange reserves to counter-balance international debt, other countries depend on donor agencies for financial assistance to promote good governance and economic development. The evaluation by the donor agencies of the importance of environmental protection for sustainable development in these countries lends a strong argument towards the necessity for enhanced regional convergence on the subject.

Environment and sustainable development are not slogans in international parleys. These are the names for livelihood sources that directly support millions of people. Thus people become the most important stake holders in every initiative that is needed for sustaining livelihoods through rational use of environmental resources. In most cases, as seen in the case studies, the governments need to carry this lesson in their political-bureaucratic endeavors for evolving development projects in the course of their quest for modernization and liberalization of economy. The ordinary and the poor understand the value of protecting their environments much more than corporations and governments do. The highly active civil society Public Interest Litigations in the region are a testimony to this factor.

CONCLUSION

A coming together of different disciplines in an analysis of the nature of economic changes has resulted in a consensus, as Hueting and Reijnders (1998) say, that "life support systems of the earth cannot be replaced completely by technology" and that "uncompensated anthropogenic environmental risk to future generations is unacceptable". The above statement stands vindicated in a world where technological progress has been found insufficient to eradicate poverty and widening income gaps even in highly industrialized countries. Having adapted their economies to the compulsions of globalization, countries in South Asia at times have exhibited their preference to economic growth over sustainable environment. In the enthusiasm for higher GDP growth, environmental concern does appear misplaced. As Chopra (2000) observes, "the call for conservation seems somewhat misplaced. However, if one moves into the broader social and cultural context which prevails in most of South Asia, it is interesting to observe that an understanding of the human interaction with nature has always been built into it. This social and cultural backdrop has made it easier for micro-level initiatives in natural resource management to emerge in these societies". These social and cultural backdrops are what we believe the building stones for meaningful regional cooperation for sustainable development.

The mechanism for regional convergence in the form of SAARC, BIMSTEC, their extended agreements and agencies are already in place. The importance of convergence on environmental issues as the basis for economic development and sustainable livelihoods has also been registered on their agenda. However, the regional convergence in South Asia suffers from the legacies of partition of the subcontinent and the mistrust that has pervaded the relationships between its largest neighbors in past five decades. The deficit of trust that regional convergence suffers from is the lynch pin to collective progress.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Sobhan (2011) finds the challenge (of convergence) for poverty alleviation that is critical to South Asian growth is compounded by three important factors:

- In South Asia, food costs constitute the average household's largest expenditure. If food prices continue to rise without a matching increase in incomes of people at the bottom of the economic ladder, it is estimated that approximately 100 million people could be pushed back into poverty.
- Over the past 25 years, natural disasters and environmental degradation have killed nearly half a million people in South Asia and inflicted colossal damages estimated at $59 billion.
- The lack of long-term energy planning by South Asian countries has caused human suffering and significantly hindered the entire region's economic growth prospects.

All the three factors outlined above are compelling enough on the region's countries to recalibrate their concept of national security, national interest and sovereignty. The progress of SAARC in the three decades and BIMSTEC in nearly two decades has important lessons in cooperation and eventual integration for South Asian countries. The arenas for cooperation and the possible gains have been explored by governments, experts, academia and donor agencies like World Bank and ADB. Countries like Japan have evinced keen interest in partnering with such initiatives for obvious economic and geopolitical gains. Compelled by globalization and market forces, individually the members of SAARC and BIMSTEC have initiated first generation policy reforms. However the next generation of reforms is besotted with challenges like the high cost of doing business, weak institutions, weak knowledge economy, high levels of corruption and poor infrastructure. Ahmad observes that South Asia also needs to expand its knowledge economy to raise the productivity of investment. These second-generation policy reforms have started; continued strong implementation will support the sustainability of growth (Ahmad & Ghani, 2007). In the same breath, Ahmad et al, also observe that regional cooperation can be an effective tool in addressing energy shortage, ensuring that no region/country is left behind, landlocked regions/countries have full access to markets, and *peace and stability are promoted*. There is a need for greater people-to-people contact through improved connectivity, phasing out of visa restrictions, and liberalizing the restrictions on the trade of services (for example, tourism, education, and health) where the risk of trade diversion is low. These initiatives would help increase investment and growth by reducing the infrastructure constraint and by lowering transaction costs. *Better regional cooperation and integration can also increase welfare by improving the regional political environment, thereby reducing conflicts* and associated social and economic costs (Ahmad & Ghani, 2007). (Emphasis added)

The most eloquent pointer for regionalism or 'constructive bilateralism' leading to political stability and economic progress is the EU. European history is a product of the continuous conflict between France and Germany. As the most prominent powers of the continent with differing philosophies, they had fought a number of wars, WWI and II inclusive. However, these two countries came together to address their differences in the most constructive manner throughthe Schuman Declaration of 1950 (EU, 1950) which states the following:

Europe will not be made all at once, or according to a single plan. It will be built through concrete achievements which first create a de facto solidarity. The coming together of the nations of Europe requires the elimination of the age-old opposition of France and Germany. Any action taken must in the first place concern these two countries.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

With this aim in view, the French Government proposes that action be taken immediately on one limited but decisive point.

It proposes that Franco-German production of coal and steel as a whole be placed under a common High Authority, within the framework of an organization open to the participation of the other countries of Europe. The pooling of coal and steel production should immediately provide for the setting up of common foundations for economic development as a first step in the federation of Europe, and will change the destinies of those regions which have long been devoted to the manufacture of munitions of war, of which they have been the most constant victims.

The solidarity in production thus established will make it plain that any war between France and Germany becomes not merely unthinkable, but materially impossible. The setting up of this powerful productive unit, open to all countries willing to take part and bound ultimately to provide all the member countries with the basic elements of industrial production on the same terms, will lay a true foundation for their economic unification. (Emphasis added)

In one step, two major issues were set aside by Schuman – the narrow concept of sovereignty and national interest. What EU is today as a major trading partner of the rest of the world and a developmental model that is worthy of emulation, was possible by eschewing both these issues through enlightened political action. A similar initiative by the political leaderships of South Asia is the most urgent need of the hour. As such the concept of sovereignty and nationhood for purely political purposes like predominance of state has undergone huge change due to the emergence of International Law Regime and a proactive UN. The ability of national governments to address all challenges for development within domestic capabilities is no more feasible in a world that is increasingly interdependent. Providing a peaceful and stable environment which is fundamental to growth also depends on the stability of regime and policy continuity in the neighborhood.

South Asia, as distinct from other regions of the world, barring Western Europe, has a unique historical bond that cuts across the geographical, religious and linguistic divides that prevail in the region. We feel that this real connecting thread is the basis for cooperation that must be maximized by countries in the region. The inter people and inter-governmental structures for convergence are already in place. It is convergence of political intent that needs to be forged in South Asia in order to make sustainable development a reality for the millions that live in these lands.

KEY TERMS AND DEFINITIONS

Climate Change: Refers to the change in weather patterns induced by ecological and environmental degradation.

Colonial Economy: Refers to the economic system formulated by the British to draw upon the natural resources of the Indian Subcontinent.

Conservation: Refers to preservation of natural environment, its protection and management by government institutions or community of people.

Ecology: Refers to the interaction between organisms and their environment. In this chapter the term is used in specific reference to the relationship between man and environment for sustenance of livelihoods and agriculture.

Environment: Refers to the natural environment encompassing all living things in it in any region of the earth.

Environmental Economics: Refers broadly to the products and services derived from natural environment.

Environmental Governance: Refers to the institutional framework for management of natural resources, and control of access to them for public and private exploitation.

Governance: Refers to the system of institutions that regulate how citizens interact with their environment.

Panchayat: Panchayat is a body of five elected representatives from the local population who form the local government at village level in India. The term is also in use in Bangladesh and Pakistan. Panchayats as local governance bodies have existed in the subcontinent for over two millennia. Panchayati Raj Institution (PRI) as they are called denotes the local governance structure established under the 73rd Amendment Bill and now prevalent across India in all villages.

Political Economy: Refers to the political and institutional control of economic activities. In this chapter, specifically refers to such control on access to natural resources.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Raj: This Hindustani word denotes government.

Regional Cooperation: Regional cooperation refers to the political and institutional mechanisms that countries in a general geographical region devise to find and strengthen common interests as well as promoting their national interests, through mutual cooperation and dialogue.

South Asia: Refers to the Indian subcontinent consisting of all eight countries in the region, without any specific reference to any one particular country.

Sustainable Development: Refers to the pragmatic exploitation of natural resources carefully balancing the need for conservation, sustainable livelihoods and developmental projects for larger public good.

Sustainable Livelihood: Refers to the consistency with which a poor citizen can continue to draw life support resources from the natural environment in which he lives without excessively degrading it either by his own actions or actions induced by developmental or industrial activities undertaken by government or private bodies.

ENDNOTES

1 The phrase is attributed to Benjamin Disraeli, the British prime minister from 1874 to 1881. He called India "the brightest jewel in the crown". In 1876, Queen Victoria was proclaimed Empress of India, and British monarchs retained the title until 1947.

2 Land Revenue includes revenue from forest produce including sale of timber

Chapter 48
Citizen Science and Its Role in Sustainable Development:
Status, Trends, Issues, and Opportunities

Hai-Ying Liu
Norwegian Institute for Air Research, Norway

Mike Kobernus
Norwegian Institute for Air Research, Norway

ABSTRACT

The chapter aims to analyse the role of citizen science in sustainable development, including case studies implementation, with specific focus on its suitability of citizen science in environmental sustainability. The authors structured this chapter in five sections: Background; Main focus; Solutions and recommendations for designing and executing citizen science initiatives; Future research directions with thoughts on the future role of citizen science; and Conclusion. In section of main focus, first, the authors reviewed the state of citizen science in sustainable development and explored the potential of citizen science for environmental research and governance. Second, authors identified and elaborated the core components that support the role of citizen science and demonstrated the practical approach to realize its objective. Third, using several citizens' observatories studies from various regions in Europe and within diverse environmental fields, authors highlighted the lessons learned, and reflected on major outcomes, challenges and opportunities.

INTRODUCTION

Participation of the public in scientific and action research, independently or in cooperation with scientists, is often referred to as 'citizen science' (Hand, 2010). Additional terms, such as 'crowd science', 'crowd-sourced science', 'civic science', or 'networked science' may be viewed as synonyms (Hand, 2010). Citizen science itself can be said to have existed since the very start of scientific practice, where it has developed in many different guises. As the internet continues to proliferate in the world, new tools like social media, mobile devices and mobile sensors are becoming the norm (Lanfranchi, Wrigley, Ire-

son, Ciravegna, & Wehn de Montalvo, 2013)). Lately, it has been witnessed a global increase of citizen science projects and citizens engaging in projects as amateur researchers, as sensors, as advocates and even watchdogs (Haklay, 2015). Further, crowdsourcing methods, data processing and visualization technologies are developing rapidly, leading to a wide range of new opportunities for public participation in a compelling range of topics (Buytaert et al., 2014). As an example, it can be seen that a tremendous increase of environmental observation activities in this area, i.e., various citizens' observatories that encompass different models of citizen science and span a diverse range of subjects (e.g., biodiversity, water, air, climate change, agriculture, disaster, etc.), empowering average people to monitor their environment, collectively generate scientific data and support environmental risk response (Liu, Kobernus, Broday, & Bartonova, 2014).

The objective of this chapter is to analyze the role of citizen science in sustainable development, including case studies in citizen science implementation, with specific focus on the suitability of citizen science in environmental sustainability. It comprises the following five sections: Background; Main focus of the chapter; Solutions and recommendations for designing and executing citizen science initiatives that help inform and create environmental action, based on evidence, sound science and citizens' needs; Future research directions with thoughts on the future role of citizen science; and The Conclusion. In the section, 'Main Focus', the authors have divided it into the following substructure:

1. First, the authors reviewed the state of citizen science in sustainable development and explored the potential of citizen science to complement more traditional ways of scientific data collection and knowledge generation for environmental research and governance;
2. Second, the authors identified and elaborated the core components that support the role of citizen science and demonstrated a practical approach to realize its objective of environmental sustainability;
3. Third, using several citizens' observatories case studies from various regions in Europe and within diverse environmental fields, the authors highlighted the lessons learned, and reflected on major outcomes, challenges and opportunities in the integration of environmental-oriented citizen science within environmental management, the role of scientific knowledge in the decision-making process, and the potential contestation to established community institutions posed by the co-generation of knowledge.

BACKGROUND

Citizen participation with environmental science has a long history, before it was termed 'citizen science' (Roy, 2012). In fact, until the late 19th century, there were no professional scientists as it is well known them today (Kight, 2012; Miller-Rushing, Primack, & Bonney, 2012). Research was typically undertaken by amateurs, often Gentlemen of Leisure or men of the cloth (Miller-Rushing et al., 2012). Charles Darwin, for example, was not a trained scientist (Kight, 2012; Dillon, 2014). Likewise, the Swedish botanist and physicist, Linnaeus, was not only a Lutheran minister for a period, but worked with a wide network of citizen volunteers who sent samples to him, a not uncommon practice (Scyphers et al., 2015). One could argue that he exemplifies the very nature of citizen science. However, these men were at the pinnacle of the scientific community, so it might be somewhat disingenuous to claim they were amateurs. Nonetheless, citizen science was an activity that many average citizens engaged in at

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

the avocational, or hobby level. Long before social media made citizen science accessible to the wider population in the digital age, amateurs found a way, adopting the participatory science model to their circumstances.

The first 'modern' large scale citizen participation began in 1999, at the University of Berkeley, California, where data from radio telescopes was analyzed using computers that otherwise would have been idle (Korpela et al., 2011). These computers belonged to citizens who simply wanted to be part of something, and by contributing their computer's CPUs, they helped crunch data. And as budgets become increasingly tight within research communities, alternative solutions to data gathering were needed and the Internet and mobile technologies provided the answer. The development of communication technologies offered many new avenues for citizens to contribute in a number of ways. Personal perceptions, comments, and even using the phone itself as a mobile sensor, all have a place. Such is the popularity of participatory sensing now that it has become a relatively common component to many projects and research studies (Lanfranchi et al., 2013). You can find active citizen participation in a wide range of topics, where people provide data on biodiversity, land use, weather, personal health, perception of cleanliness of buildings, and so much more (Liu et al., 2014).

The need to have a comprehensive understanding of environmental integrity, including function and structure, is often confounded by a lack of, or inadequate and incomplete, data and monitoring initiatives by professional scientists and government agencies. To fill the void, non-professionals and citizen organizations have emerged the world over to track trends and to work towards effective and meaningful planning, management, and stewardship (Conrad & Hilchey, 2011). This is especially facilitated by the innovative tools and ICT. For example, with the appearance of new low-cost sensor technologies, monitoring the environment is now, in a literal way, in everyone's hands (Liu et al., 2014; Kobernus et al., 2015). Novel sensor technologies open the opportunity to monitor the environment at spatial resolutions not possible to achieve with traditional monitoring systems (Liu, Skjetne, & Kobernus, 2013). Citizens can now contribute to monitor the environment in a direct and meaningful manner.

Formally, the role of citizen science has been defined as research co-design/co-creation, the systematic collection and analysis of data, development of technology, testing of natural phenomena, and the dissemination of these activities together with scientists on a primarily avocational basis (Hand, 2010). In recent years, citizen science has been viewed as an increasingly essential tool to support and promote community-based environmental governance, as it attempts to provide citizens with a voice and accountability in the future of sustainability research (Liu et al., 2014). Obviously, citizen science enables a more active role for citizens concerning understanding the environment, since citizens are traditionally considered as 'consumers' of information services at the very end of the information chain and not as 'data providers'. However, it is no longer sufficient to develop and provide passive lists of environmental indices or reports to inform citizens about changes in their environment. There is a need to engage citizens to find out how they can inform the community, and to empower citizens to improve their own health and well-being through actively making informed choices via citizen science activities and outcomes. Involving citizens at the local level by developing knowledge pools can help create an atmosphere of active participation and generate a sustainable movement that can build over time. Citizens have expectations to interact and participate in the decision-making processes, and to be engaged in a dialogue about their communities, preferences and future (Liu et al., 2012a). According to sociological research, the recent increase in pro-active participants of social IT media, with a particular

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

focus on environmental issues, results from a shift from materialism to post-materialism where more and more people are showing increasing interest in a renewable and sustainable life style, which is the key objective of environmental governance and lies at the heart of 'sustainable development' (Salonen & Åhlberg, 2013; Liu et al., 2014).

'Sustainable development' is development that meets the needs of the present without compromising the ability of future generations to meet their own needs (World Commission on Environment and Development, 1987). Citizen science is crucial in bridging the gap between environmental governance and the public, and can play a key role in sustainable development (Liu et al., 2014). However, there is no globally agreed and understood definition of 'environmental governance' and it can be interpreted in many different ways. In principle, environmental governance comprises the rules, practices, policies and institutions that shape how humans interact with their environment (UNEP, 2009). It can refer to the processes of decision-making involved in the control and management of the environment for the purpose of attaining environmentally-sustainable development. Good environmental governance takes into account the role of all actors that impact the environment, from governments to Non-Governmental Organizations (NGOs), the private sector and civil society, the individual and citizen groups. Cooperation between actors is critical to achieving effective governance that can help us move towards a more sustainable future. In this context, the key aspect of citizen science is the direct involvement of ordinary citizens, and not just that of scientists/professionals. This can be in data collection as well as harnessing the citizens' collective intelligence, i.e., the distributed information, experience and knowledge embodied within individuals and communities. This will help to bridge gaps that many areas of environmental management are still suffering from. Namely, citizen science should enable citizens' participation in environmental monitoring in order to contribute to environmental governance by providing relevant data and information that can help decision-makers make sound decisions. This can be advanced by providing citizens with a voice and supporting them with information on their environment, consequently raising their awareness and leading to higher levels of involvement. This reveals key components that underpin the core objectives of citizen science in sustainable development, i.e., raising citizens' awareness and consciousness, enabling dialogue and supporting data exchange/knowledge sharing amongst citizens, scientists, policy/decision makers, and other stakeholders (Liu et al., 2014). These three components of citizen science can explain the major links between citizen science and environmental governance, and in fact are the three pillars that comprise citizen science enabling it to support environmental governance (Kobernus et al., 2015). In the context of citizen science's contribution to environmental governance, it is important to recognize that citizens are not a monolithic group, all alike. There are stakeholders/user groups including individuals or groups of volunteers, scientists, government authorities, emergency services, etc. Hence, various actors in citizen science have different behaviors, intentions, interrelations, agendas, interests, as well as influence, resources and power on decision-making and political processes. Moreover, there are a number of questions about its potential as a democratizing force in environmental policy and management (Fore, Paulsen, & O'Laughlin, 2001; Liu et al., 2014). However, given the many contending conceptions within democratic theory (e.g., direct, representative, participatory, minimal, deliberative, aggregative, etc.), it should be noted that this aspect is a complex subject with no "one size fits all" solution. Nevertheless, citizen science has shown its potential to address issues of environmental equity and sustainability, and to improve social justice and responsibility, which is directly linked to the principles and treaties on sustainable development, including economic development, social development and environmental protection.

MAIN FOCUS OF THE CHAPTER

Status and Trends of Citizen Science in Sustainable Development

Due to the increasing significance, utility and function of citizen science for environmental research, governance and practice (Conrad & Hilchey, 2011; Roy et al., 2012), a review of existing citizen science projects ranging from small one-off local surveys to large-scale long-term programs by focusing on its status and trends including consensus, divergence and gaps is presented here. In order to comprehensively review the state of citizen science in academic journal articles, the authors reviewed citizens' observatories in varying environmental and social contexts. A review of the vast academic-and non-academic-based literature from around the globe indicates (Grossberndt & Liu, 2016):

1. For Professionals: Lack of funding and staffing for environmental monitoring; For governments: more environmental monitoring data and stakeholders needed for decision-making processes. These have led to an increase in the use of amateur scientists around the globe.
2. There are differences in the monitoring intent in different parts of the world. In parts of Europe (particularly in Britain), many of the citizen science initiatives focus on collecting data about species and habitats, whereas there is a predominance of monitoring efforts on ecosystem functions and environmental quality in North America.
3. The issue of monitoring interest often transcends government boundaries, and many NGOs responsible for cross-state, cross-province, or cross-country concerns have increased their use of citizen science.
4. Citizen science relationships with academic institutions and universities have increased, perhaps due to their capacity to provide training, lab facilities, free space, and funding.

This review is not intended to be inclusive of all types of citizen science initiatives, especially given the enormous proliferation of citizen science activities (e.g., there are more than 1,100 active and searchable global citizen science projects listed on SciStarter (Wikipedia, 2016)), but instead is representative of a variety of citizen science campaigns across the globe. Citizen science activities can differ in focus, approach or technique. The review indicates that many citizen science initiative focus on monitoring water quality, birds count, butterflies, mosquitoes, wildlife, air quality, algae, amphibians, plants, fish, worms, odors, and ice (Grossberndt & Liu, 2016).

In addition, citizen science initiatives have engaged both the commodity-based monitoring (e.g., resource fishery, resource forestry, etc.) and non-commodity-based monitoring (e.g., recreational fishery, monitoring water quality, monitoring air quality, etc.) (Grossberndt & Liu, 2016). Commodity-based monitoring deals with issues of economic as well as social and environmental importance. Non-commodity-based monitoring focuses on issues that may not seem to be directly economically important.

Citizen science initiatives also differ in the types of monitoring activities the organization undertakes (Grossberndt & Liu, 2016). Citizen science monitoring activities include many different types of assessment of the environment:

1. Status assessment (e.g., air quality status);
2. Impact assessment (e.g., effect of air pollution);
3. Adaptive management (e.g., managing based upon monitoring).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Citizen science monitoring activities also include different aspects of the environment monitored (Grossberndt & Liu, 2016):

1. Environmental composition (e.g., air, water, soil, etc.);
2. Structure (e.g., environmental analysis, key pollutants, etc.); and
3. Processes (e.g., linking human health with environmental problem). Process-based monitoring is suggested as being most desirable in many studies.

Furthermore, in a context of sustainable development, almost by definition (Bastiaensen et al., 2005), the poorer people will have difficulty to voice their concerns and even more to articulate them to (scientific) outsiders. So more often than otherwise, it therefore be expected that participative citizen science will address more main stream concerns of the local majority, or even of small dominant local elites (Buytaert et al., 2014). But in view of the post-research application of scientific findings, this usually has the advantage to facilitate rallying more and more relevant local support to implement recommendations through social action, while evidently risking to bypass critical concerns of disadvantaged groups and even to contribute to the deepening of their dispossession and exclusion. This constitutes a tricky, but often unavoidable dilemma in the implementation of citizen science, and requires a careful analysis of the social interface between the citizen science practices and the learning and struggle in local political arenas. By no means, however, does this dilemma reduce the potential contribution that science and citizen science can make to local bricolage toward better governance (Buytaert et al., 2014).

According to Buytaert et al. (2014), despite being an intrinsic part of the scientific discovery and knowledge generation process, the concept and potential of citizen science in itself only recently received increasing scientific attention. New technological developments are supporting novel and more efficient methods for data collection and processing, visualization and communication. These opportunities make reflecting upon the challenges and opportunities of citizen science, especially in a context of managing natural resources and leveraging them for human well-being, timely and relevant. This is particularly the case for water resources, which is often one of the most fundamental ecosystem services and a significant bottleneck for sustainable development and poverty alleviation. Their review of technologies reveals a large potential for increasing involvement of citizens in data collection because of the availability of inexpensive, robust and highly automated sensors, and the possibility to combine them with powerful environmental models to create rich and interactive visualization methods (Buytaert, Dewulf, De Bièvre, Clark, & Hannah, 2016). In the fields of hydrology and water resource management, Buytaert et al., (2014) highlighted that citizen science has the potential of being more inclusive methods to generate knowledge on improved uses of ecosystem services that supports sustainable development and improves human well-being. Their discussion focuses particularly on:

- The motivation and level of engagement by the non-scientists.
- The type of data monitored, and potential for participatory modelling and knowledge exchange.
- The legitimacy of the generated knowledge.
- The sustainability of the citizen science activity.
- Potential uptake in decision making/resource governance.

Core Components of Citizen Science and Its Practical Approach

In recent years, there has been a boom in citizen science projects, which allow members of the public to play an active part in monitoring and recording their environment across the globe. The increase in the prevalence of citizen science globally has been mirrored by a growth in the number of variables that are monitored, the number of monitoring locations and the different types of participating citizens (Liu et al., 2014; Kobernus et al., 2015; Grossberndt & Liu, 2016). This calls for a more integrated approach to handle the emerging complexities involved in this field (Liu et al., 2012b); but before this can be achieved, it is essential to establish a common foundation for citizen science and their usage. There are many aspects related to a citizen science project. One view is that its essence is a process that involves environmental monitoring, information gathering, data management and analysis, assessment and reporting systems. Hence, it requires the development of novel monitoring technologies and of advanced data management strategies to capture, analyze and survey the data, thus facilitating their exploitation for policy and society (Liu et al., 2014; Kobernus et al., 2015). Practically, there are many challenges in implementing the citizen science approach, such as ensuring effective citizens' participation, dealing with data privacy, accounting for ethical and security requirements, and taking into account data standards, quality and reliability. These concerns all need to be addressed in a concerted way to provide a stable, reliable and scalable citizen science program. On the other hand, the citizen science approach carries the promise of increasing public awareness for risks in their environment, which has a corollary economic value, and enhancing data acquisition at low or no cost (Liu et al., 2014; Kobernus et al., 2015).

Type of Citizen Science

Citizen science does not only serve scientific purposes, but also decision-making, since the collected data can contribute to informed policy-making. In addition, citizens can benefit by addressing the environmental issues that affect them directly in the context of participatory decision-making. In this way, the value of lay knowledge should not be underestimated (Science Communication Unit, University of the West of England, 2013). According to Haklay (2015), the following three policy dimensions can be distinguished:

1. Level of geography;
2. Policy domains; and
3. Level of engagement and type of citizen science activity.

Citizen science initiatives can influence policy decisions in a specific geographical area, i.e., local, regional, national and international. Usually, problems that affect people directly, lead to more engagement since people are both more aware and concerned (Haklay, 2015). This potential can be used to build upon observation activities through citizen science initiatives. Local citizen science is often linked to environmental activism and supports community management by working towards effective and meaningful management planning, management and stewardship (Conrad & Hilchey, 2011). Local citizen science can also apply the so-called community-based monitoring approach (CBM). CBM describes a process where concerned citizens, public authorities and further stakeholders collaborate to monitor, track and respond to issues that arise from common community concerns (Whitelaw, Vaughan, Craig, & Atkinson, 2003).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Environmental issues are very complex and would actually require additional resources. Thus, there is an increasing need for communities to fall back on citizen science approaches (or CBM respectively) and include different stakeholders with their diverse knowledge and experience into the decision-making processes (Conrad & Daoust, 2008). In addition to the decision-making bodies' saving time and money, the societal benefits of CBM will be creating environmental democracy, social capital, and increase in scientific literacy and inclusion in local issues (Conrad & Hilchey, 2011).

Policy areas can be manifold and partially overlapping. For example, city-scale infrastructure contains public transport, environmental quality, education, infrastructure and public health. Thus, cities can be a canvas for a potpourri of local monitoring activities, originating from different concerns but using the accumulated data to see the bigger picture (Grossberndt & Liu, 2016). Moving citizen science projects to regional, national or even international level is likely to meet even more challenges than there already are. Since bottom-up initiatives usually dispose of limited budgets only, it will be less likely to find community science approaches with an active involvement of citizens in all parts of the participation cycle, i.e., citizens will rather only be asked to share observations or viewpoints on certain issues. Nevertheless, national and even international initiatives including citizen science are possible and do exist. Projects funded by the European Commission (EC) and formation of international organizations like the European Citizen Science Association (ECSA) provide frameworks for national initiatives and NGOs to create synergies to promote citizen science on a larger scale and call on international institutions such as the European Environmental Agency (EEA) to promote citizen participation also at an international level (Haklay, 2015).

However, how can people actually be involved in citizen science? Haklay (2015) distinguished different levels of engagement within citizen science. As it can be seen, these categories resemble those participation levels presented earlier in this chapter. The first level is called passive sensing and describes a process where information is collected without any effort on the participants' part through their own devices. Volunteer computing is a method where participants allow scientists to use their unused computing resources on, e.g., their PC or smartphone for complex computer models while the device is not in use. The next level, volunteer thinking makes use of the citizens' cognitive abilities not used during passive leisure activities, e.g., people contribute by recognizing patterns while watching TV. The obtained data will then be further used in scientific projects. Environmental and ecological observations describe the traditional form of citizen science, where volunteers monitor and/or observe their personal environment, often based on protocols that are designed by scientists. In participatory sensing activities, the citizens are more actively involved in designing both data collection and analysis. The last activity type can be summarized as civic/community science. In this bottom-up approach, the participants can choose their level of engagement and can even be involved in the analysis and interpretation of the results and their publication/utilization. This level of engagement does not necessarily require the involvement of scientists (Grossberndt & Liu, 2016).

Citizen science initiatives should be tailored to match both interest and skills of the participants. This is crucial in order to develop successful initiatives. Although motivations vary widely, the authors find that enjoyment and enthusiasm for the goals of the initiative are two of the main drivers. As known from other research areas, the feeling of control over the scientific process can also lead to long-lived engagement (Roy et al., 2012).

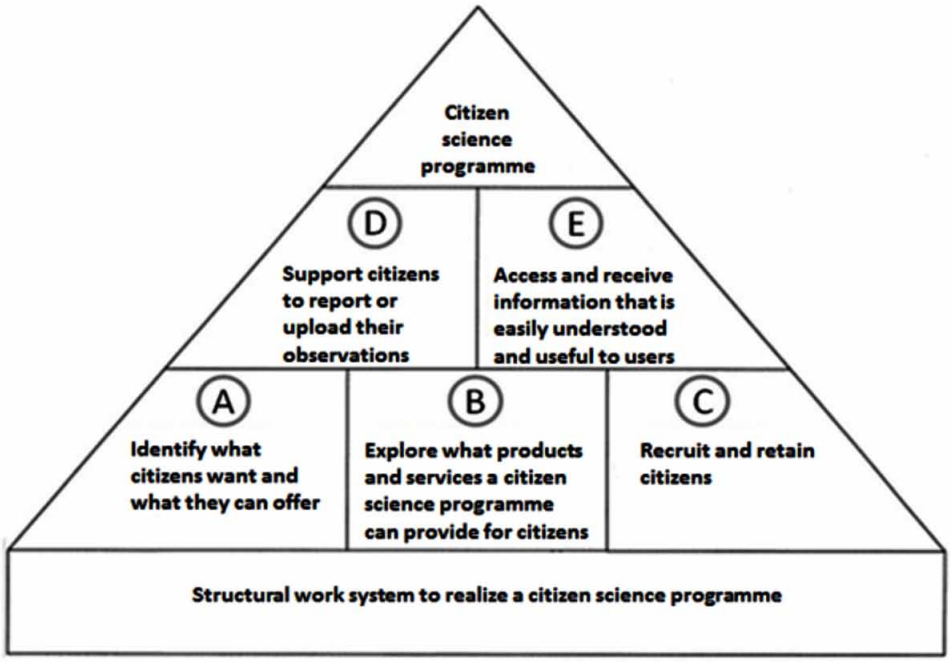
Citizen Science Framework

Overall, citizen science is based on a general framework linking citizens and scientists together, allowing the implementation of a more comprehensive scientific approach. The framework can address a particular question, tests hypotheses with appropriate data collected from a well-designed protocol, allow the interpretation and understanding of new results and can help to derive and spread original educational outputs (Kobernus et al., 2015).

To establish a citizen science program and to make it useful for society, there is a need for researchers to collaborate with citizens, citizen groups and their representatives, and with the representatives of the local authorities, to identify interests and needs (Liu et al., 2014). In a citizen science program, all parties shall be encouraged to be engaged as active participants, to create knowledge of the environmental situation in a participatory manner and to contribute to dealing with the situation (Landranchi et al., 2013). One of the main aspects of a citizen science program is the need to effectively address citizens participation in data collection, data interpretation and information delivery. According to Liu et al. (2014), this can be expressed as the following set of five sequential aspects that underlie the citizen science skeleton and support effective citizen participation (Figure 1):

a. Citizens' participation in identifying what citizens want and what a citizen science program can offer to provide information and knowledge in response to public concerns. This is achieved mainly by a dialogue among the stakeholders;
b. Citizens' participation in exploration of what products and services a citizen science program can provide for the citizens. This involves systematizing and structuring citizens-created content to make it appealing for use by citizens during their normal daily life;
c. Recruiting and retaining citizens to participate in and contribute to environmental governance: further clarify the purpose, scope and expected impact of the citizen science program, identify motivations that will promote citizens to contribute to and take part in the citizen science activities, and encourage public participation in data collection and interpretation;
d. Obtaining public participation in the relevant decision making and/or in changing their related personal priorities and behavior by gaining access to environmental data, knowledge and experience, and by using tools that can support citizens to report or upload their objective/subjective observations, inference and concerns;
e. Supplying tools to access/receive timely information on the relevant environmental issues in a manner that is both easily understood and useful to the users.



Among critical factors of success, the simplicity of each component of the framework, the structure of the scheme, the regular feedback of results to participants and a good communications strategy are crucial. Moreover, for long-term projects, the sustainability of the framework (often demanding sources of funding and people with permanent positions) should be carefully thought through (Devictor, Whittaker, & Beltrame, 2010).

Citizen Science Model in Practice

A key concept in the operation of citizen science program is the idea of a campaign that specifies stakeholders' concerns by defining the types of data that need to be collected and by describing the goal,

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Sequential aspects of a citizen science program

expected feedback and analysis outcomes in terms of maps, statistical results, etc. The raison d'être of the observatory then is to "run and orchestrate" a campaign in order to assure that sufficient data is gathered, both qualitatively and quantitatively, and to enable non-expert stakeholders to define, monitor and analyze campaigns in a way understandable to them (D'Hondt, Zaman, Philips, Boix, & De Meuter, 2014; Zaman et al., 2014).

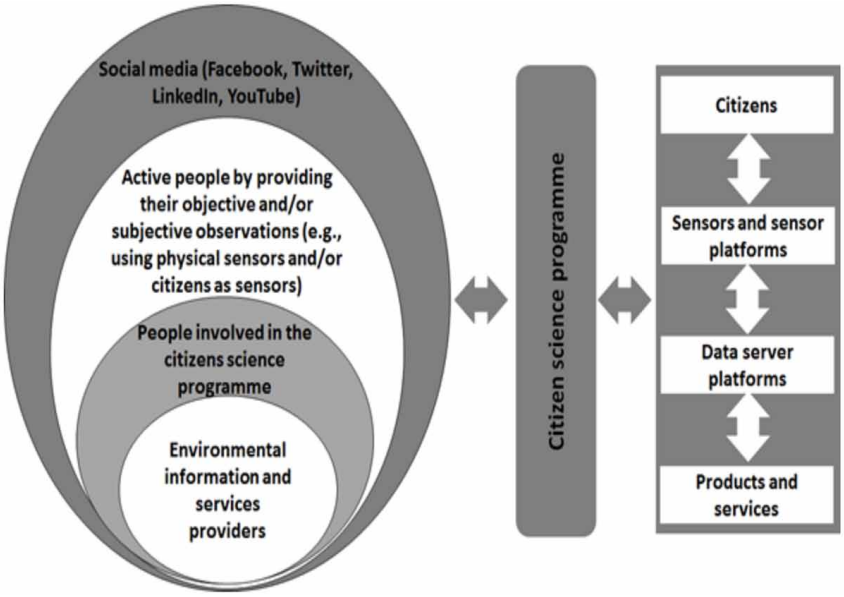


Figure 2 illustrates a common model of citizen science program: A set of concentric circles that are characterized by different types of information needs and of information gathered and shared (left part). The circles represent different types of stakeholders: environmental information and services providers and people actively involved in citizen science program (e.g., public, researchers, policy-makers, small and medium-sized enterprises (SMEs), etc.). In addition, the circles also represent different tools that different stakeholders may use to provide their observations and share their data and information, e.g., innovative low-cost physical sensors, citizens as sensors, and social media, etc. The aim of the citizen science approach is to support all stakeholders by designing various tools and applications that support co-participation (Landranchi et al., 2013).

In addition to the different stakeholders and the way to engage such stakeholders, Figure 2 also illustrates the four core components of the data flow model in various citizen science projects (right part):

1. **Citizens:** Different types of stakeholders, including the general public;
2. **Monitoring Tools and its Platforms:** Technologies for environmental monitoring (i.e., smartphone, low-cost monitoring tools and its platforms);
3. **Data Server Platforms:** Information and communication technologies (e.g., web-featured service);

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. A common citizen-science model in practice

4. **Products and Services:** Information products and services, i.e., mobile apps, web applications, social media networks, public environmental survey, etc.

The first three components (citizens, monitoring tools and its platforms, data server platforms) are the main elements of participatory sensing, reflecting the concept of communities or other groups of people contributing information in the form of data and knowledge (Dua, Bulusu, Feng, & Hu, 2009). The fourth component (products and services), linked to the usage of obtained data and knowledge, is designed and expected to be used by various stakeholders for different purposes. These components can be considered as the four pillars that support various citizen science programs in practice (Engelken-Jorge et al., 2014; Liu et al., 2014). They relate to the stakeholders' experience, expertise and expectations and are clearly important. Within these four pillars, various actors may use the tools or instruments to produce raw data that leads to a range of new products or services as well (Lanfranchi et al., 2013; Liu et al., 2014). Here, the authors present a common model of citizen science program which is being been translated into practice in several existing citizen science projects, i.e., Citclops, CITI-SENSE, Citi-Sense-MOB, Cobweb, EVERYAWARE, Omniscientis and WeSenseIt. All of these projects put an emphasis on delivering highly innovative technologies to support citizens, communities and authorities by getting 'near real-time' and/or 'up-to-date' data about environmental conditions (e.g., air quality, water quality, etc.) and situations (e.g., flooding), while respecting the different information needs and actions respond. On a technical level, these projects consists of a combination of crowdsourcing and custom applications designed to empower and foster participation with the objective of creating an enriched information and knowledge base to facilitate decision making while increasing opportunities for citizen engagement in their community (Ciravegna, Huwald, Lanfranchi, & Wehn de Montalvo, 2013; Lanfranchi et al., 2013; Liu et al., 2014). These projects base data capture on one or several of the following tools:

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

1. A set of innovative low cost sensors for monitoring environment that are designed and can be used directly by both professionals and citizens alike;
2. A set of public environmental perception surveys ("citizens as sensors") designed to be used by citizen participants;
3. Tools that enable the exploitation of the citizens' collective intelligence through crowdsourcing (e.g., Volunteered Geographic Information (VGI)) and social media platforms (e.g., Facebook page, Twitter account) analysis.

Challenges Met and Lessons Learned from Existing Citizen Science Activities

Citizen science initiatives require strict data management. Since most of the citizen science initiatives take place outside organizational frameworks, special efforts have to be made to guarantee the quality of the obtained data. This can be reached through either controlling the quality of data during their acquisition or subsequently after their acquisition by comparing them with reference data (Goodchild & Li, 2012). The first approach requires the introduction into and training of data collection and/or interpretation methods. Here, participants receive instructions and guidelines (e.g., provision of standardized equipment, instruction sheets, online training, etc.) on the use of the measuring device and how to collect data. In the case of VGI, a certain quality assurance is guaranteed when several participants deliver the same GPS (Global Positioning System) coordinates for the same object. In some occasions, some participants can also be asked to monitor and validate the data collected by participants with less experience, as for example in bird watching activities or monitoring of invasive species. Another example is Wikipedia, where a group of individuals with special rights acts as moderators or gatekeepers to avoid vandalism, remove copyrighted materials and resolving conflicts. In other occasions, it can be valuable to use existing knowledge of citizens to evaluate the validity of the data from volunteers (Grossberndt & Liu, 2016). For example, by using existing knowledge about the fauna in Norway, it is very unlikely that a giraffe will be spotted in the streets of Oslo, Norway (Goodchild & Li 2012, Haklay, 2015).

Next to data issues, there are a number of further challenges for the implementation of public participation. In their review of citizen science and community-based initiatives, Conrad & Hilchey (2011) provided a list of challenges of community-based monitoring. Apart from data issues mentioned above, these challenges include:

1. Lack of interest of the volunteers;
2. Lack of opportunities for networking;
3. Funding difficulties;
4. The participants, inability to get access to appropriate information and expertise;
5. Insufficient experimental design;
6. Utility of community-based monitoring data for, e.g., decision-making.

Another aspect that it is needed to bear in mind is the fact that even though international agencies, such as the EEA, promote approaches of inclusive governance processes, this does not mean that this advice is followed automatically on national, regional or even the local level. Not only the willingness, but also the readiness of decision-makers has to be taken into consideration when designing and implementing any participative initiative. In this context, it should also be mentioned that even if the

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

participative process has been carried out successfully, it should strive to translate the prepared work into action (Litke & Day, 1998).

Although the usage of the citizen science concept is becoming a more common practice for environmental management, challenges still exist regarding how to deal with the quality of the data collected as well as how to use it for environmental policy (Tennessee Water Resources Research Center, University of Tennessee 2004; Goeschl & Jürgens, 2012).

Such challenges suggest that the following areas should receive careful consideration (Liu et al., 2014):

1. **Data Quality (i.e., Accuracy and Uncertainty):** Especially when comparing crowd-sourced and reference data;
2. **Data Privacy and Security**: Sharing of data and information requires strong ethical and security considerations;
3. **Data Interpretation**: Qualitative indicators such as "quality of life", "well-being", "happiness", etc., should be developed in parallel with more quantitative indicators that are based not only on individual perception, but on an integrated sensor network;
4. **Systematization and Structuring of Citizens-Created Content and Feedback:** Establishing a viable model(s) to support decisions and empower the public (Engelken-Jorge et al., 2014);
5. **Involving and Maintaining a Broad Spectrum of Society**: Implementing various location-specific and target group-tailored tools in recruiting and sustaining citizens' participation in environmental monitoring (Fernandez-Gimenez, Ballard, & Sturtevant, 2008).

In practice, various citizen science programs all share a similar structure, yet in the current status, constructing a new citizen science program for a new type of campaign (e.g., air pollution, mobility patterns of users of public transportation, biodiversity, climate change, etc.) requires that all software infrastructure to be rebuilt from scratch (Liu et al., 2014). The lack of a systematic, easy and reusable methods for setting up new citizen science programs and for defining new campaigns poses an unsurmountable hurdle for communities and organizations as they usually lack the specific technical ICT-skills and programming knowledge to create the necessary server infrastructure and mobile applications. This often forces these organizations to opt for a non-technological approach (i.e., pen and paper) or to spend big chunks of their restricted budget on external ICT-consultants (D'Hondt et al., 2014; Zaman et al., 2014).

SOLUTIONS AND RECOMMENDATIONS

Citizen science has showed its potential to help meet the demands of monitoring the environment. There are several guides exist in the field of biodiversity monitoring, for example, Guide to citizen science (Tweddle, Robinson, Pocock, & Roy, 2012), Choosing and using citizen science (Pocock, Chapman, Sheppard, & Roy, 2014), Guide to running a bioblitz 2.0 (Robinson, Tweddle, Postles, West, & Sewell, 2013), User's guide for evaluating learning outcomes from citizen science (Phillips, Ferguson, Minarchek, Porticella, & Bonney, 2014). However, a generic guide that can offer the scientific community advice on how to develop, implement and evaluate citizen science projects including how to get the most out of citizen science projects in the environmental filed is needed.

In order to ensure a usable citizen science program and to maintain citizens in a citizen science project in practice, Liu et al. (2014) addressed the following development needs:

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

1. The need to adequately promote the citizen science platform and tools for raising awareness, recruiting and sustaining citizens' participation;
2. The need of a good understanding of citizens' demographics in order to develop the citizen science platform to meet their needs, especially as they change;
3. The need to build a long lasting infrastructure that uses open standards, is easily exploitable through an open Application Programming Interface (API), can be widely accessed, extended and maintained, and is seen as a generic environmental enabler rather than a project specific outcome;
4. The need to address and evaluate Citizens' Voice (Citizen' Views on certain environmental issues and its related environmental actions) and government Accountability (i.e., governments that can be held accountable for their environmental action) in the social and political context in which citizen science programs are embedded (Rocha Menocal & Sharma, 2008; Fernandez-Gimenez et al., 2008), to actively promote the Citizens' Voice and Accountability concepts as important dimensions of good environmental governance (Rocha Menocal & Sharma, 2008), to address citizen science potential role to influence environmental equity and to improve social justice (Kamar, Hacker, & Horvitz, 2012);
5. The need to develop particular channels and mechanisms that can underpin the sound environmental-social-political actions in which citizen science programs are addressed, in a manner that facilitates citizens to influence environmental governing priorities and processes;
6. The need to explore and further develop technologies, which deal with data collection and analysis by building necessary technical capacity and overcoming the 'digital divide' for environmental monitoring, data exchange, visualizing and communicating results back to the broader users (Rocha Menocal & Sharma, 2008; Brabham, 2009), managing and analyzing increasing data volumes, variety and velocity (Zikopoulos, Eaton, & Zikopoulos, 2011); reducing measurement uncertainties; developing reliable and fast Quality Assurance/Quality Control (QA/QC) tools that can work in real-time; and increasing need for interdisciplinary use of data, integration of different types of data.

FUTURE RESEARCH DIRECTIONS

The rapid diffusion of ICTs during the past decades has facilitated the process of data collection and sharing by the public and has resulted in the formation of more and more online environmental citizen observatory networks. There is no doubt that the increasing trend of citizen science programs has the potential to enhance the spatial and temporal resolution of current data streams from terrestrial and areal sensors, as well as being the best approach to increase citizen's environmental awareness.

One of the challenges is defining what is and what not citizen science is. However, due to the boom of citizen science programs that are currently been seeing, there is a need for having a clear global picture, in order to monitor the rapid growth of such initiatives, to catalogue and analyze differences and to synchronize already ongoing activities (Cobweb project, 2016; Ibercivis, 2016). The basic concept is to understand who is doing what and where.

In addition, there is also a need to understand how citizen science is changing the relationship between science and society. Therefore, a set of tools, metrics, shall be further developed and used. Among

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

others, techniques from both humanities and social networks analysis shall be developed and used, to explore whether the key stakeholders are properly engaged or not, and if there is interactive information exchange amongst the key stakeholders within any citizen science program.

Citizen science is a growing worldwide phenomenon thanks in large part to the evolving new technologies that connect people easily and effectively with the scientific community (ECSA, 2016). There is a need to explore what types of new technologies can become a useful tool for citizens to play a more active role in sustainable development, which citizens can contribute valuable information that can be used to develop and deliver policies, improve understanding and respond to many of the challenges facing society today. Furthermore, methods for analyzing and sharing citizen science tools and data are also required (Cobweb project, 2016). There is a need to identify the major requirements for citizen science project repositories and their relation to existing citizen science platforms (Cobweb project, 2016).

Methods for maximizing the value of citizen science data, including data accessibility, availability and quality in support of the sustainable development goals, are also required (Grossberndt & Liu, 2016). Citizen science has evolved over the past four decades. Recent projects place more emphasis on scientifically sound practices and measurable goals for public education. Modern citizen science differs from its historical forms primarily in the access to, and subsequent scale of, public participation. This is, in large part, due to new technology, which is credited as one of the main drivers of the recent explosion of citizen science activity.

There is an emerging trend that indicates that research will focus on cross-cutting computational topics such as optimization, dynamical models, big data, machine learning, and citizen science, applied to sustainability challenges. Advances in computational sustainability will lead, for example, to novel strategies for helping citizens to improve their quality of life.

So far, assistance from the general public is often limited to data collection, as in classical citizen science. Moreover, whether and how people actually perceive the educational outputs of citizen science programs is generally lacking and needs to be addressed more in the future citizen science studies.

In fact, citizen science programs vary from top-down to more bottom-up approaches, depending on how people are involved. Devictor, Whittaker, & Beltrame (2010) argued that such participative citizen science approaches could be even more effective in promoting positive reconnections between the general public and conservation issues. Assessing how citizen science programs are perceived by citizens themselves would also offer opportunities to initiate more challenging levels of participation, and help develop stimulating connections between scientists, authorities and the general public (Devictor et al., 2010).

The authors do believe in the near future, citizen scientists could thus not only help to set surveys and scientific investigations, but also become the best allies of managers and stakeholders in the fields of environmental sustainability. Involving citizen participants directly in monitoring and active management of environmental issues can generate very powerful management efforts, leading to positive, cumulative and measurable impacts on environmental governance.

Although it is increasingly recognized that environmental governance, informed by local knowledge and citizen observations, may be a better option than top-down environmental protection restrictions, a practical means to implement protection strategies using citizen science as a social process is still largely missing (Devictor et al., 2010). In this context, citizen science could be of great help to promote environmental sustainability based on local environmental knowledge in several socio-economic contexts (i.e., not limited to the most developed countries).

CONCLUSION

With this chapter, the authors have provided insight into a topic that creates ambivalent feelings for many, i.e., citizen science in sustainable development. Based on the information from literature and practice, it can be seen that during the last years, policy-makers are beginning to value citizen science approaches as an important tool in their decision-making process. The fact that issues related to environment and health are usually complex and uncertain calls for a paradigm shift in these methods. Integrating knowledge and experience of different citizen groups and other stakeholders will help authorities in their decision-making process.

Citizen science plays a positive role in environmental sustainability. A review of relevant citizen science projects shows that the involvement of volunteers offers high value to research, policy and practice. Two major gaps were identified:

1. A need to compare and contrast the success of citizen science activities which present sound evidence of citizen scientists influencing positive environmental changes in the local environment they monitor;
2. More case studies showing usage of citizen science data by decision-makers, or the barriers to linkages and how these might be overcome.

If new research focuses on these gaps, and on the difference of opinions that exist, the researchers will have a much better understanding of the environmental, social, economic, ecological and cultural benefits of the citizen science role in sustainable development.

As it is well known, not one approach fits all. The choice of both participants and participation methods are always context-dependent and require a thorough preparation phase. Thus, time and personnel resources are crucial preconditions. Additionally, the authors see a need in fostering bottom-up approaches to a larger degree. In this context, the authors see citizen science as an increasingly essential tool for public participation in environmental monitoring. This approach assists citizens in observing and understanding environmental related problems, as well as reporting and commenting on them by help of advanced ICTs.

The authors discovered that different ongoing citizen science related programs in the environmental domain share a common model that is significantly relevant for the outcome of sustainable development. It consists of the following elements:

1. Citizens are playing an active role in observing environment by using novel monitoring-technologies and citizen as monitor approach;
2. Unique virtual places are created to gather and share data from a variety of sources;
3. Extraction and making use of relevant citizens-related data and providing multimodal services for citizens, communities and authorities;
4. Raising citizens' environmental awareness to form a strong public voice; and
5. Enabling dialogue among citizens, researchers, policy-makers and other stakeholders.

In addition, the review reached a number of conclusions about the value of data collected by volunteers:

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

1. The development of technologies was "revolutionizing citizen science", for example through online recording and smartphone apps;
2. Data quality could be excellent, but was not fully recognized by all researchers or policy-makers;
3. It is a cost-effective way of collecting environmental data;
4. There was potential to make considerably more use of citizen science that currently was the case.

To be successful in a citizen science program, the authors recommend the following sequential steps:

1. Identifying what citizens want and what citizens can offer;
2. Exploring what products and services a citizen science program can provide for the citizens;
3. Recruiting and retaining citizens to participate in and contribute to environmental governance;
4. Providing tools that support citizens to report their observations, inference and concerns; and
5. Supplying tools to access/receive timely information on the environment in a manner that is both easily understood and useful.

With these elements in mind, a successful performance and sustainable implementation should be possible.

Citizen science programs are geographically explicit, standardized and cover large spatial and/or temporal scales. Although citizen science is not a panacea, the development of citizen science programs should be increased and encouraged in the future as they can both be highly valuable for environmental sustainability and promote the reconnection between people and nature and more generally between people and science. Yet, although their number has increased in some countries (specifically the USA and UK) during the last decade, they remain relatively rare in others.

Moreover, the strength of citizen science programs directly relies on the curiosity and pleasure of the volunteers to learn and observe things that they have never noticed in their most familiar places.

KEY TERMS AND DEFINITIONS

Citizen Engagement: The encouragement of the general public to become involved in the political process and the issues that affect the community.

Citizen Observatory: The citizens' own observations and understanding of environmentally related problems and in particularly as reporting and commenting on them.

Citizen Science: A form of research collaboration involving members of the public in scientific research projects to address real-world problems.

Environmental Governance: A concept in political ecology and environmental policy that advocates sustainability (sustainable development) as the supreme consideration for managing all human activities—political, social and economic.

Information and Communications Technology (ICT): An extended term for information technology (IT) which stresses the role of unified communications and the integration of telecommunications (telephone lines and wireless signals), computers as well as necessary enterprise software, middleware, storage, and audio-visual systems, which enable users to access, store, transmit, and manipulate information.

Sustainable Development: The development that meets the needs of the present without compromising the ability of future generations to meet their own needs.

Volunteered Geographical Information (VGI): The harnessing of tools to create, assemble, and disseminate geographic data provided voluntarily by individuals.

Chapter 49
Romanian Rural Tourism in the Context of Sustainable Development

Marian Zaharia
Petroleum-Gas University, Romania

Rodica-Manuela Gogonea
Academy of Economic Studies, Romania

Daniela Enachescu
Petroleum-Gas University, Romania

ABSTRACT

Tourism, in all its activities, is dependent on the environment, and by exploiting its resources, products are created, creating a significant added value. But all this must take into account the rational use of natural resources with risk of depletion or degradation and the ability to achieve a decent standard of living for future generations, with an equitable distribution of general or specific revenue. Based on these considerations, the aim of this chapter is to assess the evolution of touristic infrastructure both in time and in terms of regional distribution. To estimate the tourism supply of Romanian rural tourism accommodation, the main statistical indicators used were the number of agro tourist boarding houses, the existing accommodation capacity, and the accommodation capacity in operation, their territorial concentration, and the way in which the results are strategic levers in the regional development of Romania.

INTRODUCTION

Competitiveness of rural tourism, on background process development sustainability can shape and analysis from a basic element of rural touristic supply: accommodation. In relation to the location and services, rural tourism units can be competitive success of a tourist destination.

Given the economic and social changes faced by Romania, while, there have been changes in the classification of tourism facilities that operate rural tourism, which justifies the existence of the macro-

distributed data, regions of development and counties from 2000 to 2012, provided by NIS (Tempo-one line).

The conceptions of researchers and analysts have changed over time from negative opinions, which had consider rural tourism as a weak producer of value-added, to the positive one, which consider it as a important value-added creator.

The decrease in revenues from agriculture, increasing interest in sustainable development, the increasing efforts of local institutions to develop rural communities have created prerequisites of increased competitiveness of rural tourism destinations.

In this context, there has been a significant change in the market rural, characterized by a growing concern for health and the environment, which led to a significant increase in demand for accommodation and standards for this type of tourism, emphasizing the phenomenon of sustainability and attenuating seasonality (European Commission, 2000).

In the year 2013, EUROSTAT study (European Commission, 2013) results show that in predominantly rural regions across Europe, the share of services in regional GDP was lower (64.8%) in 2010, to predominantly urban regions (78, 6%) and the mixed regions.

Except Netherlands and Romania (46.8%) in almost all European countries, services that include tourism contributed with more than half of the value-added in the region predominantly rural. However, within Europe, it was determined that 32.2% of the total number of beds in all collective accommodation establishments are placed in the regions predominantly rural, which represent more than a third.

The objectives of this chapter is to evaluate the evolutions and the regional distribution of number of the agro tourist boarding houses (ATBH), existing accommodation capacity (EAC), and accommodation capacity in operation (ACO), their territorial concentration and specific modality in which the results are strategic levers in the regional development of Romania.

In the research methodology based on theoretical statements as guiding principles were used methods and techniques, ordering processes, correlation and processing information taken from official data provided by the National Institute for Statistics of Romania.

BACKGROUND: SUSTAINABILITY, SIGNIFICANT ELEMENT OF THE COMPETITIVENESS OF RURAL TOURISM

The competitiveness as a complex concept is viewed and analyzed globally, but also in terms of each component separately, considering the financial, human and organizational aspects. Regarding to this concept (Kotler, 2001) seats that it can be represented by the degree to which a nation, in a free and fair market conditions can produce goods and services that pass test of international markets, while managing to maintain and increase the real income of its citizens. National competitiveness is the result of competitive interdependence manifested at regional, local or company level.

In tourism, competitiveness can be approached from economically through the capacity of destination or of travel company to be more profitable in the tourist market. For a tourist destination, the competitiveness can be shaped by factors such as: attractions and tourist resources, support factors harmonized with other resources, favourizing conditions, demand conditions, tourism destination management, planning and development, policy implemented for raising the standard of effectiveness and profitability at international level.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Tourism enterprise competitiveness is analyzed mainly through tourism products, targeting innovation, diversification, renewal and quality, client positioning the background first.

This context creates the potential market highlighting the necessity of competitive tourism products in the contemporary period, given the living conditions conducted under stress spectrum and pollution are increasingly oriented towards ecological and biodiversity plan.

Currently, the trend in Europe is the evolution of rural tourism which is constantly expanding, with all of crises manifested but under spectrum of storage, conservation, and regeneration of all resources involved in shaping competitive rural tourism products.

Emptaz-Collomb (2009) highlight that the concern of rural communities and institutions regarding environmental conservation has led over time to a specific approach to sustainable development. However, specific events constitute result of intertwining elements of demographic, social, cultural, economic and environmental factors.

The promotion of rural tourism type is a significant factor towards the development of poorer regions economic recovery, mainly of tourism opportunities, which can improve the living conditions of local people in those regions.

Studies conducted by Mehta and Kellert (1998), and Walpole and Goodwin (2000 and 2002) showed that the attitude towards interdependence between tourism and environmental conservation is direct but rather weak (European Commission, 2013). However, reveals that the over the past 15 years numerous studies have been conducted predominantly oriented towards interdependence revenues from tourism and conservation support environment. The study carried out by Walpole and Goodwin (2002) ended with the conclusion that poor countries with poor material and financial situation negatively influence support activities and environmental preservation.

World Commission on Environment and Development (1987, p.41) has defined sustainable development in their report as "development that meets the needs of the present without compromising the ability of future generations to meet their own needs"

Michael Lemonick (2009) in his article „Top 10 Myths about Sustainability", was referring to the second myths („Sustainability is all about the environment")**,** quotes Anthony Cortese, founder and president of the organization for sustainable education "Second Nature", who said: "The economy is a wholly owned subsidiary of the biosphere. The biosphere provides everything that makes life possible, assimilates our waste or converts it back into something we can use".

World Conference on the Environment in Rio de Janeiro in 1992, paid special attention to the concept of sustainability, which involves establishing a balance between economic growth, environmental protection and finding alternative resources, defined as "the quality of a anthropogenic activities to take place without exhausting available resources without destroying the environment, so without compromising the ability to meet the needs of future generations"(Popa s.a, 2009; dexonline.ro).

At the microeconomic level, sustainable tourism development is the focus on technological developments and institutional change, touristic accommodation structures in harmony with increasing current capabilities and future ones and to meet human needs and aspirations towards recreation, restoration and spend nice time in line with the observance of ecological management. As early as the end of XX century, Welford (1997) highlighted some principles of sustainable development among which: integrated management, preventive and proactive behavior, continuous improvement, consumer information, caution, crisis strategies, contribution to the collective effort, social and environmental responsibility to the community.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Basically, sustainability is a much deeper, being linked not only to activities involving the conservation and regeneration of natural resources and other components as well as the organization of sustainable holidays, which explains further involvement in rural tourism products of the competitiveness manifested the rural tourism.

ROMANIAN RURAL TOURISM: PRESENT AND PERSPECTIVES

Measuring the Rural Touristic Supply in Terms of Sustainability

The territorial structural analyzes is based on Nomenclature of Units for Territorial Statistics (NUTS) developed by the Statistical Office of the European Union (EUROSTAT) and included in the REGIO database under NUTS territorial units which are hierarchically structured on three levels: NUTS 1 (97 regions), NUTS 2 (271 regions) and NUTS 3 (1303 regions). In Romania, following their accession to the EU, the three NUTS levels have the following structure (Table 1): NUTS 1-4 macro, NUTS 2-8 regions and NUTS 3 - counties in each region. (Regulation EC No 176/2008, Regulation EC No 1059/2003).

Given that information (the statistics data series) which are processed and interpreted are taken from NIS (NIS, 2012) end EUROSTAT (2014), we consider that it is useful to present short definitions of them.

- *Agro tourist boarding houses* are accommodation structure, for temporary tourists' installation, located in rural areas, with the capability to provide their meals and specific activities of this type of environment. It is expressed in number of units
- *Existing rural touristic accommodation capacity* represents the number of the seats available by agro tourist boarding houses in order to tourist accommodation.
- *Rural touristic accommodation capacity in operation* is a statistical indicator which assessment offer accommodation, representing the number of seats offered by agro tourist boarding house in relation to the number of days of their operation in a predetermined period. It is expressed in number of place-days.

Table 1. Romania's territorial units according to NUTS

NUTS 1	NUTS 2	NUTS 3
Macro 1	North-West	Bihor, Bistriţa-Năsăud, Cluj, Maramureş, Satu Mare, Sălaj
	Center	Alba, Braşov, Covasna, Harghita, Mureş, Sibiu
Macro 2	North - East	Bacău, Botoşani, Iaşi, Neamţ, Suceava, Vaslui
	South-East	Brăila, Buzău, Constanţa, Galaţi, Tulcea, Vrancea
Macro 3	South -Muntenia	Argeş, Călăraşi, Dâmboviţa, Giurgiu, Ialomiţa, Prahova, Teleorman
	Bucureşti-Iflov	Bucureşti, Ilfov
Macro 4	South-WestOltenia	Dolj, Gorj, Mehedinţi, Olt, Vâlcea
	West	Arad, Caraş-Severin, Hunedoara, Timiş

Source: Regulation No 176/2008 of the European Parliament and of the Council

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Context created by information taken about three indicators measuring the supply of rural tourism accommodation, allowed the application of specific indicators of structural analysis (relative sizes of the structure), dynamic indicators (average indicators) and indicators involved in the methods establish specific degree of concentration, Gini-Struck coefficient of concentration, trapezoidal method to calculate the Gini index of concentration (Ţiţan, 2012), and diversification - value Agresti (Jaba, 2002).

Struck concentration coefficient is the corrected form of the Gini coefficient and is determined independently of the number of categories considered, across time and space permitting comparability of the results, being expressed by the relation:

$$C_s = \sqrt{\frac{n\sum g_i^2 - 1}{n-1}} \in [0;1] \quad (1)$$

In view of the rigorous evaluation as in the research, the trapezoidal method was applied to calculate the Gini concentration index. This takes into account the determination of the concentration using surface concentration value (with respect to the surface of trapezoids formed on the ranges of variation of the characteristic X) by applying the relation:

$$I_G = 1 - \sum_{i-1}^{N} s_i^2 \in \left[0;1-\frac{1}{N}\right] \quad (2)$$

where:

$n = \sum n_i$ – counties number (40 countries);

q_i – share of accumulated global values up to the same level x_i

f_i – share of herds (n_i) in total collectivity ($\sum n_i$)corresponding to the level x_i of X (in the case of research: the number of agro tourist boarding houses, the number of places or the accommodation capacity in operation).

Also, diversification indicators occupy a significant place in the survey. An important role in this analysis, had diversification index, found in the specialized literature under the name of value Agresti, determined by the relation (Agresti, 1990, p.24):

$$V_s = 1 - \sum_{i-1}^{N} s_i^2 \in \left[0;1-\frac{1}{N}\right] \quad (3)$$

The maximum value is set at 0.8 by the relation: $1-\frac{1}{N}$, where N represents the number of categories (groups). In the study, as a result of the previous processing five groups were established for each characteristic (Table 2).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Supply tourist accommodation in rural areas of Romania has recorded a general upward trend since 2000, although during the global financial crisis has shown a slight decline, with the effects recorded in 2009-2011.

The increasing of the number of tourist accommodation units in 2012 compared to 2011 was significant compared with the trends from previous years. Meanwhile, the accommodation capacity, so the number of accommodation provided by rural touristic accommodation establishments registered a continuous growth, including in the financial crisis, when maintained, however, positive.

The real challenge lies in shaping management decisions imposing sustainability as a priority of running rural tourism activities with the need to maintain and reuse natural resources in rural areas and component elements that make up the rural touristic supply.

Applying research methodology outlined above constitutes a context for future economic modeling approaches through Bayesian econometrics, bringing together the interests of various groups of researchers in economics and adjacent, such as specialists in the tourism trade, services, marketing (Simionescu, 2013)

The Accommodation Supply of Rural Tourism in the Context of Sustainable Development Trend

Sustainable development of rural tourism accommodation supply manifests interrelated with the milestones for the development and sustainability of rural communities. Is the action plan are intertwined influence of public authorities with the management strategies applied by rural touristic accommodation.

The study of rural tourism accommodation supply in Romania was started by analyzing the evolution of the three main indicators definite above (number of agro tourist boarding houses, existing rural accommodation capacity and rural accommodation capacity in operation) both at general level (the Romanian territory) and regional level.

During 2000 - 2012 the number of agro tourist boarding houses (Figure 1) increased about 3.92 times from 400 registered in 2000 to 1569 agro tourist boarding houses in 2012, the annual average being 12.06%. In the period preceding the economic crisis their number increased continuously but with different rhythms being distinguished three periods of approximately linear growth:

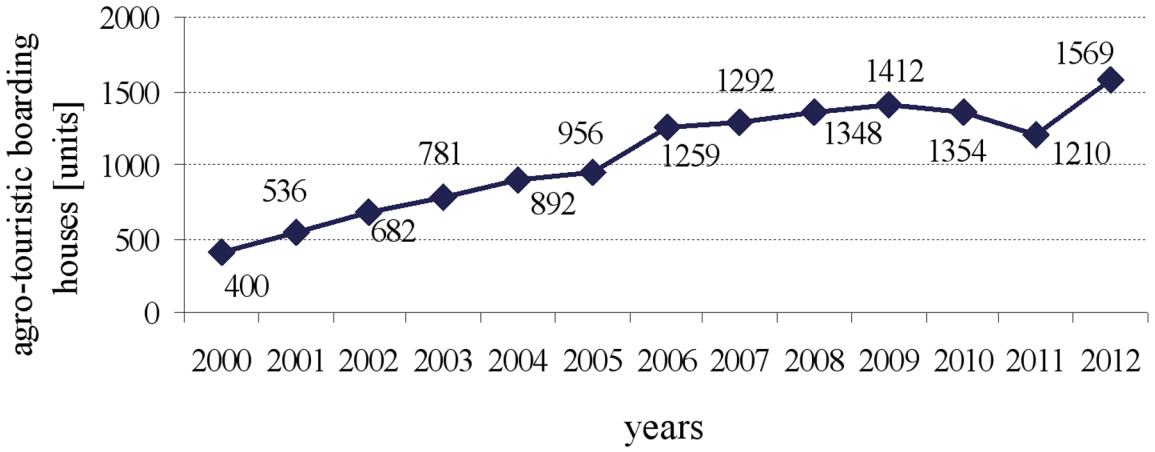

Table 2. The way of distributing of counties in the five groups in relation to each measuring indicator of the supply of rural tourism accommodation

Number of Agro Tourist Boarding Houses	Existing Accommodation Capacity (Places)	Accommodation Capacity in Operation (Places-Days)
0 - 55	0- 882	0-307187
55 - 110	882 - 1764	307187 - 614374
110 - 165	1764 - 2646	614374 - 921561
165 - 220	2646 - 3528	921561 - 1228748
220 - 275	3528 - 4410	1228748 - 1535935

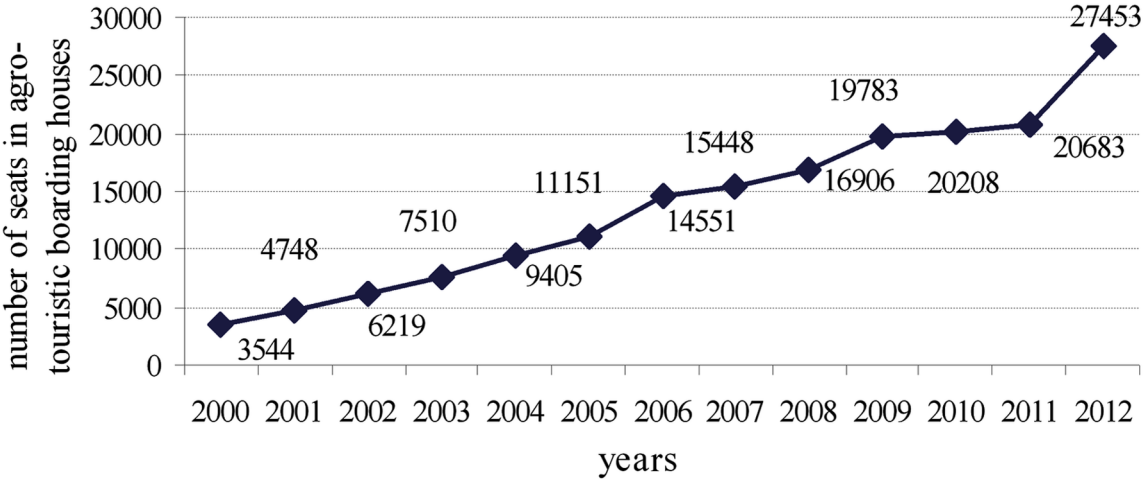
Note: The lower limit included within

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Evolution of the agro tourist boarding houses in Romania during 2000-2012
Source: authors own computation based on NIS (2013)

- The period 2000-2005 in which the average annual increase was 111.2 agro tourist boarding houses, the annual average being 19.04% with 7.34 percentage points above the annual average of the period 2000-2012,
- The period 2005-2006 have been recorded no less than 303 agro tourist boarding houses (an increase of 31.69%)
- The period 2006-2009, in which the trend of growth continues, but with an average annual increase of only 52 agro tourist boarding houses, the annual average being 3.90%, with 8.16 percentage points below the average.

Triggering the economic crisis in 2008 had a negative impact on the supply of accommodation places in the period 2009 to 2011, in which coming out of tourist circuit, a total of 202 agro tourist boarding houses, out of whom 144 in the period 1010-2011 (in the first two years of decline, the number of agro tourist boarding houses fell by 14.3%). Year 2012 brings a revival of rural tourism, at least in terms of the supply of accommodations, in the period 2011 to 2012 the number of agro tourist boarding houses increasing by 29.67%.



In the eight regions of development of Romania the number of agro tourist boarding houses is significantly different. Of these, the Centre region, number of agro tourist boarding houses is two times higher than in the North - West region, which is from this point of view, on place the second. Note that these two regions of development make up the Macro 1, comprising the counties of Transylvania.

Very close, in terms of number of agro tourist boarding houses, changing alternatively with North-West, the second and third places, there is the North-East region which has also a rich cultural, natural and historical heritage. In these three regions there are over 70% of total agro tourist boarding houses.

Evolution of existing accommodation capacity, represented by the number of seats in agro tourist boarding houses in Romania, is highlighted by the chronogram shown in Figure 2. Its upward trend is evident. Throughout the period under review, the average absolute increase is approximately 1992 places per year, while the relative increase is 18.60% per year.

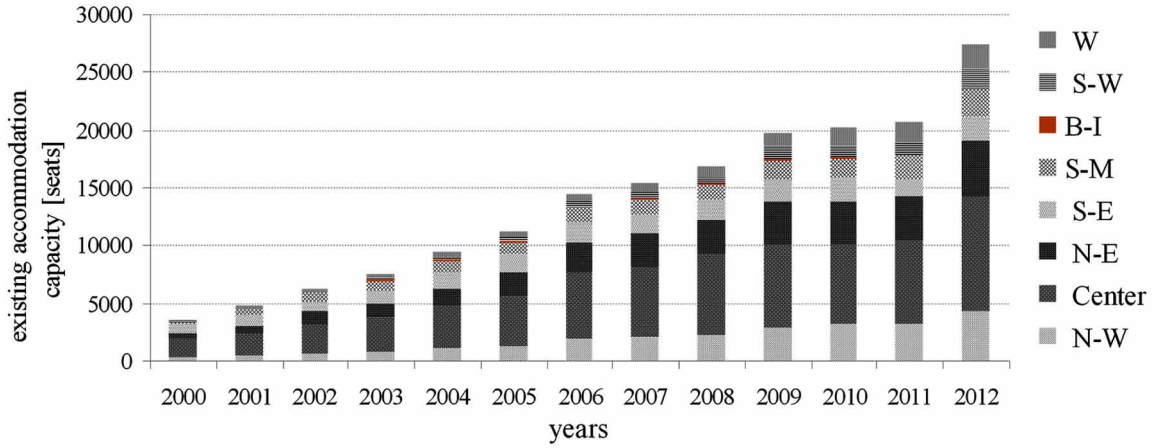
Figure 2. Evolution of existing accommodation capacity in agro tourist boarding houses, in Romania, in the period 2000-2012
Source: Authors own computation based on NIS (2013)

In the period preceding the economic crisis, the number of the accommodation places in agro tourist boarding houses shows an evolution similar to that recorded by the number of agro tourist boarding houses: In the period 2000-2005 the average annual rate was 27.77%, with 7.17 percentage points above the annual average of the period 2000 - 2012, in 2005-2006 the number of accommodation places increased by 30.49%, and in the period 2006-2009 the average annual rate was 10.78%, with 7.82 percentage points below the average for the period 2000-2012.

Although the economic crisis has led to decrease in the number of agro tourist boarding houses from 1412 in 2009 to 1210 in 2011, the supply of accommodation places continued to rise, from 19783 in 2009 to 20683 places in 2011 (an increase of 4.55%). Year 2012 brings a recovery of the supply of places in agro tourist boarding houses, their number being with 32.73% higher than in 2011.



Analyzing the evolution of the number of agro tourist boarding houses and of the accommodation places provided by them, it appears that, in the period, increased from an average of 8.83 accommodation places per agro tourist boarding houses share reported in 2000 to 18.86 accommodation places per agro tourist boarding houses in 2012. This is highlighted by the annual growth rates of the two indicators. Except for 2006, which compared to 2005, annual growth in the number of agro tourist boarding houses overtake annual growth rate of accommodation places (31.69% vs. 30.49%) throughout the period, annual growth in the number of accommodation places was higher than the annual growth of the number of agro tourist boarding house, the biggest difference, 12.99 percentage points being recorded in 2009.

Also, an important conclusion is that the economic crisis has affected to a much greater extent, agro tourist boarding houses with small accommodation capacities compared to those with higher capacities. This conclusion is underlined by the fact that although in the crisis period the number of agro tourist boarding houses fell by 202, the number of accommodation capacity increased, during the same period, with 900 seats.

Through an analysis of existing accommodation capacity of agro tourist boarding houses, by regions of development of Romania (Figure 3) results, as expected, given the distribution of them by regions of development analyzed above that, throughout the period of analysis, most of accommodations are sup-

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Evolution of the existing accommodation capacity in agro tourist boarding houses by regions of development of Romania, in the period 2000-2012
Source: authors own computation based on NIS (2013)

plyed to agro tourist boarding houses from the Center region. After the Center region, on second place since 2002, is North-East region, followed by the North-West region.

Regarding the rhythms of evolution of existing accommodation capacity per regions of development for the period 2009 - 2012, the situation is slightly different. The West region in 2010 recorded the highest growth (25%) and, although in the coming years is surpassed by growth rate of the South-Muntenia (23% in 2011) and South East (24% 2012), during the economic crisis existing accommodation capacity in agro tourist boarding houses in the West region increased by 75.97%. Note that the West region is the only region that, during the economic crisis, showed only positive values of the growth rate of existing accommodation capacity in agro tourist boarding houses.

The accommodation capacity in operation (places-days) in agro tourist boarding houses in Romania, in the period 2000-2012, both across the country and by regions of development had a similar evolution to the evolution of existing accommodation capacity across the country, respectively, by regions of development.

Thus, as in the existing accommodation capacity, the annual growth rates of accommodation capacity in operation in 2010 have been positive only in the West (22.09%), North-West (14.35%) and South-Muntenia (4.21%). In 2012, relative to 2009, in the West region, the accommodation capacity in operation doubles (204.72%). Also significant values are recorded in the South-WestOltenia (167.27%), Centre (162.78%), South-East (132.14%), North-West (131.57%) and North-East (130.37%).

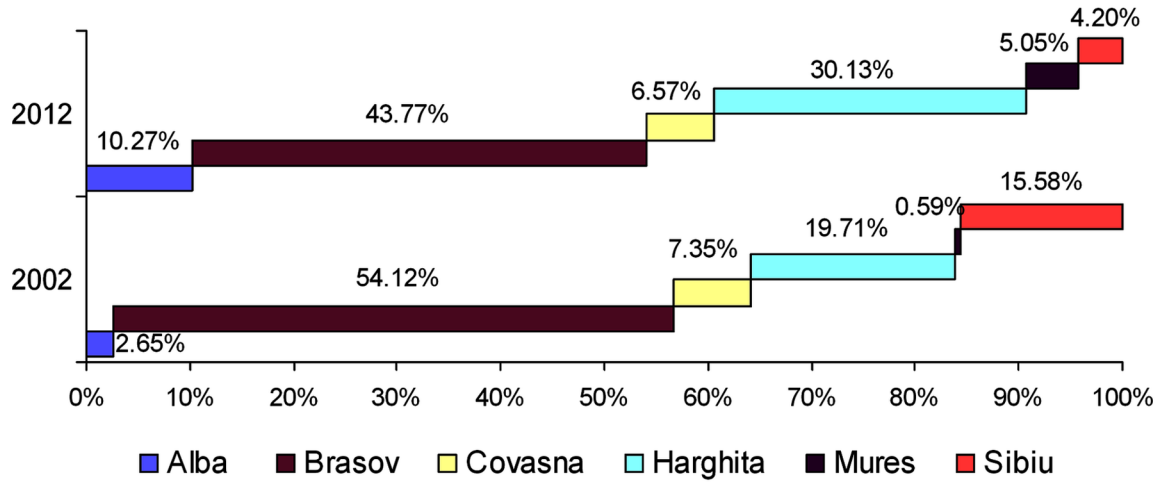
Territorial Structural Developments on Rural Touristic Supply

Studying supply Romanian rural tourism accommodation begins with analysis of the evolution of existing accommodation capacity and accommodation capacity in operation as the most representatives at both general (the Romanian territory) and particular, that from the eight macro-regions.

A structural analysis of the supply of Romanian rural tourism accommodation in the eight regions of development more clearly highlights regional differences, thus allowing the shaping of strategic insights attenuation and sustainable development territorial disparities.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

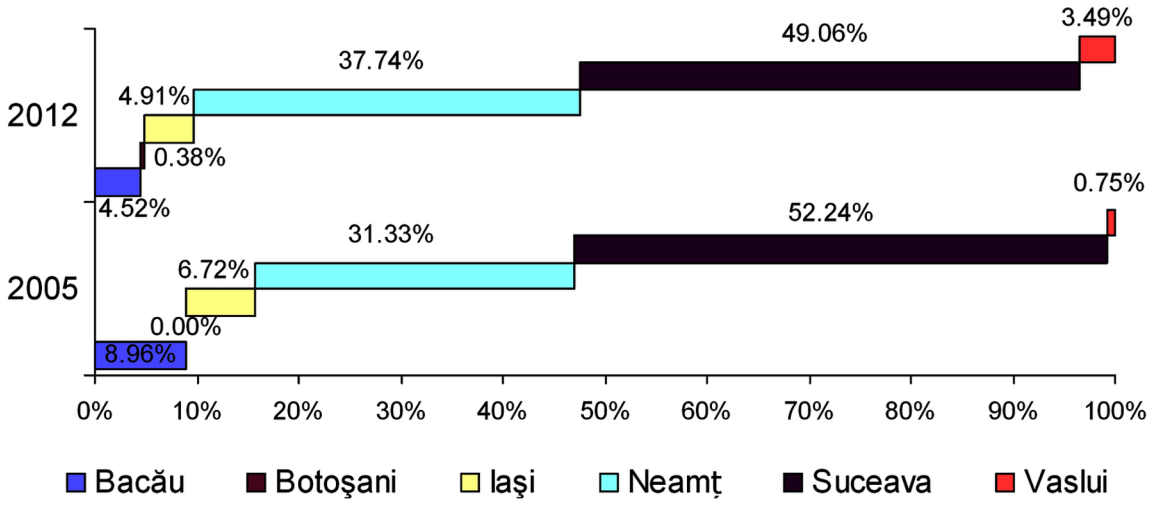
Agro tourist boarding houses structural hierarchy of the eight regions of development of Romania has changed slightly from year to year. In 2000-2012 period the trend of decreasing percentage in Central region (with the strong concentration of the total agro tourist boarding houses: from 60.60% in 2000) in favor of the other regions, so that will arrive in 2012, as territorial distribution of agro tourist boarding houses in this region corresponds to only 37.86%.



Justification situation is reported primarily in civilization, the mentality and attitude of the local community in practicing rural tourism, the implementation of appropriate policies and strategic management level. However, positive results following the establishment of agro tourist boarding houses and practicing this form of tourism are highlighted and by a detailed analysis of the distribution of their structural components counties (Alba, Brasov, Covasna, Harghita, Mures and Sibiu).

Since in Covasna and Mures were recorded hostels established in 2001 and 2002 for a clearer reflection of the situation of structural distribution of tourist hostel, comparing the 2002 with structure in in 2012, established for rural tourist pensions counties. The results (Figures 4) showed significant increases in percentage points in 2012 compared to 2002 in Alba, Harghita and Mures, while for other counties (Brasov holder of more than half of all agro tourist boarding houses, Sibiu and Covasna) are indicated only by a few percentage points decrease insignificant given the suggestive supply tourist accommodation rural county.

North Est Region, ranked second on the structural hierarchical scale of agro tourist boarding houses throughout the period 2000-2012, will determine shares varied between 11.19% in 2001 and 18.43% in 2011. In this region NE, rural touristic pensions operated from 2000 until 2005 in the territory of Bacau, Iasi, Neamt, Suceava, Vaslui in 2005 and 2011 and Botosani county area, leading to a comparative analysis of the structural set at 2012 to 2005 (considering less suggestive comparison of 2012 versus 2011).



Comparative graphical representation (Figure 5) show a significant tiebreaker for Suceava (with the 52.24% in 2005 and 49.06% in 2012) and Neamt (from 31.33% in 2005 to 37.74% in 2012) in the supply of rural touristic accommodation given, primarily, to the rich natural, historical and cultural potential, and policy maintenance, recovery and transmission of cultural values and ethno-historical folklore they have. A significant potential for rural touristic supply Iasi and Bacau counties of, although in 2012

Figure 4. Structure of agro tourist boarding houses counties of Centre region in 2002 and 2012

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 5. Structure of agro tourist boarding houses in North Est region in 2002 and 2012
Source: Authors own computation based on NIS (2013)

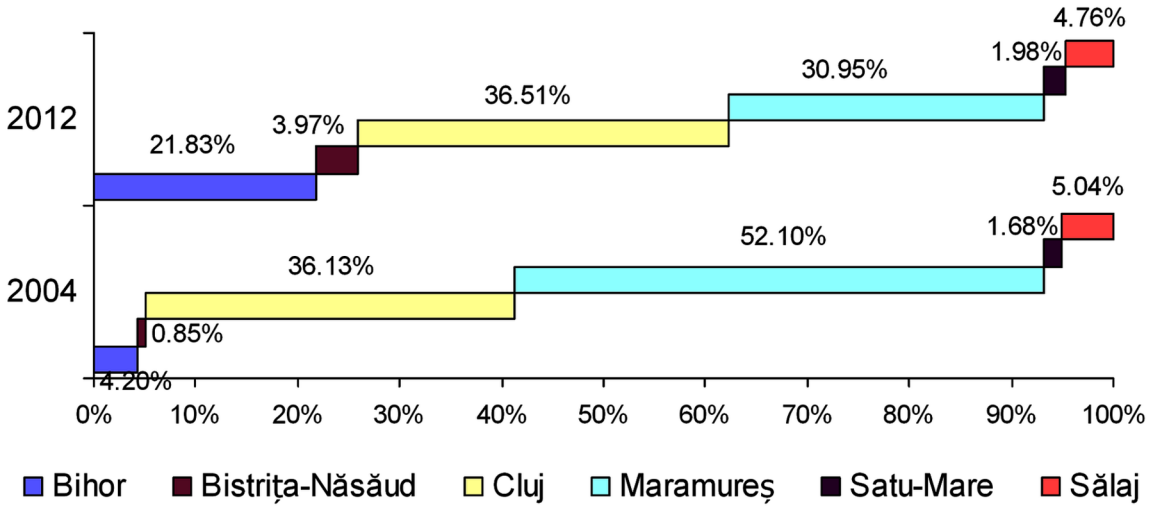
compared to 2005 as a division of the supply of accommodation known process of reducing by 1.81 and 4.44 percentage points respectively.

These counties are the foundation of sustainable development of rural tourism through the nature, material, spiritual and human reserve, features that propagate as in spectrum of conservation and reclamation involved in the inestimable value of this type of tourism.

Vaslui County granted in 2005, particular attention to developing of rural tourism, which noted the increase of 2.74 percentage points in 2012 compared to their establishment.

Throughout the period of analysis, 2000-2012, is maintained also North West region as occupies the third place in the ranking of tourist agro tourist boarding houses structural rural regions of Romania, the shares varying from 8.75% in 2000 and 19.65% in 2010.

In 2000, rural tourism is run mainly in Maramureş (which holds throughout the analysis, the largest number of rural agro tourist boarding houses)and then Cluj, Sălaj, Satu-Mare, as reported in 2002 to establish a rural tourist hostels in Bihor county, and in 2004 in Bistriţa-Năsăud, which provide opportunities for comparative structural analysis in 2012 compared to 2004.



Natural and cultural potential of inestimable value is found in the county of Maramureş creating opportunity for tourism also rural tourism especially, justifying the existence of many rural agro tourist boarding houses in the area, although with the passing years, the whole region NW share of their corresponding total is reduced with the 21.15 percentage points in 2005 compared to 2012.

Strategic policies, management of rural communities and private entrepreneurs led to the establishment of more rural accommodation also tourist facilities in other counties in the region, and to increase tourist activity in those areas (especially in Bihor county where there is a significant increase with the 17.63 percentage points in 2012 compared to 2004), except Sălaj county, where the interest for practicing this type of tourism has decreased in recent years, as evidenced by reducing by 0.28 percentage points in 2012 compared to 2004.

Regions South-East and the South-Muntenia are in constant competition to occupy third and fourth place, which led to a constantly changing of the hierarchy placement. Thus, in the process of setting up

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 6. Structure of agro tourist boarding houses in counties of North West region in 2002 and 2012
Source: Authors own computation based on NIS (2013)

or dissolution of agro tourist boarding houses during 2000-2012 led to fluctuations percentage between 6.73% (2009) and 9.51% (2001) for the region South-East, and between 6,75% (2000) and 10.99% (2004) to the other region.

In 2000, South-East region rural touristic accommodation supply is mainly based on the number of rural pensions in Vrancea, Constanţa, Tulcea, Buzău rural boarding representing 36.36%, 33.34%, 24.24% and 6 06%. In 2012 not only that there is a rural tourist facility in Braila county approved but are defined and structural changes towards increasing the Buzau County with the 41.13 percentage points, while for all other counties registers discounts: 4.02 percentage points for Tulcea, Vrancea with the 12.76 percentage points and 25.47 percentage points for Constanta.

The potential of these counties is quite low (except the counties of Tulcea and Constanţa), which requires a significant strategic directions for action modeling and managerial carried out in local communities in order to harmonize them at regional level backed towards sustainable development.

Rural tourist supply of the region South-Muntenia contribute to the practice of rural tourism primarily through extremely rich environment, natural and human, that Prahova, Arges and Dâmboviţa counties have. It is, in this way, the essence of rural tourism activities in this region, which runs through rural touristic accommodation in hostels representing 44.45%, 33.33% and 22.22% of those registered in the region in 2000. In 2003 rural tourism establishments are certified Ialomita and Giurgiu county and in 2011 in Teleorman. In 2012 compared to 2003 will be recorded increases by several percentage points for Arges, Dâmboviţa, Ialomiţa and Teleoman, Prahova and Calaraşi recorded discounts, while Giurgiu will remains again without registered rural tourist activity, while no longer functional agro tourist boarding houses are recorded.

South-Muntenia region is a region that has a great tourism potential area, therefore it is very important at this level to establish clear lines of action regarding the implementation of rural tourism activities, especially that natural environment in Arges, Dâmboviţa and Prahova can be a foundation of sustainable development of this type of tourism.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Two regions (South-West and West) compete for supremacy in the hierarchy but only for 5th and 6th place. For agro tourist boarding houses in total, each corresponding number establish the time of percentages ranging from 1.00% (2000) and 6, 88% in 2012, corresponding to the South-west region and between 1.75% in 2000 and 7.14% in 2012 to W.

Rural tourist hostels from South-West region are found in Gorj and Valcea in 2000, two areas with significant natural and human potential, which opened broad prospects for practicing rural tourism.

In 2002 established rural tourism facilities in Dolj County, and in 2004 Mehedinti allowing structural stability at this year leading to a comparison with the structural situation of agro tourist boarding houses since 2012 (in 2011 there is an approved facility in Olt County). Thus, Vîlcea, Dolj and Mehedinti counties face an increase in 2012 compared to 2004 by 1.41, 1.56, 9.88 percentage points respectively, while registered in Gorj county compared to other counties, a reduction of 12 85 percentage points.

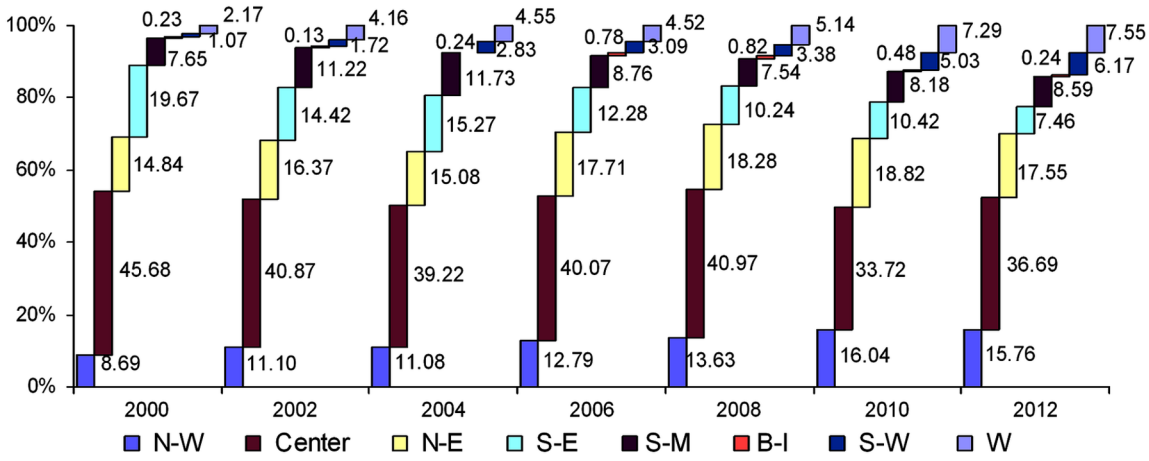
Given that Valcea relies most on extensive natural potential, directions of rural tourism development must find alternatives that lead to attraction of funds and creation of a diversified anthropogenic potential, enabling sustainable development of this type of tourism.

Caras-Severin, Arad and Hunedoara counties represent the West region and in 2000, includes some rural touristic accommodations that enable the practice of this form of tourism. In 2001, there are 25 units in Timis county, across the region, at that time, represented 64.10% of the total, the remaining percentages belonging to the other three counties. The structural situation changes in the year 2012 when Timişul lose significant percentage (51.6) in favor of other counties, Hunedoara county recording increase of 10.05 percentage points, Arad County with 15.63 percentage points and 25.92 percentage points Caras-Severin.

The attitude of communities, the level of civilization are significant advantages towards raising the standard of sustainable development of rural tourism which should adequately modeled and targeted tourism market requirements

For the last BI ranked, which corresponds to a significant number of small rural agro tourist boarding houses, the supply compared to other regions have established share between 0.13% (2012) and 0.74% (2008). Conditions and context of rural touristic supply (small area compared to the other regions, lowland area, bordering the capital of Romania), led to the placement of this area in the last step but a strategic organization and managerial adequate and sustained strategy can lead to significant insights rural development in terms of tourism supply and sustainable development with it.

The many agro tourist boarding houses in Central region leads to a large number of places supplied, aspect which shapes the possibility of getting of the first place in the ranking of the structural capacity of existing rural touristic accommodation in Romania. Figure 7 highlights the oscillatory trend of diminishing percent on accommodation supplied, ranging from 45.68% in 2000 and 36.69% in 2012.



Regarding shares established through agro tourist boarding houses places supplied in each region in their total in Romania, there is a competition for the entire period of analysis (2000-2012) between the NE and SE regions. The contest for second and third place led to a changing each hierarchy placement, thus establishing percentage fluctuations during 2000-2012, ranging between 14.66% (2001) and 19.64% (2011) for the region North-West and between 6.70% (2011) and 19.67% (2000) for the South-East. region.

Dispute fourth and fifth places is given between North-West region, which corresponds to a percentage range between 8.69% - 15.76% (in 2000 and 2012 respectively), and South-Muntenia with a percentage distribution between a minimum of 7.54% set in 2008 and a maximum of 11.73% recorded in 2004.

The same two regions (South-West and West) compete for 5th and 6th place, in the supply of accommodation in the areas referred to all places Romanian agro tourist boarding houses. Structural percent-

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 7. Tourist accommodation capacity current structure, on regions of development of Romania, during 2000-2012
Source: authors own computation based on NIS (2013)

ages established are close in value to those established for agro tourist boarding houses: between 1.07% (2000) and 6.17 in 2012 for the South-West region, ie the region of West between 2.17% in 2000 and 7.82% in 2011.

As might be expected, the last class is still BI, which corresponds to an insignificant number of places in rural touristic pensions compared to the total number of all regions is only 0.13% (2002) and 0.82% (2008).

The same trend of structural changes, as if the number of agro tourist boarding houses, there is the case of accommodation capacity in operation, showing small deviations from the percentage values for the indicator: established number of seats supplied by rural tourism in the eight regions of development of Romania.

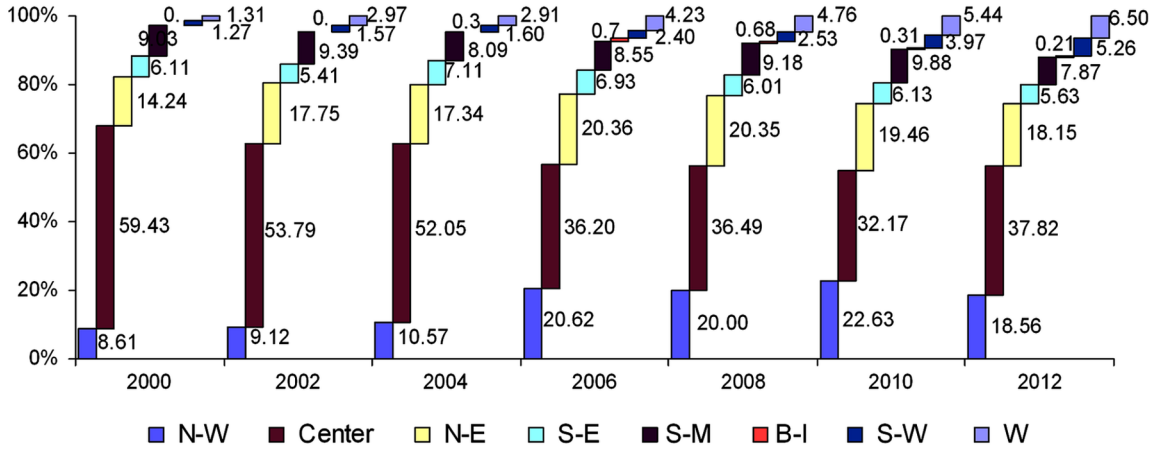


Figure 8. clearly highlights the structural developments established for accommodation capacity in operation corresponding to agro tourist boarding houses allocated in the eight regions of development of Romania.

Distribution of structural hierarchy of accommodation capacity in operation regions of development of Romania, with highs and lows percentage of the corresponding oscillation is as follows:

- First place occupied by the Central region with decreasing shares fluctuating between 59.43% (2000) and 32.17% (2012);
- Second and third place is occupied when the North-East region, when the North-West during 2000-2012 percentages ranging between 14.24% (2000) and 20.36% (2006) for North-East region and between 8 61% (2000) and 20.63% (2010) for the North-West region;
- Fourth and fifth place is disputed between regions and South-Muntenia with percentages varying between 5.33% in 2003 and 7.21% in 2005 for the first region, respectively the second between 9.03% and 10.51% recorded in the years 2000 and 2003;
- Sixth and seventh places are allocated alternatively be region West or to the South-West between 1.31% (2000) and 6.66% (2011) returning tourist accommodation capacity of the region W of

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 8. Structure of accommodation capacity in operation on developing regions of Romania, during 2000-2012
Source: authors own computation based on NIS (2013)

the total of the corresponding pensions in Romania rural tourism, and between 1.27% (2000) and 5.26% (2012) for the South-West;

- Last place belongs to region BI with percentages ranging from 0.01% (2000-2002) to 0.71% (2006).

Accommodation capacity analysis of agro tourist boarding houses presented in detail on county, highlighted the similarities and disparities that are manifesting in relation to the distribution of agro tourist boarding houses on counties and regions of development.

Concentration and Regional Diversification of Rural Touristic Accommodation Supply

Results of the analysis of the indicators of rural touristic supply are the premises to study the concentration and territorial diversification manifested in Romania.

Quantification of territorial disparities is based on various methods known in the literature by using indicators such as: coefficient (index) Gini, Theil index Hoover index or Palma report or different percentiles reports, Lorenz curve, coefficient of variation, Hirschman index or Kolm report.

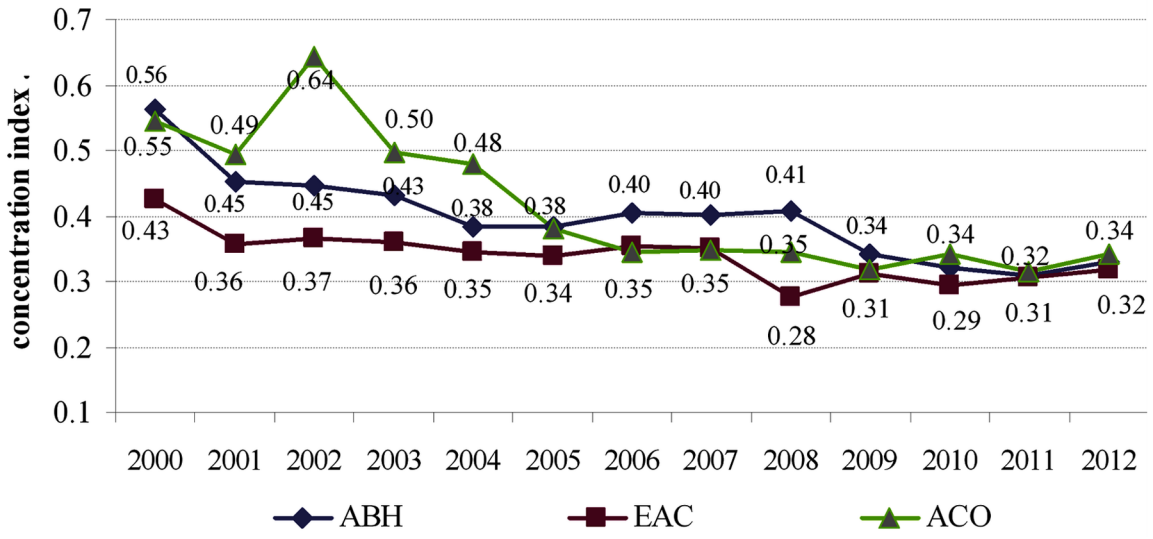
The applicability of these indicators is to adapt over time and space and different areas. Thus, targeting tourism literature are found Gini concentration ratios applied to predict the impact of the field and its role in foreshadowing flexible policies for developing tourist regions.

Julie Jie Wen and Corazon Sinha (2009) have analyzed the spatial distribution of tourism in China using Gini coefficient..Also, Miloš Bigovic used Gini coefficients to measure the concentration seasonal tourism in Montenegro, study highlighting the existence of a strong and consistent seasonality in this region (Bigovic, 2011).

However, the literature in the field presents Papakonstantinidis Leonidas, from quantifying income inequality, by applying the Gini indexes in the methodology to forecast the impact of tourism and development policy formulation in two of the most important tourist regions of Greece (Papakonstantinidis, 2012)

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

The study of the evolution of the three indicators and their corresponding structural fluctuations, on regions of development and counties in the period 2000-2012, led to obtain an overview of the Romanian tourism supply of accommodation. Trend changes, in time and space, has created framework necessary for the analysis of regional concentration and diversification of rural touristic supply in Romania, in order to shape a clearer image of the level of development of rural tourism relative to Romania's regional development strategy.



A first way of analyzing the territorial concentration of Romanian rural touristic supply is to determine the Struck concentration coefficients, at territorial development level, in the regions of Romania, whose evolution in the period 2000-2012 is shown in Figure 9.

The number of agro tourist boarding houses, at the level of each region, has allowed determination of structural coefficients, from which the coefficients were calculated annual Struck concentration. Thus, it resulted that, during 2000-2012, the concentration of the geographical spread fluctuated from year to year, as a whole, resulted a trend of reduction from a maximum of 0.5626 in 2000, to a minimum of 0.3085 in 2011.

The same trend of reduced of territorial distribution concentration was identified at Romania level, both existing accommodation capacity and the accommodation capacity in operation, as follows:

- Data on existing accommodation capacity of agro tourist boarding houses by regions of development have concluded to a concentration high enough, between a maximum of 0.426 in 2000 and 0.277 minimum in 2008;
- Significant fluctuations due to territorial distribution of accommodation capacity in operation, led to variations of the coefficient of concentration from a maximum of 0.644 in 2002, and a minimum of 0.313 in 2009.

Figure 9. Evolution of Struck territorial concentration coefficients of rural touristic supply during 2000-2012
Source: authors own computation based on NIS (2013)

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

In the whole, in Romania, compared to territorial regions of development, the rural touristic accommodation supply tends to a uniform territorial distribution, the concentration decreasing significantly in the period 2000-2012. The manifested trends was determined both by the intense and accelerated development of rural tourism since 1990, implicitly and after 2000, when it placed increasing emphasis on active and direct contact between man and nature in the context of high-level manifestation of pollution and stress, as well as by the particularities of this kind of tourism, which creates financial advantages over the others, in the crisis triggered and manifested after 2008.

For a more detailed analysis of regional concentration, starting from distributions of the number of agro tourist boarding house, of the existing accommodation capacity and of the accommodation capacity in operation by county, by applying the trapezoidal method were determined Gini concentration indices, respectively indices of diversification (Agresti value), the of 2012.

In the year 2012, the distribution of the number of counties by agro tourist boarding houses in Romania shows that, out of the 40 counties, in the majority (72.50%) were between 0 and 54 agro tourist boarding houses, in 20% were between 55 and 109 agro tourist boarding houses, while only in 7.5% of their total there are more than 109 agro tourist boarding houses (by 2.5% for each of the following three ranges of values 110-164, 165-219, respectively, 220-274 agro tourist boarding houses). Corresponding to this distribution, was resulted in a low concentration level, and highlighted by the value of 0.368 of concentration index. The same conclusion is underlined by Agresti value 0.4326 (corresponding to the distribution of the number agro tourist boarding houses by counties) led in relation to the maximum value (0.8). So the inequality between counties in terms of the number of agro tourist boarding houses is reduced.

Distribution of counties by existing accommodation capacity of agro tourist boarding houses in Romania in 2012 follows the number of agro tourist boarding houses in the sense that:

- 75.00% of all counties have existing accommodation capacity between 0 and 881 places;
- 17.50% of all counties have existing accommodation capacity between 882 and 1761 places;
- 7.50% of all counties have accommodation capacities over 1761 places (by 2.5% for each of the following three ranges of values 1764-2645, 2646-3527, respectively, 3528-4409 places)

Given the distribution of counties in groups by existing accommodation capacity supplied by agro tourist boarding houses, using the same method, resulted in a concentration index value of 0.6291 which indicate a significant concentration of existing accommodation capacity in counties of Romania. This can lead to disparities and therefore requires the application of appropriate mitigation strategies, with positive effects on the performance of rural tourism activities and tourism in general. On the other hand the value Agresti is 0.5051 and compared with the maximum value of 0.8, highlights the existence of disparity and widening trend of concentration.

Considering the territorial distribution of the values of the third indicator which characterizing the supply of rural touristic accommodation, was determined the distribution of counties by accommodation capacity in operation in agro tourist boarding houses in Romania in 2012, resulting:

- 77.50% of all counties have accommodation capacity in operation between 0 and 307186 places-days;
- 15.60% of all counties have accommodation capacity in operation between 307187 and 614373 places-days;

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

- 7.50% of all counties have accommodation capacity in operation over 614373 places-days (by 2.5% for each of the following three ranges of values 614374-921560, 921561-1228747, respectively, 1228748-1535935 places-days).

Starting from these, has result for concentrated index the value 0.3605 indicating a low concentration degree of accommodation capacity in operation of agro tourist boarding houses from Romania. Also, since Agresti value is 0.3751, it follows that there is a low degree of diversification in relation to the maximum value of 0.8, the disparities between counties in terms of accommodation capacity in operation of agro tourist boarding houses is lower than the others' two indicators analyzed.

In general, given the indicators those characterize the rural touristic supply, in the year 2012, resulted a breakdown in counties with a relatively low concentration, of the number of rural tourism and accommodation capacity in operation. The exception is existing accommodation capacity, which has a county distribution, not very favorable for future work of the Romanian tourism, requiring measures to mitigate of regional disparities.

The same "pattern" fall and the results of diversification indicator for number of hostels and accommodation capacity in operation, which shows a reduced disparity between counties, which means a distribution that tends toward uniformity, and that would allow maintaining a certain level the policies imposed by the regional development strategies for these two indicators, while for the existing accommodation capacity should be approached another development strategy.

FUTURE RESEARCH DIRECTIONS

The results of structural analysis on region, and of agro tourist boarding houses within the counties of the eight regions, indicates the distribution of the supply of the tourist accommodation area, and the degree of exploitation of tourism potential available to each. In this context it may establish implementing strategic measures, recovery and development of rural tourism potential which to run on the background of sustainability process

The National Strategy for Regional Development, which was outlined and applied on Regional Development Plans and the National Strategic Reference Framework 2007-2013, rural touristic accommodation supply analysis outlines the sustainable development level of this type of tourism and the possibilities that are foreseen in this direction.

In this context it is necessary that decisions and policies implemented through regional development strategies for development of agro tourist boarding houses and of accommodation capacity in operation to be performed within the same limits and coordinated. Regarding existing accommodation capacity, resulted a pronounced inequality in the territorial distribution of its, requiring the development and implementation of specific policies.

Currently, the basic element in the reform process, aimed at future territorial planning in Romania it is applied Strategic Concept of Territorial Development, Romania 2030 (www.mdrt.ro, 2013). It has the overall objective, affirmation process of the continental regional identity, of its role in the region, increasing spatial cohesion, the competitiveness and sustainable development of Romania that lead to ensuring Romania's integration into EU structures.

The Ministries policy advice to programs and strategies could affect tourism (Stănciulescu, 2006). So, established strategies must lead to the outline of the substantiation of territorial development, sup-

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

porting balanced development of Romania. This context created can stimulate partnerships, associations or collaborations at local, regional, and inter-institutional agreement, to promote and implement regional strategic projects.

Integrated territorial development perspective aims to establish and implement modality to use national potential with the aim eliminate development gaps. In this framework can be placed in the future and development of regional rural touristic supply, outlining a research direction to follow the effects of Romania's regional development strategies.

In relation to determining the degree of territorial concentration of Romanian rural touristic supply is required in the future adoption of strategies for mitigating regional disparities manifested positive impact on economic growth both in the rural communities that especially in Romania, all under the spectrum sustainable rural resources.

CONCLUSION

The study includes the analysis of assessment results of the trend, across time and space, of the number of agro tourist boarding houses, the existing accommodation capacity and the accommodation capacity in operation as well as the results of determination of the territorial concentration of these indicators, which can be a start point to develop and implement strategic decisions in the regional development of Romania.

Regarding to the accommodation supply of rural tourism in the context of sustainable development trend we conclude that, after 2000, when it put more emphasis on the practice of rural tourism as a result of changes in contemporary human life is impressive, the development process, fairly sustained of supply of rural tourism accommodation. This trend is the result of the support at national, regional and local level through the application of regional development strategies based on the one hand per funds that were needed in this direction, as well as maintaining a balance regional supply that not affect human communities in these areas.

The same time, the analysis of the indicators reflecting the supply of rural tourism accommodation through its peculiarities revealed that the economic crisis has had a relatively small impact, which occurred mainly in the first year after its onset, in 5 of the 8 regions of development in Romania, where, except for the Bucharest-Ilfov region, the decrease rates ranging from 0.38% in the Northeast region, and 10.06% in the South-WestOltenia. But, on the existing accommodation capacity of agro tourist boarding houses in the Bucharest-Ilfov, the impact of economic crisis was significantly (-41.69% in 2010, and still -21.38% in 2011), so in 2012 the accommodation capacity in operation has halved (44.54%) than the one registered in 2009.

The evolution of rural touristic supply in each development region has known increases and decreases in the values of evaluation indicators of rural tourist during the entire period of analysis 2000-2012. The study results show that the highest average growth rates for each indicator were recorded in the regions of development South-West Oltenia and West (average increases ranging between 25.99% and 37.23%), while lowest increases average were recorded in South-East development region, at the indicator the number of agro tourist boarding houses, and at existing accommodation capacity (with average rates of 7.77% and 9.39%), and in the Center region, at the indicator the accommodation capacity in operation (15.13%).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

The disparities between regions with high natural supply and with low natural supply are more obvious among counties in the developing regions. Significant to note is that these disparities are still quite low, being due mainly to features of rural touristic supply (traditions, culture, history of rural localities), as confirmed by the results of the concentration coefficients Struck, the indices of concentration Gini, and the diversification-value Agresti.

The rural touristic potential, specific to each development region, form the reference framework in regional development strategies. Starting on these can be established opportunities targeted to local and regional economic growth, as the result of exploitation of natural, cultural and historic potential for the decrease of the disparities between rural areas intended for tourism.

KEY TERMS AND DEFINITIONS

Agro Tourist Boarding Houses: Accommodation structure, for temporary tourists' installation, located in rural areas, with the capability to provide their meals and specific activities of this type of environment.

Existing Rural Touristic Accommodation Capacity: The number of seats available by agro tourist boarding houses in order to tourist accommodation.

Regional Concentration: Targeting mainly towards a region of the distribution of activities or elements that characterize an industry such as tourism.

Regions of Development: Territorial units established at national level as a result of an agreement between the county and local governments, given certain characteristics, officially established with purpose of developing and implementing strategies or development funds.

Rural Tourism: Is that form of tourism in which tourism services and activities take place in rural areas where there is prominent, the interdependence of the three basic elements still: nature, community, and traditional food.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Rural Touristic Accommodation Capacity in Operation: Statistical indicator assessment offer accommodation, representing the number of seats offered by agro tourist boarding house in relation to the number of days of their operation in a predetermined period.

Sustainable Development: Conducting activities aimed at progress, but having regard to saving resources and protecting the natural environment so that future generations can dispose of them in their turn.

Chapter 50
Sustainability Campaigns and Consumer Involvement:
Effects of Altruism, Locus of Control, and Long-Term Orientation

Zeynep Balanlı
Boğaziçi University, Turkey

Özlem Hesapçı
Boğaziçi University, Turkey

ABSTRACT

The main aim of this chapter is to find out the effects of NGO campaigns on consumers in terms of attitude and behavior and discover any relationship between this effect and sustainable personality factors such as altruism, locus of control, and long-term orientation. A survey is conducted with 177 consumers who reside in Turkey for at least two years that are older than 18 years. Experimented with two popular environmental NGO campaigns, results reveal clearly that altruistic personality trait has a positive effect on consumers in terms of behavior. Locus of control and long-term orientation are not correlated with environmental behavior and attitude of consumers. In addition, only age is positively correlated with consumer behavior in one of the campaigns. Demographics are not found to be sufficient to explain consumer behavior in environmental campaigns.

INTRODUCTION

The importance of sustainability is relatively a new apprehension in developing economies (Mazlum, 2004). Awareness for sustainability problems are mostly created by the efforts of non-governmental organizations (NGOs). This article aims to find out how NGO sustainability campaigns affect behavioristic patterns of Turkish consumers. Most of the prior research reveals findings from developed countries. The current study is conducted in Turkey, a country of an important emerging market. Its rapid industrialization and concerted efforts towards modernization make it a significant context for observing the developments of sustainable consumption.

While there are numerous examples to NGO initiatives for sustainability in Turkey, the effectiveness and cause effect relationships of these initiatives are not clearly comprehended. What are the reasons behind successful ones and unsuccessful ones? What are the best ways to increase consumer involvement in such initiatives? These are some of the many questions to be explored in order to understand consumer behavior and achieve more success in future developments.

The communication characteristics of a sustainability campaign that is derived by an NGO clearly play an important role in accomplishment of it. However, consumer behavior also play an important role to undertsand the underlying attributes of a successful campaign. This article aims to understand consumer personality and involvement in sustainability campaigns in terms of attitude and behavior. The correlation between personality factors of altruism, locus of control and long-term orientation and sustainability campaign attitude and behavior are investigated. The results of the research can give insight to create more successful campaigns in future.

BACKGROUND

Although the definition of sustainable development is discussed to be vague; it has different definitions in different contexts and changed over time since Brundtland Commission defined it in 1987 (Redclift, 2005). Established by the United Nations, Brundtland Comission united countries to define a map for the global environmental concerns. The comission released a report in 1987 which defined "sustainable development" and considered as the first definition of the sustainability concept. In his article, Redclift examines the development and evolution of sustainability concept from Brundtland Report's definition onward. Accoring to Redclift, by 2000s, sustainability concept refers to development of the world we live, by not only concerning the present time but also considering future generations. It has environmental, social and economic aspects which aim to achieve sustainability in all of them. Sustainable development involves governments, NGOs, corporations and consumers. In addition, since sustainable development is a broader subject which involves global problems, there is a need for managing sustainability globally.

The sustainable development concept has influenced the corporations with increasing Corporate Social Responsibility (CSR) engagements. Many business organizations are formed to support contributions of corporations to sustainable development (Smith, 2003). Some of the widespread organizations include World Business Council for Sustainable Development (WBCSD), International Business Leaders Forum (IBLF), Business for Social Responsibility (BSR) and Business in the Community (BITC). The CSR activities of firms have affected the consumers in terms of attitude and purchasing behavior in sustainability issues (Becker-Olsen et al., 2006).

Non-governmental organizations (NGOs) – another actor of sustainable development - play a significant role in political life and political changes in developing economies (Clarke, 1998). In his research, Clarke has analyzed NGOs and people organizations (Pos) in developing economies located mostly in Asia and Latin America. According to him, the recognition of NGOs and their involvement in socio-economic programs initiated after the recession in 1980. Many examples from India, Brazil, Bangladesh, Chile, Philippines, Malaysia and Thailand show that there is a correlation between political change and proliferation of NGOs and POs. The significant roles of NGOs are highly visible in promoting economic development and mobilizing broadly-based popular support for the governments. The democratization role of NGOs is ambiguous but yet it is significant that NGOs and POs strengthen civil society and the institutionalization between the society and the state. As much as for the developed world, the influential

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

importance of NGOs cannot be underestimated in developing countries since their role in politics and economy is substantial.

Wade's study on developing countries' strategies states that although NGOs have little impact on social and political strategies; they are still effective in starting out initiatives (Wade, 2003). Another study about developing economies state that "bridging organizations" is very important in social and economic development and NGOs are one of the main bridges that function as intermediary mechanisms (Brown, 1991). Examples of such "bridges" are proven as initiators of CSR activities (Becker-Olsen et al., 2006) and multinational enterprise (MNE) – NGO collaborations (Dahan et al., 2010).

NGOs contributions in sustainable development cannot be underestimated since there are many success stories in literature that link sustainability solutions to NGO initiatives (Vivian, 2008; Korten, 1990). Korten suggests that the goal of sustainable development can be achieved with the promotion of NGO activities. However, Vivian's article claims that although there may be a link between NGO activities and sustainable development, such correlations have not yet proven to be right. Vivian also adds that there are not yet analyses about the correlation between NGO promotions and sustainable development in a broader level but only regional case studies exists. Therefore, it is very hard to make a general statement about the contribution of NGO promotions in sustainable development. Vivian's study also shows a case study in Zimbabwe where she analyses the effects of rural development NGOs in sustainable development. Her findings indicate that NGO promotions can become effective in finding solution to environmental problems but they are no "magic bullets" that solve everything in a first and only attempt.

The Case of Turkey

Turkey is considered as a developing economy as a Third World country. Like many developing economies, Turkey was involved with sustainability issues and developed awareness towards sustainable development later than western countries. Although some participants of the Brundtland Comission were from developing economies, Turkey was not one of them. However, the environmental problems and concerns have always been on the agenda of many institutions and organizations in Turkey.

In Turkey's history, it seems that Brundtland Report has affected Turkey's policies on sustainable development and environmental problems (Mazlum, 2004). There are no strategies for sustainable development in 1970s and 1980s but only adressed environmental problems by the government. After the release of Brundtland Report (1987) and the subsequent Rio Summit (1992) Turkish government realizes the need for combining economic and environmental protection priorities in development (Mazlum, 2004). Sustainable development is introduced in five year development plans (FYDP) first time in the 6th FYDP for years 1990-1994. However, even with the 9th FYDP for 2007-2013 years, the government fails to implement policies to achieve sustainability (Ministry of Development, 2012). Ministry of Development itself even criticizes the current state and reports the failures in internalizing and implementing applications that are coherent with the sustainability policies.

The formation of NGOs is also relatively a late attempt in Turkey. Except Turkish Red Crescent (Red Cross of Turkey) there were no NGOs in Turkey until mid 1960s. NGOs that work for development of education, social life and health start to generate from 1970s onward. However, the first NGO that works for environmental development is founded in 1990 as ÇEKÜL - Foundation for the Protection and Promotion of the Environment and Cultural Heritage. As of today, Turkey has six primary NGOs that work for the solution of environmental problems.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Third Sector Foundation of Turkey (TÜSEV) has published a report about the NGO structure in Turkey in 2011 (TÜSEV, 2011). The report is based on an international index called CIVICUS Civil Society Index (Sivil Toplum Endeksi Projesi - STEP). According to the research, the number of NGOs in respect to population and total participation level of the society is relatively very low in Turkey when compared to other 52 countries in the index. Although the major participation (either financial or voluntary based participation) in NGOs is from the younger generation (younger than 25 years old) as 21%, it is still a very low level of participation in the international index. But, the difference is mostly caused by the lack of participation of this group in political issues. Women's participation is also very low in Turkey in all three categories of NGOs; social, political, and political activist. According to the findings of the research, the socio-economic level does not affect the participation levels in NGOs.

Environmental Consumer Behavior

Environmental issues and concerns are a vital part of sustainable development since the development of the world is highly affiliated with nature and environment. The environmental concern of consumers has attracted many researchers' attention. There are numerous studies which try to find the correlated measures for environmentally concerned behavior types. Although researchers try to correlate demographic characteristics with sustainable consumer behavior, it is very hard to define a pattern for behavior and demographics in all studies. A detailed empirical study on green consumer profiles debate inadequateness of demographics to explain green consumers (Diamantopoulos et al., 2003). Their analyses include more than 130 researches about demographics and environmentally concerned behavior types. The results indicate that demographics and attitude correlate in a way where as they do not reveal correlations with knowledge and behavior. In align with this article, a research on environmental attitude and behavior confirms no significant correlation with age, income level and education but indicates a significant difference in gender and home owners vs. renters (Mainieri et al., 1997). In addition, a research conducted in 1989 shows that environmental support, perception and behavior do not correlate with any demographic characteristics but rather correlate with political ideologies (Samdahl & Robertson, 1989). On the other hand, different behavior types and measures show dissimilar results in some researches. Another study on environmental consciousness and demographics indicates that although a significant pattern is hard to describe; age, income level and ethnicity are slightly correlated with consciousness (Krause, 1993). In another study, only age is found to be correlated with attitude towards environmental labels on products (D'Souza, Taghian, Lamb & Peretiatko, 2007). Research conducted in different cultures may also reveal dissimilar results. Contrary to many western researches mentioned above, a research conducted in Egypt indicates that men are more concerned than women in environmental issues (Mostafa, 2007). However, gender does not reveal any significant difference in environmental knowledge and attitude. Although it is very hard to define a global demographic pattern for environmental consumer behavior, demographics are still used for profiling cluster of consumer groups in terms of quality and price expectancies for environmental products (D'Souza, Taghian & Khosla, 2007).

Other than demographics, researchers have tried to find out correlations with other behavioral patterns to justify environmental consumer behavior. A recent case study for cloth diapers in Malaysia seeks to find a relation between environmental values and green purchase intention and attitude. The findings suggest that environmental consequences do not have a significant effect on attitude and purchase intention but, conservation has a positive effect on attitude (Ramayah, Lee & Mohamad, 2010). Another study

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

has found out that locus of control and alienation have a significant effect on ecological concerns where as only race and income correlates among demographic characteristics (Schwepker & Cornwell, 1991).

The characteristics of environmentally concerned consumers have also been on the agenda of Turkey. Young generations are found to be even more sensitive about environmental issues (Erdoğan, 2009). Erdoğan's research among 1295 undergraduate students from four different universities in Turkey aims to measure the New Environmental Paradigm (NEP) scale which is constructed by Dunlap et al. in 2000. The results show that 56% of university students hold pro-NEP views; a high agreement to NEP's environmental statements. However, 25% of students hold pro-DSP views which states that they mostly disagree with the NEP statements. Although the disagreement level is also high, the author suggests that cultural and historical differences among populations cause different interpretations and misunderstandings of statements. Another research with a younger profile (6th, 7th, 8th & 10th grade students) in Turkey indicates that both gender and school type (private vs. public) affects the environmental attitude of students (Tuncer et al., 2005).

Furthermore, recent researches have conducted that Turkish consumers have a tendency to be more sensitive about environmental problems. A research among 1000 residents in Istanbul has been conducted to measure the environmental sensitivity of consumers (Bodur and Sarıgöllü, 2005). The findings of the research show that less educated and poor income consumers tend to have less sensitivity and concerns in environmental issues. However, the research shows that there is no difference in sensitivity to environmental problems regards to age and gender. Other than demographics, locus of control, a personality trait, was also measured and found out that active concerned consumers are to have internal locus of control where as passive concerned have external locus of control traits. However, strong effects of locus of control in environmental concern were not significant. On the other hand, the classification built by the authors indicate that there are more than active concerned (30%) and passive concerned (43%) than there are unconcerned (27%) consumers.

Locus of control is found to be explanatory in defining environmental consumer behavior in many researches which some of them are mentioned above. Locus of control is the belief in people whether they can control their lives (internal locus of control) or environmental factors control their lives which they cannot influence (external locus of control). LoC was developed by Rotter in 1954 and adapted to Turkish by Dağ in 1991 (Rotter, 1954; Dağ, 1991). People with external locus of control believe that they have none or less control on their lives and they cannot have an impact on the events surrounding them. External LoC people usually do not engage in environmentally concerned behavior since they think that they cannot have an impact on the consequences. Dağ's research in 1991 among 532 students revealed LoC mean value of 10.37 with 1-21 range. Females believed slightly more in external LoC rather than males.

Long-term orientation is another personality trait that may be used of explaining environmental consumer behavior. Long-term orientation is defined as "fostering virtues oriented towards future rewards" (Hofstede Centre, 2012). Long-term oriented people believe that context, time and situation matter in finding the truth. They can adapt traditions easily when conditions change. The opposite side, short-term oriented people are more conservative in traditions, want to achieve quick rewards as results of their actions and saving for future is not common among them. LTO was added to original Hofstede dimensions on culture in 1988 (Hofstede & Bond, 1988; Hofstede, 1991). Long-term oriented people's anticipation for the future rewards can make them behave more environmentally concerned in certain situations or as a reaction to NGO campaigns. Since it is relatively a more recent dimension, there are no widespread researches on long-term orientation of Turkish culture.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Altruism may also be linked with environmental consciousness and behavior. Altruism is the opposite of selfishness and doing good to others without expecting any rewards. Rushton et al.'s "Self-Report Altruism Scale" is used to measure altruism personality trait (Rushton et al., 1981). The self-report altruism scale is found to be significantly and positively related with social responsibility (Rushton et al., 1981). As the altruism trait level increases, people's social responsibility increases. A study in Turkey found that as people tend to believe more in internal locus of control, their altruism and courtesy levels also increased (Basım & Şeşen, 2006).

In order to overcome the challenges in environmental problems for sustainable development, consumers' mindsets have to be changed. The changes in consumer behavior and attitude are the main research areas for many scholars. If the reason behind attitudes and behaviors are explained, then there is a chance for influencing other consumers as well to make them contribute to the environmental problems world faces today. The intermediary and bridging functions of NGOs in developing countries cannot be underestimated. Although NGO participations are low in Turkey, there has not been any research conducted to measure the participation levels in particular with *NGO campaigns*. This article aims to research the effects of particular NGO campaigns on consumer behavior with respect to personality traits in Turkey.

A CASE FROM TURKEY: CONSUMER INVOLVEMENT IN SUSTAINABILITY CAMPAIGNS

The Research

In 2013, a research has been conducted in Turkey to understand consumer behavior in terms of attitude, behavior and learning as a response to NGO campaigns in sustainability. Sustainability campaigns of NGOs which were active in years 2010-2012 in Turkey were selected as independent variables of the research. Personality traits of altruism, long-term orientation and locus of control were chosen to understand the relation between NGO campaigns and their effects on consumer behavior.

Hypotheses

H1: Since it is relatively a more recent dimension, there are no widespread researches on long-term orientation of Turkish culture. Long-term oriented people's anticipation for the future rewards can make them behave more environmentally concerned in certain situations or as a reaction to NGO campaigns. Therefore;

$H1_a$: Long-term oriented consumers will show more positive behavior towards the sustainable NGO campaigns in terms of attitude.

$H1_b$: Long-term oriented consumers will show more positive behavior towards the sustainable NGO campaigns in terms of behavior.

H2: The self-report altruism scale is found to be significantly and positively related with social responsibility (Rushton et al., 1981). If as the altruism trait level increases, people's social responsibility increases, altruistic people's behavior in response to environmental NGO campaigns should also be positively correlated. Therefore;

$H2_a$: Altruistic consumers will show more positive behavior towards the sustainable NGO campaigns in terms of attitude.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

$H2_b$: Altruistic consumers will show more positive behavior towards the sustainable NGO campaigns in terms of behavior.

H3: People with external locus of control believe that they have none or less control on their lives and they cannot have an impact on the events surrounding them. External LoC people would not engage in environmentally concerned behavior since they think that they cannot have an impact on the consequences. Therefore;

$H3_a$: Internal locus of control oriented consumers will show more positive behavior towards the sustainable NGO campaigns in terms of attitude.

$H3_b$: Internal locus of control oriented consumers will show more positive behavior towards the sustainable NGO campaigns in terms of behavior.

H4: Demographics are found to be insufficient to explain environmentally concerned behaviors of consumers (Diamantopoulos et al., 2003). But still, attitude of consumers are somehow correlated with education (Bodur & Sarıgöllü, 2005) and most researches find a difference in attitudes of gender types (Mainieri et al., 1997; Mostafa, 2007; Tuncer et al., 2005). Therefore;

$H4_a$: Demographics will have a correlation with attitude of consumers but not with behavior.

Method

An exploratory research is conducted to list all widespread NGO campaigns in Turkey. The results show that there were 24 campaigns that were initiated by NGOs and reached significant number of people in terms of their media activities in recent years. Among these campaigns 11 of them reflect environmental concerns, 6 of them social, 4 of them educational and 3 of them are campaigns for health issues.

In order to select the NGO campaigns that have already created awareness on society, an online pilot study was conducted with 89 respondents. All of the respondents were +18 years old and residents in Turkey for at least two years. (Appendix 1) The results showed that 72% remembered an educational campaign for female students in rural areas called "Baba Beni Okula Gönder" campaign. Second most remembered campaign was an environmental campaign for recycling plastic bottle caps with 66% recalling rate. The third one was Greenpeace's environmental campaign for avoiding consumption of small sized fish with 50% recalling rate.

The most recalled educational campaign was eliminated because it was not directly related with environmental concerns and did not have a direct effect on consumer behavior. Two environmental campaigns (Plastic Caps and Greenpeace's Fish campaigns) were selected to conduct further research.

An online study for measuring personality factors (i.e. locus of control, long-term orientation and altruism) and behavior towards campaigns was conducted with 177 respondents. Locus of control was measured with Rotter's scale which was adapted to Turkish by Dağ in 1991. Long-term orientation was measured with Hofstede's original LTO survey module developed in 1994. Altruism was measured with Rushton's Self-report Altruism Scale and translated to Turkish. It is structured with 20 questions on a five level Likert scale asking participants how often they have accomplished specific actions. (Appendix 2) Participants were asked to identify the two NGO campaigns that were selected and if they did not recall any of them, they were directed to the demographics questions. They were only asked questions about the campaigns which they were able to identify.

Participants' knowledge about the campaigns, their attitude towards the campaigns and behavioral outcomes were reported in a five level Likert scale.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

The link for the online survey was emailed to the participants and asked to share it with their contact lists. The survey was also shared on social media platforms.

Campaigns

Plastic Caps Campaign

Plastics caps campaign is a simple recycling campaign which people send the plastics bottle caps they collect to a certain address and caps are sold to recycling firms. The money established from these transactions is used for buying a wheelchair for the needy. The unusual characteristic about this environmental campaign is that it is not really an NGO campaign. It is an initiative started by a group of academicians in Ege University Dentistry Faculty in İzmir, Turkey. It has started in 2011 and with mass media's interest in the campaign; it became widespread in a very short time. Due to its organizational structure it may be called People's Organization (PO) but this initiative was never a sub-group of an NGO. Unfortunately the campaign ended in the beginning of 2013 due to problems with the logistics, recycling suppliers and Dean of the dentistry faculty. In two years time, the campaign collected 280 tonnes of plastic bottle caps and transported 2,039 wheelchairs to needy disabled people. With a rough calculation made, the campaign received 19,178 bottle caps per day in two years time. Plastic caps campaign is probably one of the most participated environmental campaign in Turkey.

Greenpeace Fish Campaign

The campaign has a catchy title in Turkish called "Seninki Kaç Santim?" meaning "How long is yours?" The campaign first started in social media in 2010. In a very short time Greenpeace collected 700,000 signatures and started applying to governmental units to ban fishing small sized fish. The intense interest in social media also drew mass media's attention to the campaign. By 2012, Greenpeace achieved great success by changing some laws on fishing. The secondary aim of the campaign was to create awareness among public. The awareness was surely achieved since 50% of the pilot study respondents recalled the campaign but this study will also measure if it has achieved learning on consumer behavior. Today, the campaign still continues with a less active approach.

Measures

Long-Term Orientation

Hofstede's LTO calculation is revised in 1999. The old calculation designed in 1994 contained 4 questions and the results could range from minimum -198 to maximum 302. The revised version of LTO contains 2 questions and the results can range from minimum -40 to maximum 120. Both versions of LTO is measured in this research and found out that old and new versions have a mean value of 54.3 and 66.2 respectively. However, the standard deviation values are high in both measurement and old and new versions have 77.3% and 33.1% CV respectively. Since the variance in the old LTO measurement is too high, new version is used in this research as LTO. The LTO value of 66.2 within -40 to 120 range can be considered as long-term oriented since the mid-value is 40. This is an indication that the sample is mostly expecting rewards in future, not conservative, and more flexible in many ways.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Altruism

On a 0-80 scale, the mean value for the altruism is 34.75. Rushton's samples in US have a mean value between 52-57. The altruism level of the Turkish sample seems low when compared to samples in US. The least practiced actions are "helping for a stranger's car when it's broken", "doing volunteering work for a charity" and "giving a lift to a stranger." Most common actions that are performed more often are "offering the seat on a bus or a train to a stranger", "delaying an elevator and holding the door open for a stranger" and "giving directions to a stranger". The more convenient and easy to perform actions are the ones that are more often practiced by the participants. The least practiced actions are probably very hard for participants to perform since they all live in big cities.

Locus of Control

Rotter's locus of control scale contains 29 questions with each of them having two answer choices. Six of the questions are fake which constructs 0-23 range of possible scores. The mean value of the participants is 11.6. The higher the locus of control score the more external control belief arises where as the lower scores indicate internal control beliefs. Dağ's study on students has resulted in a mean value of 10.4 for locus of control (Dağ, 1991). This sample has slightly more belief in external control like luck, fate and uncontrollable events.

Sample

The population for the sampling is defined as the Turkish consumers who are older than 18 years old and reside in Turkey at least for the last two years by February 2013. Convenience sampling of 177 consumers are used for the research. The demographic characteristics of the sample are given below in Table 1.

The Results

Total of 89.2% of the participants stated that they were familiar about Plastic Caps Campaign. Their knowledge level about the campaign was asked in a 5 level Likert scale and the mean value is computed

Table 1. Demographic characteristics of the sample

Gender		**Net Income**		**Education**	
Female	66.3%	0 - 850,00 TL	6.3%	Elementary school	0.6%
Male	33.8%	851,00 - 1.500,00 TL	12.5%	High school	6.3%
		1.501,00 - 3.000,00 TL	25.0%	Undergraduate	55.6%
Age		3.001,00 - 4.500,00 TL	24.3%	Graduate	33.1%
21-30	42.8%	4.501,00 - 6.000,00 TL	13.8%	Phd or above	4.4%
31-40	42.1%	6.001,00 - 7.500,00 TL	6.2%		
41-50	6.3%	7.501,00 - 9.000,00 TL	5.6%		
50 +	8.8%	9.001,00 TL or more	6.3%		

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

as 3.01. This means that majority of the campaign recognizants did not know any details about the campaign but also their knowledge was not insufficient. Attitude was measured with three questions that stated if they thought the campaign was right, if they liked the campaign and if they thought the campaign would be effective in finding a solution for the problem. The first and second attitude statements had mean values of 4.17 and 4.24 respectively which mean that majority liked the campaign and found the campaign reasonable. However, the third measure indicated a lower mean value (3.95) which indicated the campaign's ineffectiveness in finding a solution. The behavior was measured in four questions to understand whether they were trying to inform others about the campaign, collecting the bottle caps and sending them to the required address. Majority did not send the bottle caps by themselves but instead gave the caps to a collection point. The mean value of collecting bottle caps was high, 3.82, which indicated that the sample's involvement is also high. To measure further learning, when asked which recyclable products they were collecting, only 5% answered that they are not collecting any. 59% of the participants are collecting bottle caps. Glass, paper and battery are collected for recycling by 46%. Other plastics and food carton are collected by 32% and 28% respectively.

78.9% of the participants recalled the Greenpeace Fish Campaign and answered the questions related with the campaign. Their knowledge about the campaign has a mean score of 3.56 which means that majority of the participants agreed that they are informed about the campaign. Their attitude towards the campaign is higher than the plastic caps campaign but like the caps campaign, the least score in attitude is in believing the campaign will be effective in finding a solution for the problem. In both campaigns' attitude questions, this statement scores the lowest. This can be explained with the external locus of control tendency in the sample. As people will believe more in external control, they will not believe such campaigns can really be effective in finding solutions for the problems. The behavior measures of the campaign score lower than the attitude just like the plastic caps campaign. The least practiced behaviors are warning the fishmongers and restaurants that sold small sized fish according to the campaign. The involvement of the participants in consuming fish is also measured by asking them how often they eat fish. 46% stated that they consumed fish less than once in a week and 29% stated they consumed once in a week.

Although the attitude scores higher for the Greenpeace fish campaign, the environmental behavior is less likely to be practiced than the plastic caps campaign.

Pearson's correlation is conducted to understand the relations between the dependent and moderating variables. The results show that only altruism was correlated with consumer behavior when Greenpeace fish campaign was considered. The relation between altruism and consumer behavior towards the campaign is positively correlated meaning that the more altruistic people are the more they tend to participate in the environmental campaign. In addition, a positive correlation between attitude and behavior is significant. (Table 3)

Table 2. Descriptive statistics of the behavioral outcomes towards NGO campaigns

	Plastic Caps		**Greenpeace**	
	Attitude	**Behavior**	**Attitude**	**Behavior**
μ	4.12	3.35	4.29	3.07
σ	0.88	1.02	0.61	1.06
CV	21%	30%	14%	35%

	N	135	**135**	135	**135**	135

*. Correlation is significant at the 0.05 level (2-tailed).

**. Correlation is significant at the 0.01 level (2-tailed).

The only significant correlation between the personality traits and consumer behavior is seen between altruism and plastic caps campaign behavior. There is a positive correlation between those which indicates that more altruistic people tend to collect and send caps and inform others more about the campaign. Less significant correlations are seen between locus of control and attitude and behavior. However, these correlations are also positive therefore they suggest that external control believers tend to show more positive attitude and behavior towards the campaign. This does not make sense since external control believers would think that their actions would not change anything or they would have no impact on environmental problems. The significant positive correlation between attitude and behavior is also seen here. (Table 4)

Only significant correlation between demographics and consumer behavior in NGO campaigns is a positive correlation between fish behavior and age (Correlation 0.280 significant at 0.01 level). Older people have a tendency to participate for the Greenpeace fish campaign. In order to explain this relation, the correlation between involvement level and age is analysed. If older people were eating fish more often than younger adults then this correlation would have been justified. However, the frequence for eating fish and age levels do not correlate. The Pearson analysis and One-way Anova tests show that there is no significant difference in age levels and fish eating habits. This means that older adults were more motivated to change their consumer behavior for the Greenpeace fish campaign.

Only one of the hypotheses was proved. Altruism was correlated with behavior for both campaigns. However, altruism was not correlated with consumer attitude towards environmental campaigns. Therefore we can only accept $H2_b$. Among the other personality traits, long-term orientation had no relation with consumer behavior on NGO campaigns ($H1_a$ and $H1_b$ rejected). Locus of control was only correlated

with consumers in terms of behavior and attitude in plastic caps campaign. More research is needed to conclude about locus of control ($H3_a$ and $H3_b$) since it was not correlated at all in the other campaign. In addition, the positive attitude in correlation is suspicious since the higher scales in locus of control means people believe more in external factors than themselves as a mean to control their lives and the environment. Demographics also did not play a significant role in explaining consumer behavior. Only age was correlated with the Greenpeace fish campaign behavior. However, $H4_a$ suggested that it would be correlated with attitude but none of the demographics characteristics were correlated with attitude. Therefore we have to reject $H4_a$ too.

In addition, correlations in plastics caps campaign are more significant than in Greenpeace fish campaign. This may be due to the fact that more participants acknowledged the plastic caps campaign and therefore more data was collected in plastic caps campaign.

The limited sample size is the main obstacle of the study. Since the questionnaire was too long, many participants failed to complete it successfully. Limited number of responses led to variance problems in many of the collected data. The data was only collected online via internet which means that the sample consisted only of consumers who have access to internet.

SOLUTIONS AND RECOMMENDATIONS

In order for NGOs to achieve "bridging" function in sustainability they need to accomplish good communication with the community. This research shows the tendency to alter consumer behavior for sustainability campaigns among altruistic consumers. In order for sustainability campaigns to reach broader range of consumers the communication created may target more altruistic consumer profiles.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

If the campaigns succeed in reaching more altruistic consumers they will most probably reach more success in altering consumer behavior to participate in the campaign.

Both campaigns indicated that they were widely recognized by the consumers. However, the positive attitude in both campaigns was low when it was asked if they believed the campaign was going to be an effective solution for the problem. Although the consumers "recognized" and "liked" the campaigns, they did not fully believe that these campaigns would be a solution for the problems they were linked with. This is a major problem for NGOs to "bridge" consumers with the sustainability problems. If the consumers do not believe in the effectiveness of the campaign it will be very hard to change their mindsets and behavior for the campaign. In order to overcome this problem, any campaign should follow transparent policies and reveal all the steps taken and results achieved during the campaign. Indeed, they may need to give as much importance to communication of the campaign results as they give to the actual campaign itself.

On the other hand, the research findings indicate that NGOs does not have to put in time and effort to segment and differentiate targeted consumers according to demographical characteristics. There are no such correlations between demographics and consumer attitude and behavior in sustainability campaigns. Although this may change due to the problem the campaign is involved with or due to the environmental transformations; many previous researches have also shown the insignificance of demographics in sustainability.

FUTURE RESEARCH DIRECTIONS

The differences between the behaviors towards the two campaigns were also seen. Further research might include why consumers are responding differently to two environmental NGO campaigns. The attitude towards the fish campaign was higher than the plastic caps campaign but the behavior was not as positive as the plastic caps campaign. This may be due to the convenience and easiness of the plastic caps campaign. The learning and applying might be easier for the consumers where on the other one they had to learn sizes of the many fish which they need to be careful about. The characteristics of campaigns which affect the consumer behavior might be an interesting study to understand the reasons behind success of environmental NGO campaigns.

The growing concern for sustainability problems creates an obligation to understand consumer behavior to overcome related problems. The correlation between altruistic personality and sustainable consumer behavior leads to new research areas where altruistic behavior patterns and other correlated activities consumers tend to seek can be explored. Altruistic consumers can become the main target for many other sustainability campaigns where NGOs might need to differentiate themselves accordingly. On the contrary, there are challenges to overcome in order to attract attention of less altruistic personality types. While these two environmental campaigns in Turkey have drawn attention of altruistic consumers, ways to attract other consumers should also be researched and comprehended.

CONCLUSION

The outcomes of human civilization make sustainability policies more reasonable and acceptable each day. The universalization of sustainability policies is inevitable if one wants to see a good future ahead.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Even though governments have started to take solid steps to implement these policies to laws and regulations, there are still many steps to be taken in everyday lives of people.

Laws and regulations mostly target industries and businesses to decrease their undesirable effects on environment. In addition, most governments that work with sustainability policies try to raise awareness among public. NGOs are also additional constitutions that function to raise awareness on public and change consumer behavior. Though the consciousness level is increasing in most societies, there should be ways to reach more people by using effective communication.

There are two important results of this research on Turkish consumers. First, personality and the lack of belief among consumers in effectiveness of sustainability campaigns serve as important variables that enhances the tendency in sustainable behavior. While altruistic people are more easily attracted by sustainability campaigns and issues, there is always a challenge for initiatives to attract other personality types. In addition, any initiative that runs a sustainability campaign has to implement a transparent policy in order to demonstrate the results of the campaign and the effect people can have on the environment.

KEY TERMS AND DEFINITIONS

Altruism: Doing good to others without expecting any rewards, opposite of selfishness.
External Locus of Control: Belief in people that external factors are mostly in control of their lives.
Internal Locus of Control: Belief in people that they are mostly in control of their lives.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Long-Term Orientation: Tendency to anticipate future rewards for one's actions and behavior.

Non-Governmental Organizations (NGOs): Non-profit organizations which are not established by the government.

Sustainability: Sustainable development, which includes the four interconnected domains: ecology, economics, politics and culture.

Chapter 51
Promoting Healthy Lifestyle for Sustainable Development

Filiz Bozkurt
Doğuş University, Turkey

Ahu Ergen
Bahçeşehir University, Turkey

ABSTRACT

Economic growth, environment, and health are three significant aspects of sustainable development. Nowadays, lifestyle is increasingly evaluated as one of the most important factors influencing health. As increasing health expenditure is an important problem for sustainable development, it is essential to examine the society in terms of their health-related habits and promote healthy lifestyle to support sustainable development. In this chapter, healthy lifestyle of highly educated Istanbulites is researched. The respondents are classified into three distinct clusters according to their healthy lifestyles as "young and single individuals with low healthy lifestyle tendency." "young and middle-aged individuals consuming natural food," and "elderly, married adults leading healthy lifestyles." Afterwards, analyzing the data by ANOVA and post-hoc tests, it is found that respondents in different clusters have significantly different green consumer values and health motivations. Finally, theoretical and managerial discussions are provided and some recommendations are made for academicians and practitioners.

INTRODUCTION

1970s social marketing and green marketing schools strengthened the relation between marketing and natural environment. As the concept of sustainability became widespread, the number of consumers preferring products that won't harm the environment and their health, increased to a great extent. These consumers are sensitive about their health as well as the health of their environment. LOHAS (Lifestyle of Health and Sustainability), which is one of the latest approaches about lifestyle, brings a consumer segment who care about consumer health, environment, social justice and sustainable living (Cohen, 2010). Thus, it is impossible to take the concept of sustainability regardless from healthy lifestyle.

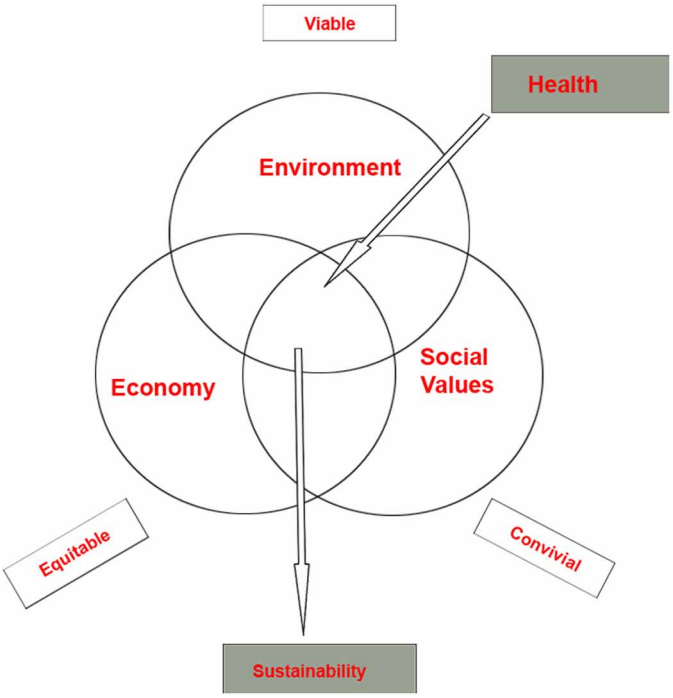
As the main focus of this study is the issue of attaining sustainable development through promoting healthy lifestyle, it is important to define the consumers in terms of their health related habits. As healthy lifestyle of groups are different from each other, there is no single public health, health education and marketing approach that will be effective on all (Gould, 1988). Therefore, marketing strategies should be designed in accordance with the characteristics of the target group.

In this study, where consumers' healthy lifestyle is evaluated in connection with health motivation and green consumer values, 377 highly educated İstanbulites are examined and they are clustered into three groups according to their healthy lifestyles. The result of variance analysis and post hoc tests indicated significant differences between the level of green consumer values and health motivation of the respondents belonging to different clusters. Depending on these findings, some suggestions are made to practitioners and academicians. It is believed that, focusing on healthy lifestyle within the framework of sustainability is not a common approach and thus will add value to the literature and guide government institutions, non-profit organizations and companies who develop policies on this issue.

BACKGROUND



Sustainable Development

The term "sustainable development" has become an important topic for governments, institutions and individuals with the Bruntland Commission Report (Our Common Future) in 1987. *"Development is the process of improving the quality of human life"* (Our planet, our health, 1992). Sustainable development is defined as "*development that meets the needs of the present without compromising the ability of future generations to meet their own needs*" (Bruntland Commission, 1987). This definition is focused on human needs and the way to meet them both today and in the future. Later in 1991, the World Wide Fund for Nature, the International Union for Conservation of Nature (IUCN), and UNEP defined sustainable development from an environmental perspective as "*improving the quality of human life within the carrying capacity of supporting ecosystems*" (UNEP, 2011). Pronk and ul Hak (1992) underlines economic growth, justice and environment with their following definition: "*economic growth that provides fairness and opportunity for all the world's people, not just the privileged few, without further destroying the world's finite natural resources and carrying capacity*". These definitions show that sustainable development means much more than economic growth. Many developing countries may perform positive economic growth rates in short term, however the citizens of these countries may live in poor environmental and social conditions, or have difficulty to reach health and education services equally. So, it is obvious that economic growth alone doesn't bring sustainable development.

The concept of sustainable development is the result of the growing awareness of the global links between mounting environmental problems, socio-economic issues to do with poverty and inequality and concerns about a healthy future for humanity. Environmental problems threaten people's health, livelihoods and lives and can cause wars and threaten future generations. It crucially embraces the key issues for humanity of how to ensure lives worth living and our relation with the planet and our relations with each other (Hopwood et al., 2005).

Figure 1. A conceptual model of sustainable development
Source: Sustainable development and health: concepts, principles and framework for action for European cities and towns (1997). European Sustainable Development and Health Series, No 1. Charles Price, Editor. Published by the WHO Regional Office for Europe, Copenhagen.

When the literature concerning sustainable development is reviewed, many articles and reports can be found. The common approach in many of them is that the term sustainable development has three main aspects. These are environmental, economic and social aspects (Figure 1) which are often considered separately, however they interact and influence each other

Health and Sustainable Development

Maybe the most important aspect in sustainable development concept is the "human capital". This perspective enables governments to invest in human capital and exploit its performance to maximum capacity. One of the ways to invest in human capital is to promote the health status (Çelik, 2011). WHO (1946) defines health as: "*..a state of complete physical, mental and social wellbeing and not merely the absence of disease and infirmity*" and positions it as one of the fundamental rights of every human being without distinction of race, religion, political belief, economic or social condition (IUCN, U. 1991). The global strategy for health development advocated by the WHO also implies that improving health requires action in three main areas: lifestyles, environment and the health care sector" (World Bank, 1993). The Rio Declaration's first principle also affirms that human beings are entitled to a healthy life (Health and Environment in Sustainable Development: Five Years after the Earth Summit, 1997).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Health is also an important stimulus to other aspects of development. Healthy people are economically more productive, which increases the economic growth rate of countries; investing in health is thus one means of accelerating development (World Bank, 1993).

On the other side, increasing health expenditures has become a serious burden on economies. Health economics is the new sub-discipline of economy going back to 1960's which is a tool to find solution to increasing health expenditures and to use resources efficiently under changing demographics and patient expectations. The main factors influencing health status are socio-demographic, economic, cultural and behavioral factors, education, genetics, health services, lifestyles and environmental factors. So, promoting healthy lifestyle is closely related with health economics and sustainable development.

Healthy Lifestyle

Healthy lifestyle, as an important determinant of health status, is a factor effecting the consumers' choices as well as their activities, interests and opinions about health and healthy living. Pender (1982) defined healthy lifestyle as "*an expression of the human actualizing tendency which is directed towards sustaining or increasing the individual's level of well-being, self-actualization and personal fulfillment",* whereas Myers et.al. (2000) defined the concept as *"a way of life, oriented toward optimal health and well-being in which body, mind and spirit are integrated by the individual to live more fully within the human and natural community."* As stated in this definition, taking environmental factors as an important determinant is quite common in the literature as it is impossible to reach optimal health in an unhealthy environment. The main problem here is that, environmental factors are more difficult and sometimes more costly to intervene and control.

The Interheart study, which covered 30.000 men and women in 52 countries showed that, factors such as smoking, cholesterol level, high blood temperature, diabetes, obesity, diet, level of physical activity, alcohol consumption, emotional stress and depression are related to various lifestyle factors (Yusuf et.al, 2004). According to the estimations of World Health Organization, 70-80% of deaths in developed countries and 40-50% of deaths in less developed countries result from lifestyle related diseases (Pirinççi et. al., 2008). There are many studies showing the effect of lifestyle choices on health and long life. Such findings underline the fact that, many diseases can be prevented just by changing the lifestyle. In many countries around the world, increasing average life and health expenditure are forcing the governments toward policies to improve peoples' health and to change their lifestyles.

Promoting Healthy Lifestyle

In the US, from the beginning of 1970's, continuous efforts have been made to determine how permanent changes could be made in personal habits and lifestyles of people. In 2007, World Health Organization highlighted the importance of health promotion which includes steps like, promoting healthy lifestyle, creating suitable environments, restructuring health services and building a government health policy (Pınar et. al., 2009).

Parallel to these developments, government organizations, non-profit organizations and health educators started to use marketing techniques to make people adopt a healthy lifestyle. Nowadays, government and nonprofit organizations are regularly running social marketing campaigns on various health issues such as nutrition, physical exercise, obesity, smoking and alcohol consumption. It is essential to educate people and create awareness about health issues in order to motivate them to change their lifestyles. Kickbush

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

and Payne (2003) support this view by stating that, knowledge is the main factor to stimulate the healthy lifestyle movement and in modern societies, the number of knowledgeable people are rapidly increasing.

Consumers can get basic health information from different personal, commercial, non-commercial, institutional and media channels. Media channels are printed media, electronic media and social media. Health practitioners and other health professionals provide more formal and basic health information. Kraft and Goodell (1993) stated that mass media campaigns by the government and local authorities significantly increased the awareness about the role of healthy lifestyle on preventing diseases. The most important lifestyle changes coming along with basic health information are; eating habits, regular health controls, reading the labels on packages, joining a health or healthy lifestyle club. Some other lifestyle changes coming with health information are; change in social life, sleeping habits, regular exercise and joining health exhibitions and seminars (Cangelosi et.al, 2009).

Although promoting healthy lifestyle is an important agenda, there are several obstacles to overcome. First of all, in social marketing, there is a competition between the desired and the alternative behavior (Grier and Bryant, 2005). For example, when healthy eating behavior is the case, competing behaviors are eating unhealthy food and snacks which are strongly supported by commercial advertising. Although healthy life has positive associations, some people think that it is not enjoyable and health educators are forcing people to do things which they don't want (Veenhoven, 2008). One of the most important difficulties in changing health related behaviors is the difficulty of changing habits and going out of the comfort zone.

Health Motivation

The concept of health motivation is; the consumers' being stimulated to adopt preventive health behavior (MacInnis et.al. 1991; Park and Mittal 1985), their desire to take a step and their interest in health behavior (Moorman and Matulich, 1993). The determinants of motivation include variables such as control of health behavior, self-discipline, social support and approval, value set, income, education, work status, self-respect, attractiveness and health status (Carter and Kulbok, 2002). Health motivation, which is an important determinant of health behavior plays an important role in organizing beliefs about health and various beliefs which interact with each other (Gochman, 1971). In this context, three mostly mentioned beliefs are; perceived sensitivity, perceived seriousness and perceived benefit. Perceived sensitivity is the probability to face health problems, perceived seriousness is the belief about the level of negative effects that may result from these health problems and perceived benefit is the expectation about the positive outcome of certain behaviors. High level of interaction between these three beliefs is considered to increase the possibility of adopting health behavior (Gochman, 1972). There are also findings showing that health motivation increases getting health information from the media, interaction with health professionals and the rate of going on a diet (Moorman and Matulich, 1993).

Green Consumer Values

Values, a dimension of culture, are considered to effect the consumer behavior. According to Schwartz (1994), values are guiding principles that lead individuals and social identities throughout their life. On the other hand, green consumer is the type of consumer, who tends to take into account the environmental effects of their consumption behaviors. Thus, consumers with stronger green values are inclined to make decisions consistent with sustainability (Bearden et.al., 2011). In the literature, there are also findings

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

showing that people valuing ecological issues and taking risks for self-actualization with an entrepreneurial approach behave in a more ecological way (Fraj and Martinez, 2006). It is also emphasized that, people who adopt healthy lifestyles are sensitive about environmental factors as well as nutrition, physical condition and stress management (Kraft and Goodell, 1993). "For years, men have focused on economic progress to increase the level of development in their countries, but they failed to realize environmental degradation" (IMKB, 2011). However, economic sustainability depends on ecologic and social sustainability, because without a planet, there will be no economy (Charter et.al., 2002).

MAIN FOCUS OF THE ARTICLE

Issues, Controversies, Problems

It is important for marketers to explore consumers' lifestyles, values and motivations in order to determine the appropriate marketing approach to persuade the target group for adopting a healthy lifestyle. So, understanding the healthy lifestyle, green consumer values and health motivations of the consumers will enable governments and other institutions to design their health related social marketing campaigns effectively.

The objective of this study is to classify the highly educated Istanbulites according to their healthy lifestyle and to understand their characteristics regarding green values and health motivation. So the present study tests the following hypothesis:

H1: According to their healthy lifestyles, respondents will be classified in different clusters.
H2: There will be statistically significant differences between the green consumer values of the consumers in different clusters.
H3: There will be statistically significant differences between the health motivations of the consumers in different clusters,

In this study, healthy lifestyle was measured by a 13-item scale. Eleven questions of the scale were used by Gil et.al (2000) and afterwards by Chen (2011). After receiving expert opinions two additional questions were added by the authors. Health motivation was measured by the 8-item scale used by Moorman ve Matulich (1993) in their study exploring the factors effecting preventive health behavior and green consumer values are measured by a 6-item scale developed by Haws et.al (2013). For these three variables, respondents answered items using a 5-point scale. The demographic characteristics of the respondents were measured by a nominal scale.

Before collecting the data, an online pre-test was held and some wording in the survey was simplified according to the feedbacks received. As the main objective was to cover Istanbulites holding bachelor and postgraduate degree, a convenience sampling was conducted and 415 surveys were collected. From 415 surveys, 28 were eliminated due to missing answers, 10 surveys were removed due to outliers. Finally, analysis were held with 377 drop-off surveys. The collected data was analyzed with the following sequence: factor analysis, reliability tests, cluster analysis and ANOVA tests. First, factor analysis was conducted for healthy lifestyle, green values and health motivation variables. Afterwards, the reliability of the factors were evaluated by Cranach's Alpha coefficient and mean inter-item correlation values. In order to explore the ideal number of clusters, first, a hierarchical cluster analysis was conducted using

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Ward's method, afterwards k-means clustering and lastly, ANOVA test was conducted to understand whether different clusters vary in health motivation and green values.

Socio-Demographics

The sample consists of high-income and well-educated profile. 66.5% of the respondents were female. Of the respondents, 52.2% were married, 70% have bachelor degrees, and 30% have graduate degrees. In terms of age distribution, 17.9% were between 18-25, 25.4% were between 26-35, 40.4% were between 36-49 and 16.35% were over 50 years old. Of them, 13.8% had monthly income between 4.000-5.000TL, 13.8% between 5.000-7.000TL, 16.9% between 7.000-10.000TL and 14.4% had monthly income over 10.000TL.

Factor Analysis

As result of the factor analysis of healthy lifestyle variable, items were grouped in four factors with Eigenvalues more than 1 and explaining 63.16% of the variance (KMO=0,769; Bartlett's p<0,005). Due to low reliability, one factor is eliminated and the remaining three factors account for 53.8% of the variance. The reliability of the factors were measured by Cronbach's Alpha coefficient and Mean-inter-item correlation. Two factors with Alpha values over 0.6 and one factor with mean inter-item correlation value between 0.2 and 0.4 were accepted as reliable (Taylor et.al., 2003). The first factor was entitled as *balanced life* (Alpha=0.75), the second as *natural food consumption* (Alpha=0.7) and the third one as *avoidance from unhealthy food* (Alpha=0.62 and mean-inter-item correlation between 0.2 and 0.4). In Gil et.al.'s (2000) study carried out in Spain, the questions concerning exercise and taking responsibility about health were grouped under the factor "health care". However, in this study these questions were not grouped under a factor. As result of the factor analysis of health motivation variable, items were grouped in two factors with Eigenvalues more than 1 and explaining 66.5% of the variance (KMO=0,724; Bartlett's p<0,005). The first factor which expresses preventive behavior towards health problems, was entitled as *proactive health motivation* (Alpha=0.71), the second factor that points out the steps after a health problem occurs, as *reactive health motivation* (Alpha=0.77). Lastly, the green consumer values variable (Alpha=0.88) was not grouped under factors.

Cluster Analysis

Cluster analysis is an analytical technique used to create significant sub-groups from individuals and objects (Gegez, 2007). In this study, two different clustering technique was used to classify the respondents according to healthy lifestyle. Firstly, hierarchical cluster analysis was conducted using Ward's method to explore the ideal number of clusters. The results of the hierarchical cluster analysis showed that solutions with two, three and four clusters were appropriate for the study. Afterwards, k-means clustering was conducted using three of the cluster alternatives. Due to the difficulty to interpret four clusters and the lack of explanatoriness for two cluster alternative, three-cluster solution was found appropriate. ANOVA results and the mean scores that will help to describe and entitle each cluster are shown in Table 1. According to ANOVA results in Table 1, three healthy lifestyle factors significantly clustered the respondents in three different clusters ($p<0.05$). So, H1 is confirmed.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Healthy lifestyle mean scores for clusters

Healthy Lifestyle	Cluster 1 (n=92)	Cluster 2 (n=86)	Cluster 3 (n=199)	F ratio	Sig.
Balanced life	*3.31*	3.81	*4.08*	46.3	0.000
Natural food consumption	*2.59*	*4.15*	4.12	243.3	0.000
Avoidance from unhealthy food	*3.08*	3.03	*4.28*	238.9	0.000

It is found that the highest healthy lifestyle scores belongs to Cluster 3. Cluster 2's scores are lower that Cluster 3 except natural food consumption and higher than Cluster 1 except avoidance from unhealthy food.

Cluster 1's all mean scores are lower than Cluster 3 and also lower than Cluster 2 except avoidance from unhealthy food. In Table 2, the cluster profiles can be seen in terms of their socio-demographic characteristics. There are significant differences between the clusters in terms of age and marital status variables. Gender, education and income variables were not significantly different. It is considered that education and income variables are not distinctive since the structure of the sample is homogeneous. After analyzing three clusters in terms of healthy lifestyle and socio-demographics, the clusters are

Table 2. Socio-Demographics of the clusters

	Cluster 1 (n=92)	Cluster 2 (n=86)	Cluster 3 (n=199)	X^2 (sig.)
Age				31.660 (0.000)
18-25	*33%*	*18%*	*11%*

named as "young and single individuals with low healthy lifestyle tendency", "young and middle-aged individuals consuming natural food" and "elderly, married adults leading healthy lifestyle" and each constituted 24%, 23% and 52% of the respondents respectively.

Cluster 1 (young and single individuals with low healthy lifestyle tendency): Cluster 1 which consists of 92 people, is the youngest group, with the highest single rate and the lowest healthy lifestyle score. 66% of the respondents are in 18-35 age group and 59% are single. Of this cluster, 76% have bachelor degree and 24% have graduate degree. 55% of the members have monthly income of 4.000TL and more. The highest healthy lifestyle dimension of Cluster 1 is with 3.31 mean score, balanced life. Natural food consumption dimension is, with 2.59 mean score, the lowest. Avoidance from unhealthy food dimension is, with 3.08 mean score, higher than Cluster 2 and lower than Cluster 3

Cluster 2 (young and middle-aged individuals consuming natural food): Cluster 2 consists of 86 people. 64% of the respondents are in 26-39 age group and 51% is married. Of this cluster, 71% have bachelor degree and 29% have graduate degree. 57% of the members have monthly income of 4.000TL and more. The highest healthy lifestyle dimension of Cluster 2 is with 4.15 mean score, natural food consumption. Avoidance from unhealthy food dimension is, with 3.03 mean score, the lowest. Balanced life dimension of Cluster 2, with 3.81 mean score, is higher than Cluster 1 and lower than Cluster 3.

Cluster 3 (elderly, married adults leading healthy lifestyles): Cluster 3 which consists of 199 people, is the elderly group with the highest healthy lifestyle mean scores. 67% of the respondents are over 36 years old and 58% are married. Of this cluster, 33% have graduate degree. 60% of the members have monthly income of 4.000TL and more. The highest healthy lifestyle dimension of Cluster 3 is with 4.28 mean score, avoidance from unhealthy food. Subsequently, balanced life follows it with 4.08 mean score. In both dimensions, Cluster 3 has the highest scores among the three clusters. Natural food consumption dimension is, with 4.12 mean score, higher than Cluster 1 and lower than Cluster 2.

ANOVA Test

In order to explore the significant differences between the clusters in terms of green values and health motivation, ANOVA and post-hoc tests are conducted. It is found that there are significant differences between the cluster means (F2;372) =14,586, p<0,05. Post-hoc Scheffe test shows that members of Cluster 3 have the highest green consumer values mean (M=4.21), whereas members of Cluster 1 have the lowest (M=3.79). So, H_2 is confirmed. The elderly group with the highest married rate has the highest green consumer values mean. This finding reminds Bodur and Sarıgöllü's (2005) research about Turkish consumers' attitudes and behaviors towards the environment. In their research, it was found that a number of older respondents were highly concerned about the environment mostly because they worry about the future of their grandchildren. Also, in their research held with 1.000 respondents, three distinct segments were found: active concerned, passive concerned and unconcerned. The active concerned were better educated and more affluent.

Also, significant differences are found between the different clusters' respondents' answers to proactive health motivation questions (F2;373)=18,543, p<0,05. Post-hoc Scheffe test shows that members of Cluster 3 have the highest proactive health motivation mean (M=3.78), whereas members of Cluster 1 have the lowest (M=3.19). There are also significant differences in terms of reactive health motivation means of the clusters (F2;373)=12,679 p<0,05. Post-hoc Scheffe test shows that members of Cluster 1 have the highest reactive health motivation mean (M=3.04), whereas members of Cluster 3 have the lowest (M=2.53). So, H_3 is confirmed.

SOLUTIONS AND RECOMMENDATIONS

According to Bozkurt's (2014) study, holistic healthy lifestyle scores of Turkish people need to be developed. In this study, spiritual wellbeing score of the respondents were found to be the highest which was believed to result from the cultural characteristics of the country. Nutrition and avoiding from unhealthy food is in the middle while exercise scores are low. The holistic healthy lifestyle scores are below the desired level in many studies in the literature. It is difficult to adopt a healthy lifestyle because of habits, low awareness, time pressure, economic difficulties, consumption behaviors and negative environmental factors. However, it is important to promote healthy lifestyle in order to enhance well-being of the society and contribute to sustainable development. As stated in the beginning of this study, it is essential to define the consumers in details in order to use social marketing and supporting tools in the most effective way to promote healthy lifestyle. To promote healthy lifestyle for each segment defined in this study, some recommendations are made below.

Young and single individuals with low healthy lifestyle tendency score low in natural food consumption and avoidance from unhealthy food. This finding recalls Ergen's (2014) research, clustering Turkish consumers according to their sustainable consumption behavior. Ergen found that the youngest group consisting of students and single individuals show the lowest sustainable consumption behavior and their behaviors are not influenced by environmental knowledge. In order to persuade this group to change their habits and adopt a healthy lifestyle, marketers are advised to inform this segment about health related issues and increase their awareness. It is also found that green consumer behaviors of this segment is low while proactive health motivation is high which means they have a tendency to solve health problems when they face them. From health economics point of view, low proactive and high reactive health motivation can affect the efficiency of the labor force negatively. For a country like Turkey, which has a young population with an average age of 30.4, young people with proactive health motivation is extremely important for sustainable development. As this segment mainly includes members of generation Y, marketers are advised to take into account the characteristics of this generation while designing the marketing mix. Using entertaining messages, promoting healthy lifestyle as an increasing trend, using role models popular among this segment and effective use of social media are thought to be essential while communicating with this group. As they score low in proactive health motivation, messages to convince them take responsibility about their own health and use preventive health services are thought to be essential for marketers to communicate.

Young and middle aged individuals consuming natural food: There is an interesting contradiction about nutrition habits of this segment. Although their natural food consumption is high, their avoidance from unhealthy food is low which brings to mind that both nutritional and hedonic dimensions of nutrition are important for this group. Thus, strict messages about nutrition may not be respected within this segment and this point should be taken into account while designing the marketing messages. However this segment should still be informed about the negative effects of unhealthy food. As balanced life score is above average, messages that will stimulate this segment to take part in stress management training, leisure time activities and personal development courses are thought to be effective on them. With a high score for proactive health motivation, this segment is thought to have health insurance. So, combining the insurance packages with healthy lifestyle programs can be useful in promoting healthy lifestyle to this segment. Also focusing on green values in communication may be effective on this group.

Elderly married adults leading healthy lifestyles: Members of this segment have high scores in all dimensions of healthy lifestyle, avoiding unhealthy food being the highest. In most of the studies in the

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

literature, married people score higher than singles in healthy lifestyle. In Bozkurt's (2014) study examining healthy lifestyle, the results were similar with an additional finding showing that divorced people were living healthier than singles and married people. This segment is already familiar with natural and healthy food, so they can be used as opinion leaders or health lifestyle advocates to impress other people. As their level of avoidance from unhealthy food and natural food consumption is significantly high, points of purchase and packages of nutritional food as well as health and wellness magazines can be valuable mediums to reach this segment. While communicating with this group, green values and multidimensional structure of health may be mentioned. Members of this segment score high in proactive health motivation, so they may already be using preventive health services. Social marketing campaigns targeting this segment should aim to remind the importance of living healthy and adopting healthy behaviors in various dimensions of healthy lifestyle.

It is also important to make healthy choices available for all these groups through workplace health programs. So policy makers should co-operate with and maybe support employees to motivate them design and implement such programs as a part of their human resources policies. Motivating employees to take part in these programs is an important issue to be considered for the success of these programs.

FUTURE RESEARCH DIRECTIONS

Although healthy lifestyle is an important issue for sustainable development, studies focusing on this relation is limited. So, empirical studies examining this relation can add value to the literature. It is also essential to explore the consumers to find out more about their regular activities in a day (time spent in traffic, eating and drinking, hobbies, exercise, where they shop, how they solve their health problems etc.) with in-depth interviews. Health institutions and governments should make comprehensive research in order to understand the use of preventive health services and also the barriers that should be overcome to change people's lifestyles. It is also essential to make research including other dimensions of healthy lifestyle, such as exercise and health responsibility.

In this study highly educated individuals with high income are examined. This profile is believed to be more open to receive and make use of health related messages. So people with lower education and income should also be studied in terms of their health related habits.

CONCLUSION

The starting point of this study was healthy lifestyle and sustainable development relation and how this lifestyle can be promoted among individuals with different profiles. In order to have a better understanding, healthy lifestyle is examined with green consumer values and health motivation.

One of the most effective approaches to promote healthy lifestyle is using social marketing campaigns which aim to improve health related habits of individuals to the optimal level possible within their environment. This study is believed to contribute to define the target group better and develop more effective strategies.

As Bodur and Sarıgöllü stated (2005), Turkish people are thought to be more externally controlled perhaps because of underlying characteristics such as *collectivism, shared fatalism, or spiritual beliefs*. So it is essential to convince people that they can control their health.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Another important issue regarding the healthy lifestyle is co-operation. Authorities think that "21st Century calls for a new health system which is partnership- oriented, population health-based, and proactive rather than reactive. The health sector must serve as a guide to and be a partner in these actions so that health concerns are represented appropriately at all stages of implementation" (Health and Environment in Sustainable Development: Five Years after the Earth Summit, 1997).

Chapter 52
A Fourth Wave of Education for Sustainability (EfS) in Higher Education

Mike Brown
La Trobe University, Australia

ABSTRACT

Education for Sustainability (EfS) in Higher Education (HE) is described as developing through three waves. These are overviewed in this chapter and given due acknowledgement but are shown to fall short of what is needed going forward. Consequently, a fourth wave of EfS in HE is proposed. The fourth wave of EfS in HE needs to be directed at the collaborative project of constructing "sustainable universities" (Sterling, Maxey, & Luna, 2013). The concept of "neo-sustainability" (Farley & Smith, 2014) is adopted as the basis of this next wave, as is the three nested rings model of sustainability. The argument for a strategy to educate the HE educators is outlined. It is suggested that contemporary global and local sustainability issues need to become part of student engagement within all HE courses. Finally, effort needs to be exerted by HE lecturers to develop pedagogical practices that align to the aims and principles of EfS.

INTRODUCTION

The premise of this chapter is that in our society many of us are living beyond the carrying capacities of the earth's natural ecological systems. It is essential not only to change existing lifestyles, but to develop new, sustainable lifestyles. It is argued that education is the primary process for supporting the realization of the limits and the necessary changes. This chapter looks at how Education for Sustainability (EfS) is developing across the higher education (HE) sector. Three renditions or different waves of EfS in HE are identified and explained in the literature. An overview of these leads into an argument for the need for a fourth wave, with an explanation of what this next wave might look like. The major strategies for this fourth wave are a reframing and clear articulation of the concept of sustainability. It is argued that this reframing should be based on the concept of "neo–sustainability" (Farley & Smith, 2014) and

aimed at building "the sustainable university " (Sterling, Maxey & Luna, 2013). Next, it is argued that there is also a need to reframe and add to current ideas about EfS in HE, in essence shifting the focus and concentrating on "educating the HE educators ". This educative work needs to concentrate on both (1) relevant curriculum and content, and (2) appropriately aligned pedagogical practices. However the concept of "the sustainable university" and the fourth wave of EfS in HE is very new and very much open to collaborative construction.

THE ARGUMENT

The gist of the argument is twofold. First there is a need to reframe and clarify the concept of sustainability. Second there is a need to reframe EfS in HE and concentrate on educating the educators.

The Need to Reframe Sustainability

The rise of concerns and the discourse on sustainability signify a fundamental shift in the understanding of the relationship between humanity and nature. Humanity is realizing that it is part of nature and that it depends on nature for its existence. In turn, the central concern within sustainability is that humans are living beyond the capacities of the earth's ecology systems. The world's population is living and consuming at a higher rate than what the ecological systems can re–generate and support over the long term. Central debates in sustainability focus on the use of resources, population stress, water and food security, energy, climate change, ecological balance and eco–system adaptation (Vogt, Patel–Weynarrd, Shelton, Vogt, Gordon, Mukumoto, Suntana & Roads, 2010). The subsequent conclusion derived from these debates is that current lifestyles and patterns of consumption need to change.

In short, the earth's population has outgrown the growth model. Unbridled growth is argued here to represent a mindset of abundance that favors expansion, development and growth. The mindset includes a belief that more resources exist, they just need to be found and utilized. Hence, there is a need for a counter strategy that is more attuned to current understandings. The alternative presented here is a post–abundance framing of the relationship between humanity and nature. This is a relationship based on sustainability. As Farley & Smith (2014) explain, to sustain implies maintenance, support and long–term endurance "of something", but the something which is sustained involves a value position.

Two different positions in the relationship between humanity and nature are being set out. The first concerns where we, as humanity, are at the moment. This is a position built upon the growth model, a position labeled here as reflecting an abundance mindset. The second position being presented concerns where we, as humanity, need to move. This is the preferred or desired position of living within the means and carrying capacities of global eco–systems. This is being labeled here as a post–abundance position. Throughout history, movement from abundance to a post–abundance position has often occurred through social upheaval and revolution, but in this case the movement is to occur peacefully, through education. Yet the image of the revolution helps to convey the importance of what is at stake, and the need for change. It also conveys a sense of the degree of difficulty involved and what is being asked of an educative process.

Reframing Education for Sustainability (EfS) in Higher Education (HE)

As the United Nations Educational, Scientific and Cultural Organization (UNESCO, 1997) document *Educating for a sustainable future* (para. 38) states:

It is widely agreed that education is the most effective means that society possesses for confronting the challenges of the future. Indeed, education will shape the world of tomorrow. Progress increasingly depends upon the products of educated minds: upon research, invention, innovation and adaptation. Of course, educated minds and instincts are needed not only in laboratories and research institutes, but in every walk of life. Indeed, access to education is the sine qua non for effective participation in the life of the modern world at all levels. Education, to be certain, is not the whole answer to every problem. But education, in its broadest sense, must be a vital part of all efforts to imagine and create new relations among people and to foster greater respect for the needs of the environment.

The conclusion and main strategy put forward from the analysis of the effectiveness of Education for Sustainability (EfS) in HE up to this point, is that there is a need to "educate the educators". Educators in HE should be explicitly targeted and upskilled in EfS. Education for Sustainability (EfS) in HE needs to be embedded into each and every educator's work, much the same as Occupational Health and Safety. This may be difficult to initiate as many of these educators have deep but narrow areas of expertise and may resist spending valuable time learning and developing expertise in a new area of knowledge. But all effort in educating the HE educators will be effort well spent. HE educators have the potential to influence the students who come through their courses, many of whom will be influential people themselves in the near future. Scott, Tilbury, Sharp and Deane (2012) report that two per cent of the world's population attend higher education but more than 80 per cent of the decision makers in industry, community and politics are graduates of universities. There is a need to offer EfS to our future leaders and professionals. It has been estimated that EfS in universities has the potential of reaching 135 million students across 17,000 universities. Further, these students come and go with the cohort renewed every three years (Sterling, 2013).

Likewise, a further subset of these HE educators to be prioritized for being educated about EfS includes those who work in faculties of education as teacher educators. Using the same logic, teacher educators have the potential to influence all future teachers, and through them, all future students, across all sectors of education. To this end, resources already exist with the UNESCO project, *Teaching and Learning for a sustainable future* (last updated in 2010). This program consists of around one hundred hours of self–study, organized in 27 modules. The professional development of teachers in EfS needs to be a shared responsibility, with a dual strategy of inclusion of EfS into teacher education programs along with the option of self–study driven by the teachers themselves (Robottom, 2013). Inclusion of sustainability as a cross–curriculum requirement for all schools is one strategy that will motivate teachers to learn about and develop their own expertise in EfS.

The form of EfS that is appropriate for higher education can be categorized as being either (1) curriculum and content, or (2) pedagogical practices. Much of the emphasis has been on the latter and it is suggested that more effort needs to go into the curriculum and content. With this in mind, the first theme that needs to be included into the HE curriculum is the imperative of living within the carrying capacities of the world's ecological systems. The implication of this fundamental change needs to be taken up in some way in each and every subject taught across HE.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Next there needs to be a clear conception of sustainability. Debates around Sustainable Development (SD) and sustainability have hampered political decision making. This field has a history of being everything to everyone and this cannot continue. This kind of ambiguity is unhelpful when trying to influence government, corporate and community policies and practices. Sustainability needs to be defined and understood as working through the needs of the environment, the economy and the social world, but these are not equally weighted: within a post–abundance framework the needs of the environment have primacy. Finally, the sustainability issues that are taken up within HE courses need to be customized to accommodate local and/or the most relevant issues and concerns to the subject area being studied.

Much of the emphasis of EfS has been placed on the pedagogical practices and those that are most appropriate for EfS in HE are those which logically align with the aims of sustainability. Principles for EfS have been stated in the Decade for Sustainable Development (DESD) and government documents. However, most of the principles can be argued as representing principles of good pedagogy rather than being specifically about EfS. Christie, Miller, Cooke and White (2013) explain that alternative pedagogies for EfS in HE focus on active, participatory, experiential learning; engage the head, the heart and the hands; involve interdisciplinary approaches; encourage holistic critical thinking; and include teaching "in place" by utilizing local knowledge and environments.

Transformative learning is commonly acknowledged throughout the EfS literature however it is argued here that most of these conceptualizations of transformative learning are about individual and personalized experiences of transformation. This is considered inadequate for the scope and scale of the change that is needed. While acknowledging that all change occurs one person at a time, social movements are a more efficient means for fostering change. An alternative conception of transformative learning that is potentially aligned to a social movement is tentatively suggested, though it is in its infancy and requires greater collaborative development. This alternative is a work in progress and for the most part develops out of the recent work of the sociologist E. O.Wright (2010).

SUSTAINABLE DEVELOPMENT AND SUSTAINABILITY: THE TERMS AND THE CONCEPTS

The assumption underpinning this section is that language is important and that terminology affects the way we understand a concept. Initially, made popular through United Nations processes and associated publications, sustainable development (SD) has not only come to mean different things over its years of use, but for many has become problematic and subsequently morphed into sustainability. Some see the two terms of sustainable development and sustainability as inter–changeable (Scott, Tilbury, Sharp & Deane, 2012), but for many others they represent very different positions (Sterling & Maxey, 2013). As flagged above, there is a debate that surrounds these definitions and terminology. Hopwood, Mellor and O'Brien (2005) conclude that "there is no such thing as a single unified philosophy of sustainable development" (p. 47). They explain that sustainable development becomes confusing when different people use the same words to mean a wide range of views and methods for moving towards sustainable development.

Vogt et al. (2010) explain that sustainable development has many different meanings. Nevertheless what the two terms have in common is that they combine concerns about the environment with those related to socio–economic issues. The emergence of sustainable development as a concept and a field of study, signifies a fundamental shift in the understanding of the relationship between humanity and

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

nature. This is seen as an advance on previous centuries when, guided by a mindset of abundance, nature and aspects of the ecological system were seen merely as resources to be used and exploited by humans.

In 1983, the UN General Assembly established the World Commission on Environment and Development (WCED) also known by the name of its Norwegian Chairperson, as the Brundtland Commission. This Commission was charged with addressing concerns about the accelerating deterioration of the human environment and natural resources and the consequences of the deterioration for economic and social development. Brundtland explains that the Commission was asked "to propose long–term environmental strategies for achieving sustainable development to the year 2000 and beyond" (Brundtland, 1987, p. ix). Sustainable development (SD) has been defined by the WCED Commission report, *Our common future*, as "development that meets the needs of the present without compromising the ability of future generations to meet their own needs" (Brundtland, 1987, p. 43). This definition laid the foundation for inclusiveness across the many and varied interests represented on the UN General Assembly. The definition has become iconic. But by remaining in place and by being referred back to, it also encourages and allows sustainable development to become "everything to everyone". Some nations can place their emphasis on "sustainable" while others can emphasize "development".

It is broadly acknowledged that the value of the World Commission on Environment and Development definition (Brundtland, 1987) was that politically it offered something to everyone. The issues of sustainable development are global as well as local and nation states can struggle to provide effective governance beyond their own borders, hence the importance of the United Nations (UN). The UN was established in part to look at just such cross–border and global issues. However the bar can be set quite low when it comes to reaching consensus around common denominators and acceptable middle ground through the processes of the UN. This is especially the case when the consensus involves representatives from such a diverse range of constituents, with an equally diverse range of interests. The WCED definition needs to be seen in this light. Politically, it constitutes the middle ground. It continues to be important and still offers something to most people. Accordingly, it has been instrumental in bringing people with different views to sit down at the negotiating table together.

Hansson (2010) argues that the importance of *Our common future* to late twentieth–century environmental policies cannot be overstated. He explains that it had a central position at the United Nations Conference on Environment and Development (UNCED) conference in Rio de Janeiro in 1992. It laid the foundations for many of the ideas that made their way into the Agenda 21 documents (UNCED, 1992). Many of these were subsequently adopted at that conference, but the issues and debates that it raised continued to run over into environmental politics for many years afterwards. Sustainable development has been represented pictorially as the three pillars, three interlinking rings and as the sustainability compass. The model of sustainable development that has been used extensively since the World Summit on Sustainable Development in Johannesburg in 2002 is the three pillars model of sustainable development. This is depicted as three vertical columns, representing the environment, the economy and society. The columns support a horizontal beam that spans across the top of the three columns. The horizontal beam is labeled as representing sustainable development. The model of SD depicted as three interlinking rings is quite similar, in that each circle is labeled as representing the social, the economic and the environmental dimensions, with the compartment where all three intersect at once labeled as sustainability. The three rings are also said to represent the triple bottom line as explained by Elkington (1999). The criticisms leveled at these two models are that they show each of the three contributing influences as equal. The model of the sustainability compass is another model that appears throughout the literature. In many ways it is an extension of these two previous models in that it introduces a fourth

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

domain into the mix, that of the political, to become: the political, the social, the natural and the economic. This is significant, as this inclusion of the political encourages readers to ask about the process of decision making and in particular, "who is making the decisions"?

UNESCO has further refined their definitions to state that "sustainable development is a vision of development that encompasses respect for all life—human and non–human—and natural resources, as well as integrating concerns such as poverty reduction, gender equality, human rights, education for all, health, human security and intercultural dialogue" (UNESCO, 2013). In this way sustainable development is said to now have four dimensions. These are society, environment, culture and economy (UNESCO, 2013). In contrast, the term sustainability is used in UN literature to reflect the longer–term goal of achieving "a more sustainable world" (UNESCO, 2013). More recently, some have brought these terms together to suggest that sustainability is the long–term goal, while sustainable development is the process or pathway for achieving it (Sterling, 2013, p. 2).

In very general terms, sustainability on its own is preferred by some to represent and acknowledge that growth and development may not provide the unrivalled strategy and appeal that it once did. In market capitalism, growth is argued as being a way to expand the economy with the intention that most will find employment and prosper. Further, the claim is made that a trickle–down effect will ensure that living conditions improve. The trickle down argument is presented as utilitarian in that it explains that this is the way to provide the most good and improvement for the most number of people. It is also happens to be a very effective way of increasing scale, turnover and subsequent profits.

Baer (2012) presents a compelling critique of this argument. Initially he draws on the eleven propositions that are used by Wright (2010) to show the contradictions within the capitalist world system. He argues that global capitalism is based on the treadmill of production and consumption leading to profit making. Such a system has a need for continuous economic expansion and to this point has been based on the use of fossil fuels. Baer (2012) argues that capitalism is at loggerheads with environmental sustainability and the causes of climate change. Instead he argues for a democratic eco–socialist world system to be built on two principles, social equity and justice, and environmental sustainability.

Joining together the terms sustainable and development as "sustainable development", is considered to represent a softer version of sustainability. This is a version that places less emphasis on sustaining the resources drawn and used from the planet's ecological systems. The concept of sustainable development originally emanated from the coalition of interests of those from Less Developing Countries (LDCs), where development is still considered a much desired and necessary goal. As noted in the WCED report, for developing countries to reach the same outputs from manufacturing as exists in westernized countries, then they need to increase their outputs by a factor of between five and ten times. Importantly, the notion of western countries reducing their outputs is not as often discussed (Farley & Smith, 2014).

At the center of this ongoing debate are challenges about the environment and equity. The key features and ideas about the environment emphasize sustainability of ecological resources, limits to growth, and the idea of the carrying capacity of these resources to sustain a growing global population (Meadows, Randers & Meadows, 2004). While the WCED saw resources from an anthropocentric position, that is, resources serving the needs of humans, with the ability to substitute resources through the use of technology, still others emphasize more systemic differences around conservation or preservation. Alongside equity, the key features in the debates concern poverty reduction, food and water security, access to healthcare and general wellbeing. Burgmann and Baer (2012) in their description of the climate justice movement, explain that the effects of environmental degradation are not shared out evenly. They discuss how some of the poorest people appear to be hardest hit by climate change, hence the call for climate justice.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Hopwood, Mellor and O'Brien (2005) have identified and mapped three distinct versions of sustainable development. On the vertical axis they plot changes in socio–economic, wellbeing and equality concerns, starting from inequality and moving up to a position of full equality. The horizontal axis covers the priority of the environment from its beginning with no environmental concerns through techno–centered in the middle, up to eco–centered at the maximum. Next, these authors plot various reports, organizations, along with some different social movements by giving them positions on how they see these in relation to the coverage of the two axes. Some of these items are seen as taking up extreme positions; for example, neo–liberal economists are located at the intersection of the origins of the axis, where inequality and virtually no environmental concerns intersect. In contrast, deep ecologists are located at the high end of the environmental concerns but with low socio–economic wellbeing and equality concerns; socialist cornucopia are placed high on equality but with very low environmental concerns. This research by Hopwood et al. (2005) determines and locates many of these extreme positions as being outside the mainstream debate on sustainable development.

Hopwood et al. (2005) distinguish between three forms of sustainable development as ranging from "status quo", to "reform" and through to "transformation". Those in the status quo band aspire to a belief in "business as usual" and that sustainable development can be achieved within existing structures. They believe that adjustments can be made without fundamental change to society, the processes for decision–making or existing power relations. Development will occur through growth and growth will lift people out of hunger and poverty. This view entails the belief that business, private ownership of resources and markets, providing there is only minimal regulation, shall prevail. Reduction in the role of governments, sympathy for cuts in social wages, change to taxation and support for privatization are commonly stated. This viewpoint has a weak commitment to environmental sustainability, low concern for both poverty reduction and lack of equity in political power. The "business as usual" form of sustainable development reflects the abundance mindset.

Reformist models occupy the next rung up and are explained as recognizing that there are mounting problems with the environment and equity. Reformists are critical of current policies of government and business. They see the "business as usual" approach as contributing to increasing inequality, poverty, environmental degradation and world instability. They generally support capitalism but want the government to regulate market processes and provide balance. Green economists argue that the market needs modification to redress market failure and regulation to achieve ecological sustainability. The *Limits to growth* report (Meadows, Meadows, Randers & Brehren, 1972) tackled the promotion of growth head on but Brundtland rejected this notion of environmental limits in the WCED report. *Limits to growth* is seen as being strongly reformist while the WCED report is located by Hopwood et al. (2005) on the cusp between status quo (business as usual) and reform.

Those who subscribe to the transformative approaches to sustainable development see mounting problems, and believe these to be a fundamental feature of contemporary society. They see potential crises and collapse of society as possible. These are caused by the economic and power structures of society because these structures have not been set up to foster human wellbeing or environmental sustainability. This approach has a strong commitment to social equity with a view that access to livelihood, good health, resources and economic and political decision–making are connected (Hopwood et al., 2005). This perspective contains a loose coalition of eco–feminists, campaigners for anti–capitalism, anti–globalization and those working towards environmental justice. Environmental justice is aimed at social transformation that meets human needs, enhancing quality of life, economic equality, health care,

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

human rights, species preservation and democracy. Bringing about such changes is considered to need major restructuring or even entirely different social orders.

EDUCATION FOR CHANGE AND EDUCATION FOR SUSTAINABILITY (EfS)

The notion of "education for sustainable development" (ESD) brings together two areas that have substantial histories with the United Nations (UN), education and sustainable development. As stated in the UNESCO (1997) publication *Educating for a sustainable future* (para. 103),

… achieving sustainability will depend ultimately on changes in behavior and lifestyles, changes which will need to be motivated by a shift in values and rooted in the cultural and moral precepts upon which behavior is predicated. Without change of this kind, even the most enlightened legislation, the cleanest technology, the most sophisticated research will not succeed in steering society towards the long–term goal of sustainability. Education in the broadest sense will by necessity play a pivotal role in bringing about the deep change required, in both tangible and intangible ways.

There are four major thrusts that support ESD and EfS which have their origins in the Agenda 21 document borne out of the UNCED conference in Rio in 1992, (UNCED, 1992). These are, to improve access to high quality education; re–orientate existing education programs; develop public understanding and awareness, and provide training. All of which remain present in most ESD and EfS initiatives. Some general principles and ideals that underpin ESD and EfS are articulated in the UNESCO (2005a) implementation document, namely, intergenerational equity, gender equity, social tolerance, poverty alleviation, environmental protection and restoration, natural resource conservation and just and peaceful societies.

In 2002, at the World Summit on Sustainable Development at Johannesburg, the United Nations adopted a resolution to designate 2005–2014 to be the Decade of Education for Sustainable Development (DESD). This reinforces the view that education is the tool for shaping a more sustainable future. The overall goal for the DESD is to integrate the principles, values and practices of SD into all aspects of education and learning. The DESD approach attempts to change traditional educational approaches to become interdisciplinary and holistic, values–based, critically reflective, multimodal, to include participatory decision–making and focus on locally relevant information (Australian Research Institute for Environment and Sustainability [ARIES] 2009: 2). Much is made in the guiding literature of the need for ESD and EfS to have local relevance and be culturally specific. Subsequently, ESD and EfS take on many different forms in different places around the world.

The key and essential characteristics of ESD though are listed by UNESCO (2005a) as, (i) based on the principles and values that underpin sustainable development; (ii) dealing with the wellbeing of all three realms of sustainability – environment, society and economy; (iii) promoting life–long learning; (iv) locally relevant and culturally appropriate; (v) based on local needs, perceptions and conditions, but acknowledging that fulfilling local needs often has international effects and consequences; (vi) engaging formal, non–formal and informal education; (vii) accommodating the evolving nature and concept of sustainability; (viii) addressing content, taking into account context, global issues and local priorities; (ix) building civil capacity for community based decision making, social tolerance, environmental stewardship, adaptable workforce and quality of life; (x) interdisciplinary; (xi) using a variety of pedagogical techniques that promote participatory learning and higher–order thinking skills.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

It is again noted that these can take many forms when they are implemented around the world in a locally relevant and culturally appropriate manner. Each country or region has to develop its own specific understandings; likewise for the concept of "Education for Sustainability" (EfS).

A LOCAL ORIENTATION TO EDUCATION FOR SUSTAINABILITY (EfS)

The Australian government developed its overall strategy paper in response to the UN DESD which it titled *Caring for our future*, and released in 2007 (Department of Environment and Heritage, 2007). This policy framework identified six themes to underpin its subsequent work. These were, communicating the concepts; basing their approach on sound research; ensuring momentum; promoting a whole of government approach; building partnerships and monitoring and evaluation. These were followed up two years later with the release of the National Action Plan called *Living sustainably* (Department of Environment, Water, Heritage and Arts [DEWHA], 2009). This plan signals a conscious shift away from ESD to the clearer notion of Education for Sustainability (EfS). EfS is acknowledged as having its origins in the environmental education of the 1970s. While it began with developing an awareness of natural ecosystems and their degradation, it has since transitioned to become equipping all people with the knowledge, skills and understanding needed to make decisions based upon consideration of environmental, social and economic implications.

This Action Plan argues that EfS aims to tackle the underlying causes of "unsustainable trends", (DEWHA, 2009, p. 8). The form of education advocated is to raise awareness initially, but also to develop capacities that enable the learner to take action and implement real change – informed, thoughtful and strategic action. The principles for this approach to EfS are explained as: transformation and change; education for all and lifelong learning; systems thinking; envisioning a better future; critical thinking and reflection; participation and partnerships for change (p. 9). Provision of EfS has also grown, facilitated variously by government departments, educational institutions at all levels, industry bodies, community groups, zoos, botanical gardens, national parks and environmental education centers.

Strategy 2 of *Living sustainably* commits to "Reorienting education systems to sustainability". This strategy covers all levels of education as it states, "the Australian government is committed to using education as a critical resource to prepare Australia for the emerging social, economic and environmental challenges of the twenty–first century. A transformative approach to education is needed, involving whole of institution engagement, innovative teaching and learning and changes to curricula (DEWHA, 2009, p. 21). The second objective set out for achieving Strategy 2 states that action needs to be taken so that "Education for sustainability is integrated into all university courses/subject areas and campuses are managed in a sustainable way".

In Australia, like numerous other countries across the globe, sustainability issues have global significance but are nationally specific. They must be tackled by global and national institutions – and yet also have their manifestations at the level of communities and individuals. Of particular importance to the discussion in this chapter, and this section on EfS, is that the recent reports from the CSIRO (Hajcowicz, Cook & Littleboy, 2012); the National Sustainability Council (NSC, 2013), the Murray Darling Basin Authority (MDBA, 2012); ClimateWorks Australia (2013, 2010); and the Intergovernmental Panel on Climate Change (IPCC) (2013), all request that the community read their reports, discuss them and consider their implications. One might react by suggesting that even asking people to read these documents is very optimistic and it is highly unlikely to occur, yet it could equally be argued that this is the

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

responsibility dimension of being an active citizen living in a democracy. However, where better to have conversations on the ideas and issues being addressed in these reports than in our educational institutions and especially those dedicated to higher education. Somehow, somewhere the space must be found for consideration and discussion of these highly important twenty–first century issues.

THE THREE WAVES OF EfS IN HIGHER EDUCATION

Wals and Blewitt (2010) explain the three waves of EfS that have influenced higher education. The first wave is described as having its beginnings with the introduction of environmental education into universities in the 1970s and 80s. Courses such as Environmental Science were implemented, as were subjects like "Engineering and the environment". Students from across universities were given access to aspects of Environmental science and related issues. The issues were twentieth–century issues that had relevance to a broad range of citizens and professionals alike. In the main these subjects were about ethics, values and "education *about* sustainability".

The second wave of EfS they explain as when University administrators committed to environmental sustainability through such means as "The Talloires Declaration". This was a ten–point action plan for incorporating sustainability into teaching, research, operations and community connections. Alongside these and other early agreements came the greening of the campus initiatives that modeled energy saving and campus–based examples of ecological protection, conservation and preservation. The second wave extended EfS (EfS) beyond courses, to the university's management and through to their operations. Universities became very conscious of their ecological footprint and took to modeling energy saving, waste separation and recycling. On the curriculum and teaching side, the second wave also ushered in a different way of incorporating sustainability into teaching courses. Some argued for "a golden thread" of sustainability to run through all courses. Others started to make more use of immediate and local surroundings such as environmental walks, native flora and natural habitats. Sustainability became part of many existing courses.

The third wave of EfS is described as being a more integrated and holistic approach to EfS. The range of responses considered part of the third wave includes, universities signing the next generation of declarations; further greening and modelling of sustainability across the campuses and operations of the university; the introduction of aspects of sustainability into all courses; a change to the way that the teaching and learning occurs, (challenges to traditional university pedagogy to become more consistent or aligned with general principles of sustainability. These changes involved the introduction of more discussion, critical engagement and an increase in learner–centered learning); increased co–operation across the universities has also been advocated. This will encourage multi– and inter–disciplinary team approaches to research, and the development of community connections and partnerships.

At this stage in the development of sustainability, there has been a fundamental shift in attempting to ensure that the commitments that are made actually transpire into actions. One of the major problems and shortfalls with EfS has been the lack of impact in bringing about actual change. The UN Decade for Education for Sustainable Development (DESD) is drawing to a close. There has been ten years of concentrated effort and yet there still remains a chasm between what has been achieved, and what remains to be done (Sterling, 2013; Tilbury, 2013; UNESCO, 2005b).

Some argue that universities need to be fundamentally changed in order to align truly with the provision of higher education and sustainability. Tilbury (2013) has called for "a global rebooting of higher

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

education", and other calls for transformation are common (Sterling, 2013). Brookfield (2013) a leading academic in adult education, in his discussion of transformation with respect to education and learning, explains that "transformation" is a very large word that promises a great deal. For some working in higher education, though, calls for transformation appear to overstep the mark. Universities are steeped in tradition, they are often organized around disciplines and can therefore be notoriously difficult to change. Others are adopting sustainability across the board as part of recognizing the rationality of arguments for the need to change. Clearly there is a range of responses across the various universities with regard to their degree of buy–in and take–up of EfS. For some universities the rationality angle of sustainability is imperative enough, while others are adopting sustainability as part of marketing strategies as they try to appeal to the young adult population who are potential and prospective students. The range of responses and ways of engaging with EfS within higher education are very usefully categorized through the three models of sustainable development explained by Hopwood et al. (2005) as "business as usual", reformist and transformative.

TRANSFORMATION AND EfS IN HIGHER EDUCATION

Transformative education can mean many things, as can transformative learning (Boyd & Meyers, 1988; Cranton, 1994; Cranton & Taylor 2013; Freire, 1970; Mezirow, 2012; O'Sullivan, 1999; Shor 1996). I now turn my attention to the notion of transformative learning as it applies to EfS in the context of higher education. Originally explained by Mezirow in the 1970s, transformative learning has been the subject of ongoing development and debate ever since. Mezirow's version of transformative learning is tied to critical social theory and the ideas expressed by Habermas. Mezirow's ten step model (2012) begins with the learner experiencing "a disorientating dilemma". Learners find this experience to be very confronting and one where the learner is unable to assimilate with existing understandings. Hence new frames of reference are needed and these are developed to accommodate the new experiences. This development of a new frame of reference is the transformative dimension of this form of learning.

The initiation of transformative learning by a disorientating dilemma makes this a very powerful experience. Though it is learning that is often based on experience of a unique significant event. Yet clearly, there is an ethical issue associated with educators initiating and/or facilitating disorientating dilemmas. Some adult educators consider it difficult to consciously facilitate transformative learning through a designated program or course of study. This need for learners to experience a powerful personal dilemma makes transformative learning in any educational setting highly problematic. While often cited, Mezirow's model is not the only form of transformative learning (Taylor & Cranton, 2013).

Most models of transformative learning can be criticized for being aimed primarily at bringing about deep individual change, for while this can be an effective model for social transformation, an even more efficient model is one aimed at developing social movements. Social movements are based on collective actions, and collective action shares out the work required to bring about change. Recent work by Erik Olin Wright (2010) holds out promise in this regard but the project of appropriating and applying this work as a form of transformative learning remains a work in progress. This is not Wright's intention and remains a project to be undertaken by educators to develop such an approach. It is enough to say at this point that Wright locates his sociology within emancipatory social science and that his project of "Envisioning real utopias" is divided into three sections. The first provides a diagnosis and critique of

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

capitalism in late modernity. The second outlines and explains a range of alternatives as desired possibilities and exemplars, while the third section outlines a hybridized theory of transformation.

THE FOUNDATIONS OF THE FOURTH WAVE OF EfS IN HIGHER EDUCATION

At the top of the list in looking to transform the university, the staff and the learners, is the need for clarity about the key concepts being used in the discussions. These concepts cannot drive action if there is wide variance and discrepancies in what they mean. Scott et al (2012), in their report on *Turnaround Leadership for higher education institutions interested in developing their EfS* identify a need to "sharpen the focus and understanding of EfS as it applies in higher education". Meanwhile, Farley and Smith (2014) suggest that it seems like some of these key concepts and terms are being used to do too much. Time and effort spent clarifying the key concepts and how they relate to the context of universities will be effort well spent.

Farley and Smith (2014) make the point that the two key concepts of sustainable development and sustainability are not the same thing and should not be used inter–changeably. Sterling and Maxey (2013) explain how they see the differences: "sustainability is about securing economic viability, social coherence and ecological integrity at local to global scales – where these system conditions are seen as deeply co–dependent rather than as separate dynamics". One further definition is that suggested by Agyeman, Bullard and Evans (2003) in their work *Just sustainabilities*, when they venture further, and rather than presenting the three spheres as co–dependent, argue instead for the primacy of the environment and the importance of recognizing limits. They define sustainability as "the need to ensure a better life for all, now and into the future, in a just and equitable manner, while living within the limits of supporting ecosystems" (p.5). Sterling and Macey (2103) explain that "sustainable development is the journey towards these conditions" (p. 2).

Scott et al.'s (2012) basic premise for their notion of *Turnaround leadership for EfS in Higher education* is that universities are at a crossroads. They write that this is a turnaround moment where the traditional nineteenth–century didactic, fixed timetables, two–semester campus–based model of higher education is coming under increasing pressure. They point out that access to HE is broadening. HE is subject to funding cuts and student expectations are changing. There is an increasing use of ICT, and employers are looking for graduates who can manage change.

They place these changes alongside broader forces for change identified by Global University Network Innovation (GUNI), and list these as: the UN DESD and global efforts to integrate sustainability; the Rio +20 Conference in Brazil calling for universities to become models of best practice and transformation; the formal Higher Education Treaty commitment to transformational change (Higher Education Treaty Circle, 2012); and the UN establishment of a global network of Regional Centres for ESD. In Australia there is also the 2009 National Action Plan for EfS (DEWHA, 2009). Scott et al (2012) provide a summarizing comment that "higher education needs to transform itself if it is to assist societal transformation for a more sustainable future". Clearly, they are arguing that to be successful into the future, there needs to be a root and branch change of what universities do and how they do it.

Sterling (2004) argues that addressing sustainability requires a paradigm shift and the adoption of new and different epistemology. This new way of viewing knowledge refers to the need to always be cognizant of carrying capacities and limits to ecological systems. Such considerations will make some future strategies and actions possible and others, which have been popular in the past, will need to be

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

abandoned. Anderson (2009a, 2009b) argues for such a shift in the field of Technical and Vocational Education and Training, and calls for a re–orientating of TVET away from its location within what Giddens has called "productivism" (Giddens, 1994) to be instead conceptualized and contextualized by the notion of "ecologism".

Blewitt (2013) criticizes EfS in higher education when he states that EfS has become tainted through accepting the capitalist mode of production as a given. EfS educators have worked within the existing system. Ball (2012) argues that best practice in education is now naturally commodified, as it is bought and sold for profit. Blewitt (2013) is very blunt when he states corporatized higher education has been charged with producing obedient neoliberal subjects (Blewitt 2013). EfS educators have been working within parameters and understandings shaped by this approach to economics.

Giroux (2002), in his work on neoliberalism and higher education, argues that when left unchallenged neoliberalism respects few boundaries based on self–restraint and the public good and is unresponsive to broader human values that are central to democratic culture (p. 431). Neoliberal economics continues to see the effects of greenhouse gas emissions as an "externality". As a contextualizing ideology and discourse, neoliberalism gives EfS in higher education a specific conceptualization. It ensures that sustainability is about photos of Vice Chancellors and Deans signing agreements, having separate bins on campus for waste separation and doing far less about advancing equity and poverty reduction. It is envisaged that to be effective, HE educators involved in the fourth wave will need to break away from this hegemony.

Blewitt (2013, p. 58) suggests that, "although higher education may not yet be a totally unconstructed cheerleader for corporate capitalism the connection between knowledge and power, learning and economic needs of the private corporations has certainly been "refreshed". Further he brings his criticism back to sustainability educators when he writes, "sustainability educators are now confronted with a serious challenge, not least because as systems thinkers working within the capitalist system, compromise, accommodation and incorporation have become their means of survival" (p. 61). But other means for contextualizing sustainability are possible – and need to be developed.

Farley and Smith (2013) argue that what is being promoted as sustainable development and sustainability represents a "faux" (false) sustainability. Instead, they argue for clarity and a reconceptualization where sustainability is about improving the social, economic and environmental conditions, not maintaining, or sustaining the damage being done. Further sustainability needs to operate within limits, with the environmental system being foundational.

To make themselves clear, Farley & Smith (2014) argue for "neo–sustainability" (or a new sustainability). Such a strategy signals the explicit choice to change direction. They define this simply as "the ability of an activity to sustain a system by improving its quality and operating within its limits" (p. 151). This is not a three pillars or a triple bottom line approach; rather, this is three concentric circles where the environment is the largest, and recognized as having primary importance. Next inside this are the social systems and then inside the social systems and dependant on the other two is the economic system. In addition they explain that neo–sustainability is based on three rules. There are natural limits to growth. The limits are dictated by the environment, and actions within any system must adhere to the carrying capacity of the earth's natural systems. As the environmental, social and economic are nested systems then actions must be based on systems thinking with multi–level and multi–domain impacts.

Transformation requires new thinking and new approaches to permeate into educational practices through the architecture and technology, to curriculum and pedagogical practices. Littledyke, Manolas and Littledyke (2013) conducted a study in three universities across three different countries. They

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

found that to achieve effective EfS, there needs to be an integrated systems model for coordinating EfS which encourages distributed leadership to empower all university members to be active in sustainability practices. The system they suggest integrates structures, decision–making and governance; infrastructure and sustainable practices; and learning about and experiencing sustainability through the curriculum.

Cotton and Winter (2010) conducted small–scale surveys of educators in higher education and asked them about teaching and learning for EfS. They concluded that educators align EfS with active and participatory learning processes. They found that role plays and simulations, group discussions, stimulus activities such as initiating a discussion based on a video or newspaper clipping, debates, critical incidents, case studies, reflexive accounts, critical reading and writing, problem–based learning, fieldwork and outdoor learning and modeling of good practice were identified as active learning techniques (Cotton & Winter, 2010). Similar findings appear in the review conducted by Tilbury (2011). These pedagogical practices align with the components of EfS, such as visioning a better future, critical thinking and reflection, participation partnerships and systemic thinking, as listed in the Australian government funded guides to EfS (Australian Research Institute for Environment and Sustainability, 2009). For Thomas (2009), "the development of thinking is the critical element in education related to sustainability" (p. 246). He places thinking at the center of achieving transformative learning through the implementation of problem–based learning. There are many good case studies and exemplars of good practice in the literature demonstrating how EfS involves more active and participatory learning, encourages critical inquiry and discussion, is interdisciplinary and supports the students in exploring value positions. There is also strong research evidence to the contrary – that shows that the pedagogical practices associated with EfS may be less commonly implemented than what might be thought.

A study by Christie, Miller, Cooke and White (2013) starts with a review of literature and acknowledges that alternative pedagogies for EfS focus on active, participatory, experiential learning, engaging head, heart and hands, interdisciplinary approaches, holistic critical thinking and teaching "in place" by utilizing local environments. Teachers are considered facilitators rather than directors. The teaching and learning processes are explained as being more open and democratic. In their study, these researchers received responses to their questionnaire from 1819 academics or 6 per cent of the entire academic workforce from across Australian universities. The majority of respondents from non–environmental disciplines (71.9%, n= 701) indicated that they did not teach EfS "at all". While there were some differences across the range of disciplines the majority indicated that they did not teach EfS "at all" (71.3% – 78.9%). Where respondents did say they taught EfS they indicated that it was through "passing comments" or "just a few times across the semester". For those who taught EfS, second, following the use of passing comments, the most used method was through the use of critical thinking which they reported as doing only a few times throughout the semester. Discussions and case studies were the third and fourth most used teaching methods associated with EfS.

The view of lectures as a didactic, one–way transmission and a boring way to learn was not a view shared by Australian academics, with most explaining that they used interactive lecture formats dispersing a mix of questions and brief response exercises within the lecture. These researchers concluded from their study that academics rarely employed teaching methods that are based on the interactive and student–led pedagogies which have been advocated for EfS within the literature, such as problem–based learning and place–based education" (p. 403). Interestingly, respondents reported using the same teaching methods when they taught EfS as when they were not. This study establishes that distinctive EfS pedagogies are not being practiced by Australian academics (Christie et al., 2013, p. 403) and that EfS is not yet being widely practiced in university classrooms across the disciplines (Christie et al., 2013. P. 405).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

From this study it is clear that the pedagogies for EfS are not yet happening at the level of the teaching and the learning and therefore as educators we are not yet where we need to be. This is "business as usual" and a long way off matching the big ideals of transformative education and transformative learning. As Leihy and Salazar (2011) argue "each university will produce its own kind of EfS, there is not a one–size–fits–all formula for all university settings" (p.vi). They note that all institutions will need to invest in academic development to meet their commitments to EfS. Consequently, for EfS to reach its much–needed potential, much more effort must go into educating the HE educators.

CONCLUSION

EfS is a strategy that has been initiated to bring about much needed change. It is the use of education to challenge and facilitate movement from practices and behaviors associated with a mindset of abundance to those associated with post–abundance. It is about developing the appropriate knowledge and understanding but it also about doing things differently. A Decade of Education for Sustainable Development has been used to re–orientate systems of education to sustainability. The DESD has also supported a third wave of EfS in higher education and, along with its own achievements, this work has made what needs to be done next that much clearer. Higher education is thought to be experiencing particular pressures to change – potentially "a turnaround moment". The strategies of the fourth wave need to take up this turnaround moment. This involves basing EfS on a tighter understanding of sustainability based on what Farley and Smith (2014) call "neo–sustainability" and the three nested circles that give primacy to the environment. The focus on educating the HE educators needs to occur and EfS needs to be part of each and every HE educator's job. There is a need to continue to develop curriculum and content. This should involve a range of global issues along with local customization, and a range of contemporary reports should be utilized for inclusion creatively and where appropriate, as course content.

Consideration of the pedagogical practices aligned with EfS may even need to involve rethinking the architecture of the HE teaching spaces. However there appears to be a discrepancy in the research findings. Reports of good practice and successful exemplars being presented as case studies (Bartlett & Chase, 2013; Jones, Selby & Sterling, 2010) are at loggerheads with findings from a large scale Australian study of HE. The research by Christie et al (2013) provides contrast to the international case studies, where the Australian academics were found to use the same teaching methods with minimal active learning and participation, whether they were teaching EfS or not. In regard to EfS, this signals that there is much still left to do.

KEY TERMS AND DEFINITIONS

Education for Sustainability (EfS): Education that is aimed at bringing about sustainability through developing the knowledge, skills and understanding needed to make decisions based upon consideration of environmental, social and economic implications.

Education for Sustainable Development (ESD): The initial program of education aimed at bringing about sustainable development.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Neo-Sustainability: A new conceptualization of sustainability that encapsulates the embedded model of sustainability that privileges and sees the environment as primary. This is defined as the ability of an activity to sustain a system by improving its quality and operating within its limits.

Sustainability: The need to ensure a better life for all, now and into the future, in a just and equitable manner while living within the limits of the supporting ecosystems.

The Decade of Education for Sustainable Development (DESD): The decade from 2005 - 2014 was designated by the United Nations at the 2002 World Summit on Sustainable Development at Johannesburg as 'the decade of education for sustainable development'.

Chapter 53
Environmental and Economic Impacts of Wave Energy:
Some Public Policy Recommendations for Implementation in Turkey

Sevda Akar
Bandırma Onyedi Eylul University, Turkey

Dilek Akbaş Akdoğan
Marmara University, Turkey

ABSTRACT

The wave energy is one of the most important renewable energy sources and it has many advantages compared to other renewable energies. First, it is more reliable. Second, the cost of wave energy is competitive with other sources when it is used as a primary power source. Third, its energy density and deployment potential are higher than the wind and solar energy. Fourth, the wave energy has minor negative environmental impacts and production amount of the wave energy is more predictable. In the study, the applications of wave energy production are discussed in European Union countries in which have started to operate wave energy, recently. It is also tried to evaluate the feasibility of wave energy production opportunities in Turkey. As a result of the study, it can be said that the Black Sea has the highest wave energy potential in Turkey. Industrial production of wave energy actualized by fiscal incentives and this may lead to many social benefits such as increasing employment, reducing external dependency and diminishing greenhouse gases emission.

INTRODUCTION

The fossil fuels were used as the main energy source in many countries after the industrial revolution because they are affordable and easily accessible. The issues of global warming and climate change came to the fore and the harmful environmental effects of fossil fuels have begun to be discuss in most countries. In this context, countries have tended to use less environmentally damaging resources to

reduce greenhouse gas emissions. Renewable energy sources such as solar, wind, geothermal, biomass, wave and tidal energy are defined as energy that comes from resources that are naturally replenished.

Wave energy is unlimited, clean, and environmentally friendly. Moreover, it does not destroy favorable agricultural areas. Hence, many countries are interested in it. Also, wave energy has reduced dependence on foreign energy sources. This kind of energy is new and has a growing importance in other renewable energy sources. The wave energy has many advantages compared to other renewable energy sources. For example, electricity power extraction from wave energy is continuous 90% of the day, but that ratio is 20% for the wind energy and 30% for the solar energy.

In Turkey, there is no industrial electricity generation from wave energy. Due to geographical location, Turkey has high wave energy potential. There is less study about the wave energy resources in Turkey in the literature. This study is expected to contribute to the literature by discussing the issue of electricity generation from wave energy in Turkey.

The study is organized as follows. In the first section, renewable energy sources are defined and wave energy is presented. Besides, wave energy has been compared with other energy sources and the cost of wave energy is clarified. In the second section, the environmental and economic impacts of wave energy are discussed and the problems of externalities are investigated. In the third section, the situation of wave energy is unfolded in the European Union (EU) member states. In the fourth section, the status of wave energy and wave energy potential for Turkey are evaluated. The fiscal policy recommendations for implementation of wave energy in Turkey are also noted. The study is completed with a conclusion and recommendations.

THE RISING TREND OF RENEWABLE ENERGY RESOURCES: WAVE ENERGY

Climate change is one of the great challenges of the 21st century. The United Nations Framework Convention on Climate Change (UNFCCC) define *climate change* as "a change of climate which is attributed directly or indirectly to human activity that alters the composition of the global atmosphere and which is in addition to natural climate variability observed over comparable time periods". It is obvious that "a low-carbon energy revolution" (IEA, 2009, p. 45) is required in an effort to achieve climate change mitigation. Increased gas emissions accelerated after the Second World War has started to change the Earth's climate. The environment has been exposed to negative impacts due to exploiting of industrialized countries' insatiably and welfare increase and use of the resources has increased among developed and developing countries (Chichilnisky, 1997, p. 467).

World energy consumption has been rapidly increasing and it is estimated to rise considerably over the next decades. It is known that fossil fuel resources have a fundamental role in meeting rising energy demands across the globe. It is further known that fossil fuels are shown to be contributing to the global climate change so virulently. Global climate change and energy security concerns constitute two central issues in today's world energy policies.

The International Energy Agency define renewable energy as "the energy derived from natural processes that are replenished at a faster rate than they are consumed" and clarifies geothermal, hydropower, bioenergy, solar photovoltaic, solar power and wind and marine (tide and wave) energy as renewable (IEA, 2015, p. 2). However solar, wind and wave energy and other renewable energy sources are replenished and not exhausted. As they constantly renew themselves, destocking cannot happen.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

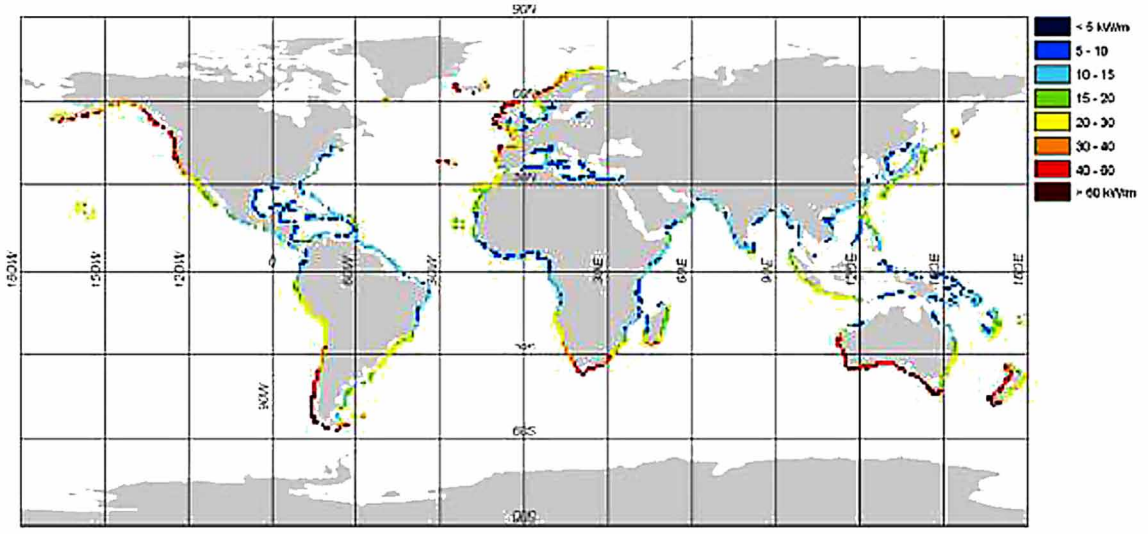
Renewable energy is shown as a shining solution to the problems of climate change and energy security. Renewable energy sources can make a contribution to economic and social development, to energy access and to a sustainable energy supply and can help reduce the negative impacts of energy provision on the environment and human health. Renewable energy can play a significant role in meeting energy requirements in a local and industrial level to reach sustainable development. According to Karaca and Erdoğdu (2012), renewable energy resources have great energy potential for regional and rural development through creating employment opportunities and strengthening domestic industry. Renewable energy sources have less or negligible environmental impacts and they offer a variety of energy sources with more flexible options for usage when compared with energy sources. Renewable energy sources new economic opportunities can help create and provide energy access to billions of people still living without modern energy services.

Comparison to Other Renewable Energies: Why Wave Energy?

Generating energy from waves has been an attractive research area for many years. The idea of converting energy of ocean surface waves into useful energy forms is not new; nowadays, as the negative effects of fossil fuels increase and fear of extinction of fossil fuels also increases and, accordingly, external dependency problem of economies becomes more critical, it has led to increased interest in renewable energy sources in wave energy.

Ocean energy is new compared with other renewable energy sources.IEA (2015) specifies five different ocean energy technologies under development aimed to extract energy from the oceans: tidal power, tidal (marine) currents, wave power, temperature gradients and salinity gradients. The most common energy originated from the ocean energy is wave and tidal.

MacKay (2009) declared that "sun makes wind and wind makes waves". Most of the sunlight hits the surface of the Earth and it warms the oceans. The warmed water warms the air above and then generates water vapor. As warm air rises, cooler air moves in to fill the void. In fact, wind is second-hand solar energy. As wind rushes across open water, it generates waves. Thereby, waves are third-hand solar energy.



When wind blows across the sea surface, it transfers energy to the waves. This energy transfer provides a convenient and natural concentration of wind energy in the water near the free surface. Created waves can travel thousands of kilometers with little energy loss. The energy fluxes occurring in deep sea waves can be very large. The power of a wave is proportional to the square of the amplitude and to the period of the motion (Clement *et al*., 2002, p. 408).

Wave energy is found in nature just like other renewable energy sources. It is sustainable and, on the contrary, fossil fuels do not emit greenhouse gases. Thereby, it is "clean" energy sources. Wave power offers the form of ocean energy with the highest deployment potential in European waters, which is related to a global potential 30 times higher than tidal energy (Magagna & Uihlein, 2015, p. 31).

World Energy Outlook (2012) states that electricity generating marine energy, including wave and tidal power, is expected to increase to 60 TWh in 2035 (IEA, 2012, p. 230).Wave energy power is enormous and more reliable than other renewable resources such as solar and wind energy because its density 2–3 kW/m^{2}is greater the wind 0.4–0.6 kW/m^2 and the solar 0.1– 0.2 kW/m^2 (Lopezandreu *et al.,* 2013, p. 414).Global wave energy resources are estimated at 17 TW h/year (Lund, 2007, p. 920).Annual net wave power worldwide is shown in Figure 1.

**For a more accurate representation see the electronic version.*

According to Figure 1, the largest power levels occur on the western coasts. In Europe, the largest waves occur in Scotland and Ireland. In America, the largest waves occur in Oregon, British Columbia and Alaska; in the Southern Hemisphere, it is Chile, South Africa, Australia and New Zealand.

Vining and Muetze (2009) suggested there is about 8000–80,000 TWh/yr or 1–10 TW of wave energy in the oceans; thus, it provides more available energy sources per square meter than either wind or solar energy. Table 1 shows the capital cost comparison with renewable energy sources. According to Table 1, wave energy comes after wind and solar energy.

Table 2 illustrates the operating cost comparison with power sources, respectively. Table 2 clarifies that wave energy has costs comparable with the other energy sources. As a result, the cost of wave energy is competitive with other sources when it is used as a primary power source.

Levelized electricity costs for electricity generation by renewable and nonrenewable technologies are shown in Table 3. Marine resources consist of tidal streams and wave technology. In this group, wave energy is less costly than tidal energy. Further, wave energy may compete with other energy sources.

Wave energy offers significant benefits over other renewable energy sources. These are (Fadaeenejad *et al.,* 2014, p. 346):

Table 1. Capital cost comparison with renewable energy sources

Energy Source	Cost as Primary Source (100MW)	Cost as Secondary Source (1MW)
Coal Plants	1,500-3,500	-
Fuel Cells	-	5,000
Wind/Solar	4,000	8,000
Wave	2,300	6,200

Note: Capital costs decrease moderately with technical process. It may be offset by an increase in the real price of fossil fuels. So its expected future costs are not known exactly.

- Wave energy has the highest energy density;
- Wave energy has minor negative environmental impacts;
- Wave energy is predictable;
- Wave energy satisfies electricity demand changes;
- Electricity power extraction from wave energy is continuous 90% of the day, but that ratio is 20% and 30% for wind and solar energy.

Wave Energy Converter (WEC) Technologies and Their Classification

Recently, increasing demand for energy has inspired acceleration for the development of wave energy around the world, which will lead to further development of wave energy converters (WECs) or wave farms. In the wave energy generating systems, there is a mechanism that changes the motion of the water into electricity (Copping *et al.,* 2014, p. 5).

WECs are different from wind turbines. An offshore wind farm's capital expenditure spent on electrical infrastructure is between 20% and 25%. Thus, the ratio is expected to be the same with wave energy. It may have various peaks in the average ratio in the same area. Thus, WECs must tackle resources with a high peak-to-average ratio. For instance, if WEC has a rating of 1MW and a capacity factor of 30%, the average annual output would be 300 kW. If the same WEC had the same average annual output but a capacity factor of 10%, WEC would have a peak rating of 3 MW (Sharkey *et al.,* 2013, p. 58).

According to Lok *et al.* (2014) despite irregular waves, WEC's average energy power output is predicted within 11%. In this study, irregular waves are defined as frequencies less than 3 hz and wave heights bigger than 30mm.

Allan *et al.,*(2011)claimed that the levelized costs of wave generation are £190/MWh. Trust (2006) found that the long-term learning rate in cost of energy for wave energy converters is possibly between 10% and 15%. Wave technology construction cost means first production models of between £1700/kW and £4300/kW. Furthermore, they estimated that £3622/kW for wave lines. They also suggested component costs for wave generation in the United Kingdom (Table 4), along with costs used for 1 MW wave generation.

Astariz & Iglesias (2015) submitted that the costs of wave energy (especially offshore wave energy farms) are divided into five categories. The main costs and rate in a wave energy plant areas follows: preparation costs about 0.26%; initial investment about 34.68%; replacement costs 24.81%; operations and maintenance costs about 40.19% and decommissioning costs about 0.07%.Yumurtacı & Bekiroğlu (2005) claimed that the installation cost of wave energy is about 1200–2000 $/kW, the unit energy cost range of wave energy is 2.70–3.60 cent/kwh and the yield of wave energy is 91%.

Table 4. Component costs used for 1 MW wave generation

	Total (£000s)	**%**

THE ENVIRONMENTAL AND ECONOMIC IMPACTS OF WAVE ENERGY: THE ISSUE OF EXTERNALITIES

This part of the study will examine the environmental and economic impacts of wave energy. Also, the issue of externalities in wave energy technology is evaluated.

Environmental Impacts of Wave Energy

Water is the most concentrated source of renewable energy on Earth. Wave energy is a type of solar energy. Wave energy has many advantages: stable resource, predictability, low visual impact and no fuel input or carbon emissions or price volatility (Klure, 2007, p. 5).

WECs practices are limited; for this reason, its effects on habitats is not known exactly. So, the installation site must be chosen carefully; otherwise, it may affect fishing and other uses of the sea. Langhamer et al. (2010) suggested that WECs environmental effects typically emerge in the five-year period after construction. Fridandoeni *et al.* (2011) claimed that WECs had only small direct impacts on the benthic community. All wet renewable energy devices represent a significant and clear resource and have potential to deliver low carbon energy.

According to Fadaeenejad *et al.* (2014) wave energy application in offshore islands would have positive impacts on the tourism industry because, in these islands, there would be successful sustainable development and maintain high-quality environment. The Electricity Innovation Institute (2004) also suggested that the sheltered water behind WECs may ensure attraction to some water sports: for instance, scuba diving and canoeing. Thus, WECs have important and positive impacts on recreation and tourism. When wave energy converters are established in the sea, the efficient agricultural area will not disappear. Also, Bedard (2007) claimed that, because of deployment, operations, maintenance and decommissioning, wave energy would be one of the most environmental-friendly electricity-generation technologies.

There are those who argue the negative impacts of wave energy. Copping *et al.* (2014) stated that the underwater sound from the installation and operation of wave energy converters (WECs) could harm marine animals. However, WECs would constitute approximately 3%–15% of incident wave energy. Thus, this decrease will cause wave shoaling and sediment transport (Leeney *et al.,* 2014, p. 14).

Wave energy has positive and negative environmental impacts. Table 5 summarizes the environmental impacts of wave energy devices.

Table 5. Environmental effects of WECs

The Type of Environmental Impact	The Rate of Impact
Land Use	Weak
Construction and Maintenance	Weak
Coastal Erosion	Weak or Medium
Fish	Weak
Noise	Weak

Source: Fadaeenejad et al. (2014).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Environmental impacts of wave power generation are similar in many ways to those of offshore wind power generation. These include (Gill, 2005, p. 611; Leeney *et al.,* 2014:, p. 14; Electricity Innovation Institute, 2004, p. 3; McMurray, 2007, p. 25):

- Ecological-based mitigation;
- Noise and visual appearences;
- Alteration of currents and waves;
- Coastal sedimentary interaction;
- Emission of electromagnetic field;
- Recreation and tourism.

Emissions Benefits of Wave Energy

In recent years, because of increasing emphasis on global climate change, governments have tended to reduce the emission of greenhouse gases. Thus, governments have begun to prefer renewable energy sources. Wave energy is considered as an alternative to wind energy.

Fossil fuels emit several pollutants linked to environmental problems such as acid rain, urban ozone and global climate change. Wave energy is represented by social benefits over traditional fossil fuel generation options. These social benefits of wave energy include (Bedard, 2007, p. 48):

- Providing a new, environmental friendly and easily assimilated grid;
- Avoiding plague so many infrastructure projects;
- Reducing dependence on imported energy supplies and the risk of future fossil fuel price volatility;
- Reducing emissions of greenhouse gases;
- Promoting local job creation and economic development.

Subsequently, wave energy devices do not produce gases harmful to environment when they operate electricity production. Wave energy technology could help to reduce the emission of these gases.

Economic and Socio Economic Impacts of Wave Energy

Bedard (2007) submitted that wave energy is an emerging technology; thus, its economic opportunities are important. The minor investment by governments could stimulate the energy industry to increase economic output and employment. Furthermore, compared with wind and solar energy, wave energy is potentially more easily assimilated into the grid. According to EPRI estimates, U.S. wave resource potential could be associated with 6.5% of 2004 U.S. national electricity energy demand (Bedard, 2007, p. 44).

Wave energy ensures substantial contribution to an affordable electricity price in the long run. A country's high dependence of fossil fuel imports leads to energy diversity. Thus, they have considered renewable energy sources such as wind, wave, etc. This also may increase domestic energy supplies. Among these renewable energies, wave energy increases demand for local added value. However, an economic least-cost option is an important market barrier for wave energy (Sorensen & Naef, 2008, p. 27).

Table 6 summarizes the drivers and barriers related to wave energy. Consequently, wave energy technology stimulates employment (especially, it ensures local job creation), economic development and output. Wave energy has a significant potential for positive economic impact and job creation. Based on

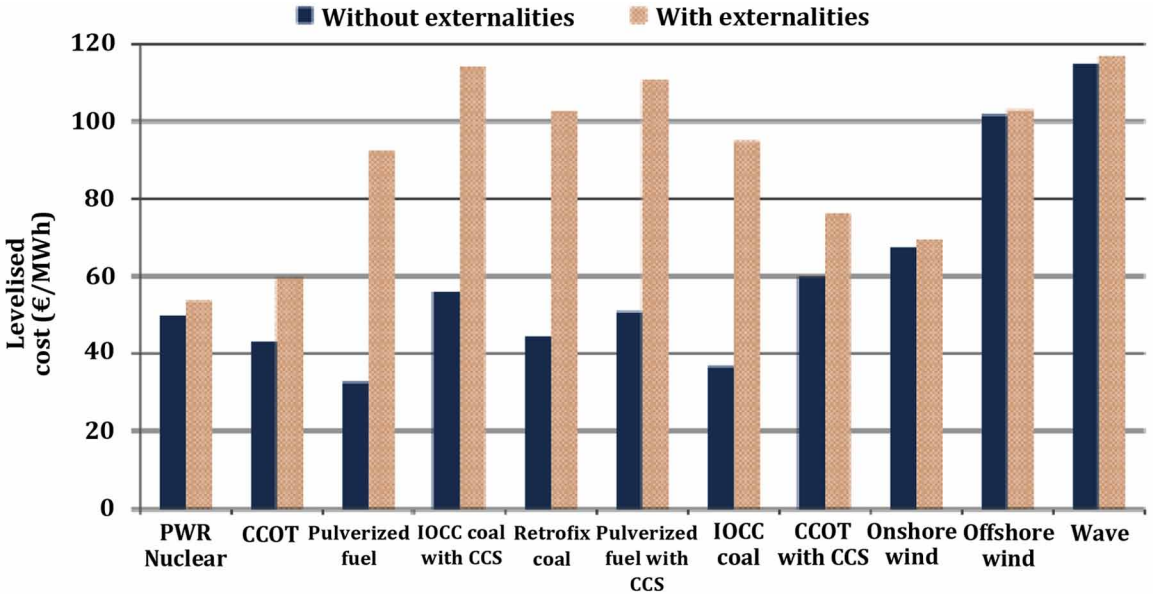
projections for installed capacity, by 2020, the wave energy sector will generate over 4000 jobs and, by 2050, these numbers will increase to 264,323 jobs (WAVEPLAM, 2010, p. 9).

Leeney *et al.* (2014) suggested that wave energy's potential impact on fisheries and fish habitats are evaluated within the socioeconomic category. The closing of a wave energy area may enhance fishing activities. It may provide fish breeding and growing. Thus, this could have spillover impacts onto other areas. These devices may help recuperate ethnic regions.



Accounting Some Externalities

Energy production has positive and negative impacts that must be considered in the total energy cost. This issue is known in the literature as externalities. Renewable energy sources have had a minor environmental impact due to minor externalities (Bedard, 2007, p. 48). In order to determine energy costs, externalities should be internalized. Therefore, the positive and negative impacts of energy production must be determined. For instance, carbon emissions in wave energy are estimated at about 6 gCO2/kWh, but the rate for conventional energy sources are about 250 gCO2/kWh. Thus, decline of 244 gCO2/kWh would be achieved by wave energy production. This should be included in the energy price of wave energy production. Furthermore, wave energy production supplies new jobs and these positive externalities should be considered separately. Figure 2 demonstrates the externalities in which technology is the most viable (Astariz & Iglesias, 2015, p. 7348).

Owen (2006) emphasized that the environmental externalities of energy production could be divided into two net costs categories:

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Levelized cost of different energy technologies including external costs
Source: Copyright from Astariz &Iglesias. (2015).

- Costs of the damage caused to health and environment by emissions of pollutants,
- Costs resulting from the impact of climate change. Thus, the argument of "polluter pays principle" would be to internalize as many of the externalities of energy generation in theory as possible (Owen, 2006, p. 636).

When considering wave energy installation, it also should be discussed with stakeholders. Potential negative externalities could be avoided or minimized (Bedard, 2007, p. 47).

WAVE ENERGY IN EUROPE: ITS GROWING ROLE IN RENEWABLE ENERGY POLICIES

The European Commission has identified the goal of a resilient Energy Union. A fundamental transformation of Europe's energy system will be required to achieve this goal. Renewable energy is essential to ensure this transformation. Moreover, it makes a contribution to all of the Energy Union's objectives: the delivery of security of supply, a transition to a sustainable energy system with reduced greenhouse gas emissions, industrial development leading to grow then jobs and lower energy costs for the EU economy (European Commission, 2015a, p. 2).

The Renewable Energy Directive adopted in 2009 establishes an overall policy for the production and promotion of energy from renewable sources in the European Union. It requires the EU to carry out at least 20% of its total energy needs with renewable energy by 2020. All EU countries also must guarantee that at least 10% of their transport fuels come from renewable sources by 2020 (European Commission, 2009, p. 1). The achievement of these 2020 targets cannot be met only with a single renewable source,

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

but a variety of renewable energy sources should be used simultaneously. Diversification of the energy mix is a major policy driver for renewables (IEA, 2015, p. 1).

The European Commission formed an initiative called Blue Growth to further benefit from the potential of oceans, seas and coasts. Blue Growth is the long-term strategy of the European Union. The aim of this strategy is to completely support sustainable growth in the marine and maritime sectors. Oceans and seas are drivers for the European economy and they have a great potential, which can be used productively for innovation and growth. Blue Growth focus areas are blue energy, aquaculture, maritime, coastal and cruise tourism, marine mineral resources and blue biotechnology (European Commission, 2015b, p. 1). EU's blue economy, including all economic sea-based activities, presents 5.4 million jobs and a gross added value of just under €500 billion per year. Seventy-five percent of Europe's external trade and 37% of trade within the EU is sea borne and most of (not all) this activity is intensive around Europe's coasts (European Commission, 2012, p. 3).

The European Union is considered for test sites for developed or partially funded wave energy by local governments. To promote wave energy development in the European Union, the Marine Renewable Commercialization Fund (MRCF) for Wave First Array Support Programme was founded. The fund was made available when wave energy Technologies would not have been able to supply the needs for UK MEAD (The United Kingdom Marine Energy Array Demonstrator) funding. The purpose of this schedule is to fund projects that should help wave energy technology to improve its commercialization (Magagna &Uihlein, 2015, p. 39).

European industry in the global ocean energy market is currently strong. Many EU member states have researched wave energy and a number have had wave energy devices in their waters. A great number of developers have invested in wave energy R&D and creating projects. Whereas more than 100 wave energy developers were declared in 2011, EMEC declared that, for the time being, there are 254 wave energy developers all around the world. About 45% of wave energy developers are presently based or are developing projects in the EU (EMEC, 2015, p. 1; Magagna & Uihlein, 2015, p. 36).

The most convenient zones to use wave energy technologies in Europe are across the Atlantic Arc, the stretch of coastline facing the Atlantic Ocean. Other areas also have potential for future developments, but they submit limited resources compared with the Atlantic Ocean. 10 countries have been chosen as high potential areas for the development of wave and tidal energy (marine) energy technology: the United Kingdom, France, Portugal, Ireland, Spain, Denmark and Norway. Some of the strongest currents the world over are found around Orkney, PentlandFirthand Anglesey in the United Kingdom (Magagna & Uihlein, 2014, p. 31; Corsatea & Magagna, 2013, p. 8). Another report prepared by the Marine Institute and Sustainable Energy Ireland expressed that "Europe's accessible wave power resource is calculated to be of the order of 320,000 MW with the highest resource available on Earth west of Ireland" (SEAI, 2005, p. 2).

Table 7 shows the estimation of total contribution expected from ocean, wave, tidal and offshore wind. These predictions reflect the 2020 targets of selected EU member countries.

Some EU member states have wave power installed capacity: for example, 4.3 MW in UK; 0.15 MW in Sweden; 0.25 in Denmark; and 0.7 MW in Portugal. Sweden has several developers of wave energy; one of them is Seabased, the world's largest wave energy plant, at about 10 MW. The first MW was enabled during 2013 and the remaining 9 MW during 2014.It has been considered that approximately 400 units will be deployed on the Swedish west coast. Commercial delivery is expected from 2015. At an estimated cost of energy of €5 cents per kWh, it will be commercially viable without any subsidies. The prototype of wave energy has been tested in Denmark. These prototypes are made up of 39 kW energy

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 7. Estimation of total contribution expected from ocean, wave, tidal and offshore wind to meet the 2020 targets (MW)

Member State	Source	2010	2013	2014	2015	2017	2020
France	Ocean, Wave, Tidal	240	271	287	302	333	380
	Offshore Wind	5542	8512	9572	2667	4000	6000

Source: O'Hagan et al. (2015).

power (Ernst& Young, 2013, p. 4). The United Kingdom is a global leader in wave energy and wave energy devices. In the United Kingdom, there were 31 WECs under development in 2007. In 2012, 14 wave devices totaling 3.6 MW were deployed for testing. Therefore, increasing the commercial visibility of the WECs needs to be commercially viable with financial subsidies (Lok *et al.,* 2014, p. 2). Ireland and Portugal aimed to achieve at least 500 MW energy from wave energy by 2020. Portugal wants to be a market leader in wave energy technology. Therefore, Portugal supports wave energy projects and has implemented tariffs and policies for this energy source (Dalton *et al.,* 2009, p. 4).

The United Kingdom has ensured revenue support with the renewable energy obligation credits method for wave energy industry. The renewable energy obligation credits price is nearly £0.045. In the United Kingdom, the incentives for wave energy are two renewable energy obligation credits on top of the market price (£0.09/kWh). However, Ireland has a program of tax relief of corporate investment for wave energy (Dalton *et al.,* 2009, p. 3). There was the Wave Hub Project, which was launched in 2010 off the northern coast of Cornwall in England. The Wave Hub Project is proposed to set up a wave farm demonstration and assessment site off the coast (Drew *et al.,* 2009, p. 892).

Wide scale wave energy technologies will be further developed and commercialized. Therefore, governments should give priority to national support programs and national innovation systems. On the other hand, firms that are related to wave energy may consider that foreign opportunities as an entrepreneurial strategy to overcome capital barriers. Companies do not only search for subsidies but also national innovation systems. Thus, policymakers should take an active stand to support the development of the wave energy industry (Løvdal & Neumann, 2011, p. 1094).

Vining and Muetze (2009) asserted that the most common incentives for wave energy are as follows;

- **Property Sales Tax Reduction:** These take part in indirect cash incentives. The property tax affects wave energy developers; thus, by reducing these taxes, wave energy can be promoted.
- **Project Loan Guarantees:** These incentives take part in low-cost debt financing incentives. They are an alternative to subsidized loans. This helps wave energy to obtain credit for financing.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Andor and Voss (2014) analyzed the optimal promotion instruments and policies for all the renewable energy. Furthermore, the optimal promotion schemes are the demand independent fixed feed in tariffs, which are popular in many countries. If positive externalities arise from the production and installation of wave energy capacity generation based instruments, then feed-in tariffs are suboptimal. Instead, the optimal promotion scheme for wave energy is a capacity subsidy. This subsidy is equivalent to the externality that would maximize welfare.

For example, early R&D activities in the wave energy sector of the past decade relied on significant private investment, with some grant support from EU institutions and member states. Governments have recognized that the wave energy sectors can be major players in meeting EU energy targets, security and jobs. Thus, the United Kingdom has revealed financial subsidies for public grants and private equity of technology push and market pull mechanisms such as feed-in tariffs. This has attracted significant investment in UK companies and test centers from across Europe. Ireland has put capital and revenue subsidy programs to develop wave energy market activities. In Ireland, this subsidy has generated the opportunity to secure grants from the European Commission's Horizon 2020 program. This subsidy mechanism has been assisting EU member states to set the appropriate tariffs to suit domestic aims, market conditions and progress on cost reduction for wave energy technology. These incentives have pulled down the cost curve without penalizing progress (SI Ocean, 2014, p. 19).

WAVE ENERGY STATUS AND OPPORTUNITIES IN TURKEY

There is no industrial electricity generation from wave energy in Turkey. But wave energy potential has a significant potential in renewable energy sources. Furthermore, wave energy is economical and is waiting for further evaluation. Therefore, generation of electricity from wave energy issues should be discussed. Few studies in the literature are related to wave energy in Turkey. Mostly, these studies discuss wave energy potential and identify the best areas for wave energy in Turkey. In this part of the study, we consider briefly the wave energy potential in Turkey. Then, we discuss public policy and incentives for wave energy.

In Turkey, especially in the Aegean Sea and the Mediterranean with the wind potential of about 4–17 kW/m annual average, sea waves are emerging as the most appropriate place for the production of wave energy. The best place between Izmir and Antalya region will benefit from wave energy. However, the area between Dalaman-Finike is suitable for the generation of electricity from wave energy; too. Regional average wave intensity in Turkey is shown in Table 8 (Sağlam & Uyar, 2005, p. 3; Alptekin, 2014, p. 22). According to Table 8, wave energy potential regions in Turkey are İzmir-Antalya, Aegean Sea, Mediterranean, Black Sea and Marmara.

The total coastline of Turkey is 8210 cm. In other words, it is assumed that one fifth of coastline can be used to obtain energy from sea waves. Thus, the wave energy technical potential is estimated to be 18.5 billion kWh, which is approximately 13% of Turkey energy needs. Thus, wave energy is higher than expected. Moreover, Uygur *et al.* (2004) assumed that, because of wave formation, the Black Sea region is the most fertile area. They also claim that earthquakes increase the average wave height and this situation makes a direct impact on wave power capacity.

Sağlam and Uyar (2005) suggested that only a small-scale wave converter can be producing approximately at least 10 TWh/year energy. This rate is between the annual 4–7 kW/m water wave power. This

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

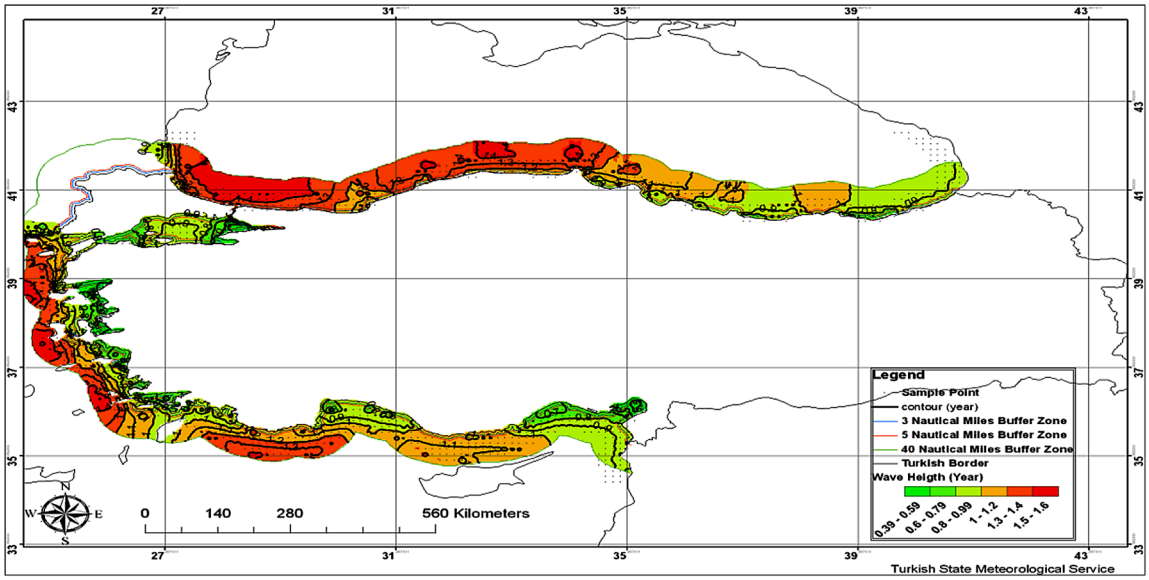
Table 8. Wave energy potential in Turkey

Region	Power
Black Sea	1,96-4,22 kWh/m
Marmara Sea	0,31-0,69 kWh/m
Aegean Sea	2,86-8,75 kWh/m
Mediterranean	2,59-8,26 kWh/m
İzmir-Antalya	3,91-12,05 kWh/m

Source: Sağlam and Uyar (2005).

is 12.5% of the hydropower potential of Turkey. Sağlam and Uyar (2005) also claim that Kalkan is the best area of wave energy; Kalkan has about 6.6–7.6 kW/m wave power density.

The best places conceived to generate wave energy are west of the Black Sea, north of Bosporus, southwest of the Aegean Sea and between Marmaris and Finike. These waters are considered to be suitable for initial experiments. Thus, investors should prefer these areas (Sağlam & Uyar, 2005, p. 4; Alptekin, 2014, p. 22). According to Özdamar (2000), the average wave power of Çeşme is changing between 7.16–39.66 kW/m. This rate is considerably higher than the average for the Çeşme. Additionally, the average wave power of the Black Sea would be expected to be higher than Çeşme (Örer *et al.,* 2003, p. 4).



Güngör (2013) assumed that 33% of the Mediterranean coastal strip (not suitable for tourism field) could produce electricity from wave electricity generation. This could supply 20% of electricity needs of the Mediterranean region. The platform, which will generate electricity from wave energy, should be built in the Tisan, Boğusak, Kumköy and Özlü regions. Such a wave energy platform may provide a contribution of around $200 million to the regional economy. With these systems, energy can be provided to consumers at 5 cents and when producing wave energy, the cost of energy can be calculated as follows: 3 cents for the repayment of the investment, 1 cent for the maintenance and costs and other 1 cent for profit. The cost of a 3 megawatt wave energy platform can be around $5.9 million.

With cooperation of the National Boron Research Institute (BOREN), the General Directorate of Turkish Electro mechanics Industry (TEMSAN) launched the Electricity Generation from Wave Energy project in 2008. This project carried out the design of a system that converts electrical energy to the movement of sea waves. Wave energy production system field test studies were performed in Karasu-Sakarya. It takes about 20 days at the end of the fieldwork. Eventually, 5 kWh electricity production per day had been successfully realized. If industrial production in the project of designing the wave energy systems is carried out, electricity demand in the residential area of Turkey's coast can be met by wave energy, which is a clean, limitless energy source and environmental friendly. Boron magnets, which are used in wave energy systems, will increase domestic boron consumption, thus adding value and creating employment opportunities which will contribute to the national economy (Press Release, www.boren.gov.tr).

Generation of electricity from wave energy for determining the Karasu district is shown in Figures 3 and 4, respectively. Figure 3 illustrates that annual period; the probabilities of occurrence in areas of wave height are at least 10%. Figure 4 shows the annual average wave height map. Figure 3 and 4 also state that the Black Sea is the best region for wave energy. In other words, Kırklareli, Istanbul, Kocaeli, Sakarya, Düzce, Zonguldak, Bartın, Kastamonuand Sinop are suitable for wave energy. Moreover, the coast of the Aegean Sea is suitable for electricity generation from wave energy.

Electricity generation from wave energy is not only for corporate alliances but also for individual initiatives in Turkey. For example, an engineer, Çoktan from Turkey, started a model working in "the Black Sea Ereğli" district in 2004. Çoktan appealed for support to his project. But, the project was ended due to financial problems (Çoktan, 2009, p. 1). Another engineer, Güneş from Turkey, created a domestic device to generate electricity from sea waves. He did his first work in the Akçakoca district in Turkey in 2011; he generated 1.5 kWh electricity. However, Güneş could not get support to increase the device's capacity (www.enerjienstitusu.com).

There is also the legal infrastructure related to renewable energy in Turkey. The 4628 Electricity Market Law was enacted in Turkey in 2001. This law generated two policies and precautions related to renewables. First, the law has reduced costs associated with reducing total license fees or the license for construction and renewable energy facilities are exempt from license fees for the first eight years following the completion date. Second, the Turkish Electricity Transmission Company (TEIAS) and distribution companies are required to give priority status for renewable facility system connections. Turkey has enacted its first special law on renewable energy in 2005 (Law Number 5346).

The Renewable Energy Law No 5346 regarding Renewable Energy Resources for the Generation of Electric Energy is dated 10 May 2005. In this law, renewable energy resources are defined and some incentives are introduced. Renewable energy resources are within the scope of this law. Electrical energy generation resources suitable for wind, solar, geothermal, biomass, biogas (including landfill gas), wave, current and tidal energy resources together with hydraulic generation plants either canal or run of river type or with a reservoir area of less than 15 square kilometers. The law is applicable for a period of 10 years for production licenses subject to the RES support mechanism that are or will be commissioned as from 18.5.2005 when this law was enacted, until 31.12.2015. The feed-in tariff is provided in the rate of prices specified in the schedule of the law for 10 years (Law Number 5346).

A feed-in tariff in Turkey has a relatively low rate and is given in a limited time when compared with other countries. Thus, investors have preferred not to invest or prefer to sell their products in the spot market. Changes made in the law (Law Number 5346) in 2010: tariffs have been differentiated according to the type of technology. Payment of premiums has been brought by law. This payment is for projects using domestic technology during the first five years (Acar *et al.,* 2015, p. 12-13). The incentives have been increased by the 5627 Energy Efficiency Law enacted in 2007 and by the changes in the 5784 Electricity Market Law in 2008. Finally, the 6446 Electricity Market Law and the Regulations for Licensing and Supporting of Renewable Energy Resources based on the 6446 Law were introduced in 2013.

Correspondingly, the EU directive in the field of renewable energy, the Renewable Energy Action Plan, has been prepared by the Republic of Turkey Ministry of Energy and Natural Resources: Renewable Energy General Directorate for the period of 2013–2023.As stated in this action plan, Turkey is aimed to meet at least 30% of total electricity demand with the renewable energy by 2023. It is planned that 10% of the requirements of the transportation sector will be met by renewable energy by 2023. Turkey aims to reduce by at least 20% energy intensity, namely, the amount of energy consumed per unit GDP in the year 2023 (MENR, 2014, p. 10).

Renewable energy investments are subsidized within the scope of the General Investment Incentive Plan. Exemption of value added tax and customs duty and income tax withholding supports are ensured providing investment should be in the district[2] (6th District) which would gain the highest support in Turkey. Financial support, including the licensing process and allocation and electricity purchase issues and other supports are prescribed for the purpose of development and facilitating operation of renewable

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

energy projects (Acar *et al.,* 2015, p. 13). But this subsidy should be extended to the districts that are appropriated for generating electricity from wave energy. Because, apart from the 6. district, all other districts include a county that is suitable for wave energy. Therefore, it should be applied as an exception to the wave energy subsidy in the General Investment Incentive Plan.

An annual license fee is charged according to installation power of facilities from the production facilities producing electricity in the scope of license regulations in Turkey. Energy production facilities from renewable sources are exempt from the license fee for the first eight years. In later years, they will pay 10% of specified value (Eser & Polat, 2015, p. 219).In addition, while license applications are assessed, applications of the facilities making production from renewable resources have been given priority by the (EMRA, 2013, p.5346 article 6/C).In other respects, renewable energy production facilities that have installed power under the 500 kWh have no obligation to obtain a license and establish a company. However, facilities can buy and sell their products with the support of the feed-in tariff to the energy distribution companies (Delolite, 2011, p. 27).

Wave energy is solely mentioned as a type of renewable resource. In the laws and regulations about electricity production from renewable energy, currently there are no licensed operations in Turkey that generate electricity from wave energy. But, according to Figures 3 and 4, industrial production of wave energy can be carried out in Turkey. Turkey has great potential and the work of obtaining electricity from wave energy in Turkey has gained momentum in recent years.

All attempts had to stop because sufficient support could not be provided. Renewable energy projects that are subject to R&D should be supported by governments or private and/or state-owned institutions. Turkey needs to significantly increase the annual wave energy R&D budgets. Besides one of the barriers of entrepreneurs is that financial support is usually given after spending. Providing flexibility should be useful in this area.

Furthermore, governments can consider public and private sector partnerships. Due to the impact of neoliberal currents, many countries have tended to public and private sector partnerships mostly to ensure the sustainability of the provision of infrastructure services or to provide services to the public. Public and private sector partnerships are seen especially in areas such as transport, energy, infrastructure, public safety, waste management and water distribution. To the development of wave energy, public and private sector partnerships can be considered as an alternative.

Government incentives vary according to the maturity of the market. Investments incentives are more appropriate for the immature markets such as the wave energy market and for the new technologies being developed (Delolite, 2011, p. 10). Investments related to renewable energy resources in Turkey are mostly ensured by the private sector. Stimulation of these investments, renewable energy resources are made possible with the assistance given by the government of production and consumption (Karaca & Erdoğdu, 2012, p. 23). The consistency and relevance of different policy and economic instruments are important for investment in Turkey. A framework of consistent financial support, capital grants, clear consenting procedures and timely grid access will create the secure investment environment the industry to grow. One of the steps for the government is to set Renewable Portfolio Standards (RPS) requiring utilities to ensure a certain percentage of electricity from renewable sources in coming years. Therefore, RPS might gradually become more important drivers of the wave energy industries than are tax subsidies (Erdoğdu & Karaca, 2014, p. 82).

However, governments can grant some incentives for wave energy in Turkey. These incentives may be market push, market pull, indirect and direct cash assistance, low-cost debt financing and customer

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

choice. Moreover, governments should grant tax incentives: for example, excise duty, value added tax, energy tax exemptions. This type of tax incentives may increase wave energy demand. If the investment subsidy in wave energy is given priority, it can increase wave energy projects.

CONCLUSION AND POLICY RECOMMENDATIONS

Renewable energy sources are defined as energy that comes from resources that are naturally replenished. Renewable energy sources are composed of solar, wind, geothermal, biomass, wave, and tidal energy. Acceded to Kyoto Protocol, many countries are trying to get a big share from renewable energies. Turkey is no different in this respect and is following developments in wave energy all over the world.

Incentives for fossil fuels make renewable energy resources relatively costly. Through encouragement, renewable energy should become competitive with fossil fuels. Turkey should revise its national energy policy. Thus, more investment in clean and inexhaustible energy must be provided in Turkey, which is rich in terms of renewable energy.

With technological improvements and additional public support for the early stage of development, the ocean energy sector can develop a similar scale as off shore wind over time. Ocean energy currently is an infant industry, in which wave and tidal stream technologies are relatively less developed than other technologies.

The cost of wave energy is competitive with other sources when it is used as a primary power source. Wave energy has the highest energy density, minor negative environmental impacts, it is predictable, and it satisfies electricity demand changes. There is no need for fuel to produce electricity from wave energy and it does not create pollution in the stage of energy production. Operating and maintenance costs are very low. When compared with wind, the wind loses its power within a few minutes, but a wave can move thousands of miles.

The wave energy generating system transforms the motion of the water into electricity. Wave energy generating is known as wave energy devices (WEC). In other words, wave energy devices have many advantages. For example, it is a stable resource; it has low visual impact and no fuel input or carbon emissions or price volatility.

Wave energy ensures a substantial contribution to affordable electricity prices in the long run. Also, wave energy may increase domestic energy supplies and it may help to reduce current account deficits. According to the Turkish Statistical Institute data, the proportion of imports covered by exports averaged 64.1% in the period of 2000–2014. This is reported as 65.1% for 2014. In order to avoid energy imports and energy dependence and also to provide energy supply security, renewable energy sources, especially with the high capacity wave energy, should be further addressed. Hence, it will reduce external dependence comparatively in its production.

Furthermore, wave energy increases demand for local added value. Wave energy production creates new job areas. It may contribute to regional development and the tourism sector. The manufacturing, transportation, installation, operation and maintenance of wave energy facilities will generate revenue and employment. Thus, these positive externalities should be considered. It has also few or negligible negative externalities. However, its potential negative externalities could be avoided or minimized. These issues also should be discussed with stakeholders.

Although a few attempts and experiences exist, there is no industrial electricity generation from wave energy in Turkey. However, Turkey has potential due to its geographical location and it has capacity

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

and experience to raise and develop a wave energy industry. It is suggested that the Black Sea is the best region for wave energy. In other words, Kırklareli, Istanbul, Kocaeli, Sakarya, Düzce, Zonguldak, Bartın, Kastamonu and Sinop are suitable for wave energy. Moreover, the Aegean Sea coast is suitable for electricity generation from wave energy in Turkey.

Industrial production of wave energy can be carried out in Turkey. Thus, wave energy should be encouraged. For this, governments first should increase R&D expenditures; wave energy converter projects also should be supported in this stage. Furthermore, governments can consider public and private sector partnerships. A variety of incentives can be implemented to provide financial support for wave energy. The incentives given for coal mining and production still have a significant size in Turkey. The incentives for fossil fuels make renewable energy resources relatively costly. Fossil fuel subsidies should be phased out gradually. Doing so may increase investment for wave energy and other renewable energy resources.

One of the most important fiscal policy instruments of a government is taxation. The incentive can be provided through tax reduction aimed at wave energy production. Reduction of the rate of corporation income tax to ensure getting into the market of wave energy production may be accomplished. Furthermore, national and/or international standards for wave energy devices can be developed. Thus, governments may provide incentives for electricity production from wave energy in Turkey. The government can establish capital grant investment subsidies. These financial incentives would increase demand for wave energy and could raise projects that are related to wave energy. The power of wave movements in the seas should be evaluated by establishing wave power plants; thus, it will contribute to the energy needs of Turkey. Consequently, incentives may promote industrial electricity generation from wave energy in Turkey.

Building successful policymaking for wave energy, thus establishing policy goals, is needed. The Republic of Turkey's Ministry of Energy and Natural Resources should establish a wave energy strategy group and it should get in contact with other departments of government. This strategy group should contain policies supporting innovation and manufacturing. Turkey has had political and economic stabilization for many years. The consistency of the government policies is crucial for implementing in Turkey.

In this context, government incentives aimed at electricity production from wave energy should be selected according to the conditions and maturity of the market. It seems imperative that the government should consider more incentive mechanisms to develop the wave energy industry.

Researchers might consider the following critical points for future studies: data that are related to wave energy converters should be collected, the performance of WECs should be observed, input–output and cost benefit analysis should be done, the adverse effects of WECs should be observed and assessed and governments should promote partnership agreements with the wave energy industry. Moreover, researchers, private sector managers and policymakers should work together toward early application of wave energy. The government should prepare national support schemes for wave energy, which should include the optimizing aim of the industry.

Chapter 54
Interdisciplinary Approaches to Sustainable Development in Higher Education:
A Case Study From Croatia

Dunja Anđić
University of Rijeka, Croatia

Sanja Tatalović Vorkapić
University of Rijeka, Croatia

ABSTRACT

This chapter aims to test the positive change in students' sustainable behavior that is expected to be found under the influence of relevant subjects. Therefore, a simple quasi-experimental design was applied to test the differences between those groups of students who have not taken the subject Pedagogy of sustainable development and those who have. Since studies for primary school and preschool teachers at the Faculty of Teacher Education, University of Rijeka, Croatia are designed for building needed competencies in future educators, the case study was expected to determine statistically significant differences between those groups of students who have taken relevant subject and those students who have not. Finally, correlation analyses were run for relationship between life satisfaction, optimism, and sustainable behavior to be analyzed. Based on previous research studies and theoretical models, it was expected to determine significant positive relationship between students' sustainable behavior and their levels of life satisfaction and optimism. Both hypotheses are confirmed in this study. All findings are discussed in this chapter within theoretical models and future study guidelines. The results confirm the usefulness of the course Pedagogy of sustainable behavior within higher education of future educators, and its influence within positive change in their sustainable behavior. Besides, the expected positive relationship of life satisfaction and optimism with sustainable behavior was confirmed and so provided a platform for creating a suggestion of implementation of the interdisciplinary course/subject of Pedagogy of Sustainable development and Positive psychology.

INTRODUCTION

Higher education represents one of the most important segments of society, and thus those expectations that demand of it the responsibility for the organization of all those activities that lead to the better, happier and more quality life of humankind are completely justified. Highly educated young people are those who create the future, and thus their actions are not only bound to their personal responsibilities – in addition, future teachers and educators are expected to take responsibility for the future behavior of the generations of teacher they will teach. Thus, it is of exceptional importance to create study programs that will directly influence the creation of competent and responsible teachers and educators, individuals that possess a readiness for lifelong learning and a positive outlook towards themselves, others, children and the environment the life inside. However, it is also of equal importance to leave enough free room within study programs for deliberation and contemplation, i.e. studying in the truest sense of the word, in which a critical approach can be used to discuss the development of (pre) school children, their needs and interests and how to satisfy them, and how to teach them and instill in them fundamental human values with the aim of producing individuals with fulfilled, satisfied and quality levels of to achieve sustainability. This is not an easy task, and thus all institutions that are the bearers of higher education are forced to grapple with this problem in one way or another.

This chapter has two main goals – the first pertains to testing the influence of the pedagogy of sustainable development on the creation of sustainable behavior among future educators and teachers. The second goal encompasses an analysis of the connections between this manner of sustainable behavior and the fundamental concepts of positive psychology, such as optimism and life satisfaction. Our expectations are that the results of both the analyses will allow for the formation of conclusions that can serve as the bedrock for creating an interdisciplinary approach to sustainable development in higher education, one that will also implement the fundamental principles of positive psychology. It is thus evident that the importance of this topic is reflected on the possibility of creating interdisciplinary connections between sustainable behavior and a pedagogical approach to education for sustainable development with the fundamental concepts from positive psychology. The results of the research completed point towards a significant possibility of the influence of the knowledge/information obtained through courses on sustainable development and their pedagogical context for the formation of more sustainable behavior in future educators and school teachers or educational workers. When viewed in this fashion, there is a justifiable basis for deliberating options for creating interdisciplinary courses as part of the education of teachers and thus creating a more innovative approach to practice in modern higher education institutions.

The development of courses for the initial training of educators/teachers conceived in this interdisciplinary fashion – with the pedagogical principles of sustainability on one side and the principles of positive psychology on the other – represent the foundation for innovation and deliberation on the means of approaching teaching for sustainable development in education. In addition, they are focused on stimulating a more quality, satisfied and optimistic way of life that are based on the satisfaction of the needs of present and future generations through the encouragement of more sustainable ways of thinking, acting and living and their transmission to educational practice.

HISTORICAL BACKGROUND

The National Context

Developmentally speaking, a significant number of authors from the local science and research scene have deliberated the issues of ecology, environmental education, environmental problems and the concept of sustainable development.

Already in the 1970s and 1980s, the work of a large number of authors from the field of sociology bestowed significant attention upon issues pertaining to ecology and the environment (Dizdarević, 1974, 1987; Janković, 1976; Marković, 1986; Klepac, 1988; Čulig, 1987, 1991; Stanković, 1988; Čaldarović, 1989; Cifrić, 1989; etc.) and, in particularly from the 1990s onwards, with the concept of sustainable development (Kešina 2002; Pravdić, 2003; Rogić, 2003; Lay, 2001, 2005, 2008; Uzelac, 1990, 2010.). Research on environmental views and value dates back to the 1980s, and was mostly the focus of sociologists (Cifrić & Karajić, 1998) – the interest of scholars from the area of pedagogy and other similar areas only began to grow in the late 1990s. Cifrić, for example, studied the problem of environmental awareness among youth, the problem of responsibility and the individual everyday behavior of modern man in connection with environmental modes of behavior (1997, 1998.).

Many sociological studies were conducted: Šimleša (2008/2009), *Renewable Energy Sources in Croatia*; Lay (2009/2010), *Action Plan for the Sustainable development of Gacka and the City of Otočac*; Šimleša & Lay (2011), *The Sustainable development of Croatia: Development of Croatian national interests through the prism of the concept of sustainable development* ; Čolić (2007-2011), *The Cultures of Consumerism and Sustainability: Global Challenges to the Sociocultural Development of the Republic of Croatia*; Mišetić (2011), *Social Sustainability and Processes of Urban Transformation in Croatia*. The following publications are also used in the course The Pedagogy of Sustainable development: V. Lay, (2007), Eds., *Development for the Future: Contributions to Deliberation on Croatia's Sustainable development*; Geiger Zeman & Zeman (2010), *Introduction to the Sociology of (Sustainable) Communities*); Lay & Šimleša (2012), *The National Interests of Croatia as Viewed through the Concept of Sustainable development*. We wish to stress particularly Lay's (2005) concept on the development of integrated sustainability as a criteria for sustainable development as a project/process and the process of educating (for social values) and teaching (knowledge). For Lay (2005, p. 354) "deliberating on education and teaching processes and systems aimed towards achieving integral sustainability and sustainable development in Croatia is, even today, still an innovative and isolated intellectual affair". He gives his contribution to pedagogical deliberations on integral sustainability with his proposition on ten so-called "sheaves" of general content for educating and teaching integral sustainability and sustainable development: 1. Life and the living world is a fundamental value (the theory and practice of biocentrism instead of anthropocentrism, the issue of the culture of life, health, life, individual and collective self-realization, environmental safety instead of uncertainty and unsafety – a spiritual quest for a holistic life and a sustainable world); 2. Self-determination and action (towards greater benefit) as political principles, the theory and practice of the subject (individual, group, profession, society, country, etc.) as a social actor and creator of his own life and life quality; 3. Integrate sustainability: society, the environment/nature and the economy are interdependent (theoretical and social activities in the spirit of integral sustainability; environmental sensitivity – economic vitality – social welfare is three interconnected and interdependent layers of integrated sustainability); 4. The right of citizens and civil society groups to cooperate and participate in decision making; 5. The needs and rights of the generations to

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

come; 6. Diversity – biological, economic, social, cultural – as a central lifestyle value that aims towards sustainability; 7. Sustainable development and the "load capacity" of the ecosystem; 8. Quality of life and justice in the distribution of chances for achieving a quality life; 9. Education and teaching for integral sustainability and sustainable development (learning about learning - adapting the content of curricula to different age groups and various cultural profiles) and 10. The tentativeness / limited nature of current knowledge on the principles of (un)sustainability/applying caution in action.

During the past few years, a certain interdisciplinary approach to research on this topic and a departure from the narrow areas of science can be observed. There has also been an increase in the number of studies in the areas of geography (Kuvedžić, 1999), economy (Sustainable development, Innovation and the Regional Policy of the Republic of Croatia, Starc, 2007; Ham, 2009), technical sciences, naval research (Kovačić, Bošković & Favro, 2006; Šerić & Luković, 2009), and, in particular, the area of tourism, where there is a wealth of conferences, research (Bučar, Škorić & Prebežac, 2010; Vukonić, 2010; Zlatar, 2010) and study programs at all levels of higher education.

As far as we know, studies on sustainable behavior have not been conducted in the national context of Croatia as of yet. In the area of pedagogical research, the studies that have been/are being conducted are largely based on testing the views of students and educational workers. In the context of pedagogical research, it ought to be stated that local authors have been mostly dealing with the issues of changes in schools and the influence of current social developments on the role of the school today and in the future, and with the issues of the development and implementation of the concept of education for sustainable development into educational institutions, whether kindergartens, primary and secondary schools or universities. There are the works of many authors presented in a series of books titled *Lifelong Learning for Sustainable development* (international conference held in Croatia in 2008 and organized by Faculty of Teacher education in Rijeka), voles. 1., 2.,3. V. Uzelac & L. Vujičić (Eds), and other publications: Anđić (2006), *Analysis of the Condition and Vision of Teacher Training for the Environment*; Rončević, Ledić & Ćulum (2008/2009), *"I'm not sure what it is, but it is important"*; Ledić, Turk & Buchberger (2010), *Empowering Communities for Sustainable development*; Anđić (2011), *The Schools in the Promotion of Education for Sustainable development*; Rončević & Rafajac (2012*), Sustainable development – A Challenge for the University?*. The systematic examination of the views of students and their knowledge of sustainable development and the role of the faculty or university in the promotion and/or implementation of the ideas and principles of sustainable development has received fairly little attention in Croatia, with the exception of the works by Cifrić, 2005; Pravdić, 2001; Lay, 1998, 2005, 2007; Uzelac & Vujičić, 2008; Uzelac& Pejčić, 2003 (as cited in Rončević, 2010, p. 44).

Out of the existing, we wish to stress several more important studies that particularly underlined the need for an interdisciplinary approach to the education of educational workers. Important breakthroughs in the field of pedagogy have been made with the systematic and continued research from the early 1990s to the late 2000s through the studies and publications by V. Uzelac *Environmental Education and Educators/Teachers* (1989); *The Fundamentals of Environmental Education* (1990); *The Environment-Education-Educators-Teachers* (1996); *Environmental Elements in the Curricula for Future Teachers* (1999*); Children and the Environment* (1999); *Educating Students for the Environment* (2002); *Educating Teacher Trainees for the Environment* (1997-2002); *Further Educating Teacher Trainees for the Environment* (2002-2006); *Lifelong Learning for Sustainable development* (2008). Uzelac has been systematically and continually pointing towards the need for the initial and professional training of educators/teachers and students in the area of environmental education and education for sustainable development, while demanding the stronger development of environmental literacy and its implementation into the educa-

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

tion system – both when it comes to formal and informal education. In her research (1999-2006), she examined the views and values of educators, teachers and students of teacher training faculties, while on the education of future educators and teachers she concludes the following: "the problem of their education is reflected in the need and necessity for finding interdisciplinary forms of work and content, and broader possibilities for organizing lessons, discussions on environmental problems, problem teaching, didactical games, research, trips, projects and other various forms of teaching" (Uzelac, 2001, p. 218). Through an analysis of all levels of the education system (from preschool to higher education) in the Republic of Croatia regarding the area of education for sustainable development in the context of lifelong learning, in her further research the author makes conclusions on the dearth of practice and education. In doing so, she alerts that its state has been to the traditional level and points towards the neglect of the intensity and extensity of changes reduced. As a significant cause of this condition, the author identifies the lack of conceptions of lifelong learning for sustainable development. "Future development will depend on the quality of work and mutual cooperation through new and higher forms of networking between various factors" (Uzelac, 2008, p. 22), which includes the influence on global movements towards sustainability on the reshaping of the local, and networking and communication at an academic, scientific, educational and research level.

In their research conducted in 2007 (2009), Rončević, Ledić & Ćulum analyzed the role of higher education institutions in the promotion of the idea of sustainable development, and presented their own results on knowledge and understanding of the concept of sustainable development, plus views and behaviors connected with some aspects of this concept. The results pointed towards significant weaknesses regarding knowledge of the concept, while the views and habits tested did not demonstrate an affinity to this area and did not acknowledge the responsibility of schools. The most important role in the promotion of sustainable development was to the dimension of politics, followed by civil groups and the media given. The research subjects concluded that "political will is the first step in the promotion of the idea of sustainable development, from where it should spread to the rest of society. Without initial action from the political level, the promotion of the idea of sustainable development is not possible" (Rončević, Ledić & Ćulum, 2009, p. 72). Borić & Jindra (2008) stress that lifelong learning for sustainable development is one of the priorities of the knowledge society. With the accession of the Republic of Croatia to the European Union, this priority will become even more significant, particularly when it comes to the training of future educational workers. Their research indicated that students of teacher training studies hold that sustainable development improves the quality of life of current and future generations, while future kindergarten educators proved to be the most informed about this topic and its implementation in practice. The study showed that, for university professors, sustainable development is still a hot topic, but not yet an adopted way of living and they fail to identify expectations for the implementation of sustainable development in their own practice. "This fact is a cause for concern, as university professors conduct undergraduate programs, through which lifelong learning for sustainable development is promoted the most efficiently, while also educating future teachers and educators and through them, indirectly, influencing the education of preschool children. The reason for this is that 'the professional training of university professors' has not been systematically organized" (Borić, Jindra & Škugor, 2008, p. 325). Still, steps forward are visible from these results, not only in educational practice but also in the initial education of future teachers and educators. The authors concluded this study with recommendations for the initiation and implementation of changes "in the higher education system, as all of its output indirectly influences the input in other parts of the education system" (Borić, Jindra & Škugor, 2008, p. 325). Study by Uzelac & Anđić (2006) has pointed towards certain flaws in the practice

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

of teachers and educators and a lack of strategy, programs and materials in initial teacher education and professional training. However, newer research (Anđić, 2011) points towards significant steps forward, particularly when it comes to the values, views and perceptions of students/future educators and teachers regarding the topic of sustainable development. Unfortunately still, the professional training of teachers is rated as insufficient and lies in the hands of the teachers themselves, as self-education is its most common form. However, positive steps forward can be observed in the examples of schools that have departed from the narrow conception of sustainability through environmentally-focused work and are striving to develop more integrated forms of work that encompass the economic, political and, above all, social dimensions of sustainability. At the same time, they are also developing a vision for schools in the future whose operation will encompass a holistic approach to the implementation of education for sustainable development.

The Case Context

The first time was a course pertaining to ecology presented at the Faculty of Teacher education in Rijeka in the academic year of 2000/2001, when a course under the name of Fundamentals of Ecology was as part of the study program introduced for the initial education of teachers and educators. The same year a course of similar content, Pedagogical Ecology, was as an elective course introduced as part of the postgraduate university masters study of pedagogy at the Faculty of Arts and Social Sciences in Rijeka. At this time, our institution for the training of teachers and educators still operated under the name of the Teacher Training College in Rijeka, as it only became an autonomous faculty and began operating under its current name, the Faculty of Teacher education of the University of Rijeka, in 2006.

In addition to acquainting future primary school and preschool teachers with the basic tenets of ecology and environmental issues, the course Fundamentals of Ecology also dealt with the methodics of working in schools and kindergartens. This initial step of introducing such subject matter into study programs was, above all, thanks to one of the most important pedagogists and scholars in the Republic of Croatia, Vinka Uzelac, Ph.D made, whose work has, for many years, been focused on a pedagogical approach to environmental and sustainable education. In cooperation with the Ministry of Science, Education and Sport, she has continually been working on the promotion of this problem and its implementation in initial teacher training and professional training programs since the late 1980s and early 1990s. In this, of particular importance are her research projects approved by the Ministry – Educating Teacher Trainees for the Environment 1997-2002 and Further Educating Teacher Trainees for the Environment 2001-2006. The long-standing work of Vinka Uzelac resulted in the significant implementation of this problem at the level of the initial training and further professional training of teachers and educators in the Republic of Croatia, while also spurring interest in this topic at a regional and national level.

The course Fundamentals of Ecology was restructured and built upon in 2005, which was a change motivated by the developments in education for the environment and sustainable development at a national level. In 1997, the Republic of Croatia became one of the signatories of the Kyoto Protocol, which came into force in 2007, while an official document issued by the Ministry under the name of National Primary School Curriculum for 2006 included a separate part that pertained to education for the environment and sustainable development. Thus, this topic became an integral part of the primary education system known as environmental education and education for sustainable development.

With the enactment of the strategy for sustainable development and the UN's proclamation of the 2005-2014 as the Decade of Education for Sustainable Development, the said issues became the leit-

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

motif for the construction of the courses that are part of the initial training of teachers and educators. A new course titled Pedagogical Ecology vividly illustrates this new focus on pedagogy, didactically and methodologically equipping future teachers in the implementation of content pertaining to environmental education and education for sustainable development. During this period, significant breakthroughs in research work were also made, in which a significant milestone was the largest international professional conference created under the initiative of Vinka Uzelac and organized by the Faculty of Teacher education in Rijeka with the support of the Ministry of Science, Education and Sport. This conference was in 2008 held under the name Lifelong Learning for Sustainable development and gathered a great number of researchers, scholars and practitioners that had made significant breakthroughs in this area, and who were thus able to point out both the pros and cons of the implementation of this issue at a local, regional and national level. Important steps forward in interdisciplinary research certainly contributed to the incorporation of this issue into the programs of other faculties. Among these, we particularly want to stress the following: the Faculty of Tourism and Hospitality Management, the Faculty of Economics, the Faculty of Forestry, the Faculty of Food Technology and Biotechnology. In ways that are in accordance with their study programs (sustainable development and tourism, the fundamentals of ecology, protection of the environment), there are also other faculties that are interested in environmental education and education for sustainable development. However, the development of pedagogically and psychologically rooted approaches to this problem also points towards an increase of the implementation of this topic in study programs for the initial training of teachers and educators, particularly after the introduction of the Bologna Process.

Up to the academic year of 2005/2006, courses titled Pedagogical Ecology were at the full-time and part-time study programs held in the professional training of teachers and educators at the Faculty of Teacher education in Rijeka. However, the adoption of the Bologna Declaration and the harmonization of the higher education system with its principles resulted in great changes in study programs.

This new reconstruction of course programs was with these significant changes harmonized; studies were university studies and an integrated undergraduate and graduate teacher education study transformed into and was in the academic year of 2005/2006 initiated, while alterations and additions to its program were made in 2008. During this period, an obligatory course held in this study was Pedagogical Ecology, which was in accordance with the university level of the study modernized and paid a lot of attention to the problem of sustainable development. In 2009, i.e. the academic year of 2010/2011, the first university level study of early and preschool care and education being in the Republic of Croatia began conducting. A course under the name of The Pedagogy of Sustainable development was as a regular course conducted, while the course Education for Sustainable development in Open Spaces was as an elective course conducted. During the same academic year was the teacher education study again reconstructed and changes were also made in the course of Pedagogical Ecology – its content was reconstructed and it was renamed as The Pedagogy of Sustainable development.

Courses that deal with the problem of ecology are still conducted only at the teacher training faculties of the Republic of Croatia – at the Faculty of Teacher education in Rijeka and at the faculties in Osijek, Pula, Petrinja and Zadar. At these faculties, the titles of their courses can be as indicators of their programs viewed. At the University of Juraj Dobrila in Pula, the Department for Teacher Training conducts the courses of The Fundamentals of Ecology and Pedagogical Ecology; the Petrinja branch of the Teacher education Faculty in Zagreb conducts a course known as Pedagogical Ecology, the Department for the Education of Teachers and Educators in Zadar holds the elective course Ecology, while the Gospić branch that was up to 2011 part of the Faculty of Teacher education in Rijeka conducted Pedagogical

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Ecology as a compulsory course. The Faculty of Teacher education in Osijek has the broadest selection of courses dealing with the problem of ecology/the environment/sustainable development: an elective course titled Environmental Education as a part of Natural Sciences at the integrated undergraduate and graduate teacher training study; Environmental Education in Kindergartens as an elective course at the undergraduate study of early and preschool care and education; while at the graduate level of early and preschool the compulsory courses The Pedagogy of Sustainable development, Ecology for Sustainable development and History of the Environment appear, together with an elective course titled Games in Environmental Education. It ought to be noted that professional studies have been conducted since 2005, and university studies since 2009/2010.

In addition to initiating a university level study of preschool care and education, the Faculty of Teacher education also initialized a lifelong learning program intended for educators that completed a professional level study. This lifelong learning program has been termed as a differential program for enrollment at the graduate level of preschool care and education, and comprises 7 courses that are different to the university level of the undergraduate study. Among these seven courses, a course under the name of Sustainable development in the Context of Lifelong Learning has also been included. The faculties of teacher education in Zagreb and Osijek have initiated similar differential programs, but their structure does not contain courses that deal with environmental issues/sustainable development. Since the academic year of 2012/2013, the course Education for Sustainable development has also been on offer as an elective course in the doctoral study of pedagogy at the University of Rijeka.

SETTING THE STAGE

Part 1: Sustainable Behavior

There exist several terms in literature that can be connected with the issue of behavior and its formation/influences within an ecological, sustainable context. The terminological determination of pro-environmental/environmental/sustainable forms of behavior is not simple, but a review of literature on the topic leads to the conclusion that it is limited to the views, convictions, values and certain actions of an individual that are determined by the intensity and extensity of behavior. Different types of behavior are determined through various combinations of causal factors (Stern, 2000, pp. 409-411). Stern differentiates between several types of behavior that he defines as environmentally significant: environmental activism, non-activist behavior in the public sphere, ecological behavior (environmentalism) in the private sphere and other environmentally significant forms of behavior. According to Krajhanzl (2010) environmentally relevant behavior encompasses deliberate or non-deliberate forms of behavior that involve the conscious and/or unconscious influence of the individual on the environment. In contrast to environmental behavior, pro-environmental behavior is evaluated within the social context as a protective form of environmental behavior, i.e. the application of environmentally sound and socially responsible ethics to lifestyle choices), which includes actions aimed towards the reduction of "ecological footprints" (Akpan et al., 2003, p. 7). Such behavior is also described as preservation/protection of the environment; environmentally responsible behavior, ecological behavior; environmentally destructive behavior; environmentally adverse behaviors sustainable behavior (Krajhanzl, 2010, Akpan et al., 2003, p. 7). In addition to the aforementioned, terms such as consumer behavior also appear, in which it is widely accepted that users' consumption decisions and lifestyle have a considerable effect on the

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

environmental impact of a product's lifecycle (Yilmaz, 2011, p.1). Another term we wish to point out as very important for our research is the term of environmental citizenship and its three types (Liberal, Civic Republican and Post-cosmopolitan), which pertains to public and private pro-environmental behavior that is based on a conviction for participating in the enactment of sustainable policies, i.e. the active participation of citizens, and to principles and values, i.e. an approach grounded in values that stimulate pro-environmental behavior (Dobson, 2003, 2010; Huckle, 2008,).

Huckle's conception of environmental citizenship (2008) expands on the idea of the sustainable citizen and individual, which presupposes the development of competencies based on the *head, heart, hand and spirit* approach. Huckle differentiates between *head competencies* that presuppose environmental knowledge, the abilities of systematic thinking, creative problem solving and applying ethically approaching new situations, and the ability of estimating the influences of human technologies and actions and the long-term consequences of decisions. *Heart competencies* encompass a deep sensitivity that does not only pertain to caring for the welfare of the Earth and the environment, but also to empathy and the ability to view things from multiple angles, possessing a commitment to equality, justice and respect for all people, and the skill of creating, managing and maintaining communities. *Hand competencies* encompass the ability of applying environmental knowledge to practice, making environmentally-conscious decisions, possessing practical skills for the creation of means (tools), objects and procedures needed by the community, the ability to estimate and adapt the use of energy and other resources and the capability of turning convictions into practical and efficient actions. *Spirit competencies* pertain to a sense of wonder, a deep respect for and feeling of connection with the natural world and the ability of invoking these feelings. The distinguishing features of this approach lie in the fact that the development of *head, heart, hand and spirit competencies* are focused on the development of the individual and a citizen that will possess the *ability to design and maintain sustainable societies* (Anđić, 2011, p. 75 as cited in Huckle, 1994, Huckle, 2008).

The focus of our work are those types of sustainable behavior that, according to Najera, presuppose the following: "a set of effective, deliberate, and anticipated actions aimed at accepting responsibility for conservation and preservation of physical and cultural resources. These resources include integrity of animal and plant species, as well as individual and social well-being, and safety of present and future human generations" (Najera, 2010, p.29.). Najera extrapolated this definition by modifying Corral-Verdugo and Pinheiro's definition from 2004 and grounding it in her own sociopsychological model.

Research on environmental and pro-environmental behavior and the internal and external factors that stimulate/participate in/influence their formation is the long-standing research focus of many sciences. Steg and Vlek (2009) point towards the existence of 4 important research areas within a systematic approach for the stimulation of pro-environmental behavior. These are: 1. the research areas that study the selection, evaluation of behavior; 2. research areas focused on the identification of factors that determine behavior (motivational factors and contextual factors); 3. research areas focused on interventions for stimulating pro-environmental behavior (informative strategies, structural strategies) and 4. research areas focused on evaluation (of the success of interventions).

In the research conducted heretofore, of particular prominence are psychological, social, economic and pedagogical studies. Many approaches, theories, concepts and models were structured that attempted to explain and determine the characteristics and/or factors that influence the formation of such behaviors. Table 1 presents a short overview of some of the theories and behavior models that we have included in our research.

Table 1. The Theories and behavior models overview

Factors		Model/Theory in Explaining Behaviour
Norms -Values - Beliefs – Attitudes (motivation, fear)		Norm Activation Theory, Schwartz, S. (1977) Theory of Reasoned Action, Fishbein, M. & Ajzen, I. (1975) Health Belief Model, Rosenstock, I. (1974) Protection Motivation Theory, Rogers, R.W. (1975, revision, 1983) Universal values theory, Schwartz, S. (1994) Schematic Causal Model of Environmental Concern Stern, P. et al's (1995) Values Beliefs Norms Theory, Stern, P. et al's (1999) Model of Ecological behavior as a function of environmental attitude extended by responsibility feelings, Kaiser, F. et al's (1999)
Agency - Efficacy -Control		Theory of Self Efficacy, Bandura, A. (1977) Theory of Planned Behavior, Ajzen, I. (1986) Model of Pro-Environmental Behavior, Kolmuss, A. & Agyeman, J. (2002)
Socio-psychological models		
Internal factors External factors	Values, Attitudes, Norms, Motivation, Needs, Knowledge (different forms), Emotional Involvement (Feelings, Fear, Happines) Infrastructure, Political, Social, Cultural factors, Economic situation, Technology etc.	The Needs Opportunity Ability model, Gatersleben, B. &Vlek, C. (1998)
		Ecological behavior as a function of environmental attitude extended by responsibility feelings, Kaiser, F. et al's (1999)
		Model of Pro-Environmental Behavior, Kollmuss, A. & Agyeman, J. (2002)
		Modelling social behavior with the sociopsychological simulation approach, Moser, H.J. (2004)
		Theory of Interpersonal Behavior, Jackson, T. (2005)
		Community-based social marketing model, McKenzie- Mohr, D. (2008)
		The concept of affinity towards diversity, Corral-Verdugo, V., Mireles-Acosta, J., Tapia-Fonllem, C. & Fraijo-Sing, B. (2009).
		Sociopychological model of sustainable behavior, Najera, M.J. (2010)

As is evident from this table, certain theories and models have grounded their starting points in either the external or the internal factors that explain pro-environmental/environmental/sustainable forms of behavior. Sociopsychological models mostly encompass both of these factors. Our focus is on Najera's model (2010). This model is in several important theories that attempt to explain and examine sustainable behavior grounded, significant for our research and case that we build upon it. Two key elements serve as a starting point of the model: values and responsibilities. The point of departure for explaining the values in the model is on Schwarz's theory of universal values (1994) based. This theory is rooted in the view that values differ among themselves primarily according to the type of motivational goal they are focused on. For Schwartz, values are conscious goals that reflect the three universal demands of human existence: biological needs, the need for coordinated social interaction and the need for surviving and functioning in a group. Based on the aforementioned, he developed a typology of different value contents, i.e. 10 related motivational goals for which he claims to be of universal character, which he proved with his research in 13 countries around the world (Schwartz, 1996). He presented the content of the ten motivational types of values through 56 specific values, which he depicted on a circular structure of 4 fundamental value categories he grouped them in: *openness to change opposite to conservation* and *self-transcendence opposite to self-enhancement*. At the same time, Schwartz's universal values are in significant connection with the topics and values promoted by education for sustainable development. Schwartz's universal values are: Self-Direction (Independent thought and action; choosing, creating,

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

exploring), Stimulation (Excitement, novelty, and challenge in life), Hedonism (Pleasure and sensuous gratification for oneself), Achievement (Personal success through demonstrating competence according to social standards), Power (Social status and prestige, control or dominance over people and resources), Security (Safety, harmony, and stability of society, of relationships, and of self), Conformity (Restraint of actions, inclinations, and impulses likely to upset or harm others and violate social expectations or norms), Tradition (Respect, commitment, and acceptance of the customs and ideas that traditional culture or religion provide the self), Benevolence, Preserving and enhancing the welfare of those with whom one is in frequent personal contact (the 'in-group') and Universalism (Understanding, appreciation, tolerance, and protection for the welfare of all people and for nature) (Schwartz, 1994). The values and topics of key importance to the concept of sustainable development and education for sustainable development are: human rights, health promotion, sustainable production and consumption, gender equality, information and communication technology, rural transformation, and intercultural understanding and peace (adapted from Najera, 2010, p. 58, p. 60). Because of this, Najera created a foundation for examining values through a questionnaire that tested the sustainable behavior of students of two universities.

Schwartz's norm activation theory (1977), i.e. Stern's adaptation (1999) of this theory and its modification of it within the context of the VBN theory (Stern, 1999), together with the adoption of the scale of the NEP (new environmental paradigm) comprise the foundation of Najera's sociopsychological model (2010). In his adaptation of Schwartz's theory, Stern includes the VBN (value-beliefs-norm, Stern, 1999.) theory and the theory of environmental values (the presupposition that there are three different value orientation orientations that are likely to motivate pro-environmental behavior – egoistic, altruistic and biosphere-related, Schwartz, 1977). The connection between values and environmentalism, whose mediators are also particular convictions, is an important part of the foundation of this theory. Information that shapes convictions can influence pro-environmental personal norms and represent a predisposition for taking pro-environmental action (Stern, 2000, p. 414). Environmentally-aware intentions represent only one of the factors that influence behavior, and usually not the most important one. According to Stern, variables can be grouped into 4 factor types: 1. factors that encompass norms, convictions and values, but also other factors, e.g. pro-environmental intentions. Stern describes the aforementioned as attitudinal factors; 2. factors that encompass interpersonal influences such as convincing and modeling, which he terms contextual forces; 3. factors that encompass knowledge and skills involved with certain actions, which he terms personal abilities and 4. factors encompassing the last type of causal variables – habit or routine (Stern, 2000, p. 417). Different types of grouped causal variables are dominant in different types of pro-environmental behavior, depending on the behavior in question (Stern 2000, p. 417, as cited in Gardner and Stern, 1996; Stern, 2000). In further elaborations of the sociopsychological model, two fundamental terms distinguish themselves: awareness of consequences and the ascription of responsibility. According to Huckle (2006, p. 20) the ethics of sustainability encompass the term of values, while the foundation of the concept of education for sustainable development comprises reexamination and taking responsibility for oneself, others, things done or left undone, the past, the present and the future (Huckle, 2006). The ethics of sustainability presuppose 5 dimensions of sustainable development (the economic, environmental, social, cultural and personal dimensions), while the aim is to create a balance between all five. This includes the continued reaffirmation of democratic values such as freedom, equality, human rights, rationality and balancing between the interests of the global population, future generations and the rest of the environment. The author stresses the sense of general responsibility that emanates from the connection between the local and global and the role of the citizen and individual. For Huckle, responsibility is of a global and collective nature but is, at the same time, also local and

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

individual, in which "Everyone shares responsibility for the present and future well-being of the human family and the larger living world" (Huckle, 2008, p. 3). The question of responsibility is the central issue in S. Schwartz's norm activation theory (1977).

The foundation for the stimulation/activation of personal moral norms for the initialization pro-environmental forms of behavior or participation in them is awareness of one's own actions and the actions of others, together with the acceptance of personal responsibility and the responsibility of those who are responsible for certain consequences. Prior to this was the NEP scale developed by Dunlop and Van Liere (based on the sociological approach of the so-called New ecological paradigm scale, it comprised 15 particles in 1978 and was revised later), which measured the worldviews of citizens. It comprises a set of 15 particles grouped into three categories that pertain to harmony with nature, the restriction of development and man's domination of nature. However, further examination of this scale proves the existence of two or even more dimensions and a scale consisting of only 12 particles (Dunlop, Van Liere, Mertig & Jones, 2000, p. 430). In the last thirty years or so, this scale has also been reduced to 5, 6, 7, 8 or 10 item(s) (Hawcroft & Milfont, 2010). The authors, however, suggest the unidimensional, i.e. single-variable use of the scale (Dunlop, Van Liere, Mertig & Jones, 2000,p. 431).

The part of Gardner's multiple intelligence theory (2011) pertaining to interpersonal and intrapersonal intelligence is a constitutive part of this model and is based on the principles of emotional intelligence. Interpersonal and intrapersonal intelligence are analyzed through the 5 psychological dimensions of sustainability, based on the instrument for measuring emotional intelligence.

Emotional intelligence was first defined by Salovey & Mayer (1990) as the ability to monitor one's own and others' feelings and emotions, to discriminate among them and to use this information to guide one's thinking and actions. In 2000 Mayer, Caruso & Salovey, revised the initial definition to include the capacity to perceive emotions, assimilate emotion-related feelings, understand the information of these emotions and manage them. They adopted the theoretical foothold for their conception of emotional intelligence from Gardner and Sternberg, who developed two intelligence theories - Gardner's model of multiple (independent) intelligences (1983) and Sternberg's triarchic theory of intelligence, i.e. practical intelligence (1985, 1990, 1999). Gardner distinguishes between seven basic forms of intelligence: musical bodily-kinesthetic, logical-mathematical, linguistic, spatial and social (interpersonal and intrapersonal). With time, he expanded his theory to encompass naturalist intelligence, existentialist intelligence (the intelligence that leads human beings to pose big 'existential questions'), and pedagogical intelligence (the intelligence that enables human beings to convey knowledge and skills to other human beings who have varying degrees of knowledge) (Gardner, 2011). According to Gardner, interpersonal intelligence is defined as the ability of identifying, understanding, acknowledging and communicating with others depending on their various needs, moods, temperaments, desires, views and motivations. In other words, it presupposes a relationship, interaction with and focus on other people. Intrapersonal orientation is a focus on oneself, and is defined as the ability to create a correct and reliable cognitive model of one's own person and abilities and to use this model to successfully function in life (Gardner et al.,1999).

This model uses the theory of emotional intelligence, i.e. instrument for measuring emotional intelligence developed by Boyatzis et al. (2000, 2002, 2004). It is based on an integrated concept of emotional intelligence that encompasses personality structure, activity theory and job performance. Goleman (1998) defined emotional competence as "a learned capability based on emotional intelligence which results in outstanding performance at work". In other words, if a competency is an "underlying characteristic of

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

the person that leads to or causes effective or superior performance" (Boyatzis, 1982) then the competency of emotional intelligence is the ability to recognize, understand and use emotional information on oneself and others, which stimulates a more efficient or superior performance. This definition is further expanded in the manner that emotional intelligence represents a set of competencies or abilities by the virtue of which a person is: a) self-aware; b) self-managing; c) socially aware; d) manages his relationships with others. In this, among the competencies pertaining to emotional intelligence are: a) The Self-awareness Cluster included Emotional Self-Awareness, Accurate Self-assessment, and Self-confidence; b) The Self-Management Cluster included Emotional Self-control, Achievement, Initiative, Transparency, Adaptability, and Optimism; c) The Social Awareness Cluster included Empathy, Service Orientation, and Organizational Awareness; d) The Relationship Management Cluster included Inspirational Leadership, Influence, Conflict Management, Change Catalyst, Developing Others, Teamwork and Collaboration.

In their study (2004) Corral-Verdugo &Pinheiro give an overview of relevant research and differentiate between the terms of sustainability, pro-environmental and sustainable behavior. Based on their research, they differentiate between different types of sustainable behavior. In addition, they stress that not all forms of behavior that stimulate a high level of environmental welfare are, at the same time, also useless in an economic, political and social sense. The study pointed towards the need for the categorization of sustainable behaviors, in which it is clear that they apply psychological criteria for individual and group behaviors. The authors set the condition that, in the determination of levels of sustainable forms of behavior, an interdisciplinary approach ought to be involved, as it is possible to recognize social, economic, political and environmental influences in their determination. In other words, the authors include economic, political, social and environmental factors among the predictors of pro-sustainable behavior. In light of the aforementioned aspects, the authors define sustainable behavior as a set of efficient and intentional actions that are necessary for the preservation of natural resources (which includes both animal and plant species) and for the individual and social benefit of both current and future generations (Corral-Verdugo & Pinheiro, 2004, p. 10). In the continuation of their conceptualization of sustainable forms of behavior, Corral-Verdugo & Pinheiro (2004) dissect the mental characteristics involved in sustainable behavior and name them the psychological dimensions of sustainability. Sustainable behavior should be in accordance with at least five psychological characteristics, which are identified as: 1) effectiveness, 2) deliberation, 3) anticipation, 4) solidarity and 5) austerity. Efficiency presupposes responsibility at work or a responsibility regarding demands in a physical and social sense, while deliberation means that behavior must occur with the purpose or special intention of preserving the environment and promoting the welfare of all living creatures. Anticipation means that, although the behavior is completed on time, the individual separates himself for a moment and projects his behavior in the future, which is the time that this behavior is focused on. Solidarity manifests itself as a set of trends and actions through which the individual is engaged in an altruistic care for others. Austerity opens the need for the implementation of a lifestyle that is restricted to those goods and natural resources that are a necessity. According to these authors, it is necessary to determine the behavioral dimensions of sustainability at a psychological level, and they propose these initial five dimensions. According to the results of research and the model presented, the presence of an integrative construct can be identified; however, there is still room for other scholars to add new dimensions and offer alternative explanation models. The given model's purpose is integrating the coherent and inclusive explanations of sustainability, in which the psychological component is with other dimensions integrated (Corral-Verdugo & Pinheiro, 2004, p. 22).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Part 2: Positive Psychology and Sustainable Behavior

Research on environmental and pro-environment behaviors, both external and internal, and the factors that encourage, participate and influence their formation have been a longstanding focus of research in psychology. There are a number of structured theories, concepts and models that attempt to explain the characteristics of such behavior. As has been described earlier, this chapter focuses on the socio-psychological model by Najera (2010), based on which we constructed the questionnaire that was used in this study. An interdisciplinary approach is evident in the value categories, which include the core values of the concept of ESD, but also in the concept of responsibility that is crucial. Value systems and responsibility, among other things; represent a very important part of those human virtues (Peterson & Seligman, 2004) that are studied within positive psychology. Human virtues as positive personality characteristics are crucial in positive psychology research. Responsibility was first as one of the fifteen Roman virtues emphasized and, since then, it has been described and measured as part of the Gallup talents classification (Clifton, Anderson & Schreiner, 2006). Other human virtues such as independence, humanity, social justice, etc. are described in all three models of human virtues: Gallups' talents classification, VIA classification (Peterson & Seligman, 2004) and Forty developmental advantages (Rijavec, Miljković & Brdar, 2008). Individuals whose human virtues are better developed show more life satisfaction (Park, Peterson & Seligman, 2004) and optimism (Kashdanm, Pelham, Lang, Hoza, Jacob, Jennings, Blumenthal & Gnagy, 2002). Therefore, we can logically expect to find significant positive correlations between sustainable behavior, which consists of human values, and life satisfaction and optimism. Positive personality characteristics are significantly positively correlated with positive thinking (optimism) and this, in the end, resulted in a person highly satisfied with his/her life.

Furthermore, dimensions of sustainability form the basis for the explanation of the possible models of the SD concept, and include models that attempt to explain its complexity with the use of a psychological approach (Kumar, 2005; Selby, 2007). According to O'Brien (2012), there is a significant basis for an interdisciplinary approach to the implementation of the concepts of ESD, sustainable happiness, well-being and positive psychology. The results of our study suggest an extension of this approach to pedagogical issues and the fundamental structure the course PSD. The concept of sustainable happiness was by O'Brien (2012) developed, who emphasized that it was indispensible for building and increasing the quality of life and described it as "happiness that contributes to individual well-being, the well-being of the community and/or global well-being without exploiting other people, the environment or future generations." The Concept of ESD ought to include the concept of sustainable happiness because it is an integral part of a sustainable future, and of the need to expand research that examines the relationship/connection between environmental sustainability, quality of life and life satisfaction. Positive psychology possesses potential as a means by which sustainable happiness and well-being could be enhanced and understood in the context of ESD. Sustainable happiness and well-being are an integral part of the concept of ESD, therefore it is necessary to consider them in this context. Consequently, graduate programs for early and preschool education include the course Positive psychology (Tatalović Vorkapić & Vujičić, 2013), and we believe it will find an important place within the new reconstruction of the study program for teacher education. When it comes to the inevitable connection between positive psychology and the pedagogy of sustainable development, the second part of this chapter will be grounded in the empirical links between optimism, life satisfaction and sustainable behavior, which we expect to determine through our examination of students of the Faculty of Teacher education in Rijeka. According to Scheier and Carver (1985), optimism is the general expectation that good rather than bad things will occur in our

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

lives (dispositional optimism), while life satisfaction variable is operationalized as the general cognitive evaluation of the satisfaction with life in students ((Diener, Emmons, Larsen & Griffin, 1985). Within this research, we expect to find significant positive correlations between optimism, life satisfaction, and sustainable behavior among future preschool and primary school teachers. Based on the findings of this research, could be future guidelines for creating an interdisciplinary course that encompasses the main principles of the pedagogy of sustainable development and the tenets of positive psychology created.

CASE DESCRIPTION

Part 1: Education As Predictor of Sustainable Behavior

Education is, in both its formal and informal manifestations, according to article 36 of Agenda 21 indispensable and vital for achieving environmental and ethical awareness, values and views that are in accordance with sustainable development and the efficient participation of the public in decision making. Education is a significant predictor and/or mediator of proenvironmental/environmental/ sustainable forms of behavior, to which many studies are testament. Research results testify that education is an important predictor /mediator of pro-environmental/environmental/sustainable forms of behavior (Hawthorne & Alabaster, 1999). However, in contrast with the aforementioned, important studies were conducted that indicated that formal knowledge and information are by themselves not sufficient to stimulate changes in behavior or influence the formation of desirable forms of behavior (Schahn, 1993; Gardner & Stern, 1996; McKenzie-Mohr, 2000; Stern 2000; Kaiser & Fuhrer, 2003; Nolet 2009; Finger 2010). Hawthorne & Alabaster (1999, p. 40) claim that "environmental citizens are not produced merely by education, but by a whole range of factors with which education may interact". According to these authors, the other significant predictors of sustainable behavior are: emotionality, which presupposes development through the emotional aspect of learning, religious affiliation, social class, a sense of personal success and personal responsibility.

Pol's model (2000) examines the theoretical assumption that environmental behavior is always under the influence of four important factors (depending on the case and the weight of each factor). The factors that he terms as spheres of sustainability are: the sphere of information and rationality, the sphere of emotiveness, the sphere of functionality and the sphere of social influence. In 2007 in a study conducted on students of three universities, he also added a fifth sphere that he termed manifested environmental behavior. The results of his study indicated that information and knowledge are not a guarantee for coherent and harmonious behavior. An Education in itself does also not imply pro-environmental habits or forms of behavior. On the grounds of this research, the author brought into question the sustainability model, i.e. the type of education applied at universities heretofore.

Education influences the formation of environmental views and pro-environmental forms of behavior, for the longer the education, the more comprehensive the knowledge on issues pertaining to the environment – however, this does also not have to necessarily presuppose an increase in pro-environmental behavior (Kollmuss & Agyeman, 2002, p. 248.). In other words, education is necessary, as it is a mediator, but also important are other factors that may interact with education. Akpan, Del Matto, Hunsberger, Rehbein, Rogozinski, Rosenthal & Shaw (2003) present an interesting conceptual framework for the promotion of pro-environmental behavior. This framework is grounded in the assumption that "environmental knowledge and values are positively related to pro-environmental behavior, that educational strategies

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

can be used to promote environmental knowledge and that increased knowledge, in combination with training … leads to increased pro-environmental behavior, including institutional factors…" (Akpan et al., 2003, p. 8). However, the research conducted confirmed that though "environmental education can influence pro-environmental behavior change, it is by itself not sufficient to accomplish this. Adequate communication strategies that address barriers and provide incentives for change, as well strong institutional commitment and support, work together with providing education to enhance opportunities for the adoption of pro-environmental behavior" (Akpan et al., 2003, p. 34).

According to McKenzie-Mohr (2008), more conventional approaches based on advertising, comprehensive information and education are not sufficient to stimulate sustainable forms of behavior. Thus the author offers his model - community-based social marketing that consists of 5 fundamental steps: a careful selection of the behavior (s) to be promoted; identification of the barriers and benefits to the behavior, development of a strategy that addresses these barriers and benefits; pilot testing the strategy; and finally; broad scale implementation (McKenzie-Mohr, 2008, p. 1). This model allows for the further development of this technique and, according to the author, enables the identification of inner barriers, thus offering a possible framework for effective programs for both educating and informing.

When it comes to the stimulation and development of pro-environmental/environmental/ sustainable forms of behavior, researchers also preoccupied themselves with those forms of knowledge that can influence/be predictors of/mediate such forms of behavior. Studies connected with the factor of knowledge as a predictor/mediator of pro-environmental/environmental/sustainable forms of behavior pointed towards several important facts: it is not only knowledge that is a key factor/predictor/mediator of behavior, but also its manner of manifestation, i.e. the form this knowledge takes. Frisk & Larson (2011, pp. 5, 6) give an overview of some of the important theories and models that studied the connection of behavior and forms of knowledge as predictors of behavior. Through their Information Deficit Model, Kollmuss & Agyeman (2002) researched pro-environmental behavior and used declarative knowledge (Understanding of how the environmental systems function) predictor in the form of Technical information, Awareness of environmental problems and the Mechanical understanding of issues. As predictors of Responsible Environmental Behavior and proenvironmental behavior, several theories used forms of procedural knowledge (Awareness of how to undertake particular actions): Process-oriented 'how to' information (the Information Deficit Model by Kollmuss & Agyeman, 2002; Model of Responsible Environmental Behavior by Hines et al. 1986); Structural influences & limits and Situational constraints & opportunities (Value-Beliefs-Norms by Stern, 2000; Community-Based Social Marketing by McKenzie-Mohr, 2000).

In the Effectiveness knowledge domain (Views of the outcomes of different behaviors) predictors were: Personal efficacy & locus of control (Value-Beliefs-Norms Theory by Stern, 2000; the Model of Responsible Environmental Behavior by Hines et al. 1986; Fishbein and Ajzen's Theory of Reasoned Action, 1975, 1980; Community-Based Social Marketing by McKenzie-Mohr, 2000); the Perceived consequences of actions (Value-Beliefs-Norms Theory by Stern, 2000); Attitudinal evaluations of outcome (Fishbein and Ajzen's Theory of Reasoned Action, 1975, 1980; Ajzen's Theory of Planned Behavior, 1986). These models or theories tackled the research and prediction of Behavior, Responsible Environmental Behavior and Sustainable behavior. The last knowledge domain expounded by Frisk & Larson (2011, p. 6) is social knowledge (the awareness of the motives and intentions of other people or society). In this instance, as predictors of responsible environmental behavior, environmentally sustaining behavior and sustainable behavior the following were used: Ascribed responsibilities to self & others (Model of Responsible Environmental Behavior by Hines et al., 1986); Beliefs about social norms & expectations (Fishbein & Ajzen's Theory of Reasoned Action, 1975, 1980; Ajzen's Theory of Planned

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

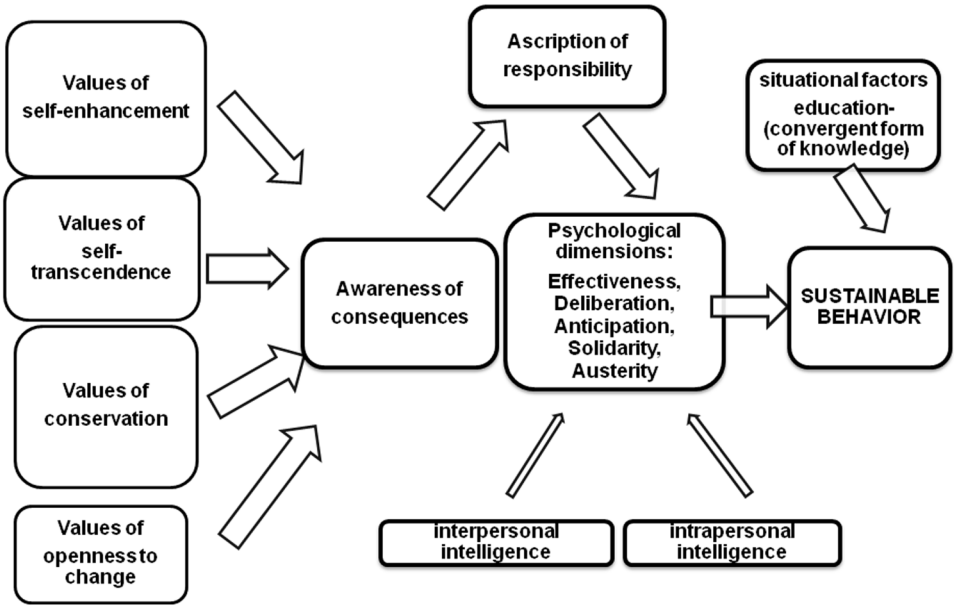
Behavior, 1986) and Perceptions & pressures conveying what is dis/approved (Community-Based Social Marketing by McKenzie-Mohr, 2000).

Studies focused on only certain forms of knowledge in the prediction of behavior most frequently yielded little or no effect. In the research conducted by Thielking & Moore (2001, p. 67) high levels of factual and conceptual knowledge proved to be significant independent predictors of environmental behavior and intentions, and of a stronger feeling of personal responsibility for the environment – but only among women. Among men, no form of knowledge proved to be a significant predictor of behavior. However, it ought to be noted that research based on differences in sex and age as predictors of pro-environmental/environmental/sustainable forms of behavior represent a separate issue that we will not be tackling in this work.

In their research of the dependence of environmental behavior on various forms of knowledge, Kaiser & Fuhrer (2003, pp. 598-613) view knowledge through three important categories: declarative (environmental) knowledge (knowledge on how the ecosystem works); procedural knowledge (action-focused knowledge aimed at the issue of how to achieve a certain goal; it presupposes behavioral options and possible courses of action, and can be differentiated further to, e.g. Sorting and avoidance knowledge etc.); effectiveness knowledge (about the relative conservations effectiveness, relevant when behavior is instrumental in optimizing a person's cost-benefit ratio) and social knowledge. According to these authors, there exist two types of social knowledge: 1. social knowledge that refers to the motives and intentions of others; socially shared or common knowledge (depends heavily on socialization and consists mainly of normative beliefs about what people think they have to do). The authors connect this type of knowledge with social norms (moral and conventional) and Ajzen & Fishbein's (1980) theory of reasoned action. In the continuation, the authors advocate the convergence of knowledge, which means that even when different forms of knowledge are already acquired, knowledge is successful in its endeavor only when different knowledge forms promote ecological behavior jointly and convergently. In their study, the authors conclude the following: different forms of knowledge have to converge towards the common ecological goal. Hence, it is not the mere amount of knowledge available that determines ecological behavior, but the strength of the convergence of this knowledge. It promotes ecological behavior more significantly than any exclusive form of knowledge alone (Kaiser & Fuhrer, 2003, p. 604). Regardless of the fact that many factors can limit/decrease the influence of knowledge on the formation of behavior, nevertheless, knowledge remains an important and highly significant predictor of ecological behavior (Kaiser & Fuhrer, 2003, p. 609).

In their study on the environmental behavior of citizens, Hungerford & Volk (1990) propose behavior changes through education for the environment. This study yielded the identification of key educational components that curricula ought to include, as they possess a significant influence on the formation of desirable forms of behavior. In addition, the authors present two teaching models, which have shown to be influential on the formation of such behavior. They stress three categories of variables (major and minor) that they presented in their model for behavior change: Entry-level Variables (prerequisite variables or at least variables that will strengthen the decision-making. The major variable in this category is environmental sensitivity that is defined as "an empathetic perspective toward the environment". Minor variables are Androgyny, knowledge of ecology and attitude toward pollution/technology/economics); Ownership Variables (environmental issues that are important at a personal level, they are critical to responsible environmental behavior, includes in-depth knowledge of the issues and personal investment). Empowerment Variables (strengthen the sense that we can change and are able to solve environmental problems to make a better world. Knowledge and skill in using environmental action strategies are the best

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use



predictor of pro-environmental behavior because it brings self-confidence to help resolve environmental problems. Locus of control refers to believing in being for a certain behavior reinforced. A person with internal locus control believes that he/she will be for doing something reinforced. Intention to act is to empowerment variables related. If a person's intent is to take action, the chances of that action occurring are increased (Hungerford & Volk, 1990, pp. 8-21).

A majority of researchers point towards the need for knowledge that is able to spur the transformation at many different levels. In other words, in demand are concepts that "through the integration of knowledge domains that speak to ecological knowledge as well as social norms, beliefs about behaviors, and how-to information about specific problems and actions, aim to develop an educational approach that resonates with behavioral science and core competencies for sustainability" (Frisk & Larson, 2011, p. 3). Frisk & Larson thus propose a model of Integrating disparate fields for an interdisciplinary approach to sustainability education. This model encompasses: 1. the role of varying types of knowledge, information, and education in changing behaviors (also including broader theoretical and empirical insights about what motivates and constrains environmental actions). 2. Integration of the educational and sustainability literature (achieving sustainability competencies by particular teaching approaches, specifically focusing on transformative actions in the context of systems thinking, a future orientation, and collaborative decision making). 3. Reflection on critical challenges and opportunities for educational initiatives aimed at changing behaviors for sustainability. (Frisk &Larson, 2011, p. 3).

This work will place an emphasis on the sociopsychological model by Najera (2010), based on which we constructed a questionnaire that we applied to our research (Figure 1).

The description of the sociopsychological model that we have used in our experiment, together with the aforementioned studies, provides us with a foundation for creating hypotheses for the examination of students, i.e. future teachers/educators regarding their sustainable behavior. In this, the convergent form of knowledge we have been developing through the interdisciplinary content of the course The

Figure 1. The sociopsychological model of Najera (adapted and modified by Najera, 2010, p. 59; Anđić & Tatalović Vorkapić, 2013)

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Pedagogy of Sustainable development is a predictor – one we presume shall evoke a transformation of their values, responsibilities, awareness, actions and behavior.

Part 2: The Course *The Pedagogy of Sustainable Development* Overview

Approach and Aims

The course The Pedagogy of Sustainable development (PSD)[1] is as an obligatory course conducted in the 4th semester of the Undergraduate Study of Early and Preschool Education, and in the 8th semester of Integrated Undergraduate and Graduate Study of Primary School Teacher education (4% ECTS credits). The objectives of the course are: to develop knowledge of the general and fundamental concepts of PSD in relation to the historical and social concept of development; to encourage the development of students' critical thinking and their understanding of research breakthroughs, and to familiarize them with the theories on and approaches to the modern pedagogical conceptions of EE[2] and ESD[3].

Through the exploration and the constructivist approach of this course, students develop their abilities as reflective practitioners through the theoretical creation of lessons pertaining to sustainable development and its implementation in educational practice. By successfully completing this course, students will acquire:

- Independent research skills, an affinity for teamwork, interaction and cooperation grounded in partnership and forms of cooperative learning;
- The ability to think critically, derive logical conclusions, make connections and express relevant opinions in an argumented fashion;
- The skill of following up-to-date global information pertaining to social pedagogy and the concept of sustainable development, and using this knowledge to develop their own views and accepting responsibility for both their own lifelong learning for sustainable development and that of humanity in general.

The methods and means of stimulating general competencies encompass motivating students to actively participate in classes (both lectures and seminars) and to complete e-learning activities. Students' activities encompass asking questions, making comments and discussing at lectures; independently selecting, creating and presenting a paper; using information, communication and multimedia technology through the MUDRI e-learning interface and perusing optional literature according to their own choice. In addition, visits to exhibitions, field classes, and various forms of cooperation with social institutions, visits to Eco schools/kindergartens or educational institutions can also be organized in connection with the content of this course.

Course Content

There are three key structural units of this course program consisting of 15 substantive themes:

1. The development of man's thoughts on the environment (man – ecology – environment – SD),
2. From EE to ESD (2. Paradigmatic aspects of ESDs. 3. SD: models, dimensions, problems and perspectives - a sustainable future; 4. Values in ESD - ethics of sustainability; 5. Starting points

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

and approaches to ESD as a concept - multidimensionality and development through the concept of SD to education in the UN Decade for ESD; 6. First steps in EE and SD - from EE to ESD in kindergartens and schools; 7. the theoretical and practical framework of ESD in early and preschool/primary education; 8. Children's play in the context of EE/ESD, activities in kindergartens/schools as one of the preconditions for SD; 9. Elements of the kindergarten/school curriculum that develops children's/students' sensitivity towards SD - creating a kindergarten/school environment, calendar of ESD in kindergarten/school facilities; 10. Educational projects and EE and ESD in kindergarten/school facilities; 11. Kindergarten/school management and SD; 12. A holistic approach to ESD (school/nursery as a whole, eco-and sustainable school/kindergarten);

3. 13.Lifelong learning in ESD (roles, problems and prospects in the process of lifelong learning for SD (NGOs, etc.)); 14. Model competencies of educators/teachers for ESD; 15. Analyzing one's own activities; the development of critical and analytical competences and the professional dimensions of future educators.

Competencies

The stimulation of systematic, interpersonal and instrumental competences encompasses activities that are to be performed individually or in a group during the conduct of the course (at university or via e-learning). After completing these activities, the students are expected to be able to:

- Research the problem of sustainable development both independently and in a team while making use of indirect sources such as ICT technology, and also of direct sources of knowledge on education for sustainable development that can be found in their current social context and the practice of educational institutions;
- Follow current social and pedagogical issues pertaining to the environment and sustainable development, describe, analyze, critically deliberate and express their opinion on current social issues, reflectively create and implement in practice various educational activities for preschool institutions;
- Efficiently construct the educational context, activities, projects and other forms of work needed to position the issue of education for sustainable development as an integral part of the kindergarten curriculum and of educational practice in preschool institutions;
- Independently and critically deliberate on the necessity of lifelong learning and to accept the problem of sustainable development as an inextricable part of their own future and the future of the world.

Forms of Learning and Teaching

Forms of learning, teaching and activities for stimulating specific competencies in students encompass: connecting and interpreting questions and critically and argumentatively discussing current issues pertaining to the pedagogy of sustainable development, which presupposes the skill of writing a critical essay, analysis or overview. These activities are through two work assignments conceived. The first assignment can involve: a) deliberating and constructing theoretical and practical concepts; b) describing ecological activities based on visits to educational institutions, or research through literature and ICT technology;

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

c) recognizing, defining, differentiating between and augmenting the fundamental principles of sustainability through task-oriented movie watching; d) writing a critical review of a movie, exhibition or event.

Students can opt to complete the 1st assignment that pertains to visiting an exhibition, visiting a Greenpeace ship or conceiving practical activities for school or kindergarten on the basis of the theory mastered; or by analyzing a movie that thematizes the problem of ecology.

The 2nd assignment is realized by making connections between the dimensions of sustainable development, i.e. by applying the theoretical and practical concepts of sustainable development with examples of regional, local, national and /or global importance. This assignment demands a perusal and analysis of the problem selected through the lens of the social, economic, ecological, cultural and political dimensions of sustainability and their corresponding values. The aim of this assignment is to raise awareness of the interconnectedness and mutual influences of the dimensions of sustainability and the values they promote.

The 3rd assignment pertains to the development of specific competences through the planning and/or preparation of activities/project. This task involves making connections between theoretical and practical concepts and implementing them in educational practice. It is realized through the concrete creation/ construction of examples of activities or projects connected with a certain topic that can be applied as part of the educational practice of schools and kindergartens (projects on the topic of plants, animals, food, water, human rights, tolerance, natural and cultural heritage and diversity – in accordance with the topics prescribed in the curricula or kindergartens and primary schools).

This course is conducted in hybrid form – through lectures and seminars held at the faculty and through the e-learning interface of the MUDRI-system tool for e-learning. The course has been uploaded to the MUDRI with the purpose of sharing information and opinions, stimulating discussions and enabling students to ask questions and consult teachers regarding lectures, papers and other unclarities. Students can use the e-learning course to communicate with professors and other students, write a blog, participate in discussions on the forum, and create a wiki, share links and upload assignments for consultation/evaluation. Lessons are organized in a manner that enables students to make comments, share their opinions and to ask questions freely. Lessons are conducted regularly in the form of two hours of lectures and two hours of seminars held in the faculty's classrooms or through various forms of extracurricular lessons, e.g. visits to either exhibitions or important events or field classes.

MudRi is a remote learning system based on Moodle software. Moodle is an open-source system intended for the creation of electronic learning materials and conducting remote lessons. All members of the academic and school community have the right to use this system completely free of charge and are entitled to all the assistance they need regarding its use. AAI@EduHr is an infrastructure for the authentication and authorization within the science and higher education system of the Republic of Croatia. The AAI@EduHr has been technically realized through the use of distributed LDAP directories. The Faculty of Teacher education in Rijeka, as part of the AAI@EduHr directory system, issues students and staff a unique electronic identity (user account) that enables authorization and authentication. AAI@EduHr user accounts are opened automatically, and are active as long as the user is affiliated with the Faculty of Teacher education. During their application, students obtain a sheet containing the information needed for logging in to the Mudri system and its courses and to the resources and services described. Students' unique electronic identities also serve as their e-mail addresses at the domain of the Faculty of Teacher education in Rijeka (Carnet, n. d.). This remote learning system has been in use at the Faculty of Teacher education in Rijeka since the academic year of 2008/2009, and at present 50% of courses in all faculties of the University of Rijeka apply this system as a resource, teaching aid or to conduct hybrid lessons.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

As part of the hours intended for academic papers, students have the opportunity to freely select a topic pertaining to the problem of the environment/sustainable development that suits their individual interests and needs. Regardless of whether the topic of the paper is offered or freely selected by the student, before writing and presenting their work students are obliged to hand in a synopsis of their proposed paper. They must then discuss this topic with the professor during consultation hours and obtain his/her permission for the topic, form and manner of writing and presenting of the paper. Students present their papers in the way that suits them best – this can be individually, in pairs or in teams. Individual presentations make use media to expand the content of the paper, work in pairs may take the form of a workshop, while teamwork can involve discussions and debates. During introductory seminar classes, students are given the necessary information on how to present a paper. The presentation of a paper through discussion presupposes discussion as a particular form of group interaction in which members (participants) consider issues of mutual interest together, exchange views and examine the different aspects of their answers, increase knowledge and understanding, confirm or refute opinions, decisions, solutions or activities pertaining to the problem (topic) discussed. The discussion technique that will be depends on the goals set selected, the number of participants, the manner and scope in which opinions are presented, the length of preparation, the sources used etc. The number of participants must not be larger than 4 students. The presentation of a paper topic through a debate presupposes the simulation of a public discussion on the topic assigned in which two teams are confronted – one that advocates a thesis, and one that opposes it. The number of participants must not be larger than 6 students, out of which three are members of the negating team, and three members of the affirming one. The choice of topics is broad: any ecological, political, economic, social, scientific or cultural topic can be chosen that connect with the issue of sustainable development and has possible pedagogical implications for educational practice in kindergartens and schools. (see Table 2)

The evaluation of the presentation and the creation of the paper encompasses the following elements: research on the topic (4% ECTS[4]), creation of the paper according to the rules for writing papers (1%ECTS), connection with educational practice (5% ECTS), evaluation of the presentation of the paper (form of the presentation, methodical approach, tools and aids) and the participation evoked from students (0-3% ECTS). Evaluation of work on the course comprises three midterm exams (10%ECTS) and a final written (25% ECTS) and oral exam (5%ECTS).

Grounds for the Course: The National Context

The justification for a course whose content and activities stimulate the development of general and specific student competencies in this manner is in the following arguments grounded. The education system of the Republic of Croatia is determined through several official documents that give a blueprint for work, i.e. educational practice in preschool and primary education institutions. The fundamental document known as the National Curriculum Framework for Preschool Education and Compulsory Basic and Secondary Education (MSESRC, 2010)[5] defines sustainable development as an educational value and part of the general educational goals of the Republic of Croatia. The basic structure of the preschool curriculum is divided into three large sub-areas in which a child acquires competences: 1. Me (one's image of oneself), 2. Myself and others (family, other children, the social community, kindergarten and local environment), 3. The world around me (the natural and broader social environment, cultural heritage, sustainable development). In the structure of the curriculum for primary and secondary schools, environmental education and education for sustainable development is as an interdisciplinary course

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Discussion themes/thesis options, Debate themes/thesis options, workshop themes and open (personal) choice themes/thesis for Academic years 2011 /2012; 2012 /2013

Discussion Thesis/ Themes Options	Debate Themes/ Thesis Options	Workshops Themes	Individual Presentation Themes	Open (Personal) Choice Themes/Thesis
Natural Heritage and Sustainable development	Vegetarianism (Vegetarianism is/not a healthy way of life)	Recycling	Alternative energy sources	Teletransmitter on mount Učka (local issue)
Kindergartens of the future	Genetic engineering (Genetic engineering is /not contributes to the future)	School garden	Eco or sustainable kindergartens	Illegal dumping sites (local, national and global level of issue)
Human rights (Health environment; tolerance, expression)	Cloning (Cloning is/not justified)	Eco project and how to develop it	Cultural heritage (personal choice: Island of Pag, City of Senj)	Oil spill in bay of Kaštela (local issue)
Healthy food	Globalization (Globalization promotes/is/not development)	Unformal and hidden curriculum- how to implement (promotion) activities of ESD, the role of the teacher	Basic activities of ESD in national curriculum	Dumping site Marišćina (local issue)
Eco tourism	Fur & Leather-Fashion (The use of fur and leather in fashion purposes is/not justified)	Eco activities in kindergarten /school	The need to preserve the future	Industrial hemp (global issue)
Industrial hemp	Global warming (The Global warming is/not exists)	Eco stories	Role of kindergarten teacher/primary school teacher in constructing/ implementing ESD activities in to curriculum	Initiative „For a Family“ - amending the constitution and implications for same-sex unions and their rights (national issue)
	Water (Water will be/not be the cause of future wars)	Healthy food	Natural disasters	
		Eco movies	Cultural sustainability of kindergarten/school	
		Kindergartens/ Schools in promoting sustainable communities	Media and sustainable development	
		Trafficking (guest lecturer)	Protected plant and animal species	
		Alternative energy sources	School management and sustainable development	
		Sustainable design and development-kindergarten and school design (indoor and outdoor)		

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

defined. These are topics of special importance and exceptional content that are not realized through one school subject, as "the operationalization of interdisciplinary topics is one of the ways in which we can contribute to making connections between educational areas and subjects and meld them into a harmonious unit of knowledge, skills and opinions". The description of the interdisciplinary topic of Health, Safety and Preservation of the Environment is as follows (MSESRC, 2010, p. 24).

The national primary school curriculum of the Republic of the Croatia, which is the second official document that we wish to stress, defines the following: "The issue of the preservation of the environment and of sustainable development is a strategic issue for every country. It is at the center of attention of the international community and the subject of many declarations, conventions and international treaties. In order to ensure sustainable development, which presupposes a form of economic and social development that preserves the quality of the environment and uses natural resources reasonably, education is of pivotal meaning. Thorough changes are in order to alter the centuries-old collective idea on the inexhaustibility of the environment needed, changes that will contribute to improving all the violation caused by human activity. New generations must create a different stance towards the environment and develop skills and abilities that will assist them in facing inherited and newly arisen problems. Environmental education and education for sustainable development encompasses everything that surrounds us and includes the natural, social, cultural, traditional and economic aspects of the environment. As it is based on the construction of a positive value system in the individual, a frequent topic is also the internal environment, which pertains to a respect for the phenomenon of life, compassion and respect for the needs of others, satisfying one's own needs in a manner that takes care of not jeopardizing the needs of future generations and other living creatures, the creation of awareness of one's own values, strengths and possibilities and the establishment of quality relationships with other people, nature and with oneself" (MSESRC, 2006)[6]. The task of schools is to create and implement content pertaining to environmental education and education for sustainable development. Apart from being implemented through existing subjects, environmental education and education for sustainable development can be realized through extracurricular activities and other organized forms of work: integrated extracurricular lessons, days of integrated lessons in the school, environmentally-focused school projects (particularly in cooperation with the local community, professional institutions, associations and companies), the organization of debates and participation in various regional, national and international projects. Projects and programs that focus on preservation of the environment and sustainable development, such as the international programs GLOBE and SEMEP, the ECO-school project, the national program of Young Protectors of the Environment etc. give a framework for the topic and content for activities pertaining to environmental education, enable networking between schools with similar interests and allow for mutual support and an exchange of experiences. Environmental education and education for sustainable development represents a relevant part of lifelong learning. It is also desirable to involve both parents/caregivers and the local community in the realization of this program (MSESRC, 2006).

From *The Strategy For Sustainable development of the Republic of Croatia* (2009) among the principles published is also education for sustainable development. A separate chapter is devoted to social justice and cohesion, in which the following are, among other things, given as activities or measures for realizing the main goal and its corresponding concrete goals: giving special attention to the protection of childhood and the development of children, improving the quality of the entire education system and ensuring it is available to all and improving the education of teachers in the area of the Republic of Croatia through continued professional development. The chapter pertaining to the prerequisites for further development stresses 8 key challenges, out of which a society based on knowledge/education

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

for sustainable development is given as the second key challenge. This chapter states that education for sustainable development should be implemented at three levels: at the level of formal education in educational institutions, at the level of informal education, and at the level of the media and processes of implementation in everyday life as a third (informal) level, while stressing the necessity of improving the quality of education at all levels as a key prerequisite. In addition to the topic of education, which is defined identically as in the UN's Decade of Education for Sustainable development (2005-2014), education for sustainable development is defined as a part of lifelong learning. The same document states that it is necessary to "alter and adapt existing curricula for all levels of formal education so that they include the principles and values of sustainability and the interdisciplinary intertwining of its three constituents to a greater extent"(Croation Parliament, 2009)[7].

The Strategy of The University of Rijeka defines completing tasks in harmony with the needs of the sustainable development of the community as part of the university's mission. The University defines itself as a research-oriented university focused on sustainable development that seeks to base its development on human resources equipped for sustainable development. It understands education for sustainable development not only as preservation of the environment, but also as a means of achieving changes in society, in which it refers to the strategy for sustainable development of the Republic of Croatia and lifelong learning, while also planning the foundation of a University Center for Sustainable development.

Grounds for the Course: The International/European Context

Among the significant documents issued in Europe in the area of pedagogy, of particular importance are:

- **The OECD competency framework** which gives a generalization and classification of key competencies for education for sustainable development at the level of general education (Stevens, 2006). Competencies in education for sustainable development are an integral part of international trends in education and have the complete support of UNESCO. Competencies and their development are defined as the priority task in a holistic, cross-curricular approach, i.e. a multidimensional (the ecological, social, political and economic aspects of sustainability), interdisciplinary and integrative concept. In the further text, the competencies stated allow for the formation of a framework of core competencies in education for sustainable development.
    1. **Subject-related competencies** encompass knowledge, facts, definitions, concepts and systems, i.e. encompass thematic areas that are rooted in the fundamental principles of sustainability and development.
    2. **Methodical competencies** encompass the skills of looking up facts, analyzing and problem solving, i.e. presupposes the didactical and methodical skills for the implementation of content and the development of the same competencies through learning material. Their importance is in the strategic approaches to teaching and learning in schools reflected.
    3. **Social competencies** encompass various forms and types of communication (internal, external, personal and interpersonal), interactive work, the public. The importance of the development of these competencies is with democratic decision-making, school management, the school's ethic and cooperation with external factors such as the pupils' families, the local community, educational institutions and supervising bodies connected.
    4. **Personal competencies** encompass those views, values and ethical principles that are subject to change under the influence of new types of learning and teaching, but with the change

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

coming from inside, from the individual himself – pupils, teachers, schools as communities, the local community, society. These competencies are particularly in the sensibilities of both educational workers and pupils reflected, while consequentially manifesting as a motivation for change based on the *heart-head-hands* approach, for learning, active participation and training.

Competencies classified in this manner are part of the core curriculum for the implementation of education for sustainable development in kindergartens/schools.

- **The dynamic model for the development of ESD competencies in teacher education (2008)** that was developed as part of the *COMENIUS, SOCRATES* and *EU* projects. It is considered one of the most important educational frameworks created on European soil. Future programs for the education and professional training of primary school teachers should be towards the development of professional and general competencies directed.
- **Professional competencies** represent the area of the professional dimension in which the teacher is not as a "instructor" but as an individual perceived, that has complex interactions with his pupils, his colleagues and his environment. The teacher is no longer considered a mere transmitter of knowledge, but a member of an institution that possesses a collective focus regarding the ways in which all members of an institution (in this case, an educational institution, i.e. school) learn and develop, with all of them involved in a dynamic society that demands facing issues pertaining to sustainability. For all these levels, teachers require specific competencies such as a value system and ethics, action, knowledge, emotions and systematic deliberation on future learning processes, both local and global, which also includes the development of general competencies.
- **General competencies** are connected with the professional domain, and include, as the first competency, the development of *communication* (both internal and external), *envisioning* or *reflection* as the process of transforming educational processes and the foundation for the construction of sustainable schools, with particular emphasis on action research. Action research represents a key tool for the realization of these processes. The third competency is *networking* and encompasses connections with workers in other schools and the exchange of cooperation, experiences and materials. Competencies thus defined ought to be developed through the initial education of teachers and their further professional training, which can be modified in accordance with geographical factors, the status of the school and the education and work experience of teachers in order to achieve higher levels of competency, qualification and knowledge in the development of a holistic approach to education for sustainable development in schools.

According to the Tuning project (2006), competences are as a dynamic set of personal characteristics defined (knowledge and insights, cognitive and practical skills, and values and views) that is the result of the processes of education at a certain level. They are in an integrative approach grounded, in which individual possibilities are the dynamic combination of characteristics as that enable a competent performance or are part of the final product of the educational process viewed. They also encompass three types of knowledge: knowledge and understanding (theoretical knowledge of an academic area, the capacity for cognizance and understanding), 3. knowledge on how to act (the practical application of knowledge in certain situations) and 3. knowledge on how to be (values as an integral part of acknowledging and living with others in a social context). Within the Tuning project, competences represent a blend of these characteristics, in which knowledge and its application, views, skills and responsibilities take into

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

consideration to describe the level at which an individual is prepared to use them. (Tuning, 2006, p. 5). Tuning distinguishes between three types of general or generic competencies:

- **Instrumental Competences:** Cognitive abilities, methodological abilities, technological abilities and linguistic abilities; the ability of analysis and synthesis, organization and planning skills; basic general knowledge; oral and written communication in the mother tongue; knowledge of a second language; basic math skills; information management skills (the ability to acknowledge and analyze information from different sources); problem solving and decision making
- **Interpersonal Competencies:** Individual abilities like social skills (social interaction and cooperation); being critical and self-critical; teamwork; interpersonal skills; the ability to work in an interdisciplinary team; the ability of communicating with experts in other areas; accepting diversity and multiculturalism; the ability of working in an international environment and acting ethically
- **Systemic Competences:** abilities and skills concerning whole systems (combination of understanding, sensibility and knowledge; prior acquisition of instrumental and interpersonal competences required); the ability to apply knowledge in practice, research skills; learning skills; the ability to adapt to new situations; the ability to create new ideas (creativity); leadership; understanding the culture and customs of other countries; the ability to work independently (autonomy); creating and managing projects; taking initiative and possessing an entrepreneurial spirit; awareness of quality (culture of quality); a desire for success.

The teachers at the University are obliged to create the syllabi for their courses based on the indicators described in the Tuning project (2006).

Part 3: Research Aim, Problems and Hypothesis

The main aim of this study was to analyze the effect of the course The Pedagogy of Sustainable development on sustainable behavior in students enrolled in Faculty of Teacher education, and to explore the relationship between students' sustainable behavior and their optimism and life satisfaction.

This aim encompassed the following problem questions:

Table 3. Levels of Learning competences

Level	Description of learning competence
1.	Accepting to be guided through learning
2.	Seeking to be guided through learning
3.	Taking responsibility for one's own learning
4.	Expressing an orientation on the self in learning
5.	Valuing one's own learning and recognizing the need for further learning
6.	Consistently valuing one's own learning and identifying the need for learning
7.	Possessing learning autonomy and having a good understanding of learning processes
8.	Developing new ideas or processes and having a very good understanding of learning processes

(University of Rijeka (2007). *Strategy 2007–2013.* Appendix of Figure 1.13)

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

1. Is there any difference in sustainable behavior (as measured through four dimensions: human values, awareness of consequences (AC), ascription of responsibility (AR) and intra-personal and inter-personal intelligences) between the group of students who completed the course and those who had not (control group)?;
2. What is the relationship between students' sustainable behavior (as measured through four dimensions: human values, awareness of consequences (AC), ascription of responsibility (AR) and intra-personal and inter-personal intelligences) and their optimism and satisfaction with life?

The following hypotheses were formed based on these questions, previous studies and relevant theoretical models:

1. Since the course The Pedagogy of Sustainable development has the goal to encourage the development of critical thinking about sustainability in students' lives (among other things) it significant differences are expected between the experimental and control groups. In other words, we expect to find significantly higher levels of all four dimensions within sustainable behavior in students who have completed The Pedagogy of Sustainable development when compared to those who had not.
2. In connection with recent studies on sustainable happiness, we expect to determine a significant positive correlation between sustainable behavior (all four dimensions) and optimism and life satisfaction in the total sample of students.

Methods

Participants

A total of 126 subjects (M=20.94 years, SD=1.75, range: 18-27) participated in this study. The sample consisted of undergraduate students (three of them were male students) from Faculty of Teacher education of the University in Rijeka, Croatia. Sixty-three of them were enrolled in the second year of study program Early and Preschool Education and Care (M=19. 68 years, SD=1. 23, range: 18-25), and sixty-three of them were enrolled in the fourth year of study program Primary Teacher education (M=22. 19 years, SD=1. 22, range: 21-27). Sixty-four students (31 of them were enrolled at Early and Preschool Education and Care and 33 of them were enrolled in Primary Teacher education) attended the course The Pedagogy of Sustainable development (experimental group). The average age of students in the experimental group was M=21. 28 years, SD=1. 52, range: 19-27). Sixty-two students (32 of them were enrolled at Early and Preschool Education and Care and 30 of them were enrolled in Primary Teacher education) had not completed the course (control group). The average age of students in the control group was M=20. 58 years, SD=1. 91, range: 18-25).

Measurement

For the measurement of sustainable behavior, a Croatian adaptation of the *"Questionnaire on Sustainable behavior"* (Nájera, 2010)[8] has been applied. This questionnaire measures: a) human values (21 items) according to Schwartz's ten value categories (HV), b) subjects' activations and responsibilities determined by their moral norms (two subscales: each subscale comprising 9 items – awareness of consequences

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

(AC) and ascription of responsibility (AR) and c) intra- and inter-personal intelligence (comprising 20 items, INT). This questionnaire of self-assessment satisfied has already satisfied psychometric properties (validity, reliability) in prior research (Anđić & Tatalović Vorkapić, in press), which has been confirmed in this study, as well: in the first measurement (rHV=0.773; rAC=0.881; rAR=0.823; rINT=0.745) and in the second measurement (rHV=0.801; rAC=0.859; rAR=0.849; rINT=0.668). In the first and the third subscales, participants answered by choosing between one of the answers from the Likert scale given (1-strongly agree; 2-somewhat agree; 3-undecided; 4-somewhat disagree; 5-strongly disagree). In the second subscale, subjects answered by choosing between one out of three answers (1-very serious problem; 2-somewhat serious problem; 3-no serious problem), and in the fourth subscale by choosing one out of five answers (1-never; 2-rarely; 3-sometimes; 4-often; 5-consistently). The sample item from the first subscale of human values was: "Responsible"; from the second subscale of awareness of consequences it was: "Do you think that the destruction of rainforests will be a problem for the country as a whole?"; from the third subscale of Ascription of responsibility it was: "Business and industry should reduce their emissions to help prevent climate change."; and from the fourth subscale of intra- and interpersonal intelligence it was: "Keeping your promises". A Kolmogorov-Smirnov test showed that there was a significant difference in the distribution of the results in the second subscale of awareness of consequences between the first measurement (K-Sz=1.790, p=0.003) and the second measurement (K-Sz=1.890, p=0.002). In addition, there were no significant differences between the distribution results of the other three subscales and normal distribution, i.e. the first and second measurement.

- **Life Satisfaction Scale** (Diener, Emmons, Larsen & Griffin, 1985).This questionnaire consists of 5 items that were used to give a cognitive assessment of life satisfaction. The scale has been translated to Croatian adapted to our country (Rijavec, Miljković & Brdar, 2008), and showed one-factor structure. Participants in this study are assessed through their answers on a Likert scale of 5 degrees (from 1-strongly disagree, to 5-strongly agree). The total score was calculated by adding up the estimates for all items, with a higher score reflecting a higher estimate of life satisfaction. An example of one item is: *"I am satisfied with my life*." The scale has satisfactory psychometric properties, as indicated by the Cronbach's alpha reliability coefficients in the first (r = 0.817) and the second measurement (r=0.846) of this study. Similar reliability levels were obtained in previous studies on Croatian samples (Brdar &Anić, 2010; Brkić & Rijavec, 2011; Kararić et al., 2012). A Kolmogorov-Smirnov test showed that there were significant differences between the distribution of results on life satisfaction subscale and normal distribution only in the first measurement (K-Sz=1. 429, p=0. 034).
- **Life Orientation Test (LOT)** (Scheier & Carver, 1985). This questionnaire consisted of 6 items that were used to measure dispositional optimism. The participants are assessed by answering on a Likert scale of 5 degrees (from 1-I disagree a lot, to 5-I agree a lot). The total score was by adding up the estimates for all items calculated, with a higher score reflecting greater dispositional optimism. An example of an item: *"Overall, I expect more good things to happen to me than bad."*. The scale was adapted to our language in previous studies that had shown satisfactory psychometric properties (Rijavec, Miljković & Brdar, 2008). This study determined the Cronbach's alpha in the first (r = 0.722) and the second measurement (r=0.752). A Kolmogorov-Smirnov test showed that there was no significant difference between the distribution of results regard in optimism and normal distribution, in either the first or the second measurement.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Procedure

Prior to examination, approval for collecting data was from the directorate of Faculty of Teacher education obtained. The questionnaire described was applied at the beginning of spring semester (1st measurement) and at the end of the same semester of the academic year of 2011/2012 (2nd measurement) in the experimental group, and at the beginning of the winter semester (1st measurement) and at the end of the same semester of academic year or of 2012/2013 (2nd measurement) in the control group. Therefore, measurement took place two times in both groups. Subjects participated in the study voluntarily and anonymously, and they received course credit for their participation in the study. Filling out the questionnaire took about 10-15 minutes at each measurement time.

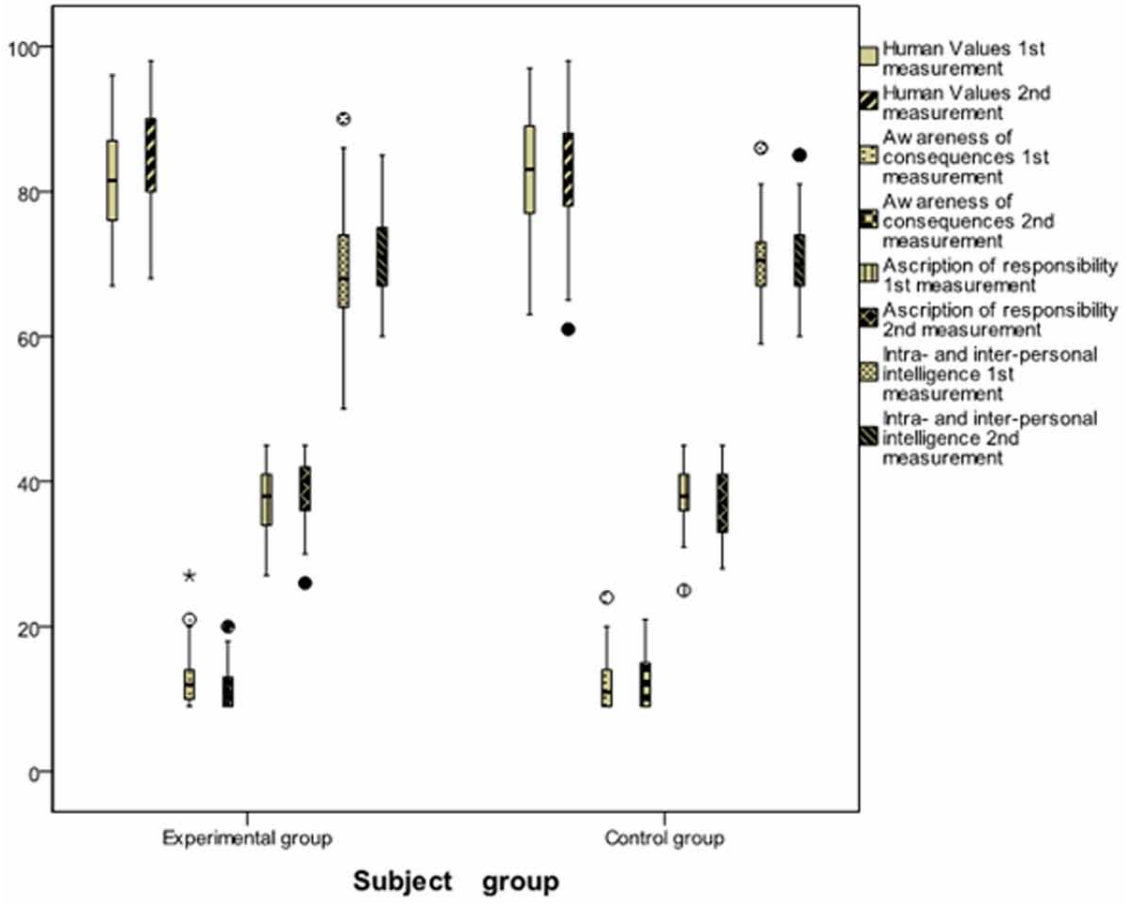
After informing students about general aim of this research, the following instructions were given to them: "Sustainable behavior is evaluated through this questionnaire in accordance with the following definition: a set of effective, deliberate, and anticipated actions aimed at accepting responsibility for the conservation and preservation of physical and cultural resources. These resources include the integrity of animal and plant species, as well as individual and social well-being, and the safety of present and future human generations. In this study, we kindly ask you for your opinions on these items in the context of sustainable behavior. Therefore, please read all the items carefully and assess the extent to which you agree with each of them by circling one of the following numbers: 1, 2,3,4,5. Thank you very much for your cooperation."

After the collection of the data was completed, it was statistically processed through: a reliability analysis of all analyzed variables, descriptive analysis, t-tests on paired samples for all four sustainable behavior dimensions and correlational analysis between sustainable behavior and students' satisfaction with life and optimism. The statistical program SPSS 18.0 was used.

Results

Overall, the results confirmed our first hypothesis, which stated that the course The Pedagogy of Sustainable development would significantly influence positive changes in the students' sustainable behavior. In other words, a statistically significant difference in sustainable behavior was determined between the control and the experimental group. This result vividly demonstrates the usefulness of content pertaining to sustainable development in the training of Croatian primary and preschool teachers, and implicates the importance of sustainable behavior in other professions.

In Table 4 and Figure 2, means and standard deviations could be observed in the experimental group in all four dimensions of sustainable behavior in the first and second measurement. Besides descriptive statistics, results from t-test for paired samples and their significant levels could be seen, too. As it was expected, the findings confirmed higher levels of sustainable behavior after students have attended subject course Pedagogy of Sustainable development.



Their results at three subscales were significantly higher in the second measurement: at the Human Values subscale, Ascription of responsibility subscale and Intra- and inter-personal intelligence subscale. In those cases, higher results meant higher levels of human values, ascription of responsibility subscale and intra- and inter-personal intelligence, while in the case of awareness of consequences lower result meant higher levels of that awareness. Therefore, students showed significant results' decline only at Awareness of consequences subscale. This means that awareness of consequences was significantly higher in the second measurement, what was expected, too.

Table 4. Descriptive statistics, t-tests for paired samples and their significance levels for four dimensions on the questionnaire on sustainable behavior: human values, awareness of consequences, ascription of responsibility and intra- and inter-personal intelligence in the experimental group

Four dimensions of Sustainable behavior in both measurements		Mean	Standard Deviation	t-test for paired samples	p
Human values	1st measurement	81.625	6.713	-4.788	**.000**
	2nd measurement	84.938	6.948		
Awareness of consequences	1st measurement	12.594	3.449	2.613	**.011**
	2nd measurement	11.375	2.597		
Ascription of responsibility	1st measurement	37.109	4.557	-2.808	**.007**
	2nd measurement	38.766	4.078		
Intra- and inter-personal intelligence	1st measurement	69.031	7.191	-3.171	**.002**
	2nd measurement	71.062	5.497		

Figure 2. Boxplot of four dimensions on the questionnaire on sustainable behavior: human values, awareness of consequences, ascription of responsibility and intra- and inter-personal intelligence in the control group in experimental and control group

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

In addition, as it was expected, participants from the control group (who did not complete the same course or a similar one) did not demonstrate any significant changes in all four dimensions of sustainable behavior. Table 5 and Figure 2 show the means and standard deviations for the control group in all four dimensions of sustainable behavior in the first and second measurement. It was determined that the most stable dimension of sustainable behavior was human values, where the same mean was determined in both measurements. Even though they had a somewhat smaller stability, no significant changes in all other three dimensions of sustainable behavior were determined. These findings in the control group of subjects definitely showed that prior significant changes in experimental group could be ascribed to the influence of completing the course The Pedagogy of Sustainable development.

The Pearson correlation coefficients (r) between the four dimensions of sustainable behavior: Human values, Awareness of consequences, Ascription of responsibility and Intra- and inter-personal intelligence in the control group and students' optimism and life satisfaction in the first measurement (upper diagonal) and in the second measurement (lower diagonal) are displayed in Table 6. Overall, the correlation analysis of sustainable behavior and students' optimism and life satisfaction showed significant relationships, as expected. It was determined that students who showed higher levels of human values also showed higher levels of optimism and life satisfaction. These significant positive correlations between human values and optimism and life satisfaction were determined in both measurements. A similar relationship was determined between intra- and inter-personal intelligence and optimism and life satisfaction – students with higher levels of intra- and inter-personal intelligence also showed significantly higher levels of optimism and life satisfaction. This relationship is stronger in the second measurement. According to these two dimensions of sustainable behavior, it can be concluded that they showed demonstrated an expected correlation with optimism and life satisfaction. In contrast, awareness of consequences and ascription of responsibility did not show any significant correlation with optimism and life satisfaction.

Discussion

The results of our research indicate towards and corroborate our initial hypothesis that education/ knowledge is a mediator and/or predictor of sustainable behavior. After actively participating in the course, the

Table 5. Descriptive statistics, t-tests for paired samples and their significance levels for the four dimensions on the Questionnaire on Sustainable behavior: Human values, Awareness of consequences, Ascription of responsibility and Intra- and inter-personal intelligence in the control group

Four dimensions of Sustainable behavior in both measurements		Mean	Standard Deviation	t-test for paired samples	p

(*p<.05; **p<.01)

students from the experimental group demonstrated significantly higher evaluations when it comes to values, responsibility, awareness and intelligence, which confirms the first hypothesis. The results also indicated that, regarding the students in the control group, statistically significant differences between the first and second measurement were not obtained in those 4 dimensions of sustainable behavior, which indicates that the changes observed in the experimental group can be ascribed solely to the influence of the course. If changes in the control group had been ascertained, then the changes in the experimental group could not be ascribed exclusively to the course. Such a result, holistically speaking, indicates that an interdisciplinary course that demands a psychological and pedagogical approach to the dissemination of knowledge, including the development and stimulation of the generic / subject-related, systematic, interpersonal and instrumental competencies through various forms of knowledge and teaching and learning methods, created the foundation for the transformation of existing forms of behavior into a more sustainable behavior. The need for interdisciplinary cooperation is a prominent part of the view of many scholars who acknowledge the interdisciplinary context of both sustainable development itself and education for sustainable development. The values of education for sustainable development are not only an environmental nature and of are not just an issue of behavior in the psychological sense, but also technological, economic and sociocultural problems (Van Liere & Dunlap 1980, Messick & Brewer, 1983, Guagnano, Stern &Dietz, 1995 et al. as cited in Clark, Kotchen & Moore, 2002, pp. 237-239, Brekke, Kipperberg & Nyborg, 2010).

However, the concept of sustainable development as a value system is the axis of the development of more sustainable forms of behavior and the achievement of a more sustainable future. This is an education that strives towards the development of human abilities and an ethics of responsibility, to alter our relationship towards those social processes that have proven to be harmful and to instill a respect for other individuals and species (Rakić & Vukušić, 2010, p. 790). In accordance with the interdisciplinary context of our research, this work places an emphasis on the psychological and pedagogical aspects of sustainable behavior as applied to the context of implementation of education for sustainable development at the level of higher education (Pol, 2000, 2007.). An example of such a convergence of knowledge is

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

reflected in those forms of work within the course The Pedagogy of Sustainable development that are rooted in the view that *"It is not the amount of knowledge available that determines ecological behavior but the strength of the convergence of different forms of knowledge"* (Kaiser & Fuhrer, 2003, p. 604). The course also encompassed a historical perspective, terminological definitions and individual and group tasks that were on the clarification of the notion of values and responsibility focused. Individual work and work in a pair/team allows for both the identification and clarification of these terms and their transmission to everyday life and educational practice. The Croatian sociologist Cifrić (2002, p. 80) stressed two important demands for studies on sustainability: interdisciplinarity and research focus. He stresses two prerequisites for interdisciplinarity: terminological clarity and a consensus on their use. The second demands pertaining to the research focus as, according to the author, studies should encompass concrete social problems such as lifestyles, values and environmental problems, but also be able to deliberate on power and the influence of the various actors in current processes. They also have to be self-reflective. The clarification of terms, terminology and terminological discrepancies between various research areas, the evolution of the concept from environmental education to education for sustainable development and lifelong learning strategies are important prerequisites for the conceptualization of both explicit and implicit educational reflections and methodical approaches in the practice of educators and teachers. Huckle's (2006) stance towards the personal dimension of sustainability as an area of the problem of the ethics of sustainability is a constituent part of interdisciplinary and holistic deliberations on values and responsibilities, which also includes the concept of sustainable development and its educational manifestation. In other words, the holistic perspective offered by the model of sustainable development both gives the student an opportunity to reflect and self-reflect on his own values, responsibilities and actions in his everyday life and his student (professional) life.

Research results indicate that students in the experimental group demonstrated significantly larger statistical steps forward when it comes to the area of Schwartz's universal values, which also includes the values of education for sustainable development and particles that are in opposition to them. Values are a category that is difficult to change, and from the studies conducted heretofore, it is evident that they have been a frequent subject of research, as has been their influence on the formation of behavior. Support for this can be in many studies found, for example, those by Inglehart (1977-1997) in which he attempted to prove the connection between value systems and socioeconomic systems. For this author, an increase in care for the environment occurs as the consequence of a paradigm shift[9]. The issue of value change is rooted in the stance on shifting from a materialistic towards a post-materialistic paradigm, i.e. from a modern to a postmodern paradigm (1997). In this, Inglehart sides with those multiple authors that hold changes/shifts/improvements of paradigm as important for the development of education for sustainable development. Value changes, particularly as viewed in the context of social and cultural values, were the focus of many researchers. Maslow's hierarchy of needs, for example, stresses that people progress through a succession of levels of need until eventually they become more interested in–or more free to pursue–personal development and self-actualization. With his S-curve, Salk (1981) underlines the existence of two epochs whose values are diametrically opposite. Tibbs (2011) gives us an overview of the aforementioned models and debates on changes in the social and cultural spheres and the conversion of values that support sustainability. The author stresses Ray's (Tibbs, 2011, p. 19 as cited in Ray, 2008, p. 1) view on defining values as *"people's most important life priorities, the basis for what they actually do, what they want to accomplish, and how they want to be"*. Viewed in this fashion, this definition of values is also in our research and in the items in our questionnaire reflected.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

The research overview and empirical study by Abdul Rashid and Abdul Wahid (2012) proves that employees that are actively involved with environmental activities at the workplace would also show a similar inclination toward performing pro-environmental behavior at home. These authors stressed two important factors that influence the positive spillover pro-environmental behavior: Organizational Factors (organizational climate according to environmental management system has three dimensions: clarity of goals; Trainings and teamwork) and Family Factors (family cohesion and family support). Thus, the explanation of these results is rooted in the fact that a value change occurred in our students, one that was the result of the influence of the course content and the teaching methods that questioned from the very beginning each student regarding the following issues – who they are, what they want to achieve and what kind of people they want to be. In other words, if we connect the issue of values in the course content with the issue of personal values, the greater the possibility for making connections between goals and achieving them, (Năftănăilă, 2010, p. 836) – or, in our case, for attaining more sustainable forms of behavior.

Deliberations on the values of sustainable development through their four dimensions (UNESCO, 1997) in an everyday context, at both the local and personal level, offer the possibility of achieving identification in this manner and provide the foundation for altering one's own value system. Through tasks conceived in this manner, students have the opportunity to transform their own values and spot common goals in their own lives, how to transmit them into the local and global level, and while also learning how to think in a more innovative fashion. Reexamining one's own views, values and responsibilities is a constituent part of this task and enable students to notice different perspectives and view things from a different angle, to observe problems from a personal, local or global level and to arrive to the crux of the problem in a holistic fashion. The selection of task problems is free and personal, which at the same time indicates a hierarchy of personal values, and how informed are students regarding current social, political, environmental, economic and other issues in a local and global context.

Also connected with the idea of values is the idea of responsibility, which completes the self-image of the individual. According to Stern, Dietz, Abel, Guagnagno & Kalof (1999) in their Theory of Support for Social Movements with which they explain 4 types of environmental behaviors (Environmental Activism, Environmental Citizenship, Policy Support and Private-Sphere Behaviors), the values that support the New Ecological Paradigm (altruistic, egoistic, traditional, openness to change) lead towards an awareness of consequences, the ascription of responsibility and the formation of proenvironmental personal norms. Thus, deliberation on responsibility in the context of work on the course is through reflection on one's own values and by improving awareness of the consequences of one's own actions and the actions of others realized. This explains the results obtained through our research.

An indispensable part of such work is involving those aspects of work that are rooted in inter- and intra- personal intelligence as measured with the particles used for the measurement of emotional intelligence. The results obtained regarding the measurement of awareness of environmental problems and interpersonal and intrapersonal intelligence as viewed through the 5 psychological dimensions of sustainability indicate statistically significant differences that are in favor of the experimental group of students. According to Najera (2010, p. 57), Gardner's multiple intelligence was the subject of some criticism in its application in the context of education. Najera stresses the following: *"However, this theory holds that: 1) multiple intelligences act on a value system whereby students with a diversity of abilities can learn and succeed; 2) that learning is exciting, and that hard work by teachers is necessary; 3) that the exchange of constructive suggestions and formal and informal ideas embedded in the curriculum and the*

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

evaluation of educational activities are valid for the students, as well as for the broader culture, 4) that the arts may be employed in order to develop people's abilities and comprehension within and across disciplines, and 5) that multiple intelligences are means to fostering high quality student work. These features are highly pursued in education for sustainability" (Najera, 2010, p. 10). On the other hand, we can also partially locate an explanation of our results in this paragraph: the course content directly stimulates students to interact with others, reflect and self-respect on their views and the views, perspectives, values and behaviors of others. Every student freely selects the topic of his/her task and paper and also the manner in which he/she desires to present it. Certainly, these demands for the professor to be prepared and to introduce the students to the topic of sustainability, while stimulating their interest and motivation regarding issues of personal, local and/or global importance. However, further implications of such a manner of teaching and developing competencies within the educational practice of teachers/educators are in the students themselves manifested.

Smith (2002) stresses that students will be happier studying issues that are directly relevant to their lives, and students that engage in issues that are directly pertinent in their own lives, that are directly related to their communities and important to the adults that surround them, will most likely find their school experience more enjoyable, engaging and valuable. The inclusion of such topics and the creation of educational activities, games and projects enables students to connect the issue of sustainability with their own environment, and also to identify better with sustainability issues in other areas as an increase in their awareness on the cause-and-effect relationships between their own actions and those of others and in their level of sensitivity has occurred.

In close relation to the 5 psychological dimensions of sustainability, the results of the research indicate positive steps forward regarding taking responsibility, deliberating on purposeful behavior now and in the future and on the causes and consequences of one's own behavior and the behavior of others, altruism towards others and the implementation of more sustainable ways of life. These results could be compared with those results obtained in the evaluation of optimism and life satisfaction, and positive relation between pro-environmental behavior and well-being (Venhoeven, Bolderdijk & Steg, 2013). The study hypothesis were set according to previously described theoretical models and empirical findings, such are those from research by Tapia-Fonllem, Corral-Verdugo, Fraijo-Sing, B. & Durón-Ramos (2013), that determined significant correlations between environmental emotions, affinity towards diversity and sustainable happiness. Related to that, we also expected to determine significant correlation between sustainable behavior (all four dimensions) and optimism and life satisfaction in the total sample of students. Nevertheless, our hypothesis have been confirmed partially, considering that the obtained significant positive correlation with optimism and life satisfaction was determined only in relation to two dimensions of sustainable behavior: human values and intelligence.

Such results were to be expected, since these are personality traits that are closely connected with the measured dispositional optimism, and thus also life satisfaction. In contrast to this, awareness and responsibility are less stable convictions and are subject to change, which can be the reason for their lack of correlation with optimism and life satisfaction. Research on optimism shows that people who demonstrate high levels of optimism are more likely to use stress-confronting and problem-solving skills, while being less likely to use evasion and avoidance of a task (Scheier, Weintraub & Carver, 1986; Carver, Scheier &Weintraub 1989; Rand 2009). This is also with a confrontation with environmental and sustainability issues connected, as the concept of education for sustainable development demands learning and teaching problem-solving skills, decision making, viewing issues from different angles etc. Weber's study (2012)

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

indicated that optimism is significantly correlated with general environmental behavior. However, it has not been ascertained that more optimistic people will act in a more environmentally-aware/sustainable way, but that they will be more likely to participate in environmental behavior.

CURRENT CHALLENGES FACING THE ORGANIZATION

Current challenges facing our organization including the following issues:

- Implementing and developing new forms of convergent knowledge in the course – as results have shown there are significant changes in sustainable behavior of our students- these changes must take long term effects. Education and convergent forms of knowledge are predictors of these changes and must be further developed and improved.
- Conducting the empirical study researches about/ of competencies especially in education for sustainable development – planned research and team project (in autumn - winter 2013/2014): that includes a variety of competencies, constructing an instrument, interdisciplinary approach (psychological, didactics, pedagogy, methodology) in building and conducting the research (including other universities)
- Competencies issues- competencies and methods needed for strengthening in learning and teaching in this course, as its development in other interdisciplinary courses;
- Constructing the frame for specific competencies and new innovative ways to develop them;
- Enhancing students in studying more interdisciplinary approaches trough selection of discussions and debate themes/thesis of local, regional, national and global issues;
- Securing students motivation and interest trough continually monitoring events and new literature, enhancing their questions, thinking, team project building and its presentations on teaching and practice trough the course.

SOLUTIONS AND RECOMMENDATIONS

According to Steiner & Posch (2006), the concept of sustainable development can give a normative framework for the introduction of innovations. These authors also hold that innovators in the introduction and integration of the problem of sustainability into higher education face dynamic non-linear phenomena and complex situations. Due to these reasons, we should identify the possibilities that emanate from sustainable behavior with the purpose of developing strategies and concrete action plans for stimulating development in the direction of sustainable development. This potential has been recognized by educational institutions long ago, as has the stimulus for transformation based on the ten-item plan of the Tallioires Declaration (1990), created by presidents, rectors, and vice chancellors of universities/ institutions of higher learning for a sustainable future. This plan stresses the pivotal role of the university as an institution that educates, explores, shapes policies and exchange information, while defining the action plan for universities all around the world regarding the implementation of sustainable development. One of these items pertains to cooperation/collaboration through interdisciplinary approaches, which involves convening all university workers, administrators and practitioners that deal with this topic to develop an

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

interdisciplinary approach to curricula, research, initiatives, operations and other activities that support an ecologically sustainable future.

We recognized the implications of one such approach in the guidelines presented by O' Brien (2012, p. 1199)[10], which are grounded in UNESCO's determinants for reorienting teacher education for sustainability and the implementation of positive psychology and the concept of sustainable happiness and welfare, as they offer us a framework that directly reflects the course The Pedagogy of Sustainable development.

Those are also possible solutions and recommendations for further interdisciplinary course development. The first guideline in the area of reorienting teacher education for sustainability (according to Unesco, 2005) encompasses coursework on sustainability for student teachers that involves interdisciplinarity and the availability of material on local and global sustainability issues. In the area of positive education and sustainable happiness it introduces student teachers to research in positive psychology and its relevance to their school and community and the subjects they will teach; the encouragement of systems thinking to integrate sustainability with positive; the influence of student well-being on learning; how individual well-being is interconnected with community well-being and the well-being of the natural environment.

Connections with the course Pedagogy of Sustainable development are evident through content aimed at introducing students to the fundamental terms within ecology – the development of man's thought on the environment up to the 20th century (interdisciplinarity, holism); familiarization with the terminology and definitions pertaining to the concept of sustainable development (its early development and its contemporary models) and the concept of education for sustainable development. In this area, students are acquainted with research results through: an international overview of research trends in the area of formal, informal and non-formal education; an overview of environmental education and education for sustainable development projects in European, Asian and North American countries, an overview of national reports on the identification of implicit and explicit criteria; support to eco-schools that incorporates sustainability principles and actions in whole school and a comparative analysis of national reports and criteria for eco-schools, i.e. on the eco-school development processes in 13 world countries (Mayer &Mogensen, 2005). Current local research. The area of values and responsibility within the concept – giving examples for individual and team student work and thematizing content in an integrative fashion that presupposes a diverse approach to the problem of values within the dimensions of sustainable development. Observing the model of sustainable development through dimensions (biophysical/ ecological, economic, sociocultural and political) and the values on which they are based and which they promote. Different concepts, values and educational topics pertaining to sustainable development are reflected upon, discussed and observed through the lens of this model. Particular emphasis is placed on a methodical approach to the implementation of environmental education and education for sustainable development that includes implementation through official educational documents and a curricular approach. The tasks are: to make connections, interpret questions and critically argument the problem of the pedagogy of sustainable development (Writing a critical essay, analysis or review – assignment 1). Papers: debates, discussions and workshops.

The second guideline for the reorientation of education towards sustainability presupposes the demonstration of pedagogical techniques that foster higher-order thinking skills, support decision-making, involve participatory learning and stimulate the formulation of questions; in connection with positive education and sustainable happiness it presupposes a critique of existing pedagogical techniques in order to determine how they contribute to or detract from teacher and student well-being, a discussion of the well-being of teachers, stress prevention and management and of model teaching practices and assessments that contribute to well-being.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

We connect these guidelines with the course content that encompasses the area of the development of environmental education into education for sustainable development. A methodical approach; orienting oneself towards, within and for the environment; elements of the curriculum; implementation through play and activities (the creation of eco-games and activities, aspects in the formation of environmentally-conscious games and activities, sources of direct and indirect reality, projects. This also includes the creation of academic papers: debates, discussions and workshops.

The third guideline for reorienting teacher education encompasses (O' Brien, 2012, p. 1199) an emphasis on the role of the citizenry in the sustainable community (the demand for active participation and decision-making in the classroom and curriculum), while in the area of positive psychology and sustainable happiness it presupposes creating opportunities for student teachers to apply positive psychology to classroom management, teaching practice and assessment strategies

The connections between this guideline and our course include deliberation on values and responsibilities – presenting examples through the individual and teamwork of students. Methodical approach – sustainable educational institution – holistic approaches to the implementation of education for sustainable development into kindergartens and schools. Evaluation and self-evaluation are/as an integral part of the holistic approach. Tasks for students involve: planning and/or preparing activities/projects, writing and presenting papers: debates, discussions, workshops.

The fourth guideline towards reorienting teacher education for sustainability presupposes discussions on social equity (e.g. gender, racial, ethnic, and generational) and identifying the ways in which the local community exhibits social tolerance, societal intolerance, equity, and discrimination; in the area of positive psychology it includes the incorporation of emerging research on social equity and well-being.

The connections between this guideline and our course encompass the area of values and responsibility within the concept – presenting examples through the individual and teamwork of students. Tasks: to make connections, interpret questions and critically argument contemporary issues within the pedagogy of sustainable development (Writing a critical essay, analysis or review).

The fifth guideline towards the reorienting of education towards sustainability encompasses analyzing of the mandated curriculum that they will be teaching and identifying topics and themes related to sustainability and those that are linked to local sustainability issues. In the area of positive education and happiness, a similar topic appears – guiding and leading student teachers to analyze the mandated curriculum they will be taught to identify topics and themes related to the individual, community and global well-being (particularly health education)

The implications of these guidelines pertain to the content encompassed by the curricular approach: an analysis of official educational documents. Every paper must include a chapter that pertains to implications or explicit work in education – the kindergarten or school. Tasks for students: planning and/or preparing activities/projects.

The sixth guideline towards the reorientation of teacher education for sustainability pertains to providing student teachers with opportunities to explore their own values and attitudes towards local sustainability problems and those of the surrounding region; while in the area of positive education and sustainable happiness it implies providing opportunities for student teachers to apply positive psychology both personally and professionally, assisting student teachers to explore their views of happiness and well-being, developing a "happiness literacy" regarding the factors that influence them and their values about happiness, encouraging critical analysis of current education practice, including program delivery, how schools are built etc.) (O' Brien, 2012, p. 1199).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

The connection of these guidelines with the course Pedagogy of Sustainable development encompasses deliberation on personal, local and global problems in the context of values and responsibilities - presenting examples through the individual and teamwork of students, the ethics of sustainability, modern childhood, strategies of lifelong learning for sustainable development, the curricular approach: an analysis of official educational documents and the design of schools and kindergartens.

The seventh guideline towards the reorientation of teacher education is on promoting understanding of global sustainability in order to encourage critical thinking and decision-making that influence personal lifestyle and economic choices focused. This guideline logically follows the previous and they can be implemented together. The guidelines for the implementation of positive education and sustainable happiness presuppose providing opportunities for student teachers to apply sustainable happiness both personally and professionally (synthesizing positive psychology with sustainability) and encouraging student teachers to think critically about the role of education for sustainable happiness and well-being.

Its implications are related to the course content given previously and encompass content on values and responsibility - presenting examples through the individual and teamwork of students; a curricular approach – holistic approaches to the implementation of education for sustainable development into kindergartens and schools. It also includes the following content: evaluation and self-evaluation as an integral part of the holistic approach; strategies of lifelong learning for sustainable development and familiarizing students with teacher competency models regarding education for sustainable development. Tasks for students: to make connections, interpret questions and critically argument contemporary issues within the pedagogy of sustainable development (Writing a critical essay, analysis or review - model of sustainable development: dimensions of sustainability, assignment 2). Papers: debates, discussions, workshops.

The eighth and final guideline is actually a herald of the further development and formation of courses that will encompass all the aforementioned guidelines for the reorientation of teacher education for sustainability and the promotion of positive psychology/education and sustainable happiness. O' Brien (2012, p. 1199) stresses that it is necessary to develop specialized Education for Sustainable development (ESD) programs for student teachers (e.g. mini-courses) with certificates of completion, so that student teachers can include them in their resumes for seeking employment and to provide teacher education courses and professional development opportunities that apply positive psychology and sustainable happiness to education and educators.

The course program is an integral part of the compulsory study program of: the integrated undergraduate and graduate teacher training study; the undergraduate study of preschool care and education; the differential program for enrolling at the graduate level of early and preschool care, and the elective course Education for Sustainable development in Open Spaces. Bachelor's and master's theses that include connections with positive psychology and the pedagogy of sustainable development are also realized at the faculty.

Finally, we also wish to stress one limitation of our research experiment, and this is the fact that the study was on a relatively small sample conducted. Our solution and recommendation for further research is not only to further develop the implications of an interdisciplinary and integrated approach to the development and implementation of courses for the training of educational workers, but also for future research to be on larger samples conducted and with more variation in age, sex and study orientation. This would allow better insight into the relationship between certain dimensions of sustainable behavior and optimism and life satisfaction. However, the evident strong connection of values and intelligence with optimism and life satisfaction empirically proves an overlap between the fundamental terms of positive

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

psychology and those from the pedagogy of sustainable development, which can serve as a basis for the creation of interdisciplinary courses that aim to develop and stimulate specific sustainability-related competencies.

Courses such as this one must include convergent forms of knowledge and enable a change of values and views, taking responsibility, reflection and self-reflection from the angle of the individual, the citizen of society, the professional employed in an educational institution and the teacher as a part of society. Such courses must equip students with competencies that will enable them to adopt the aforementioned roles and promote them at an institutional and social level.

As is stressed in Agenda 21, education is the key tool for the promotion of sustainable development, and we wish to again stress that is bearers are educational workers. The model of sustainable behavior that we have applied to our research also confirms this argument and represents a foundation for the further creation and development of more inventive forms of both initial teacher education and further professional training, and for teaching and learning for sustainable development in current and future practice at both the national and global level.

ACKNOWLEDGMENT

We would like to thank the dean of the Faculty of Teacher education, professor Jasna Krstović, Ph.D. for her institutional support for this research.

KEY TERMS AND DEFINITIONS

Education for Sustainable Development: A concept whose primary goal is the promotion and implementation of the idea of sustainable development at all levels of education, in every form of education, for every individual, community, society, including its local, regional, national and global context.

Life Satisfaction: A general cognitive evaluation of the satisfaction with life.

Optimism: The general expectation that good rather than bad things will occur in our lives (dispositional optimism).

Pedagogy of Sustainable Development: An interdisciplinary course at the Faculty of Teacher education in Rijeka. It encompasses the contents regarding pedagogical implications and implementations of education for sustainable development in primary school/preschool/kindergarten practices. It's intended to teacher students and early education/preschool teachers in developing competencies for effective practice in teaching in education for sustainable development.

Positive Psychology: A science of positive subjective experience, positive individual traits, and positive institutions promises to improve quality of life and prevent the possible pathologies.

Sustainable Behavior: Behavior that encompasses peoples' values, norms, beliefs, senses of responsibility in deliberate actions focused to providing well-being of all living beings, including present and future generations.

Teacher Students/Early Education/Preschool/Kindergarten Students: Students at the Faculty of Teacher education in Rijeka, University of Rijeka, Croatia. They are attending Integrated undergraduate and graduate study of Primary School Education and University undergraduate study of Early and Preschool Education.

[9] In Anđić (2011), this is the demand for paradigm "improvements" or "shifts", which are, according to some authors, necessary in order for us to speak of the Concept of Education for Sustainable development. According to many authors, Environmental Education is defined as a part of the modern paradigm, while Education for Sustainable development is considered a part of the postmodern paradigm. Locally and abroad, this issue was the thematized by Cifrić, 1990; Beck, 1995; Tilbury & Waterford, 1996; Capra 1998; Sterling 2001; Raumolin 2001, 2002; Myerson 2002; Novalić, 2003; Šantić 2003; UN Commission on Sustainable development, 2009 et al.

Chapter 55
Rule of Law: A Fundamental Pillar Enabling Sustainable Development and Reduction of Poverty in India

Gopala Anjinappa
Bangalore University, India

ABSTRACT

The world as a whole has developed in the global dimension and has flourished with prosperity. But still one can see the hurdles in the development process. One of such impediments is poverty and the other is the environmental problems. Poverty results in violation of human rights. The rule of law is crucial and is one of the means to strengthen these hurdles. One of such escalation is on the environmental development wherein it strives for achieving sustainable development and eradication of poverty. The rule of law plays a vital role in reducing extreme poverty with emphasizing on human rights. It is the very essence and the core of Good Governance. Without the principles of the rule of law, it will not be enough to achieve sustainable development and eradication of poverty. The rule of law strengthens to provide intense legal framework. It works as an effective mechanism for the enforcement of law. Innovative methods are undertaken to aim in the enforcement of sustainable development and eradication of poverty. The paper implies on effectiveness of the rule of law in providing sustainable development policies. It analyses the legal framework in India that contributes in maintaining economic imbalances. The paper explores the role of Indian Judiciary and the classic Judgments of Supreme Court of India. Keeping in view the importance of sustainable development and eradication of poverty, the paper contributes to explore the significance of the rule of law in achieving the objective of the nation. "Development is one of the primary means of improving the environment for living, or providing food, water, sanitation and shelter, of making the deserts green and the mountains habitable" (Indira Gandhi, 1972).

1. INTRODUCTION

The environment is a facet of every human activity. It must be protected as there are various threats and barrier. Only through sustainable development, the environment can be protected and preserved for the future generations. In the same way, the poverty, being a major challenge in a global aspect, needs its eradication for the human development. Reduction of poverty, being one of the biggest challenges in the world, is not only a developmental goal but it is an incredible challenge for a country. India is no exception for that. The fundamental precepts of human rights are violated due to poverty. Environmental protection and reduction of poverty are integral aspects of the developmental process. The extent and the depth of poverty may be linked to sustainable development in the same way as environmental degradation. The poverty may have significant repercussions for sustainable development through their linkages with social sustainability (Naushad Ali Azad, 2004). In this perspective, Rule of law, as one of the special features of good governance stand as a pillar for the growth and development of a country. It must be effective to provide conformity and enforcement mechanisms of environmental sustainability policies to achieve sustainable development.

2. PERSPECTIVES OF RULE OF LAW

The governance structure of the country is founded on the principles of democracy, equality and the principles of the rule of law (N.K. Uberoi, 2003). An outlook of A. V. Dicey's evaluation on the principle of rule of law embraces three ideals: 1) the absence of arbitrary and discretionary power on the part of government; 2) every man is subject to the ordinary law of the land administered by the ordinary and usual tribunals; 3) the general principles of law, the common law rules of the constitution. (Dicey, 1915)

The rule of law plays an indispensable role for sustainable development and poverty alleviation since it is the root cause for rapid economic growth. The very essence of the Rule of Law is that everyone is equal before the law and that fair justice must be conferred without fear or favour. It provides deference to constitutional supremacy and upholds human rights. "It is important to emphasize that the absence of arbitrary powers is the first essential of the Rule of Law upon which our whole constitutional system is based. In a system governed by the rule of law, discretion when conferred by upon executive authorities, must be confined within clearly defined limits" *(*Aeltemesh Rein, Advocate, Supreme Court of India v/s Union Of India And Others).

The rule of law plays a crucial role in sustaining constitutionalism and strengthening democracy in India. Indian democracy has been protected, enhanced and enriched by principles of rule of law (Dr. Singhvi L.M., 2002). It is enshrined in *Aritcle 14* of the Constitution of India that rightly said to be the "basic feature" of the constitution that cannot be destroyed even when amended under *Article 368* of the Constitution. There is a close network between the rule of law, sustainable development and eradication of poverty. Without adherence to the rule of law, there can be no sustainable development. Without the rule of law, there can be no protection and safeguard of human rights. In *Zahira Habibulla H. Sheikh v/s State of Gujarat*, the Supreme Court of India observed that, "the principles of rule of law and due process are closely linked with human rights protection…."

The outcome of the United Nations Conference well known as Earth Summit held in Rio de Janeiro, Brazil on 20-22 June, 2012 focused on the notion of sustainable development and eradication of pov-

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

erty has taken firm steps on this overwhelming background by implementing policies and programmes, executing and enforcement of laws and signatory to the various International and Regional Agreements on sustainable development.

3. RULE OF LAW IN PROMOTING SUSTAINABLE DEVELOPMENT

Sustainable development has various dimensions, viz., environmental, ecological, social, economic, financial, cultural, political, and so on. Here the concept is highlighted with the environmental sustainability. Raskin (1996), have defined environmental sustainability as the capacity of unimpaired persistence and the maintenance of the ecosystems and the natural resource base into the future (Naushad Ali Azad, 2004). Sustainable development is a process of encouraging economic growth while protecting the environment and improving our quality of life without affecting the ability of future generations. The original concept of sustainable development enunciated in *Our Common Future* (the *Brundtland Report*) is of "development that meets the needs of the present without compromising the ability of future generations to meet their own needs" (Honourable Justice *Brian J. Preston*, 2006). The precautionary principle, intergenerational and intragenerational equity, the conservation of biological diversity and ecological integrity, and the internalisation of environmental costs are the four fundamental elements of sustainable development. The triumph of sustainable development depends on effective functioning of the rule of law as it is a major force in the attainment of sustainability in the country.

United Nations Conference is a watershed event on environment and development, which is well known as Earth Summit held in Rio de Janeiro, Brazil on 3-14 June, 1992. *Agenda 21* is one of the Principles resulted by the conference that monitors the relationship between human rights, population, social development, women and human settlements, and the need for environmentally sustainable development. The second UN Conference, renowned to be Rio+20 held on 20-22 June, 2012 at Rio de Janeiro, Brazil, devastated the theme on sustainable development. The conference conveyed confronts of sustainable development including *Agenda 21* for its further implementation. India, through the instrument of rule of law has put its efforts in the implementation of *Agenda 21*.

3.1. Legal Framework and Role of Government

India has maintained a focus on sustainability. Significant progress has been made in major sectors like agriculture, forestry, energy, and environment. The contemporary legal regime governing the environment in India came basically in the wake of the Stockholm Conference of 1972, which required states to adopt measures to protect and improve the environment. Under this circumstance, the 42nd amendment to the *Constitution of India* was made in 1976 and thereby *Article 48A* of the Directive Principles of State Policy was incorporated that provides for the protection and improvement of the environment and the safeguarding of forests and wildlife. A Fundamental Duty was also set upon the citizens to 'protect and improve the natural environment, including forest, lakes, rivers and the wildlife, and to have compassion for living creatures' under *Article 51A (g)*. *Article 21* of the constitution provides for the Right to Life and the same has widened the interpretation by the judiciary to comprise right to clean environment. The ruling in *Maneka Gandhi v/s Union of India* made *Article 21* a residuary freedom clause. In this wave length, in *M.C. Mehta v/s Union of India,* the court has brought under the umbrella of *Article 21*, the right to clean environment (*C.M. Jariwala,* 2004).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

India has enacted various laws pertaining to environmental development. Few among them have been mentioned below:

- The *Wildlife (Protection) Act,* 1972 - A comprehensive legislation for the protection of wild animals, birds and plants and also lays down the law for the setting up of protected areas such as sanctuaries, national parks and closed areas.
- The *Water (Prevention and Control of Pollution) Act,* 1974 – Aims at the prevention and control of water pollution and of restoring the wholesomeness of water quality.
- The *Forest Conservation Act,* 1980 - Restricts and regulates the dereservation of forests or use of forest land for nonforest purposes without prior approval of central government.
- The *Air (Prevention and Control of Pollution) Act,* 1981 - Provides for the prevention, control and abatement of air pollution and explicitly states in its Preamble that the Act represents an implementation of the decisions taken at Stockholm
- The *Environment (Protection) Act*, 1986 - Protect, improve and prevent the environment, human beings, other living creatures, plants and property.
- The *Biological Diversity Act*, 2002 - Gives effect to the sovereign right of countries of origin over their genetic and biological resources and the acceptance of the need to share benefits flowing from commercial utilization of biological resources with holders of indigenous knowledge.
- The *Patents (Amendment) Act,* 2005 - Prevent misappropriation of indigenous knowledge of communities by making it nonpatentable.
- The *Forest Rights Act*, 2006 - Deals with the rights of the traditional forest dwellers.
- The *National Green Tribunal Act,* 2010 - Deals with the liability and compensation for the victims of pollution and other environmental damages.

3.2. Policies

- The National Forest Policy, 1988
- The National Conservation Strategy and Policy Statement on Environment and Development, 1992
- The Policy Statement on Abatement of Pollution,1992
- The National Agriculture Policy, 2000
- The National Population Policy, 2000
- The National Water Policy, 2002
- The National Environment Policy, 2006 shows interest in all facet of environmental development - The Policy seeks to extend the coverage and fill in gaps that exist in the light of present knowledge and accumulated experience. It does not displace, but builds on the earlier policies

3.3. Schemes and Programmes

- National Natural Resources Management System (NNRMS), 1983 was set up for optimal management of the natural resources and environment of the country using an optimal mix of remote sensing and conventional techniques.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Integrated Watershed Management Programme (IWMP) that intends to restore the ecological balance by preserving and developing degraded natural resources such as soil, vegetative cover and water.
- National River Conservation Plan
- Ecomark Scheme of India (ECOMARK) - Ecomark Labelling
- National Afforestation Programme - A Participatory Approach to Sustainable Development of Forests
- National Action Programme to Combat Desertification
- Grants in aid Scheme for Voluntary Agencies

3.4. Conventions

India is party to almost 35 International Conventions, Treaties and Protocolds. Some of them are as follows (Mohammad Naseem, 2011):

- The Antarctic Treaty, 1959.
- The Fund Convention, 1971
- Ramsar Convention on wetlands, 1971.
- Stockholm Declaration of the UN Conference on the Human Environment, 1972.
- The Convention on Migratory Species, 1979.
- Vienna Convention for the protection of the ozone layer, 1985.
- Montreal Protocol on substances that deplete the ozone layer, 1987.
- Basel Convention on Trans boundary Movement of Hazardous Substances, 1989.
- UN Convention on Biological Diversity, 1992.
- UN Framework Convention on Climate Change, 1992.
- UN Convention to combat Desertification, 1994.
- Kyoto Protocol, 1997.
- Rotterdam Convention on import of hazardous chemicals, 1998.
- Cartagena Protocol on Biosafety (Safe transfer, handling and use of Living Modified Organisms), 2000.

3.5. Judicial Perspective

In India, the judiciary has played a vital role in contributing to environmental development. The notion of Governance and the Rule of Law are basically intertwined and that the Judiciary, interacting with the human affairs as the final arbiter, has both the responsibility and the duty to dispense justice by upholding the Rule of Law (Lal Kurukulasuriya, 2003). Environmental jurisprudence is significant particularly in three aspects; (a) there is a new dimension given to the dormant procedural provisions on public nuisance as crime, (b) there has been rejection of traditional common law doctrines of strict liability, creating instead of absolute liability for hazardous and inherently dangerous industrial activities, (c) the past few years have witnessed the creation of what amount to a fundamental human right to a clean environment guaranteed under the Constitution of India (C. M. Abraham, 1999) . The following is a brief outline of the developments in the aspect of judicial facet.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

3.5.1. Right to Life

In N.D. Jayal v/s Union of India, the Court linked the concept of "sustainable development" with the "right to life" and observed:

…. the adherence to sustainable development principle is a sine qua non for the maintenance of the symbiotic balance between the rights to environment and development. Right to environment is a fundamental right. On the other hand, right to development is also one. Here the "right to sustainable development" cannot be singled out. Therefore the concept of "sustainable development" is to be treated as an integral part of "life" Article 21 of the Constitution of India." (A.K. Tiwari, 2006)

3.5.2. Access to Information

In *M.C. Mehta v/s Union of India and others (*WP (Civil) No. 860 of 1991), the Supreme Court of India, in response to a petitioner's request for issuing a court directive on the importance of public information in environmental matters, called on cinemas and video parlours to project environmental messages and films about environmental issues and requested that radio companies make programs on environment and pollution.

3.5.3. Precautionary Principle

When confronted with an action that sought to stop industries from discharging untreated effluent into agricultural fields, the Court in *Vellore Citizens Welfare Forum v/s Union of India,* called upon the government to create an authority that would address polluting industries. After announcing that the precautionary principle had become an international customary law, the Court recommended that the announced authority consider this principle.

3.5.4. Polluter Pays

The polluter pays principle has been recognized by the Supreme Court of India, in *Vellore Citizens Welfare Forum v/s Union of India,* held that "along with the precautionary principle - the polluter pays principle is a part of customary international law".

3.5.5. Public Trust Doctrine

In *MC Mehta v/s Kamal Nath & Ors,* the Supreme Court of India has applied the public trust doctrine in regard to natural resources and the environment.

3.5.6. Right to Clean Environment

The Supreme Court of India in *M.C. Mehta v/s Union of India* ordered the relocation of hazardous industries located near residential areas in New Delhi. The Court held that the citizens' 'right to clean environment' is in turn derived from the protection of life and liberty enumerated in Article 21. In *T. N.*

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Godavarman Thirumalpad v/s Union of India, Hygienic environment is an integral facet of the right to a healthy life and it would be impossible to live without a humane and healthy environment.

3.5.7. Promotion of Sustainable Development

The Supreme Court of India in *Narmada Bachao Andolan v/s Union of India* defined sustainable development in a case concerning to the construction of a dam which mean to "what type or extent of development can take place which can be sustained by nature / ecology with or without mitigation". In *State of Himachal Pradesh v/s Ganesh Wood Products,* the Supreme Court of India upheld the applicability and significance of the concept of sustainable development. The Court said:

Intergenerational equity means the concern for the generations to come. The present generation has no right to impede the safety and well-being of the next generation or the generation so to come thereafter.

4. RULE OF LAW IN COMBATING POVERTY: A MULTI-LEVEL CHALLENGE

Poverty is multi-dimensional involving number of parameters of human development and human empowerment. When compared to urban and rural estimates of poverty, confirms that, poverty in the rural areas is more severely entrenched (Naushad Ali Azad, 2004). The great Visionary Former President A.P.J. Abdul Kalam vision is that true of making India a developed country by 2020, not by adopting the age old theory of redistribution of income and wealth which has seized its relevance at least at present, but instead of it, we should adopt the policy of reduction of number of poor (Vimal Shankar Singh, Shweta Singh and Subraha Singh, 2010).

India, as a nation that has been actively associated with the global pursuit of sustainable development, is in exertion to achieve the objectives underlying the principles of Agenda 21 which is the central of planning in India. Since Independence, the country has paved the way towards social development through multi-faceted development planning, guided by the objectives of poverty eradication. The government, over the years has developing a number of programmes that aim at eradicating poverty (N.K. Uberoi, 2003).

The last few decades have made comprehensible progress in the field of economic growth and development. The development towards agriculture, industry, trade, infrastructure, banking and finance, investment, encouraging foreign investment, widening of international market, removing barriers to trade and commerce by eliminating controls over private sector. All these have outcome the growth rate in the Indian economy. The other direction to eradicate poverty was the implementation of policies, programmes and schemes emphasizing on health, education and women's empowerment. The government strived towards the achievement of UN Millennium Development Goals (MDGs) pertaining to poverty eradication.

4.1. Policies

- The *National Agricultural Policy (NAP)* seek to promote technically sound, economically viable, environmentally nondegrading, and socially acceptable use of country's natural resources to promote sustainable development of agriculture.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

- The *Food Security Policy* provides nutritional support to the poor through subsidized food grains and ensuring price stability.
- The *Industrial Policy Statement* of 1991 has been established to encourage entrepreneurship, develop indigenous technology through investment in research and development, bring in new technology, dismantle the license permit system, develop the capital markets and increase competitiveness for the benefit of the individual.
- The policy towards deregulation of *Foreign Direct Investment (FDI)* has played a major role in the economic growth of the country.

4.2. Programmes

- *National Food Security Mission (NFSM)* that aims to increase the production of rice by 10 million tonnes, wheat by 8 million tonnes and pulses by 2 million tones by the end of Eleventh Five Year Plan (2007-2012).
- *Rashtriya Krishi Vikaas Yojna (RKVY)* that seeks to achieve an annual growth rate of 4 percent in the agricultural sector during the Eleventh Five Year Plan (2007-12).
- The *Twenty Point Programme* was introduced in 2006. The programme is an umbrella package of social sector schemes and programmes that are administered by various Ministries and implemented by State/Union Territory Governments with the basic objectives of poverty eradication and improving the quality of life of the poor and the under privileged population of the country.

4.3. Schemes

- The Public Distribution System (PDS);
- Antyodaya Anna Yojana (AAY);
- The National Programme of Nutritional Support to Primary Education, also known as “mid day meal scheme”;
- The Integrated Child Development Services (ICDS);
- Annapurna;
- The National Old Age Pension Scheme (NOAPS);
- The National Maternity Benefit Scheme (NMBS);
- The National Family Benefit Scheme (NFBS).

4.4. Conventions

India is a signatory to a number of major International Conventions and Treaties on Human Rights and Sustainable Development.

- International Convention on the Elimination of All Forms of Racial Discrimination,1968.
- World Intellectual Property Organization (WIPO), 1975.
- International Covenant on Civil and Political Rights, 1979.
- Convention on the Rights of the Child, 1992.
- Convention on the Elimination of All Forms of Discrimination against Women, 1993
- World Trade Organization (WTO), 1995

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

4.5. Legal Regime

Comprehensive and landmark legislation in reduction of poverty and enabling sustainable development.

- The pillars of sustainable development are inserted in the *fundamental rights* of the Indian Constitution. *Article 21* of the constitution provides for the Right to Life and the same has widened the interpretation by the judiciary to comprise right to food, right to livelihood, right to live with dignity and other similar rights.
- The Human Rights Act, 1993, has been enacted in protection of human rights ensures justice for all.
- *People with Disabilities Act*, 1995 and the *National Trust Act,* 1999 protect the rights of the disabled and seeks to set up a national level body to ensure the welfare of the disabled respectively.
- The *Right to Information Act*, 2005 promotes transparency and accountability in the working of public authorities.
- The *National Rural Employment Guarantee Act*, 2005 aims to provide a legal guarantee of a minimum 100 days of wage employment in a financial year to every rural household.
- *The Maintenance and Welfare of Parents and Senior Citizens Act*, 2007, protecting the rights of the senior citizen to a dignified old age.
- The *Right of Children to Free and Compulsory Education Act*, 2009, has been enacted vowing to the obligation towards the youth.

The Planning Commission, being a prime bureau, periodically estimates poverty lines by conducting research and analysis on the poverty. The Planning Commission under the Chairmanship *Suresh D. Tendulkar,* known as *Tendulkar Committee* has issued poverty line.

Table 1 shows national poverty levels. According to these estimates, poverty declined at an average rate of 0.74 percentage points per year between 1993-94 and 2004-05, and at 2.18 percentage points per year between 2004-05 and 2011-12.

It is evident that the percentage of the population in poverty has been falling consistently. The *Eleventh Five Year Plan* laid great stress on implementation of the accompanying projects and programmes. The following are some important indicators (Vivek Mehra, 2013).

- GDP growth (see Table 2) in the Eleventh Plan 2007–08 to 2011–12 was 8 per cent compared with 7.6 per cent in the Tenth Plan (2002–03 to 2006–07) and only 5.7 per cent in the Ninth Plan (1997–98 to 2001–02). The growth rate of 7.9 per cent in the Eleventh Plan period is one of the highest of any country in that period which saw two global crises.

Table 1. National poverty estimates (% below Poverty Line) 1993 – 2012 (Press Note, Planning Commission, 2013)

Year	Rural	Urban	Total
1993 – 94	50.1	31.8	45.3
2004 – 05	41.8	25.7	37.2
2009 – 10	33.8	20.9	29.8
2011 – 12	25.7	13.7	21.9

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Gross domestic product (GDP) growth rate from 2005 to 2014 (Statista, 2014)

2005	2006	2007	2008	2009	2010	2011	2012	2013	2014
9.04%	9.53%	10%	6.9%	5.88%	10.09%	7.9%	4.9%	5.9%	6.4%

- Agricultural GDP growth accelerated in the Eleventh Plan, to an average rate of 3.7 per cent, compared with 2.4 per cent in the Tenth Plan, and 2.5 per cent in the Ninth Plan.
- The percentage of the population below the poverty line declined at the rate of 1.5 percentage points (ppt) per year in the period 2004–05 to 2009–10, twice the rate at which it declined in the previous period 1993–94 to 2004–05. (When the data for the latest NSSO survey for 2011–12 become available, it is likely that the rate of decline may be close to 2 ppt per year.)
- The rate of growth of real consumption per capita in rural areas in the period 2004–05 to 2011–12 was 3.4 per cent per year which was four times the rate in the previous period 1993–94 to 2004–05.
- The rate of unemployment declined from 8.2 per cent in 2004–05 to 6.6 per cent in 2009–10 reversing the trend observed in the earlier period when it had actually increased from 6.1 per cent in 1993–94 to 8.2 per cent in 2004–05.
- Rural real wages increased 6.8 per cent per year in the Eleventh Plan (2007–08 to 2011–12) compared to an average 1.1 per cent per year in the previous decade, led largely by the government's rural policies and initiatives.

4.6. The Goal and Target that Guide the Twelfth Five Year Plan (Vivek Mehra, 2013)

4.6.1. Economic Growth

1. Real GDP Growth Rate of 8.0 per cent.
2. Agriculture Growth Rate of 4.0 per cent.
3. Manufacturing Growth Rate of 10.0 per cent.
4. Every State must have an average growth rate in the Twelfth Plan preferably higher than that achieved in the Eleventh Plan.

4.6.2. Poverty and Employment

1. Headcount ratio of consumption poverty to be reduced by 10 percentage points over the preceding estimates by the end of Twelfth Five Year Plan.
2. Generate 50 million new work opportunities in the nonfarm sector and provide skill certification to equivalent numbers during the Twelfth Five Year Plan.

4.6.3. Environment and Sustainability

1. Increase green cover (as measured by satellite imagery) by 1 million hectare every year during the Twelfth Five Year Plan.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

2. Add 30,000 MW of renewable energy capacity in the Twelfth Plan.
3. Reduce emission intensity of GDP in line with the target of 20 per cent to 25 per cent reduction over 2005 levels by 2020.

5. ENVIRONMENTAL SUSTAINABILITY

Greening rural development is essential for ensuring the environmental sustainability of economic growth. Poverty reduction and economic growth can be sustained only if natural resources are managed on a sustainable basis. Greening rural development can stimulate rural economies, create jobs and help maintain critical ecosystem services and strengthen and strengthen climate resilience of the rural poor.

Greening rural development refers to five broad green outcomes:

- Improved natural resource conservation,
- Increased efficiency of resource use,
- Reduced negative environmental impacts,
- Strengthened climate resilience of communities, and
- Contribution to climate change mitigation.

The rationale for greening rural development emerges from the Twelfth Five Year Plan (2012-17) strategy of faster, sustainable and inclusive growth for poverty alleviation and to reduce rural poverty and ensure a better quality of life especially for the poor.

Sustainable use of environmental resources can contribute to growth and stability. Direct economic benefits from environmental policies will accrue mainly over the long term, green policies can contribute to short-term economic growth (World Bank, 2012). This strengthens the case for paying attention to environmental sustainability. Rural development schemes provide a strong opportunity to aggregate 'small initiatives' in several locations to improve natural capital on a macro scale. These self-governing institutions and their capacities will be key to greater effectiveness of regulatory and market instruments in ecosystem regeneration and improving natural capital. Natural capital or environmental resources are an important complement to such planned investment in achieving development goals (Ravi Chopra, 2012). The Planning Commission notes in its Approach Paper to the 12th Five year Plan that "economic development will be sustainable only if it is pursued in a manner which protects the environment. With acceleration of economic growth, these pressures are expected to intensify, and we therefore, need to pay greater attention to the management of water, forests and land (Planning Commission, 2011. pg 10).

Sustainable development has been embedded in the planning process of the country since the 1990s. The Ninth Five-Year Plan (1997–2002) explicitly recognized the synergy between environment, health and development and identified as one of its core objectives the need for ensuring environmental sustainability of the development process that also promote sustainability of economic growth. India's planning focuses on development that strives for improvement in the standard of living and quality of life of the people. The period after the 1992 Earth Summit saw the introduction of various government programmes and schemes to address sustainability concerns as discussed in earlier sections. A list of key programmes along with the recent budget allocation is presented in Table 3 (Ministry of Environment and Forests, Government of India, 2011).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

5.1. Expenditure on Sustainability Programmes (in INR Million) (Ministry of Environment and Forests, Government of India, 2011)

1. Mahatma Gandhi National Rural Employment Guarantee Scheme (MGNREGS) – 401000
2. National Rural Livelihood Mission/Swarna Jayanti Gramin SwarojgarYojana (SGSY) – 26830
3. Indira Awas Yojana – 93335
4. Renewable Energy for Rural Applications – 1620
5. Renewable Energy for Urban, Industrial and Commercial Applications – 370
6. Jawahar Lal Nehru National Urban Renewal Mission (JNNURM) – 200
7. Swarna Jayanti Shahari National Rural Health Mission (NRHM) - 135402.6
8. Forest Conservation, Development and Regeneration - 567.3
9. National Afforestation and Eco-development Programme – 2530
10. Prevention and Control of Pollution – 8075

5.2. Judicial Reform

Human rights provide a framework for poverty eradication. Poverty at the same time is the cause and the consequences of the human rights violations. Applying to human rights perspective to poverty establishes a relationship between strategies to fight against poverty. The Public Interest Litigation has provided broad access to justice and judicial redress to all persons that are in a position of poverty (Maritza Formisano Prada, 2011)

The judiciary set forth in eliminating poverty and upholding the human rights by means of exerting the right to life of the citizens. The programme on "National Conference of High Courts on Poverty Eradication, Combating Social Exclusion and Advancing Social Justice: Role of Courts", organized at National Judicial Academy, Bhopal on October 24-25, 2009 aimed at the idea of social justice and alleviation of poverty, mainly focusing on Poverty related challenges (Court News, 2009).

While hearing to a Public Interest Litigation case (People's Union for Civil Liberties (PUCL) *vs*. *Union of India* and *Others),* on the right to food filed by People's Union for Civil Liberties (PUCL), the court heard the PUCL's lawyer, Colin Gonsalves, who had brought a report published in the *Hindustan Times* ("India lets grain rot instead of feeding poor", *HT*, July 26, 2010) to the court's attention. The Court held that, it was a crime to waste food in a poor country. The Court criticized Additional Solicitor General Mohan Parasaran: "If you cannot store the grain, give it to the people to eat (The Hindu, 9th August, 2010)." The right to food can be seen as an implication of the fundamental "right to life", enshrined in *Article 21* of the Constitution. *Article 21* should be read with *Articles 39(a) and 47* to understand the nature of the obligation of the State in order to ensure the effective realization of this right. *Article 39(a)* enunciated as one of the Directive Principles, fundamental in the governance of the country, requires the State to direct its policy towards securing that the citizens, men and women equally, have the right to an adequate means of livelihood. *Article 47* spells out the duty of the State to raise the level of nutrition and the standard of living of its people as a primary responsibility. An interim order focused on eight food related schemes, viz., PDS, AAY, National Programme of Nutritional Support to Primary Education (mid-day meal scheme), ICDS, Annapurna, NOAPS, NMBS and NFBS.

Essentially, the interim order converted the benefits of these eight "schemes" into legal entitlements. The government should be held accountable to what it claims to be doing to protect the right to food, i.e.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

implement these food related schemes. It also directed the government to replace monthly "dry rations" of grain with daily, cooked midday meals. The Court Orders further for:

1. Identification of BPL families,
2. Accessibility of ration shops and regular supply of grain, and
3. Permission to buy in installments

The judiciary also shines in protecting human rights. In *Coralie v/s Union Territory of Delhi*, court observed:

We think that the right to life includes the right to live with human dignity and all that goes along with it, namely, the bare necessaries of life such as adequate nutrition, clothing and shelter over the head and facilities for reading, writing and expressing one self in diverse forms, freely moving about and mixing and commingling with fellow human beings. (Brinder Pal Singh Sehgal, 2008)

The Supreme Court of India in *Anthony v/s Bihar Gold Mines Ltd.,* has interpreted *Article 21* with the principles enshrined in *Article 39(a)*. "The sweep of the right to life conferred by Article 21 is wide and far reaching.…An equally important facet of that right is the right to livelihood because, no person can live without the means of living, that is, the means of livelihood. *If the right to livelihood is not treated as a part of the constitutional right to life, the easiest way of depriving a person of his right to life would be to deprive him of his means of livelihood to the point of abrogation*. Such deprivation would not only denude the life of its effective content and meaningfulness but it would make life impossible to live…."

6. CONCLUSION AND SUGGESTION

Even though the progress has been made by the principle of the rule of law in enhancing substantial development and reduction of poverty in innovative ways, there are many manifestations of these problems such as high growth of population, the food disaster, unemployment, inequality and so on. Hence, there is a need to overcome such challenges and threats. The rule of law will exert in resolving these impediments. India is a signatory to the various International and Regional Agreements on sustainable development. Currently, the upshot of many policies, programmes, various laws, agreements and the contribution of judiciary illustrates the development of sustainability. However, vibrant judiciary is essential in furtherance to uphold the rule of law. Chief Justice, R.K.Agrawal, Madras High Court, has divulged in his speech on "Rule of Law and Access to Justice" that,

…due to a poverty 'access to justice' has remained elusive to the masses. The Government, in its welfare role, has tried to alleviate poverty through various schemes. Yet, the enforcement of these rights often requires the intervention of Courts. The role of Indian Courts ensures greater 'access to justice' through 'Public Interest Litigation' and other procedural innovations.

Nevertheless, poverty is a great threat to the political fidelity. Indeed, focus must be enhanced to greater extent for sustainable development. Efforts must be made by implementing and enforcing innovative laws. Legal reform and judicial interference is very much important for comprehensive develop-

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

ment. Steps must be taken to remove barriers in the development. Struggle must be made to convene the prospective between the different policies and programmes, to avoid the leakages to ensure the fruits of the schemes that reach the beneficiaries, adoption of innovative approaches to environmental regulation and to improve the technical and managerial skill. Ultimately, the rule of law must work in progress in order to well-build the incentives and regulatory framework with relevance to reduction of poverty and sustainable development. The developmental Planning must aim at the reduction of poverty line from the grass root level. The perfection must be in overall system of the government, central, state or local bodies. Coordination is an imperative for efficient public delivery and effective functioning of the politico-administrative machinery in the country. To attain sustainability and reduction of poverty, it is thus only possible with the effective enforcement of the rule of law which is a cornerstone in upholding human rights. Certainly, the rule of law is vindicated by judicial independence.

ACKNOWLEDGMENT

The paper presents the small anthology of evaluations that identifies positive outcome of the rule of law in its impact on sustainable development and reduction of poverty. The author in his honest endeavor and persistent effort to do the maximum possible to this article, he owes his sincere thanks to many who are directly and indirectly associated. With immense respect and privilege, the author record his deep sense of gratitude to his guide *Dr. N. Dasharath,* for the guidance, encouragement and support that has lead to the progress in his work. The author expresses the heartfelt gratitude to the *Conference Team of TIIKM* for their encouragement, support and hospitality. The author acknowledges the gratitude straight from heart to Isanka P Gamage, Conference Secretariat, ICPSD 2014, for providing valuable opportunity to participate in the "International conference on Poverty and Sustainable Development, Colombo (ICPSD 2014), Srilanka".

Chapter 56
Are University Lecturers Literate in Sustainability?

Noora Kokkarinen
Liverpool John Moores University, UK

Alison J. Cotgrave
Liverpool John Moores University, UK

ABSTRACT

An extensive body of knowledge exists about students and education for sustainable development; though very little can be found for educators. This chapter will review existing literature and relate how it is relevant for educators to be sustainability literate in order to promote the skill among students. A purely qualitative approach was used for this study. Eleven lecturers were interviewed in order to ascertain their level of sustainability knowledge. The interview transcripts were analysed using phenomenography. Findings indicate that built environment academics were particularly literate in sustainability matters. Recommendations as to how other institutions can assess the sustainable literacy level of educators are made.

INTRODUCTION

Sustainable development education has been the focus of much research (Pappas, 2012; Murray, 2011; Wright, 2010; Sibbel, 2009; Murray and Cotgrave, 2007; Cotgrave and Alkhaddar, 2006; Reid and Petocz, 2006; Thomas, 2004); largely due to the United Nations decade of education for sustainable development as well as the worldwide attention sustainability has been given.

The most cited definition of sustainable development comes from the United Nations World Commission on Environment and Development (WCED, 1987) Brundtland Report which states that "sustainable development seeks to make sure that developments meet the needs of the present without limiting future generations from meeting their needs". However other ways of defining it exist. The 'triple bottom line' considers sustainability in environmental, economic and social terms (Hueting and Reijnders, 2004; Murray, 2011). Whereas Faber, Jorna and van Engelen (2005, p. 5) suggested that "sustainability refers to an equilibrium between an artefact and its supporting environment, where they interact with each other

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

without mutual detrimental effects". Although there are numerous definitions for sustainability, (WCED, 1987; Leal Filho, 2000; Hueting and Reijdners, 2004; Faber et al., 2005; Atkinson, 2008; Shepherd et al*.,* 2009; Murray 2011) the basic premise of all of them appear to be how sustaining the well-being of living systems can be achieved over time (Moore, 2005; Atkinson, 2008). It would therefore be safe to say that there will likely never be a universal definition for sustainability as it means different things to different people (Mann, Dall'Alba, and Radcliffe, 2007). The authors argued that a reason for that is that people's understanding is influenced by their own background, work experience, previous training and their views on political and economic aspects.

The UK government has passed legislation such as the Duty of Care which places the responsibility of appropriately disposing of waste to those that are in contact with materials, including producers and importers (Dainty and Brooke, 2004). It has also published reports such as the Office of Government Commerce which provided details as to how the construction industry can achieve sustainable procurement (OGC, 2007; Cotgrave and Kokkarinen, 2010b). Research conducted by Cotgrave and Alkhaddar (2006) found that final year students did not possess in-depth knowledge regarding environmental or sustainable issues when holding presentations on the subject. The following year Murray and Cotgrave (2007) wrote that the Sustainable Development Education Panel (SDEP) proposed that all professional bodies should incorporate sustainability in their course accreditation criteria. As observations like this have still been made even with government and professional body involvement, it emphasizes the need to educate people on sustainable development, particularly in higher education, as this is most often the last chance people have to gain full theoretical knowledge before being able to practically apply that knowledge in a job.

The influence that sustainable development education has on students has been researched as they will have the potential to endorse sustainable practices in the industry once they obtain their degree. In spite of this, the community, industry and university groups have a limited knowledge of how educators at university level understand and incorporate the concept of sustainability in their teaching (Reid and Petocz, 2006).

Studies promoting sustainable development education in students have proposed educational theories such as collaborative and transformational learning (Moore, 2005). A central tenet for collaborative learning is that students from many disciplines work together to build their knowledge and understanding on a subject matter. The assumption for this type of learning is that every discipline has something to contribute towards this production of knowledge (Moore, 2005). Transformational learning is when learning changes problematic frames of reference into ones which are more reflective, inclusive and emotionally able to change (Moore, 2005; Dirkx, Mezirow and Cranton, 2006). This means that an opinion changes once enough knowledge is gained which challenges the previous point of view that was held by an individual.

If academics are found to have a deep knowledge on sustainable issues, knowledge on collaborative and transformational learning might enable them to think of different educational tasks by which to encourage transformational learning to occur amongst their students. Not only that, but academics themselves could benefit by applying certain principles from these theories into exchanging ideas with other members of staff regarding their knowledge on sustainability as this may vary from subject to subject. As sustainable development means different things to different people, incorporating collaborative and transformational learning theories to form a new understanding of what sustainability means, particularly in the built environment, which reflects the knowledge of each academic in every discipline is needed.

In addition to sustainable development education, sustainable literacy is another component which has been heavily researched (Thomas, 2004; Murray and Cotgrave, 2007; Fortuin and Bush, 2010; Murray, 2011). By being sustainability literate, individuals would have the right values, knowledge and skills to have a significant impact in securing the future (Murray, 2011). It is a skill that is believed to give graduates the ability to apply sustainable principles and practices in their careers after obtaining their degree and perhaps even in their personal lives. Sustainability literacy is a learning outcome that is expected to arise after successful sustainable development education. Even so, it should also be considered a skill set that is correspondingly required by educators to possess in order for students to gain it as a skill.

This chapter will attempt to address what Reid and Petocz (2006) pointed out that there is a need to understand the way in which educators themselves understand sustainability in a discipline-specific way. In this particular case study, the understanding of academics from the built environment will be explored through a qualitative research design. The objectives are to find out how sustainability literate lecturers are by having them describe in their own words how they understand sustainability as well as how they see sustainability benefitting their discipline. Academics will be asked to consider whether there are any potential barriers they see affecting the assimilation of sustainability knowledge by students.

ORGANIZATION BACKGROUND

Following a Research Assessment Exercise (RAE) conducted in 2008, the School of the Built Environment at Liverpool John Moores University (LJMU) was ranked first among post-1992 universities in the United Kingdom based on the quality of research produced (Higher Education Funding Council for England, HEFCE, 2012).

LJMU's School of the Built Environment offers undergraduate courses in seven areas which are: Architectural Technology, Building Services Engineering, Building Surveying, Civil Engineering, Construction Management, Quantity Surveying and Real Estate Management. Additionally, the school has several post-graduate programs as well as a doctoral research department. Most programs can be studied full- or part- time while in some cases distance learning is offered. Throughout all of these programs, sustainability is promoted to some extent, in a way that most appropriately addresses each course of study.

When studied full-time, most undergraduate studies last three years in UK universities. These comprise of level four for first year students, level five for second year students and level six for final year students. For the purpose of this study, academics who taught Civil Engineering students were not interviewed because Civil Engineering students did not partake in an educational intervention which followed the interviews of academics.

SETTING THE STAGE

UNESCO declared 2005-2014 to be the Decade of Education for Sustainable Development. In a similar vein, business leaders and national governments have been trying to promote sustainable practices with the help of international agreements or transparent business plans (Murray, 2011). Thus far however, the desired level of effect has not been reached as more and more sustainable development initiatives are being devised. This begs the question whether they are meant to take the place of already existing ones or whether a new approach is being implemented if older ones have not yielded expected results.

Recognising the barriers facing consumers to making sustainable choices shifts the focus to the training of professionals who manage the resources, educate the public or design the options from which choices are made. The institution of higher education is where these professionals are trained. In fact, many argue that the higher education sector bears a significant responsibility for sustainability by virtue of its influence on society and academic freedom to explore ideas (Sibbel, 2009, p. 74; Wright, 2010; Pappas, 2012).

Barraza and Robottom (2008) noted that education for sustainable development directs educational tactics to promote, understand and implement sustainable development through bringing together seemingly discordant ideas of conservation and development. Although what Sibbel (2009) postulates is valid, the assessment of skills should be done for those who are meant to teach future professionals. Notable barriers that have been identified in incorporating sustainability into higher education are the lack of experts in sustainability (Kokkarinen and Cotgrave, 2010a). Many academics may already have other areas in which they teach and therefore do not have the time to attend training courses to update their sustainability knowledge consequently passing on information that is out of date to their students (Thomas, 2004; Velázquez, Munguía, and Sánchez, 2005; Sibbel, 2009; Kokkarinen and Cotgrave, 2010a).

Educational theories support sustainable development education by promoting collaborative learning in which students work together to build their knowledge and understanding on a subject matter (Moore, 2005). Transformational learning is another theory in which the learning of new information changes a previous frame of reference that a person has had (Moore, 2005; Dirkx et al., 2006). The focus of this theory in most cases has been to understand adult learning but it has also been used in higher education: "abstract and idealized, grounded in the nature of human communication" (Dirkx et al., 2006; Taylor, 2007; p.173). Aspects of the theory are rooted into developmental stages but most of the theory focuses on the understanding of the process of using a previous notion to devise a new or revised interpretation of meaning of an individual's experience in order to direct future action. Moore (2005) gave the example of critically reflecting on consumption patterns and production and how this knowledge may impact a persons' own consumptive behaviour.

Theories such as these are helpful in directing educational efforts to help students understand sustainability yet an area that has been overlooked has been the role that academics have in educating university students about sustainability. More importantly it raises the question as to whether they have the necessary knowledge on such a complex notion. If academics were to implement collaborative or transformational learning into teaching their students, they could make use of certain principles from these theories to improve their own knowledge on sustainability by seeking to exchange ideas and information with other colleagues.

Marton (2007) described a theory of learning which was based on a phenomenographic approach in which teachers thought critically about how they present teaching materials and what they have to do to make sure that students can easily learn from what is presented to them. Phenomenography is defined as a research method that describes the qualitatively different ways in which phenomenon is experienced, conceptualized or understood, based on an analysis of accounts of experiences as they are formed in descriptions (Hasselgren and Beach, 1997). While transformative learning uses different methods to change an individual's perspective, the content which transformational educators teach is no different from what non-transformational educators teach (Dirkx, 1998). Transformative learning can be periodic or augmentative and can involve objective or task-oriented as well as subjective (self-reflective) reframing (Dirkx et al*.,* 2006). In most cases the support from others is needed in order to fulfil subjective

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

reframing (Dirkx et al., 2006). Therefore elements such as group work and having a reflective element to it may help promote transformational learning experiences. Moore (2005) pointed out that new models of interdisciplinary education promote teamwork exercises. However, she continued by stating that these aims are difficult to implement in current curricula as the focus is on marking the individual, hence making the implementation of transformative learning more difficult. Moore (2005) noted that academics have freedom in both teaching and research, yet few engage in different methods of teaching, nor do they emphasise the intended learning outcome of social change. A phenomenographic approach is particularly useful in trying to assess whether a transformative learning experience has taken place in an individual as it allows analysis of experiences that happened prior to and after the fact.

Sustainable literacy is another component that is often researched (Thomas, 2004; Murray and Cotgrave, 2007; Fortuin and Bush, 2010; Murray, 2011) and could be described as a learning outcome for sustainable development education. It is a skill that will give graduates the ability to apply sustainable principles and practices in their careers after obtaining their degree in order to move the sustainable development agenda forward. Even the United Kingdom's Sustainable Development Strategy has mentioned the need to instil this competency into professional graduates (DEFRA, 2005, p. 39), "we need to make 'sustainability literacy' a core competency for professional graduates". While it is clear that mechanisms to help students gain an understanding of sustainability are in place, there appears to be little work on the skills educators should have in order to teach sustainability effectively.
