Reid and Petocz (2006) explored the kind of sustainability conceptions that academics from multiple disciplines held and what efforts they made in trying to integrate sustainability into their lesson plans. The academics that were interviewed were not from environmental science disciplines. This resulted in the conclusion that their conceptions and experiences of sustainability differed greatly from the conceptions and experiences which lecturers who are familiar with sustainability have expressed. Particularly, Reid and Petocz (2006) asserted that the range of explanations given by interviewees did not match the rhetoric that sustainability experts would use to describe sustainable development issues. Despite these findings, their work is noteworthy as it is one of the only available publications which attempted to assess the sustainability knowledge of educators-providing support to the fact that an equal, if not more attention should be paid to their capabilities and knowledge than those of students.

In order to address the lack of research regarding the role of the educator, this chapter will outline a case study which qualitatively assessed the sustainability knowledge that academic staff in LJMU had on sustainability.

CASE DESCRIPTION

Eleven academics from LJMU were interviewed using a semi-structured interview schedule. The reason why the sample size was so small is because these academics were the module or program leaders, thus having the most involvement in creating the material and choosing the topics that are covered in lectures and tutorials.

An interview schedule containing 11 questions was developed based on several articles and issues which had been identified through existing literature (Dirkx, 1998; Mezirow, 2003; Moore, 2005; Dirkx et al., 2006; Taylor, 2007; Wright, 2010). The questions intended to gain academics' understanding about sustainability, any barriers they thought would inhibit the inclusion of sustainability in the courses and

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

lastly, questions regarding transformational learning were asked to see if academics believed that this would be an effective way of promoting sustainability knowledge (Taylor, 2007; Wright, 2010). Table 1 contains a selection of the questions included in the interview schedule.

Each interview lasted between 30 and 60 minutes. In the case that respondents did not understand the question that was being asked, the researcher clarified what was meant. The interviews were transcribed verbatim by a third party who specializes in transcription. The interview transcripts were checked by the authors to make sure that the audio recording coincided with what was written. This then allowed for manual qualitative analysis to take place.

In line with previous research (Moore, 2005; Mann et al., 2007), phenomenography was deemed the appropriate method to analyze the data because its origins lay in investigating learning among university students, although it has also been applied to understanding the experience of teaching; which this case study intends to convey (Hasselgren and Beach, 1997; Mann et al., 2007). "Phenomenography takes a second order approach, as it is the experiences of others rather than that of the researcher, which are the base of the investigation" (Mann et al., 2007, p. 7).

Phenomenography emerged in the 1980's in Gothenburg as a research approach that describes people's experiences. These types of experiences have covered elements such as the experience of teaching and learning as well as the ways of experiencing the learned content (Mann et al*.,* 2007). Experience is defined as non-dualistic because internal relationships exist between the participant and world (Hasselgren and Beach, 1997; Giorgi, 1999; Mann et al., 2007). It therefore does not take a positivist or objective approach which is free of human interpretation yet it does not rely on a subjectivist approach either (Mann et al., 2007). Hasselgren and Beach (1997) summarised the history of phenomenography as a method which described qualitative differences in the ways in which a phenomenon is experienced, understood or conceptualized.

Qualitative analysis often relies on an inductive approach through the use of thematic networks. Inductive, because the transcripts allow for broad generalizations to emerge from specific anecdotes rather than having to deduce what the specific conclusions were from general data (David and Sutton, 2011). Thematic networks explain the understanding of an issue by making connections between the statements that people make and the meaning they are trying to impart through conversation, or discourse (Attride-Stirling, 2001). A systematic extraction method was proposed by Attride-Stirling (2001) which firstly includes identifying basic themes which are key words immediately found in the text. This is then followed by grouping basic themes together which summarize abstract principles forming organizing themes. Finally, after the organizing themes are found, they too are regrouped to form global themes which in turn are the umbrella terms for the overall content that the interview covered.

Table 1. A selection of questions included in the interview schedule

Questions
1. What does the term sustainable/sustainable development mean to you?
3. What, if any barriers do you see preventing the module or program from engaging in sustainability initiatives?
5. Do you foresee different barriers and challenges in the future?
9. Do you think the promotion of sustainability in the construction industry (once students graduate) will be more likely to happen if the students have a transformative experience through educational interventions/increased sustainability knowledge while at university?

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

The manual analytical process began by reading the transcriptions several times to become familiar with their content and to think of the transcripts as a whole set (Mann et al., 2007). Open, inductive coding (David and Sutton, 2011) was used in the first instance. Key words and phrases were highlighted from every line of dialogue that the interviewee gave and a note of it was made on paper. Once open codes had been created for each interview transcript, the notecards were grouped together where similar individual meanings were mentioned. The similarities within and differences between groups were then clarified (Mann et al., 2007). These essentially formed the organizational themes which Attride-Stirling (2001) mentioned. This was followed by a further regrouping of the themes and a description was written for each category which emerged using quotes from the transcripts to support the description of each umbrella term. Examples of these will be outlined in the solutions and recommendations section of the chapter.

Mann et al. (2007) emphasized that the first attempt of forming categories would not be final and is likely to change but it provided the researcher with a different way by which to see the data and allow for further categories to be developed. Once the final categories were identified, they were organized into a hierarchy of increased comprehensiveness. It is this hierarchical representation which is referred to researchers as the outcome space (Loughland et al*.,* 2002; Mann et al., 2007).

In order to ascertain whether the categories which the researcher came up with seemed valid, the differences were discussed with other sustainability experts for their thoughts on the logic behind the categories. The overall cohesiveness of these groupings and implications were also discussed with others demonstrating that the analysis of the data was triangulated (Kitto, Chesters, and Grbich, 2008). David and Sutton (2011, p. 637) described triangulation as "approaching the same topic from a number of different approaches. Triangulation may involve the use of more than one researcher or research team, more than one round of data collection, different types of data collection, or different theoretical frameworks". Denzin (1978 as cited in Burke Johnson, Onwuegbuzie, and Turner, 2007) considered the use more than one researcher to discuss final conclusions as investigator triangulation.

CURRENT CHALLENGES FACING THE ORGANIZATION

Construction programs are accredited by professional bodies in the United Kingdom. It is often the requirements of these professional bodies that dictates the material or subject areas that each course should focus on, so that students are able to become fully charted members once they graduate and begin work. Therefore a challenge facing not only Liverpool John Moores University, but all UK universities is the fact that the requirements set by professional bodies are vague, leaving universities to interpret and implement sustainability requirements by themselves; resulting in each university having its own way of addressing the topic, which may cause discord when students become professionals.

The Royal Institute of British Architects (RIBA) accredits architectural programs. Their validation procedure outlines that sustainability should be understood through the legal framework specifically in relation to "environmental and sustainable legislation" which are relevant to architectural design and construction (RIBA, 2011, p. 56).

The Chartered Institute of Architectural Technologists (CIAT) accredits architectural technology programs. When reviewing the benchmark statement, sustainability was only mentioned in relation to the design of the course so that the needs of industry and the profession are typically met stating that the program should "emphasise the value placed on detailed design, health and safety and production

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

information, including technical regulatory factors affecting buildability, sustainability and performance" (Quality Assurance Agency, 2007, p. 2).

The Royal Institution of Chartered Surveyors (RICS) accredits real estate, building and quantity surveying courses. According to a review conducted by Murray and Cotgrave (2007), the RICS states the need to address sustainable development education but did not propose any formal requirements by which to achieve it.

The Chartered Institute of Building (CIOB) mostly accredits construction management programs. In their educational framework, the CIOB is keen to promote knowledge and awareness of sustainable design and construction to future construction professionals. For undergraduate programmes, the framework mentions environmental sustainability, but at masters level sustainability is focused on much more in depth (CIOB, 2007).

As can be seen from the statements of the above professional bodies, sustainability is mentioned; but a solution as how to achieve or promote it is not offered. The effect of this is potentially that educators of built environment courses are unable to determine what elements of sustainability they should know themselves, and pass on to their students. It is feasible that other areas also face similar problems from their respective governing bodies.

SOLUTIONS AND RECOMMENDATIONS

The results from the phenomenographic analysis revealed that academics at LJMU were very aware of sustainability and the importance of it in built environment curriculum. Analysis demonstrated that the outcome space for sustainability was understood in a hierarchy of five tiers. These were built environment and construction practices, economic and financial aspects, social aspects, usage implications and future proofing.

The hierarchy of these categories firstly reflected that all of the interviewees thought about sustainability in terms of their primary role- as built environment practitioners and educators. From the time that they have learned the core skills of their given topic areas, they have picked up sustainability knowledge and have internalized it in a way which could be practiced in their fields: *"it means inception of an idea, and planning it and building it and then maintaining it… building will last and be pleasant for people to use". "…means longevity of not just the construction or the techniques of the processes. It means a sustainable asset which will endure through its occupation".*

Secondly, LJMU lecturers saw sustainability as a possibility to enhance the financial or economic status of the construction industry either by entering new markets or adding value to property: *"Asset… ability to have an economic return for a long period of time".*

The third level related to social aspects of sustainability. Whatever is constructed, such as buildings or offices, need to benefit its occupants and society at large such as *"sustainable communities"*. They should serve a purpose for as long as possible.

Environmental aspects were mentioned in a specific way: resource use which was the fourth level in the hierarchy. Central to sustainability are three aspects: economic, environmental and social (Hueting and Reijnders, 2004; Murray, 2011). This concept was reiterated in the understanding of interviewees as they gave examples of what their respective built environment field could experience as sustainable. Such things included minimizing the use of resources, or saving them for future generations. It was implied that sustainability was an umbrella term for anything relating to environmental protection. However when

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

further immersing into the transcripts this implication about resource use, energy consumption related to economic and social aspects as well. "*Safeguarding our existing resources and making the best use of our existing natural resources for the future". "Has longevity in relation to economic and functional use".*

The fifth and final category as to how lecturers understood sustainability could be summarized as future proofing. Buildings that are constructed need to reflect sustainable know-how. An implicit concern became evident from the interview transcripts as the amount of knowledge to be able to make appropriate decisions was expressed. It was mentioned that more information on sustainability would improve values and parameters. This knowledge should be used to make the correct decision for the relatively immediate benefit of present generations but also endure for the use and benefit of future generations. The Brundtland report and the famous definition was mentioned in relation to future proofing as it seeks to ensure that present and future generations have their needs met. This was also expressed by other respondents but they did not call the report by its name. Terms such as *"longevity"* resonates with this category as it was mentioned several times that buildings should last a long time.

During the interviews, none of the academics mentioned barriers which had been highlighted by previous research such as lack of experts in sustainability or lack of time or training opportunities. Instead, the barriers they identified regarded issues of knowledge and finance. Knowledge seemed to be a potential barrier. *"How much information students have had when they arrive to undertake this project"* and where will students' sustainability knowledge fit in professional practice: *"It could be that the younger people in the profession might be challenging the…more established…perceptions."*

On the whole however, economic factors were considered quite a barrier amongst all academics. These included funding, understanding financial return and its associations with sustainability and environmental protection. *"At the moment sustainability is just seen as a marketing tool and therefore the barrier with our students is making them see the link that sustainability has for enhanced asset value and improved growth in rentals and capital." "Building Surveying students have to understand that their decisions have a commercial effect as well as an environmental one. So that's always the barrier in the challenge between the two."*

Questions regarding transformational learning had to be clarified to a few of the interviewees. This was done by giving the example of students who had completely changed their mind about sustainability in a positive way after having learned more about the subject. Once this clarification was made, all academics fully understood the question. This led to eight out of eleven academics saying that transformational experiences would promote student learning, while two said no and one did not answer. A particular interviewee described witnessing transformational learning experiences and believing they are a central part of promoting learning about sustainability by stating: *"I'm absolutely positive because I've already seen it happen in a number of initiatives for the last couple of years. Just individual initiatives from staff and students who are looking for challenges in terms of their overall research project and their dissertation."*

Although only one academic mentioned a clear example of transformational experiences happening to students because they had seen it first hand, others described the kinds of methods they were using in order to promote transformational experiences such as taking them on site visits and guest lectures from practicing professionals: *"We try to bring in people from industry to help them understand and to see the application of a theory in waste management, in planning, in things like that".*

"Yes, yes that is important…the students are going to visit the BRE [Building Research Establishment] *Innovations Center at Watford. Looking specifically at the promotion and trying to give the*

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

students some sort of experience in sustainability. In other words, trying to broaden their knowledge of this particular matter".

"…if you give a student an idea, let's say we take them to BRE and they see how these houses are operating…you sow the seeds, those seeds will eventually get back into industry…"

"I'm sure the students will respond in different ways… But even if it's just a small number you know that small number is replicated on RICS [Royal Institute of Chartered Surveyors] *courses across the country…"*

As the academics mentioned that they did not foresee any barriers affecting sustainability being learned by students, it could be inferred that this particular cohort of built environment academics are particularly literate in sustainability. Academics were able to describe the benefit that sustainability had in relation to their own field in quite a lot of detail. Contrary to what Reid and Petocz (2006) found, the academics who were interviewed at LJMU were very aware of sustainable issues and were able to use fairly elaborate yet specific explanations and definitions when describing their conceptions of it. Although not an environmental subject as such, it appears as though the built environment is hugely aware of its impact on nature and resource use, therefore being an appropriate subject area to promote sustainable development education.

This qualitative assessment of the level of sustainability knowledge that academics have at LJMU gave a certain degree of confidence that they have a firm grasp on the notion and are able to deliver sustainability knowledge to students in relation to their field of study. Although the decade of education for sustainable development is coming to an end, it has left a good legacy of not only what works to promote sustainable literacy among learners, but to also focus on the skill level that is needed by the educators themselves. It must be noted however, that the group of eleven academics that were interviewed was a very small sample size, and therefore the positivity that was expressed by this cohort may not be representative of the overall attitude of built environment academic staff. This may partly be due to the fact the LJMU is a supporter of the sustainability agenda and its promotion throughout the university.

FUTURE RESEARCH DIRECTIONS

The aims of this case study were met as built environment academics explained in their own words what sustainability and sustainable development mean to them and the benefit sustainability could have within their discipline. Academics were also asked about any potential barriers they felt may hinder the incorporation of sustainability into teaching but none of the barriers that had been identified through the literature review were mentioned (Thomas, 2004; Velázquez, Munguía, and Sánchez, 2005; Sibbel, 2009; Kokkarinen and Cotgrave, 2010a).

The eleven academics that were interviewed possessed a significant amount of knowledge regarding sustainable development and provided detailed anecdotes as to how sustainability was relevant in their discipline, something that Reid and Petocz (2006) did not find in their study. Academics were also very specific in the way that sustainable development had been incorporated into the courses that they taught as well.

The use of a phenomenographic approach provided a far detailed report than had this case relied upon a quantitative approach. Through the use of semi-structured interviews the experience of how built environment academics experience sustainable development and as a result, how much knowledge they

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

are able to pass on to their students was identified. What is particularly remarkable is that the different ways in which sustainability was experienced was then condensed into an outcome space which described five levels of understanding that could be expected from other built environment academics (Hasselgren and Beach, 1997; Mann et al., 2007). The findings reported here could serve as a benchmark to other built environment institutions wanting to compare the knowledge possessed by their staff. In a similar vein, this process could easily be adapted to suit other disciplines that would also like to understand their level of sustainability literacy. This could be done by keeping the questions generic to gauge levels of knowledge and allowing interviewees to elaborate further if they believe they engage in sustainable practices to some extent (Reid and Petocz, 2006).

Promoting sustainable development is a chain reaction of knowledgeable educators influencing students who are likely to become sustainable construction professionals in the near future. Therefore other educational establishments may find it beneficial to take stock of the knowledge that educators possess in order to ascertain whether there is a good chance of students walking away with a sound understanding of sustainability and how to encourage sustainable development. This could be achieved by holding appropriate refresher or training courses for the level of knowledge that is lacking or needs improvement.

Chapter 57
Energy Cost Saving Tips in Distributed Power Networks

Alain Tcheukam Siwe
New York University, USA

Hamidou Tembine
New York University, USA

ABSTRACT

This chapter studies energy cost saving strategies in power networks. A prosumer is a user that not only consumes electricity, but can also produce and store electricity. Three tips are considered: distributed power network architecture, peak energy shaving with the integration of prosumers' contribution and prosumers market. The proposed distributed power network architecture reduces significantly the transmission costs and can reduce significantly the global energy cost up to 42 percent. Different types of prosumer who use self-charging renewable energy systems, are able to intelligently buy energy from, or sell it, to the power grid. Therein, prosumers interact during the purchase or sale of electric power using a double auction with negotiation mechanism. Using a two-step combined learning and optimization scheme, each prosumer can learn its optimal bidding strategy and forecast its energy production, consumption and storage. Our simulation results show that the integration of prosumers can reduce peak hour costs up to 17 percent and 6 percent for eligible prosumers.

INTRODUCTION

As energy efficiency and clean energy technologies become more common, system challenges require to rethink traditional paradigms of energy system planning and operation. Historically, central plants have been an integral part of the electric grid, in which large generating facilities are specifically located far from populated load centers. These, in turn, supply the traditional transmission and distribution grid that distributes bulk power to load centers and from there to consumers. Nowadays, distribution generation technologies have open the door to decentralized or distributed power network management systems. For

reasons of reliability, distributed generation resources would be interconnected to the same transmission grid as central stations. Various technical and economic issues will occur in the integration of these resources into a grid. Technical problems arise in the areas of power quality, voltage stability, harmonics, reliability, protection, and control. Behavior of protective devices on the grid must be examined for all combinations of distributed and central station generation. A large scale deployment of distributed generation may affect grid-wide functions such as frequency control and allocation of reserves. As a result smart grid functions, virtual power plants and grid energy storage such as power to gas stations are added to the grid. At the energy market, Wholesale transactions (bids and offers) in electricity are typically cleared and settled by the market operator or a special-purpose independent entity charged exclusively with that function. Market operators do not clear trades but often require knowledge of the trade in order to maintain generation and load balance. The commodities within an electric market generally consist of two types: power and energy. Wholesale transactions (bids and offers) in electricity are typically cleared and settled by the market operator or a special-purpose independent entity charged exclusively with that function. Market operators do not clear trades but often require knowledge of the trade in order to maintain generation and load balance. The commodities within an electric market generally consist of two types: power and energy.

At the consumer level, there is an opportunity for consumers to play a significant role in the operation of the electric grid by reducing or shifting their electricity usage during peak periods in response to time-based rates or other forms of financial incentives. The goal of this chapter is to analyze the energy cost saving tips in centralized and decentralized power network. The chapter is structured as follow: The first section offers an introduction on power networks. It focuses on power network operation and explores different aspect of energy production, transmission and consumption in both the centralized and decentralized power approach. The section gives also a background of learning and optimization techniques used in the chapter. Then different energy saving approaches are presented from consumer incentive to renewable energy sources integration into the distributed power network. Next, we study the prosumer energy profiling in a distributed power network. Therein, prosumers interact in a distributed environment during the purchase or sale of electric power using a double auction with negotiation mechanism. Using a two-step combined learning and optimization scheme, each prosumer can learn its optimal bidding strategy and forecast its energy production, consumption and storage. The simulation results show that the integration of the prosumer in the power grid help to reduce the peak energy consumption and to lower the electricity cost for the population of prosumers. Discussions and future research directions are presented in the last part of the chapter.

BACKGROUND

Reinforcement Learning

In the field of machine learning, one way for an intelligent agent to interact dynamically with the environment from which it has no information is to use reinforcement learning techniques (Barto et al (1983)). The reinforcement learning can be subdivided into 2 steps: the choice of the action to be executed and the reward to be assigned to that action. As the agent has no exact information about the state of the environment (it depends on the behaviour of other agents involved), the choice of an action is made probabilistically, according to a distribution which depends on past experiences. The reward assigned

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

to the action taken is based on the result of the interaction with the environment. The probabilities of actions are then modified in such a way to increase the long-run reward. The reinforcement learning approach is similar to the El Farol bar problem in economics and the minority game in statistical physics (Challet et al. 1997). The class of algorithms used by the authors is known as temporal difference method (Sutton, 1988). Extension of reinforcement learning to multi-agemts systems and game theoretic learning can be found in Tembine (2012).

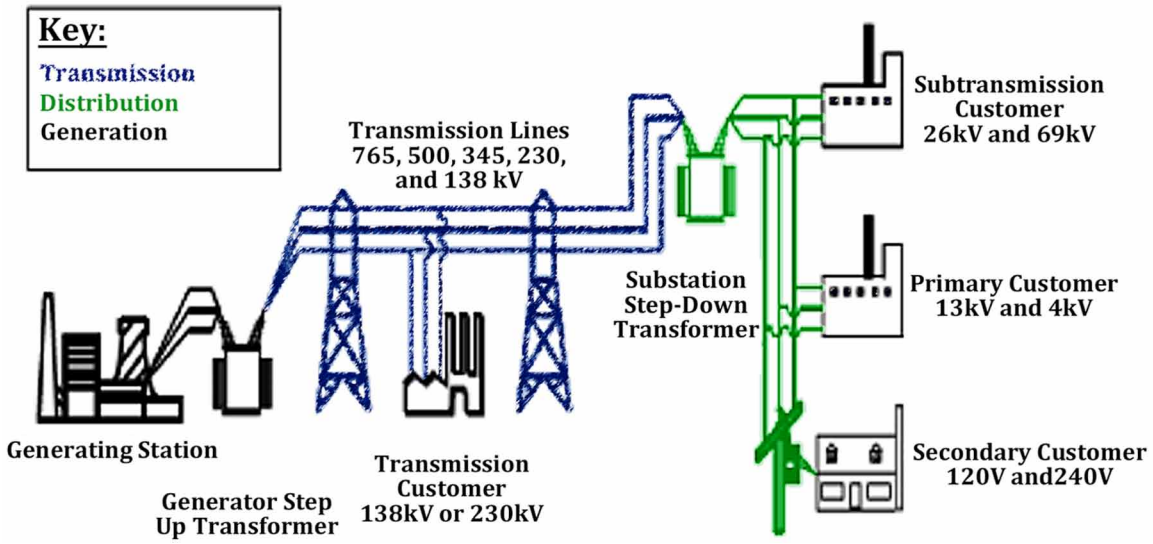
Dynamic Programming

In mathematics and computer science, dynamic programming is a method for solving a complex problem by breaking it down into a collection of simpler sub-problems. Dynamic programming is both a mathematical optimization method and a computer programming method. In both contexts it refers to simplifying a complicated problem by breaking it down into simpler sub-problems in a recursive manner. While some decision problems cannot be taken apart this way, decisions that span several points in time do often break apart recursively; Bellman called this the Principle of Optimality (Bellman, 1952). Likewise, in computer science, a problem that can be solved optimally by breaking it into sub-problems and then recursively finding the optimal solutions to the sub-problems is said to have optimal substructure. If sub-problems can be nested recursively inside larger problems, so that dynamic programming methods are applicable, then there is a relation between the value of the larger problem and the values of the sub-problems. In the optimization literature this relationship is called the Bellman equation (Bellman, 1957).

Power Networks

The centralized power management system is currently used in many countries (Barroso et al. (2005)). The main feature of this model is that at the physical layer, the grid is designed for a one-way flow of the electricity. More precisely from the top, where the electricity is generated in large power plants and transported to local substations, to the bottom, final stage in the delivery of electricity to end users (see Figure 1).

The power grid operation can be subdivided into three main tasks:



- **Centralized Power Generation:** Where electricity is produced by large size energy source generation as coal plant, nuclear plant, natural gas plant and hydroelectric plant. Generally, the electricity is produced in an extra high voltage in the order of 265 to 275 KV.
- **Power Transmission:** It is a high voltage electric transmission in the order of 110 KV or above, from generating power plants to sub-stations located near to population centers. The electricity is transmitted at high voltages to reduce the energy lost in long distance transmission and power is usually transmitted through overhead power lines.
- **Electricity Distribution:** It is the final stage in the delivery of electricity to end users or consumers. It works typically at medium voltage (less than 50 KV) and low-voltage (less than 1 KV).

Literature Review

The continuously increasing cost of the energy along with the need to reduce greenhouse gas emissions to protect the environment, have made energy efficiency one of the technological challenges of

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Diagram of an electric power network (New jersey OCE (2010))

our century (Chenrui, et al. 2013). Centralized power management systems need to integrate renewable energy sources in the current model (Barroso et al., 2005) in order to reduce energy cost. This recall the integration of distributed energy resources in the power grid (Sugiyama, 2014). Decentralized power networks aim at reducing power transmission losses and allow a better integration of distributed energy generation. The question is how to propose model for handling renewable energy sources penetration? (Handschin et al. (2006)) have proposed a decentralized model based on which consumer can interact during the purchase and sell of energy. Montanari et al. (2014) have extended the previous model and have proposed a prosumer approach for the energy profiling in a distributed power network.

Critics of renewable energy often cite the fact that technologies like wind and solar only produce energy when the wind is blowing or the sun is shining (Li et al., 2014). They argue that we can't effectively utilize renewable energy until appropriate energy storage technology is developed (New jersey OCE, 2010). Demand Response solutions have to be implemented in order to reduce peak energy demand in the net (Cappers et al., 2010). High demand puts pressure on the electricity grid, and outages can occur when demand exceeds available supply (Dong et al., 2014). The question in this case is show to develop models that help to stabilize this balance, minimizing the need to activate expensive fossil fuel generators that pollute the environment and spike energy prices (Jie et al., 2014).

Electric vehicles will have tremendous potential to offset portions of the environmental impacts from both the direct transportation sector and from the electricity generation sector (Tcheukam et al., 2015). From the standpoint of the electric utility grid, electric vehicles offer an opportunity to facilitate increased penetration of renewables and reduce the need for peaking generation units during the day by acting as a distributed storage and generation source (Paranjape et al., 2014). The question is how to increase the penetration of electric vehicle in many regions (Bingtao et al., 2014)?

MAIN FOCUS OF THE CHAPTER

Power Network Architecture Paradigm Shift

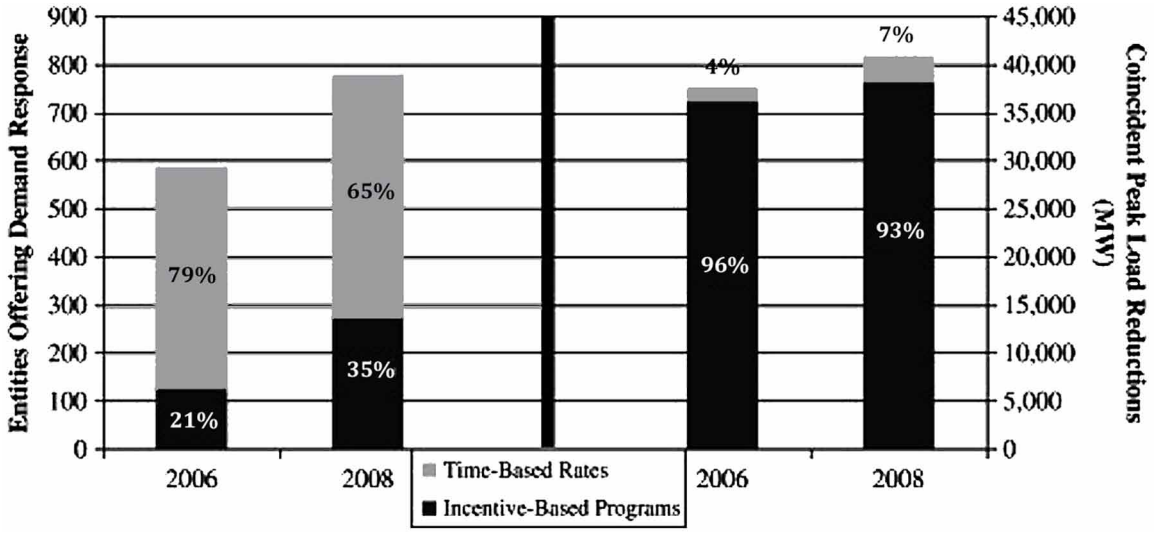
In the new era of power network, we can distinguish between two types of electricity power management systems: the centralized (see background section) and the decentralized power management system. Decentralized power management systems will play a key role in reducing greenhouse gas emissions and increasing electricity production through alternative energy sources. The idea behind the decentralized power management system is to exploit the increasing integration of decentralized energy resources (DER) into the distribution network. DER systems are modern technologies based on solar or wind power, or on other renewable energy sources. More precisely, they are small or mid-scale power generation technologies (typically in the range of 3KW to 10 MW). However establishing clean or renewable energy sources involves the problem of adequate management for networked power sources. This is due to intermittency of renewable energy source during the electricity generation and to the fact that power consumers are in the same time power producers and vice versa. For this reason, the power network needs to be managed in a distributed way. At the physical layer, the electricity flow in this power management system focuses on the distributed generation scheme. At the power market layer, small businesses and households will be able to produce and store energy through the use of solar panels, wind turbines and combined heat and power plants. They will become prosumers. A prosumer (producer - consumer) is a user that not only consumes electricity, but can also produce and store electricity.

The operation of grid systems can be shared between central and distributed generators. Control of distributed generators such as combined heat and power plant (CHP) and micro-turbines could be aggregated to form micro-grids or 'virtual' power plants to facilitate their integration both in the physical system and in the market (see Figure 2).

Figure 2. Distributed generation in micro grids (WWF (2006))

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

INCENTIVIZING CONSUMERS



The electricity cannot be indefinitely stored and therefore the system operator need to meet the demand pattern manage the network stability. One of the main issues in the electricity sector is to balance the energy demand or to reduce peak energy consumption. Two approaches can be used to manage the problem: Demand response approach and prosumer integration approach.

Demand Response (DR)

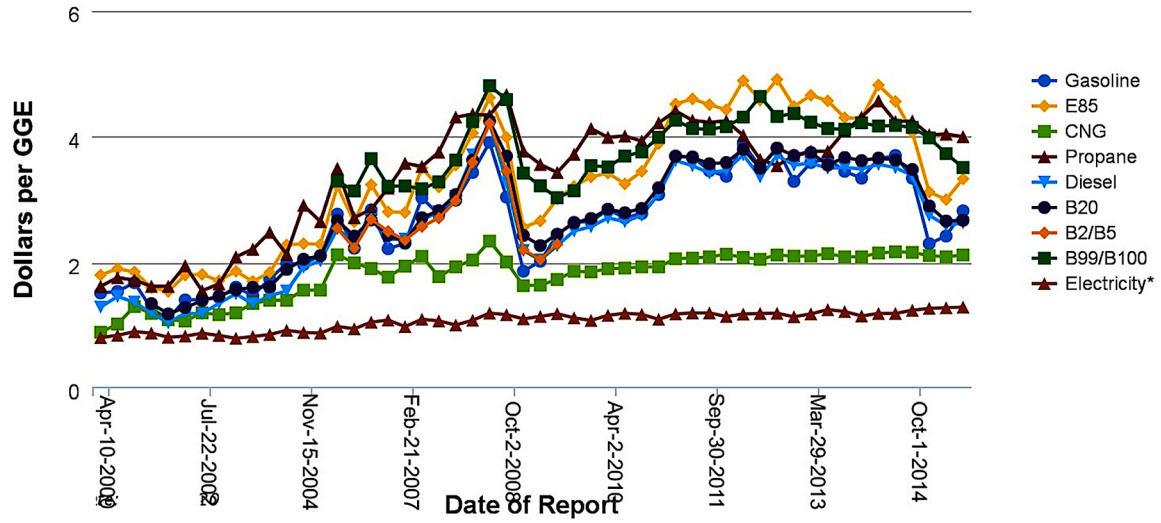
For limitations, the electricity cannot be easily stored on a large scale. As a result, supply and demand must remain in balance in real time. Traditionally utilities have leveraged peaking power plants to increase power generation to meet demand. Demand response works from the other side of the equation – instead of adding more generation to the system, it pays energy users to reduce consumption. Utilities pay for demand response capacity because it is typically cheaper and easier to procure than traditional generation. Demand response allows energy users of all kinds to act as virtual power plants, adding stability to the grid by voluntarily lowering their demand for electricity. Participants in demand response programs get paid for providing demand response capacity.

As part of the Energy Policy Act of 2005, the U.S.A Congress directed the Federal Energy Regulatory Commission (FERC) to develop a comprehensive national assessment of the size and scope of electricity Demand Response resources and advanced metering as part of a national energy policy (Cappers et al. (2010)). In the U.S.A case, there has been a significant increase (117%) in the number of entities offering DR programs: 126 in 2006 vs. 274 in 2008 (Figure 3) and about a 10% increase in the number of entities offering dynamic pricing tariffs to retail customers.

Figure 3. Estimated size of Demand Response resources in the United States (Cappers et al. (2010))

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Prosumer Integration



A prosumer (producer-consumer) is a user that not only consumes electricity, but can also produce and store electricity. Thanks to the penetration of renewable energy sources the efficiency of the power market depends also on the participation of a new costumer – prosumer – who is now able to play a key role in reducing peak energy demand in the traditional power grid. In order to the enable market integration of prosumers, prosumers should be able to choose the technology and size of equipment on the basis of their individual preferences, as well as the related market-driven costs and revenues. At the same time the regulatory framework should not provide incentives that lead to market distortions and negative impacts from the system perspective. The challenge of the prosumer will be to use control algorithm in order to optimize his (her) cost based on the power market condition. He will coordinate himself such as to minimize peak energy consumption in the power network while maximizing his profit.

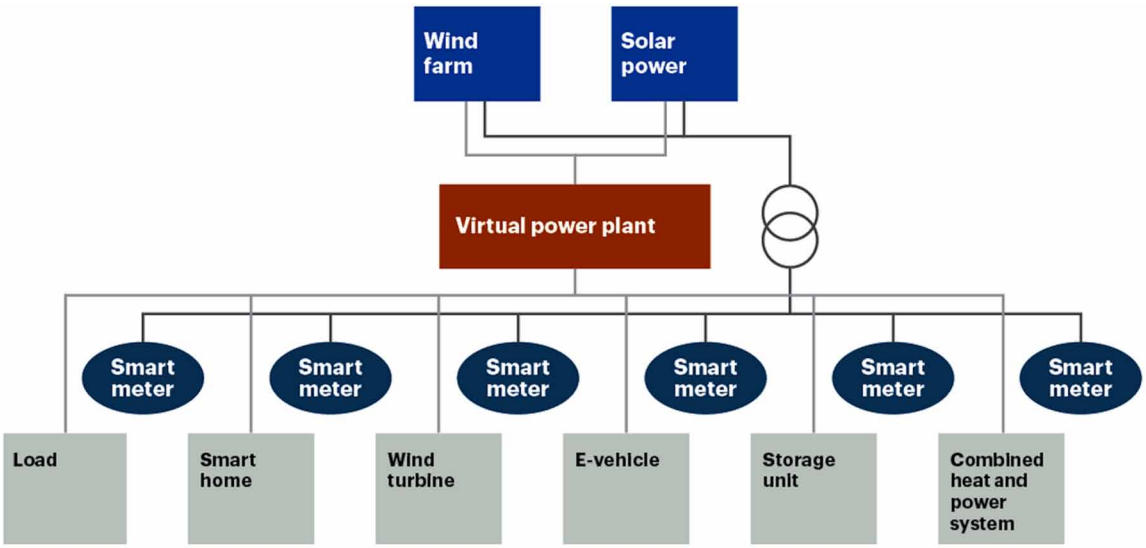
INTEGRATION OF RENEWABLE ENERGIES

Distributed Energy Generation

Fuel prices are increasing and there is a need of alternative fuels sources for lowering the energy price and meet the demand. The electric price is very cheap compared to other energy production sources. As gasoline prices increase, alternative fuels appeal more to vehicle fleet managers and consumers (Figure 4). The electric prices are reduced by a factor of 3.4 because electric motors are 3.4 times more efficient than internal combustion engines (Alternative fuel data center (2010)). Based on the US National Average Price (April 15, 2015) the electric price is $0.12/kWh is the cheapest compare to Diesel ($3.06/gallon), Natural Gas ($2.09/GGE), Propane ($2.92/gallon) and Gasoline ($2.42/gallon). The electricity can be seen as a Vehicle Fuel and can be used to power all electric vehicles and plug-in hybrid electric vehicles.

Figure 4. Average Retail Fuel Prices in the U.S

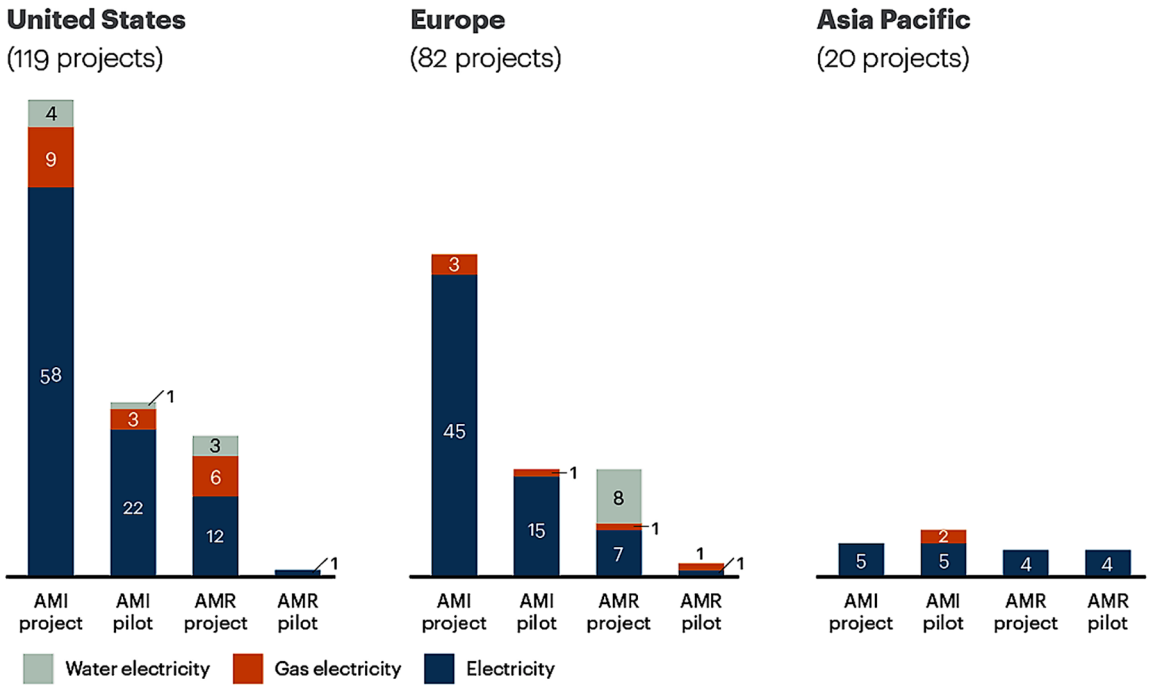
EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use



Distributed Energy systems are modern technologies based on solar, wind, geothermal, water, biomass, biofuel or other renewables energy resources (Figure 5). More precisely, they are small or mid-scale power generation technologies (typically in the range of 3KW to 10 MW). Nevertheless, the potential availability of wind, solar and biomass energy varies over time and between locations. This variation is not only caused by the resource characteristics (wind/solar regime, soil) but also by geographical (land use and land cover), techno-economic (scale, labour cost) and institutional (policy regime, legislation) factors.

The coordination of the distributed power network will require advanced metering infrastructure (AMI) and automatic metering reading (AMR). For instance new projects are arising around U.S., Europe and Asia Pacific. The aim is to propose model for addressing Smart city project (see Figure 6).

Environment Changing



The penetration of renewable energy sources can lead to landscape ruined in many cities. Harnessing power from the wind is one of the cleanest and most sustainable ways to generate electricity as it produces no toxic pollution or global warming emissions (Sellami, 2014). Despite its vast potential of wind, there are a variety of environmental impacts associated with wind power generation that should be recognized and mitigated (Araneo, 2014). The land use impact of wind power facilities varies substantially depending on the site: wind turbines placed in flat areas typically use more land than those located in hilly areas (Awadallah et al. (2015)). Sound and visual impact are the two main public health and community concerns associated with operating wind turbines (Bashir et al. (2015)). Most of the sound generated by wind turbines is aerodynamic, caused by the movement of turbine blades through the air. There is also mechanical sound generated by the turbine itself. Overall sound levels depend on turbine design and wind speed. Likewise, the sun provides a tremendous resource for generating clean

Figure 5. Distributed generation units (ATKearner analysis (2010))

Figure 6. Smart metering project around the world (ATKearner analysis (2010))

and sustainable electricity without toxic pollution or global warming emissions. Depending on their location, larger utility-scale solar facilities can raise concerns about land degradation and habitat loss. The total land area requirement varies depending on the technology, the topography of the site, and the intensity of the solar resource (Hartmann et al. (2013)).

PROSUMERS INTERACTION WITH THE POWER MARKET

Tradition Power Market

The use of market-based approaches in the electricity system operation continues to mature (Tcheukam, 2013). In general the electricity market is subdivided into two categories: the wholesale market and the retail sale market. These two markets interact with each other. The wholesale market involves Generator Company (GenCo), Load Service Entities (LSE) or retailer as brokers and distribution companies (DisCo) in a trading market. In the retail market, brokers forecast the aggregated resource needs of consumer and shop in the wholesale markets available to them. Moreover, the wholesale electricity market (also called Spot Electricity Market) can be subdivided into three subsequent markets:

- **The Day-Ahead Market (DA):** Which is a market finalized for the exchange of wholesale power between producers, traders and eligible customers. It takes place a day before the effective dispatch of the electricity.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

- **The Intra-Day Market (IDM):** Is an adjustment market on which operators can modify the programs established in response to the Day-Ahead Market submitting further bids on the sale or purchase. It takes place an hour before the effective dispatch of electricity.
- **The Ancillary Services Market (ASM):** Is the market where the traders make offers of availability of an increase or reduction of the power injected or withdrawn in the grid. This information is used by the transmission system operator to correct programs that violate the limits of transit, and to balance the system in real time against deviations from the program.

These three markets operate in the pool market, which is under the control of a single operator, who is normally known as Independent Market Operator (IMO). The role of the Independent Market Operator in a wholesale electricity market is to manage the security of the power system in real time and co-ordinate the supply of and demand for electricity, in a manner that avoids fluctuations in frequency or interruptions of supply.

Distributed Power Network Approach

We focus on power market models in which prosumers interact in a distributed environment during the purchase or sale of electric power. We propose a hierarchical distributed model which is based on reinforcement learning and optimization. Different types of prosumer are able to intelligently buy energy from, or sell it to, the power market. Our simulation results show that the integration of the aggregator in the power grid help to reduce the peak energy consumption and to lower the electricity cost for the population of prosumers.

We introduce a micro grid negotiation concept that enables the energy balancing in the entire power grid and we term it DIPONET. The approach is more dynamic since it provides the consumer/prosumer a more efficient way to interact in the distributed power network. The DIPONET (Tcheukam et al. (2015)) approach is based on the previous project DEZENT (Handschin et al. (2006)). The limitation of the producer/consumer in the previous project is that it only make use of reinforcement learning when buying/selling energy from/to the power market. The consumer in that approach is static in the sense that it is not able to anticipate or to delay energy consumption. Moreover at the power market layer, a negative bidding strategy used by the static producer/consumer was affecting its portfolio.

The novelty of our approach is that it combines both distributed learning and optimization to predict supply/demand and storage in a more efficient way. More specifically we use reinforcement learning to adapt prosumer's price strategy at the power market and dynamic programming to predict future outcomes. The learning accounts for the fact that the power producer/consumer will need to use his/her best strategy when buying/selling energy quantities from/to the power market. The dynamic programming approach is due to the fact that a short term optimization might not be suitable in the event that a power consumer needs to plan his/her energy consumption over a period of a day, a week or even a month.

Prosumer Planning and Adaptation Model

The power grid of interest consists of a multi-level micro-grids architecture which is subdivided into 4 levels. The first level (0.4 kV) is a low-range network covering subdivisions (a neighborhood). The second level (10 kV) is a medium-range area network covering a suburb (regional grid). The third level (110 kV) is a long distance energy transport network. Finally in the fourth level (380 kV) the electric-

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

ity is produced from large power plants (coal, gas or nuclear). Power needs of prosumers are covered through alternative energy sources within the first 2 layers and additional power needs will be covered at the latest by the fourth level.

At the power market layer, we consider a multi-stage negotiation system through which the energy produced by microgrids (at various tiers) are auctioned to/by the prosumers. The balancing of demand and supply between participants is carried out through balancing group managers (BGMs) which are located in different network layers and operate in parallel on each grid. The BGM balances the supply and the demand of electricity between a producer and a consumer who have submitted a similar bid.

A prosumer in such a power grid can be viewed as user who has the ability to independently modify his/her power requirements optimizing his cost. In our model, we believe that independent planning by the prosumers may improve significantly the matching between production and consumption in the power grid. In practice, this could mean to help balancing the power market, since the price will favor low consumption/high production when the cost is high and vice versa. Moreover, our approach is not centralized and, in this sense, is different from demand side supply management. The idea is to exploit the (limited) ability of prosumers of planning in an autonomous way their consumption/production. Hence they do not sign any contract leaving the planning to others: our independent consumer planning is a local matter involving only one prosumer

Control Strategy of the Prosumer in the DIPONET Approach

The challenge of the prosumer is to make elastic the demand for, and the supply of, electricity in order to optimize its energy cost based on power market conditions and on suitable constraints on their power consumption. Prosumer strategies are concerned with two separate phases. On one hand, prosumers should compete on the DIPONET power market: they should negotiate a deal with a close partner, thus achieving a better price. On the other hand they should concentrate as much as possible their energy consumption in the periods when the prices are more convenient.

We now described the combined scheme DIPONET.

Step 1: Reinforcement learning

At the end of a negotiation, the final achieved price by the consumer is normalized according to the frame size of the negotiation. Then, the temporal difference method of Sutton is used to derive the reward of the negotiation strategy currently executed.

$$P(t+1,s) := P(t,s) + \alpha\,(r(t,s) - P(t,s)) \tag{1}$$

where $P(t,s)$ is the value of the reward associated to action s at time t, $r(t,s)$ is the reward associated to action s at time t and α is real parameter, $0 \leq \alpha \leq 1$.

Step 2: Optimization

For clarity we consider the case of a consumer. The consumer is characterized by the class of energy variation profiles (s)he can adopt during the day.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Controllable inputs: we denote by x(t) the vector of controllable inputs of the consumer. The consumer has the ability to increase/decrease its energy consumption.

Uncontrollable inputs: the total power produced by renewable energy sources in the power grid can be less than, equal to or great than the total energy demanded in the grid and this may cause an increasing cost of the electricity in the dynamic power market.

State of the consumer: the state of the consumer is given by the level of the energy reserve R(t).

Objective function: the objective of the consumer is to minimize the electricity cost achieved at the end of the day.

$$\min (o(x(1))+q(1))c(1) + (o(x)+q(2))c(2) + \ldots + (o(x(T))+q(T))c(T) \quad (2)$$

where the minimization is over x (t), t be the time index. o(x(t)) is the additional cost paid for the transmission cost, q(t) is the amount of energy consumed at time index t and c(t) is the unitary energy cost achieved after the negotiation.

Constraints

1. Summing up all the variations from the beginning of the day to any time, we cannot exceed a lower and an upper bound of the energy reserve. This constraint accounts for available energy storage media, like electric vehicle batteries or thermic accumulations due to anticipated heating, or delayed air conditioning.

$$\forall 1 \leq t \leq T,\ 0 \leq R(0) + x(1) + \ldots\ x(T) \leq R \quad (3)$$

where R(0) is the initial energy reserve capacity and R is the maximal energy reserve capacity.

2. The sum of all the energy variations in the whole day for the consumer is zero, i.e. if in some slot the variation is positive, in some other slot it must be negative.

$$x(1) + x(2) + \ldots + x(T) = 0, \quad (4)$$

Proposed algorithm: we propose an efficient dynamic programming algorithm for planning the energy consumption/production. The control algorithm of the consumer has three inputs: (i) the definition of the class of allowed profiles Q; and (ii) the cost of a unit of energy which is the result of the negotiation in each time step of the previous day. Hereafter, the optimization problem and the proposed dynamic programming algorithm used to solve it are defined.

Let $Z(t,Y(t)): R \cup \{\infty\}, t=1,\ldots,T, 0 \leq Y(t) \leq R$ be the optimal energy costs for time step 1, . . ., T, when the final energy reserve at time t is Y(t). Here $Z(t,Y(t)) = \infty$ if energy reserve Y(t) cannot be achieved at time step t . Thus Z(0,Y(0)) (no slot has elapsed yet) is everywhere ∞ except for $Z(0,R(0)) = 0$.

$$Z(t,Y(t)) = \min_\{x(t)\} \sum (o(x(t)) + q(t))c(t),\ t= 1,\ldots T \quad (5)$$

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$\forall k\ 1 \leq k \leq T,\ 0 \leq R(0) + \sum x(i) \leq R,\ 1 \leq i \leq k \tag{6}$$

$$R(0) + \sum x(i) = y(t)\ 1 \leq i \leq t,\ 0 \leq y(t) \leq R \tag{7}$$

Dynamic Programming

$$Z(t,Y(t)) = \min_\{x(t)\}\ Z(t-1,Y(t) - x(t)) + (o(x(t)) + q(t))c(t),\ t = 1,\ldots T \tag{8}$$

Such that $-k \leq x(t) \leq k$ and $0 \leq y(t) - x(t) \leq R$

$$Z(0,Y(0)) = \text{if } Y(0) = R(0) \text{ then } 0 \text{ else } \infty \tag{9}$$

$$Z(T,R(0)) = Z \tag{10}$$

The value of Z(t) at time t is computed sequentially in terms of $Z(t-1)$ by looking backwards for $Z(t,Y(t))$ to the optimal energy costs at slot $t - 1$ for eligible values $Y(t) - x(t)$ of the energy reserve. Finally, an optimal strategy S is any sequence

$S = (x(1), Y(1)), \ldots (x(T), R(0))$, such that the values of x(t) and of Y(t-1) are computed backwards from Y(t), t= 1,…T by letting $Y(T) = R(0)$, the final reserve being R(0). Formally: optimal strategy

$$Z(t,Y(t)) = Z(t-1,Y(t)- x(t)) + (o(x(t)) + q(t))c(t),\ t = 1,\ldots T \tag{11}$$

$$Y(t-1) = Y(t) - x(t) \tag{12}$$

$$Y(T) = R(0) \tag{13}$$

The time and space complexity of the algorithm are O(TRk) and O(TR) respectively. Where T is length of the day, R is the maximal energy variation capacity and k is the maximum energy variation level.

We compare the behavior, in terms of energy cost minimization, of a consumer in our approach with that of a consumer of the DEZENT approach

Setup: the space of the experiments is based on the available DIPONET and DEZENT simulator and on the implementation of the two types of aggregator. It depends essentially on three parameters: (i) the free market power cost, which can exhibit high or low variance: for this we chose real data from the day ahead market prices of Switzerland (date: March 9, 2013); (ii) the prosumers environment, namely heavy production or heavy consumption, in which the total amount of the electricity produced in the subnet is respectively greater than or less than, the total amount needed in the subnet. In the heavy consumption situations, the additional, needed power is made available at the large power plant level, at a price which depends on the time of the day. Analogously for the heavy production situations. In all these cases, the

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

profile cost of the electricity at the global level (namely at the large power plant level) was the same for all days; (iii) the available energy reserve capacity of the virtual prosumers characterizing the aggregator is considered finite. The experiments were conducted on the NYUAD cluster at the division of Engineering laboratory, simulating a 3 days service period (see Table 1). Here the last day has been considered, since in this way transitory effects are minimized.

DIPONET vs DEZENT: in the first experiment we compare the behavior of a consumer in the DEZENT approach with that of our approach. The comparative study is based on the total cost of the electricity paid at the end of the last day. We recall that the consumer in DEZENT only make use of reinforcement learning while the consumer in the DIPONET approach uses both reinforcement learning and optimization. In Figure 7 the consumer in DEZENT (dashed curve) has spent more than the DIPONET consumer (solid curve). The saving of the DIPONET consumer is about 8,23%. This is due to the fact that the DIPONET consumer is able to anticipate or delay energy consumption thanks to its flexibility.

Aggregator models: in the second experiment comparative studies were based on the total cost of the electricity paid at the end of the last day by the consumer population and on the profit realized by the aggregators. Figure 8 synthesizes the optimal controller of the one prosumer of the centralized aggregator. The two upper curves of Figure 8 represent the unitary cost of energy as resulting from the negotiation phase at day 2 (solid curve) and at day 3 (dashed curve). The difference between the two upper curves gives an idea of the possible variations between the outcomes of different negotiations. Notice that the profile of the global energy cost and the context of competing prosumers is the same in both days. The lower dashed curve (respectively lower solid curve) represents the result of the optimization algorithm applied to the curve of day 2 (respectively of day 3). The curves plot the sum (from the beginning of the day) of the suggested variations: according to the constraints we assumed on the virtual prosumers profiles, the sum of the variation must be not greater than the aggregates reserve capacity and should end up at 0. Notice that the controller correctly suggests variations which are opposite with respect to the negotiated cost.

Table 1. Setup of the DIPONET ENVIRONMENT

Architecture	Negotiation Level: 1 BGM on Level 1: 1 Clients: 23 Producers (50−350 KW): 10 Consumers (50−300 KW): 10 Prosumers (50−300 KW): 3

Figure 9 reports the result of the placebo test on the behavior of the consumer population. In Figure 9, the upper dashed curve represents the energy cost achieved in each hour by the entire population when there is no aggregator in the power market. Analogously, the middle bullet curve represents the case in which the centralized aggregator is active and the lowest solid curve the case in which the decentralized aggregator is active. The observation we have is that the consumers population when the aggregator is active has spent less during peak energy consumption period.

In Figure 10, the final cost achieved at the end of day 3 by the population of consumers in which the aggregator was active (solid curve for the decentralized approach and bullet curve for the centralized approach) is less than the case in which there was no aggregator (dashed curve). This positive effect is due to the introduction of an aggregator. The two curves when the aggregator is active are overlapped and this is due to the fact the available reserve charactering the aggregators are the same in both cases. The percentage of global energy cost reduction is about 3,2%.

In Figure 11 we compare the actual profit of the two aggregator approaches. The solid curve reports the energy cost (actual profit) realized by the decentralized aggregator in the power market. The profit is given by the sum of the entire profit realized by the virtual prosumers characterizing the aggregator. Analogously, the dashed curve reports the actual profit of the centralized aggregator. The profit in the centralized case is given by the sum of energy cost achieved in every time slot. There is a remarkable difference between the two gains and the centralized aggregator exhibits a superior behavior. This is due to the fact that the centralized aggregator uses cooperative informations of virtual prosumer characterizing its portfolio. The information about the difference between the two gains of Figure 7 can be well studied if we compare the actual profit of each aggregator with its expected one.

Figure 9. Energy cost achieved by the consumer population

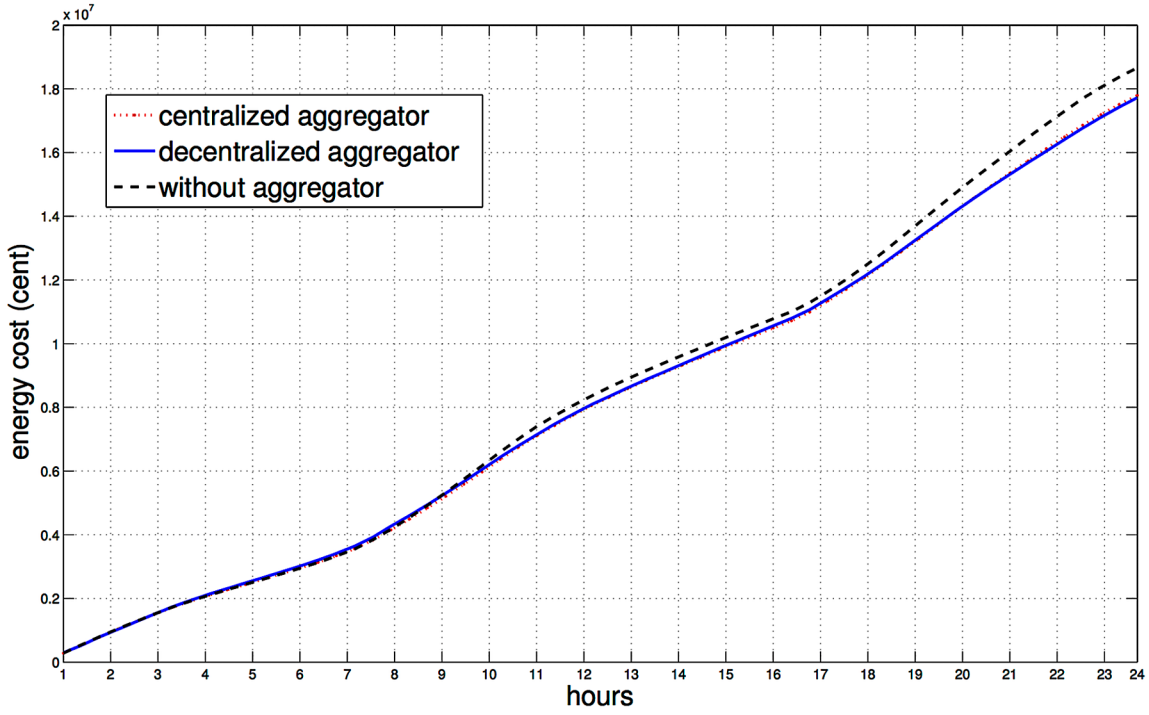
Figure 10. Energy cost at the end of the day achieved by the consumer population



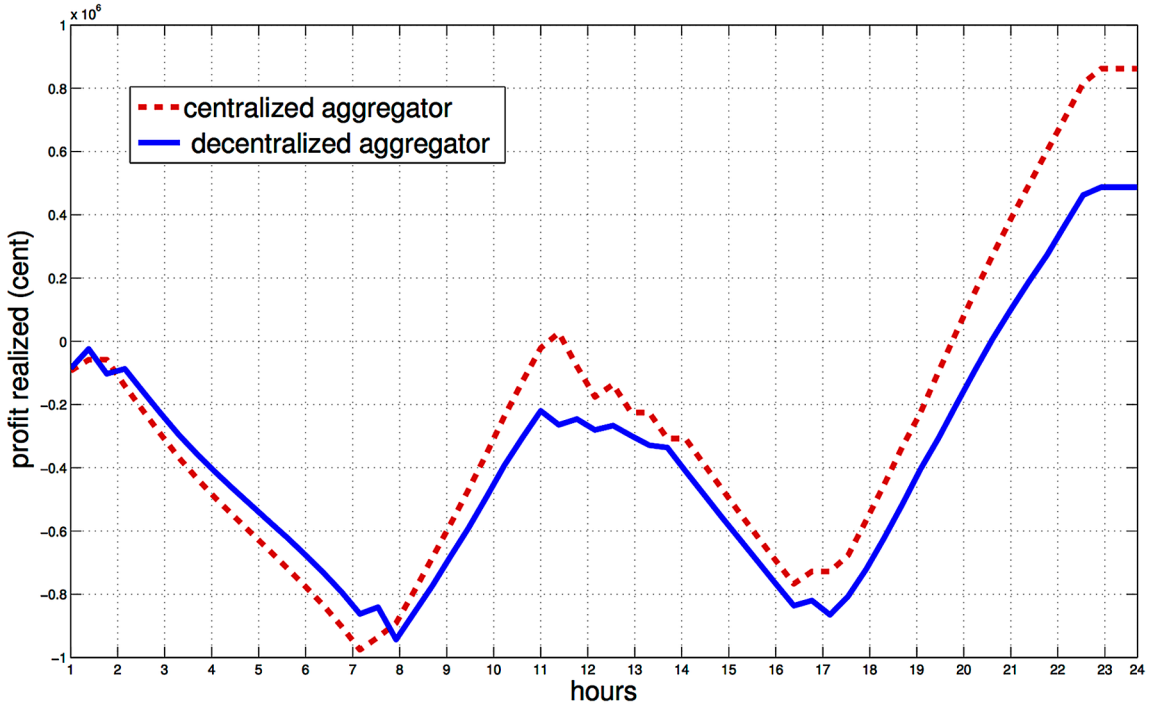


Figure 11. Aggregators: profit realized

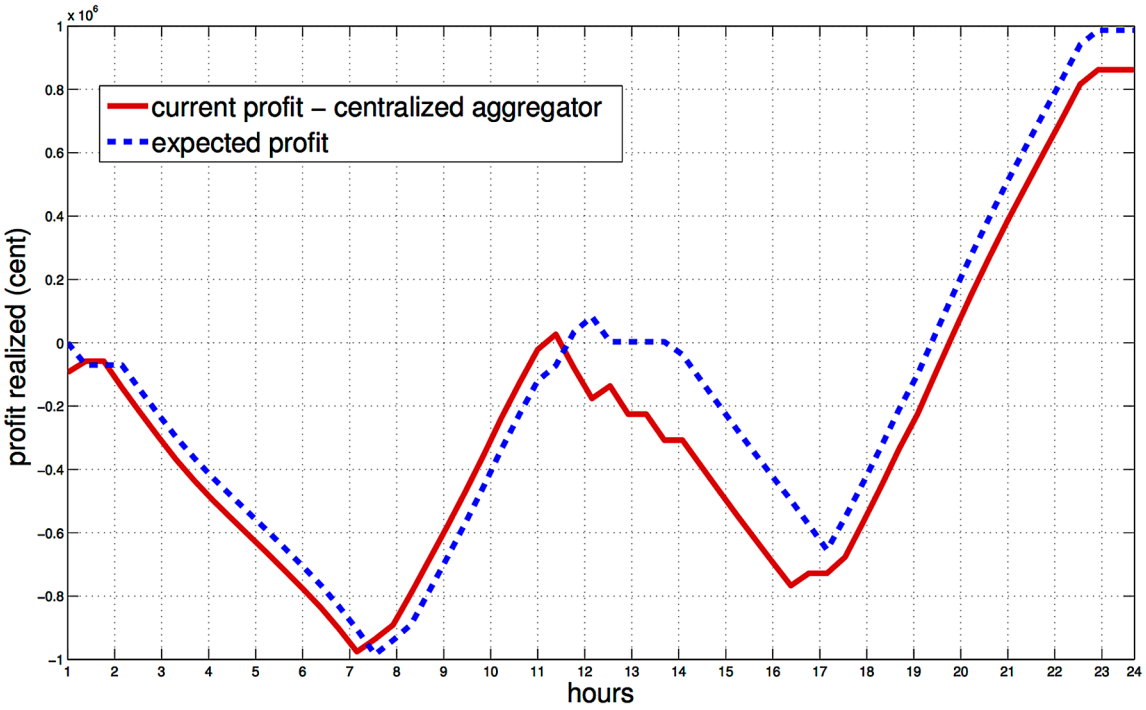
EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

In Figure 12 the dashed curve represents the expected profit of the decentralized aggregator at the end of day 3. The curve is computed by assuming known in advance the energy cost. That curve has been obtained by summing up all the energy costs of the optimal profile of day 3 of the virtual prosumers.

Analogously, in Figure 13 the dashed curve represents the expected profit in the decentralized aggregator case at the end of day 3. That curve is given by the energy costs of the optimal profile of day 3 of the centralized aggregator. Notice that the difference between the expected gain and the actual gain of the aggregator in the decentralized case is greater than that of the centralized case.

SOLUTIONS AND RECOMMENDATIONS

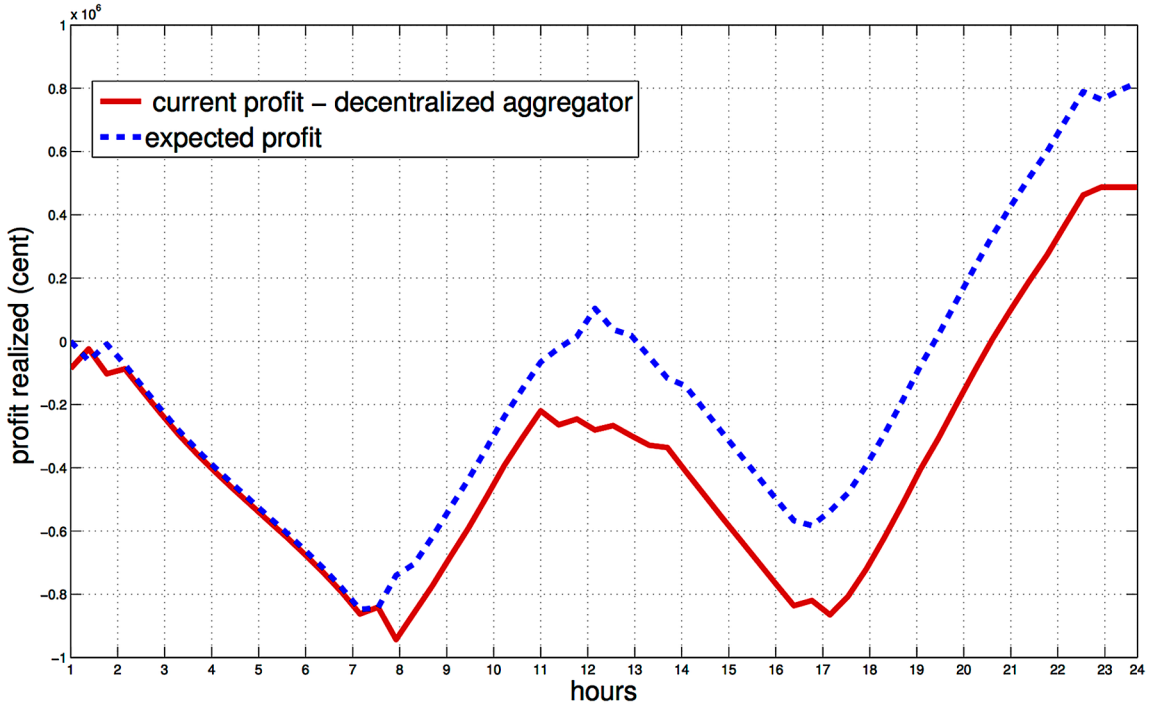
See Table 2.



FUTURE RESEARCH DIRECTIONS

This section discusses future and emerging trends.

Combination of the Centralized and Decentralized Power Management System



The first step is to identify the strengths and weaknesses associated with Centralized power network and Distributed power network infrastructure for the future electric grid system. There are many reasons for

Figure 12. Centralized aggregators, expected cost vs real cost

Figure 13. Decentralized aggregators, expected cost vs real cost

considering the extent to which a planning and operation decision about centralized generation (CG) and distributed generation (DG) should be based. This will involve the development of indices for an economical scale study of DG relative to CG, and consider which is the most cost-effective to accommodate new markets. In order to assess the robustness of DG and CG under different load conditions, different indices for measuring the combination of CG/DG with respect to their capability and resilience to handling unforeseen events. This will involve development of new tools with stability measures and reliability as constraints.

Enhancing the Reliability of Power Grid: Power Quality

Today's energy availability to users is largely dependent on the resiliency of the power grid supplying the need of the consumers. Provision needs to be taken into consideration should power demand exceed power generated. In a particular region under consideration, required energy consumption increases with population. Therefore, a need arises to have a power grid expansion options during the installation of either a DG or CG systems.

As CG/DG systems continue to grow in size and capabilities, the current state of art in power system reliability is being pushed to its limit. While power engineers try as much as possible to ensure that there is constant power availability to users, considerations of some natural disasters such as earthquakes, hurricanes, tornadoes, and snow storms, continually mitigate the availability of continued power being supplied to these consumers. The question to be addressed now is: will either CG/DG or both power grids architecture be best to improve the reliability of power consumption?

Table 2. Summary of the main focus of the chapter

	Pros	Cons
Centralized architecture	• Reliable power transmission • Top down power management • Easy power stability management.	• Power transmission cost due to joule effect. • Non penetration of Renewable energy sources • Greenhouse gas emissions
Distributed architecture	• Transmission cost reduction • Better exploitation of renewable energy sources • reduction of greenhouse gas emissions	• Two ways energy flow to be managed • Meet power demand (intermittency RES) • Power grid instability
Demand response	• Reduction of peak energy consumption • Electricity cost minimization • Grid stability management	• Consumer change behavior • Enhanced heating and cooling systems in the population
New market participant: prosumer	• Household and small businesses can also produce and stored energy • Electric vehicles penetration	• Energy profiling scheduling • New market strategies needed for small participants
Environment	• Greenhouse gas reduction • Clean energy penetration • Building for smart cities	• Landscape ruined • New technology needed for renewable energy systems recycling
Distributed energy resources (DERs)	Penetration of mid-scale technologies • Solar panel, wind farms, • Combined heat and power plant • Biomass, biofuel, geothermal, water	• High cost energy production (currently) • Intermittency of energy production • Power grid management
Centralized power market	Subdivided in three parts: • Day ahead • Intra-day (hourly) markets • Real time power market	• Do not exploit efficiently renewable energy sources •Consumer cannot directly participate to the market
Distributed power market	• Energy cost reduction • New market mechanism • Incentive strategy for prosumers • Aggregator penetration	•Mismatch between supply and demand • ICT systems need to be developed

New Form of Energy Production for Lowering Energy Cost

The production cost of the energy through alternative energy sources is still high and new technologies have to be developed for lowering the energy price in the future. Scientists will race to perfect greener sources of energy to improve the environment and reduce dependence on oil and other fossil fuels. Some predict a hydrogen economy. Others say solar is the way to go. Wilder schemes involve sky-high wind turbines or antimatter engines.

Sustainability of the Environment

Sustainable energy has two key components: renewable energy and energy efficiency. Distributed power network encompass any generation built near to a consumer's load regardless of size or energy source. The energy system lies at the core of sustainability just as balanced energy supply and demand can assist increase resource efficiency; minimize unwanted wastes thereby reducing the adverse environmental impacts of energy production. Sustainability in a power network system would thereby aim at addressing the following: energy consumption reduction, reduction of sources of energy waste, minimization of energy production pollution and minimization of life-cycle costs of renewable energy resources.

CONCLUSION

In this chapter we have studied the energy saving tips in distributed power network. It turns out that there is a need of technology improvement, new models and algorithms for a better integration of renewable energy source in the traditional centralized power network. The question is how to efficiently combine centralized and decentralized power generations models so as to minimize the energy cost and maximize the power network stability? The answer of this question requires co-optimizing distributed generation and centralized generation in a future electric grid.

The first approach considers a centralized power network and introduces demand response strategies for reducing peak energy demand in the grid. The weak point of the approach is that the system does not exploit more renewable energy sources and there is a need to reduce greenhouse gas emissions.

The second approach is to shift from centralized power to distributed power network. Namely, integrate distributed generation in a more efficient way in the power grid and optimize the power grid operation through demand response. At this point, the authors proposed a prosumer interaction model in a distributed power network. The prosumer combines both distributed learning and optimization to predict supply/demand in a more efficient way. Simulations results showed that our approach is more efficient than the approach used in DEZENT. The learning scheme of the prosumer in our model can be extended through a CODIPAS learning model (Tembine, 2012).

KEY TERMS AND DEFINITIONS

Auction Games: Deal with how people behave and act in auction markets.

Demand Response: Is a change in energy usage by end-use customers from their normal consumption patterns in response to changes in the price of electricity over time, or to incentive payments.

Distributed Power Network: Is a power network where the energy is generated or stored in a distributed way by a variety of small, grid-connected devices referred to as distributed energy resources systems.

Energy Profiling: Is the prediction of the variation of the energy load over the time.

Game Theory: Is the study of mathematical models of conflict and cooperation between decision-makers.

Optimization: Finding an alternative with the most cost effective or highest achievable performance under the given constraints, by maximizing or minimizing desired factors.

Power Market: Is a system enabling purchases, through bids to buy; sales, through offers to sell; and short-term trades.

Prosumers: Is a user that not only consumes electricity, but can also produce and possibly store electricity.

Renewable Energy Sources: Energy that come from resources which are naturally replenished on a human timescale, such as sunlight, wind, rain, tides, waves, and geothermal heat.

Strategic Learning: Learning in which decisions and outcomes depend on the strategies used by other participants.

This research was previously published in Smart Grid as a Solution for Renewable and Efficient Energy edited by Ayaz Ahmad and Naveed Ul Hassan, pages 26-48, copyright year 2016 by Information Science Reference (an imprint of IGI Global).

Chapter 58
Ecological Influences on the Evolving Planning System in Turkey

Ufuk Fatih Küçükali
Istanbul Aydin University, Turkey

ABSTRACT

Many developing countries' national plans and urbanization policies lack effective measures to address environmental degradation and support the sustainable use of natural resources. Sustainable urban development policies, the most important pillar of socio-economic development, have not been produced and/or integrated to the urban planning system in Turkey. Suggesting that economic growth may be equaled to wealth and welfare is only possible in environments where certain requirements are satisfied. These requirements may be enumerated as not surpassing the natural renovation capacity, minimizing pollution risks, optimal protection and preservation of non-renewable resources, use of natural resources according to protection-utilization principles. This chapter firstly addresses planning tradition in conceptual background, and analyses relationship of this convention with urban development. Secondly and final phase it addresses the ecological influences created by the urban development shaped by urban planning tradition on the environment, and presents suggestions for solution.

INTRODUCTION

The purpose of the chapter is to state the influence of the increased population growth and urbanization on the development, and role of ecological needs in Turkey's planning system in the context of impacts of population growth and rapid urbanization on the developing world. Due to lack of failure to apply proper planning policies in Turkey, and in connection therewith, lack of sustainable urban development policies, examination of urban planning system in the context of sustainable urban development poses various difficulties in terms of methodology. For this reason, in order to make a general evaluation to overcome such difficulties, in this part of the study, the planning tradition upon which the urban planning system is based and which is determined by a legal framework and formed with historical know-how

of the system has been addressed in the first place, and evaluations have been made with regard to the relationship of this tradition with the basic paradigms of sustainable urban development. Subsequently, the impact of urban development shaped by urban planning tradition on environment has been canvassed, and criticisms and proposals have been presented.

BACKGROUND

The development of urban planning as a discipline and as an area of policy application has been accompanied by various images as to the scope, issues, concerns, and the type of activities with which the field is preoccupied. Different aspects are held by the ordinary citizen, by professionals in related disciplines, and crucially by planners themselves. This variety is not new to the profession. There is reason to believe, however, that it has increased greatly with the past decade (M. Needleman & C. Needleman 1974; Erber, 1970; Eldredge, 1967) and that it is departing fundamentally from the conventional and popular definitions associated with the field in its earlier years. In tracing the evolution of planning thought over the past two decades, the dynamics of consensus and conflict among planners, and the problems associated with circumscribing the emerging themes of planning theory are suggested to be critical to an understanding of the state-of-the-art in planning theory nowadays. Planning at this time is essentially different from planning at the turn of the century because of the increased recognition of the plurality of values in society and in the profession and because of the expanded scope of substantive area applications of planning (Galloway & Mahayni, 2007). "The diversity within the planning area raises a number of important questions concerning the present and future role of planning in urban policy making. This diversity has sprung from a number of alternative planning definitions and strategies. Policy makers concerned with decisions governing the role of planning in their organizations are having an increasingly difficult time sorting out the planning process and the field to which this process relates. This appears true for governmental officials at all levels and administrators in higher education governing academic programs in planning as well as the public at large. The field of planning as a discipline justifiably has taken pride in the eclecticism, spontaneity, and innovative thrusts that have characterized the field over the past decades" (Godschalk, 1974).

THE EVOLUTION OF PLANNING TRADITION/SYTEMS IN TURKEY

The concept of urban planning emerged in industrialized societies to solve multi-faceted urban problems brought by industry. On the other hand, urban planning followed a different route in countries like Turkey that remained behind in the industrialization process. The first zoning movements in Turkey which could be considered in the context of urban planning "were initiated to seek solutions for initial integration of pre-industrial towns with the world economy" (Tekeli, 1991). In Turkey, the urban planning system has reached the present, undergoing different stages throughout the Republican period. In this context, the evaluation of the urban planning system in Turkey has been conducted by periods which represent break points that influenced planning. Tekeli's grouping (Tekeli, 1998) has been relied upon in the determination of such periods, and 1923 - 1950 period, 1950 - 1960 period, 1960 - 1980 period and post-1980 period have been used.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

In this framework, when the first period is considered in general terms, Ankara was the first city that the Republican management considered in the planning studies as they wanted the new capital to be a modern city. Aside from this, other cities were subject to planning under existing laws. In 1933, a new law was enacted in relation to zoning, and planning was carried out in accordance with that law. In this framework, The Law on Structures and Roads Nr. 2290 guided planning activities between the years 1923 – 1950. However, because the said law was a "law of foreign origin" (Çetiner, 1984), the fact that the prepared plans only sought to specify physical formations and failed to consider socio-economic and other data sufficiently had been a significant matter of criticism.

The second period between the years 1950 – 1960 is prominent as a process when changes in several basic paradigms were experienced in the area of urban planning. Turkey switched to the multi-party system in this period which represented the post-World Ward II (WW2) era. USA introduced the policies called Marshall Plan for the recovery of European countries that were destroyed after the WW2, and these policies incredibly increased urbanization rate particularly in Turkey. With the assistance program in question, mechanization in agriculture and new employment opportunities in the cities triggered a flow of population from rural areas to urban areas, and cities started to become overpopulated. The significant rise of urban populations had a destructive effect on the urban texture which were tried in the previous periods to be shaped as widely-spread housing areas with gardens. The general housing pattern in the cities was specified as multi-story buildings with deficient infrastructure. In the same period, the shanty phenomenon emerged due to the populist and income-oriented policies of the government of the time in Turkey. In the face of all these negative developments, a new zoning law was needed, and the Zoning Law Nr. 6785 was adopted in 1956. As a result, this had been a period with an urban planning system based on comprehensive, multi-faceted researches and during which steps towards an approach that went beyond the physical formation approach of the previous period were taken. However, the most important criticism raised against this period in terms of the planning system was that the urbanization rate was ahead of the planning.

The most prominent characteristic of the 1960 – 1980 period is the 1961 Constitution that adopted the principle of social state. In this connection, the state obliged itself to meet the basic requirements of its citizens and demonstrated its influence in several areas. In addition, another important characteristic of 1961 constitution is the importance attached to the concept of planning. In this direction, the idea of planning gained respect, and enabled comprehension and inspection of the spatial dimensions of development and social change to be seen as an achievable purpose (Tekeli, 1998). In this framework, the State Planning Organization was established. This period should be considered in two/ dimensions in terms of planning. The first dimension is to create regional plans in line with the mission of DPT "to carry out necessary researches and prepare short term regional plans and programs", (Keleş, 2004) a mission specified in the law regarding the foundation of this organization and its formation and duties. The second dimension is to create a phenomenon of town planning. In this context, regional plans were made for Zonguldak, Eastern Marmara, Antalya and Cukurova in this period. Although these plans could not be put into practice entirely due to uncertainty of institutional arrangements in the implementation process, they, at least, provided great contribution to the inventory efforts for future planning. Secondly, the most prominent feature of the 1960 – 1980 period with regard to town planning is the understanding that these plans could not simply consist of physical plans and that economic and social dimensions cannot be neglected. In other words, a "comprehensive - rationalist practice of planning" (Tekeli, 1998) started to rule growth pattern in the country. In this framework, a new understanding was adopted, which "changed the plan production stage and placed emphasis on lack of researches" (Çetiner, 1984).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Political and economic structural changes that emerged in the world since 1980s left important effect on spatial structure. In the same period, in Turkey that endeavored to integrate itself to the global capitalist system, spatial decisions subject to income policies were made within a system where market conditions ruled. While central government had weight in planning until 1985, the influence of the central government was reduced with the Zoning Law dated 1985 and number 3194, and these authorities were assigned to local governments. Thereby, with the planning studies performed by local governments, application, monitoring and inspection could not be performed sufficiently, and as a result, towns failed to preserve their spatial structures, and entered a fast phase of transformation. Subject to these developments, it is undoubted that non-renewable natural sources will be polluted and destroyed.

Today, there are important problems in regard to application of plans in Turkey, and the understanding of planned urban development is replaced by an irregular, unplanned development. The zoning law was re-assessed at different times with the purpose of preventing illegal housing, and amendments were devised.

As a result, an understanding of planning, which can be summarized as producing fragmental and temporary solutions, rather than presenting fundamental solutions for a healthy urban development, has emerged. On the other hand, according to another approach which supports this view and asserts that Turkey is far from having a planning philosophy. According to this view "it is clear that urban planning experience has been a failure in Turkey. In Turkey, plans cannot be applied for certain reasons and the plan structure occurs as a bulky and bureaucratic planning approach which has very limited effect on urban development and quite far from exhibiting flexibility" (Işık, 1994). Such a structure that fails to address spatial structure along with other dimensions and adopts a minimalist approach to planning will inevitably be shaped solely according to economy and determinant actors of economy.

ECOLOGIC EFFECTS OF ECONOMIC GROWTH ON THE URBAN ENVIRONMENT

Urban ecological systems are characterized by complex interactions among social, economic, institutional, environmental and physical geography variables. These interactions generate complex human-dominated landscapes, which significantly influence the functioning of local and global earth ecosystems and the services they provide to humans and other ecosystems on earth. Urban development fragments, isolates, transforms and degrades natural habitats; simplifies and homogenizes species composition; disrupts hydrological systems; and modifies energy flow and nutrient cycling. Urban areas also appropriate a major share of earth's carrying capacity from other regions in terms of resource input and waste sinks. Change in ecological conditions that result from human activities in urban areas finally affect human health and well-being (Alberti, 2005). The future of earth ecosystems is progressively dependent on the patterns of urban growth. Cities are growing rapidly globally. "The world's urban population has multiplied more than tenfold during the past century, from 224 million in 1900 to 2.9 billion in 1999 (United Nations [UN], 1999). It has also risen from 14 to 50 percent of total world population. In 1900, only sixteen cities had a population exceeding 1 million; by 2000, more than four hundred did. By the year 2030, more than 60 percent (4.9 billion) of the estimated world population (8.1 billion) will live in cities: 56.2 percent of the population of developing countries (3.88 billion) and 83.5 percent of that of the developed countries" (1.01 billion) (UN, 1999).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Highly concentrated human populations cause changes in natural disturbances (i.e., more frequent flooding, air pollution) and unprecedented catastrophic disturbances. How alternative urban development patterns and environmental politics influence ecological systems along this tendency, however, is not known. Although many studies have addressed the correlation between urbanization and ecosystems (McDonnell & Pickett, 1993), few have asked directly how alternative urban patterns control the distribution of energy, materials, and organisms in urban ecosystems (Sukopp et al., 1995; Alberti, 2005). Most studies of the impacts of urbanization on environmental systems correlate changes in environmental systems with simple aggregated measures of urbanization and socio-economic indicators (e.g., human population density, percentage impervious surface).

More recently, varied disciplinary approaches have been combined to research the interactions between complex human behaviors and ecosystem function. Scientists have started to recognize that urban ecosystems consist of several interlinked subsystems— social, economic, institutional, environmental and ecologic—each representing a complex system of its own and affecting all the others at various structural and functional levels. In studying the interactions between humans and ecological processes in urban ecosystems, researchers need to consider that many socio-economic and biophysical factors work simultaneously at various levels with substantial feedback mechanisms. These complex interactions give rise to emergent phenomena whose characteristics cannot be understood by studying the properties of the socio-economic and ecological systems in isolation (Grimm et al., 2000; Pickett et al., 2000; Alberti et al., 2003).

The most important tool that helps guide urban development, urban planning plays a determinant role in the urbanization process, and the relationship between urbanization and environment expresses the entirety of acts and policies laid down by urban planning.

In this framework, the interaction between urbanization and environment can be examined under topics such as air, water and soil pollution, industrial site selection, illegal housing, historical - cultural setting, agricultural soils, forest areas, terrestrial and aquatic ecosystems and diverse ecosystems, biological diversity, intra-city transportation and other physical geography elements.

The first subject to be addressed under the pollution topic is air pollution, which can be assessed under two headings as pollutants from natural events and pollutants from artificial sources caused by human activity. Dusts dragged/blown by winds, dusts and particles emitted to the atmosphere as a result of forest fires and volcanic activities are natural sources of pollution. Besides these, sources of pollution caused by human activity include, inter alia, transportation, solid fuel, power stations, fuels used for industry and heating, and industrial processes. Air and noise pollution is widespread phenomenon in urban areas. The presence of many motor vehicles in urban areas produces noise and air pollutants such as carbon dioxide and carbon monoxide. Emissions from industrial buildings and plants such as sulphur dioxide and nitrogen oxides are very toxic and poisonous to both human beings and environment. Sources of air pollution arising from urbanization include crowded urban population, extremely dense population density, selection of habitation and industrial sites which are not appropriate to urban topography and meteorological conditions, and urban heating systems and urban transportation (Haq, 2011). The most typical examples in Turkey for air pollution caused by inappropriate site selection that do not suit urban topography and meteorological conditions are Ankara, Bursa, Konya and Yozgat. In these cities, air pollution occurs as a result of discharge of the flue gases of thermal power plants without proper treatment, and flue gases created by use of low-quality coals for heating in downtown Bursa and rural settlement areas and exhaust emissions from vehicles. Subject to natural thresholds created by urban geomorphologic structure and dominant wind direction, polluted air mass remains suspended over the

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

urban center, and affects water sources and vegetation adversely with inversion and acid rains. It is seen that development plans made in such cities are unsuccessful in preventing air pollution.

Besides, comparing with rural areas, differences and diversity in solar input, rainfall pattern, temperature and microclimatic features are usual in urban areas. Solar radiation, air temperature, wind speed, wind direction and relative humidity vary remarkably due to the built environment in cities (Heidt et al., 2008). Urban heat island effect is caused by the extensive areas of heat absorbing surfaces, in combination of high energy use in cities. Urban heat island effect can increase urban temperatures by 2°C - 5°C (Bolund et al., 1999). This phenomenon can be seen in many metropolitan cities (Istanbul, Ankara, Bursa and Adana) in Turkey.

The most evident pressure of urbanization in Turkey on water sources is ever-increasing housing around catchment basins near the cities (Atabay, 2001). In this context, pollution caused by housing near catchment basins appears most widely around water dams and lakes which preserve the very scarce fresh water supply of Istanbul. Particularly, Omerli Catchment Basin located in Anatolian side is under urbanization pressure despite all protection measures. In addition, Elmalı, Kücükcekmece and Büyükcekmece Catchment Basins are alike under heavy pressure by planned and unplanned housing. As a result of fragmental plans that are produced by county municipalities in breach of upper scale plans, industry and human settlement cause pollution and pollution risks in these catchment basins. Other issues that impact pollution of water sources are industrial and agricultural activities. Aside from these, transportation activities increased by industrialization and urbanization play a non-negligible role in water pollution. On the other hand, toxic gases released to the atmosphere by industries and houses (like sulfur) penetrate into the sea and fresh waters through acid rains (Brooks et al., 1996). Exhaust gases from vehicles and nitrogen oxides from fixed burning plants are released to the atmosphere. These gases enter the natural gas cycle and complete chain reactions resulting in formation of nitric acid (HNO3), and fall onto earth as acid rains. Acid rain affects soil structure and washes off elements like calcium and magnesium and carries them to the ground water, and causes water to acidify and reduces agricultural efficiency (Kirby et al., 1994). All these processes naturally reach the water source and have an adverse effect on water quality. On the other hand, waste water problem is important as another dimension of the relationship between urbanization and environment. In this framework, according to 1997 official data of the Turkish Statistics Institute, "Only 43 out of more than 3000 municipalities where 76% of the population of Turkey live, in other words, only fifteen ten thousandths of the said municipalities have water treatment plants. Only 20% of the domestic waste water produced in the cities in a year can only be treated at treatment facilities" (State Planning Organization [SPO], 1999). Although the basic reason of pollution is lack of treatment, there are significant deficiencies in sewage and treatment facilities in our country. Unfortunately, the most common means of removal of waste waters in our country have been discharge of untreated or partially treated waste waters to the ground waters and disposal to waste lands far from areas of settlement (SPO, 1999). Aside from all these, other sources of pollution include domestic waste waters, water leakage from cesspools at places with insufficient sewage infrastructure, discharges from industrial activities to soil surface or illegal wells, underground water pollution due to chemical fertilizers and pesticides used in agricultural activities. However, Turkey lacks sufficient number of academic papers and researches on this issue.

The factors that contribute to soil pollution in Turkey include use of various fertilizers and pesticides to increase quantity and quality of agricultural production, discharge of solid and liquid waste, sludge applications, use of low-quality water in agricultural irrigation (such as Bafra and Carsamba Plain), atmospheric precipitation, erosion, thermal power plants (volatile ashes, stack emissions and storage

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

sites), incidental release of industrial and urban treatment sludge to the soil or its use for fertilization purposes, irregular urbanization, establishment of industrial sites on inappropriate land (1st and 2nd class agricultural land, etc.), brick and roof tile industrial institutions, and use of polluted water in agricultural irrigation.

In the first years of the Republic, in regard to selection of industrial sites which is another area of interaction between urbanization and environment, a country-wide balanced distribution of industry was projected and important industrial areas were selected in a balanced fashion over the country subject to the transportation system of the country. However, in the subsequent years, industrial facilities were established on the most efficient agricultural areas such as Bursa and Konya Plain, and these agricultural areas faced the risk of extinction. However, investment decisions regarding as sector which is has an important place in the country's development have to be included in development plans that are placed at the highest rank in the planning level, and should be incorporated into regional plans, environmental plans and ultimately in local-scale plans, respectively.

The most important effects of urban development on environment are illegal housing and settlement. In addition to illegal housing areas that develop without a plan, settlement areas with high natural ecologic sensitivity and/or high income potential that are opened to settlement within the framework of a plan are seen as the biggest problems. Keleş defines this problem as "a plunder through a plan" (Keleş, 1997) and states that urban plans in Turkey pave the way to illegal housing and says "social values can be used as a vehicle to destroy environmental values" (Keleş, 1997). In this direction, the most important problem with urban planning has been the intention to derive benefits for some interest and pressure groups rather than to produce plans for public benefit. No doubt this is largely to the shift from a planning phenomenon which is driven by public power and public benefit to a planning approach rather driven by market power, overlapping with market purposes and reducing cities to a meta (Loomis, 2000). What is behind the ongoing illegal housing is the lack of a favor in the general community for public benefit, and that local governments that have a concern for individual unearned income as well as an obligation to apply the plan intend to share unearned income with voter segments for political reasons.

When another dimension which is to protect cultural environment is examined the historical and cultural heritage owned by cities are very important in the formation of a city identity. The planning of protected areas that have a historical, cultural and natural heritage is carried out through protection-oriented zoning plans caused to be prepared by the Ministry of Culture and Tourism and Provincial Private Administrations. Although there are many settlements in Turkey, for which protection-oriented zoning plans have been made, these plans have not been sufficient for a sustainable protection of the relevant areas. Aside from many problems experienced in practice, since protection-oriented zoning plans evaluate and decide upon protection areas in the lower scale, isolating protection areas from other parts of the city, they are not consistent with the general point of view of planning.

Another example in Turkey in the framework of urbanization - environment relationship is the use of efficient agricultural areas for other purposes. When the reasons for use for other purposes are investigated, they include the tendency of the cities to exceed the projected population and area occupation targets and spread beyond. In line with this, plains become the most preferred areas for such spread as they represent the most suitable geographical formation in terms of topography for the selection of settlement sites. Plains consisting of efficient agricultural areas qualified as class I and class II areas of land where this phenomenon is seen in Turkey's plains such as Gediz Plain, Kucuk Menderes Plain and Buyuk Menderes Plain are polluted and destroyed with their selection as areas of settlement and industry. In terms of urban planning, detailed researches should indeed be carried out as regards structure, capability and efficiency

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

of the soil during the analysis stage. These analyses are used in the determination of areas suitable for settlement, however, when it comes decision-making, areas that have high efficiency and land quality become the most preferred areas for settlement since they represent the easiest threshold to overcome compared with other parameters (Jorgensen, 1991). Therefore, land requirements of the industry that develops very fast in Turkey and of the population that consequentially increases caused construction of illegal housing and industrial facilities around existing industrial facilities and connecting roads, and increased the pressure on efficient agricultural land. Thus, industrial zones formed along main transportation roads that connect cities to each other caused efficient agricultural land to disappear in a manner not to be regained again. Fast population growth and industrialization led to shift of agricultural land to urban and industrial settlement, damage to forests, and pollution of water sources.

The condition of forests, which is another issue, shows great similarities with agricultural land in terms of urban planning. Activities that lead to loss of forest area in Turkey are urbanization, tourism, and opening agricultural areas for other illegal purposes. Biological diversity is another important phenomenon that suffers damage due to urbanization and environmental interaction. The phenomenon of biological diversity, which is, maybe, the least considered factor in urban planning should be included in the analysis stage of the settlements to be planned, and should be correlated with urban planning.

SOLUTIONS AND RECOMMENDATIONS

As a result, when planning is considered in the context of general historical process, despite Turkey's nearly 60 years' planning experience, the planning system appears to be open to criticism in several aspects. In the light of these criticisms, all shareholders agree that the planning practice should change. When the main criticisms on Turkey's planning practice are evaluated, the top priority issue is that spatial planning systematic and strategy which are directly linked with national development planning have not yet been formed. Because this systematic and strategy have not matured, the principle of evaluating social, cultural and economic dimensions and providing input to planning cannot be realized in depth. In addition, there is a sustainable planning vision and strategy which is agreed upon by all stakeholders. For instance, researchers do not have a future vision and spatial strategy that takes into account physico-biological and ecological sensitivities and relationships of factors such as reduction of foreign dependency in transportation planning and energy requirement, diversity in energy, site selection for industrial zones and the environmental pollution and pollution risks caused by such selection (Power et al., 1997), elimination of socio-economic inequalities between regions, global climate change and Turkey's desertification risk, natural disasters and problems caused by misuse of land. It is seen that the selection of sites for mega projects such as the channel project, airport, nuclear power plants underway in Turkey has not been performed taking the above criteria into account. When unearned income promised by these mega projects and urban unearned income are not used for public benefit, but for the benefit of certain interest groups, spatial – social inequalities cannot be avoided. This attitude allows administrators who decide upon such policies to take autonomous decisions and maintain an unearned income-oriented development planning approach that reduces planning to housing.

In Turkey, many institutions in the existing planning system are producing physical plans at different levels and in very different processes. In the horizontal plane, there is no coordination and flow of information among the institutions that produce these plans, whereas on the vertical plane, there is no sufficient harmony and audit between physical plans produced at different levels. The Provincial Private

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Administration Law Nr. 5302 and the Municipalities Law Nr. 5393 delegate administrative power in many aspects to the local governments in accordance with the decentralization principle and localization policy, whereas in regard to upper scale planning, the law number 4856 and the Environmental Law Nr. 5491/2872 define the authorities related to upper scale plans. Furthermore, the Zoning Law delegates the duty related to Regional Plans to State Planning Organization. The fact that the current legal arrangements that guide Turkey's planning practice do not sufficiently include written rules and principles for the coordination that must be assured in the horizontal and vertical platforms, along with the uncertainty of strategies, prevent the establishment of integrity between levels. However, for the harmony of macro-spatial strategies established on a country level with the spatial strategies developed on a regional and local level, spatial strategies developed on every level should be developed with the participation and coordination of all investor institutions and should be applied in cooperation.

The exceptional articles of the Zoning Law amended several times on a project basis and the lobby created with the influence groups in Turkey, sectoral plans prepared by different institutions, arrangements that support local planning and the resulting fragmented plan making and approval authorities give rise to occurrence of fragmental practices and a confusion of authorities in the planning system. This situation prevents the establishment of audit mechanisms in planning. More than one institution possessing planning authority in the same area or part of an area being planned by a particular institution and other part being planned by another institution and the ambiguity with regards to holders of powers prevent production of planning decisions in coordination. All these processes lead to production of conflicting planning decisions on the same area and difficulties in the implementation stage of decisions made.

Areas of authority laid down by the Zoning Law and other relevant legal arrangements, and the mismatch between plan boundaries that need to assure a planning area integrity which is meaningful within itself and the catchment boundaries that specify an ecologic whole give rise to problems not only in planning processes, but also in practice. Because areas that have very intense physical, ecologic, economic, social and cultural relationships with each other and which in fact create an integrity of settlements are located inside different administrative boundaries, they are planned through different planning processes by different planners who are independent of each other and at different times. As such, lack of relationship causes sometimes production of conflicting plan decisions or make it difficult to put decisions into action.

Taking into account the living conditions in rural settlements, the population of the rural segment, the phenomenon of migration and urban-rural continuity, rural segment planning has been neglected in Turkey. In today's planning practice, rural areas exist only in the context of determination of development conditions and this existence falls within the scope of "rural settlement area boundaries" or "non-settlement areas". However, problems like loss of natural landscape of rural areas, loss of population in rural settlement areas, reduced agricultural production, rural poverty, loss of local architectural characteristics, etc., are problematic areas which must in fact be solved within the spatial planning system.

In Turkey's current planning system, systematic data may not be obtained, necessary analysis may not be performed for the reduction of natural disaster and settlement risks starting from country level down to the application plan scale, and strategies aimed at reducing risks cannot be developed. However, the basic purpose of planning is, in the first place, to assure sustainability of life. For this reason, the top priority in planning processes in all levels must be to reduce natural disaster and settlement risks.

For reasons such as the removal of obstacles before fragmental planning with the zoning law, lack of inspection mechanisms in planning and implementation, and failure to develop rules of professional ethics, etc., very wide areas have been planned particularly through additional and regional plans. This

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

has been underpinned by sectoral planning and central housing investments as well as repentance laws. As such, areas planned regionally have been expanded further by integrating them with both upper scale plans and zoning plans. Drifting away from staging in lower scale planning and plan application has aggravated this problem. Today, areas which have been planned as urban development areas through zoning plans in several cities of Turkey have reached as big areas as to accommodate twice the population of what has been projected in the twenty-year projections of the city. In areas which have been planned as urban development areas, fast zoning applications have been carried out, and leapfrog and isolated settlement units outside of the urban settlement areas have been supported. Such big urban development areas have been planned, unfortunately, on qualified agricultural areas to a large extent. Such a practice gives great damage to the environment, and causes cities to grow beyond natural thresholds subject to these processes, and to exceed ecologic values, and to destroy non-renewable natural sources.

Also in this problematic area which is directly related to the above problem, leapfrog development and urban sprawl causes trade, housing and educational facilities, etc. which choose a site outside the city to give damage to environment, and increases their transportation costs and the cost to supply urban services (Burgess, 2000). Another very important negative consequence of urban sprawl is the vacation of urban centers, isolation of citizens from each other and loss of the color and wealth of urban life (Burton, 2002). For this reason, such a pattern of growth should be prevented.

Although it is a scientific imperative and also there is consensus in all platforms that planning should take place with the participation of specialists in an interdisciplinary environment, the practice of planning in Turkey has not, for long years, been carried out in that fashion. This imperative which has been partially met only in the planning stage of large cities or in special planning areas is carried out only by town planners in medium-size cities and small cities. However, aside from a city planner, specialists such as an eco-planner, architect, biologist, zoologist, geologist, agriculturalist, climatologist, hydro-geologist, sociologist, urban economy specialist, etc., should carry out an interdisciplinary spatial planning study.

For the success of planning and its recognition by the public, democratic participation and inspection mechanisms must be activated in the production and implementation of the plans. Although the necessity and benefits of participation in planning processes and urban management are recognized by the public in Turkey, concrete steps have not sufficiently been taken in practice. The taking of planning decisions without consulting different segments of the society gives rise to inconsistency of such decisions with the local reality and makes it difficult to put those plan decisions into action. Another important result of failure to assure participation is the lack of public inspection. Lack of inspection does not only lead to unhealthy living environments but also gives rise to irregular practices on the benefit of urban land and undermines the confidence of the society in the planning institution. For this reason also, effective audit mechanism should be developed.

In terms of planning levels in Turkey, development plans – regional plans – environmental plans and zoning plans are prepared, and development plans involve upper scale decisions which also include socio-economic decisions that need to be prepared with broad institutional participation. Although the State Planning Organization has been empowered in respect of regional planning, a planning that covers all catchment basins country-wide has not been made to date. At this point, regional plans to be prepared by the State Planning Organization should have strategies to guide lower scale plans, and on a regional level, environmental plans should be prepared with the participation of Provincial Private Administrations, Municipalities, non-governmental organizations, universities, and professional chambers.

FUTURE RESEARCH DIRECTIONS

The chapter reports that the most important effects of urban development on environment are illegal housing and settlement. Accordingly, future researches in developing countries such as Turkey, it would be useful to focus on these issues. Besides, this kind of scientific studies carried out in developing countries needs to expand the literature with focus on relating planning function within the context of governance and the requirement for effective planning and development guidance to facilitate sustainable urban and national development. A clear framework from literature review would guide exploration of planning tradition in developing countries enabling the identification if issues and problems and explaining how and why they come to be. At the same time, in future researches there is a need to expand this to incorporate discussions relating to planning, urban management and governance, on one hand, and also issues of urban sustainability, including resources use, environmental impact and systemic effects resulting from current practices.

CONCLUSION

Planning studies at every level require a systematic database. In Turkey, there is a need for an institutional structure that decides in which detail, by which institution and through which means and by what kind of a system such data will be collected, archived, made available to users in regard to the industrial, housing, transportation, energy, tourism sectors, etc. in relation to spatially-oriented natural and cultural values, natural disaster and settlement risks. Establishment of a "national data center" that will assure coordination between institutions like Turkish Statistical Institute, The Scientific and Technological Research Council of Turkey, other non-governmental organizations that gather data on a country level today will enable to satisfy this very important requirement and to develop more consistent spatial strategies. In the scope of the National Program for the Adoption of the EU Acquis carried out by the Secretariat-General of European Union, the duty to collect spatial data and determine use of land as specified in the INSPIRE (Infrastructure for Spatial Information in Europe) has been assigned to the Ministry of Environment and Forestry in Turkey. The Environment Chapter (Chapter 27) published in the scope of this program details the activities to be carried out by the Ministry of Environment and Forestry for Turkey's integration with INSPIRE. In this framework, it is obvious that an infrastructure for spatial information systems must be established at the Ministry of Environment and Forestry, and in order to have a very strong database for the plans in near future, information technologies should be used, and plans and changes and audits thereof should be carried out and controlled by a single authority.

As a result of these observations, planning should not be simply a physical intervention tool in Turkey, and a planning paradigm should be created taking into account different variables that are able to descend from upper scales down to lower scales and define and establish spatial structure (environment, tourism, history, cultural assets, etc.). Interactions between urban patterns and ecosystem function are controlled by multiple stressors. Furthermore researchers will need to investigate relationships between urban patterns and human-induced stressors, interactions among multiple stressors associated with these patterns, and the existence of thresholds in these relationships.

KEY TERMS AND DEFINITIONS

Ecological Planning: Ecological planning is the process of understanding, evaluating, and providing options for the use of landscape to ensure a better fit with human habitation.

Ecology: The study of the relationship of organisms with their environment.

Natural Resource: Natural resources are materials and components that can be found within the environment.

Sustainable Urban Development: Development that meets the needs of current generations without compromising the ability of future generations to meet their own needs.

Urban Development: Urban development is the social, cultural, economic and physical development of cities, as well as the underlying causes of these processes.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Urban Planning: Urban planning is a technical and political process concerned with the use of land, protection and use of the environment, public welfare, and the design of the urban environment, including air, water, and the infrastructure passing into and out of urban areas such as transportation, communications, and distribution networks.

Urbanization: The process by which towns and cities are formed and become larger as more and more people begin living and working in central areas.

Chapter 59
Rural Tourism in Transitional Russia's Economics:
Fake or Real Alternative to Traditional Agricultural Production?

Anna Ivolga
Stavropol State Agrarian University, Russia

ABSTRACT

This chapter assesses the potential of rural tourism in Russia, addresses such threats to sustainable rural development as unemployment and depopulation, and substantiates the practicality of diversification of traditional rural sources of income by means of tourism and other alternative activities. The system approach is utilized, which envisages systematization and stocktaking of various aspects of sustainable development: available resources, economic conditions of agricultural production, market capacity and demand for agricultural commodities and food, employment and social issues, environmental conditions, and alternative sources of income for rural inhabitants.

INTRODUCTION

In the conditions of growing urbanization, more and more countries face challenges of ensurance of social and economic progress of their rural areas. Specific of agricultural production stipulates the main bottleneck: possibilities to replace labour and land with capital are very limited. That is why sustainability of rural areas in general terms means retention of rural inhabitants in their traditional environment by means of provision of sustainable employment and income.

Rural territories have great natural, demographic, economic and cultural potential. Rational utilization of that wealth is able to provide diversified development, full employment, high living standards and quality of life of rural population. However, real situation very much differs from that ideal picture, especially in developing countries, where agriculture usually takes significant part in the overall structure of GDP, and share of rural population pushes up to one third (and even higher) of the nation.

Russia is considered as developed country; nevertheless, its rural territories have serious problems on their way to sustainable economic and social development: depopulation, unemployment, social tensions, low effectiveness of agricultural production, degradation of lands and rural infrastructure, etc. Such problems are the most severe in the southern under-industrialized parts of Russia, where agriculture dominates in regional products, and rural way of life is traditional for local people. During transformation of Russia's economy in 1990s agriculture became one of the most unattractive for investments because of its longer capital turnover, low return, outdated infrastructure and specific natural conditions of production. That, in turn, decreased level of income of rural people, created unemployment and forced migration to urban centers. Consequently, traditional rural regions in the South of Russia lacked not only capital, but also labour, that led to degradation of agricultural production and rural infrastructure, and arose social tensions.

Therefore, rural areas need additional sources of income to balance the economic development. For the southern parts of Russia, with their unique natural, climatic and resort potentials, rural tourism is one of the perspective ways to give new impulse to rural areas and ensure sustainable rural development. The objective of the chapter is to analyze the current state of rural development in Russia and to substantiate rural tourism as an alternative source of income for rural inhabitants.

The analysis is conducted on the case of Stavropol Region of Russia, which is located in the southern part of the country. The analyses involved 26 territorial districts of Stavropol Region, distributed by their levels of their social and economic development. The selection of the region is explained by its agricultural specialization, significant share of rural areas in region's acreage, prevailing rural population, and unique environmental and agricultural resources.

However, rural tourism itself is not enough to replace traditional agricultural activities in such "agriculturally-oriented" regions, as southern part of Russia, where agriculture dominates in domestic gross product. In order to achieve sustainability, rural tourism may act as only one of the tools. Potentially, it gives more employment opportunities (one of the key conditions of sustainable rural development), which provides rural inhabitants with sustainable income, competitive in comparison to urban territories.

Since recently, Russia's Government gives special weight to ensurance of sustainable rural development, including through rural tourism. General programs and concepts, accepted on the federal level, define the main state approaches to issues of rural tourism, but concrete rural areas need real and effective mechanisms. In order to manage rural tourism in an effective manner, it is necessary to assess the main agricultural, economic and social indicators of rural areas, to define the main threats and to discover potential points of growth of rural tourism. That is especially important taking into account high differentiation of rural territories (even within one region).

BACKGROUND

As to the definition of rural tourism itself, there are a lot of approaches. The official definition, accepted in Russia, is provided by the Federal Tourism Agency. It refers rural tourism as a kind of tourism, which facilitates permanent residence of tourists in rural areas for a purpose of rest and/or involvement into agricultural activities (Almukhamedova & Vilenskaya, 2013). The obligatory condition is the fact that accommodation facilities, both individual and specialized, have to be located in rural area or small towns without industrial or multi-storey constructions (Almukhamedova & Vilenskaya, 2013).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

However, we consider rural tourism as a much broader phenomenon, than set by its traditional definition. It is not only accommodation in rural areas in the conditions, as much close to rural ones as possible (house, furniture, clothes, etc.). Such a "territorial" approach to rural tourism limits its opportunities and retards development, as well as does not correspond to the real demands of broad segments of the population, looking for as much diversified forms of rest and relax, as possible.

Another approach to rural tourism is concluded in dedicated travels to rural areas with relatively undisturbed ecosystems and ethnocultural complexes, which have a direct impact into rural development and are subjects for control in the purposes of sustainable rural development. The given concept includes two major definitions. Firstly, rural tourism is referred to as an environmentally-oriented tourist product on the domestic and international tourist markets. Secondly, rural tourism is expected to act as one of the tools for sustainable rural development.

Referring to other approaches of rural tourism, provided by Russian researches (A. Kuskov, Y. Dzhaladyan, M. Birzhakov) (Kazmina, 2012), as well as World Tourism Organization (UNWTO) and Association for Development of Rural Tourism, we have accepted the following concept of rural tourism for the purposes of the current research: rural tourism is a kind of activity, related to organization of dedicated travels to rural areas, which provides tourists with a complex tourist product (accommodation, meals, excursion services, and entertainment), reflects and preserves natural and cultural identity of regions, and ensures economic benefits for hosting communities by development of employment opportunities and alternative sources of income for local population.

MAIN FOCUS OF THE CHAPTER

Approaches to Rural Tourism

The world experiences a change from mass tourism to more content-related travels. Concept of three "S" (Sun, Sea, and Sand) is becoming replaced by the concept of three "L" (Landscape, Lore, and Leisure). All those new tendencies are related to rural tourism to the fullest extent.

Rural tourism is a relatively new direction of tourism industry. It is also referred to as agricultural tourism or green tourism.

Traditional way of spending vacation at seashore is getting changed by preference to visit intact places, authentic in cultural and natural way. This segment in the tourism industry has been rapidly growing in the past decade, leading to rural tourism becoming not just a good business prospect, but a genuine vacation trend. The fundamental reasons for such kind of shift from traditional tourism to its variations are concluded in the growing technogenic burden on people, and in a far bigger amount of new emotional and educational impressions, obtained from natural and rural-oriented activities, in comparison with traditional set of tourist and recreational services in tourist centers.

Rural tourism focuses on actively participating in a rural lifestyle. It can be a variant of ecotourism. Many rural villages can facilitate tourism because many villagers are hospitable and eager to welcome visitors. Agriculture is becoming highly mechanized and therefore, requires less manual labor. This trend is causing economic pressure on some villages, which in turn causes young people to move to urban areas. There is however, a segment of the urban population that is interested in visiting the rural areas and understanding the lifestyle.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

What is the difference between rural tourism and the traditional one, so it requires separate theoretical and practical approaches? As we outlined above, rural tourists spend their time in rural areas, and not just outdoors (forest or mountains). Such kind of recreation attracts those urban inhabitants, who have never been to village before, or who miss rural way of life. Tourists are accommodated in rural settlements, with no industries and multi-storey buildings. There is a variety of accommodations: guest houses and rooms with necessary furniture, utensils, bed clothes, etc. It is possible to rent a room or a house for a weekend, or longer period, for example, through a whole summer time. Such a recreation is beneficial with its naturality, fresh air and healthy food, cooked with environmentally pure organic products.

Not every rural area or settlement is suitable for organization of rural tourism. Usually tourists seek for a quiet and regular life-style somewhere outside the accustomed urban civilization, with stillness, comfort living conditions, hospitality, moderate prices, natural food, pleasant impressions, and a rich variety of entertainments for children and adults. However, being isolated from urban noise, such rural areas have to have good transport network between settlements, entertainment infrastructure (cafes, restaurants, sport facilities, horse riding schools, hunter points, animal farms, zoos, etc.), as well as good and stable communications (Wi-Fi access, telephone). Entertainments may include beach-related rest on a river bank, fishing, hunting, mushroom and berries picking, sauna, cycling and horse riding, tours of local sightseeing and places of interest, excursions to animal and plant farms, animal feeding, and others (Sysoeva, 2014).

Concluding overview of theoretical and practical approaches to rural tourism, we have to emphasize its major social and economic impact to development of rural areas:

- Relaxation of urban inhabitants in rural areas;
- Awareness about rural way of life and various cultures and nationalities;
- Flow of funds from developed urban territories to underdeveloped rural areas;
- Establishment of new employment opportunities and alternative sources of income for rural people;
- Development of living standards and income levels of rural inhabitants;
- Retention of economically active population and young people in rural areas, lower migration outflows;
- Decrease of social tensions in rural areas;
- Establishment of market for local agricultural and organic products, local specialties and products of folk crafts;
- Development of infrastructure in rural territories, including road network, communications, distribution and entertainment facilities;
- Preservation of natural, environmental and cultural heritage of rural areas.

However, bearing a full set of benefits in theory, rural tourism is still not widely introduced into practice. There are certain difficulties and barriers on the way to its effective development, different depending on the country and separate regions, as well as success stories, which have to be studied in order to discover the best international practices and accommodate them for local conditions.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

RURAL TOURISM IN THE WORLD: HISTORY AND CONTEMPORARY PRACTICES

There are various opinions on origination of rural tourism as a separate segment of tourist market. In 1952 authorities of France supported the idea of accommodation of tourists on farms. It was expected that such an activity provided a secondary source of income for rural people, however by 1970s incomes from rural tourism of some farms even surpassed the ones from traditional farming activities (Ichetkina, 2012). Italy was also among the very first countries, who started rural tourism in 1960-1970s. Since that time, it flashed around the Europe and turned out to one of the most perspective kinds of tourism.

Analysis of international experience and historical issues of rural tourism in Europe let us to conclude five main preconditions for such a rapid growth of that kind of tourist activity in Europe:

1. Many of European people and, more important, governments of European countries started to consider growing environmental problems of big European cities and agglomerations in the early 1970s. The demand for naturality, fresh air, natural quietness and environmentally pure products arose at that time together with the strong awareness of environmental way of life and sustainable development.
2. On the very early stages of its development (1970-1980s) rural tourism was a part of state protectionism policy in Italy and France, which supported establishment of new job opportunities in rural areas.
3. Other countries were forced to look for alternatives to traditional agricultural activities in their rural areas as well, due to worsened economic and social situation in rural areas and shortage of resources to support domestic agricultural producers.
4. Agricultural production in most of the European countries demanded additional internal sources of income and support in order to ensure its development in the conditions of growing internationalization.
5. Demand for rural tourism services grew rapidly, since customers appreciated that new kind of recreation because of combination of environmental, recreational, cultural, and even historical approaches.

According to the UNWTO, annual increment of rural tourism as about 6%, while overall tourist industry grows on 2% (Almukhamedova & Vilenskaya, 2013). Such an outstripping growth rate of rural tourism confirms its perspective and importance for the tourist market in general.

Currently, there are over 700 mln tourists worldwide annually; 12% of them prefer rural-related recreation (Andreeva, 2011). Correspondingly, those figures characterize international flows only; however amounts of domestic rural tourists in some of the countries are quite substantial. Since rural tourism unites a wide range of various kinds of tourism, based on natural, historical, cultural, and other resources or particular rural areas, it grows rapidly. Over the past two decades, rural tourism in the USA and EU turned out to an independent high-profitable tourist industry. As of the UNWTO, rural tourism is now among five major strategic development directions of tourism until 2020 (Baranov & Bisko, 2012).

Rural tourism is popular in EU and USA for a number of reasons:

1. Growing mobility of people due to better availability and coverage of transport networks, including automobiles.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

2. Better organization of vacation time (weekends, holidays, shorter, but more frequents vacations, etc.).
3. Increasing dynamics of urban life and level of related stresses.
4. Variety and quality of tourist services, offered in rural areas, their specialization (educational, cultural, historic, ethnographic, gastronomy tourism, hunting, fishing, entertainments for children, etc.).
5. Popularity of outdoor social events (excursions, walks, cycling, horse riding, other specific kinds of sport).
6. Growing interest to cultural heritage of certain regions and territories, their traditions, local specialties and holidays (Kazmina, 2012).

Rural tourism is particularly relevant in developing nations where farmland has become fragmented due to population growth. The wealth that rural tourism can provide to poor households creates great prospects for development. However, world leading countries in the sphere of rural tourism are developed ones: USA, France, Spain, and Poland. Rural sector of tourist market is especially developed in Europe. There is the European Federation of Village and Farm Tourism, which unites 24 countries. Rural tourism encounters up to 20-25% of overall income of tourism industry in Europe, and that level increases year by year (Sysoeva, 2014).

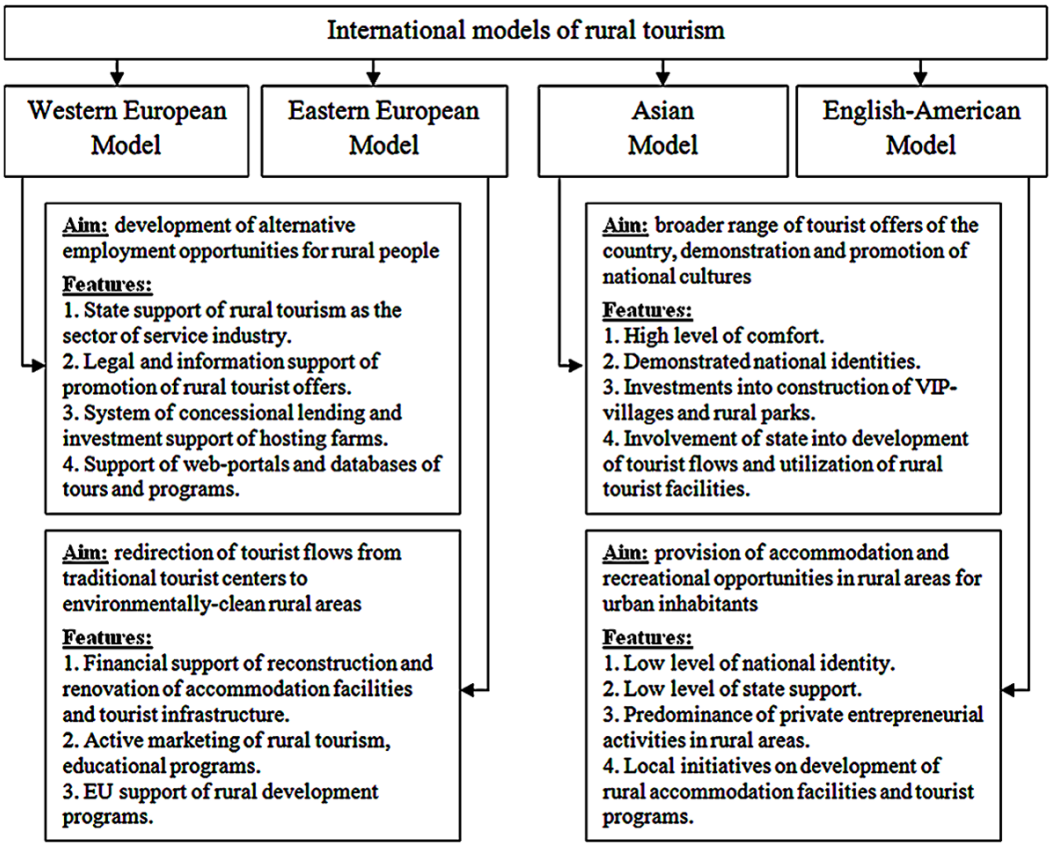
Rural tourism exists in developed nations in the form of providing accommodation in a scenic location, ideal for rest and relaxation. We have studied contemporary practices of several countries, where rural tourism is the most developed, particularly USA, France, Spain, and Poland.

According the USDA, Cooperative State, Education and Extension Service, tourism is becoming increasingly important to the U.S. economy (USDA, 2008). Many niche tourism programs are located in rural areas. From wine tours and eco-tourism, to rural tourism and seasonal events, tourism can be a viable economic component in rural community development. The publication "Promoting Tourism in Rural America" (LaCaille, 2008) explains the need for planning and marketing rural communities, as well as weighing the pros and cons of the impacts of tourism. Local citizen participation is helpful and should be included in starting any kind of a tourism program. Being prepared when planning tourism can assist in a successful program that enhances the community. An estimate from the Federal Reserve Board in Kansas, based on 2000 data, shows that basic travel and tourism industries accounted for 3.6% of all U.S. employment (Wilkerson, 2003). Data from the Travel Industry Association of America indicate that one out of every 18 people in the U.S. has a job directly resulting from travel expenditures (Travel Industry Association of America, 2004).

Rural tourism is one of the major parts of tourist industry for some of the European countries as well. Thus, rural tourism in France is mediated by the National Organization of Recreation and Green Tourism. This organization provides recreational services, accredited according to the high national quality standards. France is visited by 7 mln tourists annually, who prefer rural recreations. There is a program of children's rural recreation during school holidays. Children aged 3-13 years are accommodated in families, get acquainted with rural household, play outside, and go hiking. They also learn folk dances, crafts, and foreign languages. The quality of such recreation is controlled and certified by the Ministry of Health Care and Social Support and the Ministry of Youth and Sport (Kundius & Chermyanina, 2011).

Rural tourism is also developed in Spain. This country attracts more foreign tourists into its rural areas (about 1.2 annually), in comparison with its domestic rural tourist flows. Spain offers over 5,000

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use



thousand various programs of rural recreation. Its rural sector is able to accommodate over 27,000 tourists at once. The prices are appropriate – $25-100 per night (Kundius & Chermyanina, 2011).

Another European country, where rural tourism is developed, is Poland. There is a target educational program "Green Schools", which includes obligatory two-week accommodation of children from urban areas in rural settlements, in specialized rural tourist households. Such recreation gives children opportunity not only to rest, but also to learn rural way of life. There are special education courses offered, for example "From Grain to Loaf", when children are involved in bread making (grain milling in a windmill, dough making and bread making) (Kundius & Chermyanina, 2011).

Studying the history and international experiences of rural tourism in various countries of the world, we have emphasized four models of rural tourism (Figure 1).

There are certain differences between four models, including two European ones. While the Western European Model aims at promotion of alternative sources of income for rural people through new employment opportunities, countries of Eastern European focus on redirection of their tourist flows from traditional tourist centers to rural areas. However, the final aim is to support those areas, since many of them are economically-depressed.

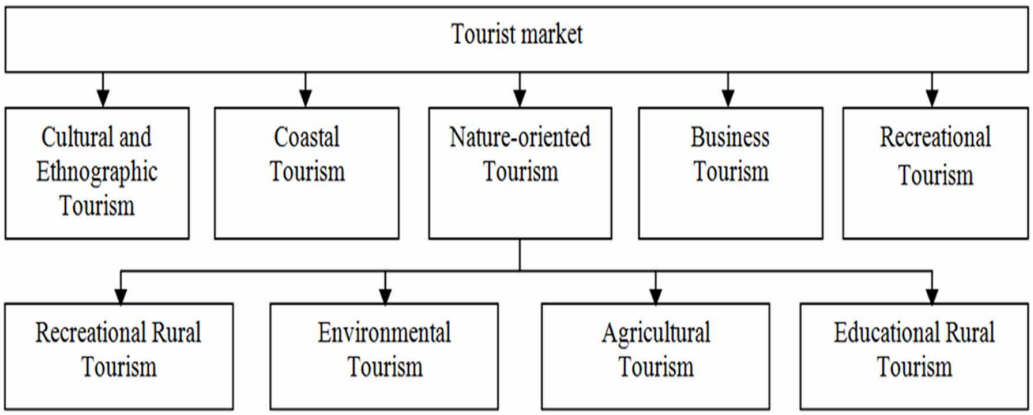
Figure 1. Major models of rural tourism and their features
Source: Author's development.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Asian countries are very active in large-scale projects in rural areas. Governments support big constructions; the whole new complexes are established. It is very important for Asian countries to promote their national cultures and identities through historical, cultural and ethnographic programs in rural areas.

English-American Model of rural tourism is very conservative. It is oriented on provision of recreational opportunities for rural inhabitants in rural areas, and more focused on rural issues (rural way of life, contact zoos, etc.), than on national identities.

Anyway, regardless of the region and model, the portrait of an average rural tourist is as follows. That is likely a woman: women-men ratio is about 65% to 35%. Tourists are usually come with families with two kids in average. They are usually active sport people, would like to be closer to nature, and are open-minded to new impressions and opportunities. About 37% of rural tourists worldwide are aged 35-49; others are young people, attracted by rural romantics, and the older generation, who would like to rest from noisy cities. Tourists are more likely have medium or high level of income, and live in big cities (Sysoeva, 2014).



Rural Tourism in Russia: Weaknesses and Challenges

International tendencies are widespread, and new countries are getting involved into rural tourism activities. That is also the case of Russia, where rural tourism becomes more popular year by year.

Contemporary tourist market of Russia has several major segments (Figure 2).

The major preconditions of effective development of rural tourism are, on one hand, unique natural conditions, cultural potential of rural areas, national identity, and interesting traditions and customs, on other hand, demand for such type of recreation from urban inhabitants. As rural tourism is on the very early stage of development in Russia, there is no big competition in this market niche. The most developed regions in terms of rural tourism are Krasnodar Krai, Republics of Altay and Karelia, Leningradskaya, Pskovskaya, Yaroslavskaya, Ryazanskaya, and Kaliningradskaya Oblasts. Nevertheless, experts forecast a rapid growth of demand for rural recreation and related activities in most of the regions of Russia within the next few years (Sysoeva, 2014). Internet portal Hopes&Fears included development of local and, in particular, rural tourism, into the top-ten business trends in Russia (Kopylova, 2014).

Figure 2. Major segments of domestic tourist market of Russia with focus on rural and related tourism
Source: Author's development.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

As international experience shows, rural tourism not only creates new employment opportunities, but also supports preservation of small rural settlements and rural way of life, increases living standards of rural people and their incomes, and retains young people in rural areas. In turn, urban people have an opportunity to spend time outdoors, to test organic food, and to learn more about agriculture. The major directions of development of rural tourism in Russia are establishment of tourist villages on the basis of existing rural settlements with traditional architecture; rural tours with accommodation and meals for tourists; acquaintance with traditional rural way of life and crafts; rent of houses and rooms in environmentally clean districts (What is Rural Tourism, 2010).

Motivation of accelerated development of rural tourism in Russia includes the following reasons:

1. Deterioration of environmental conditions in big cities, growing level of technogenic burden and stress.
2. Temptation to spend holidays in environmentally clean areas.
3. Reappearance of interest to elements of traditional folk culture: architecture, cuisine, crafts, folklore art, and language.
4. Search of new sources of alternative (non-agricultural) income for rural people.
5. Desire to broaden communication network.
6. Growing competition in traditional spheres of investments in rural areas, search of new spheres and objects for investments.

According to the survey, held by Volkov (2012), the most popular kinds of nature-related recreation are hunting, fishing, and gastronomy tourism. The older generations are more interested in visiting historical and cultural places. The average period of tourist mobility is about 5-10 days. Shorter tours on holidays are demanded as well. The preferred time of recreation is summer. Winter recreations for hunting and fishing are also popular. Spring and autumn are low seasons in rural tourism (Sysoeva, 2014).

The resource potential of Russia is favorable for development of rural tourism. There are vast areas of agricultural land of appropriate quality and environmental conditions, high cultural and natural diversity of the country, well preserved local traditions and identities, and rich historical and cultural potential.

Unfortunately, having such huge potentials, most of the rural areas in Russia are far behind the ones in the above studied developed countries. Tourist companies, involved in rural tourism, seek for state support, since tourist flow is still low, and rural infrastructure is underdeveloped. However, in some of the regions of Russia local authorities started to pay their attention to infant industry of rural tourism.

Particularly, Rostov Oblast, one of the most industrially and agriculturally developed region in the southern part of Russia, develops two of its competitive advantages in the sphere of rural tourism: agricultural and ethnographic. Regional government together with local administrations organizes series of interesting events, which attract urban people to rural settlements. They are, for example, All-Russian festival of literature and folklore "Sholokhov Spring" in Veshenskaya settlement, regional ethnographic festival "Don Vine", and folklore theatrical performance "Festival of Don Fish Soup" (Almukhamedova & Vilenskaya, 2013).

Another region of Russia, which supports domestic rural tourism, is Kaliningrad Oblast. Kaliningrad's projects, related to rural tourism, were also supported by the European Union. The most western region of Russia is attractive for Europeans, since it shares boarders with Poland and some other EU countries. The region is popular among people from Moscow and Saint Petersburg as a holiday destination, attractive by unique environment, mild climate, Baltic seashore, and amber crafts (Kopylova, 2014).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Moscow and Saint Petersburg, being the biggest cities in Russia, form a potential market for rural tourism. Located at a distance of 700 km from each other, they are the sources of effective demand for rural recreations for the regions between them. That is why development of rural tourist infrastructure in neighbor Tverskaya, Yaroslavskaya, Novgorodskaya, and Pskovskaya oblasts (apart from Moskovskaya and Leningradsksya themselves), is very perspective. There are many abandoned and destroyed villages between those agglomerations, since most of the population migrated to cities seeking better employment opportunities. However, those villages are attractive for investments, since constriction of ethnographic and rural tourist facilities is possible from scratch. There are whole villages in Yaroslavl Oblast, where tourists may follow master classes on various crafts. Such attraction points are becoming more and more popular among Russian and foreign tourists (Rural Tourism, 2012).

Small private museums and other attractions are also popular. There are over 30 such mini-museums of dolls, vodka, or teapots in Uglich. Every small town or rural settlement has the same opportunity. The main thing is how to position the tourist object and promote it, attracting potential partners and visitors. Effectiveness of rural tourism is very often in a direct correlation with efforts undertaken and ideas generated, since tourism is always about selling new impressions and positive emotions (Rural Tourism, 2012).

The analysis of contemporary market of rural tourism in various regions of Russia let us to discover the most common forms of rural tourism. They are target regional programs; rural tourism in national parks; tourist programs of individual entrepreneurs and rural households; rural tourism on farms; guest houses in rural areas; big tourist complexes and ethnographic villages.

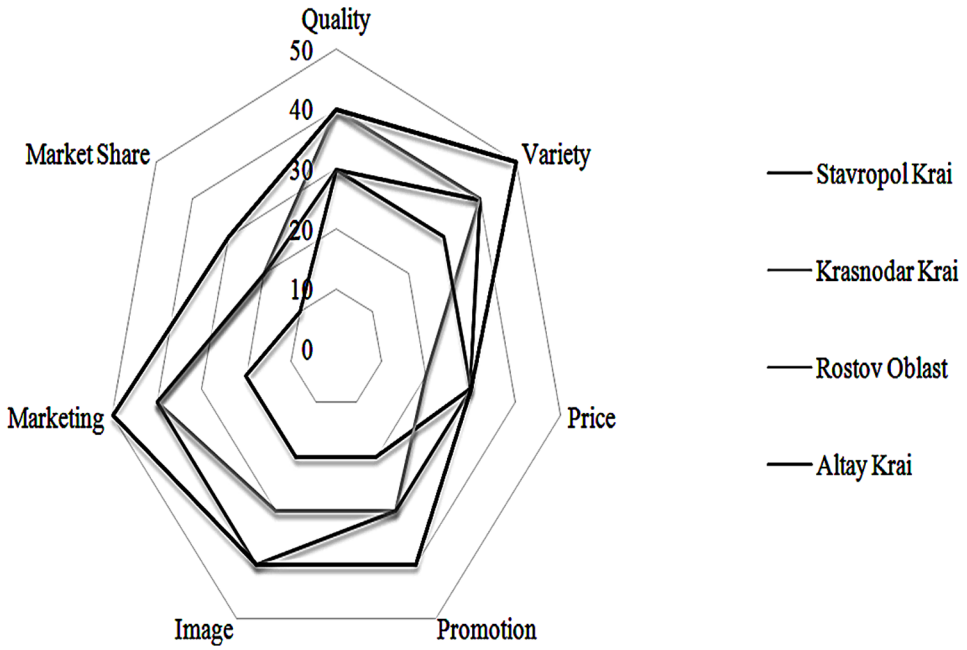
Being the residents of the Stavropol State Agrarian University, located in Stavropol Krai, one of the regions of the southern Russia, we have also studied the contemporary state and potentials of rural tourism in that area. Doing that, we have compared the region with neighbor regions of Krasnodar and Rostov, and with Altay Krai, one of the leading regions of Russia in terms of development of rural tourism. The analysis of competitors included seven criteria:

1. Quality of services in the sphere of rural tourism and recreation.
2. Variety of rural tourist product, assortment of services and activities available.
3. Average price (holiday of a family of three people is accepted as a comparative base).
4. Promotion of tourist services and products, information network.
5. Image of the region, variety of its cultural, historical and ethnographical identities.
6. Development of marketing channels and ways of distribution of tourist products and services.
7. Domestic market share of rural tourism.

Each criterion is weighted: the lowest weight is 1 (poor), the highest is 5 (excellent). The assessment of four regions and seven criteria is concluded in the Table 1.

Analysis let us to discover strengths and weaknesses of each region, as well as their overall competitiveness in the sphere of rural tourism. It provides an overview of existing competitive advantages, targets, implemented strategies and tools. We may see, that Stavropol Krai, having a good variety of recreational and tourist opportunities (developed agricultural production, vast rural area, clean environment, mild climate, spa resorts, mountain tourism, rich ethnographical heritage, etc.), is still weak in promotion, marketing and distribution of those products and services to customers.

Based on the above presented assessment we have developed the "competitiveness polygon", which gives a picture of current levels of development of rural tourism in four regions (Figure 3).



EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Assessment of comparative effectiveness and development level of rural tourism in selected regions of Russia

Criteria	Stavropol Krai	Krasnodar Krai	Rostov Oblast	Altay Krai
Quality of tourist product and services	3	4	3	4
Variety and assortment of tourist product	4	4	3	5
Average price	3	2	3	3
Promotion of tourist products and services	2	3	3	4
Image of the region, variety of identities	2	3	4	4
Marketing and distribution	2	4	4	5
Market share of rural tourist in the region	1	2	2	3

Source: Author's development.

Figure 3. Competitiveness polygon of rural tourism in selected regions of Russia
Source: Author's development.

Despite the essential differentiation of Russia's region in the context of development of rural tourism and various practices implemented, the overall tendencies are more or less the same. Obtaining a wide variety of competitive advantages and potentials for rapid development of rural tourism, Russia is still very far behind a number of developed (and even developing) countries. We have concluded the major competitive advantages and weaknesses of rural tourism in Russia, and combined discovered advantages (as strengths) and weaknesses (as threats) into the matrix of threats to sustainable development of rural tourism (Table 2).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Matrix of major threats to sustainable development of rural tourism in Russia

		Threats			
		1. Seasonal character (workers may lose income during low seasons)	2. Limited opportunities for high-qualified labour force	3. Destruction of local cultural and ethnographic environment	4. Shortage of resources available for traditional agricultural activities
Strengths	1. Natural and environmental resources, including vast rural areas 2. Differentiated historical, cultural and ethnographical identities of various regions 3. Alternative employment opportunities for rural people 4. Modernization and development of rural infrastructure 5. Retention of labour force in rural areas, its professional development 6. Development of organic production 7. Better environmental awareness of society	Diversification of tourist services and products. Stronger promotion of "low season" activities: ethnographic, gastronomy, and cultural events, not very much dependent of season	Programs for education and professional development of rural people. Special programs of career development for younger generations in order to retain them in traditional rural environment	Prioritization of "identity points" for each region, district and even settlement. Deeper specialization of tourist programs. Promotion of local cultural and ethnographic identities through special events, festivals, educational programs.	Diversification of income sources for rural people. Support of local agricultural production (including organic one), as a food base of a growing sector of rural tourism. Supply of incoming tourists with healthy local food and products.

Source: Author's development.

The major threats to sustainable development of rural tourism in Russia included its seasonal character (tourists prefer to come during summer or winter, but not in spring or autumn); limited opportunities for implementation of high-qualified labour force (until now most of the employees with high qualification leave rural areas and seek for better jobs and financial benefits in cities); "erosion" of local cultural and ethnographic environment (it is easier to offer tourists some popular product or service, than to develop a new one on the basis of local identity and to promote it); shortage of financial and labour resources for traditional agricultural production. Certainly, there are many more threats, which may be discovered and should be considered as essential ones for development of rural tourism. Some of them are hidden, nevertheless are even more substantial, than the tangible ones. Since Russia still has not adopted federal law in the sphere of rural tourism, there are uncertainties over administration, taxation, and other regulations. Because of that many rural household do not want publicity, and work in a "shadow". That is some kind of a vicious circle: one will never increase number of customers substantially without advertising, however the more you advertise yourself, the more you attract attention of controlling bodies (sanitarian and fire inspections, tax inspection, police, etc.). In case of undeveloped legislation, those inspections may easily change into either administrative pressure or even corruption cases. There are regularities for big hotels and restaurants, but they should not be implemented to small rural households, which decided to open a small guesthouse of café. There should be developed separate requirements (Kopylova, 2014).

Analysis of existing practices and positive experiences of various regions of Russia let us to elaborate a range of recommendations in the sphere of rural tourism, related to development of legislation and state support on federal and regional levels. The major are:

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

1. Establishment of the unified register of subjects of potential entrepreneurship in the sphere of rural tourism and development of classification for products and services, produced within a rural settlement or district, which may be potentially utilized for the purposes of rural recreation. Such measure would let to discover competitive advantages of certain territory, and prioritize them.
2. Encouragement of businesses to promote rural products and services. In case of rural tourism, there should be organizational and information support of tourist agencies, which market rural recreation, in case of organic production – farms and distributors.
3. Correction of system of extension, consulting and educational services for rural tourism needs. There should be both federal corrections, and regional target programs and initiatives.

Rural tourism should become the economic growth point in rural areas, which drives entrepreneurship and supports solution of numerous social and economic problems of rural settlements. There should be also a system of state support developed for non-governmental and non-commercial organizations in rural areas, which would facilitate the overall process of sustainable rural development, including tourist, recreational, social, and cultural activities.

For its effective development, rural tourism has to be considered as a very perspective business and attractive field for investments. According to Ichetkina (2012), potential rural tourist market in Russia is about $2 bln annually; its profitability is expected to be 15-30%. As per one administrative district, potential annual income from rural tourism is assessed as $1 mln. There are over a thousand of administrative districts in Russia, which have appropriate and favorable conditions for development of rural tourism. That means a potential annual effect of rural tourism in Russia in the amount of $1bln. In case of complex approach (tourism plus development of related agricultural activities), an effect may grow up to $2 bln (Ichetkina, 2012). That confirms importance of rural tourism for rural areas as a source of income, alternative to traditional agricultural production, and a tool to diversify rural economy and to ensure sustainable rural development in the conditions of high vulnerability of international economics and growing international competition.

Tourism as a Factor of Sustainable Rural Development

As our analysis shows, rural tourism allows the creation of a replacement source of income in the non-agricultural sector for rural dwellers. The added income from rural tourism can contribute to the revival of lost folk art and handicrafts.

One of the most severe threats to sustainable rural development is unemployment in rural areas. Levels of unemployment and poverty are twofold higher in comparison to urban areas; while rural labour compensations are twofold lower than the ones in other industries. Small and medium farming is being developed slowly; rural economy stays sector-specific; recreational potential is underutilized. According to the All-Russian research institute of rural economy (VNIIESH), over one third of rural people consider an opportunity to leave rural areas in favour of cities. Among young people that share is even bigger – up to a half (Bondarenko, 2011). In 2000-2013 employment in rural areas was essentially lower in comparison to cities. There is an overall growth of employment rate, observed both in rural and urban areas in 2000-2013, however the growth rate for urban areas is threefold bigger, than in the rural ones. Employment rate for urban areas in 2013 gained 7.5 percentage points in comparison with 2000, while the one for rural areas – only 2.4 (Erokhin, 2014).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

However, high level of unemployment may be turned into an advantage. When employment opportunities are limited, people try to find alternative sources of income by themselves, establishing new businesses and implementing new ideas (Erokhin et al, 2014). For the purposes of rural tourism, unemployment means labour resources, not involved into other industries, which may be easily welcomed by newly established rural tourist facilities. Qualification of such free labour resources may be developed through special education programs and trainings.

Apart from unemployment, rural tourism is one of the ways to solve other problems of rural areas (primarily, deterioration of environment, soils and water resources, decreasing biodiversity) and ensure their sustainable development. Rural tourism is a tool to diversify rural economic, increase demand for local products and services. Such approach changes position of rural households and people: they become producers of agricultural products and providers of qualitative tourist services, demanded by local and external customers (Erokhin & Ivolga, 2013).

As international experience shows, rural tourism is also a way to elaborate strategies of rural development and enhancement of the role of local authorities. Local authorities and other structures across Europe consider development of rural areas as a priority direction of their activities in the context of integration with other aspects of rural life.

Sustainable rural tourism assumes solution of the whole range of problems: development of environmental tourist product; rational utilization of natural and cultural heritage of the region; consideration of interests of local economy on the basis of interaction and cross-fertilization; support of rural entrepreneurship and encouragement of enterprises, related to rural tourism; involvement of rural population and local communities into development of rural tourism and related industries; coordination of interests of businesses and local inhabitants on the basis of partnership and mutually advantageous collaboration (Kazmina, 2012).

In case of developing countries, where investments into agriculture and volume of state support are manifold lower in comparison to the developed ones, rural tourism has a serious potential to grow into a real alternative to traditional agricultural production, since it allows creating new sources of income for rural people without substantial investments (Erokhin & Ivolga, 2012). Certainly, more investments will be required as rural tourist market grows, but only accommodation facilities, people and some kind of entertainment program are needed to start up the business. As soon as new tourist offer becomes attractive, market mechanisms will automatically bring more investments into the business with high return rate.

Most of the businesses and authorities acknowledge prospective viability of rural tourism. However, are there real market preconditions for its development in Russia nowadays? Is it possible for rural tourism to turn into a real alternative to traditional agricultural production in the foreseeable future or that is just a fake? Interest to agricultural production in Russia is growing very slowly. As long as there are other industries with better return rate (oil and gas, metals, etc.), agriculture will lack investments (Erokhin et al, 2014). Misbalance may be corrected by state support and redistribution of financial resources, but such artificial mechanisms are always not very much effective and sufficient. There is a certain interest to organic production and consumption of environmentally clean products in Russia. The market is still very narrow, but year by year people more and more consider of what they eat. However, the demand is not always effective, since only consumers with a certain level of income in Moscow, Saint Petersburg or other big cities are ready to pay price premium for better qualities of organic products and food. They even ready to pay more, than in restaurants, if the organic approach is successfully marketed. People with lower incomes are not ready for higher prices, although they aware of organic food. Those categories

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

are two major target groups for rural households. Farm food, offered in rural households during touring, is an excellent alternative to expensive organic products from supermarkets. People may see the whole production process, or even participate in it, and it provides farm food with an additional value.

In spite of interest to rural tourism and declaration of its importance for rural economic, there are no further actions from the government. There is no real support of rural tourism on the national level. However, as we have already discovered above, there are regions in Russia, which support rural tourism on their territories. Regional and local authorities see the potential of rural tourism, and do much for its support through target programs and other administrative, legislative and economic initiatives, where possible. Altay Krai is one of the most advanced in this way among other regions of Russia. Regional government supports rural tourism on the regional level; there is the regional target program implemented. Such regions as Kaluzhskaya, Belgorodskaya and Arkhangelskaya oblasts, and Republic of Karelia put over development of rural tourist households. Kaliningrad Oblasts starts to develop that direction as well (Kopylova, 2014).

SOLUTIONS AND RECOMMENDATIONS

Studying development programs in the sphere of rural tourism, implemented or currently existing in the regions of Russia, we have emphasized six major characteristics:

1. Involvement of administrative advantage.
2. Association of wade range of shareholders.
3. Assessment of resource potential of a territory.
4. Program staffing.
5. Investments into infrastructure of a territory.
6. Establishment of distribution channels for rural tourist offers and programs.

Governmental support is not able to do anything without development of entrepreneurial activities of rural people and businesspersons. Since rural tourism is a brand new kind of business in Russia, there are certain risks and uncertainties involved (long period of business start-up, difficulties in promotion and marketing of tourist products and services, high environmental standards to be met, and negative attitude of local people at least in the first instance).

Those difficulties may be loosening by joint involvement of local authorities, businesses, and rural people into development of rural tourism. It is possible to do through integration of all shareholders. There is the National Association of Country Tourism Organization, established in Russia in 2008, which is involved into consulting and education in the sphere of rural tourism, as well as brings together concerned parties. Regional associations and unions in the sphere of rural tourism should be established as well in order to accumulate Russian and international experience and best practices of rural tourism; establish extension, consulting and professional development centers for adults and educational centers for children; support regional government and related administrative bodies in development and implementation of target programs in the sphere of rural tourism; provide professional expertise of tourist programs and projects on the part of business, society and environment; develop tourist standards; provide certification opportunities for local farms and rural households; organize fairs and exhibitions.

FUTURE RESEARCH DIRECTIONS

Alongside with the discovered problems and obstacles, the conducted research resulted with a range of perspectives of rural tourism in Russia. They are increasing employment opportunities for rural people, development of market for local agricultural (including organic) and souvenir products, alternative sources of income for rural people, prioritization of economic growth points for certain territories, cooperation of farms and rural households and development of regional infrastructure for rural tourism, promotion of new image of a territory as a provider of diversified and qualitative agricultural and tourist product, and growth of investment attractiveness of a region.

Contemporary state-of-the-art of rural tourism in Russia is still far behind the majority of the developed countries. Russia has essential resources for development of rural tourism, but real utilization of existing potentials is true for several regions of the country only. Further investigations in the sphere of effectiveness and sustainability of rural tourism are vitally important. Supported by adoption of the federal law, elaboration of the federal development program in the sphere of rural tourism, and targeted state policy, they may unlock the potential of rural tourism in Russia.

CONCLUSION

Rural tourism has to be considered as one of the directions of anti-crisis policy in rural areas. Development of tourism and recreation in rural areas leads to creation of new working places and alternative income opportunities in rural areas, attracts investments and promotes interest to rural way of life and traditions.

Rural tourism as an alternative source of income in addition to the traditional agricultural production is especially perspective in developing countries, where investments into agriculture and volume of state support are manifold lower in comparison to the developed ones. However, developing countries still face many problems when start developing their domestic rural tourist industries.

In order to ensure sustainable development or rural tourism, the management concept is required to be adopted. That should be the system of approaches to ensurance of favorable conditions for development of rural tourism as a high-effective, low-cost and competitive industry with positive social and cultural effects for local population and entire society. Such concept has to be based on the following principles:

1. Environmental friendliness, which is an aspiration to align mechanisms of preservation and reclamation of natural, social and cultural environment with business purposes.
2. Sustainable development, which is an optimization of development parameters with consideration of growth ceiling, determined by internal characteristics of production system and external environmental factors.
3. Effectiveness, which is the basis of production and market.
4. Social partnership between administration, business, local communities, and a wide range of other shareholders, including non-governmental and non-commercial organizations.
5. Relevance of adopted measures to specifics and peculiarities of rural tourism in certain territories.
6. Differentiation of approach to organization and implementation of various measures and events in the sphere of development of rural tourism.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

In case of Russia the above mentioned principles have to be introduced through the system state support of rural tourism as a socially and economically important industry, regulatory support of rural tourism development, elaboration and support of development programs in various regions of Russia, and establishment of federal and regional associations and unions of rural tourism shareholders. The latter measure is also related to development of extension services in the sphere or rural tourism. Extension and consulting networks should bring specialists together in order to support newly established and already existing businesses. Those centers may also accommodate professional development programs and trainings in the sphere of non-agricultural business and other alternative income opportunities in rural areas.

KEY TERMS AND DEFINITIONS

Agricultural Production: Animal breeding and plant production by means of natural forces.

Alternative: One of the available variants of economic behavior compared to another variant in order to choose the best way of action.

Organic Production: System of farm management and agricultural production, which combines environmental methods of production, high level of variability, preservation of natural resources, and high environmental standards of agricultural production.

Rural Tourism: A kind of activity, related to organization of dedicated travels to rural areas, which provides tourists with a complex tourist product (accommodation, meals, excursion services, and entertainment), reflects and preserves natural and cultural identity of regions, and ensures economic benefits for hosting communities by development of employment opportunities and alternative sources of income for local population.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Sustainable Development: A model of social development, which implementation satisfies all major vital requirements of current and every other generation under preservation of natural and environmental diversity.

Transition: A process of state transition, when radical transformation of entire social and economic systems occurs (transformation of property relations, social and economic institutes, management tools, and targets of economic development).

Chapter 60
Challenges and Opportunities for the Development and Management of Urban Green Areas in Addis Ababa:
The Case of Cooperative Housing Green Areas and Street Trees in Nifas Silk Lafto Sub-City

Gebrye Kefelew
Addis Ababa University, Ethiopia

Tebarek Lika
Addis Ababa University, Ethiopia

ABSTRACT

This chapter examines the challenges of, and opportunities for, the development and management of cooperative housing green areas and street trees. To deal with this issue effectively, the study employed mixed research methods and used questionnaires, in-depth interviews, focus group discussions, observations and desk reviews, for the purposes of data collection. The findings of this study identify a lack of awareness on the part of the public and of government employees, weak institutional capacities, a lack of coordination among stakeholders, and the absence of clear ownership and enforcement mechanisms, as representing the major challenges impacting the development and management of cooperative housing green areas and street trees. Therefore, in order to develop and manage these green areas properly, the study recommends that the good will, the coordination and the efforts of all stakeholders, including communities, government authority, and non-governmental bodies, be enhanced and duly coordinated.

The concept of the smart city is not a static one: there is no absolute definition of the smart city, no end point, but rather a process, or series of steps, by which cities become more "livable" and resilient, and thus able to respond more quickly to new challenges. The Office for the Revision of the Addis Ababa Master Plan has also explained that a smart city includes not only smart technologies, but also smart residents, smart mobility, a smart economy, smart housing, smart governance, and smart urban green area development and management. Thus, the development and management of urban green areas such as cooperative housing green areas and street trees, which are the focus of this chapter, are part of the definition of the Smart City in Addis Ababa. This is due to the fact that the development of multi-functional cooperative housing green areas and street trees contributes towards the aims of the smart city in terms of the improvement in the quality of life and environment for the city's population (Alamrew, 2002). The preservation of cooperative housing green areas and street trees in and around the city, also provides psychological satisfaction for the residents. An interesting insight into the purpose of urban green areas and their contribution to smart city development, is provided by Wondimu (2006). He argues that a city or town without sufficient green space can be qualified as an organism with no respiratory system.

As the city of Addis Ababa is now in the process of rapid economic transformation and urbanization, there is growing concern about the fate of green areas. The capital was once called the "forest city". In fact, at the beginning of the 20th century, some 10 million trees were imported from Australia and planted all over Addis Ababa (Berlan, 1963 cited in Wondimu, 2006). Since the nationalization of land in 1975, the green areas in the capital have been subjected to excessive exploitation and severe degradation due to the lack of careful management of green areas and inadequate greening activities (Horst, 2006). Recently, the city administration has been also unable to keep pace with the expectation emanating from the services and facilities of urban green areas and the city's international notion. Moreover, the smart development and management of urban green areas in Addis Ababa barely meets the standards set by other rival African cities, or even the standards set out in the master plan of the city itself (ORAAMP[1], 1996).

The smart development of cooperative housing green areas and street trees is usually planned and indicated in the settlement plan and road design of Addis Ababa. However, these green areas are not operating properly, or are not used appropriately by the residents of Addis Ababa. There are many problems related to these urban green areas, one of which is the level of cleanness. It is true that cleanness is one of the operational attributes for the good quality of urban green spaces, as this creates comfort and convenience for its users. Addis Ababa, however, is not lucky enough to have clean cooperative housing green areas and street trees. Indeed, in some cases these urban spaces are places where homeless people live, dump their garbage and use as toilets. Furthermore, the absence of the effective, timely cleaning and maintenance of these spaces further aggravates the problems.

Cooperative housing green areas also have problems concerning their current functionality and operation. In principle, they should serve all members of the housing cooperative; and they have to be accessible to such members. However, some of these areas are closed, or are simply vacant lots which do not offer any kind of public service. This situation also negatively impacts the environment, the appearance and the economic development of the city.

Generally, these green areas suffer in terms of their appearance, maintenance and cleaning. Moreover, there are also problems related to the extent of the availability and practicality of these urban spaces. However, Addis Ababa is going through a process of transition. Planning for future development and the implementation of management strategies are therefore essential for such urban spaces. However, very little systematic research has been carried out into cooperative housing green areas and street trees in Addis Ababa City.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

All the aforementioned problems are also true in the subject area of this study, Nifas Silk Lafto sub-city (NSLSC[2] BPCDM[3] office report, 2011). They are once again the result of the approach taken to the planning and development of these spaces, or of their management, or perhaps the combination of all such factors. Therefore, the challenges faced by cooperative housing green areas and street trees need to be analyzed in terms of planning for development and introducing better management mechanisms to expand the available services by taking advantage of existing opportunities in Nifas Silk Lafto sub-city.

This chapter aims to answer the following questions:

1. What problems are involved in the development and management of cooperative housing green areas and street trees?
2. What are the current local strategic practices for developing and managing cooperative housing green areas and street trees?
3. In what ways are the stakeholders involved in the planning, development and management of co-operative housing green areas and street trees?
4. What opportunities exist for the development and management of cooperative housing green areas and street trees?

THEORETICAL INSIGHTS

The Development and Management of Urban Green Areas as a Contribution towards the Development of Smart Cities

The concept of smart cities is difficult to define. The idea underlying the term "Smart City" is that by using innovation and technology, resources can be used much more efficiently. The term has a technological background and origins. Recently the concept of smart cities has gone beyond mere technological advancement, and many actors from different disciplines have tried to use various characteristics to define the concept of Smart City. For instance, Giffinger (2007) used six smart categories – People, Mobility, Living, Government, Economy and Environment – for an international ranking of Smart Cities. This typology has also been used by the European Commission (2014).

As we have inferred from the aforementioned concept of the Smart City, aspects of the urban environment such as green areas are considered to constitute smart city categories. The quality of life is also a major objective for most Smart City strategies. Well-functioning, attractive public spaces, together with an attractive environment, can act as symbols of a city and of living together, and may create a sense of ownership of the city among its population (European Commission, 2014). The same author also explained that public open spaces such as cooperative housing green areas and street trees are important factors when defining a city's "smartness".

Urban Green Area Development and Management

Recent studies have shown that planning the development and management of urban green areas requires the integration of the views of both planner and user. For instance, a study in Madina showed that the majority of users (80%) and (71%) want grass / turf and evergreen plants in their green spaces respectively (Irum et al., 2002). This indicates that during the planning, development and management

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

process, users' views should be taken into account. If urban green space development strategies fail to include stakeholders' participation, this implies that social and environmental functions are being neglected (Balram & Dragicevic, 2005).

A study in Ankara, Turkey, shows that green space users' preferences include sitting on benches, walking and running facilities, a pleasant landscape, visual elements, nearness to water and a peaceful atmosphere (Oguz, 2000). In the pursuit of the development of quality green spaces, the standards should be set locally to accommodate requested activities and future changes. Public participation in the urban green area development and management process is very important if their values and ways of life are to be incorporated into the process[4].

Experiences involving the development of urban green areas also demonstrate that an effective way of managing urban green areas should be formulated according to an integrated approach and through subject-specific (thematic) strategies. An integrated approach entails the active involvement of the community, together with cooperative, enabling partnerships between local authorities, local businesses and voluntary groups (Bartone et al., 1994). The management of urban green areas within the overall functional area of a political authority and/or built-up city is also a thematic strategy (European Commission, 2007). Moreover, this approach is based on cross-departmental/sectoral cooperation, engagement with all relevant stakeholders, and the integration of local, regional and national policies[5].

Baycan-Levent and Nijkamp (2004) stated that urban green area development and management requires the active involvement of public, private and non-governmental actors at individual, community, city and national levels. Urban green area development and management should therefore involve those whose interests are affected both by green problems and by management strategies and action plans; that is, those who exercise control over the instruments used for implementing green management strategies, and those who possess the relevant information on a wide range of green issues.

Practical Experience of the Planning of Urban Green Areas in Ethiopia

The consideration of urban green areas in country's urban planning ventures and other social and economic development undertakings, has paramount importance for sustainable development. In this regard, the urban planning process in Ethiopia has been incorporating the issue of urban green areas in the overall planning exercise since 1886 (Fetsum, 2003). Fetsum (2003) also pointed out that this is reflected in the incorporation of green areas and parks in urban plans, the consideration of the compatibility of various land uses, the incorporation of generalized environmental objectives, and the identification of hazardous areas. In spite of such efforts, the facilities in urban green areas, even in the capital of Ethiopia, hardly meet the standards set by other rival African cities (ORAAMP, 1996). In order to address these problems, the government of Ethiopia has issued various supporting guidelines, policies and proclamation. These include the Ethiopian Constitution of 1995 (FDRE, 1995), the Ethiopian Environmental Policy of 1997 (FDRE, 1997), the Ethiopian Urban Development Policy of 2006 (Ministry of Federal Affairs, 2006), and its Urban Planning Proclamation no. 574/2008c (FDRE, 2008)

The Ethiopian Constitution establishes a series of general principles requiring that all people be given the opportunity to live in a clean, healthy environment. The concept of sustainable development and environmental rights are also enshrined in Article 43, 44 and 92 of the Constitution of the Federal Democratic Republic of Ethiopia (FDRE). While different action plans and proclamations are designed in line with the Constitution, federal, regional and local governments can design and implement sup-

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

porting proclamations and various action plans designed to develop and manage cooperative housing green areas and street trees.

Moreover, the Environmental Policy of Ethiopia has recognized the importance of planning and creating green spaces within urban areas. This provision also creates opportunities for various stakeholders to develop and manage cooperative housing green areas and street trees as elements of urban green areas. Moreover, the Urban Development Policy of Ethiopia has recognized cities as entities that strive to work towards minimizing any serious risks to the urban environment. The policy document also pledged that the city government would work towards:

The development and protection of urban green areas, designing and developing environmental friendly development projects, planting and protecting institutional parks, residential green areas, street tree[s], and informal green areas, ensuring that an exemplary and leading role is played by the government and [ensuring] the participation of the private sector in environmental protection, selecting and adapting best practices, experiences and technologies suitable for urban environmental protection (Ministry of Federal Affairs, 2006).

Thus, urban development policy has rendered city governments responsible for the development and management of residential green areas such as cooperative housing green areas and street trees, with the joint involvement of other stakeholders. Furthermore, Urban Planning Proclamation no. 574/2008c has made chartered cities and urban administrations one of the institutional areas for environmental protection in Ethiopia. It has also prohibited any kind of urban development project that fails to take account of the detrimental impact on the urban environment in general, and on urban green areas in particular. All these are very important advances in the urban green area development and management in Ethiopia.

Experiences in Addis Ababa

The idea of a radial ring road surrounded by green belts was introduced by the second master plan for Addis Ababa. The plan was prepared by the planner of Greater London, Patrick Abercrombie (ORAAMP, 1996), upon request from Emperor Haile Selassie I. However, cooperative housing is a recent phenomena which only saw the light of day in the late 1970s as a result of the 1975 revolution.

The development and management of cooperative housing green areas and street trees are fundamentally inadequate. In order to rectify this situation, CGAA (2011) has introduced a number of undertakings, plans and actions comprising, among others, the City Development Plan of Addis Ababa, the Clean and Green Addis Ababa Development Plan, and the manual of the BPCDM Agency of the City Government of Addis Ababa. The Development Plan of Addis Ababa, which is currently under review, called for tree planting along the city's ring roads and existing streets, and imposed one-plot-one-tree requirements. The Clean and Green Addis Ababa Development Plan (CGAADP) was prepared in 2004 by the City Government of Addis Ababa in partnership with the Clean and Green Addis Ababa Society. The plan covered the period 2004-2025, and contained a number of interesting measures and ambitious programs regarding the greening of roadsides, median strips and open spaces. Moreover, the manual of the BPCDM Agency of Addis Ababa's city Government indicated a series of different institutions through which local residents could be involved in the development and management of cooperative housing green areas and street trees. The institutions and their corresponding responsibilities, are as follows:

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Urban Plan Preparation and Information Office: responsible for preparing plans for cooperative housing green areas' development.
- Land Development and Ownership Administration Office: responsible for providing land records and other legal documents for cooperative housing green areas.
- Design and Construction Management Office: responsible for providing design standards for the development of cooperative housing green areas and street trees.
- Environmental Protection Authority Office: responsible for implementing Ethiopia's environmental policy with regard to the development and management of cooperative housing green areas and street trees; and for providing tree species planted on cooperative housing green areas and at road junctions.
- Addis Ababa Road Authority: responsible to provide evidences about the location of utilities which are found at the right-ways of the road.
- Water Development Office of the city: responsible for providing water services for the development of cooperative housing green areas and street trees.
- Justice Office: responsible for interpreting different environmental protection proclamations for the management of cooperative housing green areas and street trees.

RESULTS AND DISCUSSIONS

Challenges for the Development and Management of Cooperative Housing Green Areas and Street Trees

As the experience of Addis Ababa shows, the provision of land for citizens to construct houses through cooperatives also includes land designated as green space. In this regard, all 130 respondents (100%) replied that they had received land for the purpose of creating green areas, while the government provided them with land to construct houses through local cooperatives. In principle, these areas are allotted as breathing, recreational and social spaces for local neighborhoods. However, an examination of the archives in the study areas revealed that the development and management of cooperative housing green areas has deteriorated over the course of time.

Survey respondents were also asked to identify the challenges which hinder the development and management of cooperative housing green areas in their neighborhoods. 40% of respondents (52) said that the development and management of cooperative housing green areas is hindered due to public and government employees' lack of awareness of the causes and consequences of cooperative housing green areas' degradation, and of the benefits of the development and management of these areas. These may aggravate the loss, degradation and occupation of cooperative housing green areas by different sections of the community. The second largest group, 35% (45), said that the lack of active participation among stakeholders weakens the joint efforts of various actors to influence the process of development and management of cooperative housing green areas. A quarter of respondents (33) also mentioned that the hindered development and management of cooperative housing green areas was due to the lack of clear ownership and enforcement mechanisms. Such situations leave residents with limited opportunities to develop and maintain their cooperative housing green areas.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Key informants from different government offices[6] directly or indirectly involved in the issue at hand, also confirmed the above-mentioned factors. Moreover, they described more specific challenges affecting the development and management of cooperative housing green areas. In their view, these challenges include:

- The lack of commitment, among different sections of the public, to complying with various drafted and enacted environmental proclamations, hinders the applicability of various proclamations to the management and maintenance of cooperative housing green areas; the lack of a clear, up-to-date database of cooperative housing green areas. For instance, the GIS map of the sub-city shows cooperative housing green areas as empty spaces, leading government to use the areas for other purposes. For this reason, cooperative housing green areas such as the green area of the Tewahido cooperative housing, are being used for waste dumping purposes; and
- The lack of cross-sectoral cooperation and the rival agendas of the offices in question, has contributed towards hindering the development and management of cooperative housing green areas. "Cooperative housing's green areas development and management have not been given sufficient attention even in the preparation of local development plans" due to the lack of coordination among the urban planners, the information office and the BPCDM office of the sub-city. However, Bartone et al. (1994) argue that the effective and sustainable development and management of urban green areas will only be achieved when the development and management of urban green areas are given sufficient weight when preparing local development plans. Thus, what is actually being done in the study area is different from this standpoint.

Politicians working on land-lease related issues sometimes allocate cooperative housing green areas for other uses in order to save land for different forms of development. Similarly, the focus group participants have pointed to various challenges that affect the development and management of cooperative housing green areas. In their view, these challenges include:

- The lack of proper plan implementation, which offers opportunities for the conversion of cooperative housing green areas for other purposes such as housing, waste dumping, stores for the residents' *Iddir*[7]*,* etc.;
- The lack of education and research regarding cooperative housing green areas, in order to plan appropriate action for the future greening of the areas;
- The disintegration of various cooperatives, thus limiting members' ability to develop and manage their common spaces in a coordinated, integrated manner;
- The lack of proper protection, follow-up, monitoring and evaluation of activities pertaining to the use and conservation of the areas by the government organs in question. This situation has created an environment conducive to incursion into cooperative housing green areas so as to use these areas for other purposes, such as official and unofficial housing construction, parking, for the residents' *Iddir*, and so on;
- Insufficient media coverage of cooperative housing green areas has contributed to the limited public awareness of the importance of the areas in question;
- The lack of any real links between government agencies and the members of the cooperatives, thus hindering the joint efforts needed for the development and management of cooperative housing green areas;

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

- The various different government offices responsible for the development and management of cooperative housing green areas are not duly coordinated, and are accountable to other, different offices. This leads to competition between such offices, rather than cooperation, as a result of a conflict of interests; and
- The lack of accountability among the members of the cooperatives with regard to their green areas, which manifests itself in their lack of concern regarding the degradation of their cooperative housing green areas.

Local Strategies and Practices for the Development and Management of Cooperative Housing Green Areas

In the manual of the CGAA's BPCDM agency, the overall strategies for green area development and management are set out in a manner revealing a clear hierarchy of politicians, municipal administrations and other city stakeholders at all levels. The manual also mentions the fact that the strategies for the development and management of cooperative housing green areas are run by the sub-city and woredas' BPCDM offices, in conjunction with other government institutions[8] and with the members of the housing cooperatives. However, the various institutions responsible for designing local strategies do not work in conjunction with the BPCDM office. The reasons for this are as follows:

- Most of these institutions often focus on contingent, highly visible problems such as poverty, unemployment, the lack of housing, etc.;
- Some of these institutions have overlooked the environmental benefits and services associated with cooperative housing green areas, thus making them less inclined to design and implement specific strategies for the development and management of such spaces; and
- The above-mentioned institutions are more likely to compete with each other than to cooperate, which in turn reduces their commitment to designing and implementing the various strategies jointly.

Cooperative housing green areas are developed and managed by the members and committees of the housing cooperatives or *Iddirs* in the study area. However, this strategy is ineffective since most cooperative housing green areas are not clearly registered as the property of the cooperatives.

As far as concerns local strategic practices, a conference was held in 2010 in conjunction with the members of the Medirok and American housing cooperatives, on the topic of the importance of green areas to cooperative housing. The following forms of support were also provided to the members of Medirok and American housing cooperatives by the Woreda (District) 1 BPCDM office:

- Programs to raise awareness of the benefits of cooperative housing green areas;
- Networks were created with, and various supporting letters written to, other infrastructural sector offices such as the water and electricity boards, in order to readily obtain water and electricity services for their green areas;
- Legal letters were sent and land administration authority requested, in order to get cooperative housing green areas recognized as the property of the members of the cooperatives. Recognition was given as a result of such;

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Guiding and monitoring the activities carried out within the green areas of the housing cooperatives, in order to facilitate the management of green areas for environmental and recreational purposes.

Following the conference and the abovementioned forms of support, the committees of the Medirok and American housing cooperatives acted as lobbies in an attempt to persuade government officials of the importance of cooperative housing green areas for urban life. Therefore, providing different awareness-raising programs to the members of the cooperative, with regard to cooperative housing green areas, and ensuring the tenure security of the green areas in question, are vitally important if appropriate strategies are to be designed and implemented. Current research supports this argument, since the members of the two housing cooperatives in question have started to maintain their green areas as shown below.

On the other hand, not all members of the various housing cooperatives were willing to contribute money; and could not take initiatives to design strategies for the development and management of their cooperatives housing green areas due to:

- The residents' limited awareness of the benefits of the development and management of cooperative green areas;
- The lack of confidence among the members of the cooperatives with regard to the tenure system of cooperative housing green areas. This situation lowered the willingness of cooperative members to participate in the design and implementation of various strategies for the development and management of their green areas.

Moreover, field observations show that most cooperative housing green areas have not been properly developed and managed; no greening or conservation has been undertaken, and they have become dumping areas rather than recreational spaces. This situation clearly indicates that local strategies for the development and management of cooperative housing green areas are incapable of addressing the problems relating to the development and management of the areas.

The Stakeholders' Involvement in Planning, Developing, and Managing Cooperative Housing Green Areas

Beer and Jorgensen (2003), in their study of Scandinavian cities, reported that residents' involvement in the development and management of cooperative housing green areas processes had increased the quality and the facilities of the green spaces in question. The current study, on the contrary, reveals that 69% (90) of survey respondents did not participate in the planning, development or management of cooperative housing green areas, with only 31% (40) of respondents replying that they were involved in those processes. Community involvement in planning green areas takes a variety of different forms, such as providing funding, attending awareness-raising programs, offering technical assistance, and also submitting ideas. However, survey results show that contributing money was preponderant, followed by attending the occasional awareness-raising program. Of this group of respondents, none of them had offered technical assistance, or submitted ideas for the planning and assessing of the community's needs. Of those respondents who did not participate in any way, almost 71% (64) said a lack of opportunities, unclear property rights regarding their green areas, and a lack of information, prevented them from

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

participating in the planning process. Some 29% (26) also responded that their participation had been hindered due to the lack of motivation in the communities in question.

Of the 31% (40) of respondents who declared that they had participated in the development and management of cooperative housing green areas, 58.3% (23) replied that they had contributed money to, 18% (7) said that they had attended the occasional awareness-raising program organized by the government, 13.7% (6) responded they had participated in the planting of trees and the sowing of grass in their green areas, while 10% (4) replied that they had participated in community clean-up campaigns to rid the green areas of various types of litter and waste.

The survey results also indicate that the majority of the respondents had participated in the development and management of cooperative housing green areas through the contribution of money. Their participation in various awareness-raising programmes, and in planting trees, sowing grass and cleaning litter from their green areas, was relatively limited.

Key informants from different government offices (institutions) directly or indirectly involved in the issue, have confirmed the aforementioned nature of local residents' involvement in the planning, development, and management of cooperative housing green areas. As far as planning is concerned, the manual of the CGAA's BPCDM office reveals that there is no professional planner assigned to the planning of the green areas' development. Responsibility for such planning activity has been given to the sub-city's Urban Plan Preparation and Information Office. According to the aforesaid manual, the BPCDM office is responsible for conducting need assessments in relation to green areas, in line with the development of the settlements in question. However, this arrangement is "a fact on file", as no expert from the BPCDM office has ever been actually involved in the preparation of local development plans. This is also an indication that what is actually being done does not correspond to what is set out in the manual or the guidelines. This is due to a lack of interest among the various professionals concerned in working in a coordinated manner.

Notwithstanding the foregoing, the three Woredas' BPCDM core process officers stated that their offices had done their share in providing a number of development and management concessions, together with continuous follow-ups and support for the members of the cooperatives. The officers also mentioned that the members of the cooperatives are responsible for any capital investment costs for the development and management of their green areas. Furthermore, the performance standards to be met by the green areas are to be established by their offices, according to the Officers.

Observations regarding those green areas, the management of which has been taken over by the members of the cooperatives, reveals that there has been a certain improvement in the aforesaid green areas. The registered improvements in the green areas of the Abenezer housing cooperative can be attributed to the management system employed. This finding also tallies with Beer and Jorgensen's work which indicated that residents' involvement in the management of cooperative housing green areas improved the quality of the areas in Scandinavian cities. On the contrary, findings regarding green areas not run by the members of the cooperatives in question show that the areas are being used for waste dumping purposes.

Different stakeholder institutions explained that they did not actively participate in the planning, development or management of cooperative housing green areas. Moreover, officers from the NSLSC code enforcement office explained that the office was unable to resolve the problems of the illegal misuse of, and encroachment upon, cooperative housing green areas, due to a lack of clear laws and regulations governing cooperative housing green areas. In this regard, one code enforcement officer from Woreda 3 recounted his experience as follows:

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

The invasion of the 'Dirbiabir' cooperative housing green area by the official construction boom was brought to the attention of my office. Subsequently another code enforcement officer and me, we went to the area and told the owner of the construction site that the area was a green area of the Dirbiabir housing cooperative. However, the owner of the construction site produced his legal construction permission and property deed that had been issued by the sub-city's land development and ownership administration office. We then went to our office and asked the Woreda's urban planning officer to check its legality. The Officer said that the area in question was the green area of the cooperative, according to the map of the cooperative. Therefore, due to the absence of any clear enforcement mechanism and of coordination among stakeholders, we cannot implement any preventive measures or redress the problem.

Opportunities for the Development and Management of Cooperative Housing Green Areas

Recently, the lack of green areas has become a concern of the entire community throughout Addis Ababa. This concern has generated some interesting opportunities (initiatives, plans, and actions) at different administrative levels. Such opportunities include the formulation of general policy frameworks such as the Environmental Policy, the Urban Development Policy, the Urban Planning Proclamation no. 574/2008c, and the Constitution of Ethiopia containing a general framework for the development and management of urban green areas. Moreover, the City Development Plan of Addis Ababa and the Clean and Green Addis Ababa Development Plan of 2004 contained a general framework for the development and management of urban green areas. Different areas covered by this study reveal the existence of certain opportunities to help develop and manage cooperative housing green areas. In fact, certain actions and the involvement of housing cooperative members in the development and preservation of their green areas are encouraging.

Survey respondents were asked to describe what opportunities there were to help develop and manage cooperative housing green areas in their neighborhoods. Of the 130 respondents, the majority 61% (79) replied that the existence of their green areas as vacant land represented an opportunity to develop such areas in the future. Some 30.7% (40) stated that the existence of a strong community based organization like *Iddir* was a good opportunity for joint undertakings aimed at the development and management of their cooperative housing green areas. Only 8.3% (11) thought that clean, green initiatives undertaken by the community and other stakeholders represented a good chance to develop and manage their cooperative housing green areas. On the other hand, the focus group participants pointed out that these opportunities can only be grasped if they are accompanied by awareness-raising programs, continuous follow-up and monitoring services.

Key informants from different government offices have also confirmed the benefits of the aforementioned opportunities for the development and management of cooperative housing green areas. They have also indicated the following opportunities:

- The establishment of BPCDM offices at different levels of the city;
- The manual of local development plan preparation explicitly cites urban green areas as essential elements of urban services;
- The existence of undeveloped and semi-developed green areas in the hands of cooperative members, the introduction of GIS and remote sensing to the office as another opportunity for managing land designed for different purposes, such as land reserved for green areas; and

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

- The office's recently formulated enforcement manual which shows its intra- and inter-sectoral linkages with other offices.

Challenges for the Growth and Management of Street Trees

Street junctions and median strips comprise the most important opportunities for planting trees within the city. These trees also provide multiple benefits for business communities, residents and tourists. In order to obtain these advantages, different types of tree species have been planted both at the sides and in the medians strips of the roads comprised within the study areas, as shown in Table 1.

However, the aforementioned data revealed that 55% (1019) of the planted trees had died; only 45% (821) had survived. One can also see that the surviving street trees are not getting proper maintenance and protection in the study areas. Field observations of the surviving street trees have revealed that their growth and management are poor.

In an attempt to get residents' views regarding the growth and management of street trees, 130 respondents who were living adjacent to street trees were asked to express their opinions. 84.6% (110) of respondents said that the street trees were not growing properly or being duly maintained. Only 15.4% (20) of respondents reported that the street trees were being managed fairly well. From this, one can see that the street trees in question are not being properly cared for.

Survey respondents were also asked to identify the problems associated with the growth and management of street trees in their neighborhoods. 47% (61) of respondents stated that the community's wrong perception of the purpose of street trees hindered their development and management. Consequently, communities failed to act in order to care for and conserve these trees. The second largest group – 28% (36) – said that stakeholders' lack of participation had weakened the joint efforts of various actors needed for the growth and management of street trees. 25% (33) of them also mentioned that the growth and management of street trees had been hindered by street vending. This unofficial form of trading had a negative impact on the growth and management of street trees. Key informants have confirmed the above-mentioned factors. In addition, they have also mentioned specific problems affecting the growth and management of street trees. For example, insufficient institutional capacities characterized by the absence of continuous follow-up, the lack of trained staff capable of creating more effective, integrated partnerships with business communities, and the lack of financial resources, were perceived as critical factors for the BPCDM office's failure to fulfill their responsibilities effectively. Various different unofficial activities relating to the construction industry, such as the dumping of construction materials near to the street trees, also affected the latter's development and management. Furthermore, the poor selection

Table 1. Planted street trees and their status within the study areas

No.	Plant Types	Places Where Street Trees Are Planted	Number of Planted Trees	Surviving Trees (%)	Protected Trees (%)
1	Gravilia	Around Jemo	400	42	30
2	Jacaranda	Around Micheal Square	400	25	20
3	Zenbabaselen	Around Mekanisa and Jermen square	640	43	26
4	Zenbabapicok	Around Bisrate Gebreal and Sar Bet	400	47	35

(Source: NSLSC BPCDM office street trees inventory report, 2011)

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

of tree species designed to combat carbon dioxide emissions, and the installation of urban infrastructural facilities such as fiber-optic lines, all negatively affect the growth of street trees.

The focus group discussants, key informants and survey respondents together identified the following problems affecting the growth and management of street trees:

- The lack of an integrated data base of street trees, which affects the efforts of various stakeholders to design and execute appropriate course of action for the growth and management of street trees;
- The communities do not feel that the trees belong to them. This feeling discourages the communities from participating in the development and management processes;
- The absence of integrated systems for the management of the street trees in different parts of the neighborhood;
- The lack of action plans for volunteers, resulting in lower volunteer participation in the growth and management of street trees;
- The absence of clear norms and standards governing the minimum distance to be observed between main roads and footpaths, and the places where the street trees are to be planted. Consequently, street trees are planted on footpaths and pedestrian ways, which leads to their deterioration as a result of the transit of pedestrians;
- Traffic accidents have also contributed towards the deterioration of street trees.

Local Strategic Practices Aimed at the Growth and Management of Street Trees

Local authorities are expected to take the lead in forming partnership with other local public sector agencies to develop wider community strategies for improving the economic, social and environmental well-being of their local areas. This would help them contribute towards the achievement of sustainable development (European Commission, 2007, p. 7). These strategies are often prepared and implemented by local authorities through local strategic partnerships bringing together different sections of the community, such as businesses and others. Therefore, it is a good idea to assess the types of local strategic practice being followed to develop and manage street trees in the study areas.

The Nifas Silk Lafto sub-city BPCDM officer mentioned various factors, such as the need for continuous maintenance of street trees under a sustainable system, the increasing damage to street trees, and the public's misperception of the value (benefits) of street trees within the sub-city, as having prompted the office to devise a long-term strategy for street tree development and management. According to her, the strategy has been adopted by the Woredas' BPCDM core process offices.

The three Woredas' street tree development and management policy document states that street trees are grown and managed by government officials, residents, business communities and voluntary groups. As for strategies, the development and management of street trees will be assigned to the abovementioned stakeholders in the form of adoption modalities by Woredas BPCDM core process officers. The strategies also set out a long-term vision for the development and management of street trees in an integrated framework, which is to be complied with and followed-up continuously. To demonstrate the values of street trees to partners, the strategy also provides evidence of the contribution made by street trees to the general appearance of the city and to urban life in particular.

Accordingly, the core processes resulted in a number of street tree development and management agreements between local government officials, residents, business communities and voluntary groups. However, an evaluation of the implemented strategies indicated in Woredas' street tree assessment report,

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

shows that only 35% of the drafted strategies were actually implemented. According to the informants and focus group participants, the lack of implementation was attributed to insufficient awareness of the benefits of the strategies on the part of those officers concerned, together with the non-provision of incentives to volunteers. However, the study's findings also revealed that there are significant differences between those trees given to business communities, and those that are not.

Stakeholders' Involvement in Planning, Growing, and Managing Street Trees

According to the literature, stakeholders' participation involves the combined efforts of a great many institutions, organizations and individuals, aimed at the successful planning, development and management of urban green areas. It also indicates that cooperation among stakeholders is the way to achieve a greater synergy involving more than just the exchange of information or even collective decision making: partnerships, mutual trust and understanding are also required.

Contrary to the above arguments, the results of our questionnaires indicate that 65% (85) of respondents do not participate in the planning, growth or management of street trees. Almost 68% (58) of such respondents said that the lack of opportunities to do so prevented them from participating. Some 32% (27) responded that their participation was hindered by the lack of information. Moreover, almost 80% (68) of those respondents who do not participate in the street tree planning, development and management processes also said that government was doing this work. The remaining 12.5% (11) and 7.5% (6) of respondents, respectively, said that business communities or NGOs were participating in the planning, growth and management of street trees.

Stakeholders' involvement in growing and managing street trees takes different forms, such as the provision of suitable soil and water, planting trees, preparing holes for the planting of trees, and so on. Of the 35% (45) of survey respondents who participated in the growing of street trees in their neighborhoods, 33% (24) replied that they did so by providing suitable soil; 24.5% (11) responded that they contributed by planting trees along the ring roads; and 22.2% (10) answered that they dug holes to plant the trees. Others were involved by both planting trees along the ring roads and by digging holes for the trees. On the other hand, 78.3% (35) of said participants responded that their involvement consisted in watering the trees; 20% (9) said they were involved in the fencing off and protection of the street trees; and 1.7% (1) responded that they took part in raising the community's awareness of the fact that the trees belonged to them.

According to the BPCDM agency's manual, BPCDM offices at various different administrative levels are in charge of the planning, growth and management of street trees with the active involvement of different stakeholders such as local residents, business communities and NGOs. In order to know to what extent the government institutions in question fulfilled their responsibilities, officials from said government institutions were duly interviewed. The information obtained from the key informants is reviewed below.

According to the BPCDM agency manual, the street tree plan needs to be discussed in detail with experts from the Addis Ababa Road Authority. Recently, a number of discussions have been held with the Addis Ababa Road Authority regarding street trees planning. The road property protection and management team leader at AARA stated this point. A team leader also stated that "CGAA's BPCDM agency and its office at sub-city level, together with AARA, discuss and evaluate their plans and strategies twice a year".

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

BPCDM offices at the sub-city and Woredas level have taken various forms of action for the purposes of the decoration, greening and protection of streets in the sub-city, by planting and maintaining street trees. The BPCDM agency's manual states that the Clean and Green Addis Ababa Development Plan (CGADP) is being implemented by BPCDM office at different levels of the sub-city with the involvement of other stakeholders such as business communities and NGOs. Similarly, the three Woredas' BPCDM core process officers said that various activities are being carried out by their offices and by different business communities, but the results have been insignificant. This is because various initiatives and actions are not implemented in a sustainable manner and with massive community involvement, due to:

- The lack of trained personnel capable of growing and managing street trees systematically;
- The fact that staff turnover has led to a lack of any integrated database and information about the status of the street trees;
- The unwillingness of professionals to provide home-to-home awareness raising programs concerning street trees for the communities; and
- The fact that large business communities are no longer interested in participating in planting trees along roads and at junctions owing to conflicts of interests.

As far as the development and management of street trees are concerned, field observations in different parts of the study areas revealed that the situation is very discouraging. However, those street trees that have been planted nearest to voluntary groups are receiving proper care.

Opportunities for the Growth and Management of Street Trees

All the different policies, plans and proclamations drawn up, such as the Constitution of Ethiopia, the Environmental Policy, the Urban Development Policy, and Urban Planning Proclamation no.574/2008c, contain general provisions for the development and management of urban green areas. More specifically, the City Development Plan of Addis Ababa, and the Clean and Green Addis Ababa Development Plan of 2004, see the greening of roadsides and median strips as one way of developing and nurturing green areas in the city of Addis Ababa. All these provisions should create conditions conducive to the specific implementation of courses of actions for the growth and management of street trees.

Moreover, survey respondents were asked to describe the opportunities for the creation of an environment conducive to the growth and management of street trees in their neighborhoods. Accordingly, about 52.3% (68) of respondents said that government involvement in street tree development and management represented a good opportunity. Some 30.8% (40) said that clean, green initiatives by the community and other stakeholders such as NGOs represented a good chance to develop and manage these trees. The remaining 16.9% (22) suggested that the business community's involvement in the growth and management of street trees should be perceived as a good opportunity for the creation of such an environment. Key informants from different government offices also identified similar opportunities. They also pointed to the establishment of BPCDM offices at different municipal levels; to the BPCDM agency's recently drafted enforcement manual that reveals its intra and inter-sector links with other offices; and to recent government partnerships with private concerns such as voluntary groups, business communities and social groups, involving their participation in such projects, all of which are perceived as good opportunities for the development and preservation of street trees.

CONCLUSION

A lack of awareness on the part of the public and of government employees, together with limited institutional capacities, a lack of coordination among stakeholders, the absence of an up-to date data base, and the lack of clear ownership and enforcement mechanisms, have emerged as serious problems affecting the development and management of cooperative housing green areas. Similarly, the public's misperception of the benefits of street trees, the non-participation of stakeholders in the development and management of green areas and street trees, and the absence of an integrated data base containing precise details of the city's street trees, have together impeded the growth and management of street trees. Moreover, a weak institutional capacity characterized by staff shortages and the lack of trained staff, the absence of any regular follow-ups and protective measures, the poor selection of tree species, the lack of norms and standards regarding exactly where street trees should be planted, traffic accidents, and the installation of utilities, are all factors impeding proper street tree development and management.

As far as regards local strategic practices, while cooperative housing green areas are developed and managed by the members of cooperatives and *Iddirs*, the study reveals that this strategy is ineffective due to the lack of awareness and of property deeds relating to the green areas in question. On the other hand, street trees are grown and managed by the sub-city's BPCDM offices and Woredas, with the involvement of other stakeholders; however, this strategy has been poorly implemented and has been significantly constrained by a general lack of awareness, by insufficient follow up by the BPCDM experts in question, and by the absence of incentives to volunteers.

The study also found that there is a general lack of stakeholders' participation in the planning, development and management of these spaces. However, the Federal Democratic Republic of Ethiopia's Constitution, the Environmental Policy of Ethiopia, the Urban Development Policy, and Urban Planning Proclamation no. 574/2008c, all contain general provisions regarding the development and management of urban green areas by the stakeholders in question. The study also revealed that BPCDM's recently formulated enforcement manual, together with the office's intra and inter-sectoral links, represent good opportunities for the sector to implement green development and management projects in a coordinated manner. The involvement of housing cooperative members in the development and management of their own green areas, together with the recent establishment of private partnerships to develop and preserve street trees, are also deemed positive measures and practices.

KEY TERMS AND DEFINITIONS

Challenges: Constraints that act as a bottleneck for the development and management of cooperative housing green areas and street trees in Nifas Silk Lafto Sub-city.

Community Based Organizations: This term denotes Iddirs and local business communities.

Cooperative Housing Green Areas: The green areas of cooperative houses that were built during the Dergue regime and by the current government through the adoption of a self-help approach in Nifas Silk Lafto Sub-city.

Local Strategic Practices: Refers to a set of actions designed to improve cooperative housing green areas and street trees in Nifas Silk Lafto Sub-city.

Opportunities: Refers to the initiatives and actions taken by the stakeholders to enhance the development and management of cooperative housing green areas and street trees in Nifas Silk Lafto Sub-city.

Stakeholders: Refers to those actors, including government institutions, communities or community-based organizations, and voluntary groups (NGOs), that are responsible for the development and management of cooperative housing green areas and street trees in Nifas Silk Lafto Sub-city.

Street Trees: Refers to trees planted both at the sides of roads and along median strips in Nifas Silk Lafto Sub-city.

Urban Green Area Development: Refers to improvement to cooperative housing green areas and street trees designed to maximize their benefits for urban life in Nifas Silk Lafto Sub-city.

Urban Green Area Management: Refers to the preservation and protection of cooperative housing green areas and street trees so as to meet the intended objectives in Nifas Silk Lafto Sub-city.

Woreda: District-level administrative unit.

ABSTRACT

This chapter gives an overall summary of the challenges faced by European countries regarding the adoption of nZEBs, particularly focusing in the training needs in the Southern Mediterranean countries, and on the experience reached so far by the ongoing SouthZEB Project. Therefore, it first elaborates on the nZEB concept definition framework focusing on the relevance of the topic to local and regional development purposes. Secondly, the chapter gives an overview of the definitions that may be used to the adoption of nZEB across European countries. The perspective presented is first through a top-down approach, based on the policy implementation efforts developed by the European Commission and, after that, based on a bottom-up perspective, including an overview of existent voluntary standards that may be regarded as contributing to the adoption of near zero energy buildings. Thirdly, the chapter reflects on some of the barriers encountered that hamper nZEB adoption, specifically addressing the need for professional training in Southern European countries. Finally, the methodology used by the SouthZEB Project to define the training and certification needs, which is based on the participatory process, is presented along with an overview of the project major results achieved until now and the main difficulties identified so far.

INTRODUCTION

The implementation of European Energy/Climate policies fully comply with the goals of regional development and the buildings sector is one of the most relevant to tackle both dimensions. On the one hand, buildings are at the spotlight of the EU's energy efficiency policy, as nearly 40% of final energy consumption and 36% of greenhouse gas emissions is carried in the European building stock, such as residences, offices, shops and other types of buildings. On the other, it is a crucial sector to spatial development dynamics of a territory.

The 2030 European Commission Communications, published in July 2014, highlight the key role of the building sector, stating that "the majority of the energy saving potential is in the building sector". Therefore, improving the energy performance of Europe's building stock is crucial to achieve the EU Energy/Climate targets and, beyond these, to bring about drastic greenhouse gas emission reductions in the building sector of 88 to 91% compared to 1990 by 2050 (European Commission, 2011).

Over the past decade, energy efficiency has consistently reduced annual energy consumption and confirms its place as the first fuel option for the economy, according to the 2014 Energy Efficiency Market Report (International Energy Agency, 2014). In particular, the report evaluates 18 IEA[1] countries where energy efficiency has had the largest percentage improvements in the residential sector, driven by improvements in space heating, water heating, lighting and appliances, and where energy demand has been reduced by 5% in the period between 2001 and 2011. In this way, energy efficiency is strengthening its position as a fuel option for countries in their efforts to balance supply and demand in support of growth and competitiveness, energy security and environmental objectives. This strategy is far more pressing in Europe where final consumers' electricity bills are expected to continue on the rise, at least for the next following two decades (Rezessy, 2014) (Eurelectric, 2014).

It is in this given context of high potential for reducing the buildings' energy requirements, that the amendment act to the EU's Energy Performance of Buildings Directive introduced in 2002 (Official Jour-

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

nal of the European Union, 2002) emerged in 2010 (Official Journal of the European Union, 2010) and became the main legislative instrument for improving the energy performance of the European building stock. In this amendment two key mechanisms are highlighted as guidelines for the energy performance improvement: the principle of *nearly zero energy buildings* (article 9 and article 2.2) and the principle of *cost-optimality* (article 5, article 2.14 and annex). In particular, the amendment establishes that by 2020, all new buildings constructed in Europe must be near zero energy buildings and, from 2018 onward, all new buildings occupied and owned by public authorities should be near zero energy buildings.

Parallel to the requirements of the recast of EPBD directive, the Energy Efficiency Directive (Official Journal of the European Union, 2012) establishes a common framework of measures for the promotion of energy efficiency within the European Union in order to ensure the achievement of the 2020 20% headline target. The measures focus on both the public transport and building sectors, which are the two largest sectors with energy savings potential. The public sector shall lead in the building sector by renovating 3% of buildings owned and occupied by the central governments starting from 01 January 2014 and by including energy efficiency considerations in public procurement, so as to purchase energy efficient buildings. Also, the Renewable Energy Directive (Official Journal of the European Union, 2009) sets requirements related to buildings. This directive stipulates that by 2014 all member states' building regulations and codes will require the use of minimum levels of energy from renewable sources in new buildings and in existing buildings that are subject to major renovation. This directive also states that from 2012 onwards, member states should ensure that new and existing public buildings that are subject to major renovation must fulfil an exemplary role, either at national, regional or local level.

Achieving Europe's 2020 and 2030 Energy/Climate targets is challenging and forces decision makers at multiple levels, urban planners, engineers and architects to re-design and adapt the built environment, mostly concentrating in cities, as the world continues to become more urbanized (United Nations, 2014). Local governments play a crucial role in mitigating the effects of climate change, contributing to energy savings and the rationale use of energy in their territories, particularly when one realizes that 80% of energy consumption and CO_2 emissions is associated with urban activity. However, often municipalities lack sufficiently high quality information to empower them to take ambitious decisions in this respect and even if decision makers at the local and regional levels want to start an energy relevant action, they often have no idea how to proceed.

With this in mind, the Covenant of Mayors was created by the European Commission in 2008, subsequent to the EU Climate Energy Package, to endorse and support the efforts deployed by local authorities in the implementation of sustainable energy policies. In order to translate their political commitment into concrete measures and projects, Covenant signatories undertake to prepare a Baseline Emission Inventory and submit, within the year following their signature, a Sustainable Energy Action Plan outlining the key actions they plan to undertake. Beyond energy savings, the results of signatories' actions are manifold: creation of skilled and stable jobs, not subject to delocalization; healthier environment and quality of life; enhanced economic competitiveness and greater energy independence. These actions serve as examples for others to follow, notably through referring to the "Benchmarks of Excellence", a database of best practices submitted by Covenant signatories. The Catalogue of "Sustainable Energy Action Plans" is another such unique source of inspiration, as it shows at a glance the ambitious objectives set by other signatories and the key measures they have identified to reach them (Covenant of Mayors, 2015).

Another example to keep in mind would be the project AIDA – Affirmative Integrated Design Action that took place from April 2012 to March 2015. The AIDA project aims at accelerating the market entry of nearly zero energy buildings (nZEB), the number of building professionals trained on integrated

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

energy design and the number of municipalities starting to build/refurbish buildings to nZEB levels. This project works in close co-operation with leading experts from Italy, Spain, France, Austria, Germany, UK and Hungary and assists dedicated municipalities in these seven countries to develop tenders for new and renovated nearly zero energy buildings and increase the visibility of front runners by offering study visits for more than 3000 European building professionals and local decision makers. Moreover, it is expected to train at least 1500 building professionals on integrated energy design tools. In this way, it contributes to raise the awareness of decision makers and citizens under the belief that citizens will be better prepared and more willing to adopt nZEB, if their municipality sets an example thus giving them direct access to and experience of nZEB. Therefore, AIDA offers essential information to municipalities, supports them in setting up own ways and strategies to contribute to the 20-20-20 targets (AIDA Project, 2015).

As architects, engineers and builders start experimenting with more efficient integrated building design and as windows, appliances, lighting and buildings become more efficient and affordable, the adoption of nearly Zero Energy Buildings (nZEB) is expected to become mainstream. This will assure, in the long run, increased energy efficiency and enable coordinated exchange of energy between buildings and the electricity grids, while also providing comfortable healthy indoor environment to their users and moving towards a paradigm of decentralized energy generations and highly interconnected urban infrastructures, in the longer run. In fact, such buildings will become an interactive node of larger networks – the smart grids. Furthermore, not only will buildings meet most of their energy needs and operate independent of the grid, but in some cases, buildings may also provide more reliable energy services at lower cost to the grid, adding resiliency to it when it is stressed (Sioshansi, 2015).

In the meantime, a multitude of initiatives, actions and projects still need to be implemented throughout Europe to assist the achievement of widespread near Zero Energy buildings adoption. These range from those that provide financing schemes to energy efficiency and renewables in buildings, contribute to raising awareness and information of citizens, demonstration and pilot projects, supervision of energy performances (such as, energy audits), implementation of energy performance certification schemes, education and training to municipal workers, architects, builders and engineers.

One of the ongoing actions is the SouthZEB project which promotes the capacitation of engineers, architects, municipality technicians and decision makers, providing them training on nZEB concepts, specifically directed to Southern European countries, where nZEB adoption is shown to be lagging behind. The training to be provided to these professionals leverages on the know-how of front-runner countries participating in the project (Austria, UK, Northern Italy), but are also based on the participatory experience and counselling of representatives of the main entities working on the field in the Southern partner countries (Portugal, Southern Italy, Greece and Cyprus), that has been named the SouthZEB National Support Groups.

This chapter gives an overall summary of the challenges faced by European countries regarding the adoption of nZEBs, particularly focusing in the training needs in the Southern Mediterranean countries, and on the experience reached so far by the ongoing SouthZEB Project. Therefore, it first elaborates on the nZEB concept definition framework focusing on the relevance of the topic to local and regional development purposes. Secondly, the chapter gives an overview of the definitions that may be used to the adoption of nZEB across European countries. The perspective presented is first through a top-down approach, based on the policy implementation efforts developed by the European Commission and, after that, based on a bottom-up perspective, including an overview of existent voluntary standards that may be regarded as contributing to the adoption of near zero energy buildings. Thirdly, the chapter reflects

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

on some of the barriers encountered that hamper nZEB adoption, specifically addressing the need for professional training in Southern European countries. Finally, the methodology used by the SouthZEB Project to define the training and certification needs, which is based on the participatory process, is presented along with an overview of the project major results achieved until now and the main difficulties identified so far. The chapter finishes with overall conclusions.

NEAR ZERO ENERGY BUILDING: FROM CONCEPT TO DEFINITION

The term near Zero Energy Building (nZEB) has been included in the recast of the EPBD directive as meaning a building that has very high energy performance, whose the near zero or very low amount of energy required should be covered to a very significant extent by energy from renewable sources, including energy from renewable sources produced on-site or nearby (Official Journal of the European Union, 2010).

This definition is broad and conceptual, therefore, the term nZEB is seldom used "commercially", without a clear understanding of the dimensions behind it. Moreover, countries have been enacting policies and national targets based on a concept without a clear definition in place.

The term "near zero energy building" is very often used as a synonym of "Net zero energy building", despite that these two concepts are not exactly the same when looked at in a stricter sense. One first difference is that the "Net zero" focus is on the null energy balance requirement, possibly overweighting the importance of on-site renewable energy generation in disregard to the initial attempt to use passive energy efficiency measures that reduce energy demand needs, emphasising the local generation side of the energy balance. The "near zero" focus, on the other hand, is on the attempt to reduce the energy use of the building at an initial stage of the conception, as much as possible, and then, cover the remainder energy needs with on-site renewable energy generation. This difference will tend to dissipate while energy efficiency measures become more mainstream and cost-efficient.

Some other differences are much more relevant and based on scientific and technical differentiation of the underlying accounting terms and of the building system boundaries considered and have been studied by several authors, such as (Kurnitski, et al., 2012), (Marszal, et al., 2011), (Sartori, Napolitano, & Voss, 2012) in order to find a common and operational definition of the term near Zero Energy Building, not only in Europe, but more generally worldwide[2].

According to (Kurnitski, et al., 2012) a Net zero energy building (NZEB) is a building with an energy use of 0 kWh/(m^2 a) primary energy. For these authors, a Net ZEB is typically a grid connected building with very high energy performance and also it balances its primary energy use so that the primary energy feed-in to the grid or other energy network equals to the primary energy delivered to ZEB from energy networks. Annual balance of 0 kWh/(m2 a) primary energy use typically leads to the situation where significant amount of the on-site energy generation will be exchanged with the grid. Therefore, a Net ZEB produces energy when conditions are suitable and uses delivered energy during the rest of the time.

The definition proposed by the same authors (Kurnitski, et al., 2012) to refer to a "nearly Net zero energy building (nZEB) is a building with a technically reasonable achievable national energy use of > 0 kWh/(m2 a) primary energy achieved with best practice energy efficiency measures and renewable energy technologies which may or may not be cost optimal. To note that not all renewable energy technologies needed for nearly zero energy buildings have to be cost-effective, if appropriate financial incentives are not available.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Another relevant term used in the amendment of the EPBD directive and also defined by the same authors (Kurnitski, et al., 2012) is the definition of the term *energy performance of the building* based on EN 15316-1:2007. According to these authors, it is the calculated or measured amount of energy delivered and exported actually used or estimated to meet the different needs associated with standardized use of the building, which may include, *inter alia*, energy used for heating, cooling, ventilation, domestic hot water, lighting and appliances. This energy performance of a building shall be expressed with a numeric indicator of primary energy use, based on primary energy factors per energy carrier, which may be based on national or regional annual weighted averages or a specific value of on-site production. Appliances (households and outlets) have been later on added to the original definition of EN 15316-1:2007.

One of the main reasons for the term near Zero Energy Building to come up then would be that the Net zero target, at the time of the recast directive, in 2010, was so hard to achieve and so challenging to design that, when buildings created almost as much energy as they consumed they were called near zero energy buildings (Cole, 2015). More recently, with the will to push off limits towards sustainability goals, one can encounter examples of more ambitious design of "net positive energy buildings", those that so highly performant that achieve a positive energy balance and can actively contribute to its surroundings, such as, for instance, charging electric vehicles out of the building energy services (Kylili & Fokaides, 2015).

As it is referred by this author (Cole, 2015), over the past decade, numerous building projects have been presented as having "net zero energy performance". Such claims have been using a variety of different approaches: on- and off-site renewable technologies, the purchase of energy credits, among others. Efforts, subsequently, have been directed towards refining the formulation of a definition of "net zero" and these have provided some degree of clarity and theoretical framing. The spatial and temporal boundaries - identifying what is included and excluded from the analysis- and the definition of indicators and metrics are hugely important for writing the balance of net zero energy building. According to (Cole, 2015) one needs to clarify what energy use refers to, namely, whether it is calculated for energy demand or actual measured energy consumption. Also one needs to know what type of energy use is included in the balance, namely, if it is only building related or if it considers also the user related. Additionally, one needs to know how to include the building – grid interaction.

The (Marszal, et al., 2011) study indicates that the metric, the period and the types of energy included in the energy balance together with the renewable energy supply options, the connection to the energy infrastructure and energy efficiency, the indoor climate and the building–grid interaction requirements are the most important issues to be elaborated before defining a harmonized ZEB understanding.

Table 1 illustrates one possible framework definition proposed within an international joint projects effort undergone within the International Energy Agency (IEA) Task 40 on Solar Heating and Cooling (SHC) and Annex 52 Energy Conservation in Buildings and Community systems (ECBCS) titled "Towards Net Zero Energy Solar Buildings" (Sartori, Napolitano, & Voss, 2012). Table 1 results from that effort and frames the definitions of a Net ZEB and consequently differentiating it from a near Zero Energy Building. A Net Zero Energy Building is the "building system" delimited by a set physical boundaries, connected to any energy infrastructure, which the balance between its weighted energy loads and supplies is zero. The main difference between Net Zero Energy Building and near Zero Energy Building regards the balance metric, balance boundaries and generation systems localization.

According to (Aelenei & Gonçalves, 2014)) there is some consensus that zero energy buildings design should start from solar passive sustainable design. According to this, the Net zero energy performance may be achieved as a result of executing two fundamental steps: (a) reduce building energy demand -

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Suggested definition of n(ear)ZEB coming from the N(et)ZEB

		Nearly Net ZEB	Net ZEB Primary	Net ZEB Strategic	Net ZEB Emission
Building system boundary	Balance boundary	Heating DHW cooling ventilation auxiliaries built-in lighting (only non-residential buildings)	Heating DHW cooling ventilation auxiliaries built-in lighting plug loads	Heating DHW cooling ventilation auxiliaries built-in lighting plug loads	Heating DHW cooling ventilation auxiliaries built-in lighting plug loads embodied energy
Weighting system	Metric	Primary energy	Primary energy	whichever metric	emission
	Symmetric	Symmetric	symmetric	Symmetric or asymmetric	Symmetric or asymmetric
	Times dependent accounting	Static	Static	Static	Static
Net ZEB balance	Energy efficiency	National/local energy efficiency requirements are fulfilled	National/local energy efficiency requirements are fulfilled	Any national/local energy efficiency requirements has to be fulfilled	Any national/local energy efficiency requirements has to be fulfilled
	Energy supply	On site generation driven by on/off site sources	On site generation driven by on/off site sources	On/off site generation driven by on/off site sources	On site generation driven by on/off site sources

energy efficiency and (b) generate electricity or other energy carriers, to get enough credits to achieve the desired energy balance - energy generating. Nonetheless there is no exact approach for designing and realizing a "Net zero energy building" as there are many different possible combinations of building envelope, utility equipment and on-site energy production equipment able to achieve Net zero energy performance. In fact, the definition of any ZEB building is very much dependent on the *local and regional context*, as well as on *the building type*.

A research group within the IEA's Task 40 "Towards Net Zero Energy Solar Buildings" project has analysed and evaluated the conceptual approaches and performance of almost 300 Net Zero-Energy and Energy-Plus buildings worldwide. This analysis shows a remarkable gap between the number of examples among the different European regions, while simultaneously there is an enormous need for the examples to have a geographical spread and be site specific since energy consumption in buildings varies greatly throughout Europe due to differences in climate, socio-economic factors, building techniques etc. The environmental impacts also vary due to different carbon intensities of energy systems.

The study developed by (Buildings Performance Institute Europe, 2011) highlight some of these existing differences, while it considers three European regions divided by climate, building typology and market similarities. The study estimates that there are 25 billion m^2 of useful floor space in the EU-27, Switzerland and Norway and it concludes that half of the total estimated floor space is located in the North & West region of Europe, while the remaining 36% and 14% are contained in the South and Central & East regions, respectively. Non-residential buildings account for 25% of the total stock in Europe and comprise a more complex and heterogeneous sector compared to the residential sector, which accounts for 75% of the building stock.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Moreover, according to the same study (Buildings Performance Institute Europe, 2011), a substantial share of the stock in Europe is older than 50 years with many buildings in use today that are hundreds of years old. More than 40% of European residential buildings have been constructed before the 1960s, when energy building regulations were very limited. Table 2 highlights the construction period of EU building stock, depending on the European region.

Also, annual growth rates in the residential sector are around 1% average for whole Europe, while most countries encountered a decrease in the rate of new build in the recent years, reflecting the impact of the current financial crisis on the construction sector (Buildings Performance Institute Europe, 2011)

Despite the considerable differences between the various European countries climates, workforce capacitation and buildings regulations, on average, the residential building stock is responsible for 30% of total final energy consumption (Mlecnik, Visscher, & van Hal, 2010). Also, on average, domestic hot water and space heating are responsible for over 60% of the final energy consumption in both residential and non-residential stocks (Mlecnik, Visscher, & van Hal, 2010). This means that a direct and major impact could be achieved in residential primary energy consumption and space heating, in particular.

Over the last 20 years electricity consumption in European non-residential buildings has increased by a remarkable 74%, according to a recent report developed by (ECOFYs, 2014) which is caused by technological advances over the decades during and an increasing penetration of ICT equipment, air-conditioning systems etc. Also because of that, this study concludes that Building Automation has a key role to play in the implementation of nearly zero energy buildings. Building Automation is the connector of all the single requirements for nZEB, such as a well-insulated and airtight building shell, efficient HVAC system and a high share of renewable energy.

A TOP-DOWN APPROACH TO nZEB IMPLEMENTATION

As it was discussed in the previous section, the term near zero energy building means according to the recast of the EPBD, a building that has very high energy performance. The near zero or very low amount of energy required should be covered to a very significant extent by energy from renewable sources, including energy from renewable sources produced on-site or nearby (Official Journal of the European Union, 2010). Since the Commission does not give minimum or maximum harmonized requirements, it has been up to the member states to define what for them exactly constitutes a "very high energy performance". This means also that a specific definition and implementation of near zero energy buildings is decided by each member state and there is currently a strong need for more guidance and common understanding for implementing sustainable but yet feasible near Zero Energy Building definitions (Buildings Performance Institute Europe, 2011).

Table 2. Age categorization of housing stock in Europe (Buildings Performance Institute Europe, 2011)

	South	North & West	Central & East
Pre 1960	37%	42%	35%
1961-1990	49%	39%	48%
1991-2010	14%	19%	17%

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

It is recognised by (Sartori, Napolitano, & Voss, 2012) that different definitions are possible in order to be consistent with the purposes and political targets that may lay behind the promotion of Net ZEBs. Therefore, evaluating the criteria, and selecting the related options becomes a methodology for elaborating Net ZEBs definition in a systematic, comprehensive and consistent way. This can create the basis for legislation and action plans effectively achieve the political targets. The choice of a proper balance metrics and weighting system should depend on targets in the political agenda and not being driven solely by feasibility of Net ZEB projects or minimization of investment costs (Sartori, Napolitano, & Voss, 2012). It is important that authorities and competent national and regional bodies and legislators are fully aware of the effect of the weighting factors when deciding upon the metrics to adopt for the Net ZEB definition they want to set in place.

National roadmaps towards nearly zero energy buildings are needed for all member states and all countries shall draw up national plans for increasing the number of nearly zero-energy buildings. These national plans may include targets differentiated according to the category of building. Furthermore, each country, following the leading example of the public sector, should develop policies and take measures such as the setting of targets in order to stimulate the transformation of buildings that are refurbished into nearly zero energy buildings, and inform the Commission thereof in their national plans. The national plans shall include, inter alia, the following elements:

- The member state's detailed application in practice of the definition of nearly zero-energy buildings, reflecting their national, regional or local conditions and including a numerical indicator of primary energy use expressed in kWh/m2 per year. Primary energy factors used for the determination of the primary energy use may be based on national or regional yearly average values and may take into account relevant European standards;
- Intermediate targets for improving the energy performance of new buildings, by 2015;
- Information on the policies and financial or other measures adopted in the context of for the promotion of nearly zero-energy buildings, including details of national requirements and measures concerning the use of energy from renewable sources in new buildings and existing buildings undergoing major renovation.

In March 2013, according to (Concerted Action, 2013) from a total of 19 European countries that provided detailed information six had their nZEB application fixed in a legal document and other six had the application ready but not yet legally fixed. The remaining seven countries were at various stages of developing the application of the nZEB definition, with national studies performed under evaluation or with studies underway.

Some months after, according to the progress report of the European Commission of June 2013, too little progress was recognized as having been made by the member states in their preparations towards nZEBs by 2020. Also, only limited information from the member states was made available at the time[3], preventing a proper evaluation of the national plans, and in particular of the adequacy of the measures envisaged by the member states in relation to the objectives of the EPBD (ECOFYs a, 2014).

In order to assist the comprehensive reporting and the possibility of comparison among the different European countries, the European Commission ordered a study near the end of 2013 that has been developed by ECOFYs. This progress report (ECOFYs a, 2014) is analysed herein so that it is possible to keep in mind the most recent available implementation data analysis on this issue.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

The (ECOFYs a, 2014) report concludes that despite nZEB reporting requirements intertwines with requirements from other current national reporting obligations, namely within NEEAPs (National Energy Efficiency Action Plan) and NREAP (National Renewable Energy Action Plan), one fundamental requirement is missing and needs to be addressed from scratch. This requirement consists of "requirement 1" establishing a national detailed application of the definition in practice for nearly zero energy buildings available, reflecting their national, regional or local conditions and including a numerical indicator of primary energy use. These have been the categories that seem to have been the most difficult to report among member states.

Until September 2014, with the exception of Greece and Spain, all member states submitted their national plans and almost all of them also submitted the consolidated information. Belgium and Austria submitted regional reports (ECOFYs b, 2014).

The analysis of the available information shows that more than half of the member states already implemented a nZEB definition in some form in September 2014. Among these countries are Belgium (Brussels and Flanders), Austria (all provinces), Czech Republic, Croatia, Denmark, Estonia, France, Ireland, Luxembourg, Latvia, Lithuania, Netherlands and Slovakia. Some other countries have had their nZEB definition still under approval, namely, Belgium, Hungary, Italy, Poland and Slovenia. Moreover, a few member states mentioned objectives that go beyond nZEB requirements, including zero energy buildings in the Netherlands, positive energy buildings in Denmark and France, climate neutral new buildings in Germany and the zero carbon standard in the UK (ECOFYs b, 2014). In particular, where a numerical indicator is set for the nZEB definition among countries, the requirements range rather widely from 0 kWh/m2/y to 270 kWh/m2/y and are mainly given as primary energy use in kWh/m2/y. The higher values are mainly from hospitals or other special non-residential buildings. For residential buildings the maximal primary energy consumptions ranges between 33 kWh/m2/y in Croatia (Littoral) and 95 kWh/m2/y in Latvia with a majority of the countries, like Belgium (Brussels), Estonia, France, Ireland, aiming at 45 or 50 kWh/m2/y. Other member states such as Belgium, Latvia and the Netherlands use a non-dimensional value (e.g. Belgium (Walloon) were an E-level of 60 is set at the moment) or an energy performance class (e.g. Latvia where nZEB have to comply with building class A++) as indicator. In some cases, member states (e.g. Czech Republic) did not define nZEBs for all building categories of the regulations, but in that specific example only for single family houses while definitions for other buildings are under development (ECOFYs b, 2014).

As regards the share of renewable energy the reporting is quite diverse, with only a few countries defining a specific minimum percentage and the majority making qualitative statements, such as Belgium (Brussels and Flanders), Bulgaria, Czech Republic, Germany, Denmark, France, Ireland, Italy, Latvia, Lithuania, Netherlands, Romania, Sweden, Slovakia and United Kingdom).

Intermediary Targets and Instruments in Use in Europe

Among the main results which are possible to identify so far from the implementation of the recast of the EPBD directive across all European countries are tighter energy performance regulations for construction and renovations, several building certification schemes and increased certification and inspections for heating and air-conditioning systems.

Different approaches have been used to setting intermediate targets (ECOFYs b, 2014). A majority of countries define intermediary targets as minimum energy performance requirements (e.g. 50 kWh/m2/y in 2015) or as required Energy Performance Certificate level by a certain year (e.g. level B by

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

2015). Other member states define intermediate targets by stating that "all new buildings" or "all new public buildings" will be nZEB by 2015. Few member states (Belgium, Malta and the Netherlands) have set actual numbers for new buildings or new public buildings to be constructed by the year 2015. For instance, the Netherlands aims to build 60,000 new nZEB dwellings by 2015 and Malta set a minimum of 5% of the new buildings occupied and owned by the public authorities will be built according to nZEB (ECOFYs b, 2014).

The exemplary role of the public sector has been emphasised by several countries, such as Belgium (Brussels, Walloon), Bulgaria, Germany, Denmark, Estonia, Finland, France, Ireland, Italy, Latvia, Luxembourg, Malta and UK, through the establishment of specific intermediate targets for public buildings. Additionally, few countries set other targets, i.e. for the refurbishment of existing buildings into nZEBs, such as Belgium (Walloon), Denmark, Germany, Ireland, Slovakia and Slovenia. Other targets, such as a minimum share of nZEB are also set as an intermediate target for improving the performance of new buildings by 2015 (ECOFYs b, 2014).

MAIN POLICIES AND MEASURES IN SUPPORT FOR NEW nZEBs IN EUROPE

European countries reported a wide range of policies and measures in support of the nZEB objectives in their national plans and NEEAPs (National Energy Efficiency Action Plans), although it is often not clear to what extent these measures specifically target nZEBs (ECOFYs b, 2014). Compared to the 2013 Commission progress report, the number of policies and measures reported have increased.

According to this report, more than two third of the countries have polices and measures in the categories "awareness raising and education", "strengthening building regulation" and "energy performance certificates measures" in place.

Another focus of measures to promote nZEB are financial instruments and support measures - including, for instance, incentive policies, energy bonuses for private individuals, grant scheme for installation of renewable energy sources -, provide special guidance and financing for at-risk populations and subsidized mortgage interest rates for energy efficient homes. Exemplary countries using these policies are namely Austria, Belgium (Brussels, Walloon and Flanders), Czech Republic, Bulgaria, Hungary, Denmark, Finland, France, Germany, Italy, Luxembourg, Netherlands, Poland, Portugal, Slovenia and United Kingdom.

Various member states have policies and measures for "strengthening building regulations" which include tightening energy minimum standards for buildings or the minimum level of renewable energy in housing in place. Other measures which are often used by the member states are" energy performance certification" (e.g. certificate provides information about opportunities to improve building energy efficiency or scaled energy certificates), "demonstration and pilot projects" (e.g. project tenders with the topic "Sustainable home" or pilot projects "Existing nearly zero-energy buildings") and "supervision" (e.g. establish an efficient, high-quality system of energy audits or rollout of smart meters). Research and development policy measures are used less, only in Denmark, Finland, France, Germany, Italy, Netherlands and Slovenia.

Most of the policies and measures reported by the member states also apply for public buildings. The scope of measures for public buildings varies substantially between member states ranging from central government buildings only to all publicly-owned buildings or all buildings used for public purposes. Some member states have also specific measures for public buildings. Those are mainly monitoring

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

campaigns (e.g. "NRClick" is an energy accounting system for the comparison of different municipalities in Belgium) and demonstration projects (e.g. in Germany the Zero-energy building for the Federal Environmental Agency (Umweltbundesamt)).

A BOTTOM-UP APPROACH TO IMPLEMENTATION

So far, near zero energy building (nZEB) is not a technical standard but a policy requirement leading to the tightening of future buildings' standards both for new buildings and renovations.

Some voluntary standards have emerged and have been widely adopted most of all in the so-called front runner countries. This voluntary wave is moved by the underlying fact that development of a regional energy economy should be optimized according to the available energy flows in the region using, for instance, a network system analysis method, which provides solutions for developing sustainable energy models, as exemplified in (Klevas, Biekša, & Murauskaité, 2014). In this sense, nZEB projects, which first aim to improve the energy efficiency in buildings and then integrate renewable energy sources in a way to cover the remaining energy needs, both in new and renovated buildings, fully comply with regional development strategic goals. Moreover, their implementation has a positive impact on security of energy supply, provides financial economies and improved comfort and health and has a multiplier effect for new jobs involving small and medium enterprises, as well as a reduction of environmental impacts.

In fact, production, distribution and use of energy resources in a region are key challenges for central and local governments, businesses and social service, customers and stakeholders. The most promising energy related factors contributing to regional development goals can be seen as the potential for energy savings and increased efficiency at the end-user side, such as renovation of old uneconomic buildings (Klevas, Biekša, & Murauskaité, 2014).

According to (Emtairah, Tojo, Thidell, Rozite, & Hayes, 2008), in most Nordic markets, building codes are claimed to be most influential instruments for creating the demand for energy efficiency in buildings. The effect however has been limited to certain areas of applications, mainly insulations and heat recovery. This and a historic emphasis on technical specifications (u-values of wall materials) rather than performance specifications (end energy demand per functional units) led to incremental improvements rather than radical changes.

Noteworthy on this respect is also the conclusion found by (Mlecnik, Visscher, & van Hal, 2010) that the diffusion of emerging and already existing voluntary European standards for highly energy-efficient houses is needed. Their complexity should be lowered and their relative advantage, trialability, observability, and compatibility should be increased.

Among some of the already existing building standards that contribute to near zero energy building the most well-known are the Passive House (Germany), Minergie House (Switzerland), Plus Energy House (Germany), Effinergie House (France), CasaClima (Italy) (Buildings Performance Institute Europe, 2011). Below an overview of these standards is presented.

Passive House

The term *Passive house* (*Passivhaus* in German) refers to a rigorous voluntary standard for energy efficiency in a building, reducing its ecological footprint. It has been originally developed by the German researcher, Wolfgang Feist, from the Passivhaus Institut (PHI), since the late 80s and results in ultra-low

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

energy buildings that require little energy for space heating or cooling. This standard has progressively gained wide acceptance throughout Europe, with 32,000 buildings having this seal, in cities like Frankfurt (Germany), Brussels (Belgium) or in Lleida (Catalonia, Spain), among many others (Edifícios e Energia, 2014).

The Passive house design is not an add-in to architectural design, but a design process that is integrated. Although it is mostly applied to new buildings, it has also been used for refurbishments.

The Passive House standard was developed for heating load dominated climates of Central and Northern Europe and most of the existing Passive Houses are located in Austria, Germany, Northern France, Sweden and Switzerland. In Austria and Germany, for instance, the Passive house standard has been adopted as mandatory. Nonetheless, the design solutions of the Passive house standard can be successfully adopted to the requirements of warmer Southern Europe countries and some design guidelines have been already developed, namely, within the Passive-On Project (Passive-On Project, 2015). According to this project, homes built to the Passive house standard are buildings which assure a comfortable indoor climate in winter without the need for a conventional heating system. To allow for this, it is essential that the building's space heat load does not exceed 10 W/m^2 living area in order to be able to use a simple air preheater. Simulations and measurements have shown that for a typical German climate such a design leads to an annual demand for space heating of 15 kWh/(m^2a). Homes built to the standard, therefore, require roughly 85% less energy to heat that a house built to existing German building regulations.

The basics of the Passive house underlying principles and concepts are further explained as well as the certification standards.

Passive House Underlying Concepts

1. **Efficiency:** No matter the climate or region, Passive house can maintain a comfortable temperature throughout the year, with minimum energy consumption. These buildings are heated in a passive way: through the efficient use of solar energy, sources of internal heat and heat recovery, making unnecessary conventional heating systems, even in periods of colder winter. During the warmer months, the *Passive house* uses passive cooling techniques such as strategic shading to maintain indoor comfort temperatures. Anyway, the upper components, combined with a careful design can ensure the permanence comfortable temperatures all year round.
2. **Sustainability:** The *Passive house* uses up to 90% less energy than traditional buildings of Central Europe, requiring less than 1.5 liters of oil or 1.5 cubic meters of gas to heat a square meter for a year. In warm climates, also has been able to demonstrate a high energy savings, although these buildings typically require use of active cooling systems. Reducing energy consumption means reducing emissions of greenhouse gases, and the *Passive house* a truly sustainable alternative compared to conventional construction.
3. **Accessibility:** To determine the actual costs of a building, it must analyze the life cycle, and thus find that building a *Passive house* building involves an initial cost plus, but a high long-term economy. Currently, the construction of these buildings is now accessible. The initial investment in building components of superior quality demanded by the *Passive house* standard, is mitigated by the elimination of heating and cooling systems with high costs. Available for the construction of buildings liabilities, financial support makes this building even more viable.
4. **Comfort:** *Passive house* can achieve pleasant temperatures with reduced levels of energy use. Permanent ventilation systems provide fresh air needed, contributing to increased indoor air qual-

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

ity. The mixture temperatures consistent and appropriate exchange of air prevents the appearance of damp and mold growth.

5. **Versatility:** The *Passive house* standard is purely based on performance and quality standards and therefore does not identify specific construction methods. Is a solid construction, wood or composites, architects are free to be creative in their designs Passive house. Manufacturers of prefabricated houses now offer models of Passive house buildings. The versatile the Passive house standard is also increasingly being applied in rehabilitation, through standard EnerPHit as well as in non-residential buildings, such as schools, office buildings, factories and hotels. Once the Passive house concepts are based on physical principles, each building can and should be adapted to your climate that surrounds it.

Passive House Underlying Principles

1. **Insulation and acclimatization:** Proper insulation of the building envelope prevents heat loss during the cold months and overheating during hot months.
2. **Passive house windows:** The strategic positioning and the high level of insulation provide the efficient use of solar energy.
3. **Ventilation with heat mechanical recovery:** The Passive house ventilation systems provide abundant fresh air, free of pollen and dust, with high energy efficiency by recovering heat.
4. **Airtightness:** Passive house buildings are designed to prevent leaks in surrounding thus increase energy efficiency, preventing heat loss and moisture damage.
5. **Free design of thermal bridges:** Prevention of thermal bridges, one of the main weaknesses of the building envelope, contributes to the achievement of pleasant temperatures, for the removal of moisture damage and improving energy efficiency.

Criteria for Certification

1. **Heating:**
   Heating Needs – $\leq$ 5kWh/m^{2}a
   Heating Loads – $\leq$ 10W/m^2
2. **Cooling (Including Dehumidification):**
   Cooling Needs – $\leq$ 15kWh/(m^{2}a) + 0,3 W(m^{2}aK)*G
   Cooling Loads – $\leq$ 10W/m^2
   Cooling Needs – $\leq$ 4kWh/(m^{2}aK)*Θe + 2*0,3 W(m^{2}aK)*G
   Inferior to – 45kWh/(m^{2}a) + 0,3 W(m^{2}aK)*G
3. **Primary Energy:**
   Primary energy needs for heating, cooling, water heating and power – $\leq$ 120 kWh/m^{2}a
4. **Airtightness:**
   Test for pressure difference η_{50} – $\leq$ 0,6 h^{-1}

Minergie House

Minergie is a registered quality standard for new and refurbished low-energy-consumption buildings mostly used in Switzerland, whose first idea was developed in 1994 by Heinz Uebersax and Ruedi Kriesi. This

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

label is managed by the Minergie Association since 1997 and mutually supported by the Swiss Confederation, the Swiss Cantons and the Principality of Liechtenstein along with Trade and Industry. At the end of 2001, a further, more stringent standard for so-called passive housing was introduced, Minergie-P. Since then, further applications of the label have been defined, such as those for specific building components. The label is registered in Switzerland but also found around the world (MINERGIE, 2015).

The Minergie label may only be used for buildings, services and components that actually meet the Minergie standard. Today around 30,000 buildings have Minergie standard. Aslo, at present around 13% of new buildings and 2% of refurbishment projects are Minergie certified. These are mostly residential buildings. The goals of the Swiss national Swiss Energy Infrastructure and Environment Programme call for 20% of new construction and 5-10% of refurbishment projects to be Minergie certified. The Minergie standard is somewhat comparable to German KfW40 (new buildings) and KfW60 (refurbishment) standards.

Lessons learnt according to the MountEE project report (MountEE Project, 2015): Minergie is a powerful driving force in sustainable renovation and construction promoting regional markets for sustainable buildings and creating business opportunities for innovative builders, investors, enterprises and authorities. Minergie is meeting the objectives mentioned above to additional costs of only 10%. Moreover some strengths can also be criticized. Minergie took the monopole of quality labels in Switzerland. Anyhow, in other countries, it is difficult to use this label which is not always comparable to the national standards. Minergie does not take into account external site or mobility.

BBC Effinergie House (Bâtiment de Basse Consommation Énergétique)

A low-energy house BBC Effinergie house (BBC-Bâtiment de basse consommation énergétique) is a building that respects the French law set up by the order of May 8th, 2007 published in the Official Journal (Journal Officielle de la Republique Française) of May 15, 2007 which specifies that for the new residential constructions, the objective of maximal consumption in primary energy is fixed to 50 kWh/m^2 year, to modulate according to regions and altitude. Taken into account is the consumption of so-called conventional primary energy: heating, cooling, ventilation, auxiliaries, production of domestic hot water and lighting facilities. The BBC Effinergie label is assigned to houses that meet the requirements of the label Low Consumption Building (BBC 2005-Bâtiment de basse consommation énergétique) with the constraint of the airtightness of the building with the obligation to measure the impermeability in the air. As for appliances, there are seven classes ranging from economical housing (Class A) with an annual consumption of primary energy for heating, hot water and cooling below 51kWh/m2.year, up to a full energy housing (G). Effinergie can be compared to other standards used in Europe such as the above mentioned Minergie, in Switzerland, or the Passive house, in Germany.

Effinergie first label was launched in 2007and it has had a strong impact in stimulating the development of the French thermal regulation by establishing the objective of energy consumption average of 50 kWhep m^2/year. This value was taken as a basis of the RT2012. The association continues to work and offers several labels such as the "Effinergie +" in order to anticipate future RT2020 and encourage the enthronement of BEPOS constructive as standard.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

CasaClima

ClimateHouse is a reliable and proven methodology of Energy Audit and Certification (KLIMAHOUSE, 2015). Since 2002 this initiative aims to save energy and create a cultural change in the way people think – making ClimateHouse synonymous to health and well-being. Buildings designed according to the ClimateHouse standards can save up to 90% of the energy compared to traditionally built residences - thereby resulting in CO_2 reductions and financial savings.

The KlimaHaus-CasaClima promotes the adoption of building construction methods that meet energy saving and environment protection criteria. It offers easily understandable information as to the energy performance of a building, thus protecting consumer interests and helping to make better informed choice.

Plus Energy House

PlusEnergy is a term used in building design to describe a structure that produces more energy than it uses. The term was coined in 1994 by Rolf Dischwhen building his private residence, the Heliotrope, in Freiburg, Germany, as the first PlusEnergy house in the world. Disch then went on to refine the concepts involved with several more projects built by his company Rolf Disch Solar Architecture in order to promote PlusEnergy for wider adoption in residential, commercial and retail spaces. Disch maintains that PlusEnergy is more than just a method of producing environmentally-friendly housing, but also an integrated ecological and architectural concept. As such, PlusEnergy is intended to be superior to low-energy or zero-energy designs such as those of Passive house.

BARRIERS TO IMPLEMENTATION

There is a vast gap between the average energy use in current new buildings and what is required when the EPBD directive is implemented, in the near future. The implementation of the directive is, therefore, a tremendous challenge in all member states, both for society and the construction industry.

According to the (ECOFYs b, 2014) report, a real technology gap to be bridged until 2021 is not perceived, despite that nZEB are still positioned beyond "cost optimality". In fact, it is believed that current technologies related to energy savings, energy efficiency and renewable energies are sufficient to reach, in combination, a suitable target for near zero energy buildings. This cost optimality could be achieved by carrying out investment to allow for cost reductions, improved performance of components and systems or energy storage solutions which in turn can positively influence the viability and introduction of near zero energy buildings. Limitations, however, may arise particularly for renewable systems[4] due to disparities in time or place, especially if one technology would be significantly favoured by the market or by policies (ECOFYs b, 2014).

In this sense, investments need to increase to satisfy additional demand created by new nZEBs, despite that there are some differences regarding the different technologies at hand. The highest growth rates for achieving a well-developed nZEB market were identified by (Buildings Performance Institute Europe, 2011) for ventilation systems with heat recovery and for triple glazed windows. For these components the market is really small compared to what it should be to satisfy the necessary demand for full nZEB implementation. As for other nZEB technologies the gap is smaller. For instance, to satisfy the calculated

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

demand, the current market for insulation materials should grow by about 2-3 times. The market for heat pumps, pellet boilers and solar thermal systems should grow at least in the same range.

Apart from these market deployment barriers, other barriers can be found regarding the transfer of knowledge and know-how among professionals. Authors in (Emtairah, Tojo, Thidell, Rozite, & Hayes, 2008) highlight the intrinsic characteristics of the construction industry to justify some specific difficulties in the innovation adoption process during the sector's operations. First of all, it is a project-based structured activity and, as such, creates several constraints for effective learning and transfer of knowledge between professionals and projects, necessary for innovation. Also, the process of buildings construction is tacit and codified to those actors involved, with a large amount of knowledge gained during the actual building process that rarely is documented or transformed into an organizational learning. Therefore, the cooperation based on temporary contracts between changing configurations of actors makes the learning process more difficult and slows down innovation (Goverse, Hekkert, & Worrell, 2001). Moreover, lessons learned in one system area often do not get passed on to another. For instance, building materials suppliers are often not involved in the design or building process and the design phase is often separated from the construction phase.

The same authors (Emtairah, Tojo, Thidell, Rozite, & Hayes, 2008) also recall that the weak relationships with formal knowledge institutions such as research centers and universities have been cited on several occasions as a reason for lower innovation adoption in the buildings and construction sector. Another fundamental weakness is the absence of energy efficiency learning from the traditional training of designers, engineers and consultants. Although one could find specialized courses on climatic design, passive buildings, alternative heating and cooling technologies as examples, these tend to remain outside the traditional specializations accessible to building sector (Emtairah, Tojo, Thidell, Rozite, & Hayes, 2008).

Therefore, when one looks at the current practices in the field of near Zero Energy Buildings, to date, only one percent of all new buildings in Germany are built according to the Passive house standard, therefore, it can be assumed that at EU level the percentage is smaller than one percent. The factor by which it should increase is, therefore, bigger than 100. A question that arises is whether the number of architects and engineers that are able to deal with new technologies and standards is adequate. There are about 3000 certified passive house planners around the world and 73 certified passive house certifiers (Passive House Planner, 2015). In the next few years, there will be about 2 million residential and non-residential buildings newly built per year in Europe. The gap is a considerable barrier to implementing the nZEB requirements for all new buildings in the near future. Technically every architect should be able to build an nZEB, however in practice that requires keeping up with standards and requirements that have to be fulfilled to build nZEB levels.

It should be stated that the design of nZEB requires an integrated design approach to minimize the building's energy consumption, while meeting all the occupants' needs. Thus architects, civil, mechanical and HVAC engineers, energy experts and installers should know the specificities related to the design of an nZEB (new technologies and standards) and work together in multidisciplinary teams from the beginning of the design phase, requiring know-how and skills (IEA Solar Heating & Cooling Program, 2003). However, the integrated approach and the knowledge of the exigencies of designing an nZEB is not common for architects and engineers among most European countries, leading in many cases to inefficient solutions, non-optimized buildings and higher costs due to extra measures for integration of energy efficiency measures and renewable energy systems. In this context, there is a substantial need for professionals such as architects and engineers specifically trained and educated in nZEB design ap-

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

proach, addressing the integration of sustainable energy in buildings and built environment, not only to produce buildings meeting current EPBD standards, but especially for buildings within the near zero energy concept.

Training programs could overcome knowledge and know-how barriers. Some attempts have already been made within EU by developing training and certification schemes for nZEBs professionals, all of them carried by NGOs and none of them has become official. Some countries have shown significant commitment to the EU targets and have focused on nZEB prior to others (Austria, Czech Republic, Denmark, Finland, France, Germany, Switzerland, UK). In most of the countries in Southern Europe though, there is still a lot to be done. As seen in section 3, in Spain or Greece, for example, very few steps have been made even towards the definition of low energy buildings and their specifics.

The SouthZEB Project comes to fill-in this gap and to address the need of developing training and assessment schemes for intermediate and senior professionals involved in the nZEB building process (engineers, architects, municipality employees and decision makers) focusing especially on the transfer of successful practices and knowledge from front runner countries to the EU countries less advanced in this area. The training modules to be developed will be adapted to the participating countries' specific needs and regulations. A key novelty of this project is also special emphasis that will be given to the building tradition of the participating countries. The training modules will also present the integrated approach that is needed in the design of nZEB.

THE SOUTHZEB PROJECT

It has been identified that there is a substantial need for professionals such as architects and engineers specifically trained and educated in nZEB design approach. These professionals must be able to work in integrated multi-disciplinary teams, to improve energy performance of buildings and to address the integration of sustainable energy in buildings and built environment, to design buildings meeting EPBD standards and especially buildings within the nearly zero-energy concept.

It is generally also recognized that a number of Southern EU counties lag behind on certain issue on the implementation of the EPBD and RES Directives and some aspects can be improved in all target countries, namely the possibility to provide more specific training on the nZEB area since the existing training is more focused on the building energy certification process.

As the Central and Northern EU countries are more advanced in implementing a number of articles within the directives, an opportunity is recognized to exist to develop the training material necessary to assist the Southern EU countries to catch up in their progress toward nZEB.

It is in this particular context that the SouthZEB project emerged and began in March 2014 with an estimated duration of 30 months, until September 2016. The project is carried by nine European partners, including Universities, Energy Services Companies and Vocational Training Centers, namely, the Applied Mechanics Laboratory from the University of Patras in Greece (Coordinator), GARnet Energy Savings in Cyprus, Cyprus University of Technology, Distretto Technologico Trentino in Italy, Building Research Establishment in UK, University of Minho in Portugal, Instituto Superior Técnico R&D Association from the University of Lisbon in Portugal, BEST Gmbh in Austria and EUROTRAINING in Greece.

The SouthZEB Project aims to identify training needs required for the target Southern European countries (Greece, Cyprus, Italy (south) and Portugal) less advanced on the progress towards nearly Zero Energy Buildings (nZEB). Additionally the project intends to initiate a wide-scale roll out of accessible

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

and recognized continuous professional development courses. In this sense, it addresses the Intelligent Energy Europe priority on Continuous Professional Development (SouthZEB Project, 2014).

In this context, the SouthZEB project aims to support the building sector intermediate and senior professionals in the Southern European countries (focusing on Greece, Cyprus, Italy and Portugal) to keep up to date with the market progression. To this end, the project is focused on the design and development of the training modules and on the assessment of the programs for these professionals. To support the large scale roll-out of the developed programs, the project is also engaged in training specialized trainers in order to enable multiplication effects in the direct transfer of knowledge to the stakeholders. Moreover, the Project will make the educational and certification programs available through a unique e-learning portal, available in five EU languages, and the course level of the modules are compatible with European Qualification Framework (EQF) at level 4.

The expected results from the SouthZEB Project have been set to train at least 1,500 professionals, including at least 400 professionals trained remotely through the e-learning platform and including 150 trainers, which have been divided among the four target countries according to key buildings sectors indicators. In Portugal, these goals are to train at least 26 trainers and 260 trainees; in Greece, to train at least 30 trainers and 300 trainees; in Cyprus, at least 12 trainers and 120 trainees; and in Italy, to train at least 82 trainers and 820 trainees. Also, the SouthZEB Project expects to achieve at least 3,000 users that will be the e-learning platform, thus broadening the impact of the project.

METHODOLOGY: AN INTEGRATIVE DESIGN OF nZEB TRAINING MODULES AND CERTIFICATION

In the framework of the project SouthZEB a Focus Group entitled National Support Group (NSG) has been created in each target country. It gathers key stakeholders on the buildings energy efficiency areas and also representatives from national architects and engineer associations, energy agencies, universities, research centres and private sector companies. Additionally, the consortium has also constituted one Advisory Board of Experts to assist the overall project formed by five renowned European professionals. This Board plays an important role in the implementation of the project and in the evaluation of its outcomes. As some of the modules specific areas are not within the exact fit of expertise of all target country partners, the feedback from the National Support Group (NSG) is of extreme importance.

A set of design meetings will be organized in each of these four Southern European target countries with each of the respective NSG to assess specific training and certification needs on each country considering regional and local context and the different several stages of implementation of the project. So far two rounds of design meetings have taken place, while two more are expected until the end of the project. The first round of meetings occurred between May 19th and July 3rd 2014 in each of the target countries, while the second round took place between February 9th and February 20th 2015. In all the Design Meetings held participants underlined the relevance and the opportunity of the SouthZEB project.

In the *first round of design meetings* the main issues under analysis have been to assess training and certification specific needs and the adequacy of the training modules proposed in the project Grant Agreement to the local context. In the *second round of design meetings* the main topics under discussion have been the minimum curricular or technical experience requirements to both trainers and trainees balanced with the proposed training objectives within the project duration; the certification structure within the project timeline and the role of the NSG members and project partners in the dissemination and training

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

efforts. One particular topic addressed in Portugal and Italy has been the possible accreditation for the training modules by the existing professional associations and the future inclusion of SouthZEB outputs in their training offerings.

MAIN ACHIEVEMENTS UNTIL NOW

According to the Grant Agreement of the SouthZEB Project, the training modules will be based on recognized and successful professional development courses and will be adapted to the participating countries' specific needs and regulations. Special emphasis will be paid to the building traditions of participating countries. Training modules will also be developed for construction management and field supervision of nZEB as well as for training the decision makers in the preparation of appropriate funding schemes and other incentives for promoting nZEB. Best practice examples from successful programs in the most advanced (in this area) EU countries will be used in the training programs.

Based on the joint assessment of the *first round of design meetings*, a total of ten revised training modules have been defined relative to what was previewed in the Grant Agreement and which are summarized in Table 3. These represent some adjustments relative to the initial modules description in the Grant Agreement proposal. Among them, training modules 1 and 2 should be mandatory for all participants (trainees and trainers) and a minimum number of four training modules (out of the 10 available) need to have a positive evaluation on the exam in order to receive the "nZEB Designer" or "nZEB Trainer" certificate. Several new nZEB related topics have been incorporated into already existent training modules, such as (1) Adaptive Thermal Comfort, (2) User Acceptance of Technical Solutions to nZEB, (3) Cost Optimality of near Zero Energy Building technical solutions, among others described above. Also, new training modules have been created to address some of the suggestions made by participants in the first set of design meetings. One example is the renewed "Module 4 – Thermal Comfort" and "Module

Table 3. Near Zero Energy Buildings training modules (SouthZEB Project, 2014)

Module	Name	Hours	Target Audience
Module 1	nZEB Basic module	20h	Engineers, architects
Module 2	nZEB Advanced module	40h	Engineers, architects
Module 3	Thermal bridging	20h	Engineers, architects
Module 4	Thermal Comfort	20h	Engineers, architects
Module 5	SouthZEB framework module and local architectural regulations	30h	Engineers, architects, municipal employees
Module 6	nZEB simulation and design software module	30h	Engineers, architects, building technicians
Module 7	Low carbon technology and automation for nZEB	20h	Engineers, architects, building technicians
Module 8	Retrofitting towards nZEB	40h	Engineers, architects, municipal employees
Module 9	Construction management and field supervision of nZEB	40h	Professionals from construction sector
Module 10	Preparation of funding schemes and other incentives for nZEB	20h	Municipalities, local/ national authorities

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

7 – "Low carbon technology and automation for near Zero Energy Buildings". More detailed information on the results from the first set of design meetings can be found in the SouthZEB Project webpage, on Deliverable 2.2 (SouthZEB Project, 2014). Table 3 presents the final set of training modules proposed.

The current detailed features of the training modules are documented in Deliverable 3.1, available in the SouthZEB website. Currently, the overall results from the set of second design meetings is under evaluation and the the project partners are in hands with the planning of the training modules sessions. These first will be directed towards training the trainers, during the second semester of 2015 and, after that, towards training the trainees.

DIFFICULTIES AND LESSONS LEARNED SO FAR

The project is currently progressing well, within the initial expectations of the consortium. Meanwhile, some difficulties have already been identified and overcome. Those difficulties considered most relevant presenting lessons to be learnt are summarized below.

National and Regional Issues

One of the concerns is relative to the coherence of the views on the nZEB underlying concept among the different modules and among the different target countries. It is recognized to be quite difficult to develop training in nZEB topic, as this training has to be in coherence with national building legislation and indications/methodology, which in this very moment are still missing. The challenge is to develop a common framework of these courses between the participant countries, even when it is verified that in some of these countries the definition of nZEB is not yet applied. The training and certification framework has been initiated at the European level, based on the introduction of the Energy Performance of Buildings Directive and other Directives and Regulations. The program of training modules and the certification framework is intended to be applicable across Cyprus, Greece, Italy and Portugal. Therefore, reference to national building regulations and standards is considered to be essential in the training modules.

In order to address this major concern, the technical and scientific principles behind each of the published training modules has remained consistent across all regions, while actual course content has been adapted in order to best address the regional narrative and requirements in each area. The approach taken in nine out of the ten courses has been to focus 80% on the technical and related background information, with around 20% being inclusion of regional, national and local issues. Module 5 is much more specific to local architecture and regulation (see Table 3) and is therefore 70% focused on local issues.

Number of Trainers and Trainees per Target Country

A core issue that came up in the early months of implementation of the project was the number of trainers and trainees each country should train and certify, as these have not been previewed in the Grant Agreement. Therefore, all responsible partners prepared a proposal, mainly based on the population of each country and the number of the professionals in the building industry which was discussed in one of the project meetings. The allocation of the trainers and trainees in the target countries was determined. Each target country has been tied to the goal to train a minimum of 12 trainers. Moreover, it is also a concern

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

the engagement of both trainers and trainees in the courses to be developed in each target country. The theme is core and very much up to date, but there is a high risk that other issue such as available time and budget from trainees may overcome these positive expectations.

CONCLUSION

The definition of nZEB is still not consensual and conceptually can vary according to different perspectives and countries. Therefore, the term nZEB is seldom used "commercially", without a clear understanding of the dimensions behind it. Moreover, countries have been enacting policies and national targets based on a concept without a clear definition in place.

However, as it was presented in section 2, there is some consensus that near or Net zero energy buildings design should start from solar passive sustainable design and may be achieved as a result of executing two steps: (a) reduce building energy demand/energy efficiency and (b) generate electricity or other energy carriers, to get enough credits to achieve the desired energy balance /energy generating.

The exact approach for designing and realizing a near zero energy building has many different possible combinations of building envelope, utility equipment and on-site energy production equipment. Consequently, the definition of any ZEB building is very much dependent on the *local and regional context*, as well as on *the building type* and policy implementation has been progressing on a step-by-step basis, not as fast as it would be desirable as shown in section 3.

Meanwhile, some voluntary standards reviewed in section 4 have emerged and have been widely adopted most of all in the so-called front runner countries. This voluntary wave is moved by the underlying fact that development of a regional energy economy should be optimized according to the efficient use of the available resources and energy flows in that same region using, for instance, a network system analysis method, which provides solutions for developing sustainable energy models.

Section 5 highlights the fact that the definition of the near Zero Energy Building it is not the only problem to overtake, despite there is a vast gap between the average energy use in current new buildings and what is required when the EPBD directive is implemented in the near future. A significant and wide number of barriers have to be overcome. There are some limitations regarding market deployment of some technologies but also regarding the transfer of knowledge and know-how among professionals due to the intrinsic characteristics of the construction sector, such as being a project-based structured activity, in which a large amount of knowledge gained during the actual building process it is not documented or transformed into an organizational learning. Therefore, the number of architects and engineers that are able to deal with new technologies and standards are insufficient. To sum up, it is necessary to improve the skills and to expand the number of qualified buildings professionals, from architects, construction engineers to installers and workers. Moreover, municipalities occupy a key role when it comes to energy savings in existing housing. They are involved right from the beginning in renovation and restructuring plans and have a decisive contribution to make in energy saving and energy provision. Despite that, one of the main methodological problems to integrate energy efficiency and renewables projects into regional/local development procedures so that these energy elements may compile in integral uniformity in terms of regional/local goals identified by (Klevas, Streimikiene, & Klevas, 2009) is to have municipal officials that are willing and cooperative implementing these processes.

The nZEB training modules developed within the SouthZEB project aim at shortening the knowledge gap of professionals in the Southern European countries in nZEB concepts as this has been identified as

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

a major barrier for the achievement at a national and regional level of the objectives established on the recast of the EPBD directive. As it was described in section 6, to this end, a series of relevant institutions and professionals in the buildings and energy efficiency fields have been involved in the educational contents definition process. This included the formal constitution of four Focus Groups to advice, one in each pilot country. The convergence of views related to the scope and contents of all training modules was found through discussions carried at each of the national design meetings held. One of the main challenges ahead is reaching the maximum number professionals to engage in the training sessions. The organisation and development of the 10 training modules on nZEB, the e-learning platform and the experience of the courses undertaken under the SouthZEB project are not expected to simply end with the completion of the project. In the future, training and certification will continue to officially exist on the basis of a future collaboration agreement and business model agreed upon by all the project partners.

With training and diffusion of knowledge to the building professionals within the SouthZEB project, such as building engineers and scientist, architects and architectural technologists, planners, civil and structural engineers, housing authority asset managers, facility and property managers, construction and accountancy professionals it is expected that changes will be facilitated and enabled. One is that nZEB design considerations are brought to the construction sector in Southern European countries right from the initial phase of the process of building new buildings or renovating existing ones. In this way, innovative technologies (for instance, application of PV panels to the building structures, geothermal heat pump systems) or design and construction methods (for instance, Building Information Modelling BIM which consist of intelligent 3D model-based process from planning, design, construction and management of the buildings) will become more easily used. Also it is expected that municipalities' executives in Southern Europe become more cooperative and willing to find the best way to integrate energy efficiency and renewables into the regional and local development goals, including developing specific local financial instruments to promote nZEB projects in each of the pilot country. Moreover, new energy services companies (ESCOs) will find a proper market to their offers of new energy solutions (for instance, the leasing of a PV rooftop system in a building whose ownership is from the company and not the building owner). Ultimately, all these innovative approaches and business models proportionated by the changes brought by nZEB buildings will enable higher overall efficiency, delay expensive investments in the grids and improve living standards and quality of life.

KEY TERMS AND DEFINITIONS

Certified Training: Teaching of knowledge, skills and useful competencies developed within a certain recognized body of experts' framework.

Front Runners Countries: Countries that show more advancements in the achievement of stated goals.

Implementation of Directives: Actions with the aim to achieve the goals stated in the directive.

Nearly Zero Energy Buildings (nZEB): Buildings that have very high energy performance and who's nearly zero energy needs are covered as much as possible by renewable energy sources.

Net Zero Energy Buildings (NZEB): Identical to nearly Energy Buildings with an emphasis on the positive side of the energy balance and on this being delivered by renewable energy sources.

Regional Development: Stimulus to socio-economic activities based on endogenous resources.

SouthZEB Project: European project within the framework of Intelligent Energy Europe developing certified training for building professionals.

ENDNOTES

1 The 18 IEA countries evaluated by the International Energy Agency Energy Efficiency Market 2014 Report are Australia, Austria, Canada, Czech Republic, Denmark, France, Finland, Germany, Italy, Japan, Korea, the Netherlands, New Zealand, Spain, Sweden, Switzerland, the United Kingdom and the United States and represent more than 83% of total final energy consumption in OECD member countries and 33% of the total final energy consumption worldwide.

2 Around the world the terms used are not necessarily the same. For instance, in the United States the term used to refer to Zero Energy Buildings is Zero Net Energy.

3 According to this report 20 countries from EU-28 delivered the national report plan as required by article 9 of the EPBD are: Austria, Belgium, Bulgaria, Croatia, Cyprus, Denmark, Finland, France, Germany, Hungary, Ireland, Italy, Lithuania, Luxembourg, Netherlands, Romania, Slovakia, Slovenia, Sweden and United Kingdom. Those that did not include are: Czech Republic, Estonia, Greece, Latvia, Malta, Poland, Portugal and Spain.

4 The renewables technologies refer to photovoltaic/building-integrated photovoltaic, wind turbines, solar thermal (solar water heaters), heat pumps, and district heating/cooling. In general, most of these are rather well established. However, the wide diffusion of PV and wind turbines generation may cause, among other things, power instability and compromise the quality of existing electricity grid structure. nZEBs should ideally be designed to function in synergy with the local utility grid and not putting extra stress on the existing electricity infrastructure (Li, Yang, & Lam, 2013).

Chapter 62
Conditions for Development of Renewable Energy in Poland

Katarzyna Osiecka-Brzeska
University of Gdansk, Poland

ABSTRACT

The Paper examines legal and financial tools which are used in Poland to succor the development of energy from renewable resources. In the first part a definition of sustainable development is given and the short history of this idea is shown. Then the concept of Sustainable energy is introduced. The second part describes main policies of European Union on sustainable policy and the Polish Legal System on Renewable Energy is described. The fifth part of the paper analyzes the sustainable development indicators provided by Eurostat for the energy produced from renewable resources. there are 6 indicators analyzed. In the end the forecasts for the development of RES in Poland is given. There are clues for development of different technologies in different provinces of Poland. There are also forecasts for the development of the renewable energy market in Poland.

INTRODUCTION

The environment has played a significant role in many theories of economics already in the nineteenth century, while its importance to the economy began to be noticed not until the second half of the twentieth century. Since then, environmental social, economic aspects connected altogether in one theory of sustainable development (SD) have become an important part of modern macroeconomic policy. In today's global economy, the European Union has adopted the role of a leader and promoter of sustainable development. Thanks to the efforts of the EU, a number of countries has managed to make significant commitments on the environment. At the same time, the European Union requires its members to fulfill the obligations to the protect the environment in the context of sustainable development. These requirements were a base to carry out studies showing changes in the field of sustainable development in Poland.

As energy is an integral part of SD, this paper will explain the meaning of energy in the theory of sustainability. It will also present the Polish renewable energy market and its changes during 2004 – 2013 period. In most cases the data is provided for 28 Member States of European Union (EU 28), but in some

indicators the last available data was for 2011– before Croatia joined EU., so this data is for 27 Member States of European Union (EU 27). In the end the changes in sustainable energy indicators for Poland will be described and guideline to the further development of renewable energy installations will be given.

DEFINITION OF SUSTAINABLE ENERGY

Reflections on the human impact on the environment have their origins back in the mid of 20th century. The greatest importance for conceptualization of sustainable development had the first scientific publications on the impact of synthetic chemicals on the human health, reports on the environmental limits of economic growth, as well as the papers on relations of the human population size and the state of the environment. The main works which highlighted environmental problems were: Silent Spring by Rachel Carson published in 1962, Tragedy of the Commons by Garret Hardin published in 1968, Limits to Growth by Club of Rome published in 1972 and Deep Ecology by Arne Naess published in 1973 in *Inquiry Magazine* (Charkiewicz & van Benmekom, 2001).

Concerns that have arisen as a result of these publications convinced the United Nations (UN) to organize meetings, which aimed to recognize humanity's connection with environment. In 1972, UN held the Conference on the Human Environment, which focused on human – environmental interconnections. As a result of the Conference, the Declaration of the United Nations Conference on the Human Environment was created. It became the first document in international environmental law, which delineated the human right to a healthy environment (Kozłowski, 2000, pp. 105–106).

UN continued their work on effects of human actions on environment. In 1980, together with the International Union for the Conservation of Natural Resources (IUCN), UN published the World Conservation Strategy (WCS). This document, as a result of previously taken actions, proved that there is an interdependence between environmental conservation and economical development. WCS built the basis for the idea of sustainable development by highlighting that development depends on Earth protection.

In 1983 UN created the World Commission on Environment and Development (WCED), which main task was to prepare an agenda for global change into more environmental direction. As a result, in 1987 WCED released *Our Common Future* Report (called also Brundtland Report), in which it was stated that "the environment does not exist as a sphere separate from human actions, ambitions, and needs, and therefore it should not be considered in isolation from human concerns. The environment is where we all live; and development is what we all do in attempting to improve our lot within that abode. The two are inseparable." In these words WCED created the idea of development which joined economic, social and environmental issues accompanied by global solutions. This concept of development, for the first time called the sustainable development, addresses "the needs of the present without compromising the ability of future generations to meet their own needs". This broad definition orders present generation to act responsibly in three important dimensions, so that the future generations will be able to lead their lives at least at the same level as we do now. Those three dimensions submitted in Brundtland Report are: environmental sustainability, economic sustainability and social sustainability (Seema, 2010).

In Our Common Future it was proved that social and economic systems cannot run separately and without the influence on the environment. All, past, present and future generations, lead their lives by fulfilling different and often competing needs of society members. At the same time human beings live within limitations imposed by the environment, social rules and economic possibilities. This is why the idea of sustainable development needs to be treated as a system in which every all three spheres are

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

connected and influence each other. The results of actions taken in any of those spheres are valid not only for today but also for the future. For example, leaking waste-water pipes can contaminate the soil, which may not harvest and cause hunger (The World Conservation Congress (WCC), 2004).

As apparent form the example, the pillars of sustainability should be considered as equal factors of development and equal attention should be put to them. In the theory, the three pillars play the same part, but the practice shows that development is often driven only by one need and only one sustainable pillar is taken under consideration. Present generation put the greatest attention to the economical problems forgetting that environment has an enormous influence on both social and economical sector. But sustainable development is not only about environmental condition and limits but also about ensuring healthy and just society operating in prosperous economy. To achieve this, the unsustainable development should be no longer pursued.

Energy is one of the most important issues to achieve sustainable development goals. Nowadays, energy is needed in every single aspect of everyday life. More and more of human actions depend on energy. Energy considered as electricity, fuels or heat and cold has an enormous impact on living conditions. When considering energy as one of issues of sustainability, it can be seen that energy has interconnections with all three pillars. In the field of environmental actions, sustainable energy is responsible for reduction of natural resources consumption, minimization of waste and pollution or reduction of primary energy consumption. Energy is also important for the society, because the prices of energy influence the living costs, the energy grids use public space and energy independence is strictly connected with national safety. Last but not least, energy is an important factor for the economy as it allows production to run, it is responsible for transportation, energy security etc.

Energy security is one of most important problems of modern energy policy. It concerns the ability of the free-market energy suppliers (producers, mines, refineries, power plants, transporters, suppliers, distributors), as well as regulatory, financial and R&D institutions, to deliver demanded amount of energy to the final consumer at a competitive price. Energy system has to consider a wide variety of potential disruptions. According to OECD (Organisation for Economic Co-operation and Development (OECD), 2007) The most worrisome and potential disruptions can be connected to:

- Extreme and unfriendly weather condition,
- Mismatch of an amount of energy supplied and demanded,
- Failures regulation process,
- Concentration of nonrenewable energy resources in certain regions of the world.

All those threats can have a negative influence on both social (higher energy prices, energy cuts) and environmental (air pollution, oil leakage) issues. The best impact of energy supply sector on the sustainable development is increasing the energy efficiency in everyday use and ensuring the delivery of secure and environmental-friendly energy. To achieve this a lot of work need to be done by international and national institutions, privet business sector and societies. One of pillars of building energy security is to extend the share of sustainable energy in the energy mix (OECD, 2007).

Sustainable energy is a form of energy acquired from renewable resources. This means that the production and consumption of sustainable energy serves the present generations without limiting future generations in terms of energy. Currently the sustainable energy consist of three main divisions: Energy Productions from Renewable Resources, Energy Conservation and Sustainable Transport (Shakeer Publishing BV, 2009).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Energy Conservation and Efficiency policy is about reducing consumption of the energy by using less of energy service (conservation) or by using the lower amount of energy for certain actions (efficiency). To give an example – a lower amount of hot water used for heating is an example of energy conservation. The same amount of hot water used for heating a larger leaving space is an example of energy efficiency. Opponents of energy conservation complain that it limits energy services. Supporters prove that it reduces natural resources depletion and increases quality of the environment. It also has a positive influence on personal spending and national energy security (Zehner, 2015).

Sustainability in transportation is considered to be a very complex concept. It is composed of environmental factors such as fossil-based fuels consumption and emission controls (greenhouse gas emission, air pollution and smog). Transport is one of human activities that has an enormously negative impact on condition of the environment. The goal of a long term sustainable transport policy is a swift to renewable energy resources. Social aspect of sustainable transport is regarded in terms of roads' safety and number of crashes, time taken for commuting or fuel prices changes. Traffic congestion creates socio – economic costs by slowing goods and services flow. Last but not least, sustainable transport is based on third pillar – economical and technical efficiency. This is measured by the number of vehicles used for road, water and air transport, the source of energy as well as the infrastructure used. What is interesting, pipelines for transporting liquid or gas materials as also considered as components of sustainability in transportation, which is by transportation system efficiency and effectiveness as well as the environmental impacts of it (Leslie, Pearce & Harrap, 2012, pp. 295-311).

Production from renewable resources promotes energy technologies which use naturally replenished resources – such as wind energy, solar energy, bioenergy and hydroelectricity (including wave power, geothermal energy and tidal power). In 2014 energy from renewable resources took a share of 19% of global energy consumption and 22% of global electricity generation. The great advantage of renewable is that they exist all over the world, in the oppose to nonrenewable resources, which reserves can be found in limited number of countries. Many renewable energy projects are large-scale, renewable technologies are also suited to rural and remote areas and developing countries. As in those areas energy is crucial for the development and proper functioning of societies, building renewable energy power plants results in increase of energy security, positive climate change mitigation, economic benefits and human development. This is why the deployment of renewable energy is growing worldwide. In 2014, at least 30 nations already had a share of renewable energy in energy mix higher than 20%. Renewable energy markets are expected to continue to grow in next decades. In 2013, global investments in renewable technologies amounted to more than US$ 214 billion. The country that invested the most in renewable energy in 2013 was China, which increased a number of wind, hydro, solar and biofuels installations (Renewable energy Policy network for the 21st Century (REN21), 2015).

SUSTAINABLE ENERGY POLICY IN USA AND CHINA

When comparing data on a total capacity or generation of renewable power, the first place in different categories is taken by USA, China or Member States of European Union. To give an example, Denmark is a world leader in Renewable power capacity *per capica* and wind power capacity *per capita*. In both cases Denmark is followed by other EU countries like Germany, Sweden and Spain). Spain is a leader of Concentrating solar thermal power (CSP) (followed by USA). Germany lead the solar PV capacity (followed by China) and solar PV capacity *per capita* (followed by Italy, Belgium and Spain) (REN21,

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

2015). As the Renewable Energy Policy of European Union will be described below, now the policy of China and USA will be described.

According to REN21, in 2014 China was a world leader in many aspects of renewable energy. It had a greatest renewable power (including and not including hydropower) installed. It also had the greatest hydro and wind power capacity as well as hydropower generation in the world. This is mainly because in 2013 China installed more renewable energy plants than all EU Member States. To achieve this China has implemented four important actions: support of new and renewable energy investments, implementation of various energy-saving renovations, improvement of civil energy use conditions and increased environmental protection (China's Energy Policy, 2012).

Although China is a leader in so many sustainable aspects, the country does not stop where it is. In the 12th Five Year Plan China plans to develop new renewable energy sources, what should allow China to increase the consumption of renewable energy to the level of 15% of a total energy consumption by 2020. The development of renewable power plants, based mainly on hydropower, should also boost up the local employment, investments and living standards. (China's Energy Policy, 2012). To encourage the development of renewable power plants Chinese government uses such policies and financial tools as (REN21, 2014):

- Renewable energy targeting,
- Feed-in tariff and premium payment,
- Electric utility quota obligation
- Renewable Portfolio Standard (RPS),
- Tendering,
- Heat obligation or mandate,
- Biofuels obligation,
- Capital subsidy,
- Investment or production tax credit,
- Reductions in sales, energy, CO2, value-added Tax (VAT) and other taxes,
- Energy production payment,
- Public investment, loans and grants.

As biomass and solar power create a great potential for heating and power production, Chinese Government promotes and encourages the development of solar power plants, solar heating and cooling systems in big cities and industry and biomass systems in rural areas (China's Energy Policy, 2012).

China is a world leader of wind power production. This is why, the Government invests more in R&D studies in wind-power equipment production and development of offshore wind farms. At the same time standards and control in the wind power sector are improved and the wind power production is optimized (China's Energy Policy, 2012).

USA is the world's second energy consumer (19.2% of world's energy consumption) and this is the reason why the US Government decided to change the energy policy based on fossil fuels to a sustainable energy with a greater share of renewable. The first "pro – sustainability" Act was the American Recovery and Reinvestment Act. After its introduction in 2009 the Department of Energy was obliged to invest more than USD 31 billion in improvement of energy infrastructure as well as development of clean energy projects and energy efficiency (International Energy Agency (IEA), 2014).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

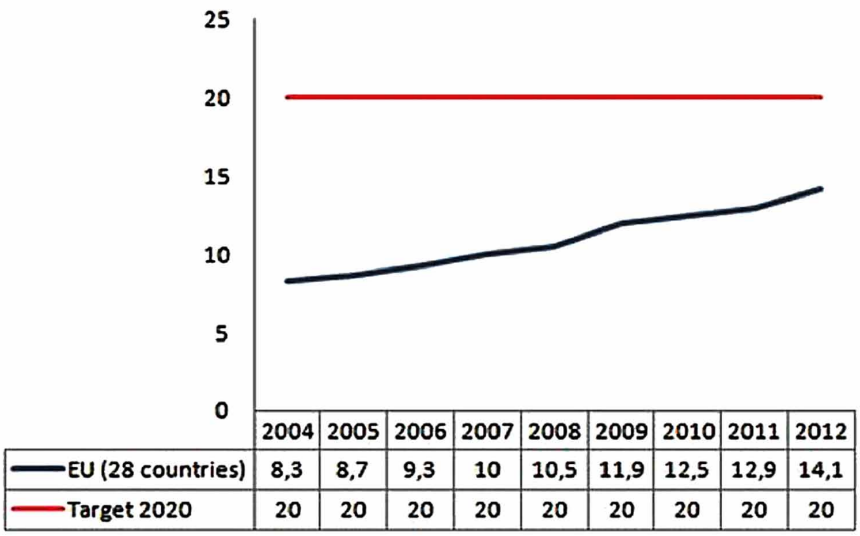
Second to come was the President's Blueprint for a Secure Energy Future (2011). It set an agenda for the federal energy policy, which main goal was to double the generation of wind, solar and geothermal electricity by 2020. It also aims to double the energy productivity by 2030. By those actions USA plans to become a world leader in clean energy production and consumption by 2030(IEA, 2014).

In 2012 US Government introduced the "All-of-the-above" strategy (2012) which main goal was to support the energy security and develop low-carbon energy technologies(IEA), 2014). To achieve this US Government has a different support polices, fiscal incentives and public financing tools. Among them may be mentioned (REN21, 2014):

- Renewable energy targeting (revised; sub-national level),
- Feed-in tariff and premium payment (revised, sub-national level),
- Electric utility quota obligation (revised, sub-national level),
- Renewable Portfolio Standard (RPS) (revised, sub-national level),
- Net metering (revised, sub-national level),
- Tradable Renewable Energy Certificate (REC) (existing, national level),
- Tendering (revised, national level),
- Heat obligation / mandate (existing, national level),
- Biofuels obligation / mandate (revised, national level),
- Capital subsidy or Rebeta (existing, sub-national level),
- Reductions in sales, energy, CO_2, value-added Tax (VAT), or other taxes (existing, sub-national level),
- Energy production payment (existing, sub-national level),
- Public investment, loans, or grants (revised, national level).

SUSTAINABLE ENERGY POLICY IN EU AND POLAND

In 1992 European Member States agreed that sustainable energy would play an important part in European Energy Policy. This is why the share of renewable energy in energy production and consumption keeps growing and the whole renewable energy sector is developing (see: Figure 1). In the Amsterdam Treaty, it was decided that sustainable development, with renewable energy as its part, would be treated as a principle objective for all EU countries.



In 1992, at the UN Conference on Environment and Development held in Rio de Janeiro it was highlighted that the current levels of energy consumption and production are not sustainable. It was also stressed that the energy demand would continue to increase, what imposes the importance of development of renewable energy technologies. This should not only have a positive influence human health, the atmosphere and the natural environment, but also on energy independence and safety in all regions of the world.

In 2002, during Johannesburg Summit, UN set the actions for the development of sustainable energy. The main challenges of the Johannesburg Plan of Implementation ware (United Nations (UN), 2002):

- Improvement of the access to reliable and affordable energy services;
- Correlate the level of energy services with the improvement of living standards;
- Development of renewable energy technologies;

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Share of renewable energy in gross final energy consumption; data in %
Eurostat, 2015.

	2004	2005	2006	2007	2008	2009	2010	2011	2012
EU (28 countries)	8,3	8,7	9,3	10	10,5	11,9	12,5	12,9	14,1
Target 2020	20	20	20	20	20	20	20	20	20

- Enlargement of renewable energy share in the global energy mix;
- Diversification of energy supply by development of more efficient and cost-effective energy technologies;
- Conjugation of a range of energy technologies to fulfill the growing demand for energy services;
- Dissemination and deployment of cleaner and more affordable technologies for both – energy conservation and efficiency.

Unfortunately, Rio and Johannesburg Summits failed to impose radical changes in the world's energy market, the European Union continued its sustainable policy rather strictly. Although during UN Summits no recommendations nor targets ware given, EU decided to introduce an annual increase of share of renewable energy in energy production and consumption at the level of 1,5% a year until 2010. As it would not be enough, EU created a group of "pioneer countries", which decided to set national and regional sustainable energy goals. Among 80 countries that joined the group, such countries as New Zealand, Brazil, South Africa and all EU members ware listed.

Yet, in 2004, during the European Conference for Renewable Energy in Berlin, EU set new ambitious goals for its member states. It was decided that 20% of European consumption should be produced from renewable resources by 2020. Those targets get binding for EU Member States in 2009, when Renewable Directive was set. This Directive set also a new goal for transportation – a 10% share of renewable energy sources used in all transport sectors. What is interesting, each Member State sets its own goals, which can be higher or lower than general EU targets.

In 2010, EU introduced a new development policy – Europe 2020. The main goal of this policy is to create a smart, sustainable and inclusive economy. It is believed that this will help European Union to reach high employment, competitive productivity and social cohesion with eco-friendly economy at the same time. In Europe 2020, the EU set five objectives for employment, innovation, education, social inclusion and last, but not least - climate and energy. Those targets need to be reached by 2020, but

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

similarly as in previous case, each Member State could adopted its own national targets. Among climate and energy goals one can find highly ambitious targets which aim to reduce greenhouse gas emissions by 20% from the level measured in 1990. If the conditions are conducive, the reduction can reach even 30%. The other goals aim to increase the energy efficiency by 20% and reach a share of 20% of renewable energy in EU energy consumption (European Union (EU), 2010).

On October 23rd 2014, European Union supplemented goals from Europe 2020 with new targets for 2030 (European Council (EC), 2014). The new policy origins in all previous policies and is built on EU's experience and growing energy needs of EU inhabitants. The policy takes into account the earlier set targets and long term perspective. It is based on Roadmap for moving to a competitive low carbon economy in 2050, the Energy Roadmap 2050 and the Transport White Paper. The main goals for 2030 are (Osiecka-Brzeska, 2013, p. 28):

1. Reduction of greenhouse gas emission by at least 40% in comparison to the 1990: sectors acting within EU emissions trading system (EU ETS) - such as power plants, industrial plants and others, will have to reduce its emissions by 43% by 2030. Sectors not covered by EU ETS are obliged to cut its emissions by 30%.
2. Increasing the share of renewable energy to at least 27%: this is supposed to changes EU energy system into more competitive, secure and sustainable system. This target was endorsed as binding at EU level.
3. Increasing energy efficiency by at least 27%: EU industry is about 19% less energy intensive than in 2001 and new buildings use 50% less energy than in 1980s and the trends are still improving. This is why EU set the target of 27%, but noted, that it will be reviewed in 2020 and may be changed into 30%.
4. Reform of the EU emissions trading system: in recent years the surplus of emission allowances has built up. The reform should ensure, that the EU ETS will be effecting and encouraging in promoting eco-friendly investments. It should also stabilize the market and become the main instrument to control and reduce greenhouse gas emission.
5. New governance system: each Member State is obliged to create a national plan for competitive, secure and sustainable energy. Transparent and reliable governance system should ensure the equal development of renewable energy and desirable reduction of greenhouse gasses. It should also help member states to introduce transparent national policies and effective support instruments for sustainable energy.

Five years earlier than 2030 goals, in 2009, European Union created Roadmap 2050. This document presents practical and objective analysis of ways to reach a low-carbon economy in Europe. The European Council set the goal to reduce greenhouse gas emissions by 80 - 95% below levels of 1990 by 2050. What is useful, this document not only sets the objectives but mainly addresses a high level greenhouse gasses emissions across all sectors of EU economy and analyses the power sector in depth, drawing conclusions based on facts from industry practice ad academic knowledge. Yet, the EU goals are thought to be inflated and some specialists are afraid that they can have an inhibitory influence on EU economy.

Among EU energy policies one of the most important is Directive 2009/28/EC, called also The Renewables Directive. It requires EU Member States to create National Renewable Energy Action Plans (NREAP), which will be a roadmap to reach targets set for 2020. This directive is binding for Poland and stipulates that the country will have a share of 15% of renewable energy resources (RES) in gross

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

final consumption of energy. It is expected that in 2020 Polish economy will consume 69,200 ktoe and 10,380 ktoe will be come from renewable sources. What is more, the 15-percent-goal is a weighted average of three components, i.e. share of RES in electricity sector, in heating/cooling sector and in transport sector. As for polish targets the numbers are expected to reach the level of 19.13% (electricity), 17.05% (heating/ cooling) and 10.14% (transport) by 2020 (Eurostat, 2015). The goal adopted by Poland sets the country in the middle of requirements established by other EU Member States. In 2012, last data provided by Eurostat, Poland achieved 73% of its target for 2020, which means that the country reached a share of 11% of RES in gross final consumption of energy. (For more detail data please check Table 1).

Table 1. Sustainable energy share in energy mix in EU member states; data in %

	Geo\Time	2009	2012	Target 2020	% of 2020 Target Achieved in 2012	Status for 2012
1	Sweden	48.20	51.00	49.00	104%	Target achieved
2	Estonia	23.00	25.80	25.00	103%	Target achieved

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Poland is a EU Member since 2004. It's the ninth largest country in Europe (a total area of 312,679 square kilometers) the sixth most populous and the most populous post-communist member of the European Union (a population of over 38.5 million people). Polish GDP in 2014 reached 413,133.9 million euro, making Poland the eighth economy of the EU. Since the accession to the EU, Polish GDP has more than doubled - from 204,848 million euro in 2004 to 413,133.9 million euro in 2014. Although the GDP per capita is also growing (from 5,400 in 2004 to 10,700 in 2014), this indicator puts Poland on one of the last places in EU - the welfare of citizens is lower only in Bulgaria, Romania, Croatia and Hungary. Although Polish investments in R&D are higher every year (0.56% of GDP in 2004 to 0.87% in 2013), Poland took nineteenth place among EU Member States in 2013 with investments 2.4 times lower than EU average. The low investment has its output on eco-innovation of the country – Poland is the second last eco-innovative country of EU, with eco-innovation index at the level of 42% of EU average.

The Directive 2009/28/EC forced Member States to create NREAP until 2013. In 2013 Polish government passed an Act called "Small Energy Package". Among regulations about electricity end-users and gas distributors, the "Small Energy Package" defined the rules for the generation of electricity in micro-installations and electricity devices with a capacity of less than 40 kilowatts. Owners of micro-installations producing electricity are exempt from the obligation to run a business. What is more, the electricity generated in micro-installations should be bought at a price of 80% of average selling prices of electricity in the previous year. This was a great step for development of Polish renewable energy production, as it gave the chance to join the energy market by small producers. Yet, the Act put those producers in a less competitive position, as it obliged them to sell the electricity 20% below the market price. The "Small Energy Package" Act also amended Polish Energy Law, adding the obligation to develop the national action plan for renewable energy sources and create monitoring system for: renewable electricity market, heat and cooling from renewable sources market, agricultural biogas and bio market, liquid fuels and liquid biofuels used for transport (Ministry of Economy, Government of Poland (ME), 2013).

On 20th February 2015, Polish Government passed an Act on RES on renewable energy sources and handed it to sign by Polish President. The new RES Act is in line with EU policy for 2020 and 2030 and will allow Poland to reach the required share of renewable energy in gross energy production. What is more, the Act is beneficial for individuals who produce primarily electricity for their own use and sell any surplus to the grid. According to the Act, owners of domestic micro-installations up to 10 kW are guaranteed redemption surplus at a price higher than the market. Nowadays, the price of electricity in Poland is around 0,15 EUR per 1 kWh and micro-installations owners will be able to sell self-produced electricity at a price of 0,18 EUR per 1 kWh. This is a great change, which makes the sustainable energy from micro-installations more competitive than any other source of energy. This may be a unique chance for Polish renewable energy market to develop much faster than before (ME, 2014).

In addition to these recent legislative changes, Polish energy market offers a variety of tools to support the development of renewable energy. The most important Polish act on RES development is the Energy law from 1997. Renewable energy, as an integral part of energy market, is controlled by rules from the Energy law, although it regulates the entire energy sector. The main rules for power plants using RES in Energy law are (ME, 2014):

- Special rules for connection to the power grid and transmission of electricity generated,
- Ensured sale of the total amount of electricity generated,
- The right to issue and trade the Certificates of Origin (also called Green Certificates).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

One of the tools supporting investments in renewable energy is a reduction of fees for connection to the grid. Those fees are reduced by 50% for those of power plants which generate electricity from RES and their electric energy capacity does not exceed 5 MW. The other type energy company that can be exempt from fees are those which cogenerate electricity - this means they combine power and heat and their electric capacity is lower than 1 MW. Please keep in mind, that according to newly introduced RES Act, individual micro-installation owners do not have to pay this fee at all (ME, 2014).

Additionally, to a free grid connection, renewable energy power plants have a priority in transmission of electricity. This means that energy system operators have to collect all surplus of energy produced in renewable power plants and provide a transmission and distribution service. What is more the sustainable electricity has a priority to be collected before electricity produced in a non-sustainable way.

As a result of compulsion of renewable energy collection, energy-selling companies are obliged to purchase the surplus of electricity generated from RES which is interconnected to the grid located within the area in which the seller operates. There is also a purchase obligation for heat energy. According to the Energy law, heat-selling companies are obliged to purchase heat generated from renewable heat producer interconnected to the grid located in the area of a seller. There is a difference between heat and electricity selling obligation – whole surplus of electricity must be bought by operators, but at the same time operators may buy the sustainable heat surplus only to the extent of the demand of customers interconnected to that grid (ME, 2014).

What is also important the price of the energy generated from RES and sold to the energy system is predetermined in the Energy law. This price is equal to the average price of electricity or heat in the previous calendar year. The actual price for renewable electricity and grid is calculated and published by the Head of the Energy Regulatory Authority (ERA). For example, the average price of the electricity in 2012 was 48,4 EUR and this was the settlement value and a price of renewable electricity during all 2013 (ME, 2014).

Another type of tools implemented to support the development and promotion of renewable energy production are the Certificates of Origin. As it is regulated in Article 9th of the Energy law, the electricity generated in renewable power plant should receive a certified that proves that the energy is sustainable. Nowadays every electricity producer in Poland needs to have a share of sustainable energy in the energy mix. The companies have a choice between production of "green energy" which would ensure them the Certificates of Origin or a payment of substitution charge. The substitution charge is a way out, in which energy producer pays a legally established fee.

If the company produce sufficient amount of sustainable energy, it will receive a proper amount of Certificates and apply for their redemption at the ERA. If not, the company may buy the Certificates from other companies – the price of the certificate is determined on a Energy Stock Exchange. RES power plants, whose electricity capacity is not higher than 5 MW, are exempt from paying fees for registration in the Green Certificate Registration System and from stamp duty for the issue of Certificates of Origin.

In 2007 Polish government introduced a similar system of certificates for energy generated from combined heat and power production. However, there is no exemptions applied for certificates issued for energy generated from high performance co-generation to register in the Green Certificate Registration System and stamp duty.

Among the tools used for development of renewable energy, licensing is one of the most popular in the whole European Union. All the business activity connected with the production, distribution and trading of the energy, and renewable energy as well, requires a license issued by the Head of ERA. Licenses are issued for a definite time – usually between 10 and 50 years, but the applicant has a right to apply for

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

a shorter license. The license to run a business in the field of energy is granted after application with a duty stamp (worth around 148 EUR). Each license holder has also to pay an annual fee to the ERA. The amount of the fee depends on the annual revenue received from the licensed activity of the company and a fixed coefficient – 0,0006.

The energy license can be granted to the individuals and companies who meet the following requirements (Polish Information and foreign investment Agency (PIFIA), 2015):

- Have residence or are incorporated in the EU Member State or EFTA Member State being a signatory of the agreement on the European Economic Area, or in Switzerland;
- Has sufficient financial funds or is able to document the capacity to obtain such funds;
- Has technical capabilities ensuring a regular business activity;
- Ensures employment of personnel having adequate qualifications, as provided in the Energy law;
- Has obtained a relevant zoning decision.

Although the license is quite easy to obtain, it can be also easily denied to individuals or companies who are in a state of bankruptcy or liquidation. Individuals or enterprises which lost their license during the last 3or were removed from the register of a regulated activity for reasons enumerated in the Freedom of Business Activity Act will also not receive a license. The third case in which a person or a company will be denied is the situation when this person on members of the board of the company have been sentenced for crimes related to the activities regulated by the Energy law (PIFIA, 2015).

Although all mentioned above instruments support the functioning and development of renewable energy in Poland, the sustainable energy still need to be subsidized. As energy projects in the area of sustainable energy are relatively expensive, investors in this energy sector may count on direct benefits, such as tax benefits and subsidies. Electricity generated from RES is exempt from excise tax. The exemption takes place when Certificates of Origin issued are redeemed (PIFIA, 2015).

Investments in renewable energy projects can receive subsidies from various EU funds, as well as Polish national funds. Most popular are the EU cohesion funds, which are available within the Infrastructure and Environment Operational Program. In Poland is is also possible to acquire a support from 16 Regional Operational Programs (RPO). Very important role in development of RES plays the National Fund for Environmental Protection and Water Management (NFOŚiGW). It offers additional funding in which renewable energy projects are eligible and favored. What is more, individuals pay an agriculture tax can reduce their payments by counting in the costs of investment in renewable energy infrastructure. The discount may reach 25% of the documented sustainable investment (Osiecka-Brzeska, 2013).

POLISH RENEWABLE ENERGY MARKET

Energy intensity of Polish economy is rather high (294.7 kg of oil equivalent per 1000 EUR), as the country is still developing, it is not expected that the energy intensity will fall. The problem is, that the Polish economy depends mostly on domestic coal mining. More than 60% of electricity produced in Poland comes from coal power stations. The country is trying to do the best they can to invest more in the development of renewable energy resource (Central Statistics Office of Poland (CSO), 2014)

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

In period 2004 – 2012 the share of renewable energy in primary energy production was growing steadily. In 2012, when EU countries had a 22.3% share of renewable in the energy mix, in Poland renewable energy amounted to 11,7% of primary energy production. There was an 8% growth since 2011.

Since 2008 the share of renewable energy sources in total primary energy production grew in EU from 16.2 to 22.3% and in Poland from 7.6 to 11.9%. At the same time the amount of energy produced from renewable resources grew by 28% in EU and 57% in Poland. This means that the growth of sustainable energy is higher than the growth of total energy production. This situation is presented in Table 2.

During 2008 - 2013 period the greatest amount of energy was produced from solid bio- fuels. The share of other renewable energy resources changes – there is a clear upward trend of liquid bio- fuels, wind, biogas and solar power. Only water has noticed a cline in the power production. The share of different renewable energy technologies in the total energy production from renewable sources is shown in Table 3.

In 2013 energy produced from bio- fuels was more than 88% of all renewable energy produced I Poland. Solid bio- fuel produced 80% and liquid – 8,2% of renewable energy. The third place took wind energy with 6,05% share and water energy was nearly 2,5% of Polish renewable energy. Others energy sources produced less than 0,5% each. More accurate data is shown in Figure 3.

Figure 2. A share of renewable energy sources in a total energy production in UE and Poland; data in %
CSO, 2014, p. 21.

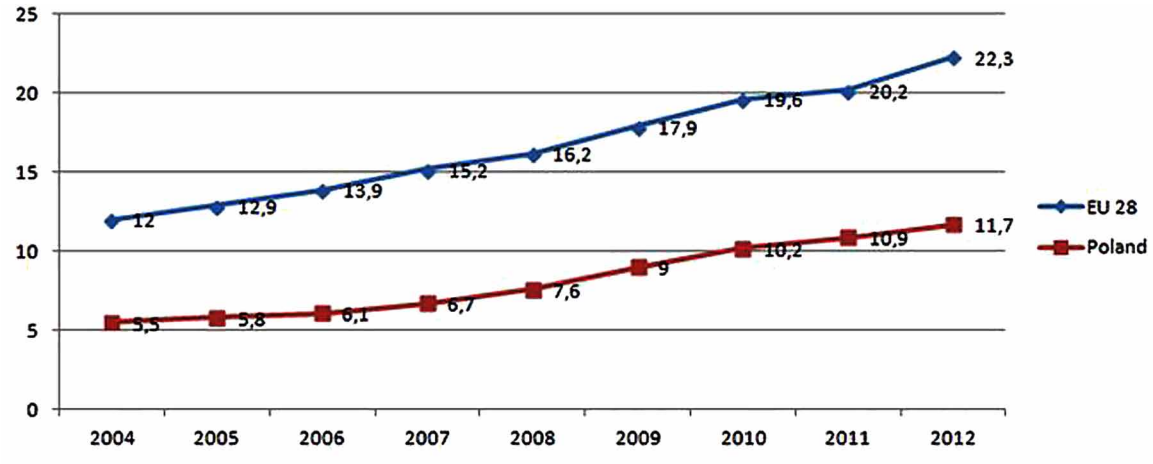

Table 2. The share of RES in energy production in years 2008-2013; data in TJ

	2008	2009	2010	2011	2012	2013
Total production of primary energy	29,985,356	2,816,880	284,028	2,882,363	3,038,291	2,005,544

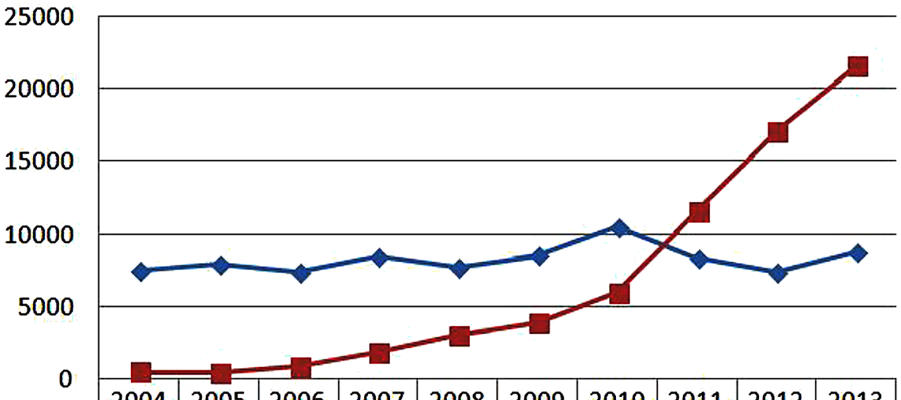
Figure 3. The share of renewable energy technologies in a total production of energy from renewable sources in 2013
CSO, 2014, p. 30.

In the period of 2004 – 2012 there was a stable growth of energy produced and consumed from solid bio – fuels. In 2013 there was a slight - 2,2% decrease in both of those sizes when compared to the year 2012. Still, if one compares 2013 to the same time in 2004 the growth would be higher than 68%. In the years 2004 – 2013, the structure of the consumption of solid biofuels changed.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Since 2008, there has been a systematic increase of production of solar energy. Until 2008 Polish Main Statistics Office was analyzing only trade and service companies in terms of solar energy production. Since 2009 there has been a new study, which is carried out periodically with 3-year intervals. This study includes solar energy consumption in households, which is helpful to acquire additional data and show a full picture of Polish Solar energy market. Statistics results for 2013 showed that the total size of installed collector area was approximately 700 thousand m^2. Some sources differ on this data, e.g. The Renewable Energy Institute's research on sale of solar panels proved that the total size if installations was 1 480 thousand m^2.



Between 2004 and 2013 there was a steady increase in the use of wind energy – from 512 TJ in 2004 to 21 614 TJ in 2013. This means that energy production from wind is 42 time higher than is was a decade ago. As it is shown in table, the energy production from water is kept at rather stable level. There have been some fluctuations, but the main trend is kept between 7 500 and 8 500 TJ. The highest production from water resources was in 2010, when it hit the level of 10 500 TJ.

During 2004 - 2013 period, the number of biogas increased steadily. Production of biogas in 2013 increased by 8.0% in comparison to a previous year. For the input of energy transformations 76.7% of biogas were used and the final consumption accounted for 23.3%. Most of the biogas 954.9%) was produced in for companies from the sector of trade and service.

From 2004 to 2011 there was a systematic increase in the extraction of landfill biogas. However, in 2012 and 2013 the amount of landfill biogas produced was lower by 3.2% and 4.1% compared to the previous year. The landfill biogas was mainly used in industrial power plants to generate electricity and heat. In the analyzed period of 2004 – 2013, there was an increase in the amount of biogas produced from sewage treatment plants. In 2012 there was an 19.7% increase in comparison to the previous year and in 2013 the increase was at the level of 1.0%.

When considering energy production from renewable energy resources in Poland, the production of electricity should be discussed separately. This is because the electricity determines a great share of energy produced from RES, especially the power from wind, water and sun. The general information

Figure 4. Changes of energy produced from wind and water in Poland in 2004 – 2013; data in TJ
Author's calculations on: CSO, 2014, p. 42.

	2004	2005	2006	2007	2008	2009	2010	2011	2012	2013
Water energy	7494	7924	7352	8468	7748	8550	10512	8393	7333	8781
Wind energy	512	488	922	1878	3012	3878	5992	11536	17088	21614

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

about electricity production from RES can be found in Table 3 in the time period of 2004 – 2013 the production of energy from RES grew systematically. At the same time there were changes in the size of shares different technologies in the production of renewable energy.

Figure 5 compares the changes in share of different technologies of renewable energy production in the year 2004 and 2013. It can be easily noticed that water technologies have lost the main position – from nearly 68% in 2004 to only 14% in 2013. The opposite trend was seen in wind energy – its share rose from 4,6% in 2004 to 35% in 2013. The share of solid bio- fuels also grew – it nearly doubled from 25% in 2004 to 46,5% in 2013. In 2004 no electricity was generated from solar of municipal waste. In 2013 it still had only a marginal significance. Picture 5 presents the changes in more details.

Electricity produced from renewable energy sources as a share of domestic gross electricity consumption accounted for 4.3% in 2008, 5.8% in 2009, 7.0% in 2010, 8.3% in 2011., 10.6% in 2012 and 10.7% in 2013. The share of electricity produced from renewable energy sources in the national gross electricity consumption is defined as the ratio of electricity acquired from renewable sources to gross electricity consumption, i.e. with losses and differences in the balance sheet.

In the years 2008 - 2013 the share of electricity generated from hydropower in total electricity production from renewable energy sources gradually decreased and reached 14.29% in 2013. At the same time, the share of electricity produced from solid biofuels remained at a high level - it reached Value of 46.43% in 2013. Another energy sources used to produce electricity (in terms of share in the total production of electricity from renewable sources) in 2013 were: wind energy - and biogas 35.18% - 4.04%. Municipal waste, solar and bioliquids were in 2013. Insignificant part in the production of electricity, which amounted to 0.049%, 0.009% and 0.003%.

THE CHANGE OF SUSTAINABLE DEVELOPMENT INDICATORS FOR POLAND

Eurostat has two head indicators, one operational and five performance indicators. Analysis of indicators for Polish is based on the data from 2004. and - depending on the data provided by Eurostat - will apply to 2010 or 2011. For a better picture of the situation, some indicators for Polish will be compared with the rates for other EU member states.

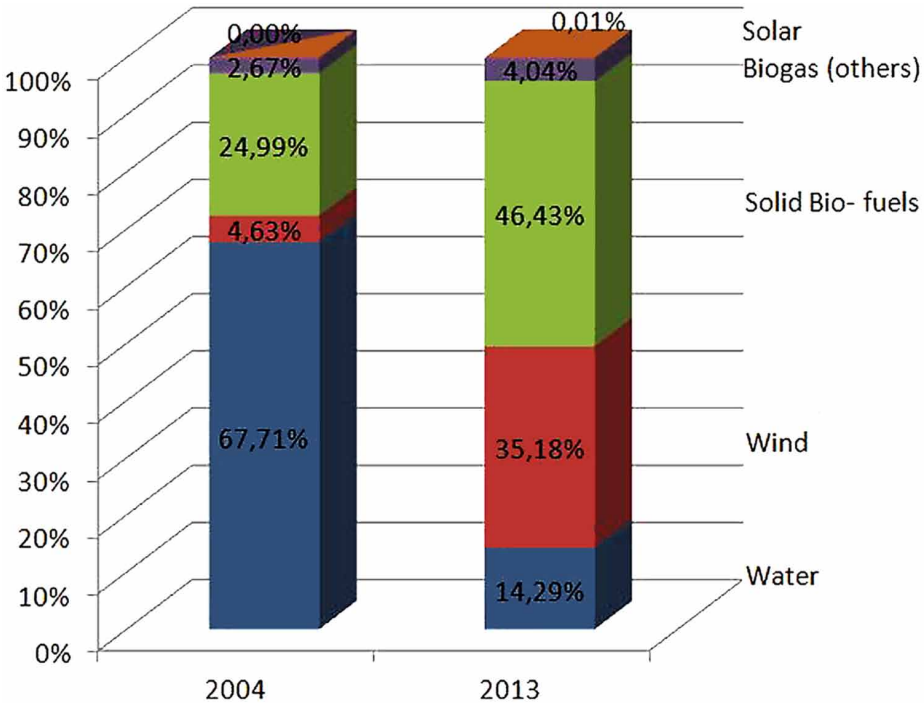


Table 3. Share of technologies in renewable energy production; time period: 2004 – 2013; data in TWh

	2004	**2005**	**2006**	**2007**	**2008**	**2009**	**2010**	**2011**	**2012**	**2013**
Total	3074.4	3847.7	4291.2	5429.3	6606.0	8678.7	10888.8	13137.0	16878.9	17.1

Figure 5. Comparison of changes in share of renewable energy technologies in production of renewable energy in Poland between 2004 and 2013
Authors calculations on: CSO, 2014, p. 29.

The first head indicator of sustainable development in Poland in the field of energy is the primary energy consumption. As it is clear from the data presented in Table 4 in the period 2004-2013 the consumption of primary energy in the 28 EU Member States decreased gradually, reaching in 2010 level of 98,9% of consumption in 2004. The primary energy consumption in Poland in the same period was characterized by fluctuations, keeping the deviation of +/- 2%. This trend is also reflected in primary

Table 4. Primary energy consumption in Poland and the EU in the years 2004 – 2013

	2004	2005	2006	2007	2008	2009	2010	2011	2012	2013
EU (mln TOE)	1706	1709	1718.2	1687.3	1686.6	1593.1	1652.4	1593	1583.9	1566.5
Poland (mln TOE)	86.9	87.7	91.7	91.6	92.8	89.9	95.8	96	92.9	93.2
Max EU - Germany (mln TOE)	320.1	317.2	327.6	310.4	315.2	296	310.4	294.4	296.8	302.5
Min EU - Malta (mln TOE)	0.9	1.0	0.9	1.0	0.9	0.9	0.9	0.9	1.0	0.8

Poland/EU (%)	5.1%	5.1%	5.3%	5.4%	5.5%	5.6%	5.8%	6.0%	5.9%	5.9%

Author's calculations on: Eurostat, 2015.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

energy consumption in Poland as a share of primary energy consumption in the EU. In 2004 Poland consumption accounted for 5.09% of Union consumption, and in 2013 it had increased to 5.95%. The increase in primary energy consumption can be explained by the economic development of the country. Unfortunately, Eurostat does not publish data on savings and energy efficiency of individual Member States.

A positive trend for Poland is the decline in the share of solid fuels and gas in gross energy consumption (see Table 5). The share of petroleum products increased until 2009, but since then it has been steadily decreasing. The good trend for Polish sustainability is also an increase in the share of renewable energy in gross inland consumption.

Both in the European Union, as well as in Poland and other member states the share of renewable energy in energy mix has been increasing. Quantitative growth of renewable energy also affects the qualitative structure of energy consumed - renewables are an increasing share of gross energy consumption. Compared to the EU, Poland in the years 2004 - 2013 showed a slightly lower rate of growth of the share of renewable energy in gross consumption (see Table 6). However, Poland, with a 10.4 percent share of renewables in energy consumption, is closer to achieving the 15 percent target set for 2020 than the EU as a whole.

Table 5. The share of energy sources in gross inland consumption in the years 2004 - 2011, together with an indication of the direction of change year on year; data in%

The Type of Raw Material	2004	2005	2006	2007	2008	2009	2010	2011
Solid fuels	58.9	↓ 58.7	↓ 58.2	↓ 56.9	↓ 55.4	↓ 54.0	↓ 53.7	↓ 53.4

Compared to other Member States, Poland, consumes relatively little energy sources. In 17 EU countries the share of sustainable energy in gross energy consumption was higher than in Poland. Between 2004 and 2013, most of the renewable energy was produced in Sweden, Latvia, Finland and Austria (compare Figure 6). The smallest production took place in Malta - the share of renewable energy was 0.4 in gross energy consumption. In 2011, many Member states (e.g. Estonia, Lithuania or Romania) got close to the target set by the EU in this field. Sweden and Bulgaria ware the two countries to exceed the target. In 2013 Poland did not reach the 2020 target.

Operational indicator for sustainable energy is the energy dependence of the country and the Community. Energy dependence is understood as a percentage of net imports of energy in energy resources in the national gross energy demand. In other words, the energy dependence shows how a given economy is forced to rely on importing energy to meet its energy needs. Eurostat energy dependence distinguishes depending on the raw energy (coal, oil, gas) or total dependence, which includes all energy resources.

As illustrated in Figure 7, Polish energy dependence in the period 2004-2013 increased. It is not a good sign from the sustainable point of view. Although Poland reported a significant increase in energy dependence (from 14.5 in 2004 to 25.8 in 2013), the Polish energy dependence is lower than the energy dependency of the EU. The EU energy dependency was at the level of 53.24 in 2013.

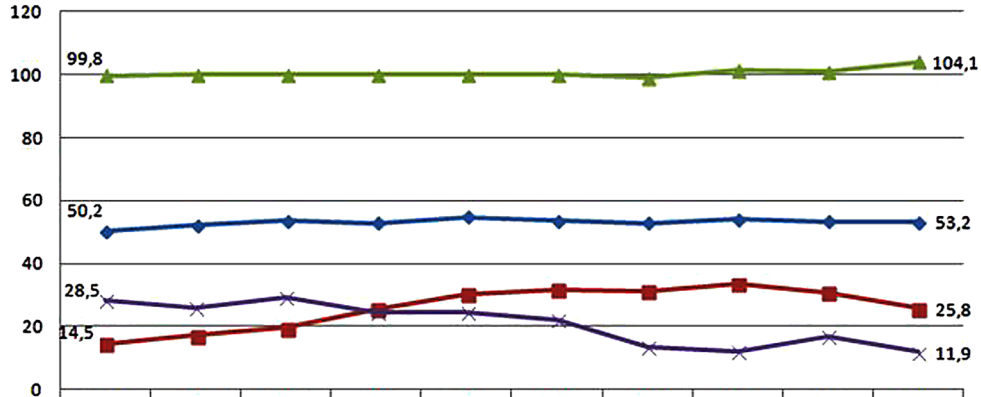

Figure 8 shows a comparison of the energy dependence of the member states and the EU-28 in 2013. The country with the highest energy dependence was Malta. Although the Polish energy dependence has increased since 2004, in 2011 Poland was still in the fourth place in terms of energy independence.

Figure 8. Energy dependence of individual EU28 countries in 2013; data in %
Eurostat, 2015.

Lower dependence on imported energy factors than Poland was demonstrated by Estonia (11.9), Denmark (12.3), Romania (18.6). Polish energy independence is connected to the huge mining and export of coal.

Production of electricity from renewable energy sources in the years 2004 - 2013 grew steadily both in Poland and in the European Union. In EU the share of renewable energy in relation to gross energy consumption increased from 14.3% to 25.4%, which means an almost 78% increase. At the same time, the growth of renewable electricity produced in Poland was 509%. By 2013, the largest producer of renewable energy was Austria, which produced over 68% of electricity from renewables.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Among the Member States of the EU, Poland is one of the six smallest producers of electricity from renewable energy sources - less renewable electricity produce only Malta, Luxembourg Hungary, Cyprus and Netherlands.

The share of renewable energy in transport fuel consumption in the years 2004 - 2008 in Poland grew three times faster than the EU28. Since then, the growth of renewable energy in transport in Poland has slowed down, but in EU kept the same trend (compare: Table 8).

It should be noted, that despite the rapid growth, the share of renewable energy in transport fuel consumption in Poland is still low. As it is presented in Figure 9, the share of biofuels in transport in Poland increased slowly from 0.7% in 2004 to 1.2% in 2007. Since 2007 a faster growth has been recorded. In 2011, it hit the level of 6.5%, but fell to 6.0% in 2013. The share of renewable energy in transport fuel consumption in the EU was 5.4%% in 2011 – it grew after a small collapse in 2011. Although in 2004 share of biofuels in transport in the EU was higher than in Poland, in 2008 Poland surpassed the EU average.

In 2011, Poland was one of the five leaders in the use of renewable energy in transport fuels, but lost this position due to rapid growth Austrian indicator. In 2013 Poland took the sixth place after Sweden, Finland, Austria, France and Germany. While the EU average was 5.4 in 2011, in Poland the use of renewable fuels amounted to 6.0%.

The data in Figure 10 shows that in 2011 in 11 EU Member States, the share of biofuels in transport fuel consumption was less than 1%, but in 2013 only Estonia (0.2%), Spain (0.4%) and Portugal (0.7%) had the share of biofuels lower than 1%. The greatest amount of fuels from renewable sources was used in Sweden (16.7%), Finland (9.9%) and Austria (7.5%). Poland took sixth place with 6.0% of biofuels.

Combined heat and power (CHP) in the years 2004 to 2013 grew much more slowly than the share of renewable energy in fuels. As seen in Table 9, the growth was stable in the EU28 as well as in Poland. The growth rate of the CHP system in Poland amounted to 3.5% and 11.4% in EU.

In Poland, the share of CHP in gross electricity production in 2004 was 17% and in 2011 it increased to 17.6%, but fell once again to 15.9% in 2013. In the EU, the share of combined heat was much lower during this period and reached 10.5% in 2004, 11.2% in 2011 and 11.7% in 2013. Interesting changes have occurred in Denmark, which was the leader of cogeneration until 2011. Now, despite the highest share of CHP in gross electricity production in the EU, Denmark recorded a decrease in the production of energy from cogeneration to 42.6% in 2006. In 2011, the share of cogeneration was 49.2%, but in both EU and Poland there was a decrease in use of combined heat. In 2012 Slovakia became the leader in this field with 78.6% and 77.0% of CHP as percentage of gross electricity generation. Specific changes in the reported period is shown in Figure 11.

The share of CHP in gross electricity production in 2013 was highest in Slovakia, which was followed by Denmark, Latvia, Lithuania, Netherlands and Finland (co-generation in these countries amounted to more than 30% of gross electricity production in 2013). Poland took 6th place, just after them with 5.9%. The data presented in Figure 12 proves that the smallest share of cogeneration is recorded by Malta (0%), Cyprus (1.4%) and France (2.4%).

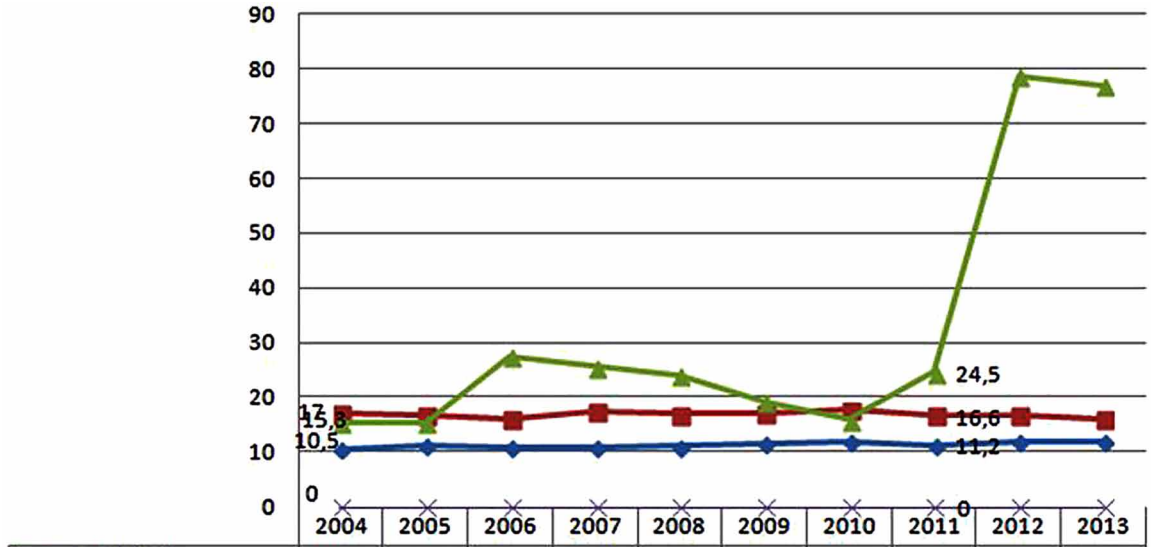
An important aspect of renewable energy in the European Union was hidden energy taxation, which increased in the years 20046- 2013 decreased by more than 10% (see Table 10). In the same period in Poland, taxation was growing steadily and as of 2013 was 22.9% higher than in 2004.



However, despite the increase in the use of hidden taxation of energy in Poland, these taxes are much lower than in the EU as a whole. As can be seen from Figure 13, the highest level of this tax in Poland occurred in 2013 and amounted to 125.82 EUR /TOE. At the same time, the EU average was 212.33 EUR/TOE. The lowest implicit tax among Member States amounted to 92.26 EUR/ OE and the highest 312.6 EUR/TOE.

In 2011, the highest energy taxation was in Denmark (EUR 417.68 / TOE), Italy (363.12 EUR / TOE) and Greece (257.19 (EUR / TOE). On the other hand, the lowest energy tax was in Slovakia 92.36 (EUR / TOE), Latvia (101.55 EUR / TOE) and Lithuania (104.76 EUR / TOE). Data for the EU Member States is shown the Figure 14.

Expenditure incurred on the development of renewable energy sources contribute to decreasing the cost of energy production, mainly through the reduction of environmental pollution and the depletion of natural resources dismissed. Financial expenditure incurred on fixed assets in the field of renewable

energy are part of fixed investment in environmental protection. In Poland in 2004 expenditure on fixed assets in the renewable energy sector valued totally to the sum of 18 million EUR. These expenditures increased in 2010 to the level of 105 million EUR. Despite almost fivefold increase, they accounted for only 3.9% of the total funds allocated to the fixed assets in the protection of the atmosphere and climate. Expenditure on fixed assets in the renewable energy sector was characterized by a lack of stability.

Fixed assets spending in renewable energy sources in rural areas recorded even greater fluctuations recorded (presented in Table 11). Expenditures for the development of renewable energy in rural areas amounted to 4.1million PLN in 2004 (0.8% of expenditures on environmental protection in this period). In 2010 expenditure on fixed assets were much higher and amounted to 88 million PLN. Their share in total expenditure on environmental protection in rural areas increased to 7.6%. Fluctuations in the level of expenditures for the years 2006, 2008 and 2010 were caused by the construction of new wind farms in rural areas in the regions of Middle and Western Pomerania.

General analysis of indicators of sustainable development give a relatively positive picture of Polish activities in this area. The increase in the production of energy (electricity and heat) from renewable energy sources, while reducing the share of solid fuels and natural gas is a positive trend in the structure

Czarski, 2011, p. 126.

of energy production in Poland. Also, the growing share of renewable energy in energy consumption is a sign of positive changes in the Polish energy sector. The share of renewable energy in Poland compared to other EU countries may seem alarmingly low. On the other hand, comparing to other EU countries, Poland has a large energy independence and this is one of the best indicators in Europe. A positive indicator for the sustainable development in Poland is the share of biofuels in transport fuel consumption. Poland is one of the leaders in the EU, and is supposed to keep its place as the indicator is changing positively. An indirect taxation of energy is also an important indicator, which in Poland is relatively low. It can be concluded that the increase in investment in fixed assets in the renewable energy sector stems from the low energy taxation, which translates the satisfaction of investors and increase funds for investments in RES.

FORECASTS FOR THE DEVELOPMENT OF RES INSTALLATIONS IN POLAND

In 2000 in the "Renewable Energy Development Strategy" it stressed that without government support the rapid development of renewable energy in Poland will be difficult, and technological potential of

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

the country will not be used. It was also recommended to support the development of renewable energy sources as soon as possible, so that Polish companies can match to the level of the global renewable energy technologies. (ME, 2000). In the "Polish Sustainable Development Strategy 2025" support environmental activities of enterprises through appropriate financial and fiscal policies was guaranteed. Thanks to this support, any eco-friendly economic activities, including the activities in the field of renewable energy sources, has become more competitive, mainly through the internalization of external costs of environmental protection (Ministry of Environment, Government of Poland (MEn), 2003).

Directive 2009/28 / EC obliges Poland to hold a 15% share of renewables in the energy mix in 2020. Achieving this level of production requires at least a 25% share of RES installations in the energy system, taking into account the technical capabilities of the Polish energy sector. According to Stryjecki (Stryjecki, *2012,* p. 22.). it is possible to achieve, providing that the total installed capacity in the Polish energy system in 2020 reach the level of 41 - 42 GW, producing about 170 - 180 TWh. This means that the total renewable power capacity will amount to approx. 10 to 12 GW, which should result in the production of energy with a capacity of approx. 35 TWh. Stryjecki stresses that to achieve a 15 per cent share of renewable energy in final energy balance by 2020 it is necessary to take into account such factors as:

- The availability of resources for the different renewable energy technologies,
- The amount of planned investments of private investors,
- Financial, organizational, and technological conditions of the implementation of investment projects for different types of renewable energy sources,
- The availability of technology,
- Environmental conditions in individual regions and for different sectors of RES,
- Social determinants of use of renewable energy technologies in different regions.

By February 2015 the Act on Renewable Energy Sources has not been submitted to sign by President of Poland, so one cannot clearly define the government's plans for the development of renewable energy . The only official document providing plans for the development of RES is the National Action Plan for Renewable Energy Sources (NAP), which assumes an increase in the production of energy from renewable sources to 4151 ktoe.

The biggest role in the development of renewable energy sources for heating is granted to biomass- an increase of 790 ktoe to the level of 4636 ktoe in 2020. On the other hand, in the production of sustainable electricity the most important place was granted to wind turbines on land (1132 ktoe in 2020, an increase of 933 ktoe with comparison to 2010) and solar (506 ktoe, an increase of 485 ktoe with comparison 2010). In this area, the NAP also assigns an important role of energy from biomass and biogas, but it is stressed that Poland does not have sufficient resources of raw materials to produce the planned level of energy from these sources. In the long term, the NAP provides for the development of technologies such as offshore wind farms (production expected in 2020 -129 ktoe) and large aquatic plants (151 ktoe in 2020.).

The NAP forecasts an increase in renewable energy production capacity by 73% (3578 ktoe) in the years 2011 - 2020. The increase in heat produced from RES should reach 1824 ktoe (approx. 51% of the total capacity increase of RES), and another 1,753 ktoe should bring the growth of renewable electricity. According to government guidelines in 2020, the largest share in the production of renewable energy should have a solid biomass - 28%, followed by small wind turbines - 20% and solar power - 13%. The NAP marginally treated plate geothermal energy and hydropower, as there is no possibility of their use

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

in the entire country. In addition, the production capacity of energy from these sources doed not significantly affect the balance of renewable energy production. Least attention is also put to forest biomass, which - in accordance with the principles of sustainable use of resources - from 2015 should not be a source of renewable energy (ME, 2010).

The prospect of the development of renewable energy sources in Poland by 2020 varies according to the type of RES and environmental conditions of the province. NAP puts greatest hopes on the development of wind energy in Western Pomerania, Pomerania, Podlasie, Kuyavian - Pomeranian and Wielkopolska. In addition, the rapid development of small wind energy should take place in eight other provinces. At the same time, despite the development of small wind power, NAP assumes that share of renewable energy in 2020 shall not exceed 1%. NAP predicts that solar energy will grow only in Wielkopolska, Mazovia, Silesia and Malopolska. In contrast, no significant development of photovoltaic is assumed, and this is because this source has a minimal impact on the balance of renewable energy.

The NAP predicts an increase in the production of energy from agricultural biogas to 384 ktoe, especially in the Warmia - Mazury, Podlasie, Kuyavian - Pomeranian, Wielkopolska and Lubuskie. Biomass from energy crops will grow best in Mazowieckie, Lublin and Subcarpathian and the straw will serve as a fuel in Pomorskie, Kujawsko - Pomeranian, Wielkopolska, Lublin and Opole (ME, 2010). When it comes to hydropower, the NAP assumes that the participation of all the technologies used in the production of hydropower will accumulate water energy to a maximum of 9% of the total production of energy from renewable sources. Geothermal energy may play a significant role in all provinces, but its development is dependent on the support provided to households and small businesses. The deep geothermal energy will be relevant only in Western Pomerania, Wielkopolska and Lodz. Hydropower based on river tides will develop slowly, and its share in the production of energy in all provinces would be negligible.

SUMMARY

Despite significant promotion and huge investment in renewable energy, its share in the Polish energy production is much lower than the EU average. In the EU in 2011 renewable energy accounted for 20.1% of total energy produced, which is twice the level of renewable energy produced in Poland. However, all indicators point to the fact that the Polish renewable energy is growing at a rapid pace, which is likely to lead to a significant increase in the number of power plants and micro-installations of RES. Thus, to increase the amount of renewable energy produced in the country. If the rate of development of the renewable energy sector is preserved, it is very likely that Poland will fulfill the objectives of the climate package - energy targets for 2020. However, to maintain such a high growth rate of renewable power capacity, tools should be maintained to support their development. Legal decisions ensure that funds supporting the development of renewable energy sources have already been allocated to be used for subsequent years. Although not all programs have a time frame up to 2020, it is known that at least until 2017, cash flows directed to investors in the modernization and construction of renewable energy sources will be not reduced. It is expected that they will lead to an equally rapid increase in production of renewable energy, as the one that had been in Poland by 2011. However, one should keep in mind, that not only financial aid is important, but also the legal conditions. In the uncertain legal situation, with changes often introduced and the lack of a final decision about the shape of the Law on renewable

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

energy sources, private investors feel insecure and give up their investments. Therefore, it is important that the Polish government refined and implemented a law regulating the activities and forms of support for renewable energy power plants in a relatively short period of time. The combination of a stable legal environment and the availability of external forms of co-investments in RES should lead positive changes in the Polish renewable energy sector.

ABSTRACT

This chapter gives the overview of social sustainability in the supply chain of manufacturing industry. The author through literature survey identifies various definitions to social sustainability and suggest the approach to social sustainability problem in the supply chain. The readers are exposed with different social sustainability problems and what are the enablers and barriers to address such problem. In addition, the author identifies various social dimensions related to manufacturing supply chain and suggest as to how it can be addressed by various practices. Finally, the author identifies the research gaps in developing countries such as India, and suggests directions for future research. This is a vital contribution to the development of theory related to social sustainability in manufacturing Industries.

1. INTRODUCTION

The importance of sustainability in manufacturing has been talked over many decades. Formerly, the corporations were focusing predominately on fast paced production and innovative technologies. Now the focus has changed to sustainable manufacturing, because of increased awareness on limited resources, coupled with strict regulations, and corporate voluntary actions to meet the stakeholder's requirements.

Sustainability is defined as "the development that meets the needs of today without compromising the ability to serve the future generations" WCED (1987) cited by Watkinson (2009). Due to climatic change and global warming, sustainability though it encompassed three dimensions such as environment, economic, and social, much emphasis was given on environmental dimension for over a decade. However, increasing stakeholder's awareness on safety, health, equity issues, and living conditions put back the focus on socially sustainable manufacturing and business practices. As more companies commit to sustainability and CSR policies, there is increasing pressure to consider social impacts throughout the supply chain. United Nations Human development Index (HDI) measures the countries based on income disparity, education and mortality, and the countries are ranked accordingly. This acts as a motivating factor for these countries to improve upon social sustainability activities. Majority of the developing countries were rated poorly because of social issues.

There were measures such as Sarbanes-Oxley act, Dow Jone's economic index (1896) and financial reporting making mandatory requirements for the corporations to be economically sustainable. Similary, there has been tremendous research done on environmental aspects of sustainability in the supply chain. However, very little has been done in terms of social sustainability in the supply chain because of very complex human issues involved in it. On the other hand, the research to study the inter relationship among the economic, environment, and society are integral to the concept of sustainability. It is very essential to characterize their interactions to understand overall impact on future generations. Although, social sustainability was included and considered as an integral part of sustainability, the role played by social is rarely equal to the economic and environmental concerns. The Global Reporting Initiative (GRI, established in 1997) has reported that social performance occurs infrequently and inconsistently across organizations. This was again described by the recent major study by Western Australian Council of Social Services (WACOSS), who noted that, "while there has been tremendous work done relate to environment and economic aspects, the social has tended to fall off the sustainability agenda.

Further, social sustainability studies were so far, discussed and emphasized on legislative, health and safety rather on comprehensive way of focusing all the relevant issues. Especially, in manufacturing supply chain, studies on social issues are bit scant. In manufacturing, the sustainability is measured based on the entire value chain of the corporate. When it comes to sustainability in the supply chain, the supply chain comprises of many individual companies. The sustainability of the chain is depending on many standalone companies who are part of the corporate value chain. The impact of sustainability is not only restricted to the manufacturing companies but also its suppliers (Ashby et al., 2012). More recently many manufacturing companies develop their supplier capabilities in developing countries for low cost advantage. Invariably, the actions and behavior of these suppliers to the societies where they operate from, impacts the global companies in their own locations. We can notice these incidents, for example the recent development of unethical standards followed by Chinese manufacturing companies, the usage of melamine tainted milk and lead-tainted toys and toxic tooth paste, defective tires and fake medicines led to 24 million customer settlements by menu foods and many companies in China (Tybout & Roehm, 2009). These acts not only tarnished the image of the buyer, it also impacted on their financial performance. Yet another example of unethical actions such as "expired meat" supplied by one of the Mc Donald's largest meat supplier damaged the image of the company. This was resulted in suspension of burger products in China and US (CBS News, 2014). There were several other incidents of social issues related to supply chain. More recently, Wal-Mart's most preferred "shrimp" was procured from Thailand based supplier, whose facilities lack the basic living conditions, health and hygiene, and poor wages, etc. This was highlighted by many social organizations.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Especially, in developing countries, the issues related to social sustainability, still needs to be addressed. The recent noble price winner Khailash Satyarthi and his social efforts recovered and rehabilitated many child and bonded labourers from manufacturing set up in India. Further, TATA, a leading corporate brand was questioned by the World Bank, for the employee living conditions in their plantations. These are many social sustainability issues faced by the employees in the supply chain of manufacturing industries (World Bank report, 2014). Most of the developing countries are still plagued with child labor, gender inequality, and poverty, health problems because of lack of awareness on social sustainability measures.

To understand the importance of social issues better, a practitioner from leading corporate house says […] "In operations, people factor involve 85% of work and decisions, and the involvement of machines and automation is only 15%" […] It means, the people play a vital role in the operations. This reinforces the need for the study, which would focus on social aspects in the supply chain which can lead to sustainability of the manufacturing.

In this chapter therefore, we attempt to bring together the available literature on social sustainability, emphasizing more on manufacturing. What enables the social sustainability? And the various impediments to social sustainability adoption were explored. In addition, the relevant social issues and how these issues should be approached and addressed were examined. So that social sustainability becomes reality in manufacturing.

2. SOCIAL SUSTAINABILITY

Many of the scholars referring to 'social sustainability' draw mainly upon the definition of sustainable development provided by the Brundtland Commision Report, *Our Common Future*: "Development that meets the needs of the present without compromising the ability of meeting future generation needs" (Bruntland, 1987). This definition appeals enormously because it holds the possibility of reconciling people needs with bio-physical environmental management goals through economic development. It captures the essence of a much larger construct that attempts to address both tangible and less tangible necessities for life which, in turn, was seen to depend on reviving growth; meeting essential needs for jobs, changing the quality of growth, food, energy, water and sanitation; conserving and enhancing the resource base; ensuring a sustainable level of population; reorienting technology and managing risk; merging the environment and economics in decision-making.

The Bruntland Commission report on sustainability much emphasized in terms of management of natural resources, but not in terms of society, people and culture (Chatterjee & Finger, 1994). Later research, advocated three important aspects of sustainability: environment, long-time focus on environment and equity (Pearce et al., 1989). Similar study conducted by a few researchers argued that sustainable development also 'embraces the need for equity' (Elkin et al., 1991). In urban planning circles sometimes sustainability means three E's: Environment, economy, and equity without much thought of whether equity alone can lead to social sustainability or not.

Many authors have also concurred with the view that for the enterprise to be sustainable, it needs to internalize social costs, grow and maintain capital stocks, foster democracy and enlarge peoples' choices and distribute property rights fairly (Gladwin et al., 1995). The United Nations Conference on Sustainable Development (UNCSD, 1998) has specified in Section 1 of Agenda 21(Economic Dimensions), promotion of economic growth; in Section 2(Social Dimensions),creation of productive employment and achieving equality; in Section3(Environmental Dimensions), reduction in use of natural resources

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

and protection of the natural environment. United Nations conference on sustainable development set an agenda for social development. It also discussed about the inter relationship between environment and social requirements. Many researchers have even proved that if the basic human needs are not addressed, it will be very difficult to address the environment sustainability goals because, in developing economies people tend to spoil the natural resources for their own personal benefits. Later, many scholars did extensive research on social sustainability; notably, Sachs (1999) and Godschalk (2004), through their research titled "Social Sustainability and Whole Development" identified a number of essential elements including equitable income and access to goods, social homogeneity and services and employment. Sachs (1999) also pointed out the importance of 'cultural sustainability' which required balancing externally imposed change with continuity and development from within, and of 'political sustainability' based on human rights, democracy and effective institutional control.

Magis and Shinn (Cited in Dillard, 2008) review the literature and found the four emergent principles of social sustainability: human well-being, equality, democratic government, democratic society. Further they argue that these four principles create self-reinforcing virtuous cycle that facilitates progress towards even environmental sustainability.

Bansal (2005) described social equity as an important component of social sustainability and asserted that all members of society had equal access to resources and opportunities. In organisations, social equity term was extended to give the meaning of "fair and equitable treatment of employees" (Krause et al., 2009).

Later, Bramley and Power (2009) asserted that social sustainability was often equated with social cohesion, social capital and social inclusion. This also underlines the importance of focusing on higher needs such as access to necessary goods and services, and basic societal development. Further, research on social sustainability have emphasised providing intra and inter-generational equity and distribution of power, employment, resources, education, freedom, provision of basic infrastructure and services, justice, and access to influential decision-making fora (Bramley & Power, 2009; Mitlin & Satterthwaite, 1996; Källström & Ljung, 2005; Redclift, 2005).

More recently, Vallance (2011) in his research titled "What is Social Sustainability" described a three-fold literature schema comprising: (1) development sustainability addressing basic needs and creation of social capital, (2) bridge sustainability concerning behavioural changes to achieve bio and physical environmental goals, and (3) maintenance sustainability, which refers to social and cultural characteristics such as ways in which people actively resist or embrace change. On the basis of the studies mentioned above and their outcomes, it is clear that social sustainability is all about social issues and the ways in which they can be addressed which may lead to long term well being of the people in the societies. In the next section, an attempt is made to identify various definitions of social sustainability.

2.1 Defining Social Sustainability

In this section, we examine the issues involved in defining social sustainability for the purpose of creating common research agenda for society and organization usage. A working definition of social sustainability is provided below. However, it was much problematic in this task of arriving at single useful definition and instead, this section suggests various useful approaches that could be adopted. As we aware that social sustainability is related much with the people and human of the particular society. Though, the social sustainability can be an universal bigger agenda, it may bound to differ in terms of "where" and "what" because of different social issues that evolve over a period in societies. These issues are highly

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

contextual. For examples, the social issues between western countries and other developing nations vary. Further to elaborate, the issues such as juvenile arrests, living wages, and recreations are not relevant in developing nations. In developing countries issues like poverty, health, safety and sanitation, hygiene and bonded and child labour becomes highly relevant. Though, all the issues irrespective of the society looks relevant under bigger umbrella, the time and priority of the issues makes it more contextual in nature.

Generally, there has been a strong focus on defining sustainability as a condition, and measuring it with a series of indicators. Social sustainability is known to be life enhancement feature within communities, and has the process that can achieve life enhancement feature. The following features are possible indicators to social sustainability:- equity in accessing the key services including health, education, transport, housing and recreation, and equity between generations: meaning that future generations should not be disadvantaged by the activities of current generations. Further, we will elaborate in detail about social dimensions and indicators under "social dimensions section". Many scholars through various researches have defined social sustainability.

To name a few, Lafferty and Langhelle (1999), Sharma and Ruud (2003) defined "social sustainability as a human code of conduct which needs to be achieved in an equitable, inclusive and prudent manner".

"Development that improves the quality of human life while living within the carrying capacity of supporting ecosystems" (WWF, UNEP, IUCN, 1991).

"The preservation of the planet and its ecosystems, society and its communities, for finest, equitable environmental and human health and wellbeing" (Hill, 1998).

Social Responsibility is defined as ''the continuing obligation by business to behave ethically and contribute to economic development while improving the quality of life of the workforce and their families, local community and society at large (WBCSD, 2000).

Polése and Stren (1999) define the social sustainability of a city as: 'Development and/or growth that is compatible with the harmonious evolution of civil society, fostering an environment conducive to the compatible cohabitation of culturally and socially diverse groups while at the same time encouraging social integration, with improvements in the quality of life for all segments of the population."

Western Australian Council of Social Services (WACOSS, 2000)

Social sustainability occurs when the formal and informal processes, systems, structures and relationships actively support the capacity of current and future generations to create healthy and liveable communities. Socially sustainable communities are equitable, diverse, connected and democratic and provide a good quality of life.

Robert Putnam (2001) describes "social capital" is an important aspect of social sustainability, just as environmentalists describe "natural capital" to environmental sustainability, and amenities.

According to Dillard et al. (2008) a working definition of social sustainability developed through seminars and workshops over a period: that social sustainability should be understood as

1. The process that generates social health and well being now and in the future and
2. Those social institutions that facilitate economic and environmental sustainability now and for future

A most appropriate definition is provided by Harris and Goodman (2001): A socially sustainable system must achieve fairness in distribution and opportunity and adequate provision of social services including health, education and gender equity and political accountability and participation

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Wackernagel (2001) pointed out the importance of social sustainability by saying: "human health aspects are essential for the well-being of a society, but they should not be confused with environmental sustainability"

Sustainability is essentially an anthropocentric concept of inter- and intra-generational justice (Grunwald 2001),

Littig and Griessler (2005) defined as "claiming the right to a dignified life to humans" The Organization for Economic Cooperation and Development (OECD) views social sustainability in two diverse dimensions: human and social. The human dimension refers to man's skills, abilities knowledge and talents, which determines an individual's performance in the labor market and is also relevant to the process of economic growth (OECD Insights, 2008) cited in Tracey & Anne (2008). Social capital facilitates collective actions that are beneficial to the society (Hobbs, 2000; Milward, 2003).

With the extensive review of literature and understanding, social sustainability was defined and touched upon various social issues that falls under the ambit of "humanness". Hence, for the purpose of understanding, a working definition can be written:

"Social sustainability is all about addressing social issues of the people of today in the societies that can create a sustainable future for future generations"

Since this study focuses on supply chain related social issues, we further limit ourselves to various social aspects that are specifically related to supply chain that are discussed in the next section.

3. SOCIAL SUSTAINABILITY IN THE SUPPLY CHAIN

Social sustainability in the supply chain of manufacturing industry is of paramount importance because of increased stake holders awareness on not only "where" the product is made but also "how" and "at what" conditions the products are produced. Though, this creates somewhat undesirable situations for the corporate, due to involvement of cost, the benefits of human capital and its importance for strategic advantage of the corporations was well researched and explored. Hence, the corporate in the modern times, understand social issues and attempt to find the different ways of integrating the human and social aspects into the supply chain. Therefore, social sustainability in the supply chain talks about how people can be protected from the products and processes that affects the human being safety, health and well being. Before we define social sustainability in the supply chain, we need to understand "Who", "What" and "How", it means who are the people being targeted? What issues should be addressed? And how should we address these issues? (Wood, 1991).

The answer to the first question: stakeholder theory that addresses all the stakeholders in the supply chain including suppliers, employees, society, NGO's, and customers (Freeman, 1984, 2004; Stieb, 2009; Campbell, 2007). Yet another research described the similar view: social responsibility was seen as an organization's ability to manage stakeholders (Waddock & Bodwell, 2004; Clarkson, 1995). Further, resource based view supports that human resources, which can't be easily imitated or copied by the competitors, gives the company a strategic advantage in the market (Barney, 1981). Second, many scholars have identified various issues related to people in the manufacturing supply chain. For instance, human rights and labour working conditions were identified by Emmelhainz and Adams (1999). The study in US emphasised on health and safety, diversity, philanthropy, human rights and ethics in the supply chain (Carter & Jennings (2002a, 2002b, 2004). This research also proved that ethics can't be used as social sustainability dimension in the supply chain.

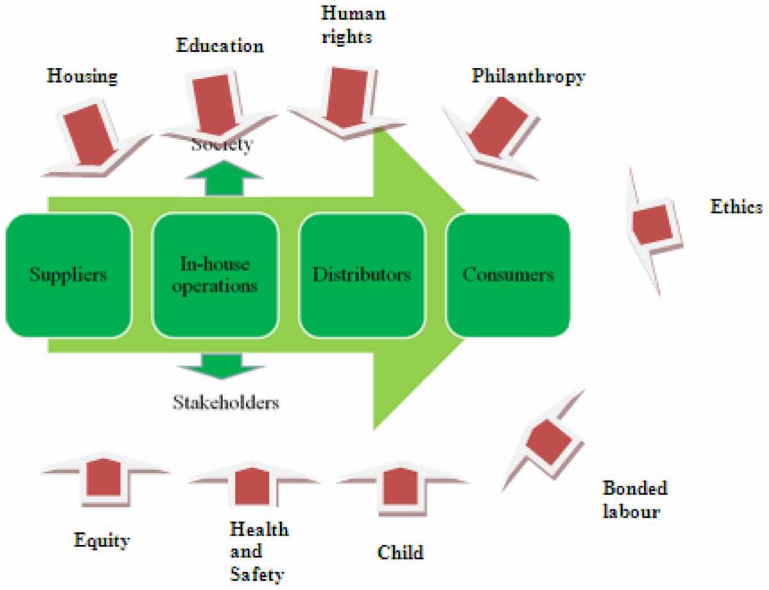
EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Dyllick and Hockerts (2002) provided one representative definition of corporate sustainability: "meeting the needs of a firm's direct and indirect stakeholders (such as shareholders, employees, clients, pressure groups, communities, etc.), without compromising its ability to meet the needs of future stakeholders as well". Further, they emphasised the importance of human capital and societal capital in social sustainability of the corporations. Similar research by many scholars insisted on various human issues such as safety, health, diversity, working conditions, child and bonded labor, and poverty in the supply chain (Whooley, 2004; Carter, 2005; Maloni & Brown, 2006; Kortelainen, 2008; Vachon & Mao, 2008; Andersen & Skjoett-Larsen, 2009). Further, some scholars have identified criteria of fair and equitable treatment, human rights, child and forced labour, training, employment and wages as issues in the supply chain (Pagell & Wu, 2009). There was another research that linked social issues of supply chain and country's economic performance through life cycle analysis (Hutchins & Sutherland, 2008).

Labuschagne et al. (2005) revealed practices related to poverty alleviation, administering justice, human rights, and welfare of all employees in the supply chain. Leire and Mont (2010) explained social issues such as reduction of unemployment, protecting employee health and safety, ensuring equal treatment and preventing social exclusion and how these dimensions were linked and incorporated in the supply chain

Finally, many authors described through various studies, in which how social issues can be addressed in the supply chain. One way to address is, incorporating these parameters in corporate's buying process known as socially responsible buying (SRB). Socially responsible buying (SRB) refers to the incorporation of social issues in purchase decisions advocated by organizational stakeholders (McWilliams & Siegel, 2001).

Further, Carter and Jennings(2002a, 2002b, 2004), Ciliberti et al. (2008) described the role of purchasing managers in the area of social responsibility within the supply chain and how the enactment of these roles could lead to improved trust and supplier commitment through purchasing social responsibility (PSR) and logistics social responsibility (LSR). Later research by Leire and Mont (2010) indicated how social criteria could be used to monitor suppliers and ensure their compliance. Bai and Sarkis (2010), Mani et al. (2014) have demonstrated usage of social parameters, in supplier selection. It means, incorporating social parameters in evaluation and selection of suppliers. Goworek (2011) in his research emphasized on socially responsible and environmentally sustainable sourcing practices and how it could be applied to clothing industries. Socially responsible supplier development (SRSD) and its importance in measuring the buyer's sustainability, and the relationship between social sustainability and supplier development efforts were established in China (see figure 1) (Lu et al., 2012).



With above analysis, we possibly can form the working definition of social sustainability in the supply chain as "how the corporate manage and addresses the various social issues such as equity, health, safety, wages, working conditions, philanthropy and labour rights across the supply chain that will help the corporate to maintain, and sustain the human resources that in turn leads to long time survival of the corporation"

4. ANTECEDENTS AND IMPEDIMENTS TO SOCIAL SUSTAINABILITY

Another aspect of social sustainability in the supply chain deals with what enables social sustainability adoption. Many renowned scholars have identified ways and means of integrating social parameters into the supply chain. For example, one researcher asserted that socially responsible organizational buying fully depended on two factors: first, the skillful policy entrepreneurs who institute new policies

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Supply chain stages in manufacturing and relevant social issues
Source: Mani et al. (2015a)

with zeal for social wellness in their policy decisions, and second, the organizational context in which decisions are made (Drumwright, 1994). There have been many other studies focusing on how social sustainability can be achieved if corporates enact their roles responsibly. Drumwright (1994), Clarkson (1995), Strong (1997), McWilliams (2001), Campbell (2007) along with Ehrgott et al. (2011) argue that various parameters such as customer requirements, stakeholder requirements, employee requirements, skilled policy entrepreneurs, economic status of corporates, and public and private regulation influence social sustainability adoption (Table 1). Mani et al (2015b) have established many new enablers for social sustainability adoption in emerging economies, which include awareness on social sustainability, social organisations pressure, pressure from employee union, investor's pressure, and financial status of the company.

There are many enablers and barriers which can lead to social sustainability adoption in the manufacturing supply chain and these are explained in the preceding section with the help of table 1.

4.1 Antecedents to Social Sustainability

a) Awareness of Social Sustainability

Awareness of social activities can act as a key parameter to accelerate social sustainability (Haugh & Talwar, 2010; Maloutas, 2003). If the manufacturing companies are aware of the social sustainability parameters and their relevance to social capital development, this may help in adoption of social sustainability in the supply chain.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Antecedents to social sustainability adoption in the supply chain

S. NO	Antecedents	References
1	People oriented organisation culture	Carter and Jennings(2000, 2002)
2	Top Management leadership or skillful policy entrepreneur	Drumwright (1994),Carter and Jennings(2000, 2002), Ehrgott(2011), Mani et al. (2015b)
3	Government regulation	Carter and Jennings(2000, 2002), Aguilera et al. (2007), Campbell (2007), Ehrgott(2011)Mani et al. (2015b)
4	Customer pressures	Carter and Jennings(2000, 2002), Ehrgott(2011), Mani et al. (2015b)
5	Individual values	Carter and Jennings(2000, 2002)
6	Pressure from employee union	Aguilera et al. (2007), Campbell (2007), Mani et al. (2015b)
7	Direct incentives	Mani et al. (2015b)
8	Awareness on social sustainability	Mani et al. (2015b)
9	Stakeholders pressure	Aguilera et al. (2007), Campbell (2007), Mani et al. (2015b)
10	Competitive pressures	Campbell (2007), Mani et al. (2015b)
11	Social concerns	Mani et al. (2015b)
12	International certifications	Mani et al. (2015b)
13	Shareholders pressure	Mani et al. (2015b)
14	Ability to spend(Financial status)	Campbell (2007), Mani et al. (2015b)
15	Social organisations pressure	Campbell (2007),Mani et al. (2015b)

b) Competitive Pressure

In modern economy, the companies are always very much conscious about the competitor's actions that may potentially strengthens the corporate capabilities. The social measures adopted by competitors may force the other corporations to adopt similar measures for sustainability (Lamming & Hampson, 1996; Sarkis, 2003; Zhu & Sarkis, 2006; Carter *et al*., 2000; Rao & Holt, 2005). For example, corporations with inimitable resources and capabilities by the competitors, are necessary for gaining sustainable advantage. Further, Rao and Holt (2005) have established relationship between sustainable measures and competitive advantages.

c) People Oriented Organizational Culture

Organization culture can be defined as set of values, believes, assumptions, and ways of thinking and shared by organizations members, and taught to the new members of the organization (Barney, 1986; Chapman & Jehn, 1994; Weiner, 1988). This means that organizational culture influence the work behavior. Similar research has established, relationship between culture and organizations success. Further it was used by Carter and Jennings and proved that it helps in social sustainability adoption (Carter & Jennings, 2000).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

d) Customer Requirements

In manufacturing, many of the companies are expected to comply with customer requirements because of dependence and the economic relationship between these organizations. Many studies have proved that these requirements and their necessity in developing socially sustainable suppliers and their impact on buyers image and financial performance (Christmann, 2004; Drumwright, 1994; Sen & Bhattacharya, 2001; Wilkes, 2008; Lu & Lee, 2012; Carter & Dresner, 2001; Klassen & Vachon, 2003; Sarkis, 2003; Zhu & Sarkis, 2006).

e) Direct Incentives

Government direct and indirect initiatives in the form of tax benefits and other subsidies may drive the social sustainability (Cerin & Karlson, 2002; Hilson & Nayee, 2002; Ostrom & Wynne, 1993). For examples extending property rights acted as incentives for corporations to practice sustainable measures (Cerin & Karlson, 2002). Governments other incentives such as permitting individual harvest, territorial rights, and price ecosystem services, coupled with public research and monitoring promote sustainability in fishing industry (Campbell, 2007).

f) Corporations Financial Ability

The company's economic health and the level of competition determine the probability of adopting socially responsive behaviors. Further, small companies first tend to focus on economic sustainability and as they move on in the ladder, they extend their focus on social sustainable measures (Campbell, 2007; AlKhidir & Zailani, 2009; Luthra *et al*., 2011).

g) International Certifications

Many international certifications that include 26000, ILO, OHSAS 18001, AA 1000, ISEA 1999 for social standards exerts pressure on the corporations for social compliance. This will in turn impact on corporate image and operational performance (Viscusi, 1979; Handfield et al., 2002; Gonzalez & Sarkis, 2008; Zuckerman, 2000). Some voluntary certifications and labeling have helped in achieving social sustainability in coffee industry (Reynolds *et al*., 2007).

h) Investors Pressure

Shareholders and investor's actions influence the adoption of social sustainability measures in the organization (Tagesson *et al*., 2009; Buchholz & Rosenthal, 2005; Laplume *et al*., 2008). The investors positive role in bringing sustainability reporting was identified by many case studies (Tagesson *et al*., 2009).

i) Easy to Implement Without Resistance

Top executives 'resistance to change' attitude acts as barriers to social sustainability adoption. On the contrary, attitude to accept the change may speed up social responsiveness in the organizations (Shrivastava, 1995).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

j) Pressure From Employee Unions

Employee unions, in the bigger organizations act as catalyst in negotiation and demanding for social sustainability measures. With bargaining power, these unions exerts pressures on the top management to address social issues and adopt corrective measures on top priority. (Sen & bhattacharya, 2001; Hansson et al., 2003; Nortan, 2014).

k) Regulatory Compliance (Government Regulation)

Regulatory authorities or Government regulations as part of external stakeholder group certify the corporations to streamline and regulate for social measures. Government –protector of the society bring in many policies to regulate and orient the companies in their socially responsive activities(Green et al., 1996; Gonzalez & Sarkis (2008); Beamon, 1999; Raynolds et al., 2007) .Further, There is a positive relationship between government regulation and social sustainability adoption in corporations(Carter & Jennings, 2000; Ehrgott et al., 2011) .

l) Skillful Policy Entrepreneur

The top executive's role in adopting social sustainability was established by many researchers. Drumwright (1994) in his research advocated the policy entrepreneur who invests to institute his policies can drive the social sustainability (Banerjee *et al*., 2003; Buckholz, 1991). Yet In another research, Carter *et al*. (2007) mapped the social network within an organization to demonstrate how a low level manager effectively championed and drove a safety related supplier management project.

m) Social Concern

The organization's social concern can have a positive role in social sustainability adoption. Many organizations, through several reporting standards display their social concern (Laufer, 2003; Walker & Preuss, 2008).

n) Social Organizations Pressure

Social groups encourage corporations to implement social sustainability practices. Walker and Preuss (2008) identified the importance of social groups for corporate performance. For example, non-governmental organizations (NGO's) that works on child and bonded labor, living conditions, gender equity, health and hygiene. In India, a few of these popular social organizations are Samhita, Ruchika, Sulabh International, Sambhav, and the Parikrma foundation.

o) Stakeholder's Pressure (Others)

Other than internal stakeholders, the external stakeholders, i.e., Media influence the organizations in social sustainability adoption (Jones, 1995; Post et al., 2002; Maignan, 2002; Sharma & Vredenburg, 1998; Sarkis et al., 2010). A research conducted by Jones (2005) on the 18 top corporations showed how

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

companies practiced social sustainability measures due to stakeholders pressure to feature their ratings in Dow Jones Sustainability Index(DJSI)

4.2 Impediments to Social Sustainability

Many scholars while discussing the barriers in the supply chain of manufacturing Industries identified various aspects leads non-adoption and act as bottle neck for the social sustainability. For instance, Bebbington and Dillard (2008) described that there are four factors contribute relative neglect of social sustainability by the organizations. First, the corporate's economic aims, commonly known as increasing the wealth of the shareholders. Second, the issues related to social sustainability has its modern origin in environmental sustainability issues. Thus social sustainability sometimes seen as related to developing world issues, such as access to water, education and health care etc. The third aspect of social sustainability is the social issues are often seen to be the responsibility of the state or society. Four, social sustainability appears to bring in severe challenges in understanding and communication than the other forms of sustainability. Further, research on social sustainability established many other barriers as described in Table 2.

a) Lack of Awareness

Lack of awareness of social sustainability measures may hinder sustainable development in the supply chain. On the other hand, awareness of relevant social activities can accelerate social sustainability (Haugh & Talwar, 2010). Maloutas (2003) emphasises the need for creating awareness of social sustainability as the lack of cognizance in adopting social measures is impeding the movement in the direction of social sustainability.

Table 2.

S. No	Impediments	References
1	Lack of awareness	Haugh & Talwar (2010), Maloutas (2003)
2	Lack of competitive pressure	Lamming and Hampson, (1996), Carter *et al.,* (2000), Rao and Holt, (2005), Campbell(2007), Rao and Holt (2005)
3	Lack of customers' requirements	Ehrgott *et al.* (2010), Christmann (2004), Drumwright (1994), Sen and Bhattacharya (2001), Wilkes(2008), Carter and Dresner (2001), Klassen and Vachon, (2003), Sarkis(2003), Zhu and Sarkis (2006).
4	Lack of investor pressure	Tagesson *et al.(*2009)
5	Lack of pressure from employee unions	Bhattacharya et al.(2012), Hansson *et al.(*2003), Haugh and Talwar (2010) Campbell (2007), Aguilera et al. (2007)
6	Lack of pressure from regulatory authorities (Government regulation	Campbell (2007), Green *et al.* (1996), Gonzalez *et al.* (2008), Beamon(1999), Raynolds *et al (*2007).
7	Lack of interest from skillful policy entrepreneur	Banerjee, 2003; Buckholz, 1991). Ehrgott *et al.* (2010)
8	Lack of social concern	Laufer (2003) Walker and Preuss *(*2008)
9	Lack of pressure from social organizations	Walker and Preuss (2008) Campbell (2007), Bartley (2003)
10	Lack of stakeholder's pressure	Jones (1995), Post *et al.,(*2002), Maignan and Ralston (2002), Sharma and Vredenburg (1998), Laplume *et al.(*2008)

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

b) Lack of Competitive Pressure

A moderate level of competition among the corporations tends to encourage them to behave in socially responsible ways. On the other hand, high or low competitions tend to make them socially less responsible (Campbell, 2007). As some organisations utilize their socially sustainable image for overall strategic advantage, other organisations are compelled to adopt socially sustainable practices. In a global environment, competitive pressure plays a vital role in the supply chain. In social sustainability, the companies will have the resources and capabilities which cannot be easily imitated by their competitors who, therefore, will be forced to own and maintain such resources of their own, helping the cause of long-term sustainability (Lamming & Hampson, 1996; Carter *et al.,* 2000; Rao & Holt, 2005). Rao and Holt (2005) identify the linkages between sustainability measures and competitive advantage and also establish the relationship between sustainability and financial performance of a firm.

c) Lack of Customer Requirements

The customers or consumers can exert a strong pressure on the firms to adopt social sustainability measures through CSR if their requirements necessitate such measures (Aguilera *et al.,* 2007). In fact, the customers' requirements with regard to social dimensions may go a long way in achieving social sustainability. These demands not only mandate the suppliers to adopt sustainable practices in the short-term but also guarantee long-term sustainability in the supply chain. The growing requirement of the development of a socially responsible supplier base and its impact on the company image and financial operations has been affirmed by several researchers (Ehrgott *et al.,* 2010; Christmann, 2004; Drumwright, 1994; Sen & Bhattacharya, 2001; Wilkes, 2008; Carter & Dresner, 2001; Klassen & Vachon, 2003; Sarkis, 2003; Zhu & Sarkis, 2006).

d) Lack of Investor Pressure

The role of investor pressure in social sustainability reporting has been brought out by many case studies. As shown by these studies, privately owned companies do not disclose as much social information as the state owned organisations (Tagesson *et al.,* 2009).

e) Lack of Pressure From Employee Unions

Employee unions are the members of the internal stakeholder group, involved in pursuing the corporates to behave in a socially responsible way through negotiations and dialogue (Campbell, 2007). Aguilera *et al.* (2007) affirm that employee unions have an important role in compelling the corporates to be more socially sustainable. They play a role of catalyst in successfully bargaining for social measures (Bhattacharya et al., 2012; Hansson *et al,* 2003; Haugh & Talwar, 2010).

f) Lack of Pressure From Regulatory Authorities (Government Regulation)

Government regulations through law enactment and law enforcement can bring in social change in the corporations (Aguilera *et al.,* 2007). The government, as part of the external stakeholder group in the developing countries, monitors the corporations in their social sustainability measures (Campbell, 2007;

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Green *et al.,* 1996; Gonzalez *et al.,* 2008; Beamon, 1999; Raynolds *et al.,* 2007). There is a positive relationship between government pressure and implementation of social sustainability measures (Ehrgott *et al.,* 2010).

g) Lack of Interest of Skillful Policy Entrepreneurs

As Drumwright (1994) affirms, socially responsible buying happens because of two key understandings: skillful policy entrepreneur who uses his resources to institute policies; and the organisational setting in which these policies operate (Banerjee, 2003; Buckholz, 1991). Ehrgott *et al.* (2010), in their research, mapped the social network within an organisation to show how a handler at the lower ranks effectively championed and drove to a safety related supplier management project.

h) Lack of Social Concern

Organisations' social concern can have a positive impact on the social sustainability measures (Laufer, 2003; Walker & Preuss, 2008). Organisations increasingly display their social measures through many reporting standards carried out to show the corporate's social concern to the stakeholders and shareholders of the organisation. Lack of social concern may hinder social sustainability in the corporations.

i) Lack of Pressure From Social Organisations

The NGOs and other social organisations that monitor the corporations for socially responsible behaviour may tend to increase social sustainability (Campbell, 2007; Bartley, 2003). Moreover, socially responsible corporate behaviour tends to overlap with the extent to which the firms belonging to the industrial and corporate systems are amenable to dialogue. The NGOs, through boycotts, campaigns and multi-party dialogues, can influence the corporates to adopt socially responsible practices (Aguilera *et al.,* 2007). Walker and Preuss (2008), in their research on sustainability, emphasise the importance of the social groups' pressure on corporate performance. In fact, the presence of active social groups warrants the adoption of social sustainability practices by the corporates.

j) Lack of Stakeholder Pressure

Internal stakeholders through their direct strategic decisions, and external stakeholders exercising their collective voice, can influence the acceptance of socially sustainable practices in the corporations (Aguilera *et al.,* 2007). On the other hand, the media stakeholders can also influence the organisations in their adoption of social sustainability criteria (Jones, 1995; Post *et al.,* 2002; Maignan & Ralston, 2002; Sharma & Vredenburg, 1998; Laplume *et al.,* 2008). An inquiry conducted by Jones (2005) in 18 top corporations revealed how companies were adopting social sustainability measures pushed primarily by the stakeholder pressure, in addition to their ratings in DJSI to be specifically recognised for their name and report.

5. SOCIAL SUSTAINABILITY DIMENSIONS

One of the fundamental questions that must be answered if we are to move forward with social sustainability in manufacturing: What are social sustainability dimensions? How do we measure these aspects in the supply chain? A consensus has not been reached on the measurements of social sustainability because it is highly contextual in nature. Further, sustainability indicators were largely developed by consultancy firms (such as Elkington's own company) who extend services to large companies by helping them to arrive at indicator system for their corporate sustainable reporting. Social sustainability is very difficult to quantify than economic and environmental impact and it is the most neglected part of triple bottom line reporting. All the social sustainability indicators are too general to be useful and specific indicators needs to be developed for particular state and industry, further down to company level. This means that the usefulness of these indicators to academic discourse in particular context of social sustainability is questionable (table 3) (Mckenzie, 2004).

Social sustainability dimensions were first proposed by United Nations Division for Sustainable Development (UNDSD, 2001) and widely accepted by the researchers, academicians and practitioners. This framework describes themes and sub themes and under sub themes-indicators etc. The first of these framework proposed by United Nations Division for Sustainable Development measures progress of social sustainability indicators that are tied to Millennium Development Goals. According to this framework, indicators first classified by the primary dimensions (Social, environmental, and economic) then by

Table 3. Comprehensive list of various social sustainability indicators adopted by many scholars across the globe.

Social Sustainability Indicators	
Human Rights	Philanthropy
Income disparity	Population
Justice to all	Poverty
Juvenile arrests	Quality Education
Life companion	Recreation
Living Wage	Reliable and sufficient social system
Objective basic Needs	Safety
Objective equal opportunities	Fair distribution of burden between generations
Objective social resources	Financial position
Abuse and disciplinary practices	Freedom of association
Cultural Sustainability	Gender Discrimination
Employment	Wages
Employment gender ratio	Working Hours
Environmental reports	Access to goods and services
Equity	Affordable housing
Ethics	Bonded labour
Gender Ratio (Employment)	Child abuse or Neglect
Harassment	Child labour
Housing Security	Creation of social capital
Social homogeneity	Cultural diversity
Subjective basic needs	Health
Subjective equal opportunities	Health Insurance
Subjective social resources

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

their theme (for example: education), and finally by sub theme(for example., literacy). The broad themes under social dimensions are: equity, health, education, housing, security, and population. Under each sub theme, at least one or as many as three quantifiable indicators associated with it. These indicators very useful and are shared to many countries by Human Development Report Office of UNEP.

Further, there is another frame work called "The sustainability Reporting Guidelines" developed in conjunction with many stakeholders, including business houses, non-profit organizations, investor organization, and trade unions. This was primarily the effort of United Nations Environment Programme (UNEP) in association with Coalition for Environmentally Responsible Economics (CERES). Though this framework is very similar to that of UNDSD, it is different in many areas. These framework differentiates "core" and "additional indicators –core indicators are more relevant to reporting organizations and stakeholders, others are named as additional indicators. However, majority of these indicators are subjective and qualitative. Within 'sustainable reporting guidelines' many of these indicators are informative however, it is very difficult to incorporate such qualitative guidelines in decision making tools required by business. Carter and Jennings (2000, 2002, 2004) through his research in US has proposed many social dimensions, including diversity, human rights, philanthropy, safety, in manufacturing Industries.

Labuschangne et al. (2005) has contributed to the improvement of sustainability framework by proposing additional indicators that incorporates criteria from number of key frameworks, namely: United Nations Commission on sustainable development, Global Reporting Initiative, Sustainability metrics of institution of chemical engineers, and Wuppertal sustainability indicators. They have concluded that the indicators within these frameworks are not "adequate" as a result eight supplement guidelines were reviewed to identify additional indicators. Similarly, Supply chain counsel has proposed, "SCOR people" framework through Supply Chain Operation Reference (SCOR) model for manufacturing supply chain. However, sustainability reporting framework, proposed by Global Reporting Initiative (GRI), A non-governmental organization is widely accepted among corporate circles (Table 4).

Though, there were many adequate dimensions and measures for social sustainability in manufacturing industries as we discussed earlier. The dimensions and indicators cannot be generalized because "socialness" evolves over a period of time in the society and social issues are highly contextual. For example the social issues in developing countries are different from that of developed economies.

Various researches conducted by many renowned scholars have identified specific social sustainability dimensions that can be used as a tool for measuring social sustainability in manufacturing industries.

For examples Sachs (1999) identified dimensions such as access to goods, employment, cultural sustainability, human rights in New York City. Further, The research done in US manufacturing companies brought many social dimensions such as, diversity philanthropy, safety, and human rights (Carter & Jennings, 2000, 2002, 2005). In this research, however the authors could not establish direct relationship between social sustainability and financial performance. Instead, they could find trust and learning played a vital role between suppliers and buyers, invariably that led to cost reduction for the buying organization. Similar study, by Gupta (2007) uncovered human rights and labour standards in Indian manufacturing companies. Yet another research in German, the social dimensions such as objective basic needs, subjective basic needs, objective social resources, subjective social resources, cultural diversity, and social security system were established and ranked based on priority (Omann & Spangenberg, 2002).

There were other social indicators including financial position, life companion, and recreation have been used by Kallstorm and Ljung (2005). In Canada, another empirical study done by Vachon and Mao

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 4. List of criteria and sub criteria and Indicators proposed by UNDSD and adopted by Mani et al. (2014) in India.

Criteria	Sub Criteria	Indicators
Equity	• Poverty • Gender equality • Gender discrimination	• Percentage of population living below poverty level • Unemployment rate • Gini index of income inequality • Percentage ratio of average female wage vs male wage • The practice of granting or denying rights of privileges based on gender
Health & Safety	• Nutritional Status • Mortality • Sanitation • Drinking Water • Healthcare Delivery • Safety measures provided by corporates	• Children nutritional status • Mortality rate under 5 years old • Population who have adequate sewage facilities (%) • Access to safe drinking water • Access to primary health care facilities • Safety measures undertaken by the company to protect the employees
Wages	Wage standard	Standard of wages against man hours spent
Education	• Literacy Level • Education Level	• Adult literacy ratio • Access to primary education up to 5th STD
Philanthropy	• Donation to Temples & MUTT • Donations to NGO's • Donations to Schools & Colleges	• Money donated to religious organizations • Money given to Non Governmental Organization (NGO's) • Money given to schools and colleges
Human Rights	Human Rights- Environment	How human rights are protected (right to associate, speak)
Child and Bonded Labour	• Child labour • Bonded labour	• The percentage of child labour employed • Percentage of bonded labour employed
Housing	Living Conditions	• Human and floor ratio • Hygienic conditions
Ethics	• Supplier Ethics • Ethical Environment	• Ethical values adopted by the supplier • Ethical environment

Source: Mani et al. (2014a)

(2008) suggested the dimensions such as labour, employment, and gender. Hutchins and Sutherland (2008) in their research in US established relationship between social sustainability indicators such as wages, health, safety, equity, quality education, and philanthropy and the financial position of the country and through life cycle analysis. In various other studies conducted by many researchers in countries such as UK, Sweden, and London, China established many social performance indicators including ethics, environment, employee compensation, philanthropy, health and safety, child labour, bonded labour, education and housing facilities, etc. as listed in Table 1 (Yakovleva et al., 2012; Kogg & Mont, 2012; Schlossberg & Zimmerman, 2010; Andersen et al., 2009; Lu & Lee, 2012; Husgafvel et al., 2014).

However, caution needs to be applied while selecting the social indicators in a particular country. This might look different view than that of conventional way of thinking that all the societies are getting merged because of globalization and liberalized economy. And we get an illusion that all the social issues may be same. However, it is not true; this can be well noticed by the research done by Mani et al. (2015c) in two different global supply chains and their social sustainability practices in India and other continents. In which, the author emphasized that the social issues and indicators to measure such issues are different from one continent to other (Table 5).

Source: Mani et al. (2015b)

CONCLUSION

A sincere attempt was made to expose the concepts and literature pertaining to social sustainability and how it was practiced in manufacturing supply chain under various domains. Based on the above literature and analysis, there were many dimensions and indicators, related to social sustainability in the supply chain, emerged. Social sustainability as a subject, it was very difficult to define due to the fact that it is highly contextual in nature further, it is a growing phenomenon, as the researcher keeps dwelling around "socialness" under various domains in different geographies. When people apply social sustainability in any domain, bit caution, and care need to be maintained as the indicators tend to vary from one domain to another. We conclude that social sustainability parameters can't be generalized and still there is research-able gaps exist in different geographies. For example, research on social sustainability in developing countries can bring in some visible and actionable results that could help in decision making and policies.

Chapter 64
Energy and Carbon Footprint-Aware Management of Geo-Distributed Cloud Data Centers: A Taxonomy, State of the Art, and Future Directions

Atefeh Khosravi
The University of Melbourne, Australia

Rajkumar Buyya
The University of Melbourne, Australia

ABSTRACT

Cloud computing provides on-demand access to computing resources for users across the world. It offers services on a pay-as-you-go model through data center sites that are scattered across diverse geographies. However, cloud data centers consume huge amount of electricity and leave high amount of carbon footprint in the ecosystem. This makes data centers responsible for 2% of the global CO2 emission. Therefore, having energy and carbon-efficient techniques for resource management in distributed cloud data centers is inevitable. This chapter presents a taxonomy and classifies the existing research works based on their target system, objective, and the technique they use for resource management in achieving a green cloud computing environment. Finally, it discusses how each work addresses the issue of energy and carbon-efficiency and also provides an insight into future directions.

INTRODUCTION

In recent years the use of services that utilize cloud computing systems has increased greatly. The technology used in cloud is not new and its main goal is to deliver computing as a utility to users. Cloud computing consists of virtualized computing resources inter-connected through a network, including private networks and the Internet. Over the years since its formation, different definitions for cloud

computing have been proposed. According to the definition by the National Institute of Standards and Technology (NIST) (Mell and Grance, 2011): "Cloud computing is a model for enabling ubiquitous, convenient, on-demand network access to a shared pool of configurable computing resources (e.g., networks, servers, storage, applications, and services) that can be rapidly provisioned and released with minimal management effort or service provider interaction. This cloud model is composed of five essential characteristics, three service models, and four deployment models". The three service models provided by the cloud providers are Infrastructure, Platform, and Software as a Service.

Cloud computing delivers service, platform, and infrastructure services to users through virtual machines deployed on the physical servers. Virtualization technology maximizes the use of hardware infrastructure and physical resources. Hardware resources are the servers located within the data centers. Data centers are distributed across the world to provide on-demand access for different businesses. Due to the distributed nature of cloud data centers, many enterprises are able to deploy their applications, such as different services, storage, and database, in cloud environments. By the increase of demand for different services, the number of data centers increases as well; which results in significant increase in energy consumption. According to Koomey (2008) energy usage by data centers increased by 16% from the year 2000 to year 2005. Energy consumption of data centers almost doubled during these five years, 0.5% and 1% of total world energy consumption in 2000 and 2005, respectively. Hence, during the recent years there has been a great work on reducing power and energy consumption of data centers and cloud computing systems. Recently, considering data centers carbon-efficiency and techniques that investigate cloud data centers energy sources, carbon footprint rate, and energy ratings have attracted lots of attention as well. The main reasons for considering carbon-efficient techniques are increase in global CO_2 and keeping the global temperature rise below 2°C before the year 2020 (Baer, 2008).

In the rest of the chapter, the authors provide an in-depth analysis of the works on energy and carbon-efficient resource management approaches in cloud data centers, based on the taxonomy showed in Figure 1. The authors explore each category and survey the works that have been done in these areas. A summary of all the works is given in Table 1.

Table 1. Summary of various techniques for energy and carbon-efficient resource management in cloud data centers

Project Name	Goal	Architecture	Technique	Carbon-Aware
Dynamic right-sizing on-line algorithm, Lin. et al. (2011)	Minimize energy consumption and total cost	Single data center	Online prediction algorithms for the number of required servers for the incoming workload	No
Green open cloud framework, Lefevre et al. (2010)	Minimize energy consumption	Single data center	Predict the number of switched-on servers through providing in-advance reservation for users	No
Prediction-based Algorithms, Aksanli et al. (2011)	Maximize renewable energy usage and minimize number of job cancellation	Single data center	Use prediction-based algorithms to run the tasks (mainly batch jobs) in the presence of renewable energies	Yes
GreenSlot scheduler, Goiri et al. (2011)	Maximize renewable energy usage and minimize cost of using brown energies	Single data center	Prediction-based algorithms for the availability of solar energy and suspending the batch jobs in the absence of green energy	Yes
Multi-dimensional energy-efficient resource allocation (MERA) algorithm, Goudarzi et al. (2012)	Minimize energy consumption and maximize servers' utilization	Single data center	VM placement heuristic to split the VMs and place them on a server with the least energy consumption	No
Multi-objective VM placement, Xu et al. (2010)	Minimize power consumption, resource wastage, and the maximum temperature on the servers	Single data center	Data center global controller places the VMs based on a multi-objective algorithm to provide balance between power consumption and temperature	No
Green SLA service class, Haque et al. (2013)	Explicit SLA to guarantee a minimum renewable energy usage to run the workload	Single data center	Power distribution infrastructure to support the service and optimization based policies to maximize cloud provider's profit while meeting user's green SLA requirements	Yes
Cost-aware VM placement problem (CAVP), Chen et al. (2013)	Minimize the operating cost	Distributed data centers	VM Placement using meta-heuristic algorithms, considering different electricity prices and WAN communication cost	No
Energy model for request mapping, Qureshi et al. (2009)	Minimize electricity cost	Distributed data centers	Request routing to data centers with lower energy price using geographical and temporal variations	No
Free Lunch architecture, Akoush et al. (2011)	Maximize renewable energy consumption	Distributed data centers	VM migration and execution between data center sites considering renewable energy availability	Yes
Energy and carbon-efficient cloud architecture, Khosravi et al. (2013)	Minimize carbon footprint and energy consumption	Distributed data centers	VM placement heuristics to place the VM on the data center/cluster with the least carbon footprint and energy consumption and on the server with the least increase in power consumption	Yes
Framework for load distribution across data centers, Le et al. (2009)	Minimize brown energy consumption and cost	Distributed data centers	User request is submitted to the data center with access to the green energy source and least electricity price	Yes
Geographical load balancing (GLB) algorithm, Liu et al. (2011)	Minimize brown energy consumption	Distributed data centers	Use the optimal mix of renewable energies (solar/wind) and energy storage in data centers to eliminate brown energy consumption	Yes

Table 1. Continued

Project Name	Goal	Architecture	Technique	Carbon-Aware
Online global load balancing algorithms, Lin et al. (2012)	Minimize brown energy consumption and cost	Distributed data centers	Route requests to the data centers with available renewable energy using online algorithms	Yes
GreenWare middleware, Zhang et al. (2011)	Maximize renewable energy usage	Distributed data centers	Submit the requests to the data center site with available renewable energy, while meeting provider's budget cost constraint	Yes
Environment-conscious meta-scheduler, Garg et al. (2011)	Minimize carbon emission and maximize cloud provider profit	Distributed data centers	Near-optimal scheduling policies to send HPC applications to the data center with the least carbon emission and maximum profit, considering application deadline	Yes
Carbon-aware green cloud architecture, Garg et al. (2011)	Minimize energy consumption and carbon footprint	Distributed data centers	Submit the user requests to the data center with the least carbon footprint, considering user deadline	Yes
MinBrown workload scheduling algorithm, Chen et al. (2012)	Minimize brown energy consumption	Distributed data centers	Copy the data in all the data centers, then based on the request deadline and the data center with least brown energy consumption executes the request	Yes
Federated CLEVER-based cloud environment, Celesti et al. (2013)	Minimize brown energy consumption and cost	Distributed data centers	Allocate the VM request to the cloud data center with the highest amount of photovoltaic energy and lowest cost	Yes
Temperature-aware workload management, Xu et al. (2013)	Minimize cooling energy and energy cost	Distributed data centers	Joint optimization of reducing cooling energy by routing requests to the site with lower ambient temperature and dynamic resource allocation of batch workloads due to their elastic nature	No
Provably-efficient on-line algorithm (GreFar), Ren et al. (2012)	Minimize energy cost	Distributed data centers	Use servers' energy efficiency information and places with low electricity prices to schedule batch jobs and if necessary suspending the jobs	No
Optimization-based framework, Le et al. (2010)	Minimize cost and brown energy consumption	Distributed data centers	Distribute the Internet services to the data centers considering different electricity prices, data center location with different time zones, and access to green energy sources	No
Dynamic load distribution policies and cooling strategies, Le et al. (2011)	Minimize cost	Distributed data centers	Intelligent placement of the VM requests to the data centers considering data centers geographical location, time zone, energy price, peak power charges, and cooling system energy consumption	No
Online job-migration, Buchbinder et al. (2011)	Minimize cost	Distributed data centers	On-line migration of running jobs to the data center with lowest energy price, while considering transport network costs	No
Spatio-temporal load balancing, Luo et al. (2015)	Minimize cost	Distributed data centers	Route the incoming requests to the data centers considering spatial and temporal variation of electricity price	No
Data centers' intelligent placement, Goiri et al. (2011)	Minimize cost, energy consumption, and carbon footprint	Distributed data centers	Find the best location for data center, considering location dependent and data center characteristics data	Yes
GreenNebula, a prototype for VM placement that follows-the-renewables, Berral et al. (2014)	Minimizing data center and renewable power plant building costs	Distributed data centers	Find the best geographical location to build data centers and renewable power plants and migrate the VMs, whenever necessary, to use a certain amount of renewables (solar or wind)	Yes

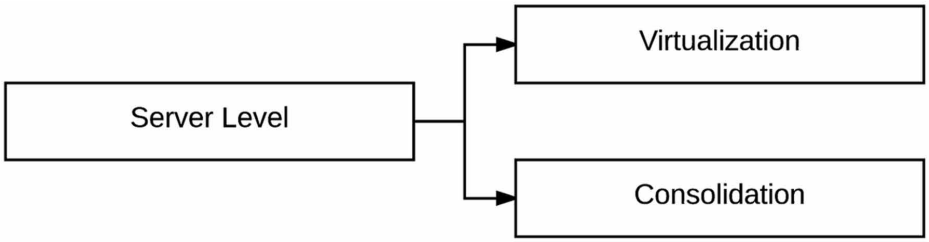
ENERGY EFFICIENCY IN SERVERS

Servers are the physical machines that run the services requested by users on a network. Servers are placed in a rack and any number of racks can be used to build a data center. Servers along with cooling systems and other electrical devices in the data centers consume 1.1-1.5% of the global electricity usage (Koomey, 2007). Hence, power and energy management of servers by the increase in users' demand for computing resources is irrefutable. Figure 2 shows a classification of techniques that are used in data center servers to reduce energy consumption. Virtualization and consolidation are two well-known strategies that make the data center servers energy-aware. These are two powerful tools that are applied in cloud data center servers in order to reduce energy consumption and accordingly carbon footprint.



Virtualization

Virtualization technology is the main feature of data center servers that leads to less energy consumption (Brey & Lamers, 2009). By having virtualized servers and resources, and using virtualization technology several virtual machines (VMs) can be built on one physical resource. Three types of virtualization that are widely used in data centers are hardware, software, and operating system virtual machines. The VMs run on the servers share the hardware components, that helps the operators to maximize server's utilization and benefit from the unused capacity. By maximizing server's utilization, huge savings in cost and energy consumption of data centers will be made. Decrease in data centers costs and energy consumption is not the only advantage of using virtualization technology. As the average life expectancy of a server is between three to five years, data and applications need to be consolidated and migrated to another server. Virtualization helps these two techniques to be done faster and with less cost and energy.

Consolidation

Server consolidation technique benefits from emerging of multi-core CPUs and virtualization technology. It's aim is to make efficient usage of computing resources to reduce data centers cost and energy consumption (Srikantaiah, Kansal, & Zhao, 2008). Consolidation is used when the utilization of servers is less than the cost associated to run the workloads (energy cost to run servers and cooling cost for data center servers). By using consolidation, servers can combine several number of running VMs and workloads from different servers and allocate them on a certain number of physical servers. Therefore, they can power-off or change the performance-level of the rest of physical servers and reduce the energy consumption, cost, and carbon footprint.

Figure 2. Server level energy and carbon-efficient techniques

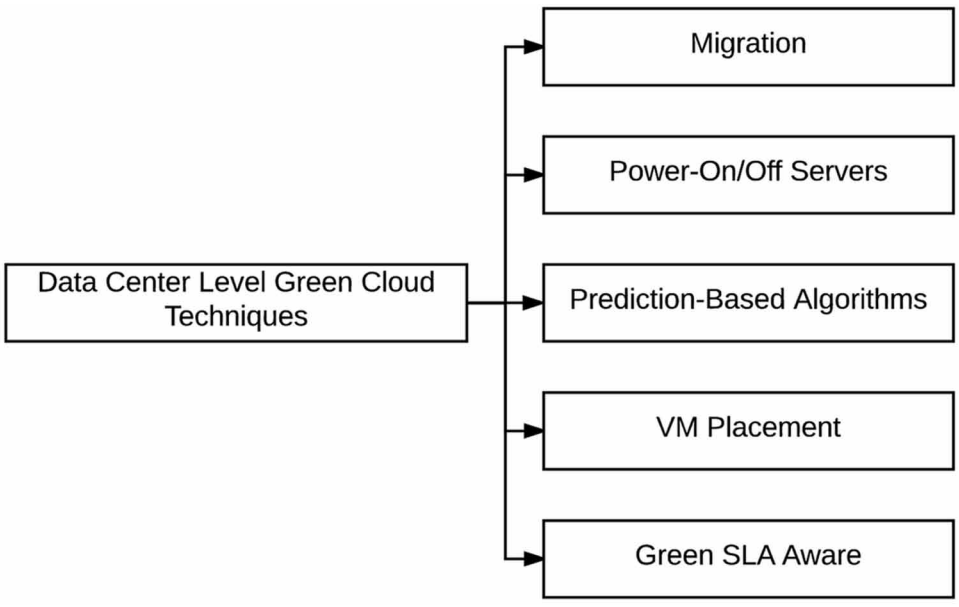
ENERGY EFFICIENCY IN DATA CENTERS



This section gives an overview of the researches that have been done at data center level to improve carbon and energy-efficiency of cloud data centers. An extensive taxonomy and survey of these techniques is done by Beloglazov, Buyya, Lee, and Zomaya (2011). Most of the works within a data center focuses on reducing energy consumption, which can indirectly result in carbon footprint reduction as well. Figure 3 classifies different approaches that have been taken for single data center. Some approaches use server level techniques (virtualization and consolidation) to migrate the current workload (user applications or virtual machines) and turn-off unused servers. Moreover, a provider could use the incoming workload pattern to place user request in the best suited cluster and server (and virtual machine for user applications) with less increase in energy consumption and carbon footprint.

Migration

Using virtualization, data center workloads migrate between servers. VM migration is the process of moving a running virtual machine from its current physical machine to another physical machine. Migration should be done in a way that all the changes be transparent to the user and the only change that user may encounter is a small increase in latency for the running VM or application.

Migration allows a virtual machine to be moved to another physical server so that the source physical server could be switched off or be moved to a power saving mode in order to reduce the energy consumption. VM migration in cloud data centers could be done off-line or live (Harney, Goasguen, Martin, Murphy, & Westall, 2007). There has been a great amount of work done in this area try to identify the VMs on the servers with low utilization that could be migrated, so that the provider can put the unused servers in idle or power-off state.

Figure 3. Data center level energy and carbon-efficient techniques

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Power-On and Off Servers

When in an idle state data centers consume around half the power of their peak utilization and power state (Barroso & Holzle, 2007). There are technologies that try to design data center servers so that they just consume power in the presence of load, otherwise they go to a power saving mode. Work that is done by Lin, Wierman, Andrew, and Thereska (2011) uses a dynamic right-sizing on-line algorithm to predict the number of active servers that is needed by the arriving workload to the data center. Based on the experiments that are done in Lin et al. (2011) dynamic right-sizing algorithm can achieve significant energy savings in the data center. We should consider that this requires servers to have different power modes and be able to transit to different states while still keeping the previous state. Moving the system to different power consumption modes is a challenging problem and requires dynamic on-line policies for resource management.

Green Open Cloud (GOC) is an architecture which is proposed by Lefèvre and Orgerie (2010) on top of the current resource management strategies. The aim of this architecture is to switch-off unused servers, predict the incoming requests, and then switch-on required servers on the arrival of new requests. GOC proposes green policies to customers in the way that they can have advance resource reservation and based on this knowledge cloud provider could estimate how many servers, and when they should be switched-on. Using this framework and strategy, they were able to save a considerable amount of energy on cloud severs.

Prediction-Based Algorithms

Aksanli, Venkatesh, Zhang, and Rosing (2012) used the data from solar and wind power installations in San Diego (MYPVDATA) and National Renewable Energy Laboratory (NREL), respectively to develop a prediction-based scheduling algorithm to serve two different types of workloads, web-services and batch-jobs. The main goal of this model was to increase the efficiency of the green energy usage in data centers. Based on the experiments of the proposed model, the number of tasks that were done by the green energy resources increased and the number of works that were terminated because of the lack of enough green energy resources decreased. This model uses a single queue per server for web services which are time sensitive applications, and for the batch-jobs it uses the Hadoop which is the general form of Map-Reduce framework.

GreenSlot scheduler (Goiri t al., 2011) also proposes a scheduling and prediction mechanism to efficiently use the green energy sources. Goiri et al. (2011) consider solar as the main source of energy and smart grid, known as brown energy, as the backup power source for the data center. The main objective of GreenSlot is to predict the availability of solar energy two days in advance so that it can maximize the use of green energy and reduce the costs associated with using brown energy. GreenSlot uses the suspension mechanism when there is not enough green energy available and based on the availability of enough solar energy it resumes the jobs. According to the experimental results that are presented in comparison with other conventional scheduling mechanisms, like backfilling scheduler (Mu'alem & Feitelson, 2001), GreenSlot scheduler can significantly increase the use of green energy for running batch-jobs and decrease the brown energy costs, which leads to less carbon footprint and moving towards a sustainable environment. Unlike web-service jobs which are time-sensitive batch-jobs are compute intensive and the deadline is not critical as web-service jobs, so the suspension will not affect the user quality of service (QoS) parameters.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

VM Placement

Users send their requests to the cloud Infrastructure as a Service (IaaS) providers in the form of VMs. Goudarzi and Pedram (2012) presented a VM placement heuristic algorithm to place the VMs in physical servers in a way to reduce data centers energy consumption. The algorithm receives the VM requests and splits each VM into several copies and places them on servers. Each copy of VM gets the same amount of physical memory but with different CPUs. The total summation of assigned CPUs for copies of a VM request will be equal to the required CPU by the VM at the time of arrival to the data center. The proposed algorithm, which is known as MERA (Multi-dimensional Energy-efficient Resource Allocation), receives the VM requests and after a certain time epoch places the VMs on the servers and calculates the consumed energy. Then, it splits the VMs and places the copies on servers and recalculates the energy consumption. Based on the calculated energies the algorithm makes decision whether to split and replicate VMs or not. This algorithm tries to increase the servers' utilization while decreasing the energy consumption without considering the physical characteristics and energy related parameters of servers and data centers. Moreover, it does not perform the VM placement dynamically. The algorithm receives a group of VMs and after a certain time epoch performs VM placement. In addition, intercommunication between replicated VMs could lead to bottleneck and high energy consumption. Finally, in the placement all VMs are treated the same. As all the replicated VMs get the same amount of physical memory, whilst for memory-intensive VMs this could result to shortage in resources and it is better to make balance between CPU intensive and memory intensive VM requests.

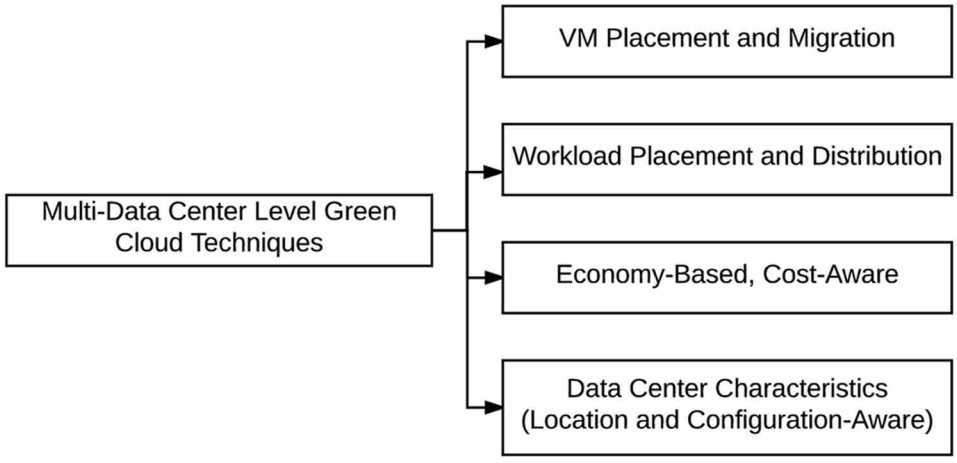
The work done by Xu and Fortes (2010) addresses the problem of data centers VM placement with the objective to simultaneously minimize resource wastage, power consumption, and maximum temperature of the servers. They used a genetic algorithm on the global controller of the data center to perform the VM placement. The global controller receives the VM requests and then based on a multi-objective VM placement algorithm assigns each VM to a server. This algorithm, same as the previously discussed work, performs VM placement after receiving all the VM requests, which is not in a dynamic manner. Moreover, the algorithm makes balance between power consumption and temperature. Therefore, it uses more servers to distribute the load and avoid hotspots in the data center. This might cause more carbon footprint as more servers will be used and more electricity will be consumed.

Green SLA Aware

Due to the high energy consumption by cloud data centers and climate concerns, cloud providers do not just rely on the electricity coming from brown energy sources. They have their own on-site green energy sources or draw it from a nearby power plant. Moreover, enterprises and individuals demand for quantifiable green cloud services. Haque, Le, Goiri, Bianchini, and Nguyen (2013) propose a new class of cloud services that provides a specific service level agreement for users to meet the required percentage of green energy used to run their workloads. They undertake a new power infrastructure in which each rack can be powered from brown or green energy sources. The optimization policies have the objective of increasing the provider's profit by admitting the incoming jobs, with Green SLA requirements. If cloud provider cannot meet the requested percentage of green energy to run the job should pay penalty to the user, which means decrease in the total gained profit of running jobs. The type of green energy used by Haque et al. (2013) in the data center is solar energy and they predict the availability and amount of solar energy based on the method proposed in Goiri et al. (2012). The experiments carried in their

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

work are based on comparison with greedy heuristics, and they show that optimization based policies outperform the greedy ones. Furthermore, among optimization based policies cloud provider can decide whether wants to increase the number of admitted jobs or violate less Green SLAs.



In the calculated total cost to run the admitted jobs in the work by Haque et al. (2013), it is not clear that whether it is the cost to run the servers or the total cost in the data center, including overhead energy cost as well. This is important because overhead energy is dependent on the data center power usage effectiveness (PUE) and this varies by the change in the data center total utilization and ambient temperature (Rasmussen, 2007; Goiri, Le, Guitart, Torres, & Bianchini, 2011). Therefore, the calculated value for profit in the optimization based policies would vary based on the two aforementioned parameters for different jobs with different configuration requirements and also time of the day.

ENERGY EFFICIENCY IN GEOGRAPHICALLY DISTRIBUTED DATA CENTERS

Applying different policies to switch-off and on servers and placing user requests within a data center could lead to reduce in energy consumption. But still these are not enough to solve the problem of high energy consumption and carbon footprint by cloud data centers.

By increasing the use of cloud computing services that leads to increase in energy consumption and carbon footprint in the environment, some cloud providers decided to use green energy as a secondary power plant. Therefore, the need to have a scheduling policy to select the data center site to run the user request based on the energy source is necessary. Moreover, data center selection based on considering different data centers energy efficiency, as it has a direct effect on total carbon footprint, reduces energy consumption and carbon dioxide in the ecosystem. This section explores different energy and carbon-efficient approaches have been taken across distributed cloud data centers. Some of the applied techniques are the same as single data center level, but with considering factors to select the data center site before cluster and server selection. Figure 4 shows the taxonomy of different approaches taken at multi data center level with different optimization objectives, such as minimizing cost, energy consumption, carbon emission, and maximizing renewable energy consumption.

Figure 4. Multi data center level energy and carbon-efficient techniques

VM Placement and Migration

Research works in this area consider initial placement of a VM and further monitoring of the running VM to meet the optimization objective. Virtual machine (VM) placement in a geographically distributed data center environment requires selection of a data center and a server within the data center based on the optimization objective and data centers characteristics. Moreover, after the VM placement considering the future state of the host data center and other data centers, cloud provider can perform VM live migration to move the VM to another data center with preferable parameters. There are a few research works that consider these two techniques.

Chen, Xu, Xi, and Chao (2013) developed a model for optimal VM placement considering a cloud provider with distributed data center sites connected through leased/dedicated lines. They introduce a cost-aware VM placement problem with the objective of reducing operational cost as a function of electricity costs to run the VMs and inter-data center communication costs. For this purpose, they take advantage of variable electricity costs at multiple locations and wide-area network (WAN) communication cost to place the VMs using a meta-heuristic algorithm. Similarly, Qureshi, Weber, Balakrishnan, Guttag, and Maggs (2009) try to minimize electricity cost of running the VMs by initially placing the VMs into data centers with low spot market prices. They take advantage of spatial and temporal variations of electricity price at different locations.

Akoush, Sohan, Rice, Moore, and Hopper (2011) propose an architecture known as Free Lunch to maximize renewable energy consumption. They consider having data center sites in different geographical locations in such a way to complement each other in terms of access to renewable energy (solar and wind) by being located in different hemisphere and time zone. The architecture considers pausing VMs execution in the absence of renewable energy or migrating the VMs to another data center site with excess renewable energy. The proposed architecture provides a good insight to harness renewable energy by having geo-distributed data center sites with dedicated network. However, this model has technical challenges and limitations dealing with VM availability, storage synchronization, VM placement and migration that have been pointed out in their work.

Work done by Khosravi, Garg, and Buyya (2013) addresses the problem of energy consumption and carbon footprint of distributed cloud data centers by proposing a novel framework and algorithm for VM placement. This system model uses a component known as Cloud Information Service (CIS) in order to get the data centers' information and updates to perform the scheduling algorithm. The information a data center sends to the CIS consists of data center's available resources, energy and carbon related parameters, such as power usage effectiveness, carbon footprint rate/s (a data center might use more than one energy source), and servers' proportional power as a metric related to the CPU frequency and utilization. The cloud broker, as the interface between users and cloud provider, uses this information to perform a dynamic two-level scheduling algorithm. The algorithm places the VM in the data center/cluster with the least carbon footprint and energy consumption (first level), and in the server with the least increase in the power consumption (second-level), while meeting the users' quality of service in terms of number of rejected VMs. The proposed algorithm reduces the carbon footprint and energy consumption considerable in comparison to other competing algorithms.

Workload Placement and Distribution

A large body of literature recently focused on reducing energy consumption and energy costs by load placement and distribution across geographically distributed data centers.

Le, Bianchini, Martonosi, and Nguyen (2009) proposed a framework to reduce cost and brown energy consumption of cloud computing systems by distributing user requests across data center sites. This is the first research that considers load distribution across data center sites with respect to their energy source and cost. The framework is composed of a front-end that receives user requests and based on a distribution policy forwards the requests to the data center site with less cost and more available green energy sources. The request distribution policy sorts the data center sites based on the percent of the load that could be completed within a time period and minimum cost to run the requests. The evaluation results show that by knowing data centers' electricity price (constant price, dynamic, or on/off-peak prices) and base/idle energy consumption of the servers', significant improvements in cost reduction will be made. Moreover, being aware of the energy sources (green or brown) in the data centers could lead to less brown energy usage with a slight increase in the total cost.

Zhang, Wang, and Wang (2011) use the idea of distributing the load among a network of geographically distributed data centers to maximize renewable energy usage. They proposed a novel middleware, known as GreenWare, that dynamically conducts user requests to a network of data centers with the objective of maximizing the percentage of renewable energy usage, subject to the cloud service provider cost budget. Experiment results show GreenWare could significantly increase the usage of renewable energies, solar and wind with intermittent nature, whilst still meeting the cost budget limitation of the cloud provider.

Following the idea of reducing brown energy consumption in data center sites, Liu, Lin, Wierman, Low, and Andrew (2011) proposed the geographical load balancing (GLB) algorithm. The algorithm takes advantage of diversity of data center sites to route requests to the places with access to renewable, solar and wind, energy sources. Considering the unpredictable nature of renewable energy, specially wind, GLB algorithm finds the optimal percentage of wind/solar energies to reduce the brown energy consumption and carbon footprint. Moreover, the authors consider the role of storage of renewable energies, when they are not available in data centers in reducing brown energy usage. Based on the experiments, by using even small-scale storage in the data centers, the need for brown energy will decrease and in some cases even will be eliminated. A question that might rise with Liu et al. (2011) work is the carbon footprint caused by the batteries in a long-term period, since renewable energy storage in the data center sites is done through reserving them in the form of batteries. Lin, Liu, Wierman, and Andrew (2012) extended the GLB algorithm to reduce the total cost along with reducing the total brown energy consumption for geographically distributed data centers. They compared their proposed algorithm with two prediction-based algorithms with a look-ahead window, known as receding horizon control (RHC) a classical control policy and an extension of RHC known as averaging fixed horizon control (AFHC) (Kwon & Pearson, 1977). The analytical modelling and the simulations carried, based on real workload traces, show that GLB algorithm can reduce the energy cost by slightly increase in network delay. Moreover, it can eliminate the use of brown energy sources by routing user requests to the sites where wind/solar energy is available.

Garg, Yeo, Anandasivam, and Buyya (2011) proposed an environment-conscious meta-scheduler for high performance computing (HPC) applications in a distributed cloud data center system. The meta-scheduler consists of two phases, mapping the applications to the data center and scheduling within

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

a data center. They treat the mapping and scheduling of applications as an NP-hard problem with the objective to reduce carbon emission and increase the cloud provider profit at the same time. They run different experiments in order to find the near optimal solution for this dual objective problem. The parameters taken into account in the simulations and scheduling algorithms are data centers' carbon footprint rate, electricity price, and data center's efficiency. The simulations carried for high urgent applications (with short deadlines) and different job arrival rates help the cloud providers to decide for each application which scheduling algorithms should be used in order to meet the objective of reducing the carbon emission or maximizing the profit. Moreover, they proposed a lower bound and an upper bound for the carbon emission and profit, respectively. Another work done by Garg, Yeo, and Buyya (2011) addresses the issue of energy efficiency of ICT industry, specially data centers. The main focus of this work is to reduce the carbon footprint of running workloads on data centers by proposing a novel carbon-aware green cloud architecture. This architecture consists of two directories, which imposes the use of green energy by data centers while meeting users and providers' requirements. In this framework, cloud providers should register their offered services in the aforementioned directories, and the users should submit their requests to the data centers through the Green Broker. The scheduling mechanism used in the broker, Carbon Efficient Green Policy (CEGP), chooses the cloud provider based on the least carbon footprint while considering users QoS parameters. The performance evaluation results of the proposed framework and policy in comparison with a traditional scheduling approach shows that CEGP can achieve a considerable reduction in energy consumption and carbon footprint in the ecosystem. However, this algorithm does not work dynamically. It receives all the job requests and based on the jobs deadline assigns them to the data center with the least carbon footprint. Moreover, it only considers high performance computing applications (non-interactive workloads) with predefined deadlines at the time of submission.

Chen, He, and Tang (2012) use the idea of geographically distributed data centers to increase usage of green energy and reduce brown energy consumption in data centers. They proposed a workload scheduling algorithm, called MinBrown, that considers green energy availability in different data centers with different time zones, cooling energy consumption for data centers based on outside temperature and data center utilization, incoming workload changes during time, and deadline of the jobs. The workload used to run the simulation is HPC jobs with sufficient slack time to allow advanced scheduling. The algorithm copies all the data in all the data centers and based on the least consumed brown energy executes the task. Based on the simulation results, the MinBrown algorithm reduces brown energy consumption in comparison to other competitive algorithms. The idea of replicated data in distributed data center sites itself results to high energy consumption that is not considered in Chen et al. (2012) work. Moreover, assignment of the jobs and tasks are based on the availability of green energy, that does not consider communication between tasks of the same job and jobs of the same workload. Finally, the scheduler does not consider an efficient resource assignment within a data center in a way to reduce the need for future consolidation of the running jobs.

The idea of federation of cloud providers can be useful for relocation of computational workload among different providers in a way to increase the use of sustainable energy. Celesti, Puliafito, Tusa, and Villari (2013) take advantage of a federated cloud scenario to reduce energy costs and CO_2 emissions. They consider cloud providers' data centers are partially powered by renewable energies along with getting the required electrical energy from electrical grids. The main contribution of their work is based on the approach of moving the workload towards the cloud data center with most available sustainable energy. This is inspired by the fact that if a provider generates more green energy than its

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

need, it would be difficult to store the exceeded amount in batteries or put it in public grids; therefore, the easiest way is to relocate the workload to the site with the excess renewable energy. The architecture is based on an Energy Manager, that is known as CLoud-Enabled Virtual Environment (CLEVER). By applying CLEVER-based scenario, the VM allocation would be based on the energy and temperature driven policies. The energy manager in the architecture receives different data centers' information, such as temperature, sun radiation, energy grid fare, photovoltaic energy, cost, and data centers' PUE and number of available slots or physical resources, and based on this data assigns VMs to the site with the most sustainable energy and least cost.

Celesti et al. (2013) work increases the use of sustainable energies and it is based on the availability of the photovoltaic (PV) energy. When a site has a high value for the PV energy, the outside temperature would be higher and this will increase the need for more energy for the cooling, and as a result higher PUE value. Relying only on the amount of used PV in the system is not enough for a green and sustainable system. Cloud providers should consider the whole picture and take into account all the parameters that affect the total CO_2 emission. Moreover, Celesti et al. (2013) assume that each new VM request would be replicated in all the federated providers. Considering the consumed energy for this replication and the effect of network distance are also important that should be considered by the time of system design.

Xu, Feng, and Li (2013) take advantage of diversity in data centers location to route the incoming workload with the objective of reducing the energy consumption and cost. They studied the effect of ambient temperature on the total energy consumed by cooling system, which is 30% to 50% of the total energy consumption of data centers (Pelley, Meisner, Wenisch, & VanGilder, 2009; Zhou et al., 2012). Energy consumption often is modelled as a constant factor, which is an over-simplification of what is happening in reality. Xu et al. (2013) considered partial PUE (power usage effectiveness) to participate cooling systems' energy along with the servers' total energy consumption. Through using partial PUE data centers can route the workload to the sites that use outside air cooling and reduce considerable amount of energy consumption. Moreover, they took advantage of having two types of incoming requests to manage the resources and reduce the energy consumption. The proposed model does not only depend on the energy consumed by interactive workload form users, instead it reduces energy costs by allocating capacity to the batch workloads, which are delay tolerant and can be run at the back-end of the data centers. The proposed joint optimization approach could reduce cooling energy and overall energy cost of data centers.

However, the proposed partial PUE only considers the energy consumed by cooling system as the total overhead energy in the data center. Based on the introduced definition by Xu et al. (2013), PUE is mainly dependent on the ambient temperature, while IT load of the data center is the second important factor affecting the PUE (Rasmussen, 2007). Finally, source of the energy used to generate the electricity and its carbon footprint is not considered. This is important because as mentioned earlier reducing energy cost does not necessarily lead to reduce in the carbon footprint in the environment.

Economy-Based, Cost-Aware

Cost associated with energy usage in large data centers is a major concern for the cloud providers. Large data centers consume megawatts of electricity, which leads to huge operational costs. Work done by Ren, He, and Xu (2012) takes advantage of different electricity prices in different geographical locations and over time to schedule batch jobs on the servers in scattered data centers. Their proposed online optimal algorithm, known as GreFar, uses servers' energy efficiency information and locations with low elec-

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

tricity prices to schedule the arrived batch jobs from different organizations. GreFar's key objective is to reduce energy cost, while assuring fairness considerations and delay constraints. The scheduling is based on a provably-efficient online algorithm, that schedules the jobs according to the current job queue lengths. Based on the simulation results, GreFar online algorithm can reduce system cost, in terms of a combination of energy cost and fairness, in comparison to the offline algorithm that has knowledge of system's future state. The algorithm's main contribution is to serve the jobs when the electricity price is low or there are energy-efficient servers in the system. To accomplish this objective, it queues jobs and suspends low priority jobs whenever the electricity price goes up or there are not enough efficient servers in the system. This approach is not applicable for interactive jobs and web requests that are time sensitive and need to be served immediately from the queue and also cannot be suspended. Moreover, the cloud provider does not consider the cost of the transmission network and its energy consumption at the time of data center selection to submit the job request.

Le, Bianchini, Nguyen, Bilgir, and Martonosi (2010) take advantage of capping the brown energy consumption to reduce the cost of serving Internet services in data centers. They proposed an optimization-based framework to distribute requests among distributed data centers, with the objective to reduce costs, while meeting users' service level agreement (SLA). The main parameters that affect the site selection by the framework are different electricity prices (on-peak and off-peak loads), different data centers location with different time zones, data centers with access to green energy sources, which enables the data center to have a mixture of brown and green energy. The front-end of the framework performs the site selection and optimization problem for the arrived requests periodically, in contrast to heuristic algorithms, which are greedy and select the best destination for each request that arrives (Qureshi et al., 2009). The optimization framework uses load prediction by Auto-Regressive Integrated Moving Average (ARIMA) modeling (Box, Jenkins, Reinsel, & Ljung, 2015) and simulated annealing (SA) (Brooks & Morgan, 1995) to predict the load for the next epoch (one week) and schedule the requests. This approach helps the front-end to decide about the power mixes at each data center for the next week, unless a significant change occurs in the system and predictions. Le et al. (2010) use simulation and real system experiments with real traces to evaluate their proposed framework and optimization policy. The evaluation results show that by taking optimization policy and using workload prediction, diversity in electricity price, taking benefit of brown energy caps, and use of green energy sources significant savings in cost related to the execution of Internet services in distributed data centers would be made. The framework assumes that all the received requests from the users are homogeneous. While in the real systems this is not the case and having heterogeneous requests and distributing them in a way to reduce resource wastage is very difficult and itself results to huge energy consumption and accordingly high costs. Moreover, it focuses on the electricity prices in different locations without considering the carbon footprint rate of the sources. Since some brown energy sources, which are cheap and lead to reducing the system overall cost, may lead to huge amount of carbon dioxide in the ecosystem.

The other work by Le et al. (2011) investigates different parameters that affect the electricity costs for geographically distributed data centers with the focus on IaaS services that run HPC workloads. According to their proposed cost computation framework for the data centers, there are two important parameters that affect the total cost, energy consumed to run the service and the cost for the peak power demand. The provider can reduce the consumed energy by selecting the sites with off-peak period electricity prices, lower outside temperature, and lower data center load, so that the energy used for cooling would be low. Because as the data center temperature rises, the provider needs to use chillers to reduce temperature, which increases the energy consumption dramatically. In order to show this relation, they

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

used a simulation model for the data center cooling system. Based on the simulation model, increase in the outside temperature and data center load forces the providers to use the chillers in order to keep the data center cool. This simulation has been carried with real workload traces from the Feitelson (2007), Parallel Workloads Archive. Le et al. (2011) compared their two proposed algorithms, cost-aware and cost-aware with migration, with baseline policies. Based on the results, considering above mentioned factors can reduce the energy cost of data centers. Moreover, predicting the need to use the chillers for system cooling and considering the transient cooling prevents the data center from overheating and would not let spikes in the temperature.

Le et al. (2011) conducted sensitivity analysis to investigate the effect of parameters, such as predicting the run-time of the jobs, the time to migrate the jobs, outside temperature, price of the energy in a region, and size of the data center on the total cost of the data center. According to the simulation results, in order to maximize the cost-saving all the electricity-related parameters should be considered in job placement in the system. One of the shortcomings of this work, similar to the previously discussed work, is not considering the source of electricity. As some brown energy sources with high carbon footprint might be cheaper and more desirable to run the services. Moreover, as the temperature changes during the day and the consumed energy for cooling changes consequently; PUE should be modelled as a dynamic parameter instead of having a constant value per data center. Considering network distance and the energy consumption of intra and inter-data centers will also affect the total cost.

Work by Buchbinder, Jain, and Menache (2011) has also the objective of reducing energy cost for a cloud provider with multi data center sites but with a different approach. They perform on-line migration of running batch jobs among data center sites, taking advantage of dynamic energy pricing and power availability at different locations, while considering the network bandwidth costs among data centers and future changes in electricity price. The total cost in their model, is the cost of energy to run the jobs at the destined data center plus the bandwidth cost to migrate the data. To attain an optimal algorithm with lower complexity comparing the optimal off-line solution, Buchbinder et al. (2011) proposed an efficient on-line algorithm (EOA) with higher performance comparing to the greedy heuristics that ignore the future outcomes. The calculated cost in their work is based on the data centers' operational cost, which focuses on the energy consumption by servers and transport network. However, a considerable part of the energy consumed by a data center is related to the overhead energy, such as cooling systems. Moreover, the objective of reducing the energy cost and routing the jobs to the data center with lowest cost without considering the energy source might lead to increase in the carbon footprint in the environment. The migration of running jobs in this work is in the context of batch jobs, which are delay tolerant in comparison to user interactive requests such as web requests that are delay sensitive. Therefore, the applicability of this algorithm should be investigated for other workloads and user requests in a cloud computing environment. Similarly, work by Luo, Rao, and Liu (2015) leverages both the spatial and temporal variation of electricity price to route the incoming requests between geographically distributed data centers targeting energy cost minimization.

Data Center Characteristics (Location and Configuration-Aware)

There are several works try to make data centers energy and carbon-efficient by reducing the number of active servers or run the virtual machines and applications on the physical machines with the least energy consumption and carbon footprint rate. However, geographical location of the data center has a direct impact on the amount of consumed energy that leads to CO_2 emission in the ecosystem. Work done by

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Goiri et al. (2011) considers intelligent placement of data centers for Internet services. Their goal is to find the best location for data center site to minimize the overall cost and respect users' response time, consistency, and availability. They classified the parameters that affect data centers overall cost into location dependent and data center characteristics data.

The location dependent data specifies the data center's distance to the network backbones, power plants, and the CO_2 emission of the power plant. Moreover, it includes the electricity, land, and water price. The last and one of the most important factors related to the location is the outside temperature. Since, when the temperature goes high the need for cooling increases as well. Cooling system is an important parameter in the data centers, which its energy consumption increases as outside temperature increases. Indeed, high temperature leads to need for more chillers and more chillers increases data center's total energy consumption. This situation eventually leads to higher PUE and energy consumption, which indirectly increases carbon footprint. Goiri et al. (2011) propose a framework to find the most optimum location for the data center to minimize the total costs. Explicit decrease in data center's cost, leads to indirect decrease in energy consumption and carbon footprint.

In order to increase the use of renewable energies, Berral et al. (2014) propose a framework to find the best location to site the data centers and renewable power plants, solar and wind in their work. In the meantime, their objective is reducing total cost for building these infrastructures to support cloud HPC services with different amounts of renewable usage. Berral et al. (2014) divided the costs of building green cloud services into capital (CAPEX) and operational (OPEX) costs and CAPEX itself is divided to costs dependent and the costs that are independent to the number of servers to be hosted. Independent CAPEX costs are cost of bringing brown energy to the data center and connecting to the backbone network. Land cost, building green power plants, cooling infrastructure, batteries, networking equipment, and servers are part of the dependent CAPEX costs. Costs incurred during the life cycle of the data center, such as network bandwidth and amount of brown energy usage are part of the OPEX. Brown energy consumption is the total energy needed by the servers and overhead parts, such as cooling and networking, minus energy derived from renewables. To calculate the overhead energy, Berral et al. (2014) use PUE as a parameter related to the location temperature. It should be noted that temperature is not the only parameter that affects PUE, data center load is also an important parameter that changes PUE value (Rasmussen, 2007).

In order to take the most of the generated renewable energy in different data centers, Berral et al. (2014) compare different approaches such as net metering, which is directing the excess renewable energy into the grid and mix it with brown energy, using batteries and having storage for renewables or not having any storage and migrating the load to the sites with available solar or wind. One of the shortcomings of their work is neglecting the network delay and amount of energy consumed due to VM migration, as the

data centers are scattered at different geographical locations. Moreover, all the data in this system are replicated at all the sites, which itself imposes overhead and increases energy consumption.

CONCLUSION AND FUTURE DIRECTIONS

In this chapter, the authors studied the research works in the area of energy and carbon footprint-aware resource management in cloud data centers. They first had an overview on the existing techniques in green cloud resource management with the focus on a single server and a single data center and the limitations facing these techniques, specially not being able to harvest renewable energy sources at different locations.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

The authors then focused more specifically on the works considering geo-distributed cloud data centers, as nowadays most of the big cloud providers have data centers in different geographical locations for disaster recovery management, higher availability, and providing better quality of experience to users.

A large body of literature in the context of distributed data centers considers assigning resources to the arrived requests in such a way to minimize brown energy consumption. They use different techniques such as applying VM placement heuristics, workload scheduling, and targeting data centers with the most available renewable energy. These works explicitly consider access to renewable energy sources to minimize brown energy consumption and carbon footprint. However, some of the research works achieve energy efficient resource management through minimizing cost and the cost of brown energy usage, which indirectly could lead to less carbon footprint in the ecosystem.

Research in the area of energy and carbon-efficient resource management in data centers is still an important field of work. Apart from the surveyed techniques in this chapter, there are still areas that can be pursued by researchers. VM migration across data center sites to harvest the renewable energy sources is still at its early stages. First of all, it is important to study the effect of minimizing brown energy usage and carbon cost versus network cost and delay imposed due the data transfer over the network. Selecting the VMs to migrate depending on the application running on top of the VM with respect to users' service level agreement is also another area of future study.

There are studies that consider storing excess renewable energy in batteries to use at times of the day that renewable sources are not available. Since main cloud providers started to build their own on-site renewable energy sources and having large scale renewable energy power plants, studying the cost-effectiveness of storing the renewable energy for future usage and contributing to the electrical grid is an important area for future study.

Chapter 65
Factors Influencing Foreign Land Acquisition and Sustainable Development in Nigeria

Yusuf Noah
University of Ilorin, Nigeria

Olatunji Abdulganiy
University of Ilorin, Nigeria

Issah Moshood
University of Ilorin, Nigeria

ABSTRACT

Of the major factors of production, land is considered the most important. Land is such a valuable resources that the desire to acquire it has been a cause of struggle among the people virtually in all hitherto existing human societies. Land acquisition is influenced by numerous factors in which all play relevant roles in understanding the dynamics of land and its utilization among the people in the society. In Africa, foreign land acquisition has become a topical issue because of the richness of the African land resources, and the scamper for these resources has been a source of concern for many observers. This chapter analyzes the factors inhibiting foreign land acquisition in a developing country like Nigeria and examines the challenges posed by such practices to the attainment of sustainable development.

INTRODUCTION

Land is fundamental to human life in many ways. Apart from the fact that it is the place of dwelling, there is virtually no human activity that could be achieved without considering the land factor. All human endeavours from religious to economic and even political activities take place on the land (Adedipe, Olawoye, Olarinde, Okediran, 1998). The Creationist theory of human evolution conceived that man is

created from land and he would eventually return into it after his demise (Quran 20:55 and Genesis 2:7). Land is a free gift of nature and a fundamental necessity of life because it remains the platform on which the social, political and economic activities of a society dwell upon (Enikuomehin, 2005).

The importance of land in human general life could also be inferred from the fact that food, clothing and shelter which are the basic essentials of human living have substantial linkages to land. "Foods grow out of land while shelter is affixed to it, and man's clothing is made largely from what grows out of land" (Babalakin, 2004:1) cited in Famuyiwa & Omirin (2011). In other words, whether in ancient times or modern society, land constitutes a significant index and an unavoidable necessity for socio-political and economic development. There is hardly any social, political or economic venture that does not require land. No wonder the classical economists such as Adams Smith and Alfred Marshal classified land as one of the fundamental factors of production (Alade, 2005). Land is an essential economic commodity. It is limited in supply and as such; the demand for it often outweighs its supply.

Land has an enormous importance to people's life generally. However, despite its huge importance, it is limited in supply. According to Alade (2005), land accounts for approximately 20% of the whole earth surface and it is not everybody or all nations that has it in abundance because of its finite quantity and essential quality. There has always been a high quest to acquire it by all and sundry. A search into the economic history of many human societies revealed several social conflicts among tribes and within nations all as a result of struggle for land acquisition. This is because of the significant relationship that exists between land acquisition and the general development of the nation. Land is a fundamental factor of production in the agricultural sector; it has an essential role to play in increasing as well as sustaining agricultural production. The extent to which this role is performed is determined in part by methods of land acquisition and arrangements for the ownership and use of land. Aside agriculture, land is also useful and needed for various other human activities which would make life easier and better for the human folk.

Land acquisition pattern do enhance the general developmental status of a nation and it has been empirically examined through the history of all hitherto existing societies that land play enormous roles in the political economy of the people in a given society. However, despite the prominent relevance of land in man's life, it is also generally influenced by several factors. Therefore, it is important to consider these factors because of the important roles that land acquisition system plays in attaining sustainable socio-economic development of any nation. Such an effort will go a long way in enhancing the optimal utilization of land resources in our nation and it would also go a long way in bringing about the socio-economic sustainable development that is generally lacking in a country such as Nigeria. It is against this background that this chapter wants to examine the linkages among the varying factors determining land acquisition, land acquisition patterns and sustainable socio-economic development in Nigeria.

CONCEPTUAL DISCUSSION

In order to make the work more comprehensive, there is the need for conceptual clarification of terms relevant to the chapter.

Foreign Land Acquisition

The history of foreign land acquisition in Africa could be traced to the coming of major European powers, such as Portugal, Spain, France and Great Britain, to Africa in search for Africa's rich mineral and

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

agricultural resources. The struggle for African lands and natural resources culminated into the popular Berlin Conference of 1884/85 in Germany which eventually led to the scrambling and partitioning of African lands. It could even be right to argue that the whole essence of imperialism and colonialism is about struggle for land acquisition. This brief insight is a pointer to the fact that, the issue of foreign land acquisition in Africa is a discourse that has a long time outstanding history. Conceptually, land acquisition could be described as the act of acquiring piece of land or large pieces of land for private or public use. Land acquisition takes the form of legal or illegal, willing or forceful acquisition of land belonging to other person or groups for private or public use. Inferring from the above, foreign land acquisition could be described as the act of acquiring (usually a large portion) a piece or pieces of land by individual or individuals who are not citizens of the community in which the land is acquired. More often than not, economic factors have always been the fundamental determinants of foreign land acquisition in many developing countries like Nigeria. In addition to economic variables, political factors could be another reason for land acquisition. In other words, because land is such a valuable political-economic resources, there has always been a high quest to acquire it by people virtually everywhere around the globe.

The political and economic history of the world clearly shows that foreign land acquisition has been a common practice in many human societies. Foreign land acquisition is so common even in traditional societies that this has always be the source of misunderstanding, conflict and sometimes outright war among many rulers in the world from time immemorial. For instance, many notable personalities in the history of mankind became very popular due to their ability to conquer foreign lands. Warriors such as Alexander the Great, Julius Cessare, Ibn Batuta, among others, are relevant examples to be cited in this direction. Indigenously, some personalities such as Uthman Dan Fodio and some rulers in the old Oyo Empire are practical examples of individuals who made history by conquering foreign lands in order to acquire landed properties. Similarly, historical names such as Adolf Hitler of Germany become a name to reckon with in human history due to his ability to conquer foreign lands, though, his thirst to capture more foreign territories led to his eventual demise. Furthermore, empirical examples could be cited of Western nations that gained enormous political and economic advantages due to their ability to conquer foreign lands. These nations were able to solve their huge and pervasive political and economic problems when they conquer foreign lands and incorporated them (the acquired lands) into their political and economic domains (Frank, 1967; Galtung, 1971). In other words, the acquisition of foreign lands by these nations eventually contributed to their remarkable economic success (Walter, 1973).

Specifically, the persistent and recent rush by the countries in the Gulf Region and Far East Asia for land acquisition in Africa was triggered by global financial crisis of 2008 which created a vacuum for international capital investment. Consequently, there has been rapid interest in establishing large farmlands in Africa regions in order to make up for the deficiency in food supply faced by those regions (Deininger, 2003a). The International Land Coalition describes this development as global commercial pressures on land and technically refers to the phenomenon as land acquisition (Matondi, Havnevik & Beyene 2011). What could be inferred from the above discussion is that foreign land acquisition is a common phenomenon in human societies since the traditional period to modern times. Although, the reason for foreign land acquisition in the past was majorly through force and mainly done for political-economic reasons, but lately, there has been some changes in the trends of foreign land acquisitions as one of the major reason why the practice is still been held is due to the problems of food shortage and the global economic meltdown. In other words, foreign land acquisition has been one of the means of showing political strength of a nation, a way of making up for food shortages and a necessary condition for economic development of many human societies.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Observing from a political-economy perspective, Friis & Reenberg, (2010) cited in Usman (2013) described land acquisition essentially as grabbing for control. That is grabbing the land and other associated resources in order to derive benefits from such resources. Fundamentally, land could be acquired for various reasons but most recent literatures such as Von-Braun & Meinzen-Dick (2009), Odhiambo (2011), and Daniel & Birhanu (2012) often see agricultural factor as the only reason why lands are acquired in recent times, ignoring the fact that land could be acquired for other various developmental activities. The latter argument could be supported by recent happenings which have shown that the acquired communal lands in some communities were used for the creation of roads, railways, harbours, and airport; construction of hospitals, schools; rural and urban electrification; provision of water and sewage facilities; urban expansion; establishment of national parks; mineral exploration; and logging of forests.

Sustainable Development Conceptualized

Although sustainable development is the term to be conceptualized, such conceptualization would be more meaningful if one examines the concept of development first. According to Olatunji (2011); every nation strives for development; this is because development is one of the basic necessities of modern life. Development is a holistic concept; it is multi-dimensional and generally inter-related. It is related to all spheres of life vis-à-vis political, economic and cultural development. Development is a difficult concept to define because it is a relative, ambiguous and complex. According to Walter (1973); development can be examined from two major perspectives: the individual and societal perspectives. At the level of individual, development is the ability of an individual to develop its innate capacities to the extent that he/she would be useful for him/herself and the society. From societal or macro perspective, development could be defined as the ability of a group or a given set of people to harness their physical environment in such a way that life will be easier and better for them. In this respect, a development cannot be worthwhile until it is sustainable.

Sustainable development is a term widely used by political and economic stakeholders all over the world, even though the notion lacks a uniform interpretation (Robert, *et.al.* Thomas & Anthony, 2005). It can be argued that the term is quite relative because the notion of sustainability varies among scholars from various disciplines and the actualization of sustainable development in any nation will cut across various sectors of the society. As early as the 1970s, the word sustainability was employed to describe an economy in equilibrium with basic ecological support systems. The term become popular after it was used by the Brundland Commission in its 1987 Report famously tagged "Our Common Future". In the Report, the Commission coined what has become the most often-quoted definition of sustainable development. The term was defined as development that meets the needs of the present without compromising the ability of future generations to meet their own needs. This definition contains some important elements. A sustainable developed system is that which:

1. Can meet the need of the present generation.
2. Would cater for the rich and the poor.
3. Would not have a devastating effect on present and future human ecology.
4. Would not affect the upcoming generations negatively.

The above definition is similar to the view of the World Conservation Union (1991) cited in Centre for Environmental Education (2007) which sees sustainable development as the general improvement

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

in the quality of life while living within the carrying capacity of the ecosystems. In the words of Solow (1999) cited in Collier & Hoeffler (2004), if sustainability is anything more than a slogan or expression of emotion, it must amount to an injunction to preserve productive capacity for the indefinite future. What could be inferred from the foregoing is that most of the definitions of sustainable development are influenced by either the economists or the ecologists conception with each defining the concept from his/her own basis of understanding. Toman (1999) captures the concept from both economist and ecologist perspectives as: system of positive change in the society which take cognizance of the whole sector of the society and which will not be causing damage to the eco-system for the present and future generations.

Furthermore, the 2002 World Summit on Sustainable Development presented three angles of sustainable development which are: economic development, social development and environmental maintenance. In this perspective, three variants of social development can be inferred. These are: (1) 'social' which includes social development, social progress, and positive social change in terms of general conditions of life. (2) 'human' which has to do with general human development in terms of morals, character and feelings, i.e. development which takes the well-being of the entire human community as important; and (3) "justice and equity" which has to do with social justice, equity and poverty alleviation. This perspective of sustainable development held that development cannot said to be sustainable unless it takes the importance of rule of law, equality before the law and upholding fundamental human rights into cognizance.

In the same vein, attempts have been made by some other scholars such as Toman (1999), Tatyana (2004), and Adebayo (2010) to conceptually classify the important elements of sustainable development into three. These are environmental, economic and social sustainability. With such conception, a social system can be said to be sustainably developed only if such a system can maintain an equilibrium level of development taking those three elements into cognizance. Furthermore, others such as Usman (2013) have suggested possible ways to delineate the concept. For example, the Circle of Sustainability Approach identified four important elements as constituting sustainable development. These are economic, ecological, political and cultural sustainability. Some scholars have gone ahead to include another important element of sustainability known as 'institutional' or 'good governance'.

According to Kundan cited in Ugoh (2008), the concept of sustainable development is the efforts at improving the environment or natural resources for the purpose of improving the quality of human life in such a way that the needs of the future generation are not jeopardized. In this regard, sustainable development is an organizing principle for human life on the planet earth. This author posits a desirable future state for human societies in which living conditions and resources meet human needs without undermining the sustainability of natural systems and the environment, so that future generations may also have their needs met. Sustainable development ties together concern for the carrying capacity of natural systems with the social and economic challenges faced by humanity.

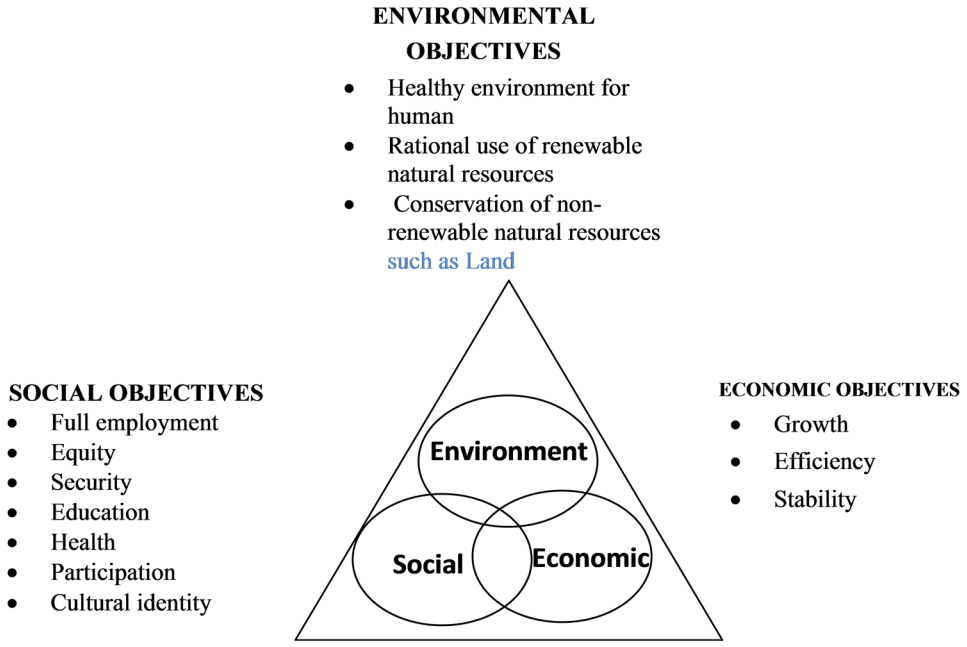
Technically, sustainable development must be able to provide answers to the following questions: What are the needs to be sustained? What needs to be developed? What needs to be sustained is the nature which comprises of the earth, (land) biodiversity, the ecosystems, community (cultures, groups, and places). What need to be developed are the people (child survival, life expectancy, education, equal opportunity; economy, wealth, productive sectors, consumption, society institutions, social capital, states, and regions) are the social facts that needs to be developed. In other words, development can only be said to be sustainable if it take these factors into consideration. It could be deduced from the discussion on sustainable development thus far that the land factor plays an immense role to achieve sustainable development in any human society. This is so because land form an important part of human ecology

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

and as such it is important to note that, a system can only said to be developed if land and its constituted resources are optimally utilized and not negatively affected for the present and the future generations. In essence, land and its constituted resources must be utilized optimally before sustainable development could be achieved in any given society. To further elaborate the importance of land factors in sustainable development process of any nation, some theoretical models are used to explain this further.

THEORETICAL MODELS

In order to make this discussion more scholarly robust, attempt has been made to use some relevant theoretical models to explain the importance of land in the general developmental process of the society. Two theoretical models were adopted in this chapter. These are the Three Pillars Model (TPM) and the Egg of Sustainability Model (ESM).



Three Pillars Model (TPM)

Three pillars model of sustainable development was popularized through the work of Tatyana (2004). According to this model, sustainability is like a structure which needs three important pillars to stand on, this means that some important pillars are necessary as a frame to make sustainable development possible, these three pillars according to this school are: economic pillar, social pillar and environmental pillar. The economic pillar encompasses developmental factors that have to do with economic viability of the people which on the longrun will lead to macro economic development in the society. Other indicators of the economic pillar are economic growth, productivity, efficiency, economic stability and so on. On the other hand, the social pillar includes those areas of living that has to do with socio-cultural dynamics of people's life. This pillar embraces factors such as full employment, equity, security, peace, education, health, popular participation, cultural identity, harmonious relationship among the people of the world, cultural preservation, etc. The environmental pillar includes issues such as healthy environment for human living, rational use of renewable natural resources such as land, and conservation of non-renewable resources.

Adapting this model to our present situation, the model could be used to justify the fact that development is a multi-dimensional phenomenon because it cuts across various aspects of human living vis-à-vis economic, social and environmental spheres. And that it is until the developmental process of a society is able to maintain an equilibrium in all these sectors before it can be regarded as being sustainable. Moreover, it could be deduced from the three pillar model that the land which is an important component of the physical environment is an important factor that determines the sustainable status of development process. In other words, the relevance of this model to this chapter is quite visible in the sense that land is an important pillar or foundation on which sustainable development could be achieved. Narrowing the application of this model to the Nigerian situation, it could be said that Nigeria as a country has not been able to witness sustainable development because it has not fully utilized its land resources. And because lands are not properly utilized, the country is unable to witness rapid and meaningful socio-economic development. The basic conception of the three pillars model is presented in the diagram below.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Diagram showing the conceptual schema of the Three Pillars Model
Source: Tatyana (2004)

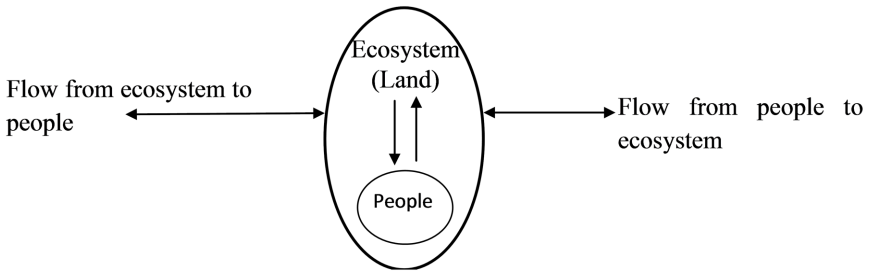
In the triangular relationships among the three pillars, it could be deduced from the figure that environment which land constitutes its major component is placed above the other two pillars. This is an indication to the fact that land constitutes the basis for any meaningful development in any human society. More so, this is a pointer to the fact that land is an important component not only to sustainable development but even to the other two fundamental pillars of sustainable development.

As could be seen from Figure 1 above, The Three Pillar Model presents a perfect theoretical frame for the understanding of the obvious links between societal pillars and the achievement of sustainable development in the society. The model has also been able to bring out the importance of land factor in the attainment of sustainable development of a nation but it fails to emphasize the impossibility of achieving an equilibrium level of sustainability through the three pillars. Despite the above palpable shortcomings, the Three Pillar Model has been able to bring out the substantial importance and relevance of land in achieving sustainable development in any human society.

The Egg of Sustainability Model (ESM)

The second theoretical model adopted in this paper is the Egg of Sustainability Model. This model was built in 1994 by the International Union for the Conservation of Nature (IUCN). The model illustrates the relationship between people and ecosystem as one circle inside another, like the yolk of an egg (Figure 2). This implies that the people are within the ecosystem, and that ultimately one is entirely dependent upon the other. In this sense, social, economic or any form of development can only take place if the environ-

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use



ment offers the necessary resources: land, raw materials, production sites and so on. Making inference from the conception of this model, it could be said that human development is entirely depending on the eco-system in which land is part and parcel of it. In this manner, land is highly crucial in achieving meaningful and sustainable national development in any human society generally and Nigeria specifically. It is the belief of this model that the eco-system and human development are super-coordinated system.

Furthermore, the Egg of Sustainability model is one model which stresses the importance of natural resources (especially land) in the general development of any nation. Another important inference that could be drawn from this model is that the extent at which a state or a country would witness sustainable and meaningful socio-economic development is highly dependent on the level on which such state or society is able to utilize its land and other natural resources. This is because, it seems development is lying fallow in nature (the eco-system) and it is through our ability to explore and utilize these resources that will determine the level of sustainable development witnessed in the country. Adapting this particular idea to the Nigerian society, it could be said that Nigeria is a country that has very great potentials to be a great nation, considering the available natural resources lying fallow within its eco-system. But, because of its inability to utilize these land resources effectively, the country is facing serious socio-economic problems, as millions of its population is living in abject poverty, and the youth unemployment is persistently increasing. In other words, the conception of this model is that if a country such as Nigeria wants to experience rapid and sustainable development, it should be able to put enormous interest on how to develop its land resources effectively.

Generally, the level of relationship between the eco-system and the attainment of sustainable development in a country could be further understood through the diagram presented in Figure 2.

As could be seen from the preceding discussion, the Egg of Sustainability model is used to explain the level of inter-dependent relationships between people and the level of land utilization and also that the achievement of sustainable development in a society is dependent on the extent at which the people could utilize their land resources. However, this model could be faulted on the premise that it has narrowed down the utilization of land to the quality of people's management of it. The model, in this sense, has neglected certain instances where the land resources are not viable to be explored. Besides, some natural occurrences such as drought, desertification, landslides and many other natural occurrences could cause a situation where proper utilization of land would be impossible even if the people are willing to do so. In spite of this limitation, the model is justifiable or useful for the analysis of high level of interconnection between the quality of people as a determinant for proper land utilization and the appropriate utilization of land resources would eventually lead to sustainable development.

FOREIGN LAND ACQUISITION AND SUSTAINABLE DEVELOPMENT: THE NEXUS

The recent intensification of foreign land acquisition in developing countries is triggered by two major socio-economic factors. These are: global food crises of 2007/2008 and global financial crisis of 2008. The global financial crisis of 2008 greatly affected most food-importing countries such as Saudi Arabia, Qatar and United Arab Emirates which hitherto referred to as the Gulf States. One of the reasons these countries are massively affected is because they were tremendously constrained by insufficient land and shortage of water, but rich in capital and seriously in need for agro product. Also, countries with extremely large populations such as China, South Korea and India faced the problem of food insecurity arising from rising rate of population growth. Thus, considering the changing global atmosphere and economic terrain, the agricultural sector clearly requires more investment (Deninger, 2003b).

As a result, there is the need for the Gulf States and countries in the far-East Asia to spread their investment tentacle outward in order to be able to tackle the problem of food scarcity they are being confronted with (Lambin, Geist & Lepers, 2003). And because Africa is a continent with rich arable lands and other physical and natural resources, Africa becomes one of the best regions to explore in this regard. Mbow (2010) argued that African continent became attractive destination for foreign land investors due to its potential and actual richness in agricultural and other natural resources. According to a joint study conducted by the Food and Agricultural Organization (FAO) and the International Institute for Environment and Development (IIED) in 2008, the study found out that since 2004, there has been nearly 2.5 million hectares worth of approved land allocations in just five African countries. These countries are: Ethiopia; Ghana; Madagascar; Mali; and Sudan (See table 1).

Table 1. Land deals in Africa

Recipient Country	Number of Deals	Magnitude (1,000ha)	
		Minimum	Maximum
Ethiopia	26	2.892	3.524
Madagascar	24	2.745	
Sudan	20	3.171	4.8999
Tanzania	15	1.717	11.000
Mali	13	2.417	2.419
Mozambique	10	10.305	
Uganda	7	1.874	1.904
DR Congo	6	11.048	
Nigeria	6	821	
Zambia	6	2.245	
Ghana	5	89	
Malawi	5	307	
Senegal	5	510	
Total (all 27 countries)	**177**	**51.415**	**63.111**

Sources: GRAIN (2008), Von-Braun and Meinzen-Dick (2009) and Gorgen, Rudloff, Ullengerg, & Nath (2009)

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

It could be deduced from Table 1, that African lands have been greatly acquired by foreign investors and many African countries welcome the development probably due to its potential effect on their Foreign Direct Investment. Consequently, some observers such as Lambin *et.al* (2012), Odhiambo (2011) and Daniel and Birhanu (2012) are of the view that such a rush if properly utilized by the host African countries would go a long way in making the African countries to experience massive transformation in its agricultural and other land related sectors of their economy. Some economists such as Sheikh (1978); Smith (2003) and Sheila (2006) regarded this as the engine room or the major drivers of sustainable national development.

In support of the above assertion, Von-Braun & Meinzen-Dick (2009) argued that because of the urgent need for greater development in rural areas and the fiscal inability of the developing country governments to provide the necessary infusion of capital, large-scale land acquisition of land can be seen as an opportunity for increased investment which would result in the creation of a potentially significant number of industries, farms, off-farm jobs, development of rural infrastructure, poverty alleviation programmes, construction of schools, health posts and so on. In other words, foreign land acquisitions have the potential of bringing rapid development to the host communities and appropriate profit to the land grabbers (Cotula, Vermulen, Leonard, & Keeley, 2009).

According to Cotula *et. al.* (2009), agricultural sector has recently drawn renewed attention as the potential source of rapid or massive economic development in the African continent. This explains why most African leaders invite foreign land investors from the Gulf States such as Saudi-Arabia, Qatar, and the United Arab Emirate (UAE) and other areas. For example the South African farmers Organization (Agri SA) recounts that the organization is invited by recipient country governments such as Ethiopia, Madagascar, Sudan, Tanzania, and Mozambique to take over abandoned state farms in an attempt to strengthen the agricultural sector (Goodspeed, 2009; Reuters Africa, 2009). Zaugg (2009) reported that government has offered as much as three hectares of the country's (Ethiopia) most fertile land to foreign investors on concessional leases of 50-99 years. This is in recognition of the fact that attracting foreign land investors to the country would enhance investment; increase the efficiency and land distribution while boosting agrarian productively and capital accumulation (De Soto, 2000; World Bank, 1989).

In Nigeria, communal land acquisitions have a long history. The acquisition of communal lands in Nigeria could be traced back to the conquering period of Usman Dan Fodio. Fodio was said to have been able to extend his Caliphate from the core north across the River Niger (Abubakar, 1980). Many historians such as Milsome (1979) and Usman (1979) are of the view that it was the coming of the colonial masters that thwarted Fodio territorial extension further south (Hunwick, 1966) and Adeleye (1971a). Another major trend in the history of land acquisition in Nigeria is experienced with the coming of colonial masters to the country. One of the major features of colonialism is the forceful acquisition of land by forcefully withholding the right of the traditional authority to land ownership (Walter, 1973). The conception of the colonial masters is that land should be forcefully taken from the native authority because the continued holding of right to land by the native authority would cause a blockade to the general developmental projects which the colonial government would want to embark on. Acquired land during the colonial period were used for several developmental projects such as the construction of roads, housing estates, industrial estates, recreational facilities, hospitals, ports, schools etc.

After independence, acquisition of land is still a common practice. In major cities in Nigeria such as Lagos and Abuja, land acquisition by government has always been a common experience. In Niger Delta Region of the country, many lands were acquired to establish oil companies and many others needed for industrial outfits. For instance, in 1966, Merdermott oil company acquired 50 acres of land

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

near Igbudu in the then Mid-Western State of Nigeria for the company's operation. Other multi-national oil companies such as Mobil, Shell BP, Texaco, among others occupied many communal lands in the region. Although these hectares of land were forcefully acquired from the host communities but it should be noted that such acquisition, according to some observers such as Chan (2003) and Ghatak, Mitra & Mookherjee (2012), led to industrial development of the region. This is so because such acquisition has not only led to increase in the level of oil production in the country but has also led to improvement in the country's Gross Domestic Product. Equally, it has generated millions of jobs for unemployed youths in the region and the country generally.

In 2004, a five-man delegate from the White Commercial Farmers Unions of South Africa and Zimbabwe was invited by the Kwara State government for fact-finding in Kwara State, Nigeria. The visit was expected to last for a week following the completion of their fact-finding; agreements were reached between the two parties for the establishment of commercial farms in the state (Ariyo & Mortimore, 2011). With this agreement, large hectares of land were acquired from the indigenous people in order to develop large scale agricultural set-up in the area.

Also in 2010, a consultant to the Federal Government of Nigeria, Mr. Idiong, stated that the Nigerian government had invited Gulf countries seeking food security to come to Nigeria and invest on farmland (Noah, 2013). According to him, Nigeria has about 71.2million hectares of farmland of which less than 50% is under use. Similarly, a Mexican Agricultural firm (Union De Iniciativa S.A. De C.V) established Banana plantation at Uekan community in Tai kingdom of Ogoni, in the Niger Delta region of Nigeria. Ollan International, an Asian agribusiness firm has also acquired 6,000 hectares of farmland in Nasarawa, Nasarawa State to establish farm plantation. Examples of such invitation are numerous in many states across the federation.

Aruwa (2011) reported that 31,000 hectares of land was acquired in Odogwu, Ibaji of Kogi State of Nigeria for the construction of an ultra modern sugar factory, worth US$510 million, jointly by the Nigeria National Petroleum Corporation, Kogi State Government and international Trans-oil Corporation of USA. This deal is expected to produce about 87 million litres of ethanol for agro-fuels annually, which is highly critical for industrial development (Oyalowo & Kadiri, 2011). Generally, land acquisition has helped the Nigerian government in changing the fortunes of her rural and urban lands at least in the host communities. In other words, it could be inferred from the foregoing that the acquisition of lands for agricultural plantations, construction of factories/industries and the building of basic social infrastructures can bring sustainable national development to Nigeria and Africa in general. This is because of their potential in bringing about an enabling investment which is the fundamental ingredients and critical drivers of socio-economic development which are highly needed in Nigeria.

FOREIGN LAND ACQUISITION IN AFRICA: A CRITIQUE

The above analysis generally highlights the potential developmental prospects of foreign land acquisition in Africa; however, it would be erroneous to conclude on the premise that the above analysis has exposed all sides of the coin regarding foreign land acquisition and sustainable development in many African countries. Although, the above presentation represents the protagonist arguments on the issue of land acquisition, it is however important to present the antagonist view of the analysis. The antagonistic view regarding foreign land acquisition sees the whole practice of land acquisition as basically a capitalist endeavour, a practice which is generally guided by capitalist principles and selfish orientation.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

The investors according to this perception invest in the host communities only to explore the natural resources, exploit the people and cause damage to the eco-system. Land acquisition practices according to this point of view do not on the long run add value to the lives of the host communities, rather it eventually make them worse off.

According to a World Bank report in (2010), the investments been made by the foreign land acquirers are giving almost zero-return back to the host communities in terms of job creation or other socio-economic compensation. World Bank studies (2010) reported that many foreign land investors failed in bringing or generating sustainable benefits to the affected communities; instead, they contributed to asset loss and usually leave the local people worse off. For instance, in Mozambique, foreign land investors established sugarcane plantation, with the promise of generating 2,650 jobs (World Bank, 2010), however, only 35-40 people were employed full time plus some 30 other persons on a seasonal employment basis despite investor's promise of 2,650 jobs. Further, these investors use local water supply and roads without compensation, thus negatively affecting the community main source of water supply (World Bank, 2010). In this regard, there is no gain-saying the fact that foreign land investment deals in most cases failed substantially in providing safety nets for people in many host communities (Behnke, 1994; Lastarria – Cornhiel, 1997; Niamr – Fuller, 1998; Gray & Kwane, 1999).

A similar example could be cited in Kenya where, a plantation farm established by the Dominion Farm disrupted the socio-economic and cultural lives of the people of the host community. The inhabitants of the community claimed that their livestock die from polluted water; women complained of increasing pregnancy miscarriages most likely due to the aftermath effects of pollution, resulting from usage of chemicals such as the aerial spraying of pesticides and herbicides. They equally complained that the farm management has blocked water or diverted some canals causing water to flood their farms and destroy crops (Peter, 2014). In addition, large-scale land acquisition can result in local people losing access to the resources on which they depend for their security and livelihoods. Increased usage of communal land for plantation, construction of factories/industries, schools, hospitals and other basic infrastructures could make the local people to be directly displaced and dispossessed of the land they live on.

Scholars like Arstan, Khalilian & Lange (2011); Von-Braun, & Meinzen-Dick (2009); Oakland Institute (2013); Thaler (2013) have argued that acquisitions of communal lands are likely to cause non-violent or violent social conflict in response to the accumulation and enclosure of their traditional land by the foreigners. Emphatically, the emerging social conflicts may be antithetical to sustainable development. In other words, there can be no meaningful and sustainable development in the atmosphere of social chaos and upheavals, which communal land acquisition could generate.

Sometimes, many inhabitants are displaced during the acquisition and accumulation of communal lands. For instance, in Democratic Republic of Congo, the acquisition of land for maize project by Zhongxing Telecommunication Equipment Corporation ZTE in 2007 led to the displacement of many local farmers. In Liberia, the acquisition of land for rice project by the foundation for African Development Aid and the Libya-Africa Investment Portfolio (ADA/LAP) in 2011 led to the displacement of 30% of the local population without compensation (World Bank, 2010). In Nigeria, rice project in North-Eastern Nigeria State of Taraba has culminated into loss of sources of livelihoods for about 45,000 inhabitants who had to vacate their lands; and the depletion of an important grazing area, Mutum Biyu Gassol Local Government Area of Taraba State, Nigeria (Noah, 2013). In Kwara State, the acquisition of lands by the Kwara State government for South African and Zimbabwean farmers resulted in the eviction of over 400 families and 1289 local farmers in 28 communities from their ancestral lands (Hofstter, 2004; Mustapha, 2010). The import of the above analysis is that victims of land acquisition do suffer some

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

devastating experiences which to a very extent could have a negative feedback on the well being of the affected people. Of which if one reflect back on the essential element of the meaning of sustainability, one would realize that land acquisition experience which follows such sequence have not followed the route of sustainable development. In other words, the critique of foreign land acquisition is of the conception that foreign land acquisition, instead of improving the social situations of the people of Africa is actually contributing to their woes. Such scenario, according to Du Toit & Neves (2007a) has a high tendency of engendering chronic poverty and massive underdevelopment in the Africa region.

By and large, the acquisition of communal lands for developmental purposes has not fully yielded the expected results partly because the land grabbers have not clearly understood the general background characteristics of the affected communities. Thus, it can be logically said that acquisition of communal land for developmental purpose may not bring about the much more needed meaningful and sustainable development in Nigeria if the socio-cultural factors as well as other important background factors of the recipient community or communities are not adequately considered.

FACTORS INFLUENCING LAND ACQUISITION IN NIGERIA

Economic Factors

The economic importance of land is one of its most vital values. The fact that land is an important factor of production has made it to attract remarkable value in human societies. This important factor has influenced land grabbing system in many African societies such as Nigeria. Traditionally, land is utilized for various economic activities such as farming, hunting, grazing etc. The fear of losing such economic activities which are the mainstay of the livelihood of the rural people usually made it difficult for them to release their lands for the government or other interested users. Land acquisition from indigenous people has become a contentious issue in Nigeria because most often, the government would acquire land without compensating the indigenous owners (Famoriyo, 1973). The general economic policies of the government also affect the general structure of the economy. According to Famariyo (1973), structural changes in the economy are likely to have some impacts on land acquisition systems in the society; he particularly observed that the advent of a monetized economy and increased aspirations for material well-being among the people are important economic factors that affect land acquisition system in many communities in Nigeria. More so, a particular community is likely to forfeit its rights over indigenous landed property if the people observe that the proposed project on the land would benefit them economically, or probably that such acquisition has benefited some communities before.

Cultural Factors

So many livelihoods and cultural practices are directly tied to land. Lands are the basis of the economy, and are often the foundation of spiritual and cultural identity (Lambin, *et.al.* 2003). The acquisition of lands for roads, railways, harbours and airports development; construction of hospitals and schools; urban and rural electrification; provision of water and sewage facilities; urban expansion; establishment of national parks; mineral exploration; logging of forests and growth of large agribusiness have the potential of affecting people's important religious or cultural sites and destroying networks of social relations, thereby weakening traditional communal bonds and support. The Habitat Agenda (2012) recognized that

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

indigenous people are socio-culturally attached to their ancestral lands. Consequently, the organization reiterated the rights of the indigenous peoples to their lands.

Specifically, cultural factors influencing land acquisition pattern of a collectivity include traditional norms, beliefs and values, cultural practices, etc. There are numerous cultural practices and sites such as shrines, grazing lands, burial grounds and other places where traditional cultural practices take place. Since these sites have important cultural/spiritual value, it is usually difficult for indigenous people to release such lands for other people who might need it for developmental purposes. Religious beliefs and practices are other cultural elements that influence land acquisition pattern on many African Societies. According to Adedipe *et.al.* (2008), the flexibility of the land tenure system in the Southern part of Nigeria is affected by the religious beliefs of the local people. For example, when communal tenure is associated with religious rites and traditions, it displays a considerable lack of adaptability to rapid change (FAO, 1953). According to Orua & Okoh, (1998), the advent of Christian missionaries during colonial period and the outbreak of the Nigerian civil war (1967-1970) hastened the productive use of hitherto sacred lands and unpermitted foods, and also relaxed gender restrictions on agricultural activities.

Cultural factors are important considerations when land is to be acquired because what might appear as an empty land to a foreigner might, in the real sense, be an ancestral burial ground or religious shrine of the indigenes (Thaler, 2013). Another cultural factor which often influence land acquisition process in Nigeria is inheritance. Many communal lands are usually inherited and because of the high numbers of individuals attached to it, it is often difficult to acquire such land massively because individual needs might differs, and as such while someone might be willing to keep the land for his upcoming upspring, another sibling might be willing to release his/her own portion for commercial leasing and another person might be willing to utilize his or her own portion for any other purpose. Such condition will consequently lead to land fragmentation which often demean the value of the land especially if such pieces of land is needed for large scale commercial activities.

Political Factor

Man has been described as a political animal. Historically, the volume of land owned by a political empire often justify the political-economic strength of such empire, as such most empires often struggle for more lands and that has been the main reason for most of the notable bloody conflicts ever recorded in human history. In Nigeria, this factor has been one of the socio-cultural factors that often influence the decision of the indigenous people to release their land for large scale agriculture and several developmental purpose, some of such people are of the view that the government acquiring their land is indirectly relegating their territorial relevance. More so, the indigenous people are also of the orientation that government often acquires their lands for political reason and that such acquisition will not benefit the people on the long-run. More so, because land arrangement pattern in many communities in Nigeria is generally overlapping and the boundary system is generally porous, such a situation often brings about conflict of interest among the political and power elites of communities when a large portion of land which cut across the boundaries of several communities are to be acquired.

Institutional Factor

Corruption has been an institutional problem in Nigeria. Consequently, several government initiated policies regarding land use and land ownership have been abused while the ordinary citizens have often

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

been misled to develop negative attitude against the government or foreigners who might have genuine intention of using the land for better developmental purpose. In other instances, previous experiences of the local people regarding some foreign land acquirers have made them to be reluctant in releasing their land to foreigners (Kadiri & Oyalowo, 2010; World Bank, 2010). Ojikutu, & Bennett (2012) observed that the practices of large-scale and general land acquisitions require improvement especially on issues that has to do with poverty, social class and many other institutional factors.

Poverty is another institutional social factor influencing people's orientation towards the release of their land for foreigner's acquisition. It was said in an interview conducted by GRAIN, an international Non-Governmental Organization of the United Small and Medium-scale Farmers' Associations of Nigeria (USMEFAN) that "the material poverty of Nigerian small holder farmers is usually exploited by governments and their local and foreign land grabbers." He described the term Responsible Agricultural Investment (RAI) as a subterfuge designed to "hoodwink Africa and make crime wear the garments of salvation" (Obasi, 2012:19 cited in Ojikutu *et.al,* 2012).

Land Tenure System

Land tenure system is a common land ownership system common throughout Africa and this system has been traditionally adopted by many communities in order to control the occurrence of disputes and social conflicts that usually occur as a result of land ownership and control. Land tenure system occurs at varying levels, from individual to group, family to community tenure ownership. However, with the advent of modernization, land tenure system became a problem issue in the general socio-economic structure on many countries in Africa. This is so because the land tenure system often encourages land compartmentalization and fragmentation which often makes the land to become un-wholesome and could not be useful for large commercial uses.

In order to overcome such shortcomings caused by the land tenure system, government often result in forcefully acquiring such volumes of land from the tenure owners so that the land can be used for large scale farming, housing schemes, industrialization or other developmental purposes. Despite the effort towards the eradication of land tenure system, the system still persist in many communities in Nigeria and this has been a cog in the wheel of development of the people in many areas of their life. Commenting on the tenure system in Eastern Nigeria, Aruah & Okoh (1998:19) assert that:

Individual tenure has not been able to meet the rising demand for land, owing mainly to the small size of individual holdings. Except for the provision of land for residential purposes, land requirements for agriculture and related industries cannot be adequately provided for by individually held land. Hence neither productivity gains nor increases in employment opportunities have been achieved through individually held land.

Another dimension from which tenure system could influence the use of land for developmental purpose is when land tenure systems prevent or limit the use of land for credit facilities, in such a situation, even if a farmer has portion of land which he could use as collateral to obtain credit facilities, the rule of the game would deter him/her, thereby limiting the developmental potential of the individual. Migot-Adholla, Benneh, & Atsu (1991) report that for sub-Saharan Africa, one of the negative features of tenure regimes concern restricting the individual holder's ability to transfer land, and even in case of transfer, there is restriction on the categories of persons to whom land may be transferred to.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Land Disputes

Land possesses economic value by virtue of competition for its use between different individuals and groups. Aruah & Okoh (1998) opine that as the area of land per caput declines, the relative value of land rises and land potentially becomes a source of conflict among individuals and communities. Going by the above observation, often times, rivalries and conflict often occur between neighboring communities due to land disputes and when such problem occur, it is often difficult for the government or any land grabber to utilize such acres of land due to the fact that the acclaimed land owners could go any length to make sure that the disputed land eventually become theirs, as a result, tussles in form of metaphysical and physical attack arise. Even though, if such disputed lands are forcefully acquired, there is high tendency that the people of the community will not give adequate security to the project the land is been used for or might be destroying it in order to show their grievances on the project. To Fabiyi & Adegboye, (1977), since title to land in many African communities is often undefined and cadastral surveys are not available, boundary disputes are indispensable. Menkiti (1972) notes that, owing to such disputes, vast tracts of prime agricultural land may be under-utilized while farmers complain of insufficient land. Even if such lands are to be utilized for other developmental purpose, such disputes will make such action impossible.

Opportunities and Risk

This factor is more or less a psychological factor; it is the situation whereby the land owners consider the risk and opportunities available for them when they release their land for commercial acquisition. The idea of opportunity and risk is similar to the utilitarian theory of human behaviour which stress that before human being engage in a particular act, he usually weigh the pros and cons and only take to those acts which he realized that the gains are more than the pains. The pain and gain factor could be used to explain the level of rational thinking of the indigenous people and how such orientation could influence their actions to release or not to release their landed properties for foreign acquisition.

CONCLUSION

This chapter has concerned itself with the issue of examining the nexus among the varying background factors, foreign land acquisition and sustainable development with particular reference to the situation in Nigeria. While land acquisition was considered a critical phenomenon in the quest towards development or to ameliorate the problems of financial crunch or for the purpose of food security, the intervening background factors were seen to be a mediating factor in the attainment of such lofty goals both for the host communities and the land grabbers. In the preceding discussion, critical attempt has been made to bring to the fore the importance of land in general human living. Historically, it has been established that land factor has been an important background factor that has a remarkable impact on the history of humanity. Further, attempt has been made to give conceptual definition of important terms relevant to the study. In order to give a sound backing for the chapter, two theoretical models were presented to explain the importance of land factor in the general process of development and it has been observed through the theoretical explanations that land is indeed an important component to be considered in the discussion on sustainable development.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Furthermore, it was observed in the chapter that land acquisition pattern is not an independent variable as the process and the overall dynamics of land acquisition pattern is influenced by numerous factors ranging from social, economic, political, and institutional and many other relevant factors. The discussion on factors influencing foreign land acquisition is based on the conception that before land acquisitions could be useful for its intended purpose of bringing about sustainable development, there is the need to take the background factors very important. By and large, in order to make land acquisition pattern useful to achieve sustainable development in the country; some recommendations were seen as very important in order to facilitate foreign land acquisition for the attainment of sustainable development in the country.

First and foremost, human being is essentially a cultural being and as such cultural factors are important factors that should be considered when acquiring land from the natives. This is necessary because there is the need to have popular consent before land are acquired, this is further necessary because any land acquired from the people without respecting the socio-cultural features of the people will be tantamount to failure. In essence, it is important that the government and the foreign or local land grabbers consider the socio-economic characteristics of the local people before assuming the ownership of the land. For instance, if a land that is hitherto utilized for religious or spiritual activities is allocated against the wish of the people, such as land might be a source of conflict and rancour between the people and the land grabbers.

Also, there is the need for the government to monitor the activities of the land tenants so that their existence in the area will not be threatening the socio-cultural existence of the people and their activities should not be that which will be causing damages to the eco-system, this is necessary because any developmental activities that is not friendly to the environment would be considered as not being a sustainable development. More importantly, there is the need for the people of the community to be creating a leveling ground for the foreign land grabbers so that the people of the community don't become a threat for their operation. In this regard, there is the need for government to find a way of making the host communities benefit immensely from the acquisition exercise so that such can serve as motivating factor for them and such would also make acquisition easier in other communities in the future. Bye and large, land is an important natural resources which must be given utmost priority by all and sundry due to its importance as the place where human being and other creations as well as non-living things dwell upon; also because it is an important factor which have an enormous influence as a determinant of sustainable development of any nation.

In furtherance of the above recommendations, this chapter also considered the recommendations given by Von-Braun & Meinzen-Dick (2009) on land issue deals is also relevant for this study. These authors recommended that: there should be transparency in the negotiation of land deals, this is very important as one of the major problems of land deals in many African countries is that the transfer arrangement are not only dubious but many at times tricky. Such a situation has led to gross disappointing experience by the host communities which on the long run make the host communities develop a harsh and unfriendly relationship with the land grabbers. In addition to the above, they also suggest sharing of benefits as an important factor to be considered in order to make land grabbing deal work for the betterment of all the parties involved. Going by the model of risk and opportunities or the gain and pain factor, the hosts are very likely to relinquish their rights to land ownership if they observe that the releasing of such land will accrue lots of benefits to the community. However, if they perceive such acquisition as been risky for the community, they are likely to reject the acquisition deal. In other words, land acquisition deals should be structured in such a way that the host community will benefit a lot from the deals.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

However, it is important to note that land is an important aspect of man's life and as such a concept or a fact that needs to serious scholarly attention. Although, this chapter has provided insight into factors influencing foreign land acquisition and sustainable development in Nigeria, it has only examined the factors as practically observed in the Nigeria setting. As such, there is the need to look into many other factors which the author has not mentioned. Similarly, such an effort could also be replicated in many other African countries because; it is observed from reviewed literatures that many African countries are having problems with land acquisition and utilization. More so, this work is a theoretical attempt, some other empirical works needs to be carried out in this direction in the future, such an effort would make one see the issue of land acquisition and utilization from more practical angle.

KEY TERMS AND DEFINITIONS

Acquisition: It literally means to gain possession of something or to establish control over it.

Culture: It means the total ways of life of the people in a particular society. It is the sum total of man's possession comprising language, arts, religion, technology and other attributes which are acquired by man in the society and are transmitted from one generation to another.

Development: Holistic concept used to describe the socio-economic and political transformation in the society.

Foreign: Something from outside a specific jurisdiction; ideas, customs and practices that are alien to a particular territory or society.

Land: It is the earth surface including the sea excluding the sky; it is one of the major factors of production.

Sustainable: Enduring socio-economic and political transformation without destroying the ecological system.

ABSTRACT

CSR is a driver unanimously recognized by companies. This is more important looking to the Horizon 2020 objectives, in which CSR will play an important role. However, at present, there are a lot of theories and regulations about CSR, which are controversial, complex, and unclear. In this confusing landscape, a critical element emerged: the importance of social enterprise as key. The authors, after a brief summary about the main CSR theories and the principal normative aspects to frame the issue, focus their attention on new sustainable models, with particular referring to the social enterprise. The authors base their starting idea on national CSR approach and support their hypothesis of CSR by bringing examples from various countries (United States, Switzerland, Germany) and from important companies. In their conclusion, the authors clarify their idea about the correct CSR approach, introducing the concept of the Gross National Happiness (GNH).

INTRODUCTION

Since the second half of the last century, the debates concerning the CSR theory were numerous (Bowen, 1953; Levitt, 1958; Friedman, 1962; Ackerman, 1973; Evan and Freeman, 1988; Freeman, 1994; Lee, 2008). Initially, this "tool" has been adopted by businesses only as "interface" towards external stakeholders needed of some social input. Today, the CSR represents a key driver for a sustainable innovation: in fact all the modern companies focus their attention not only towards economic objectives, but also towards other kind of these (environmental impact, social address, sustainable and rural development linked to the management of territories and productive contexts, etc). In this sense, the CSR could be considered as a "new behavior" that transform the company's approach regarding the modern market and the stakeholder.

The CSR is based on the valuations, resources and needs of social significance; it is directed to the creation of economic, human, social, and environmental integrated value in long term. This has been confirmed by the crisis period that has underlined the flaws of the modern economic model and society. Nowadays, in fact, the European Union (EU) is faced with an unprecedented crisis. Originated in the Unites States of America (USA), the financial crisis soon became global through complex and subtle contagion mechanisms.

Much has been written about how the financial sector has indulged in mindless risks and how this and the resulting fiscal deficits have seriously afflicted the economy (Allen et al., 2010; Stiglitz, 2010; Battiston et al., 2012). The financial crisis has brought dramatic consequences for economies and societies. Various questions emerge about responsibility for the crisis and, implicitly or explicitly irresponsibility; the obligations to take responsibility for the costs and other adverse effects of the recession; and the nature of responsibility for social welfare and business probity in future national and global governance (Herzig & Moon, 2013). EU's economic and monetary union, understood as a hybrid governance model seeking the reconciliation between centralized monetary policy and national fiscal policy, is subject to many controversies and debates.

In this context, the concept of the CSR and, in particular, the social enterprise as an alternative business model has arisen as a response to the relentless and never-changing economic and political swings. In the last 30 years or more, numerous studies have been dedicated to the relationship between CSR and financial performance (Cochran & Wood, 1984; McGuire et al., 1988; McWilliams et al., 2000; Barnett & Salomon, 2006; Ducassy, 2012). This relationship still gives rise to debate and the results remain controversial, although recent surveys of the available literature give the upper hand to a generally positive relationship between these two variables (Orlitzky et al., 2003; Margolis et al., 2007). Through the CSR application, the enterprises aim to become more competitive, producing wealth and operating in compliance with the environment and the interests of consumers (Margolis et al., 2007). In other words, an enterprise that has a series of objectives, outside the income production, will be more stimulated to reach them implementing and creating new methods and tools helping this purpose. In fact, using the old approach of the company (that linked only to the economic objectives) there is not great space to creativity and inventive because the instruments to reach economic scopes are more or less the same. Instead, through the CSR approach, it is possible to stimulate proper mind to create particular and innovative ideas to reach all the objectives. Inevitably this behaviour will bring a competitive advantage in the market. Moreover, we have to consider that many people give to charities, invest in socially responsible funds, consume "green products" (products that protect the environment and replaces artificial ingredients with natural ones), supply their blood, or give their time and sometimes even their lives for

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

good causes (Benabou & Tirole, 2010). Such social behaviours obey a complex mix of interdependent motivations. An enterprise that invest and aims to these issue, in compliance with the CSR approach, will be more interest for the consumer and it will manage to loyalty them in the long period. In general terms the CSR has been always considered a potential tool for the enterprises to fight the economic critic moments (Morsing & Schultz, 2006) but many authors believe that the CSR has been applied without the right approach (often the CSR is idea has remained closely linked to the theory and have not developed tools to implement it in certain contexts and this has determined the failure of enterprises (Hollingsworth & Boyer, 1988).

The first definition about CSR was in the Green Paper (European Union, 2001, p.6) "Promoting a European Framework for CSR: a business contribution to sustainable development", in which CSR is described as the concept whereby "companies integrate social and environmental concerns in their business operations and in their interaction with their stakeholders on a voluntary basis". Nowadays, the national and international governments have understood the importance of the CSR as tool to going towards the common sustainable objectives in line with Horizon 2020 principles. For instance, In Denmark, the first law on green accounts was passed in July 1995 In 2002 the government strengthened the law (Holgaard & Jorgensen, 2005). Or In 2002, Austrian business organizations and the Austrian Federal Ministry of Economics and Labour decided to raise the awareness of CSR in Austria by formulating a CSR guiding vision for Austrian businesses after consulting a broad variety of stakeholders. (Konrad et al., 2008). Again, Even non-governmental organizations, such as the International Organization for Standardization (ISO), OCED or UN Global Compact where play an important role. These organizations contribute through the production of voluntary standards, to orient the conduct of undertakings towards new models of development. In other words, act voluntarily acting in line with the applicable standards, contributing towards the enhancement of enterprisers' social behaviour.

Summarizing, presently, the CSR is unanimity accepted as important and strategical driver to fight the problems of the modern word: In other words, through the CSR approach is possible to create a sustainable mentality that permit to the companies and the stakeholders to have many tools (not only economic) and objectives. Nowadays, many persons are convinced that the "modern problems", as obesity, extreme globalization, industrial pollution, etc. are the main issues to be addressed. The CSR, changing the behavior of the companies and other economic actors, can contribute to become more aware of these issues in order to deal with emergency In this sense, the development of the social enterprise concept can became the new tool in opposition to the present crisis. There is the necessity to correctly conceptualize this assumption in order to put the right substrate to develop all the CSR framework in a common vision.

On the basis of the illustrated theoretical approaches (Hollingsworth & Boyer, 1988; Margolis et al., 2007; Bernabou &Tirole, 2010) this chapter has been divided in different paragraphs: in the first part we present a short view of two mean CSR theories: Friedman and Freeman. Secondly, we tell the evolution of CSR, analyzing the mean documents written towards Horizon 2020. A single paragraph is dedicated to the normative aspects at international level, determines the different CSR approaches. Finally, in the conclusions, we provide to explain our idea of social enterprise and the possible implications toward a global sustainable perspective.

In particular, the author believes in the Gross National Happiness (GNH) approach. Gross National Happiness is a term coined by His Majesty the Fourth King of Bhutan, Jigme Singye Wangchuck in the 1970s. The concept implies that sustainable development should take a holistic approach towards notions of progress and give equal importance to non-economic aspects of wellbeing: for instance the economic aspects (as GDP) are the same importance of mental health or the time that one person uses to work or

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

sleep In the Bhutan country a GNH index has implemented. This index is a single number index developed from thirty-three indicators categorized under nine domains. Omitting the methodology behind the GNH index (Ura et al., 2012), we want emphasize the theoretical innovative approach that can take his bases from the more big concept linked to the economy of Happiness The economics of happiness is an approach to assessing welfare which combines the techniques typically used by economists with those more commonly used by psychologists. The economics of happiness does not purport to replace income-based measures of welfare, but instead to complement them with broader measures of well-being (Graham, 2005). In this perspective, it is possible measure the Happiness degree inside a country or in a specific context. Through this, it is possible to correct and determine political and economic actions to improve the happiness and consequently develop also economic indicators: a happy population is a productive population (Di Tella et al., 2003). The GNH index uses two kinds of thresholds: sufficiency thresholds, and one happiness threshold. In order to measure the 9 domains of GNH, 33 indicators were developed. Figure 1 briefly shows the domains and the indicators of the GNH index.

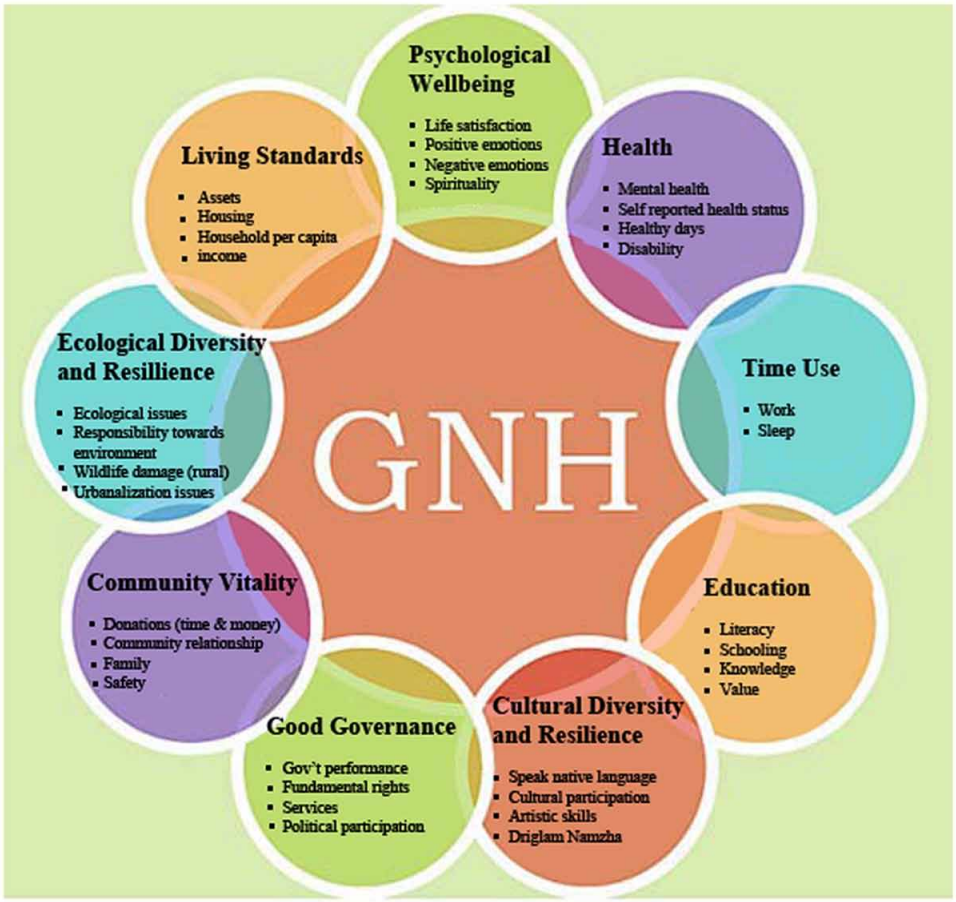
In these general terms, the companies, trough the CSR approach and all instruments linked, can contribute to develop the contest in which the population lives and works. The final scope is enhancing all the system in a sustainable vision (in this sense see Marquis et al., 2009).

THEORETICAL ASSUMPTIONS: A SHORT COMPARATIVE ANALYSIS OF TWO MEAN CSR THEORIES OF FRIEDMAN AND FREEMAN

In the theoretical approach of CSR, the opinion that the modern enterprise has not only an economic and juridical dimension but also an ethic dimension is today worldwide accepted. However, the researchers who are not agreed about the nature of this dimension. In general term, the debate evolves the proponents of "stockholder view", the fans of "stakeholder view" and, finally, the overlaps of both theories (Charreaux & Desbrieres, 2001, p. 109).

We can summarize the first vision with the following sentence: the manager has the moral duty to increase the income of the investors. In the second vision, instead, the manager has to respect all company's stakeholders. Both the theories are agreed that the manager has moral duties but they not converge about what are these.

There have been a lot of discussions about which is the right direction (Moore, 1999; Moir, 2001; Smith, 2003). At the present, all the research is agree only that there isn't a unique solution shared. Furthermore, some theories combine different approaches and use the same terminology with different meanings (Smith, 2013; Angelopoulos et al., 2013).



In this confusion, two theories constitute the base of the theoretical approach: the Milton Friedman's (stockholder view) and the theory of Ronald Edward Freeman (stakeholders view).

Friedman's Theory

The economist Friedman (1957, 1962, 1970) affirms that there is only a CSR, using the resources for activities to increase proper profits, staying inside the "play's rules", in a correct competition mechanism. The managerial decision to sacrifice corporate profits to the attainment of social objectives, such as, for example, to promote employment, eliminating discrimination nations and prevent pollution would then

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Domain and indicators of GNH index
Source: Ura et Alli, 2012.

pave the way to socialism. For Friedman, in fact, only the capitalist system can effectively guarantee the political rights. In this sense, CSR is seen only as a strategic tool to achieve economic objectives and, ultimately, wealth creation.

This thesis assumes that the company is owned by a group of investors who join between them voluntarily pooling their resources in order to reach an increase in their wealth. Given this premise, we can imagine that company does not have ethical obligations beyond those to its investors (Friedman, 1957). Friedman (1970), however, does not deny that management can engage in "Social" consistent, but he believes that it should do so only in strategic perspective, through activities that contribute to increase the profits of the company (by reducing the legal costs incurred in litigation, improving the good reputation of the organization, increasing sales, etc.). Therefore, if such activities (others might call "socially responsible") are not justifiable in terms of a gain for investors, then they should not be undertaken. A well-known approach is that which takes the straightforward contribution to maximizing the shareholder value as the supreme criterion to evaluate specific corporate social activity. Any investment in social demands that would produce an increase of the shareholder value should be made, acting without deception and fraud. In contrast, if the social demands only impose a cost of the company they should be rejected.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Freeman Theory

Instead of focusing on generic responsiveness, specific issues or on the public responsibility principle, the approach called "stakeholder management" is oriented towards people who affect or are affected by corporate policies and practices.

William, M. Evan (1988) and Ronald, Edward Freeman (1990) were responsible for the development of a theory of the firm based on the model of the stakeholders able to offer an account the nature and purpose of the enterprise and the moral claims that this must satisfy.

Advance the proposition that the managers have a "trust - relationship" to a wide range of stakeholders of the company, meaning that suppliers, customers, employees, shareholders and the local community, as well as the management in its role as agent of these groups; those individuals or groups have a legitimate interest or a legitimate claim on the company (Freeman, 1988), since they have invested time and resources in relation to it (Mitchell et al., 1997; Moir, 2001; Crane and Ruebottom, 2011).

This version of the theory finds its basis in the Kant's (2002) moral principle of respect for persons. For the German philosopher "humanity is itself dignity"; man can never be reduced to being treated by the man himself as a mere "means" but must always be treated as an end. The man regarded as a person-Kant argues—is above all price, which can never be regarded as a "half" (or for the purposes of others or for their own purposes). The dignity of man, then, consists of an "absolute intrinsic value" which requires all other rational beings (humans) the respect of both his own person that the person others (with which we are faced at par). From these thoughts you can find the basis for the approach of Freeman.

Therefore, the management treats all stakeholders as equally important and has an obligation against them (Freeman, 1994). Since it is not always possible to meet all the demands of all stakeholders, as some of they may conflict with others - sometimes it can happen that one of the groups' stakeholders can derive, from a particular managerial decisions, economic advantage statement at the expense of other groups.

For Freeman and Evan (1990), if the purpose of corporation and so its organizational structure should reflect the idea of "stakeholder management", the main "structural mechanism" is a Board of Directors composed of representatives of different groups of stakeholders elected by a special shareholders. In particular, the authors affirm that this is possible "with the responsibility to manage the affairs of the corporation in respect of the interests of its stakeholders, thus ensuring the positive resolution of any conflicts" (Freeman & Evan, 1990, p. 339).

Critics to the Theories

Both the theories of Freeman and Friedman had several critics regarding specific terms of the theoretical approaches.

Milton Friedman has often been criticized by liberal economists, especially from the Austrian school. Murray N. Rothbard (2009), anarchy, capitalist thinker, called the theories of Friedman as totalitarian and statist. In particular, he sharply criticized the contradictions in economic thinking of Friedman from many points of view, such as from a monetary point of view, and in general on the central role given to the State.

Friedman is also heavily criticized by journalist Naomi Klein (2007), area progressive Canadian, who in his book "The Shock Doctrine" argues that liberal reforms desired by Friedman and his disciples are applicable only through violent shock that capture public attention.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

The jurist Christopher Stone (2004) was responsible for the critical examination of some of the topics of Freeman's theory that could be adduced in support of the Friedman's position. According to the argument of the "promise", at the base of the obligation of the corporation to shareholders, there would be a moral duty to keep promises and management, at the same time, when he promised to shareholders of maximize their profits. In the opinion of Stone is not possible because few people invest their money in a corporation according to the express promise of the management that it will be managed in such a way to maximize their profit. In truth, few shareholders in America invest their money directly into a corporation.

The philosopher Goodpaster in many works (1991, 1994, 2004) has pointed about the CSR theories and different approaches. In particular, he has criticized the argument put forward by proponents trustee of the multi - stakeholders, according to which managers have a obligation type trustee to stakeholders (other than shareholders), as no proper basis. The unique nature of the relationship between shareholders and management is due to the fact that among them there is a relationship of agency or contract under which "agent" must act in the interests of the "main". It follows that managers have fiduciary duties of a legal nature to the shareholders who have not to the other stakeholders.

Ultimately, both theories have had many critics but also positive judgments, the foundations of which were then developed further theories (Garriga & Mele, 2004). So the CSR study field has grown significantly and today contains a great proliferation of theories, approaches and terminologies (May & Cheney, 2007; Gupta, 2014).

EVOLUTION OF CSR, FOCUSING ON NEW SUSTAINABLE MODELS: STUDY AND ANALYSIS OF MEAN DOCUMENTS WRITTEN TOWARDS HORIZON 2020

Today businesses are increasingly judged by the extent to which they consider the main interests of society. Thus, the concept of CSR has been transformed dramatically: from a pure philanthropic perspective, instead of being merely a legal compliance approach, it has developed into an explicit responsible management issue. Now a third stage of CSR, discussed as Sustainable Entrepreneurship (Intending to a new attitude of entrepreneurs who not only aims at a profit related to the present but to a club, not only economic but also linked to the long-term for their own future and that of future generations), has arrived: in this sense, the main question is the link between the modern companies and their contribute to the present challenges (Schmidpeter, 2014). There are a lot of conceptualization linked to the theory of CSR and the issues connected. In this paragraph we provide to give a synthesis of those that are considered strategic and critical towards the sustainable development (Van Marrewij, 2003; Steurer et al., 2005; Moon, 2007).

Moral Capitalism

The theory of "moral capitalism" starts from the assumption that the crisis has brought to light not only the flaws of the ruling economic model, but also the flaws of our society. Largely, we could describe what happened using the words "lack of morality". When society's laws change in such a way that so many people lose their moral compass, this tells something significant about society.

Zohar (2004), in her book "Spiritual Capital: Wealth We Can Live", said that the Capitalist, the culture and the business practices operating within it are in crisis. The capitalism, as we know it today

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

is unsustainable. So, the Capitalism seems to have changed those who allowed themselves to be enchanted by it. It is also worth remarking that the present crisis represents the most recent and serious consequence of the way in which the importance of ethics and responsibility have been neglected in the decision making process of the business environment

Moral capitalism implies that business people use their decision making power to analyze and balance their own urges, like greed and other temptations. We have in the modern age several examples: The New York Stock Exchange and NASDAQ adopted comprehensive new corporate governance regulations which substantially change the way corporations disclose information to stockholders and the public. The SEC has instituted a requirement obligating CEO's and CFO's of public companies to certify legally that their financial statements and reports are accurate and not misleading-exposing these executives to possible criminal charges if their numbers turn out to be bogus. Many large and small corporations have likewise acted quickly to adopt new practices by approving and implementing revisions to their governance structures, policies, and programs. Moral Capitalism implies an area as large as possible in which the virtue overlaps the self interest (Young, 2009). Moral Capitalism stakes a lot on our human side. It requires us to activate the divine side of this changing world, to use our virtues in order to reorient our passions.

Zohar (2009) underlines that moral capitalism cannot emerge from nothing. It is not possible create a moral and good situation without personal and constant efforts. It is our full responsibility to make good things happen: all the economic actors evolved in a complex context must give proper contribute to develop and enhance the moral issues. Family and society influence the way in which moral norms are acquired and put into practice. People have to learn how to be good.

Adam Smith and Moral Capitalism

Moral Capitalism is nothing new. Adam Smith, the icon of the free market supporters, wrote "The Theory of Moral Sentiments" (1759), a book which was published 17 years before his more famous "The Wealth of Nations". In that book he argues that, when people try to acquire the best for themselves, the individuals also create welfare for others. However, Smith believed that, in business, the individuals are capable of acting in their own interest from the perspective of the whole.

Smith underlined that the essential condition of a fair society is given by the moral character of its individuals. Smith believed that the selfish inclination towards power can be restrained, and he talks about the innate ability of perceiving what the other people feel and wish for. Smith posited, in fact, the creation of a moral capitalism instead of a greedy one.

The markets, states Smith, are the result of negotiations and commercial transactions. He affirmed that by generating jobs and revenue, the markets determine the social welfare, a goal that is not undermined by the self interest.

In his concern for the poor, for the maintenance of the institutions dealing with health, education and infrastructure, Smith believed that there must be a healthy and balanced public sector. He also underlined the importance of prosperous communities, of regulating authorities and of the role that values must play in our lives.

Another important think derived from Carleen Hawn, an economic journalist: he stated that "the spiritual father of spiritual capitalism is not Mahatma Gandhi, or Dalai Lama. It is Adam Smith" (Hawn, 2008, p. 1). After all, there must be a reason why his most famous book is called "The Wealth of Na-

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

tions", not "The Wealth of Individuals". Always in his book "The theory of moral sentiments" (1759), Smith argued that the free market, in which every person is perfectly free to follow own interests in own way, and to use both proper knowledge and capital in competition with every other person, is the best way to create wealth. He also claimed that the benefits of the free market should increase not only the welfare of individuals, but that of society as a whole.

Our Common Future and the Future We Want

The report "Our Common Future" by the World Commission on Environment and Development (WCED) in 1987 seems highly suggest a sustainable development paths ought to provide the impetus—indeed the imperative—for a renewed search for multilateral solutions and a restructured international economic system of co-operation. In other words, in this paper we take conscience that there is no need that the world economy is compared with other topics that relate to social and people first rather than business. There are described a lot of guidelines as examples to going on the development challenge: reviving Growth and Changing the quality of Growth, Meeting Essential Human Needs, Ensuring a Sustainable Level of Population, Conserving and Enhancing the Resource Base, Reorienting Technology and Managing Risk, Merging Environment and Economics in Decision Making, etc. Surly, this is not a simple challenge because cut across the divides of national sovereignty, of limited strategies for economic gain, and of separated disciplines of science. It is clear, in fact, that all nations start from different contextual framework and consequently from different economic path (D'Aveni, 2012); so, it is necessary matching up across these different to the common wealth.

The report called Our Common Future placed environmental issues firmly on the political agenda; it aimed to discuss the environment and development as one single issue. An oft-quoted definition of sustainable development is defined in the report as: "development that meets the needs of the present without compromising the ability of future generations to meet their own needs" (WCED, 1987, p. 41). In addition, key contributions of "Our Common Future" to the concept of sustainable development include the recognition that the many crises facing the planet are interlocking crises that are elements of a single crisis of the whole and of the vital need for the active participation of all sectors of society in consultation and decisions relating to sustainable development.

More recently, the world's leaders of united Nation who met in Rio de Janeiro (2012), in a paper entitled "The Future We Want" agreed to pursue the necessary steps to advance the world towards a more sustainable future. "The Future We Want", was still significant in preserving key principles of sustainable development. In particular in that document nine principles are explained: Political commitment to sustainable development, Reaffirming the 1992 Rio Principles, Reaffirming rights, Implementing existing commitments, Green economy, Sustainable development goals, Reform of the institutional framework for sustainable development, Effects on trade, Regulation of corporations

The Rio+20 conference was a milestone on the long road to sustainable development: At that time it showed up in such priority objectives to renew our commitment to sustainable development, assess the gaps until now, to recognize and address the new challenges. In particular, the topics of discussion are strong sati the Green economy and the institutional framework for sustainable development (Romero & Broder, 2012). Substantially, despite the multiple critics, It cemented support for the agreements reached at the 1992 Earth Summit and renewed the commitment of leaders to put their countries on a path towards improving people's lives today while preserving the planet for future generations. It was a

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

bright moment of international cooperation at a time of profound national and global challenges. Leaders agreed to develop a new set of sustainable development goals, building upon the achievements of the Millennium Development Goals (MDGs) that the UN launched 13 years ago and that have been so instrumental in the fight against poverty.

Sustainable development is not only about promoting economic and social well-being while protecting the environment; it is about working together, across the globe, to responsibly manage the earth's life support systems and ecosystems (Hongbo, 2013). In its broadest sense, the concept of sustainability implies the ability of a process of development to sustain over time the reproduction of global capital consists of the economic capital, human / social and natural environment.

The most widely used definition is the one provided in 1987 by the Independent Commission on Environment and Development (World Commission on Environment and Development), chaired by Gro Harlem Brundtland, according to which: "Humanity has the ability to make development sustainable, that is, to ensure that it meets the needs of the present without compromising the ability of future generations to respond to them."

The central element of this definition is the need to seek an inter-generation equity-type: future generations have the same rights as those of today. It can be seen also, though less explicitly expressed, a reference to equity between generations, i.e. within the same generation of people belonging to different political, economic, social and geographic have the same rights. The success of this utterance, primarily from the ecological, animated international debate, resulting in numerous insights and further development of the concept of sustainability, which over time has been extended to all the dimensions that contribute to development.

The "green economy" a theoretical model of economic development that stems from an econometric analysis of the economic system where in addition to the benefits (increase in Gross Domestic Product) of a production system takes into account the environmental impact that the potential environmental damage caused by full cycle of processing of raw materials from their extraction, through their transport and transformation into energy and finished products to the possible environmental damage that produces their final elimination or disposal is considered one of the important tools available for achieving sustainable development and it could provide good options for policymaker: it should contribute to eradicating poverty as well as promote sustained economic growth, enhancing social inclusion, improving human welfare and creating opportunities for employment and decent work for all, while maintaining the healthy functioning of the Earth's ecosystems.

The Role of CSR in New Sustainable Models

In a world already ravaged by the old policies and methods of exploitation, are more and more new road models related to social sustainability. Social innovation consists of new products, services, and models that simultaneously meet social needs and challenges and create new relationships and collaborations.

An application of particular interest in social innovation is constituted by social enterprises - often as an opportunity for convergence and collaboration between the public, private and third sector.

The added value is compared to a traditional business services in an effort to produce high-relational, in trying to "network" with the experiences of the third sector, to produce positive externalities for the community. The theoretical concept of social responsibility has become known since 1970, although various related concepts were integrated into the scope of organizations and governments since the nineteenth century: in fact, in that period a lot of great companies (IBM, McDonalds, Microsoft, Wall

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Mart, Auchan) started to think about a new approach in their missions. Not more only economic but also social and environmental scopes. As previously mentioned, in the past, social responsibility was mainly focused on the business sector: the companies used it just as a tool to pursue economic objectives (Schmidpeter, 2014).

Economic activities increasingly require more ethical foundations, environment, and social considerations, which are in constant development. The CSR governs the relationships among organizations and stakeholders (Carroll & Buchholt, 2011).

In recent years, many cases showed the importance of CSR/SR, have been demonstrated; a lot of companies start to develop social activities to clients and countries: for instance Pax Cult has donated 10% of profits to a social organization. Cole and Parker helped the developing countries, or again, Hero farm has organized social meetings. At the same time, the negative impacts on individuals, society and the environment have been generated when organizations do not conduct their business in a socially responsible manner think of the companies that exploit children for work or Asian countries where there are exhausting work conditions; or the oil companies that do not respect the environment.

The famous examples of Enron, WorldCom, Adelphia or Savings and Loan demonstrate that CSR is more than an exercise of public relations or a simple marketing strategy (Mills, 2003).

Above all, people constantly look for a sense and a purpose in life. And they want to find them in the very place where they spend the greatest part of their time, at work. They want to work for a good organization, one that treats both them and anybody else with respect (Mitroff, 2008).

The role of leadership is crucial due ethical CSR should not be perceived only from a rational perspective, as a transactional process. It has to reach the emotions of the people. Employees have to regard this kind of action as their natural way of living. Therefore, the organization has to be able to assure a strong congruence between its image and its personality. CSR proves to be an important vehicle (Schiopu et al., 2012).

Leaders and managers must see above their own interests, and should see their role as the one to determine the company to have goals and spiritual values, not just profit. They should also take responsibility for the world in which they operate and where they create wealth. In other words, they have to remember their self that they are, first of all, person that have the primary mission to create common welfare in every form (there are at the present companies that are coming in this direction: think to Google, Danone and Nestlè).

Leaders may give up almost anything—except responsibility—towards their employees and towards the organisation. John Rockefeller Jr. used to say, "I believe any right brings a responsibility; any opportunity, an obligation; any property, a duty" (Maxwell, 1999, p. 50).

There is a pretty prevalent prejudice in the people' mind according to which ethics and CSRcsr translate only into costs for the business community; for this reason, only those companies with a significant cash flow can afford to develop an ethical and responsible behaviour (Solomon, 2001). This prejudice reflects a misunderstanding of the notion of ethics in business. Ethics is nothing else than a kind of charity, dependent on the existence of enough sums of money to be divided among those fighting for a good cause. Ethics, in business, concerns the way in which companies are run and the way in which the reports between the companies and stakeholders are being managed (Ridderstrale, 2007).

Zohar (2009) posits that the CSR is the term that people use when they mean compassion. This think is supported from other authors (Ruiz & Vallejios, 1999; Babiak & Wolfe, 2013). Every corporation is for CSR but they don't usually practice it. But "if somebody really is compassionate, he is going to be much better at relating to your employees and the wider community" (p. 2).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

The true measure of a firm's performance go beyond the profit growth and market share, is connected to the moral values and the ethics values. The business domain has to acquire a moral dimension, becoming more oriented towards services and towards getting value.

The New Paradigm of Social Enterprise

There is no commonly agreed definition of social enterprise, although some author tried to analyze (Dahlsrud, 2008). We want try to give our definition of CSR as a practice which is motivated by the objective of solving social and/or environmental problems, but which uses the tools of capitalism, especially trade, to do so.

The New Approaches of Social Enterprise

Recent work by Sarasvathy and Venkataraman (2011) suggest that entrepreneurship may offer an alternative to the scientific method in solving some of the increasingly complex problems facing modern society. For several authors (Verreynne et al., 2013) Social Enterprise seems to have the potential to improve efficiency and effectiveness by innovating new products, processes, strategies, and/or business models to better meet their beneficiaries' needs. In other words, the Social enterprise represents a new shape of company's behaviour that permit to organize and manage the corporate system in a more efficient way, aims different and precise objectives, not only economics but also environmental and social.

The idea of social enterprise as an alternative business model has arisen as a response to the relentless and never-changing economic and political swings the world has endured over the past two centuries. Since the beginning of the Industrial Revolution, two broad ideological models have been continuously batting against each other for supremacy: capitalism and socialism (Serafinn, 2013). At the present, there are numerous recent applications about this theoretical assumption (for example see Brown, 2014).

"Social Enterprise Alliance" states that the institution of the social enterprise provides us with a viable opportunity to break from this dizzying swing of extremes, and balance the best of all ideologies. It addresses social concerns, more efficiently than government (because this is its principal mission), which no longer has the mandate or resources to solve every social problem; more sustainably and creatively than the non-profit sector, which faces declining funding streams and increased demands for innovation; and more generously than business, which is mandated to place pre-eminence on shareholder returns, but is also realizing it can't succeed in a decaying world (Kai, 2006). A social enterprise has two goals: to achieve social, cultural, community economic or environmental outcomes; and to earn revenue (Galle, 2013). On the surface, many social enterprises look, feel, and even operate like traditional businesses. But looking more deeply, we can discover the defining characteristics of the social enterprise: mission is at the centre of business, with income generation playing an important supporting role. Finally one of the future channels could be the networking (Fulk & Connie Yuan, 2013); in this vision, the new paradigm of the social enterprise will have good develops. Definitively, the social enterprise constitutes a complex and multi-sided phenomenon, which remains difficult to interpret. However we have some empirical examples that permit us to explain why specific enterprises have developed so quickly and will continue to spread.

NORMATIVE ASPECTS: WHAT, AT INTERNATIONAL LEVEL, DETERMINES THE DIFFERENT CSR APPROACHES

The CSR has become over the years an increasingly important role in the global economy and sustainable development. In Europe, the first definition of CSRcsr is contained in the Green Paper (2001) "Promoting a European framework for CSRCSR" (p. 7) in which the Commission shall specify what is meant by CSR. In particular, the focus is on the Companies that "endeavour" to raise the standards of social development, environmental protection and respect of fundamental rights and embrace open governance, reconciling interests of various stakeholders in an overall approach of quality and sustainability.

The common characteristic of social enterprises is that they have a transactional relationship with their beneficiaries, who are either purchasers of the firms' goods or services or suppliers of input (including labor) to the firm. The essence of the theory is that through these transactions, social enterprises gather information on their patron-beneficiaries' ability to transact with commercial firms (e.g., workers' skills, borrowers' creditworthiness and consumers' ability to pay). That information permits social enterprises to tailor the form and amount of subsidies to the specific needs of individual beneficiaries. This "measurement" function makes social enterprises relatively efficient vehicles for allocating subsidies as compared with more traditional donative organizations and with other forms of hybrid organization, in particular firms that pursue CSR policies (Johannisson, 1987)

Nowadays companies come out of its traditional boundaries to establish itself as a social actor and not only as an economic actor, giving a contribution to the welfare of society (Magatti & Monaci, 1999; Mariano, 2005). In other words, we can affirm that all major companies have understood the importance to pursue social and environmental objectives, not only economics. This due the changing of the consumer's behaviour that is more evolved and he looks with positive "eyes" the companies that contribute to the development of these issues. This translates in a major propensity to buy from specific "social" companies rather that other.

In this sense, there are a lot of modern examples of global companies: McDonald's Awards Suppliers for Advancing Global Sustainability Initiatives for instance is a competition in which social and environmental McDonalds suppliers behaviour are evaluated; every year McDonald publish a winner report highlighting how suppliers achieved significant results by identifying opportunities and applying sustainable solutions in diverse places around the world. McDonald's leadership and industry experts recognized sustainable accomplishments across eight platforms: Climate Change and Energy; Water; Waste; Land and Biodiversity; Human Health and Welfare; Animal Health and Welfare; Community Impact and Economics. This initiative had a great success and many McDonald's supplier have enhanced their processes in social and environmental vision (http://news.mcdonalds.com/Corporate/manual-releases/2014/McDonald-s-Award-Suppliers-for-Advancing-Global-Su).

The new Nestlé in Society 2013 report transparently shares the Company's progress and challenges in meeting its 35 forward-looking commitments that cover nutrition, water, rural development, sustainability and compliance (http://www.nestle.com/media/newsandfeatures/2013-csv-report). The report underlines Nestlé's fundamental belief that, for a company to be successful over the long term and create value for shareholders, it must also create value for society. Novartis is implementing continuous programs aiming to fight malaria and other disease in the central Africa (But there are many other examples worldwide).

The culture of enterprise changes towards the affirmation of the culture of CSR. Companies cannot restrict their business in the production of goods and services but must satisfy the needs of all its stakeholders because they are part of the social, economic and political environment in which they live.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

The European Commission in his Communication (2006) "wishes to give greater political visibility to CSR, to acknowledge what European enterprises already do in this field and to encourage them to do more" (p. 2). Commission has announced its support for the launch of an alliance aimed at European companies who are already engaged in CSR or intending to engage in this sense.

Europe has to become a pole of excellence on CSR forasmuch as the "subscription" to such a system can be a valuable contribution to sustainable development and employment.

The European strategy in the field of CSR for the period 2011-2014 was update with the Communication COM (2011) 681. One of the most important changes is the new definition of CSR: "the responsibility of enterprises for their impacts on society" (p. 6). The new definition is definitely wider and more consistent with other international instruments because not only considers the issues of environmental and social as before, but also takes account of the initiatives linked to the respect of human rights, as well as the consumer protection.

There can be two different meanings of corporate responsibility: the first one is the development of products, services and innovative business models that contribute to social well-being and leading to improved quality and productivity of jobs (Porter & Kramer, 2011). The second one is based on risk analysis in order to identify, prevent and mitigate the possible negative effects that the company may have on the surrounding environment (Cruz, 2013).

In the Communication 681 is given a real action plan that the Commission intends to carry out in order to spread the "culture" of CSR (e.g. supporting the transnational company agreements (TCAs) between enterprises and European or global workers organizations). In particular, inside the agenda chapter there are the mean activities that EU intends to bring on to promote the CSR development: give public recognition to what enterprises do in field of CSR. Moreover, the Commission has launched a wide range of programs to work with enterprises and other stakeholders on critical social and environmental issues: the Retail Forum for Sustainability; the EU Platform for Diet, Physical Activity and Health; the Business and Biodiversity Campaign; the process on corporate responsibility in the pharmaceutical industry; the European Food and Sustainable Production Round Table; the University- Business Forum; the Advertising Round Table; and the European Pact for Mental Health and Wellbeing (http://ec.europa.eu/enterprise/policies/sustainable-business/files/csr/new-csr/act_en.pdf)

The norm SA 8000 (Social Accountability, 2001) is the first standard in the international sphere, it is one of the world's first auditable social certification standards for decent workplaces, across all industrial sectors. It is based on conventions of the International Labour Organization (ILO), United Nations (UN) and national law, and spans corporate and industry codes to create a common language to measure social compliance. It takes a management systems approach by setting out the structures and procedures that companies must adopt in order to ensure that compliance with the standard is continuously reviewed. The SA8000 (2001) is designed to certify certain aspects of business management relating to CSR, such as respect for human rights, respect for the rights of workers, the protection against the exploitation of minors, and guarantees a safe and healthy workplace job. Compared with the codes developed by companies (http://www.sa8000.info/) the SA 8000 offers a greater guarantee given by an external audit, carried out by third parties, to verify compliance with the standards. SA8000 is characterized by its flexibility as it can be applied both in developing countries and in industrialized countries, from small and large organizations and the private sector and the public sector.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

The standard was developed in 1977 in New York by Social Accountability International, an organization that brings together international representatives from governments, universities, trade unions, certification and consulting company (http://www.sa-intl.org/). The main motivations, by all the involved organizations, that drive an organization to adhere to the SA 8000 standard could be summarized (Social Accountability International, 2001, p. 4):

- **To Preserve the Credibility and Reputation:** The attention to the surrounding reality, through a system of management of social responsibility, generates a positive image of company, which is reflected in a greater respectability of the mark;
- **Increased Confidence by Consumers and Social Organizations:** The confidence of the stakeholders is enhanced by the demonstration of compliance with the ethical and social principles;
- **The Improvement of Relations with the Institutions:** Compliance with the requirements of social responsibility facilitates relations with the institutions;
- **Control of Ethical and Social Correctness in the Supply Chain:** The company, through the eye of an independent third party accredited, shows that social responsibility principles are respected in the whole chain of suppliers and sub-suppliers;
- **Improvement of the Business Climate:** Workers feel protected by the company in which they operate. Companies assume commitments to the continuous improvement of working conditions and feel more involved in the achievement of corporate objectives.

The SA8000 includes eight requirements that must be met by the company seeking certification and which are related to the fundamental human rights of workers. In other word, through the regulation of this document it is possible to follow the correct guidelines in the relationship with the workers. Through the respect of these requirements the company can obtain certification with which it is shown that the organization meets the requirements social responsibility of the norm (Casotti, 2005).

The certification SA 8000 (Social Accountability International, 2001, pp. 5 - 8) social thus provides for the satisfaction of eight social requirements relating to:

1. **Child Labor:** It is forbidden the exploitation of child labor.
2. **Forced Labor:** It is forbidden to get a service through the use of threats or demand for money.
3. **Health and Wealth at Work:** The firm must comply with the minimum standards for a safe and healthy working environment, must try to prevent accidents and diseases minimizing the causes of hazards inherent in the work place.
4. Freedom of association and right to collective bargaining should be allowed the right to join or create a union and to require a collective agreement without generating retaliation or intimidation towards workers.
5. **Discrimination:** There should be no discrimination of race, caste, national origin, religion, disability, age, gender, sexual orientation, union membership, or political.
6. **Disciplinary Procedures:** Corporal punishment, coercion, physical and mental, the injury to workers are punished.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

7. **Working Time:** It must be that one established by the legislation in force.
8. **Remuneration:** The remuneration shall comply with the minimum legal requirements (Social Accountability 8000, 2008, p. 5).

The ISO 26000 (Social Responsibility. International Standard Organizations, 2010) represents a new standard for CSR and constitutes a "guide on CSR" (http://www.iso.org/iso/home/standards/iso26000.htm) which aims to empower all types of organizations about the impact of their activities on society and the environment. This is not a standard certification but a guide to harmonized principles and translate ideas into effective action, improving already developed best practices and helping to disseminate it for the benefit of the international community.

Accountability, transparency, ethics, respect for stakeholders, law enforcement, international standards of behavior, and human rights are the main elements proposed by this new guide, with these great thematic it is possible to develop in concrete the approach of Social Enterprise (Social Responsibility. International Standard Organizations, 2010). After a long bureaucratic process which lasted five years and involved representatives of one hundred forty countries and international organizations, the ISO 26000 was approved with 94% of the vote. ISO 26000 does not replace the existing social responsibility activities, but will help to further enhance them. A company that voluntarily adheres to the ISO 26000 guidelines get several benefits, including: competitive advantages, reputation, ability to attract and retain workers and customers, maintaining motivation, commitment and productivity of employees, obtaining a complete overview of investors, shareholders, donors, sponsors and the financial community, better relationships with corporations, governments, media, suppliers, peers and communities in which the company operates.

The ISO 26000 is useful for any kind of organization; it provides guidelines to explain the main characteristics of CSR: concepts, terms and definitions, orientation and characteristics, principles and practices related, subjects, issues and key topics, integration, implementation and promotion of socially responsible behavior within the enterprise and its sphere of influence, identification and involvement of stakeholders, commitment in the Communication of CSR (ISO 26000, 2010).

The main intent of the standard is to assist the organization in contributing to sustainable development. The ISO 26000 also encourages companies to find new instruments and initiatives to develop social responsibility. The guide proposes seven main themes to which every organization should pay attention. These themes presented in the text of the guide through specific sections are: the organization; human rights (with all the issues of discrimination, civil rights, political, economic, social and cultural principles and rights of workers); work practices (including the relationships among the employees, working conditions, social dialogue, health and safety in the workplace, the update for employees); the environment (pollution prevention, use of renewable resources, commitment to the issue of climate change, protection of the environment, biodiversity and restoration of natural habitats); good practices (anti-corruption, fair competition, promotion of social responsibility in the value chain, respect for the right of ownership); consumers (the promotion of marketing strategies loyal, real information and objective, fair contracts, pay attention to the health and safety of consumers, sustainable consumption, attention to service, complaints and problem solving, data protection and compliance consumer privacy, easy access to key services, attention to education and consumer awareness); the involvement and enhancement of the community (employment creation and development of the main resources of the area, development of technology, creation of wealth and income, halth and social investment

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

CONCLUSION: FROM GROSS DOMESTIC PRODUCT TO GROSS INTERNAL HAPPINESS

About CSR

The CSR (CSR) has increasingly attracted the interest of researchers from various disciplines from the start 1960. The statistics of journals and authors show that CSR issues have become a hot topic since 2000. Moreover, since 2005, many authors worldwide have published hundreds of CSR papers every year (Kotler & Lee, 2005; Maignan et al., 2006; Windsor, 2006; Maak, 2007; Porter & Kramer, 2006; Wanderley et al., 2008; Lindgren & Swaen, 2010).

Social responsibility is defined by the European Commission as "a concept through which companies integrate social and environmental concerns in their business operations and in their interaction with stakeholders on a voluntary basis" (European Commission, 2011). Now the CSR represents perhaps the most important social and human objective for the European Union in the next future. In this sense, the EU's communications are very numerous (COM (2001)366; COM (2006)136). Looking at the Horizon 2020 explain, European Union has declared (2011) that CSR could become the key driver for a real sustainable future (European Commission, 2006).

Starting from this definition we can say that CSR is a whole business culture including business ethics, consumer rights, economic and social equity, technology which do not affect the environment, fair treatment of workers, transparent relations with public authorities, moral integrity and community investment.

CSR is a critical theoretical framework considered in the academic, scientific and especially in the business world. There are a lot of interesting aspects and topics around the CSR issue. In this chapter we have tried to focus the attention in several of them: firstly, we have wanted underline how the different CSR theories have generated a long debate that is still open today. Starting from the two main theories (Friedman, 1957; Freeman, 1990) we can conclude that today the world if dived in two big groups regarding CSR: a first group is composed from so-called "extremists" persons. These would like to institute a compulsory CSR not only among the world companies but also in all contexts. On the other hand there are "skeptics" who do not believe absolutely in this instrument except as a "mask " to produce a "corporate conscience" which can then be resold. Finally, we can individuate a third group, external from the debate: those persons who advocate that the CSR is really taken by all companies, and all entities in general, as the foundation for any governance aimed at the development of the first human capital.

A particular aspect in which we strongly believe, as authors as well as persons, is the institution of the social enterprise (Centre for Community Enterprise, 2013). This aspect is very interesting because provides, with a viable opportunity, to break from this dizzying swing of extremes, and balance the best of all ideologies. It addresses social concerns, more efficiently, more sustainably and creatively, which faces declining funding streams and increased demands for innovation, proof of what works and collaboration can be make together (Social Enterprise Alliance, 2013).

In general terms, the CSR should be an expression of the small and medium-sized enterprises' idea of a concept whereby companies decide voluntarily to contribute to a better society and a cleaner. This means not only fulfilling legal expectations, but also going beyond compliance and investing more into human capital, the environment and the relations with stakeholders.

Our desire is that all the companies, facing to the challenges of a changing environment in the context of globalization and in particular the Internal Market, believe that CSR could be a strategical driver to

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

generate economic added value. Although the prime goal of a company is to generate profits, at the same time, they can contribute to social and environmental objectives, through integrating CSR as a strategic investment into their core business strategy.

A company, to be competitive on the market and to overcome moments of crisis, cannot act just in the interest of the shareholders, but must take into account the needs of all those who work, buy, contract, choose and decide in the market.

The use of CSR is not only a cost, but also an effective competitive tool which the companies can use to distinguish themselves and, if possible, stand out on the market. The company which demonstrates to be in compliance with certain environmental and social standards, in fact, has several advantages with regard to access to credit, participation in tenders, purchase of its products by consumers, which are reassured by trademarks and other signs testifying the virtuous conduct of the enterprise.

The same system of free competition requires to the company to establish and maintain the confidence gained in the market, taking a more responsible behavior in economic, environmental and social terms.

The elaboration of standards poses the problem of building a shared platform that can be applied and controlled in a uniform manner. In this direction, at the international level, the creation of a global standard commonly accepted is being proposed.

The CSR is a notion that includes a lot of activities that take place inside and outside of the organization. Beyond the speeches launched by different organization representatives, what really counts is the practice (Carroll & Buchholt, 2010). The CSR is not achieved only with the participation of one person or a small group of people. We need a whole community to act in this direction, starting with the CEO and going down to the shop worker.

There is now recognition that Maximizing GDP is not the same as maximizing wellbeing (Stiglitz, 2010), in fact, through the GDP is possible just to delineate an economic profile of a particular context or situation, while, if we want considering the welfare level or profile, we have to use other indicators. The level of Gross Domestic Product (GDP), a frequently used indicator of economic development, naturally suffers at the expense of increased leisure.

Sustainable technologies (that tools and electronic operations that have a good impact regarding social, environmental and sustainable issues) are yet to be widely implemented, and the global community trumpets the need to achieve higher levels of human development—defined as expanding people's choices—countries tend to be short sighted in helping their economies to provide now, rather than in the long-term. The CSR (CSR) is a great tool that can permit to create a revolution, now possible, to try to attack this problem.

About Our Idea

Concluding, is our opinion that, in face to this great world crisis, CSR could represent a key element for a sustainable future in which the main importance is given to the so-called Gross National Happiness (GNH) rather that to the Gross Domestic Product (GDP). First of all, in fact, The modern society is asking for new values, especially linked to the well-being status and not just linked to the economic indicators (Diener & Seligman, 2004). While there is no single official definition of GNH, the following description is widely used:

"Gross National Happiness" (GNH) (Ura et al., 2012) measures the quality of a country in more holistic way [than GNP] and believes that the beneficial development of human society takes place when material and spiritual development occurs side by side to complement and reinforce each other.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

The GNH is based in a moral principle that there are important issues beyond economic and productive ones. The general aims of the GNH approach are:

1. Setting an alternative framework of development;
2. Providing indicators to sectors to guide development;
3. Allocating resources in accordance with targets and GNH screening tools;
4. Measuring people's happiness and well being;
5. Measuring progress over time; and
6. Comparing progress across the country (Ura et al., 2012).

The GNH Index is based on a survey of 7142 people which was completed in all 20 districts of Bhutan in the year 2010 and is representative by rural and urban area and by districts or Dzongkhags.

The GNH can be considered as the next stage in the evolution of economic indicators for sustainable development, going beyond merely measuring values that can be expressed in money. GNH is an attempt to develop an indicator that accounts for all relevant values on this planet, including happiness. Moreover, by taking happiness as the objective, GNH serves as an important yardstick for a framework of Buddhist economics. Breakthrough research in quantum physics, medicine, biology, behavioral science, psychology and cognitive science, the science of the mind is more making relevant to economics. Conversely, within the profession of economics, many attempts are being made to broaden the scope of economics into the domain of psychology, which led to the emergence of economics and neuron-economics behavioral (Overbeeck et al., 2013). Summarizing, in this chapter the authors wanted to give a brief description of the CSR's theory and the normative aspects. In particular, we emphasized the new paradigms linked to the sustainable models the modern world requires. In this context, we used the GNH as examples of success to fix the mind of the companies and the other economic actors towards new approaches that have to be created to growth towards different objectives not more exclusively linked to economy issue but also to other aspect, as social and environmental ones (Brooks, 2013). In this sense the tool of CSR and its different approaches could represents a right path to a sustainable future (Christensen et al., 2007). The different examples reported from examined countries and companies confirm there is possible to create a new strong consciousness that, together a volition, could bring to a sustainable future.

KEY TERMS AND DEFINITIONS

Corporate Social Responsibility (CSR): Form of corporate self-regulation integrated into a business model; ensures its active compliance with the spirit of the law, ethical standards and international norms.

Environmental Development: Another kind of sustainable development focused on environmental, climate, and biodiversity objectives.

Gross National Happiness: Concept implies that sustainable development should take a holistic approach towards notions of progress and give equal importance to non-economic aspects of well-being.

Horizon 2020: Horizon 2020 is the biggest EU Research and Innovation programme. It promises more breakthroughs, discoveries and world-firsts by taking great ideas from the lab to the market.

Life Models: Models and styles to improve proper life and draw a specific purpose and activities.

New Sustainable Development Models: New models that, in a global common vision, ensure a sustainable development for the next young generations.

Social Enterprise: Organization that applies commercial strategies to maximize improvements in human and environmental well-being, rather than maximizing profits for external shareholders.

This research was previously published in Empowering Organizations through Corporate Social Responsibility edited by Ruth Wolf, Theodora Issa, and Monica Thiel, pages 166-190, copyright year 2015 by Business Science Reference (an imprint of IGI Global).

Chapter 67
Sustainability Criteria for Tourism Attractions:
A Case Study of Germany

Michael C. Ottenbacher
Heilbronn University, Germany

Sina Schwebler
Heilbronn University, Germany

Daniel Metzler
Munich University of Applied Sciences, Germany

Robert J. Harrington
University of Arkansas, USA

ABSTRACT

With the start of mass tourism in the 1980s, comprehensive concepts were developed not only to optimize these positive effects but also to minimize the negative impacts of tourism on the environment (Garrod & Fyall, 1998). Problematic with the development of these concepts is the variety of approaches, each with different emphases, as well as the diverse interpretations of the term 'sustainability' (Losang, 2000). However, the topic of sustainability will be one of the drivers of future tourism development and will further increase in significance (Lohmann & Aderhold, 2009). In response to the growing importance of sustainability, the government of the federal state of Baden-Württemberg, Germany, intends to implement and facilitate a sustainability check for tourism attractions. The aim of this study is to provide insight into the perception of sustainable tourism, to examine the ways how to implement it in tourism attractions in Baden-Württemberg and to determine specific sustainability criteria. Semi-structured interviews were conducted with 18 experts of the tourism industry in Germany to better understand the requirements and expectations of such a sustainability check. The results of the interviews revealed that, in general, there is strong support for the government to implement a sustainability check for the highly diverse tourism attractions within the entire state. In this context, the interviews indicated the difficulties and individual particularities which would have to be considered when implementing a comprehensive sustainability check for different types of tourism attractions. The operationalization of the sustainability concept, such as ecolabels and guidelines, builds the foundation for the implementation of sustainable development.

INTRODUCTION

According to Enzensberger (1964), tourism destroys what it seeks, indicating emphatically that tourism and the carrying capacity necessarily have to be reconciled. The rise of income in large parts of the western industrial countries together with the reinforced global transport network which are mainly conditioned by the increase of disposable time, has caused the tourism sector and especially the number of arrivals to increase enormously since the 1980s (Mowforth & Munt, 2009; Bieger, 2006). Similarly, to other mature industries, the tourism sector's fordistic modes of production were established as a result (Smeral, 2005). Tourism destinations, suited to these 'economies of scale', were little but partially accommodated to the regional circumstances and frequently led to transgressions of the regional carrying capacities (Hall, 2008). In this context, the concept of carrying capacity refers to the number of tourists that a destination is able to accommodate without negative impacts on the environment, the society and the utilization of renewable resources (Telfer & Sharpley, 2008; Hunter, 1997).

However, parallel to these progresses an awareness for the negative impacts of tourism emerged. Up to that point the focus was on the positive (mostly economical) impacts of tourism, but little by little the negative impacts on the environment, the population and the culture were also examined within a sustainable development of tourism (Steinecke, 2006). With the accession to the political Agenda 21 of the government representatives of 182 nations, at the UN Conference on Environment and Development (UNCED) in Rio de Janeiro in 1992, the term 'sustainable development' was officially stated (Baumgartner, 2008). Based on this conference, the term was manifested as a leading concept for miscellaneous future-oriented strategies (Luft, 2007). Since then many governments have embraced sustainability "as their fundamental development policy" (UNWTO, 1998, p. 21).

Thus, the 2011 newly elected federal state government of Baden-Württemberg in Germany determined the realization of the concept of sustainability as one of their guiding principles including the sustainable tourism development of the region. In response to the growing importance of sustainability, the government of the federal state of Baden-Württemberg (BW), a significant tourism destination within Germany, intends to implement and facilitate a sustainability check for tourist destinations and attractions. Earlier research has indicated a need to utilize holistic and more collective approaches to sustainable tourism to promote its objectives. These approaches represent substantial gaps in the literature and have been suggested for both future research and practice (Bramwell, 2011). Therefore, the aim of this study is a) to provide insight into the perception of sustainable tourism, b) to consider its different operationalization approaches, to examine the ways how to implement it in tourism destinations or attractions and c) to determine specific sustainability criteria in the context of regional sustainable tourism practice.

LITERATURE REVIEW

Sustainable Development and Tourism

With the publication of the report 'Our Common Future', by the World Commission on Environment and Development - also known as the 'Brundt-land-Report' – the term 'sustainable development' was coined (Becker et al., 1996; Ritchie & Crouch, 2005). Since this release, sustainability has been one of the central themes of discussions on tourism and management policies (Saarinen, 2006). A sustainable development herein is defined as follows:

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Sustainable development is development that meets the needs of the present without compromising the ability of future generations to meet their own needs (United Nations, 1987).

This 'concept of a sustainable development' on a scientific and a political level has been considered as the essential merit of the Brundtland-Report which brought it to the attention of a much wider audience (Mundt, 2011). Nevertheless, "the commonly accepted definition of sustainable development … has not been translated effectively into action" (Butler, 1998, p.31). The discussion on sustainable development was first really taken further by the United Nations Conference on Environment and Development (UNECD) in Rio de Janeiro in 1992, popularly known as the 'Rio Earth Summit' (Berry & Ladkin, 1997). Due to this conference and the emerged global action plan, called 'Agenda 21', a particularly influential basis for implementing sustainable development on a local, national and international level was outlined as a global paradigm (Miller & Twinning-Ward, 2005; Spenceley, 2008). The basic idea was that the municipality level, featuring residents and representatives of industries and organizations, should scheme for the next century based on the Rio declaration (Aronsson, 2000).

Even the movements towards certifications of tourism enterprises emerged as a result of the Agenda 21. It initially emphasized the need for all kinds of businesses to mitigate global environmental problems and to comply with environmental regulations and policies (Sasidharan et al., 2002). Especially with the commencement of mass tourism in the 1980s, comprehensive plans have been elaborated simultaneously to minimize the negative tourist impacts and to maximize its positive effects (Steinecke, 2006). One problem in the development of these concepts is the variety of approaches. With the diverse range of interpretations and viewpoints (e.g. Soft Tourism, Ecotourism, Qualitative Tourism), it is not surprising that there is little agreement on the definition of sustainable tourism (Mowforth & Munt, 2009). Butler gives an overview of different definitions and points out that "one result [of the many definitions] has been that the wide acceptance of the term (…) in many cases is simply acceptance of the phrase but not its implications" (Butler, 1999). Despite the theoretical foundation the adapted forms of tourism largely represent marketing-oriented niche approaches (Losang, 2000). A serious environmentally friendly and socially compatible meant tourism cannot be reduced to a niche segment. It is not a safe assumption that fordistic forms of tourism are necessarily unsustainable. It is rather naïve (and might be harmful) to believe that e.g. nature-focused tourism is always sustainable. It could be argued that small-scaled tourism development of tourism has less impact than other forms, but very often those small-scale development are located in sensible environments with high vulnerability and low carrying capacities. Even though the effects might be small on an individual tourist level, in toto the impact might severely damage reproducibility of the social, economical and ecological systems (Butler, 1999). Therefore the concept of sustainability not all has to incorporate all three dimensions but also the location endowments and carrying capacities.

However, this is not the case in an enormous number of concepts (Becker et al., 1996). Only with the development of 'sustainable tourism', which is based on the extension of the concept of 'soft tourism' by the triple bottom-line sustainability, a holistic approach has been created to reduce the above mentioned impacts (Losang, 2000; Schianetz et al., 2007). According to the World Tourism Organization 'NWTO', 'sustainable tourism' is about considering the current and future economical, social and environmental impacts and needs to address the needs of visitors, the industry, the environment and the host communities. In order to achieve a sustainable development of tourism, it is necessary to consolidate the environmental, economic and socio-cultural aspects, in which all three dimensions will be brought into line (UNWTO, 2012). From the UNWTO's perspective, one cannot assume a fundamental social

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

change as it already established. In fact, a holistic management is necessary in order to be able to implement a sustainable development (Baumgartner & Röhrer, 1998).

Due to the increased nature of travelling, accompanied by the negative effects of tourism, there is a need to create sustainable tourism products. Only by preserving the authenticity of the experience and the quality, tourism will continue to be a successful industrial sector on a national level (Lund-Durlacher, 2007). Although numerous destinations and regions are already affected by the negative impacts of tourism, the number of travelers is unlikely to decrease significantly, due to their individual needs and their satisfaction (Buckley, 2012). However, this brings about the need to prioritize sustainable tourism products and to create a preference for services among travelers (Lund-Durlacher, 2007). In this context, numerous operational approaches have been developed for the support and the documentation of sustainable development.

Operationalization Approaches of Sustainability in Tourism

The functional elements of the sustainability concept, such as ecolabels and guidelines, build the foundation for the implementation of a sustainable development. Only the formulation of assessable measurement parameters can ensure the evaluation of the achieved objectives (Losang, 2000). "The need for performance indicators in plans and management strategies for tourism development has been noted by several scholars Getz (1982), Gunn (1994), Inskeep (1991) and the World Tourism Organization (1993) (…). Without such indicators, the use of "sustainability" is useless." (Butler, 1999). In many cases due to imperfect markets in tourism, where often markets fail to incorporate externalities and the nature of public goods prevents resources of being allocated efficiently, government intervention might be necessary (Blake & Sinclair, 1999). Even if the focus of tourism development is necessarily the local level (Middleton & Hawkins, 1996), especially in the case of consumer protection (and information) as well as standardized monitoring systems supported by national an regional governments may well be advocated. In recent years, many comprehensive indicators have been developed, which help to attain the requirements placed on the possibilities for the evaluation of sustainable tourism development. However, there has been a necessary distinction between the indicator systems, which form the basis for planning-related decisions; certification schemes, which represent the foundation of labeling and labels themselves (ibid.).

Indicators and indicator systems have a long tradition. An indicator (from the Latin "indicare" for "to indicate") describes a measurement parameter of facts that cannot or can hardly be measured themselves (Schnorr-Bäcker, 2007). They essentially have the functions of simplifying, quantification and communication (Baumgartner, 2008). An indicator system is a set of different key figures that intends to give information and indications on certain topics (Schnorr-Bäcker, 2007). Thus, they are measured or monitored for the detection of a changing status of a particular phenomenon (Angelevska-Najdeska & Rakicevik, 2012; Miller, 2001). These facts can be used during all phases of a planning and decision making process and to help understand the current status. They can be applied for the analysis and the explanation of tangible problems as well as for monitoring; but, they also serve as a means of predicting the impacts and developments (Roberts & Tribe, 2008).

Indicator systems are often very closely connected to a sustainable development. Thus, besides the living and working conditions in a region or country also the potential of economical progress, with regard to sustainability and social justice are staying in the focus. However, the scope of the systems and the number of indicators varies considerably (Schnorr-Bäcker, 2007). Indicators of sustainability

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

must also take into account the interconnectivity of tourism systems besides the elements of traditional indicators (Roberts & Tribe, 2008).

Indicator-based measurement of sustainability in tourism is criticized by several scholars. Main topics of concern (Castellani & Sala, 2010) are (1) vague and arbitrary definitions making a common set of indicator with respective targets impossible. (2) There is no globally accepted conceptualization of sustainable tourism development, rather those concepts are influenced by local settings with different environmental, economic or social conditions. (3) Indicator-based measurement of sustainability also struggles with the long-term view, making data availability challenging and very often data on several aspects, e.g. quality of life are missing. Basically, the majority of indicator approaches is oriented towards the general guidelines of sustainability reporting which are implemented not only by the tourism industry, but also by many other companies and industries. Further, companies in various industries are increasingly recognizing the benefits of a sustainable economic management and therefore are integrating the concept of sustainable development in their business strategy. There is also a proliferation of interest by the stakeholders for information on how and which areas the three dimensions of sustainability can be implemented. In response to these changing expectations, companies are increasingly releasing a sustainability report (Clausen et al., 2002).

A key success factor of sustainability reporting is credibility. Systematic sustainability reporting gives comparable data with agreed disclosures and metrics. Although sustainability reports are voluntarily published by the company and do not have to correspond to a generally standardized form; specific principles should receive attention during the creation (Clausen et al., 2002). These principles and guidelines have been developed by different approaches and initiatives in recent years. Also in this context, governmental institutions might be of help with their reputation. As one of the most important players, the Global Reporting Initiative (GRI) needs to be considered (Gries, 2008).

With the "Global Sustainable Tourism Criteria*"* there has been close attention paid to the indicator system respective of a code of conduct specifically developed for the tourism industry (GSTC, 2008). It has set itself the goal of promoting the operations of sustainability in tourism by a credible measurement and communication. In 2007, the Global Sustainable Tourism Council (GSTC) began as a coalition of over 40 organizations with the development of criteria and now is considered a global leader in the field of sustainable tourism. The global initiative is committed to promote a sustainable, economically fair and responsible tourism that respects the environment and the society (GSTC, 2012 a). The criteria and indicators of the GSTC were developed on the basis of already recognized criteria and approaches. These include the UNWTO indicators for destinations, the GSTC set of criteria for hotels and tour operators and other recognized principles and guidelines, certification criteria and indicators (GSTC-Travel Forever, n/s). According to the company, the initiative had a close look at over 60 existing regulations during the development stage with a total of 100,000 experts being called to state their position on more than 4,500 criteria which then needed to be analyzed (GSTC, 2008). That way, possible indicators could be examined for their relevance and practicability and also for their applicability in a variety of destinations. With this information the GSTC developed the global criteria for sustainable tourism (GSTC-Travel Forever, n/s).

To correspond to the definition of sustainable tourism, destinations have to follow a multidisciplinary, holistic and integrated approach which contains criteria of the following four main objectives: demonstrate sustainable management; maximize social and economic benefits to the host community and minimize negative impacts; maximize benefits to communities, visitors and cultural heritage and minimize negative impacts; maximize benefits to the environment and minimize negative impacts. The total of 45 criteria of these four areas should lead to a common understanding of sustainable destinations.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

They represent minimum requirements which should represent a target for any tourism management organization aiming for sustainability.

The GSTC strives not only to develop and to establish a worldwide standard of tourism criteria for the implementation of sustainable development. Rather, one of the GSTC's main tasks is to synchronize numerous certification programs in the existing market (Rainforest Alliance, 2012). Over time, requirements and standards have been set for the identification and the accreditation of existing sets of regulations and certification programs in sustainable tourism. So the GSTC Accreditation Board is constantly anxious to identify and to check certifications and regulations as to whether they are credible, transparent and impartial and correspond to the GSTC criteria for sustainable tourism. Thus, it is a universal benchmark for clarity, consistency and credibility in sustainable tourism and certification services (GSTC, 2012 b).

Since the Earth Summit in 1992, certification programs have been elaborated in order to measure and define sustainability in many industries (Kroshus Medina, 2005). Generally a certification is understood as the audit of entire businesses, operational procedures or products in regard to the fulfillment of certain criteria (Busse & Riehle, 2003). This is an important issue, because they rely "on having a credible message that is remembered by the market and is crucial to purchasing decisions" (Font, 2007, p. 397). A certification is usually approved by a certification mark or a label (Busse & Riehle, 2003). Many companies, especially in the tourism industry, nowadays see great advantages in undergoing a certification. In addition to valuable information about the company itself, which can be used for an increase of the profitability, a positive corporate image, financial market advantages and even government subsidies are anticipated too (Dimitropoulos, 2012).

For tourism service providers, a certification system also represents a guide for improving the environmental and social compatibility of those who are acting on behalf of their own companies. In addition to that, a certification should intend to encourage the implementation, as well as the continuous improvement of corresponding measures (UNWTO, 2004). The range of sets of criteria of certification systems can be seen as the foundation for the certification and thus for the entire audit process. Here, the audit process can take place at three different levels of evaluation (Lund-Durlacher, 2007). The simplest, but also at the same time most subjective manner of evaluation, is the self-evaluation. It is a pure self-assessment of the company based on the set of criteria. At the second level, an evaluation can be carried out by the costumer. An evaluation by an external inspecting authority verifying compliance with the criteria forms the third evaluation level (ibid.). For Sallows & Font (2004) it is only a meaningful and genuine certification system if independent and external inspecting authorities are both attending the certification process. It should follow that the service or the product's conformity to the criteria and thus the processes or the management system would then be certified through the established set of criteria and the process would then be completed with the awarding of a label or a logo (Sallows & Font, 2004).

Certification systems can be characterized not only by the choice of evaluation but also by their respective orientation. Therefore static output-oriented certification systems are measuring the achievement of predefined indicators corresponding to a threshold level; whereas, dynamic performance-oriented certification systems aim for a continuous improvement of the company's sustainability (Freyer & Dreyer, 2004; Font, 2005). Especially the performance oriented certification which enables small businesses to participate in the documentation of sustainable development (EUROPARC Federation, 2012).

In general, the certification process terminates with the award of a label, which is composed of a logogram, symbols or icons. This label or logo simply communicates the corresponding sustainability threshold and renders the certification of a company or product visible to the travelers. Therefore, the labels usually serve as an orientation for them. They offer some kind of security or assurance, which

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

states that products and providers meet the required standards that correspond to certain criteria (UNWTO, 2004; Buckley, 2002). Accordingly, labels are seen as a marketing tool that takes the pressure off consumers during their purchase. Nevertheless, the required integral and equal consideration of all three dimensions of sustainability in the majority of certification systems has not been fulfilled. Thus, social, cultural and institutional conditions as well as the quality are often analyzed and integrated insufficiently (Baumgartner, 2002). Moreover, tourists rarely pay attention to labels – possibly due to a certain level of opaqueness (Buckley, 2002).

In summary, substantial questions remain for the concept and implementation of sustainable tourism as part of a successful regional tourism strategy. For this study, sustainable tourism is viewed as a multidisciplinary and holistic interpretation (GSTC, 2008) rather than viewing sustainable tourism as representing a niche tourism market (e.g. eco-tourism products). Regional implementation or operationalization have been vague and lack globally accepted standards for the wide range of tourism-related businesses and attractions (Castellani & Sala, 2010). Indicator-based evaluation systems and current certifications appear to lack credibility and vary by evaluation method and orientation towards sustainability in the tourism sector (Freyer & Dreyer, 2004; Font, 2005).

Therefore, this study assesses several issues related to regaional implementation of a tourism sustainablity strategy and potential certication for the Baden-Württemberg region in Germany. Specifically, the study assesses 1) whether a regional sustainability check is deemed valuable, 2) implementation issues to consider at the regional level, and 3) the perceived value of exisiting tourism sustainability certifications.

In this study, a regional sustainability check is defined as an audit process of an integrated approach which contains criteria of four main objectives: 1) demonstrate sustainable management; 2) maximize social and economic benefits to the host community and minimize negative impacts; 3) maximize benefits to communities, visitors and cultural heritage and minimize negative impacts; and 4) maximize benefits to the environment and minimize negative impacts.

METHOD

The leisure and tourism industry is not only internationally considered as a growth engine, but it also makes up for an important economic sector in Germany that contributes significantly to employment, income and regional development. According to calculations by the Federal Ministry of Economics and Technology, the tourism sector in Germany roughly offers 2.9 million jobs directly dependent on it and generates a gross value added of around 214 billion Euros in 2010 (BmWi, 2012). Apart from this purely economic importance of tourism in many regions, it has a structural facilitative or stabilizing function and provides development opportunities for structurally weak areas. Further the economic strength of the tourism industry enables capabilities of a sustainable development (DTV, 2012). In response to the growing importance of sustainability, this circumstance induced the government of the federal state of BW, Germany, to implement and facilitate a sustainability check for tourism attractions. Therefore, the fundamental implication of the current study is to assess sustainability checks and/or criteria for tourism attractions and identify their potential within a sustainable development of tourism.

The first objective was to examine the market of existing certifications and eco-labels and, thus, to examine if a current certification can serve as a basis for a sustainability check of tourism attractions in Germany. The second objective was to gain insight into the role of sustainability checks and criteria as an emerging theme in sustainable tourism development in Germany, especially in BW. Therefore,

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

qualitative semi-structured interviews were conducted with 18 experts of the tourism industry in Germany to better understand the requirements and expectations of such a sustainability check. To be able to consider the full range of relevant actors in tourism in BW, the selection of experts was based on the systematization of tourism destinations. According to the various categories, experts from diverse fields were interviewed from all over Germany. Interviewees were addressed as to their role as experts in certain fields of activity or as representative of certain groups. In addition to several industry associations, representatives of various tourism organizations and companies, individual consumer protection and environmental associations as well as existing certification schemes were included.

The interviews contained sections seeking information related to (a) the difference and global understanding of sustainability and CSR; (b) possible certifications that can serve as a basis for the sustainability check; (c) the future procedure of the sustainability check and (d) the ideal approach and final impulses. Semi-structured interviews with 23 questions in the four previously mentioned sections were chosen in order to be able to ask supplementary questions to gain more descriptive responses and understanding of more complex opinions and experiences.

RESULTS

Desk research on existing certifications and eco-labels revealed that presently the tourism industry features more than 100 national and international certification systems and labels which evaluate and award the enterprises and their tourist attractions a different aspect of sustainability (Hamele, 2012). The description of these systems and labels tend to focus on what they intend to achieve rather than an accurate definition of what they are (Kozak & Nield, 2004). To counter the challenge of the variety and complexity of existing certifications, various certification systems have been compared (Lund-Durlacher, 2007; Hamele, 2012).

The comparison is based on the requirements and key objectives of the 'Global Criteria for Sustainable Tourism'. GSTC considers existing certifications on the basis of credibility, transparency and objectivity. Furthermore, also according to the GSTC requirements, a "real" sustainability label must equally cover all three dimensions of sustainability. By comparing existing systems and labels that are awarded internationally and/or in Europe, it became obvious that the largest part of the certifications is focused on the ecological dimension, while the economic and and the social issues are either insufficiently addressed or ignored (Hamele, 2012).

After reviewing the certifications on this criteria, it is noted that only the systems of 'TourCert' and 'Green Globe' are qualified for further detailed examination since only these two consider holistically all dimensions of sustainability and are approved by GSTC (GSTC, 2012 c; Zimmer, 2012). While the international label 'Travelife' likewise regards all three sustainability areas, since its specific focus is on hotels and apartment buildings, it could not be examined more closely (Hamele, 2012). As a leitmotif (leading motif), it is deemed that the more extensively a certification system assesses the three dimensions of sustainability, the more efficiently and effectively it can contribute to sustainable development in tourism and therefore serve as a possible foundation for the sustainability check.

TourCert is a nonprofit organization for the sustainability certification of tourism enterprises. Certified businesses obtain the CSR Label "CSR TOURISM certified" (TourCert, 2012 a). It is a management system label that distinguishes the social, environmental and economical sustainability of tour operators throughout Europe. Since 2012, TourCert also certifies travel agencies (Hamele, 2012). It is monitored by

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

an independent and voluntary CSR Certification Council. This council consists of representatives from industry, science, environment, development as well as politics. It also develops the CSR certification policy, which defines the requirements for the CSR system and determines the review and certification process (TourCert, 2012 a; TourCert, 2012 b). For the receipt of the label it is necessary for companies to publish a sustainability report according to the guideline "CSR Reporting in Tourism" guideline. Additionally, the business/organization has to build a CSR management system, in which a CSR improvement program and a CSR mission statement are rooted. Furthermore, there has to be a sense of determination from the person responsible for CSR in the organization (TourCert, 2012 c).

The CSR reporting standards have more than 67 indicators and focus mainly on the relevant aspects of small and medium-sized enterprises in tourism. This can be regarded as a minimum requirement for sustainability reports (Kate et al., 2008). The guide is based on the "forum anders reisen" criteria and is also dependent on the GRI guidelines. Likewise, the core contents from the sustainability reports by the Federal Ministry for the Environment (2007) are taken into account (KATE, 2008). The public sustainability report has to be updated every three years (TourCert, 2012 c).

Green Globe is an international certification system, which was established in 1993 in Los Angeles, California (USA) and is approved by GSTC (Green Globe, 2012 a). The institution is a member of UNWTO and, since 1999, a shareholder of the WTTC (World Travel & Tourism Council). Green Globe is represented in 86 countries with 17 offices and recognized in 187 countries. So far, Green Globe has certified worldwide more than 1,000 companies (Zimmer, 2012). Due to these alliances and a relatively massive marketing campaign, the recognition within the tourism industry is one of the strengths of Green Globe (Buckley, 2001).

The label certifies companies of travel sales for tour operators, destination management organizations, the MICE and the hospitality industry. It is also aimed at the spa and health centers, cruise ships and other transport companies or suppliers of tourism enterprises (Green Globe, 2012 b). The Green Globe Standard is divided into four main sections with a total of 41 individual criteria and 337 indicators. These include 70 percent of the criteria and indicators for the environmental dimension and the remaining 30 percent is made up of the social and economical dimensions (Zimmer, 2012). The themes addressed are made up of sixteen environmental criteria, ten criteria for sustainable management as well as nine social/economic issues and four criteria concerning cultural heritage (Green Globe, 2012 c). The criteria for tourism bodies, such as hotels, convention centers and golf courses are varied and tailored to their needs. This is a dynamic certification process, which is tested annually and updated or expanded as needed by an international advisory board (Griffin & DeLacey, 2002). The fulfillment of the criteria is ensured on site by examination of an independent third party every two years (Kate et al., 2008). The accredited Green Globe auditors are professional environmental or sustainability consultants who have taken the training for the Certification (Green Globe, 2012 d).

Findings of the Interviews With Tourism Experts Regarding Requirements and Expectations on a Sustainability Check

The implementation of a sustainability check within the tourism industry of an entire state like BW represents innovation, so far. To implement such a project successfully, a solid basis of support and acceptance by the industry is necessary. With the help of 18 expert interviews, it was possible to consider both recommendations and concerns of the industry. Based on the five sections which are described in the method, the results and the findings of the interviews are discussed in general in the following account.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

By the topic of (a) Sustainability/CSR, it was possible to get an impression of the organization's or association's comprehension of sustainability and, thus, create a basis for the detailed questions of possible certification. So with 15 experts, there is an agreement that the concept of sustainability is in accord with the foundations: economy, ecology and society. This definition has been complemented by one interviewee with the addition that this triad must take place "in the light of the burden of the world and the respect for the finite nature of resources". In practice, this understanding is not yet widely established. Frequently, the term sustainability is exclusively associated or equated with the term ecology. To change this situation, it needs further educational work and information (of the employees and the customers) by the industry and politics. Mobility was cited by the majority of experts as one of the most important aspects of sustainability in tourism.

In the social sector, many participants see a need to improve the existing structures and to increase social justice (based on working hours as well as on the local population). "In this context, also the subject of skilled worker shortage and salaries should be considered." Therefore, it is stringently required to provide and to extend the right, basic conditions for the employees in tourism. The fact that this project could not yet become prevalent was also confirmed by an expert's statement that the issue of Corporate Social Responsibility (CSR) in tourism in BW, so far, is not looming large. Nevertheless, it should be considered in the selection of criteria for a sustainability check. Only in this way, it is possible to increase the acceptance and improve existing circumstances whereby a superior quality of service will ultimately be allocated.

The economical dimension is, according to the experts, especially reflected by the regional creation of value. Consequently, numerous companies have recognized that an increase in efficiency levels can often be supported by the use of local products. Therefore, customers experience sustainability not as a limitation of comfort and consumption, but as enrichment. This was confirmed by a survey of tourists in the Black Forest region of BW in 2011 (Beer et al., 2012). According to the survey, more than half of the respondents inquired as to the origin of local products. Sixty percent surveyed indicated that they were going to buy local products at the end of the holiday to take home and 79.3 percent of the tourists were willing to pay more for local products. The use of regional products is therefore often worthwhile for the companies.

Whether a sustainability check for the entire industry is considered as being useful, if the implementation can build on an existing certification as well as deciding on which specific criteria should be adapted for BW, could be determined by the second topic (b) Certification. In general, the majority of experts think that a sustainability check is helpful in order to raise awareness. Certification may improve the company's view of the issue of sustainability. However, this begs the question of whether the companies would view further certification as an advantage or a disadvantage. In addition to the cost savings (by compliance of the criteria) and improved image (externally, but also internally among employees), the marketing aspect is seen as particularly helpful for the participating companies. "Even if, it would not be a unique feature it would at least be a distinguishing feature." Therefore, the purpose of a certification is to analyze, to reflect and to improve one's own company and its actions, with the destination route to be prepared for changing conditions and requirements in the market.

The possible burdens and excessive bureaucratic demands, especially for small and medium-sized enterprises, are considered as a disadvantage, notably when consistent standards are predefined "from above". It must be the independent desire of the enterprises to submit to the certification process. Accordingly, ten of the experts in this tourism context consider advanced training to be a very relevant part of the project.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

In general, the implementation of the sustainability check in the entire tourism industry in BW is defined as difficult by 16 of the 18 experts. According to one of the experts, "a uniform certification is difficult to implement and a great aspiration, but if the whole industry and all those responsible will back the project, it can definitely be implemented." It also has to take into account in the set of criteria a significant variety of business types and visitors. The implementation for an entire industry is also considered as problematic due to the different boundary systems of the attractions. Consequently, a nature park, due to its expansiveness, is not comparable to a museum. One option here would be the certification of the organization's management (company certification). Attractions, such as national parks or biosphere reserves, currently can only be certified on the basis of their administration. A certification of all partner companies and partner hosts can only be realized after a few years.

In addition to the skepticism about whether consistent certification for the entire diversity of tourism destinations would be feasible, three experts also expressed general doubt if a sustainability check is meaningful at all at the current time. In view of the plethora of labels, the marginal advantage tends to decrease more and more. One of the experts even indicated that such a label just serves "to calm the bad conscience." Therefore, other certification models are deemed neither necessary nor useful. Three experts were not inclined to award a seal of approval, but focused more on the organization of the process, "since there is nothing all-encompassing, and most companies are only sustainable in certain sub-areas but not in a whole."

The remaining experts, who agreed the project made sense, were asked for their views regarding which existing certifications could be used as a foundation for the sustainability check. Generally, for the experts arose the question of: "Are the certifications and seals of approval (labels) relevant to the current market and do they improve the companies' reputations"?

On the one hand, concerns have been expressed since the public has little or no awareness of the existing certifications in tourism. One of the interviewees pointed out that "the existing certifications are hardly perceived and have no reputation". On the other hand, since the implementation of the sustainability check would be relatively quick to accomplish and the business could work with a clean definition (i.e. an established system), it would be useful to adapt the existing certification. According to statements of seven experts, currently the most meaningful and best solution is to award a comparable existing certification to a business in order to enable it to label itself with existing Baden-Württemberg branding. Still, it was relatively difficult for the respondents to name an existing certification which could serve as the foundation for the sustainability check. Eight experts couldn't name any certification on their own, partly because the certifications aren't known and partly because the existing ones weren't assessed as adequate.

The "Green Globe" certification was the top contender, mentioned five times by the experts. Still, this is a relatively small number, considering that 18 experts were interviewed. Four experts named the "ServiceQuality Germany" certification as a basis for a further configuration. However, its specialty is not in the area of sustainability. Also, the "EMAS Certification" was nominated three times. The certification of "Viabono", the "VDR Certification for Green Hotels" and the "DEHOGA Environmental Check" were each mentioned. But, these certifications are limited to particular areas of tourism (e.g. hotels) and do not consider all three dimensions of sustainability in an adequate and balanced way.

Further, suggestions have been given to the Global Sustainable Tourism Council regarding the research on existing certifications. To get an overview of the whole range, according to some experts, it is absolutely necessary to orientate yourself towards these international standards. In this context, the certification system "TourCert" has been mentioned as a possible basis for the future sustainability check.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

However, a detailed review of systems is needed to make sure, that it is a "real" sustainability certification which could be extended if necessary. Even though the comment was made that the development of new certification would not be synergistic and sustainable, four experts contemplated the idea to develop new certification as existing systems are currently unavailable or not compatible.

Finally, the experts were asked for their opinion on whether certification should be adapted in specific aspects or criteria for BW. The clear message was that it was less about BW specifics, but rather about industry-specific criteria, which should not overcharge the small businesses, in particular. Thus, the experts consider it more important to adopt the seal of approval (label) than to adapt the criteria. "The adaption of criteria is not crucial, but the certification should clearly contain the brand Baden-Wuerttemberg. This is after all a guarantee of quality for the tourists." This guarantee should also be supported by the use of local products. The regional purchase should be reflected by including it in the criteria, but this cannot directly be regarded as Baden-Württemberg-specific. Rather, such criteria are about consistent standards that only have to be adapted to the particular region (origin of the products, etc.)

Within the third topic (c), details on the future procedure were discussed. The focus here was on the further development of a possible set of criteria and the implementation of the audit process. Within the interviews, 13 of the experts argued in favor of a performance-oriented certification system. Notably in an industry-wide implementation of the sustainability check and the whole diversity of tourism destinations, it is virtually impossible to orientate themselves exclusively by "hard facts". One statement was that "certain requirements must be met, but it also has to be pragmatic."

Especially for companies that have so far been dealing very little with the subject and are only just beginning to implement sustainable measures in their operations, a performance-oriented approach is better and more meaningful. A uniform output-oriented set of criteria is for the majority of the respondents also not realizable due to the different tourism destinations. There is an agreement that "the criteria of a nature park are not comparable to the criteria of the Europa Park". This requires a performance-oriented certification system which is the only solution to be able to cover the entire industry.

However, four of the experts expressed doubts whether a performance-oriented system is sufficient. Therefore, a combination of performance and output-oriented criteria was proposed. Particularly, in the field of energy consumption, adherence with specified minimum standards deemed necessary. Here, although the process may be involved in the development, but at the end of the certification process a clear figure should demonstrate on which level each company is located. Only a few experts could provide accurate information on the content of the criteria. According to all respondents, it is important that all three dimensions are considered in the development of the criteria catalog.

In general, the number of criteria is not necessarily denominated as relevant, but it should be kept in mind that a reduced number is necessary to allow a practical implementation of the check (Schianetz & Kavanagh, 2008). One of the experts encapsulated it with the statement "as little as possible, as much as necessary." But, besides that, it's much more important to create awareness among the participants of the topic and to support the development. However, according to all the experts, this is only possible with transparent and credible criteria.

Furthermore, the audit process has a great importance in this context. Thus, a credible implementation of a sustainability check is possible for all respondents with an independent audit process. "Within a self-evaluation, there are too many ways to enhance the facts." Only a neutral panel with independent auditors and experts is able to guarantee the sincerity and credibility as well as the transparency of such a procedure. From experience, such an audit is especially relevant to the customer. Therefore, it is strongly recommended not to make use of self-evaluation. It is also important to the experts that certification

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

is granted only for a specific period. Hence, there should be a re-certification every two to three years, by which the companies would need to demonstrate significant advancements in the respective areas.

All experts agreed that certification should not be dependent on cost. However, there was a disagreement regarding the financing of such check. There was agreement only to the point that certification should not result in a significant additional burden for the businesses. As the financial situation of the tourism companies in BW is very different, a graduation of prices, depending on size and turnover, will be considered to be reasonable and fair.

At the end of each interview, the experts were asked for the ideal approach and final impulses in section (d). Here, it was again pointed out that at the beginning of the implementation of the sustainability check, a clear definition of the concept of sustainability should be defined and there has to be a precise definition of the objectives. For many businesses, the issue is not yet tangible. Therefore, it should be made clear at first as to which measures and implementations should be required by the companies. What would it mean to the company to implement sustainability in their strategies on a short-term basis? It should also be clear what is associated with the check and what is actually wanted to be achieved.

In the opinion of the experts, a broad dialogue process should be organized in which the participants can get involved in the industry. The whole project should also be implemented success-oriented and as one interviewee described it "not only because it is written in the coalition agreement of the government". Ultimately, the question of the future organization and integration into the existing tourism campaigns should be clarified. The implementation of the sustainability check must be well coordinated. According to the statement of eleven experts, it therefore makes sense to locate the marketing of the label at the national Tourism Marketing GmbH Baden-Württemberg (TMBW).

DISCUSSION

After a thorough examination of the concept of sustainability in tourism, the analysis of operationalization approaches (especially of existing certification systems) and the evaluation of the results of the expert interviews, it is now possible to enunciate recommendations for the selection of the tourism attractions, as well as for the future implementation and the processing of the sustainability check.

Set of Criteria and Certification

Certification, such as the planned sustainability check for BW, on the one hand, conduces to a sustainable development of tourism in the state and, on the other hand, to the certified attractions and businesses. One of the crucial questions that needs to be clarified is whether established and meaningful certification systems exist in the market which can serve as the basis for the check or whether the development of an entirely new system is necessary.

After thorough consideration of the operationalization approaches and following the confirmation of the experts in the industry, it is considered advisable to use an existing certification system as the basis for the sustainability check at this time. The adaptation of an established system allows not only a faster implementation, but also ensures compliance with international standards and experiences that have been developed over the years.

The criteria of the Global Sustainable Tourism Council are considered as a guiding principle in tourism worldwide. This global initiative is committed to promote a sustainable, economically fair and

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

responsible tourism that respects both the environment and the society and, thus, defines the minimum requirements for sustainable tourism

By comparing existing systems and labels, it became apparent that the majority of certifications focus on the ecological dimension and that the ecological and the sociocultural dimension are not or only insufficiently considered. This is also reflected in the fact that very few certifications were awarded by GSTC and thus do not meet the international standards in the field of sustainability. Only the two certifications by Green Globe and TourCert have been selected for the sustainability check. Both systems are well established but are also rigorous processes that put high requirements on the businesses. They differentiate themselves less by different sets of criteria and indicators than by their respective orientation. While Green Globe mostly acts on an international level in large companies and chains, TourCert focuses more on small and medium-sized enterprises.

Due the prevailing structures in the tourism industry in BW, this focus would speak for the election of the TourCert certification as a foundation. Another advantage is the aspect that TourCert is a German organization, whose office is located at KATE in Stuttgart. If the decision falls onto TourCert, then the organization and the implementation of the sustainability check takes place directly in the state. The organization is virtually "in the midst of events". Moreover the TourCert certification is in some areas of tourism still in the starting blocks and therefore provides the opportunity to make appropriate adjustments, as well as the possibility to create or expand the system that would be used for the sustainability check. In the case of an internationally active and oriented system such as Green Globe, this would only be conditionally possible and with appropriate expenditure of time.

At the beginning of the certification process, an analysis of the respective companies should be compiled, where the developments are documented at the bottom. Based on percentage targets for improvement, companies can then be certified because of their positive development and optimize their own performance. Here, the application of a multi-level label, depending on the level of development of the company, would be conceivable, which is also suggested by some experts.

On the basis of these considerations and the belief that only a performance-oriented system is useful, it can be said that not the elaboration of the criteria catalog, but the process is of prime importance. So the experts confirmed in the interviews that the focus of the set of criteria must be in due consideration of the three dimensions of sustainability. Referring now to the criteria of the GSTC and the accreditation of the individual certifications, it can be stated that both TourCert and Green Globe comply with this demand.

Since sustainability is arranged as a global concept and the GSTC criteria have been established in particular for the tourism industry; a complete revision of criteria, especially for BW, does not make sense and rather is regarded as a step backwards. Especially, because acceptance in the industry would only be achieved if the set of criteria is confirmed by GSTC. Therefore, in appendix 1, the GSTC set of criteria for hotels/tour operators and destinations (GSTC original versions see appendix 2 and 3) is adapted and extended to a set of criteria for attractions. This catalog covers all three dimensions of sustainability and consists of so-called minimum requirements or criteria that are internationally elaborated and approved. Also, the existing certifications according to the GSTC-standard (Green Globe and TourCert) cover these criteria from an industry perspective.

A completely new development is therefore not necessary. It should be enhanced that sustainability as a global concept is not operationalized through regionally specific indicators. However, if mandatory criteria with thresholds should be used, these limits could be adjusted. Thus, it would be possible to define limits (e.g. in the energy sector) specifically for BW in cooperation with the relevant experts (e.g.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

share of renewable energies needs to be over 20 percent). However, a region-specific set of indicators is not considered as appropriate by the interviewed experts.

Label

It has already been shown that the process of a certification terminates with the awarding of a label. This is usually made of words and/or symbols that render the certification of a company or product visible to the travelers. They contribute above all to transparency during the search by travelers for environmentally and socially sustainable offers. This aspect is important because only through information and knowledge, the habits of tourists can be modified and so sustainable offerings become increasingly in demand.

Also, the planned implementation of a sustainability check throughout the tourism industry in BW, can increase the traveler's desire for sustainable tourism and thus contribute to an increase in demand. In this context, it is important to say that the label signifies a certain guarantee of quality. Tourists, who decide to visit a tourist attraction or a company due to its label, require the continuance of certain standards. By established systems such as Green Globe and TourCert, it is possible to consider these required standards for the certification of companies.

The label is a communication tool that offers the greatest value only through the creation of a brand. It is clearly perceived by its visibility and thus strengthens the tourism destination BW and enables sustainable tourism.

To make the label Baden-Württemberg-specific for the customer, it is possible to build on the existing campaigns and brands of tourism in the country. It seems to make sense to connect the sustainability check to the campaign "Green South" of the TMBW because of the general topic. The project "Green South" is a new brand of the destination BW. The focus of this 'label' is on the marketing of environmentally acceptable, climate-friendly and highly sustainable holiday offers (TMBW, 2012). Hence, this campaign would offer the optimal framework for the sustainability check in BW.

CONCLUSION

The intended implementation of the sustainability check in BW is judged favorably, due to the diverse aforementioned reasons. The results of the expert interviews reveal that in general there is strong support for the government to implement a sustainability check for the highly diverse tourism attractions in the entire state. In this context, the interviews indicate the difficulties and individual particularities which have to be considered by implementing a comprehensive sustainability check for different types of tourist attractions. For example, theme parks have different expectations on such a sustainability check in comparison to a nature park. However, criteria need to be consistent and profound for all types of tourism attractions.

At the beginning of this realization it is very important to clarify the term 'sustainability' and to determine an exact agreement of its objectives. So it is necessary to explain to the tourism participants that this certification won't just facilitate sustainable tourism, but it will also be a benefit and a progress for companies and thus for the guests.

Henceforth, right from the start it is indispensable to make sure that the certification does not lead to an enormous additional drawback or to bureaucratic excessive demand, especially of small and medium-sized enterprises. Additionally, it has to be the company's own desire to get themselves certified. Furthermore

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

a comprehensive certification for the entire industry is only feasible as a performance-oriented system, because of the range of attractions. Such a system also offers advantages concerning the stakeholder's acceptance. The audit process should be organized by independent auditors, based on a consistent and profound set of criteria which considers the three dimensions of sustainability. The set of criteria has to orientate itself towards the global GSTC-standards. Enhancements of this set of criteria are possible, but they should not stay in the focus. For the purpose of an expeditious implementation, a high acceptance in the industry seems to be important. This circumstance will be achieved with the help of an existing system and an unmodified set of criteria.

The explicit recommendation is to bank on an existing certification system with an established process and to obtain a unique position via the assigned label at the end of the audit process. This particular label, in the case of BW, could be linked to the brand "Green South" and thereby go viral. A distinct "Baden-Württemberg-Branding" clarifies again the implementation of the check for the entire federal state and the whole tourism industry.

Chapter 68
Decision Making in Local Energy Planning: A Review

Vangelis Marinakis
National Technical University of Athens, Greece

ABSTRACT

The current financial and economic crisis, as well as the wider socioeconomic and environmental pressures, including climate change among others, put seriously into question the traditional development patterns. This is particularly true for the local and regional authorities, who face a number of challenges as regards growth, jobs and sustainability. These pressures create high expectations for coordinated actions and holistic interventions to address comprehensively the problems toward a competitive economy. In this context, this Chapter describes the main issues of the decision making in local energy planning. The policy context and relevant initiatives are outlined. A detailed review of existing methodologies for local energy planning, as well as standard techniques and methods (participatory approach, aspiration level, multi-criteria decision support, robustness analysis, indicator-based assessment frameworks) are presented. The need to support the local and regional authorities in the decision-making process for the development, implementation and monitoring of their Sustainable Energy and Climate Action Plans, especially within the framework of the Covenant of Mayors for Climate and Energy (a first-of-its-kind global initiative of cities and towns) is highlighted.

INTRODUCTION

The current financial and economic crisis, as well as the wider socioeconomic and environmental pressures, which include climate change, scarcity of natural resources, demographic change, social division, accelerated technological change, and many more, put seriously into question the traditional patterns of living, consuming, and sharing resources (Koepper et al., 2009). These pressures create high expectations for coordinated actions and holistic interventions to address comprehensively the problems of modern society and competitive economy. In particular, with regard to energy and environment issues, integrated

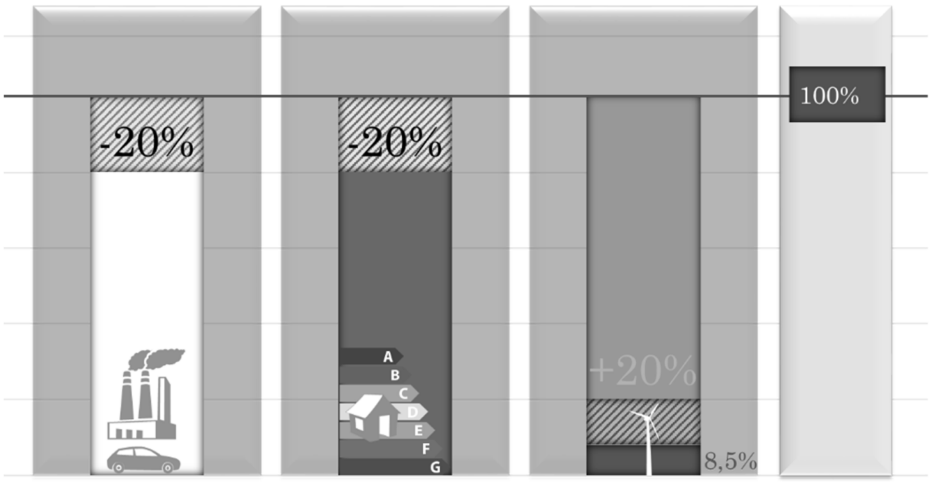
approaches and methodological frameworks are the key challenge for policy and decision-makers in order to embark them on strategies toward sustainable development and scientifically optimize energy concepts for the future (Doukas et al., 2012a; Deilmann and Bathe 2009; Stigson et al., 2009).



The importance of taking immediately action to prevent and address climate change and its environmental impacts is explicitly recognized both on political and on social level (Omer, 2008). A number of studies, such as the Stern Review on the economics of climate change (Stern 2007) reaffirms the enormous costs of inaction, as well as other relevant researches (Oxfam International 2007; UNDP 2007; UNFCCC 2007; World Bank 2009; Lund, 2007) note that developing countries will need more than 50 billion US dollars per year to tackle climate change, and far more if global emissions are not cut rapidly. In addition, the communication of the European Union (EU) in 2005, "Winning the battle against global climate change," indicated that the benefits of limiting climate change outweigh the costs of taking action (EC, 2005). Thus, mitigation of climate change and its environmental impacts is technically feasible and affordable, provided that not only an integrated and comprehensive approach in community and national policy level be followed, but also the emissions producers act immediately.

The EU had always put high in its agenda activities related to the attainment of economic growth and prosperity. The EU 2020 sustainable development vision provides an opportunity to support the global fight against climate change (EC, 2011a). The EU Climate and Energy Package (EC, 2008) has set very ambitious targets for sustainable development, known as the "20-20-20" targets for 2020 (Figure 1).

In the context of Europe 2020 strategy, a comprehensive strategic approach has been put forward for the next decade to foster inclusive and sustainable growth in Europe and to provide a framework for the EU to emerge strengthened from the current financial and economic crisis (EC, 2010c). Moreover, EU countries have agreed on a new 2030 Framework for climate and energy, including EU-wide targets and policy objectives for the period between 2020 and 2030 (EC, 2014):

- A 40% cut in greenhouse gas emissions compared to 1990 levels.
- At least a 27% share of renewable energy consumption.
- At least 27% energy savings compared with the business-as-usual scenario.

Figure 1. "20-20-20" targets for 2020

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

The Europe 2020 Strategy has been implemented in partnership with Europe's regions and communities, as the key actors who can close the "delivery" gap (EU, 2013).

National prosperity is created, not inherited. The European municipalities have considerable importance, particularly with regard to new policies for local energy planning and sustainable development (Porter, 1990).

In this context, this Chapter presents a detailed description of the problem statements for sustainable local energy planning. A detailed review of existing methodologies and tools for local energy planning is presented and discussed. In this respect, the need to support the local and regional authorities in the decision making process for the development, implementation and monitoring of their Sustainable Energy and Climate Action Plans, especially within the framework of the Covenant of Mayors for Climate and Energy (a first-of-its-kind global initiative of cities and towns) is highlighted.

Apart from the introduction, the paper is structured along five sections. Section 2 provides a description of the policy context and relevant initiatives for sustainable development at local/regional level. Sections 3 and 4 are devoted to the presentation of the decision making problem for local energy planning. Section 5 is devoted on the relevant literature review of existing methodologies and tools for the development of Sustainable Energy and Climate Action Plans. Finally, the last section just summarizes the key issues that have arisen in this Chapter.

POLICY CONTEXT AND RELEVANT INITIATIVES

The European cities should be places of advanced social progress and environmental regeneration, as well as places of attraction and engines of economic growth based on a holistic integrated approach in which all aspects of sustainability are taken into account (EC, 2011c). A number of European initiatives have been launched related to these ideas, as presented in the following paragraphs.

The municipalities, as consumers, demonstrate their willingness to implement sound local sustainable energy policies, especially through their participation in the Covenant of Mayors initiative[1]. The Covenant is the mainstream European movement involving local and regional authorities, voluntarily committing to increasing energy efficiency and use of renewable energy sources on their territories. The new "Global Covenant of Mayors for Climate and Energy", a newly merged initiative between the Covenant of Mayors and the Compact of Mayors, aims at becoming the largest movement of local governments committed to going beyond their own national climate and energy objectives. By their commitment, Covenant signatories aimed to meet and exceed the European Union 20% CO_2 reduction objective by 2020. New signatories now pledge to reduce CO_2 emissions by at least 40% by 2030 and to adopt an integrated approach to tackling mitigation and adaptation to climate change (CoM, 2017a).

The Energy-efficient Buildings Public Private Partnership in research (EC, 2010b), launched under the European Economic Recovery Plan, represents the initial and highly strategic step of a longer term set by the industry to create more efficient districts and cities while improving the quality of life of European citizens. This initiative aims to address the challenges that the European construction sector and its extended value chain are facing in their ambitious goal of researching new methods and technologies to reduce the energy footprint and CO_2 emissions related to new and renovated buildings. Specific attention will be given to the development and integration of design and simulation tools, new materials, building systems and equipment and ICT for energy efficiency. In addition, the Directive 2010/31/EU (EPBD recast) has pointed out the leading role of the public sector in the field of energy performance

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

of buildings, as new buildings occupied and owned by public authorities should be nearly zero-energy buildings, after 31 December 2018.

The European Innovation Partnership (EIP) on Smart Cities and Communities (SCC) was launched in July 2012 to achieve a meaningful large-scale deployment of smart city solutions in Europe, focusing on the intersections of ICT, energy and transport (EC, 2012). The European municipalities themselves have also taken a very pro-active role and launched the Green Digital Charter in 2009. The municipalities signing up to the Charter commit to reduce the carbon footprint of their ICT and roll-out ICT solutions which lead to more energy efficiency in areas such as buildings, transport and energy. The SCC partnership bridges the areas of energy and ICT with the objective to catalyse progress in the areas of energy production, distribution and use; and ICT are intimately linked and offer new interdisciplinary opportunities to improve services while reducing energy and resource consumption and Greenhouse Gas (GHG) and other polluting emissions. The SCC will go beyond coordinating research and innovation projects and will tackle demand side measures such as enhancing new business models for energy and ICT services.

The Smart Cities Stakeholder Platform is essentially about promoting innovation. It aims to accelerate the development and market deployment of energy efficiency and low-carbon technology applications in the urban environment. The Platform supports the EU towards its goal of an 80% reduction of GHG emissions by 2050 and the Europe's primary energy technology policy, the SET-Plan.

The European Energy Research Alliance (EERA) Joint Programme on Smart Cities was launched in September 2010. Its main objective is the development of scientific tools and methods that will enable an intelligent design, planning and operation of the energy system of an entire city in the near future. An integrated approach will be adopted for the planned research activities in order to capture the interfaces between all the relevant elements of the energy system, such as thermal and electric energy networks, buildings, energy supply technologies and the end-user.

Finally, two of the flagships of Europe 2020 strategy are the Digital Agenda for Europe and the resource-efficient Europe:

- **Digital Agenda for Europe (EC, 2010a):** The Digital Agenda for Europe provides a policy framework aiming at delivering sustainable economic and social benefits from a digital single market based on fast and ultra-fast internet and interoperable applications. In this context, the EU promotes the effective use of ICTs to address societal challenges in energy, climate, and resource efficiency. This includes initiatives in areas such as sustainable cities, energy efficient buildings, smart energy grids and climate change management. Cooperation between the public authorities and ICT sector is essential to accelerate development and wide-scale roll out of ICT-based solutions for smart grids and meters and near-zero energy buildings. The ICT sector should deliver modelling, analysis, monitoring and visualisation tools to evaluate the energy performance and emissions of buildings, cities and regions. For the different grids to work together efficiently and safely, open transmission-distribution interfaces will be needed.
- **Resource-Efficient Europe (EC, 2011b):** The flagship initiative for a resource-efficient Europe under the Europe 2020 strategy supports the shift towards a resource-efficient, low-carbon economy to achieve sustainable growth. To enjoy the benefits of a resource-efficient and low-carbon economy, three conditions need to be fulfilled:
    - First, coordinated action in a wide range of policy areas, action in need of political visibility and support;

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Secondly, urgent action due to long investment lead-times. While some actions will have a positive impact on growth and jobs in the short-term, others require an upfront investment and have long pay-back times, but will bring real economic benefits for the EU economy for decades to come;
- Thirdly, necessary is the empowerment of consumers in order to move to resource-efficient consumption, to drive continuous innovation and ensure that efficiency gains are not lost.

DECISION MAKING PROBLEM FOR LOCAL ENERGY PLANNING

Europe will not be able to reach its commitments to alleviate climate change without the full participation and involvement of the European municipalities. Not only does the local population need to be able to make the right energy choices, but most of the renewable and energy efficiency options, from wind farms, to solar, to combined heat and power, will require the willing participation of communities (FREE, 2013).

At the 6th European Summit of Regions and Cities in Athens (7-8 March 2014) the Bureau of the Committee of the Regions adopted a declaration on the mid-term review of Europe 2020, titled "A Territorial Vision for Growth and Jobs" (CoR, 2014a). The political declaration argues that the future success of the EU's growth strategy hinges on better engagement of local and regional authorities. In addition, a handbook has been developed as a part of the follow up to the adopted Committee's opinion on the role of local and regional authorities in achieving the objectives of the Europe 2020 strategy (CoR, 2014b).

As mentioned above, the Covenant of Mayors for Climate and Energy constitutes a first-of-its-kind global initiative of cities and towns committed transparent climate action. The Sustainable Energy and Climate Action Plan is the key document in which the Covenant signatory outlines how it intends to reach its long-term CO_2 reduction target. The target sectors are the buildings, equipment, facilities and transport. The sustainable energy policy may also include actions related to the local electricity production (development of photovoltaics, wind power, combined heat and power, improvement of local power generation) and local heating/cooling generation (EC, 2010d). Nowadays, the Covenant of Mayors initiative counts more than 7,200 signatories. In addition, more than 5,600 Action Plans have been submitted (CoM, 2017b).

According to Marinakis et al. (2017a), Action Plans' elaboration and development is a decision making problem (Figure 2). The decision maker, namely the local authority (the Mayor and Municipal Council), in collaboration with the Analyst (Technical Manager) should identify all the actions and measures that will be integrated in the Action Plan of the local community, taking into consideration the baseline energy and CO_2 emissions inventory. They should also identify the overall goal of CO_2 emissions reduction by 2030 (at least 40%).

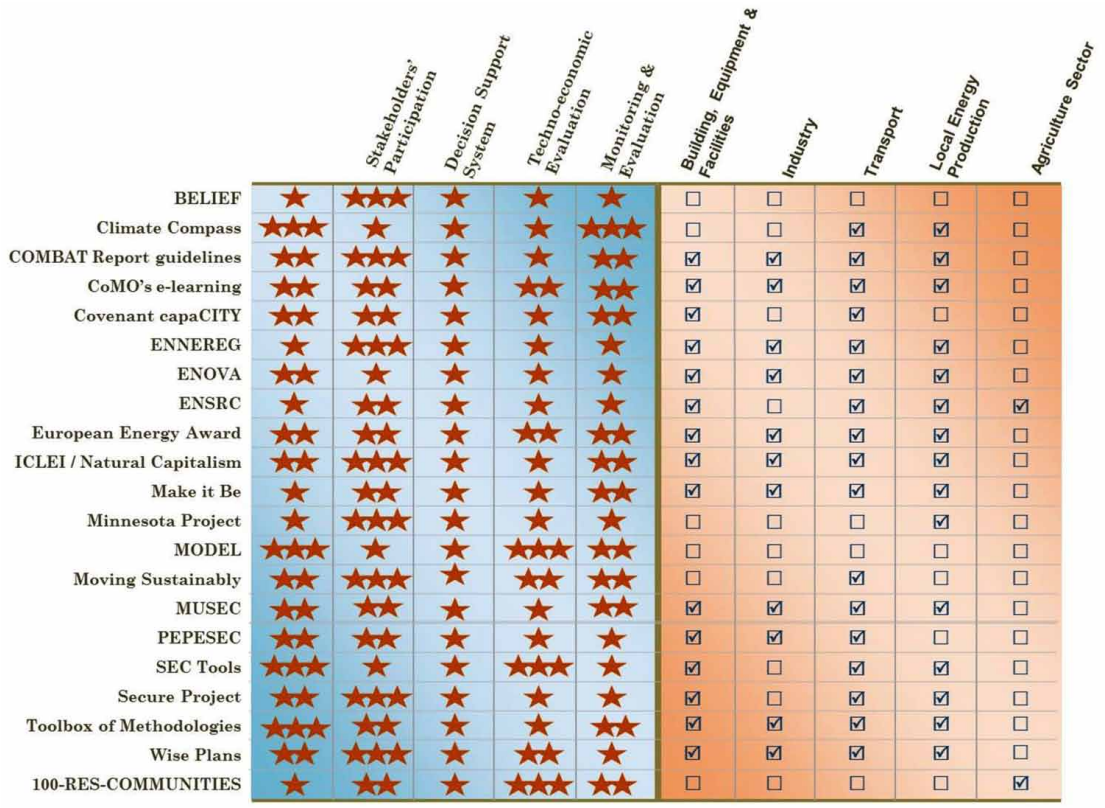
Active role in the planning process have interested stakeholders, such as energy centres, investors, companies, representatives of the local market and citizens. According to Renn et al (1993), stakeholders, experts and citizens should each contribute to the planning effort, through their particular expertise and experience. The benefits of combining participatory methods with analytical tools are widely acknowledged (Kowalski et al., 2009; Madlener et al., 2007).

Despite the high number of signatories, the lack of proper information and communication about the Covenant of Mayor's initiative and the obligations arising from its signing seems to be preventing the realization of the initiative's full potential (Christoforidis et al., 2013; 2011). In local and regional environments, fulfilling the Covenant's commitment of submitting a Sustainable Energy and Climate

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Decision-making process for the elaboration and development of sustainable energy and climate action plans

Action Plan within a one-year timeframe can come with very challenging constraints. Some communities, and in particular those which are most remote, depopulated or dependent on agriculture, already face particular challenges as regards growth, jobs and sustainability (Marinakis et al., 2012a, 2012b; Doukas et al., 2012b). These challenges include lower income levels, an unfavourable demographic situation, higher unemployment rates, a slower development of the tertiary sector, weaknesses in skills and human capital, a lack of opportunities for young people and a lack of necessary skills in parts of the agricultural sector and food processing industry (Marinakis et al., 2012c; EU, 2012; EC, 2006). This situation has been aggravated by the financial and economic crisis in the current years.



REVIEW OF EXISTING METHODOLOGIES AND TOOLS

Tools and Methods for Action Plans' Development

In the international literature, many existing studies propose methodologies and tools for the Action Plans' development and elaboration from relevant activities and mainly Intelligent Energy Europe (IEE) co-financed projects (Marinakis et al., 2017b). A first study was presented by Bertoldi et al. (2009). Figure 3 presents an overview of all the available methodologies and tools that have been developed so far (CLIMATE COMPASS, 2006; COMBAT, 2008; CoM, 2013; ENNEREG, 2013; Covenant CapaCITY, 2013; ENOVA, 2012; ENSRC, 2011; MAKE-IT-BE, 2011; Moving Sustainably Project, 2011; TMCE, 2011; 100-RES-COMMUNITIES, 2010; Energie-Cites, 2008; MODEL, 2008; PEPESEC, 2008; SEC-Tools, 2008; SECURE, 2008; European Energy Award, 2007; ICLEI, 2007; MUSEC, 2007; Wise Plans, 2007; Minnesota Project et al., 2003).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Tools and methods for the development of sustainable energy and climate action plans (Marinakis et al., 2017b)

There are methodologies that lay emphasis on the collection of energy data, while others provide alternative methods for stakeholders' engagement in the development of Action Plans. At the same time, some methodologies provide targeted guidance for different sectors of Action Plans, such as industry and transport. Moreover, relevant tools provide a series of guidelines, such as "Toolbox of Methodologies on Climate & Energy" (TMCE, 2013)", "Covenant capaCITY Training Platform (Covenant CapaCITY, 2013)" and "CoMO's e-learning (CoM, 2013)".

However, available methods and tools are not always well-adapted to cities and local/regional communities (Marinakis et al., 2017b, 2015). Moreover, they do not offer an integrated framework for the development of Sustainable Energy and Climate Action Plans and especially the selection of the appropriate combination of renewable energy and rational use of energy technologies.

Participatory Approach

All members of the society have a key role in establishing a common vision for the future and defining the paths that will make this vision come true. Indeed, their views should be integrated in the alternative Scenarios for the region. In this respect, the participatory approach can stimulate the behavioural changes that are needed to complement the Action Plans' measures.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

The benefits of combining participatory methods with analytical tools are widely acknowledged (Kowalski et al., 2009; Stagl, 2007; Munda, 2004; Polatidis & Haralambopoulos, 2004; Geurts & Joldersma, 2001). Different ways to consider participatory approach have been identified, such as "Information", "Consultation", "Deciding together", "Acting together" and "Supporting independent community initiatives" (CTB, 2014). In any case, the participation in planning could improve the quality, acceptance and effectiveness of the alternative action plans for the region.

Aspiration Level

The local authorities set the minimum longer-term target in percentage of CO_2 emissions reduction. According to the Covenant's guidelines, the target should be a minimum of 20% reduction by 2020 or 40% reduction by 2030. However, the local authorities can define a different longer-term target. This means that the examined actions and measures for the region should achieve this longer-term target. To this end, an aspiration level regarding CO_2 emissions reduction of each alternative is used, working as a filtering for the identification of feasible Scenarios.

A number of studies exist on the aspiration level approach (Nowak, 2007). More specifically, Wang and Zionts (2006) examined the relationship between aspiration levels and their mapped-to solutions in the MCDA context. Yun et al. (2004) presented an aspiration level approach using generalized data envelopment analysis and genetic algorithms in multiple criteria decision making such as engineering design problems. In the study of Granat and Makowski (2000), the specified aspiration levels are used for the generation of component achievement functions for corresponding criteria, which reflect the degree of satisfaction of results.

Multicriteria Decision Support

Multiple Criteria Decision Aid (MCDA) methods can be an important supportive tool in policy making, providing the potential to evaluate the alternatives' implications to the environmental, economical and social axes (Doukas et al., 2010; Wang et al., 2009). In decision-making involving multiple criteria, the basic problem stated by analysts and decision-makers concerns the way that the final decision should be made (Doukas et al., 2007). The main idea of the available MCDA methods, is to create a more standardized and structured process for decision making (Doukas et al., 2014; Greening and Bernow, 2004).

In the international literature, there are studies that present applications of Multicriteria Analysis on specific issues related to sustainable energy planning (Table 1). However, none of these studies offer an integrated framework for the Action Plans' development and especially the selection of the most appropriate sustainable renewable energy and rational use of energy technologies at local - regional level.

In the traditional aggregation paradigm, the criterion aggregation model is known a priori, while the global preference is unknown. On the contrary, the philosophy of disaggregation involves the inference of preference models from given global preferences (Siskos, 2001). The philosophy of preference disaggregation in multicriteria analysis is to assess/infer preference models from given preferential structures and to address decision-aiding activities through operational models. The existence of the preference model assumes the preferential independence of the criteria for the decision maker (Keeney and Raiffa, 1976), while other conditions for additivity have been proposed by Fishburn (1966, 1967). This assumption does not pose significant problems in a posteriori analyses, such as disaggregation analyses.

Robustness Analysis

The evaluation models of the multicriteria analysis are generally based on a set of acceptances, assumptions and estimations. These elements are often characterized by a high degree of uncertainty, given the complexity and uncertainty of the decision making environment (Hites et al., 2006). In this respect, another important issue is the robustness of the evaluation model (Roy, 2010). This fact has caused the intense interest of the research community. The recent studies focus on the development of integrated procedures for the robustness's analysis and measurement in different multicriteria analysis methods, as well as how these methods can adapt existing techniques to achieve the formation of stable solutions (Mavrotas et al., 2015; Siskos & Tsotsolas, 2015; Fliege & Werner, 2014). Some of the most recent UTA-type methods are UTA^{GMS}, GRIP, RUTA, extreme ranking analysis and robustness measurement control (Greco et al., 2008; Figueira et al., 2009; Kadzinski et al., 2013; Kadzinski et al. (2012); Kadzinski & Tervonen, 2013a, 2013b; Greco et al., 2012).

Indicator-Based Assessment Frameworks

In May 2014, the Covenant of the Mayors published a special guide for the monitoring of Action Plans. In this context, the "Implementation Report" should include quantitative data regarding the measures implemented, their impact on the energy consumption and the CO_2 emission. Additionally, an analysis of the actions' implementation should be enclosed, including the required corrective measures. Consequently, use of indicators is necessary for evaluating the progress of the Sustainable Energy and Climate Action Plan.

The indicators are a decision making methodological tool, as they quantify and simplify phenomena, in order to provide a better understanding of a complex reality. They represent mainly quantitative information and they elaborate different and multiple data (Androulaki et al., 2016). Different research teams have examined the basic parameters for the selection of the indicators (Rees et al. 2008, Niemeijer & de Groot, 2008). The selection of the indicators strongly depends on the nature and the goal of the researchers and the decision makers. During the selection of the indicators, criteria concerning the completeness, the adaptability and the appropriateness must be taken into account.

The literature review for the development of energy related indicators shows that the most important attempts, are located in big international organizations, focused on the following fields: environment, sustainable development, energy use and energy efficiency. "OECD (Organization for Economic Development and Cooperation)" operates in the field of environmental information; it has managed to develop a collection of directly related indicators and many collections of indexes for various fields (e.g. indicators for energy-environment, indicators for transportation-environment, etc.) The indicators for energy-environment have been developed to promote and to strengthen the integration of environmental worries in the development of the OECD countries' energy policy.

In practice, the scientific community uses composite indexes. Namely, the value of a composite index is a function of two or more individual indicators which are related to a system or a phenomenon (OECD, 2002). The proper description of such an index requires a careful selection of the individual indicators and their weighting factors. One of the main composite indexes commonly used is the Environmental Performance Index (EPI, 2015). It is a method of quantitative and numerical comparative evaluation of the environmental performances of a country and its policies.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

The development of composite indexes in the field of sustainable energy planning is limited in the international literature (Evans et al., 2009; Vera & Langlois, 2007; Afgan et al., 2000). Brown & Sovacool (2007) suggested an energy sustainability index to evaluate energy policy. Abouelnaga et al. (2010) have studied the sustainable nuclear energy indicator, while Afgan et al. (2005) focused on the modelling of sustainable development indicator.

CONCLUSION

Nowadays, sustainable energy policy has been a challenge for the local authorities. The contribution towards addressing the climate change problem, through the communities' CO_2 emissions' reduction and the creation of sustainable jobs, strengthening the extraverted economic activity at local and regional level, can comprise the success measure of this particular effort. One of the bets to be won includes the liberation of local authorities from their role to promote infrastructure projects without central planning and their connection with sustainable development's strategic goals. The disengagement from the unilateral economic development may be achieved through the progressive dissemination of renewable energy and rational use of energy actions.

The European cities have to work towards the direction of strengthening the areas' benefits, by taking advantage of existing opportunities at national and European level, in order to achieve sustainable development. As a result, the decision making problem of Action Plans' elaboration and development within the framework of Covenant's initiative is an important component in local authorities' operation towards the creation of sustainable energy communities.

The cities and communities possess a significant potential for renewable energy and rational use of energy projects implementation in order to proceed towards energy sustainability. Although the local authorities demonstrate their willingness to implement sound local sustainable energy policies, especially through their participation in the Covenant of Mayors' initiative, it seems that this underlying potential remains largely unexploited. Indeed, the lack of technical capacity and the limited resources are the most important barriers for the local and regional authorities.

However, available methods and tools are not always well-adapted to cities and local/regional communities. They do not offer an integrated framework for the development, implementation and monitoring of the Sustainable Energy and Climate Action Plans and especially the selection of the appropriate combination of renewable energy and energy efficiency actions and measures. As a result, there is the need for a methodological framework, appropriately customised to the local and regional communities' characteristics, addressing especially the interested stakeholders who are not "experts" in the field, saving resources and time. The methodology should be a useful instrument for local and regional authorities, facilitating sustainable local energy planning and decision making process.

ACKNOWLEDGMENT

A part of the current chapter was based on the relevant activities conducted within the framework of the project "Rural Web Energy Learning Network for Action – eReNet (Project no: IEE/10/224/SI2.593412), supported by the Intelligent Energy – Europe (IEE) Programme. The content of the Chapter is the sole responsibility of its author and does not necessary reflect the views of the EC.

Chapter 69
How Can ICTs Contribute Towards a More Sustainable Future?

Albena Antonova
Sofia University, Bulgaria

ABSTRACT

Since antiquity technological innovations endanger environmental balance and there is major need to keep this balance in check. Any new technology generates more business activity, leading to increased resource extraction and waste and directly affecting natural ecosystems. Thus technological progress and economic growth are based on unsustainable practices. In the last few decades, information and communication technologies (ICT) accelerated globalized business activity by making the world smaller, more connected and smarter. ICT gradually transformed all aspects of human life including work, learning, and leisure; it has a global impact on business processes and practices, communication, logistics and transportation, finance, and commerce among other aspects. This resulted in wealth accumulation, resource depletion and social divide which have led to problems, directly and indirectly, such as scarcity of natural resources, global warming, climate change, population growth, and increasing youth unemployment. This chapter outlines some of the challenges of the new technologies and ICT practices. It proposes a practice-oriented framework for adoption of more sustainable ICT strategy in companies.

INTRODUCTION

Historically, human progress and development of technologies have created a negative impact on environmental stability and integrity of ecosystems. For 10 millennia, technological innovations have fundamentally transformed the human life. Innovations gradually leaded to resource extinction, environmental exploitation and represent a global trend for the future. In the beginning of 21st century, people could not even imagine the world without technologies. However in order to continue to benefit from technologies people have to make substantial changes in their current business practices and general perceptions. Financial and economic global crises, combined with frequent natural disasters make planning of busi-

ness operations unpredictable with markets being unstable and investments riskier. In the same time, global economic activity has tripled in size since 1980, and is predicted to quintuple in the next 50 years.

The concepts of sustainable development were defined 30 years ago. However, only recently businesses and social communities have opened the discussion for a truly sustainable future. Do we still have time to reverse the global trends? Some of the most urgent problem areas for businesses nowadays are: scarcity of natural resources and their rising prices; fuels; minerals; fresh water; energy; environmental factors (ecosystems integrity, waste management and global warming effects, increased number of natural cataclysms); and social factors (cost of living, increased world population, aging society, mobility and migrations). More generally, politicians, researchers, and companies still miss the holistic approach for coping with increased sustainability challenges. The high complexity of the term "sustainability" makes possible for myriad different interpretations. Moreover, different contexts of applying sustainable concepts and tools lead to overall misunderstanding and perplexity.

Globalization and fast emergence of new technologies resulted in accelerated production and consumption models that provoked irreversible economic, social, and environment changes. New technology-based innovations formed the backbone of the recent economic growth, fueling the market competition and catalyzing social and environmental footprints around the globe. Information technologies transformed the logic of business operations and accelerated the globalization processes. Nowadays information technologies are practically involved in every aspect of human activity including business, education, communication, and entertainment. More specifically, IT plays and increasingly important role in innovations and R&D processes; cost-effectiveness and efficiency; customer services; and finally they have general impact on business competitiveness. Information technologies represent a unique expanding economy sector having large influence on overall economic activity.

Widely spread across businesses all over the world, usually ICT can have very detrimental influence on organizational environmental footprint (Jenkin, Webster, & McShane, 2011). Information technologies have short product life spans (e.g., laptops, 3–4 years; networks, 5–7 years); their manufacturing and disposal have resulted in toxic hotspots; and a large portion of organizations' electricity costs (and concomitant greenhouse gas emissions) is due to IT energy use (e.g., office buildings, 26%; data centers, 95%) (Jenkin, Webster, & McShane, 2011). In contrast to other technologies, information technologies, and especially information systems, have a large potential to reverse the negative impact. As discovered by Gartner (2007), ICTs are responsible for about 2% of global carbon emissions. The main contributing sectors within the ICT industry include the energy requirements of PCs and monitors (40%), data centres, which contribute a further 23%, and fixed and mobile telecommunications that contribute 24% of the total emissions. However, the majority of researches cited by Molla et al. (2008) believe in the potential of technologies to create sustainable business and society. It is estimated that 'Green' IT/IS can have positive impact on the environment with the potential to reduce global emissions by 15% (The Climate Group, 2008). Even dominating corporate reports in the field of green IT/IS speculate that IT has a potential to create new competitive opportunities, to reduce carbon emissions, and to improve overall business efficiency (Molla et al., 2008).

The objective of the chapter is to identify the current trends of ICT and to propose a concise holistic framework for companies to enhance their development and implementation of green IT technologies. Moreover, there is a discussion of several practical aspects and examples. It starts with a short overview of recently emerged concepts of green, sustainable and clean technologies, focusing on green IT. Some related concepts are then discussed as well as sustainable development, sustainable and eco-innovations, sustainable manufacturing. The second part proposes a holistic model for ICT development and imple-

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

mentation in companies. There it highlights the possible role of ICT to enhance companies and business organizations to approach sustainability in a practical and affordable manner. As information technologies play increasingly important roles in any aspect of the business, education and social development, IT can have major influence on sustainable development in micro-aspects. This chapter also discusses different approaches for implementation of information technologies in business settings for improving sustainable development and elaborates on a general framework for sustainable business. Finally there is a general overview of how information technologies can lead to number of sustainable transformations in business, educational and manufacturing processes, and business practices.

BACKGROUND

The background part of the chapter outlines the basic trends and terms that are emerging in research and professional/business literature in the last years. Sustainable development, sustainable manufacturing and sustainable and eco-innovations is presented as general and fundamental concepts that are influencing development of ICT sector. After that some more attention is put on different technologies aspects – green and clean. Finally detailed analysis is made on Green IT and the number of its modifications – green information systems, green networks and green computing.

Sustainable Development

Sustainable development is a well-used oxymoron as the concepts of growth endanger sustainability. The issue of sustainability is extraordinary in both magnitude and complexity and as such is one of the greatest challenges faced by modern society (Ramani et al., 2010). In 1986 sustainable development was defined as a political concept in the Brundtland Report as "…development that meets the needs of the present without compromising the ability of future generations to meet their own needs" (UN, 1987). Sustainability goes beyond the ecological aspects and scarcity of natural resources, as it also includes social and economic stability (Harmakoorpi, 2009). At the 2005 World Summit it was assumed the "three pillars" of sustainability (environment, social, and economic), built on the concepts of the triple bottom line (TBL), developed by John Elkington (1994). The triple bottom line attempts to incorporate financial, environmental, and social capital into a comprehensive framework that can help companies analyze their current processes, innovate, and identify new sources of revenue and cost reduction. According to the research of Arena et al. (2009), along with economical, ecological and social development, technological development should be considered as well. In summary, sustainable development stands for (Filho, 2000):

- Systematic, long-term use of natural resources;
- The modality of development that enables countries to progress, economically and socially, without destroying their environmental resources;
- The type of development which is socially just, ethically acceptable, morally fair and economically sound; and
- The type of development where environmental indicators are as important as economic indicators.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

According to Seliger, Kim, Kernbaum, & Zettl (2008), sustainability is a directive to enhance human living standards while improving the availability of natural resources and ecosystems for future generations. Although important and politically accepted, the concepts of sustainability often miss practical implementation in companies and social communities. Some of the key problem issues with sustainability can be summarized as:

- Too theoretical,
- Too broad,
- Too recently recognized,
- No personnel to deal with,
- It demands substantial resources,
- It lacks scientific base, and
- Too much of a fashion-word (i.e. fad) (Jucker, 2002).

In general, people are generally not aware of sustainability ideas and principles. Although there is widespread popularity of the term "sustainability" in political and social documents, several studies in UK and Germany revealed that people cannot cite any meaningful description of the sustainability (Jucker, 2002). Due to the broad and complex scope of sustainability, people are rather concerned for environment issues and wildlife protection, putting the focus away from economical and social development. Thus to progress with sustainable development, people need to consider practical issues and case studies, best practices and good examples. This will enable them to go into specifics and understand sustainability as something relevant to them, valuable and achievable.

Sustainable Manufacturing

Manufacturing industries are largely promoted to become a driving force for the creation of a sustainable society (OECD, 2009). It is recognized that manufacturing companies can design and implement integrated sustainable practices and develop products and services that contribute to better environmental performance. Moreover, many other challenges to traditional manufacturing companies exists (Anityasari, 2008) and these include increased risk for overproduction, due to fast evolving customer requirements; constant need to frequent up-to-date knowledge; expansion of business scope from design and manufacturing to provision of complex services; and end-solutions approach. Hence, manufacturing should adapt to increased expectations.

Sustainable manufacturing is a business practice of the industrial sector, which expands all the company's processes and decisions into the broader social and natural environments in which the company operates in and affects with its actions. This is executed with the explicit objective of reducing or eliminating any negative impact, while pursuing the desired level of technological and economic performance (Leahu-Aluas, 2010). The US Department of Commerce defines sustainable manufacturing as "...the creation of manufactured products that use processes that minimize negative environmental impacts, conserve energy and natural resources, are safe for employees, communities, and consumers and are economically sound..." (Leahu-Aluas, 2010).

Following the detailed literature review of Arena et al. (2009) about the state-of-the-art in sustainable manufacturing, there have been outlined different factors and sub-factors for sustainable manufacturing. The authors identified several sub-dimensions of sustainable manufacturing grouped around 4 dimensions:

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

1. **Ecological:** Resources – materials, energy, water; depletion and pollution – emissions, biodiversity and waste; human behaviour and activities: products and services, compliance, transport,
2. **Economical:** Economic performance, indirect economic impact, market presence,
3. **Social:** Work practices and work conditions, diversity and equal opportunities, relations with the community, social policy compliance, consumer health and safety and human rights, and
4. **Technological:** Increasing the productivity of natural resources, shift from overconsumption to biological models, moving from ownership to solution-based business models, reinvesting in natural capital.

The life cycle analysis (LCA) addresses all phases of the product life cycle, including the design phase, raw material production phase, manufacturing phase, distribution phase, usage phase, and end of life phase. LCA aims to maximize total product performances during the product lifetime. The life-cycle approach advocates for the attainment of total product performance, not only from an economics perspective but also from social and environmental perspectives.

Eco-Innovation and Sustainable Innovations

Some of the concepts of sustainability discussed above include idea of eco-innovation. The definition of eco-innovation, provided by Reid & Miedzinski (2008), states that "eco-innovation is the creation of novel and competitively priced goods, processes, systems, services and procedures designed to satisfy human needs and provide better quality of life for everyone, with a whole-life-cycle minimal use of natural resources (materials including energy and surface area) per unit output, and a minimal release of toxic substances." However, eco-innovation and sustainable innovations are not synonyms.

Harmaakorpi (2009) claims that sustainable innovation is an umbrella term and stands for: ecologically sustainable development; participatory innovation (including customers, employees, users and the general public); continuous innovation (the ability to continuously regenerate and break boundaries); global innovation (innovation in global cooperation using knowledge distributed everywhere); innovative management (or management encouraging innovation in organizations and society). The authors Maxwell, Sheate, & van der Vorst (2003) highlight that sustainable innovation is innovation aiming to generate benefits that are collective in terms of the environment, society and economy while reflecting a new out-of-the-box approach that very often challenges traditional systems.

Thus many scholars understand sustainable innovations as a form of disruptive innovations that are continuously changing and threatening existing economic and social models. This explains why it is extremely difficult for companies and politicians to accept, and work for, this fundamental change, and why they often prefer to substitute the term with eco-efficiency, dematerialization and ecology-friendly production (Charter, 2004). Arvidsson & Mannervik (2009) also discuss the need for revolutionary change in the innovation system, emphasizing that the old dominant conceptual model for innovations is outdated and has to be replaced by a new one.

Clean/Green Technologies

Hart (1997) decomposes sustainable development into clean technologies (i.e., environmentally sustainable technologies) and sustainable vision (i.e., plan for moving towards sustainable development) as part of the sustainability portfolio. "Clean technology" stays for the concept that both efficiency and

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

productivity can be increased by using new processes, products and services, while at the same time reducing greenhouse gas emissions and protecting natural resources (DCTI, 2013) Thus Clean technologies are competitive with, if not superior to, their conventional counterparts. Many also offer significant additional benefits, notably their ability to improve the lives of those in both developed and developing countries. The Deutches CleanTech Institute, together with KPMG and institute developed a complex framework (DCTI, 2013) including: environmentally friendly energy and energy storage; solid waste management, sustainable water management, sustainable mobility, resource efficiency, energy efficiency.

"Green" has become a popular term for describing things that are good for the environment, generally healthful and economically sensible (Prothero & Fitchett, 2000). Green in the modern business language is the color of environment, future-orientation, ethical and responsible business. In the professional literature, terms like green IT, green IS, green networks and green computing emerged, often used as synonyms.

Green IT

One of the widely accepted definitions proposed by Watson et al. (2008) is based on the differences between green IT and green IS. In general, information technologies transmit process or store information. Therefore, green IT should focus on energy efficiency and equipment utilization. That is why Molla et al. (2008) considers green IT mainly as data center efficiency and narrowly defined green IT as technologies and tools to reduce power, cooling and real estate costs, associated with data centers operations (Molla et al., 2008).

Among popular definitions is that of Watson et al. (2008): 'Green IT' addresses energy consumption and waste associated with the use of hardware and software, tends to have a direct and positive impact. Examples include improving the energy efficiency of hardware and data centers, consolidating servers using virtualization software, and reducing waste associated with obsolete equipment (Watson, Boudreau, Chen, & Huber, 2008).

From practitioners' points of view, a global survey conducted in 2009 highlight that to companies Green IT means lowering electric and cooling costs and promoting sustainable energy practices (Accenture, 2009).

After providing an overview of green IT definitions in literature, Molla et al. (2008) proposes holistic conceptualization of green IT from 4 perspectives: sourcing perspective (purchase green technologies); operation perspective (energy efficiency); service perspective (overall services for sustainability as measuring and analytical tools for greenhouse gas); and an IT life management perspective (waste and life-cycle management).

From a supply chain perspective green supply chain refers to integrating environmental thinking into the product design, sourcing, manufacturing, warehousing, distributing and end of life product management aspects of a supply chain. Thus, from a strategic perspective, green strategy articulates a business' intention to cultivate good environmental stewardship while at the same time pursuing economic goals (Olson, 2008).

Green IS

Green information systems represent an integrated and cooperating set of software using information technologies to support individual, group, organizational or societal goals. Therefore, green IS refers to the development and use of information systems to support or enable environmental sustainability

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

initiatives and, thus, tends to have an indirect and positive impact. Examples include: collaborative group software and telepresence systems to enable remote meetings and reduce the negative environmental impacts associated with travel; environmental information systems to track and monitor environmental variables such as waste, emissions, toxicity, water consumption, and carbon footprints; and supply chain systems to optimize product routing and transportation, thus reducing the amount of energy consumed moving products (Watson, Boudreau, Chen, & Huber, 2008).

Some other relevant definitions include green computing, defined by Talebi and Way (2009) as "a discipline that studies, develops and promotes techniques for improving energy efficiency and reducing waste in the full life cycle of computing equipment from initial manufacture, through delivery, use, maintenance, recycling and disposal in an economically realistic way" (Talebi & Way 2009). Chilamkurti, Zeadally, & Mentiplay (2009) describe Green Networking as covering all aspects of the network (personal computers, peripherals, switches, routers, and communication media). Energy efficiencies of all network components must be optimized to have a significant impact on the overall energy consumption by these components. Consequently, these efficiencies gained by having a Green Network will reduce CO_2 emissions and thus will help mitigate global warming. The Life Cycle Assessment (LCA) of the components must be considered. LCA is the valuation of the environmental impacts on a product from cradle to grave.

KEY ASPECTS OF GREEN IT/IS

Green IT

Some of the common criteria for defining what green products include: energy use, greenhouse gas production, raw material source, emissions (air, water), waste production, water usage, land use, end of life, toxicity, use and exposure. Any of these metrics is complex to measure and to estimate along the end-product value chain. Many of the authors and definitions above point out that green IT is mainly focused on energy efficiency and equipment utilization. Green IT substantially addresses issues related to reduced energy consumption and waste management. Moreover, one of the major concerns is the rise of datacenters (Dunn, 2010). There are estimates that in 2020 they will be 5 times more datacenters than there was 2002. Another important aspect is related to electronic waste, including obsolete computer and television equipment, mobile phones, old cables and additional IT equipment. As the number of users of ICT devices constantly increase and the lifespan of these products is between 1-3 years, e-waste is constantly accumulating and it generates serious problems in the environment.

Therefore, according to (Watson, Boudreau, Chen, & Huber, 2008) Green IT can refer to:

- Designing energy efficient chips and disk drives;
- Replacing personal computers with energy efficient thin clients;
- Use of virtualization software to run multiple operating systems on one server;
- Reducing the energy consumption of data centers;
- Using renewable energy sources to power data centers;
- Reducing electronic waste from obsolete computing equipment;
- Promoting telecommuting and remote computer administration to reduce transportation emissions.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Some recent technologies supporting Green IT include cloud computing, data centers, virtualization, social networks and Web 2.0, mobile computing and storage trends, nanotechnology and cooling systems, remote control systems, and energy management systems. The emphasis on services and cloud computing provide many promising technologies such as SaaS (software as a service), PaaS (Platform as a service), and IaaS (infrastructure as a service). In this case users don't need to purchase software licenses and up-dates or to install new programs on their computers, but can access the Internet and use the application services on-line (for example Google docs).

The list above can be largely improved as Green IT is perceived only as a final good or product, and rarely as part of larger ecosystem. The use of IT technologies is incremental as it depends on software development and software efficiency. People don't need ICT equipment per se; they require complex services involving multiple applications and supporting equipment. End-users, managers, system administrators and clients will purchase and use IT equipment only as a consequence of the services it will obtain. Therefore, Green IT should be analyzed from the service science perspective (Antonova, 2012), covering value co-creation processes with end-users. Taking into account this perspective, there should be highlight on the role of software development, quality assurance models, and studies of human-computer interaction and usability tests. Therefore Green IT should not put the focus on how to create new, better and energy-efficient equipment, but how to increase user satisfaction and utility from running quality and efficient software applications while saving time and efforts and improving quality of human-computer interaction. Many social practices can aid to improve ICT use. For example, limiting the use of Cc (i.e. Carbon copy) function on e-mails can significantly reduce the time for e-mail processing.

Green IS

Many researchers highlight the difference between green *in* IT and green *with* IT. Green IS generally refers to the design and implementation of information systems that contribute to sustainable business processes. Green IS, for example, helps an organization to (Watson, Boudreau, Chen, & Huber, 2008):

- Reduce transportation costs with a fleet management system and dynamic routing of vehicles to avoid traffic congestion and minimize energy consumption;
- Support team work and meetings when employees are distributed throughout the world, and thus reduce the impact of air travel. IS can move remote working beyond telecommuting to include systems that support collaboration, group document management, cooperative knowledge management, and so forth;
- Track environmental information (such as toxicity, energy used, water used, etc.) about the creation of products, their components, and the fulfillment of services;
- Monitor a firm's operational emissions and waste products to manage them more effectively; and
- Provides information to consumers so they can make green choices more conveniently and effectively.

Application of green information systems can lead to a substantial improvement in company performance and efficiency. Green IS has a greater potential than green IT because it tackles a much larger problem. It can make entire systems more sustainable compared to reducing the energy required to operate information technologies.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

With development of new high-technology products and services, and the emerging complex business models, the end-users can improve the overall use of products and services without the need to possess them. The key concepts of service science and value creation can enhance many green IS practices while leading to successful business models and practices. Green IS can substantially decrease the popularity of product possession models and promote service in use models. Moreover they can largely increase self-services and therefore optimize business expenditures, client satisfaction, and need.

HOW TO TRANSFORM GREEN IT/IS TO SUSTAINABLE IT/IS: INTEGRATIVE FRAMEWORK

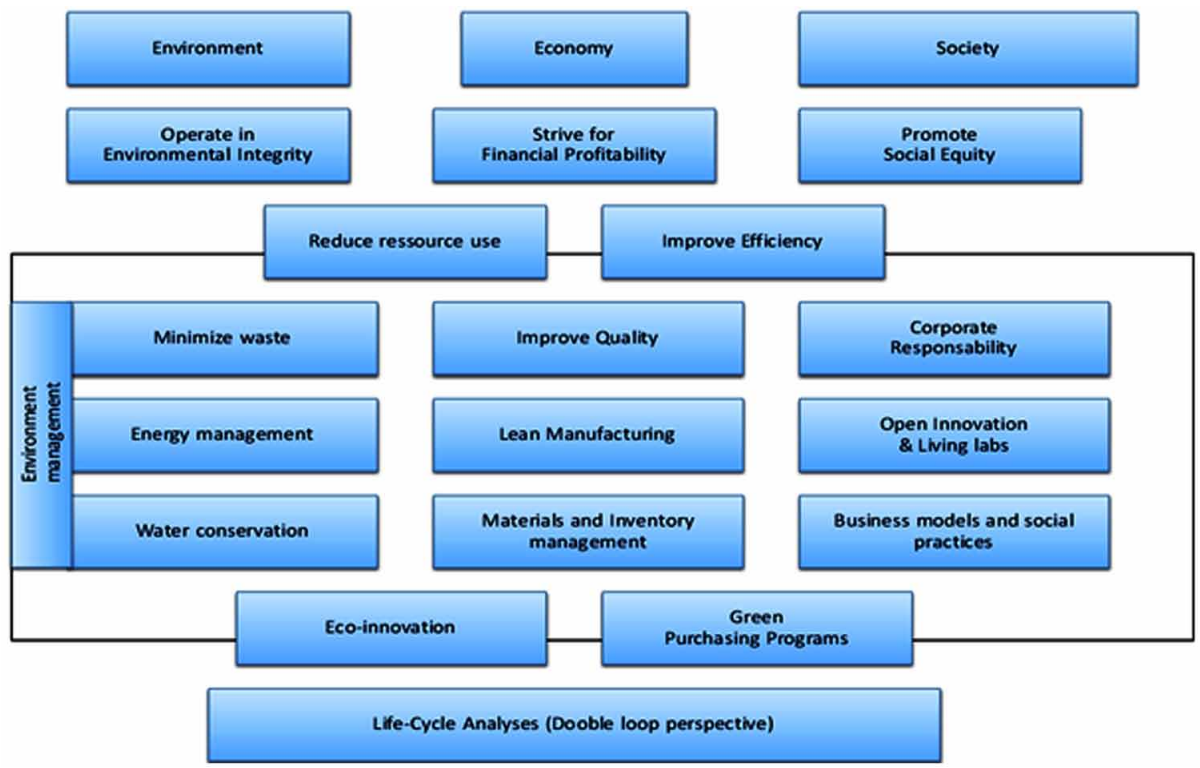
In order to facilitate the adoption of Green IS/IT, different authors proposed several models for adoption and measurement of Green IT/IS. For example Philipson (2010) proposed a green IT framework – RMIT model, called Green IT framework. Here 4 IT concepts are covered (equipment lifecycle, end-user computing, enterprise and data centers, IT as low-carbon enabler) in 5 perspectives – attitude, police, practice, technology, metrics. Based on these sections, Philipson (2010) approaches a quantified methodology to survey respondents and identify a Green IT readiness index, allowing public authority to obtain data in order to compare different industries and different periods. However, the model proposed is focused mainly on the green IT perspective.

After analysing some of the key terms covered by Green IT/IS, it is critical to understand how companies can interpret and adopt sustainable IT/IS framework. From a practical standpoint, the model is based on the considerations that:

1. Sustainable IS/IT should cover all 3 aspects of sustainability – environment, economy and society, moreover, it should support both green IT/IS and green with IT/IS approaches;
2. Sustainable IS/IT should be produced by sustainable manufacturing practice and should facilitate sustainable manufacturing processes;
3. Sustainable IS/IT is a complex ecosystem of interactions, aiming to reduce resource use and improve overall efficiency, including many technological and business practices;
4. Sustainable IS/IT leads to short term and long-term business benefits and involve large pull of interconnections in company;

A sustainable IS/IT model should cover all substantial business processes of the IS/IT life-cycle. Therefore it includes management, social and technological aspects, which highlight the role of participants in the complex eco-system:

- Conception (R&D, eco-innovations), supply of raw materials (country of origin, quality, price, eco-aspects – suppliers screening);
- Delivery of raw materials (stock piles, delivery policy, SCM);
- Production (energy consumption, pollution, quality standards, production processes, employees (work conditions, office/production energy consumption, equipment) environment (environment screening);
- Delivery of final products (stock, delivery policy, SCM), trade agreements, service;



EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

- Marketing &after sale policy (promote durability, promote buy-back policy, repairing, guarantees, long-term service);
- Business models (provide products/services people want and need – accent on conception phase and user-co-creation; open innovation processes, attention on resource use, holistic vision of the company role in the economy; testing and evaluation, living labs;
- Main results - increase efficiency, increase services and not in products.

In consideration of these stated considerations, the model of sustainable IT/IS is proposed below with the aim to improve visibility of the key sustainability issues. The model combines TBL with increased efficiency and cost/resources optimization. More importantly, it cover LCA analysis and cradle-to-cradle approach, and facilitates companies through implementation of an IS/IT strategy and to easily identify how they use and deploy IT in their business. It aims to provide a general understanding of inter-relationship between various complementary terms within the Sustainability field. Finally the framework proposes a comprehensive and multidimensional challenge in defining the road ahead and the options for sustainable future development.

The reference model (Figure 1) includes 3 main reference fields – operate in environmental integrity, strive for financial profitability, and promote social equity. Companies should discover how IT/IS on one hand responds to these conditions and on the other hand leads to these in the context of their corporate use. The environmental management includes waste minimization, energy management and water

Figure 1. Sustainable IS/IT reference model

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

conservation. Therefore companies should adopt practices and specialized systems to assess its energy efficiency and greenhouse gas effects. Time is another crucial resource and therefore companies need to consider that sustainable technologies are time-efficient and save/budget time for development, use and exploitation. Quality is a substantial part of any technology solution. The quality of IT/IS equipment is a prerequisite for use and intention to use the IT systems by users. At the same time IT/IS can support various quality assurance processes including assessments of value and quality obtained from end-users. Lean manufacturing approaches allow companies to focus on leading processes and features, concentrating on resources optimization and smarter technologies. For example new emerging practices as additive manufacturing (3D printing) can replace other much more energy-consuming technologies. Materials and inventory management requires careful policy for materials purchase, based on the principle of material substitution. Inventory management can be facilitated and improved by specific tracking and logistic systems. Corporate social responsibility (CSR) becomes a popular business practice as capability to comply with the mounting demands of different environmental groups and government regulations and practice socially oriented moral management is a major concern and an issue that might affect competitiveness. Open innovations and living labs can improve interactions between the company with end-users and third parties. Last, adoption of innovative business models and social practices will lead to substantial changes. Green purchasing programs and eco-innovations designate the continuous process of improvement, involving marketing and promotion factors across the supply chain. Life cycle analysis is the crucial element in any technology or product in the company as it shows its ecological footprint from the cradle till the final disposal.

DISCUSSION

Bleischwitz, Giljum, Kuhndt, & Schmidt-Bleek (2009) identified three main industrial areas that employ the majority of the earth resources and impacts ecology, economy and sustainable development in a global scale. The three industries are housing, mobility and food production, together with their overall supply chain and subsectors. Careful optimization of ICT use in these sectors could largely influence the production process and use of natural resources, chemicals and energy, change of consumer choice and customer habits, and can generally decrease waste and optimize the economic structure. Thus focusing a company's sustainable IS/IT practices and optimization of the information use in these specific sectors can lead to substantial improvement both in economy and ecology. Moreover, Bleischwitz et al. (2009) believe that companies will be the main drivers of eco-innovations and sustainable progress, propagating production and delivery of eco-innovative products and technologies and educating customers and citizens for sustainable use practices.

While ICTs continue to transform commercial, business and social practices on the global landscape, we can expect that new technologies will continue to emerge. Soon it is expected that new coming ubiquitous and pervasive technologies (such as augmented reality, additive manufacturing—3D printing, Internet of things, future internet and robotics) will bring many new challenges for sustainable development. These new IT/IS applications will substantially change the way products and services are designed, produced and consumed. Undoubtedly this will have larger impacts on the earth's ecosystems, employment, social divide and sustainable development as a whole. Robots and additive manufacturing systems can signifi-

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

cantly reduce the need for a low-skill labour force. Moreover, today robots can replace the highly qualified work of surgeons, while smart toilet systems can become personal bio labs, transforming fundamentally the healthcare system. At the same time the youth unemployment is increasing globally, while public social systems and pension funds are put at risk from the very large aging population.

Historically technologies and new discoveries have been continuously transforming the business and have led to social unrest since the first industrial revolution. Thus "dehumanizing" business by applying more technology solutions should not mean that working places and jobs have to disappear, or that the social and economic divide should increase. New technologies lead to new level of development. The global economy realizes an expanding wealth accumulation according to the recent reports (Credit Swiss, 2013), reaching new levels of productivity and efficiency. New emerging technologies open many new opportunities. It can be expected there to be the emergence of a new sensor-enabled digital world, where the objects have "senses" to collect and process information, accumulated through hearing, seeing, communicating, reacting, deciding, memorizing and storing. This can lead on the one hand to minimizing resource usage and waste ("cost" oriented approach) and on the other hand, it can provide improved services, based on synergy of value networks for customers (becoming "profit-centers").

However, the fast implementation of technologies in different social contexts can threaten many professions, industries and economic sectors, so the society needs to set up new understanding about the "risk price" for technology adoption. Sustainable development should become priority to companies, the public and the entire society. Instead of continuing short-term production, companies have to reconsider how to improve the quality and durability of products and services in order to limit the waste of resources during its whole life-cycle and improving recycling and ecological balance. Thus in order to change the concepts of resource extraction and use, companies will need additional support to redefine production processes, business models and value-creation mechanisms. Therefore, companies should move from simple end-products to complex service sales, designing value co-creation experiences with clients while concentrating on revenue perspectives.

CONCLUSION

Since innovations and technologies have general impact on environment, and lead to substantial growth and exploitation of economic resources, sustainability is a key concern when designing and developing new products and services. ICTs should be considered in every sector - from employing electricity and energy resources, to responsible for substantial waste accumulation. On the other hand, ICT can improve many existing production and business practices that can lead to more sustainable business and technologies.

This chapter proposes a new model for understanding sustainable technologies, that can enhance companies to understand how sustainable their ICT strategies are and which aspects are covered. While discussing different concepts of ICT, the focus on green, eco or clean are just labels toward a more general paradigm shift. ICT has too often been considered a "driver for the business", and as such has been viewed in the silo of the specific project for which it is needed. By viewing ICT strategically across the entire organization and even fundamental social infrastructure, ICT can become the "engine of the business" (Accenture, 2009).

KEY TERMS AND DEFINITIONS

Eco-Innovations: Innovations in products, services and processes that lead to more environment-friendly practices – including limiting and re-use of raw materials – decreasing waste and product disposal.

Green IS: Design and implementation of information systems that contribute for sustainable future in long-term, including technologies and business models that limit the resource use, increase energy efficiency and contribute for reconstitution of business and social practices.

Green IT: Cradle-to-cradle approach for information technologies, including design, implementation, deployment, use, recycling and disposal of IT devices (digital devices; computer-enhanced devices).

Sustainable Development: Development based on economic, social and technological progress, using limited consumption of natural resources, having minimal impact to the environment; Sustainable development should lead to the increase of humankind knowledge in order to cope on socially just and responsible for the future generations' way with environment limitations, resource use, overcoming natural and human-provoked crisis and cataclysms.

Sustainable Innovations: Innovations in products, services and processes that lead to more sustainable for the planet practices and long-term benefits. These innovations should cover the three pillars of sustainability – to be environmentally friendly, to be economically sound, to be socially just.

Ubiquitous and Pervasive Technologies: Digitally-enabled products and technologies that will enhance data and information collection, processing and delivery and Internet connectivity, increasing products usability and capacity for service delivery.

Chapter 70
A New Barrier for the Future of Energy Market in Turkey: Internal Capital Adequacy Assessment Process (ICAAP)

Esin Okay
Istanbul Commerce University, Turkey

ABSTRACT

The Banking Regulation and Supervision Agency (BRSA) in Turkey has implemented a risk based framework since 2006, making bold moves of resulted in a stellar increase of capital adequacy in Turkish Banking System. But the enactment of the new law for the Internal capital adequacy assessment process (ICAAP) is evaluated as being quite an early adoption. The Bank for International Settlements (BIS) points that Turkey has early-adopted the implementation recommending further discussions for a reconsideration of the target capital adequacy ratio. The banks have already found it difficult to follow up high capital adequacy especially while financing energy projects, as the Turkish Banking system is preparing for the requirements of Basel III framework. Under the new regulation, the ICAAP is expected to decrease the capital adequacy of banks in Turkey. Meanwhile, the challenge in adopting ICAAP can be an additional barrier standing in the way to the development of energy market.

INTRODUCTION

Measures to promote the development and use of energy and energy efficiency deserve targeted attention, because not only do they promote sustainable approaches to energy development, but they are characterized on a geo-political level by the need for environmental and supply security, on an operational level by the need for issues like "cost". So, for example the importance of energy projects and energy efficiency has resulted in the development of specific targets in US. and EU, along with changes in legal frameworks and guiding principles to remove barriers to innovation and technology development and reducing expensive up-front costs (EBRD, 2010a).

Global economy need to obtain sustainable and clean sources of energy which is an issue of financial challenges. In the last decade, the cost of renewables has decreased dramatically. Yet, large debt problems of the developed countries and a worldwide fear of risk and uncertainty still continues blocking investments and affecting global energy market and energy solutions. Especially, developing countries face problems of energy sourcing due to costs and risks.

Turkey, as a developing country, implemented policies to improve renewables and energy efficiency in line with EU requirements. After the implementation of Energy Efficiency Law (EEL) in Turkey, Turkish engineering firms show considerable interest in energy savings projects. There is a growing sign of an energy efficiency implementation in Turkey. However, energy importation costs of Turkey still present a challenge leading to huge financial burdens. Turkey has still heavy risks of regulatory and financial aside the high potential of creative energy solutions (Okay, 2015).

The key issue is "banking" to energy finance enabling risky energy projects such as renewables, energy saving solutions, innovative energy and creative engineering. Nowadays, energy financing banks in Turkey are the highest ranked in discussions with the internal capital adequacy assessment process (ICAAP). ICAAP came into effect by 31st March of 2016 by the enforcement of Banking Regulation and Supervision Agency (BRSA) in Turkey. ICAAP is one of the most important and advanced guideline by Basel II which will have direct effects on financing risky energy projects. Therefore, it became a hot issue both in the banking and energy sector. Both sides have concerns of challenges, adoption and loss. What's more, it seems that the viewpoint of BIS, as an early adoption, consider and meet all these concerns.

This study has three main objectives. The first objective is to reveal the themes behind the internal capital adequacy assessment process in the light of Basel accords. In this context, the importance of risk management and supervision in the banking sector is presented in the background of the paper. The main focus of the chapter is to extend the internal capital adequacy assessment process regarding the energy project financing and risks that banks face in Turkey. The remaining problematic issues involve in this section where Turkey's facing heavy risks of regulatory and financial aside the high potential of energy solutions. There is still a huge need to improve the financial environment and awareness for energy projects and solutions in Turkey. The study concludes with the recommendations on new requirements about ratio changes in capital adequacy for banks regarding the problems consisting of energy finance in Turkey.

BACKGROUND

The banking sector is a highly sensitized system and has learned to its cost the risk of attracting adverse publicity through failings in governance. Banking is clearly a very special sub-set of corporate governance with much of its management obligations enshrined in law or regulatory codes. These factors put banks considerably into a more complex world than in other sectors. Banks attempt to comply with the same codes of board governance as other companies but, in addition, factors like risk management, capital adequacy and funding, internal control and compliance all have an impact (Okay, 2005). As a matter of fact, banks must be surrounded with risk management principles as a firewall. Capital adequacy and related issues of funding and internal control are all going along with risk management principles.

Risk management is a main concern for the front and middle office functions of banks that became increasingly important for fund managers in the volatile financial markets of today. The current trends in risk management are de-regulation of financial markets, increasing bank supervision and regulation and technological advances (Alexander, 2003). Especially, the item of increasing bank supervision and

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

regulation is the major issue in risk management that has reached a generally accepted law in the world, the so called Basel implementations.

Basel accords are designed by Basel Committee on Banking Supervision (Committee) that was formed in 1974 with the participation of G10 countries, as a platform to provide member countries to share their knowledge and experiences in the field of banking (BRSA, 2016a). There has been a gradual extension of capital adequacy requirements to cover more types of risks: First credit risks (1988), then market risks (1996) and now operational risks (2004) (Alexander, 2003). In 1988, the Committee published the Basel Capital Accord (Basel-I) aiming to uniform different capital adequacy standards in different countries. Afterwards, Basel-II Accord was published in 2004, Basel-II.5 Accord in 2009 and Basel-III Accord in 2010, as to include the developments in financial markets and banking (BRSA, 2016a).

Before the Basel I Accord in 1988, regulators required only limited reporting of risks and imposed only some simple credit limits. The Basel I Accord introduced the first capital requirements for banks, but the requirements were product based – mainly for loans – with no offsets, netting or market sensitivities. The Basel I Amendment (1996) and the forthcoming Basel II Accord (2004) have introduced quantitative measures for capital adequacy that are risk sensitive, but not overly reactive to short term fluctuations (Alexander, 2003). Basel II is so special that it provides incentives to strengthen domestic supervision pushing banks to become more sophisticated in their management of risk (Powell, 2004). Besides Basel II intends to promote safety and soundness in the financial system, align regulatory capital requirements more closely with underlying risks, provide incentives for institutions to pursue more sophisticated and effective risk management, and demonstrate robust governance, processes, and controls to shareholders and institutions.

Risk management stand at a turning point when banks deal with energy projects. Third party financing is the most commonly used type for energy projects and it can be realized by a guaranteed saving contract. Country risk, credit risk and counterparty risk play a major role via projects with too high level of risk as for the case with energy projects. So, energy financers should have strong balance sheets. Energy financers in literature, are called Energy Service Companies (ESCOs). ESCOs may finance, or assist in financing an energy project (including renewable and sustainable energy projects) by providing an energy-improvement (saving, efficiency, conservation) guarantee. Recently, interest in ESCOs has increased due to increasing energy costs and economic penalties attached to excessive energy usage and related emissions (Akman, Okay, Okay, 2012).

On the other hand, banks must have strong assets to take on huge liabilities of clients that have long-term projects. This is extremely a big risk that points to a considerably significant size-based balance sheet to finance projects. Therefore, energy companies should be committed to risk management, as well. Energy projects should be managed with risk reduction methods like hedging instruments and venture capital. When energy companies need financial support to invest such risky projects banks analyze detailed financial statements before extending credit. Besides, banks should implement Basel II, and then Basel III (BIS, 2012).

The purpose of Basel II-III risk implementations is to provide an international standard and monitoring for legal authorities in risk measurement. Basel III, presents the latest upgrade of Basel Committee's reforms to strengthen global capital and liquidity rules with the goal of promoting a more resilient banking sector. The objective of the reforms is to improve the banking sector's ability to absorb shocks arising from financial and economic stress, whatever the source, thus reducing the risk of spillover from the financial sector to the real economy. The Committee's analysis has also covered further measures to mitigate the risks or externalities associated with systemic banks, including liquidity surcharges, tighter

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

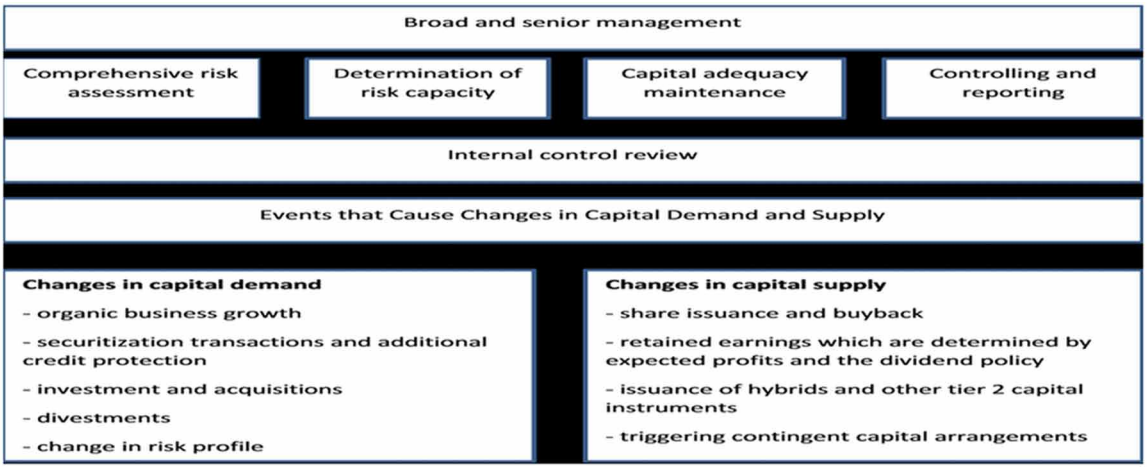
large exposure restrictions and enhanced supervision (BIS, 2011). Basel III is expected to restrict banks with heavy capital and liquidity requirements that will be unfavourable for renewable energy financing in the future.

Basel III is expected to be implemented globally between 2013 and 2019 (BIS, 2013). But the 2019 deadline can be suspended to another date because of a global economic and financial change as the risks and uncertainty rise in the world.

Internal Ratings-Based Approach (ICAAP)

Banks take on risks in order to gain return, therefore management system to identify and take on well priced risks becomes ever more important in today's competitive banking market. Basel II, Pillar 2 demands banks to put an internal capital adequacy assessment process in place. Like in any business enterprise that involves the commercial provision of products or services to meet a particular need, owners of banks require to be compensated for the resources that they invest to generate such services (Hazem, 2009).

Therefore, implementation of the Basel II Framework was crucial for serving as a catalyst to encourage greater cooperation and communication in global banking especially when Basel I became insufficient. While there are differences in supervisory approaches across countries, Basel II includes an important measure for promoting communication and transparency, a large and growing number of countries have put in place and made available to the public their Pillar 2 evaluation processes for a bank's internal capital adequacy and assessment, in short ICAAP (BIS, 2007).



By undertaking an ICAAP, banks are more equipped to assess the level of capital needed to support current and future risks, including a buffer for stress scenarios. Well-run banks view it as a core strategic activity that safeguards operations including in times of stress, rather than as a compliance exercise (IFC, 2016).

ICAAP is an advanced capital management for measuring the capital adequacy of banks by the legal authority. A thorough and comprehensive process, ICAAP is a vital component of a strong risk management programme. ICAAP should produce a level of capital adequate to support the nature and level of the bank's risk. It is the role of the supervisor to evaluate the sufficiency of the bank's internal assessment and to intervene where appropriate. When assessing whether a bank is appropriately capitalised, bank management should ensure that it properly identifies and measures the risks to which the bank is exposed. In addition, the ICAAP should incorporate stress testing to complement and help validate other quantitative and qualitative approaches so that bank management may have a more complete understanding of the bank's risks and the interaction of those risks under stressed conditions. A bank also should perform a careful analysis of its capital instruments and their potential performance during times of stress, including their ability to absorb losses and support ongoing business operations. A bank's ICAAP should address both short- and long-term needs and consider the prudence of building excess capital over benign periods of the credit cycle and also to withstand a severe and prolonged market downturn. Differences between the capital assessment under a bank's ICAAP and the supervisory assessment of capital adequacy made under Pillar 2 should trigger a dialogue that is proportionate to the depth and nature of such differences (BIS, 2009).

Pillar 2 has been implemented by the international regulator to take into consideration such sources of risk that are not part of Pillar 1 and may be difficult to quantify. Large organisations are already required to develop a comprehensive framework to assess the overall adequacy of their capital allocation with regards to the key risks their business model is exposed to. Under this framework, banks also have to

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. ICAAP principles
(Source: KPMG)

elaborate a capital planning aligned with their strategic and business plan. This capital planning has to be performed over a certain horizon of time, usually between 3 and 5 years, and is comprised of a base case with at least three different stress scenarios, including an identified worst case. This is to test the resilience of the bank's capital base (loss absorption capacity) under severe stress conditions. Last but not least, banks have to demonstrate that the ICAAP framework is embedded in their decision-making process and that it is not a one-time compliance exercise but rather a critical governance tool for top management. This could be an important change, as well as a challenge, for organisations that did not perform ICAAP exercise in the past because they may now have to consider additional capital requirements (Deloitte, 2015).

FINANCIAL BARRIERS FOR ENERGY MARKET IN TURKEY

Turkish Banks Financing Energy Projects

Studies of compliance of Turkey with Basel standards have been started with capital measurement method based on Basel I published in 1989. Various studies regarding compliance with Basel II standards have been conducted and numerous regulations have been prepared since 2005. Then, Turkey was accepted as Committee member as of May 25, 2009. Regulations on own funds, capital adequacy, liquidity, leverage and capital buffers in line with Basel III were entered into force between years 2013 -2015 (BRSA, 2016a).

The participating Turkish banks and the EBRD together created a powerful brand for sustainable energy finance, and built a lasting relationship through which new partnerships were created to finance larger projects (EBRD, 2014). However, the banks have already found it difficult to follow up high capital adequacy especially while financing energy projects, as the Turkish Banking system is preparing for the requirements of Basel III framework.

Turkish banking system, with 52 banks, is growing after 2013 as shown in Table 1. Indeed, the branches and staff are fastly growing with 12.269 branches and 217.504 as of December 2015. There has been an

important change in the asset composition of banks' balance sheets in recent years. Banks are increasingly invest in loans (especially in consumer and SME loans) while decreasing their securities portfolio. For the liability side, the main funding source is traditionally deposits although the share of interbank liabilities has been increasing (BRSA, 2016c). At the same time, with its diversified branch network and strong customer base, banking system has reached a strong profitability in recent years (BRSA, 2015).

Despite the banking sector's high capital adequacy and profit after the adoption of Basel accords, lastly Basel II, lending volumes remain depressed. This is primarily because of the risk-averse approach of the new banking system and contrarily much attributed private sector and its capital inadequacy. Unfortunately, Basel II was not implemented by the private sector in Turkey. Only large-sized firms in private sector are on the platform to establish an energy market. If they come together to form joint ventures with domestic firms or established foreign energy companies, the result might change. If not, then energy financers should have strong balance sheets. Energy companies must have strong assets to take on huge liabilities of clients that have projects of 7-10 years. This is extremely a big risk that points to a considerably significant size-based balance sheet to finance projects. Therefore, they should be committed to risk management. Turkish private sector -consisting of %99 small and medium sized (SMEs) - maintains the effects of weaknesses and inadequacies for years that provide insight on the limits to firm growth and sustainable investment. Companies in Turkey do not use risk management tools. Without risk management, SMEs in Turkey especially have to bear size risk, credit risk, capital inadequacy, regulation risk, technology risk and country risk (Okay, 2014).

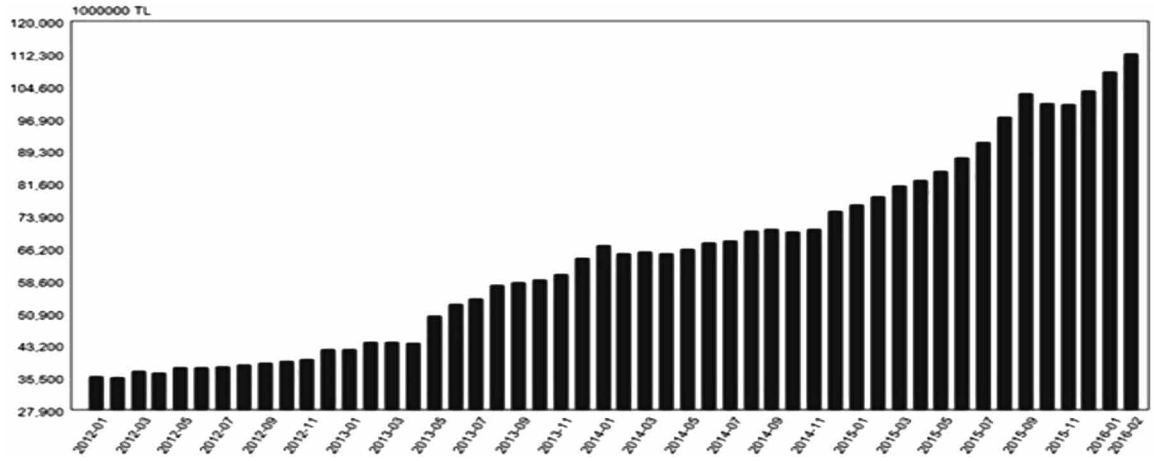
The banks in Turkey struggling to meet the demand of energy industry. Some Turkish banks, unfortunately low in number, with EBRD and World Bank together created initiation to build programmes for energy finance as shown in Table 2 (detailed in section Solutions and Recommendations). However, the number of subsidy support provider and launched programmes are not that powerful enough to influence energy market in Turkey with a huge demand in energy inspite of a potentially dynamic and strong banking system regarding quantitative and qualitative specifications.



At the same time, Turkish banks are pressing for solutions to non-performing loans. Loan defaults are on the rise and banks are facing difficulty floating US$ 50 billion of total credits to the energy sector (Dilek, Schlissel, 2016).

THE NEW BARRIER: ICAAP AND TURKISH BANKING SECTOR

Issues, Controversies, Problems

After the EEL and related subsequent regulations, one of Turkey's hot issue in the energy sector was –and still is– to establish an ESCO market. The next step will be to draw interest for international investment in the market. Without foreign capital, with merely the support of international financial institutions, the market will not be able to prosper because this is primarily a risk-based capital system that Turkey is trying to master. One of the most important difficulties that local companies face in Turkey is capital inadequacy, and therefore, they are unable to act as market makers (Okay, Okay, Akman, 2013).

On October 23, 2015, the BRSA issued sixteen new and amended regulations and communiqués in accordance with the Basel Committee's Regulatory Consistency Assessment Program (RCAP) in an effort to further harmonize Turkish banking rules with Basel III criteria. This most recent package of changes introduces Basel III standards for capital adequacy calculations and risk-weighting methods along with a new set of rules for banks' risk management disclosures for financial statements (Keskin, 2015).

One of the criteria called as ICAAP that came into effect by 31st March of 2016 is evaluated as being quite an early adoption. BIS points that Turkey has early-adopted the implementation recommending further discussions for a reconsideration of the target capital adequacy ratio. The related team of BIS considers the implementation by the BRSA of the Internal Ratings-Based (IRB) approach for credit risk to be compliant with the Basel framework. During the assessment process, the team identified a number of deviations, which were subsequently rectified by the BRSA. Currently there are no IRB banks in the Turkish market. However, many large domestic banks, mostly subsidiaries of international banks, are already using an IRB model for their internal risk management and lending process. These models were typically developed by their parent banks and received the IRB approval from their home authorities. The banks are in the process of calibrating and adjusting those models in order to appropriately capture the risks of the local market in Turkey, before submitting them for regulatory approval by the BRSA (BIS, 2016a).

Capital adequacy approach of Basel is a fairly enabling subsidy system for banking sector offering credits in a healthy way. But ICAAP is expected to decrease the capital adequacy of banks in Turkey. Meanwhile, the challenge in adopting ICAAP can be an additional barrier standing in the way to the development of energy market.

Besides, analysts expect non-performing loans in Turkey to rise in the coming years, weighing on earnings at a time when buffers have been reduced. Rapid credit growth leads to growing ratio of bad debt in the Turkish banking sector. Many loans are foreign currency denominated, increasing risk. Regulatory changes have helped reduce credit risk, and banks look well-positioned to absorb shock in all but a severe crisis. However, banks are aware of the growth in non-performing loans' volumes after years of rapid credit expansion, and are right to look to address the issue (Oxford Group, 2015).

On the other hand, lira depreciation also erodes bank capital ratios because foreign currency assets represent a higher multiple of lira-denominated equity. Fitch estimates that a 10% fall in the lira results in a 50bp fall in sector capital adequacy ratios, which reached 14.8% at end-August 2015. Banks in Turkey wishing to open new branches must operate with a 12% minimum regulatory capital ratio, meaning that banks still have significant capacity to absorb the direct hit to capital from further moderate depreciation (Caspien Energy, 2015). So, ICAAP can narrow the new investment on energy projects during a prohibition period in the banking system.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

BRSA will calculate capital adequacy, a 50% risk weight that will be applied to required foreign exchange reserves at the Central Bank, up from 0%. This is expected to decrease Turkish banks' overall capital adequacy ratio by around 100 basis points. Banks operating in Turkey, however, will face further regulatory constraints from March 2016 onwards, particularly in capital adequacy ratios, as their foreign exchange liabilities are no longer treated as risk free (Keskin, 2015).

Although banking system stands still and Turkish government taking measures to deal with the growing demand for energy, barriers remain to the development of energy efficiency and renewable energy. Turkish banks have already found it difficult to follow up high capital adequacy, as BRSA leading the sector for the requirements of Basel III framework. Banks in Turkey continued to struggle in a period of two sides cut. Some banks focused on strategies to solve this problem by developing agreement of collaboration for launching initiations of programmes in financing energy projects. EBRD programme is one of them for influencing large energy projects. The participating Turkish banks and the EBRD together created a powerful brand for sustainable energy finance, and built a lasting relationship through which new partnerships were created to finance larger projects.

Evidence through the assessment of EBRD in Turkey shows that:

- Investors lack familiarity with energy efficiency projects, and therefore misjudge the benefits and risks of such projects. Private sector investors often associate energy efficiency projects with high financial and technical risks and poor financial returns. In addition, upfront transaction costs which may arise from energy audits and feasibility studies can discourage investors. These costs can be increased by a lack of experience among the engineering service companies that would develop such projects.
- Banks are not familiar with sustainable energy projects and have insufficient capacity to evaluate them. Most local banks have limited capacity and experience in identifying, evaluating, and processing energy efficiency and renewable energy projects. As a result, they offer few, if any, financial products designed specifically to finance sustainable energy projects, and require substantial technical assistance to develop such products.
- Financial resources and dedicated lending facilities are scarce. Sustainable energy measures require long-term funding. In recent years financial institutions have had limited access to long-term financing, and in Turkey banks have traditionally relied on short-term financial products (EBRD, 2014).
- At the same time, according to World Bank local private sponsors of generation projects based on renewable energy resources face the following barriers:
- Higher pre-investment costs, relative to conventional power generation projects, due to the lack of technically reliable information on renewable energy resources and the costs of pre-feasibility, detailed feasibility engineering design, etc.
- Lack of medium-to-long term debt financing that is necessary to achieve financial viability for such small but capital intensive infrastructure projects, which tend to have longer payback periods and need debt with long maturity.
- Uncertainty about whether the soon-to be privatized distribution companies will enter into bilateral contracts to purchase electricity from small renewable power generators (World Bank, 2008).

Beyond all these barriers, unfortunately Turkey faces some tough political and economic issues that shoulde be considered. Although Turkey -as an east-west corridor- with potential supplies from

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Central Asia and the Middle East is a excellent source capable of delivering further energy supplies to the European energy market, for a long while affected by the political risks. (EBRD, 2010b). Additionally, Turkey's ongoing economic halt because of global economic turbelence had already changed the investment environment.

But, the last development with detrimental effects of coup attempt on July 15 2016 eroded both the national and international outlook of Turkey. Therefore, Turkey's ability to attract foreign direct investment and to capitilize on its geographical position as an "energy bridge" to Europe will be tested in the near future.[1]

At the same time, Standard and Poor's, following the attempted coup in Turkey, announced a negative report lowering ratings regarding to a prediction of heightened unpredictability that could constrain capital inflows into Turkey's externally leveraged economy. As a result, on July 20, 2016 S&P lowered foreign and local currency sovereign credit ratings on Turkey to 'BB/B' and 'BB+/B', respectively, from 'BB+/B' and 'BBB-/A-3'. S&P's negative outlook refers its view on political uncertainty and raising risks could further weakening in the investment environment, potentially intensifying balance-of-payment pressures (Standard & Poor's, 2016).

Also, Fitch Ratings highlighted the political risks after the coup attempt (Fitch, 2016a). Besides, Fitch mentioned that Turkish bank risks could increase following the coup attempt (Fitch, 2016b). Although, mentioning the risks that could affect the financial environment, Fitch gave fair rating to Turkey after the coup attempt one month later, but revised outlook to negative. Fitch Ratings has affirmed Turkey's Long-Term Foreign and Local Currency Issuer Default Ratings (IDR) at 'BBB-'. According to Fitch, political uncertainty is expected to impact economic performance and poses risks to economic policy but the banking system is consistent with Turkey's investment grade rating, with a 'bbb' on Fitch's Banking System Indicator because the sector functioned smoothly through the coup attempt and deposit outflows were minimal (Fitch, 2016c). Finally, Fitch Ratings has revised the outlooks to negative from stable on 18 Turkish banks, while affirming their Issuer Default Ratings (IDRs). In addition, the ratings of those banks' financial subsidiaries, which are driven by institutional support, are affirmed and their outlooks are revised to negative (Reuters, 2016).

On the other hand, Moody's placed Turkey's Baa3 long-term issuer and senior unsecured bond ratings on review for downgrade. The review is driven by the need to assess the medium-term impact of the failed military coup on Turkey's economic growth, policymaking institutions and external buffers, given the existing challenges in all of these areas (Moody's, 2016a). However, Moody's review of Turkey's Baa3 rating remained ongoing. But, Moody's view remained that even though the coup failed, it is likely that it will exacerbate existing challenges in business climate, policymaking institutions and growth prospects. The rating agency planned to conclude the review within 90 days of its announcement on 18 July (Moody's, 2016b). Then lastly, Moody's has downgraded the Government of Turkey's long-term issuer and senior unsecured bond ratings to Ba1 from Baa3 and assigned a stable outlook. This concludes the review for downgrade that was initiated on 18 July. The drivers of the downgrade are as follows:

1. The increase in the risks related to the country's sizeable external funding requirements.
2. The weakening in previously supportive credit fundamentals, particularly growth and institutional strength. At the same time, Moody's has downgraded the long-term debt and deposit ratings of 14 banks and confirmed the ratings of three others (Moody's, 2016c).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

SOLUTIONS AND RECOMMENDATIONS

Turkey's banks have proved resilient over the past 10 years, the result of prudent regulation and sound balance sheets, fostering confidence in the overall Turkish economy. But, the deteriorating financial performance of energy companies has burdened the banking sector (Dilek, & Schlisse, 2016).

Therefore, Turkey should take into account the necessary measures in order to provide a robust system against criterias like ICAAP maintaining a stable environment both for the energy market and financial services. Tukish banks should find foreign investors or international subsidy agencies to develop collaboration for launching initiations of programmes in financing energy projects. The current programmes are unlikely to be sufficient to influence and flourish energy market in Turkey.

For instance, in 2007-2009 REEP identified the areas of opportunity for the financial sector to engage and accelerate its participation in renewable energy projects, particularly at a micro and small-scale level. This was classified as an awareness raising effort to accelerate investments in renewable energies and promote the sustainable use of energy in the future. It was a project of € 100,000 including co-funding from United Nations Environment Programme (UNEP), Comision Nacional de Actividades Espaciales (CONAE). REEP conducted a market opportunity assessment and a review of existing financial products; developed a strategy to increase awareness, engagement and capacity building of the financial sector; hosted a consultation meeting with the main stakeholders within the energy and financial market monitoring and evaluating the results and piloted a project that implements the strategies within one of the programmes that CONAE is is currently developing: solar water heaters.

REEP's expectations can be a guideline for government and energy financing banks in Turkey:

- At least one commercial bank engaging in financing small scale renewable and energ efficiency
- Projects;
- Increasing the interest and awareness of local banks in the sustainable energy business (Expression of interest from at least three local banks);
- Contributing to clarifying the renewable energy market opportunities in Mexico aiming to increase the awareness and engagement of the local financial sector and consequently accelerate investments;
- Contribute to the design of future government initiatives to increase investment in the sustainable;
- Energy (REEP, 2009).

Similarly, there are some energy initiatives in Turkey like Turkish Sustainable Energy Financing Facility (TURSEFF) but these kinds of organizations should be fastly growing. The launch of TURSEFF marked the entry of the European Bank for Reconstruction and Development (EBRD) into Turkey's sustainable energy market, laying the foundations for a series of sustainable energy finance operations that continue to grow. The EBRD used its own funding, as well as financing from the Clean Technology Fund (CTF) and the European Union to support five major Turkish banks, Akbank, Denizbank, Garantibank, Isbank, and Vakifbank, as they created lending products for sustainable energy, developed a project pipeline, assessed loan requests, and verified the implementation of projects (EBRD, 2014).

Another initiation is The Turkish Mid-size Sustainable Energy Financing Facility (MidSEFF) launched by the European Bank for Reconstruction and Development (EBRD) with the support from the European

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Investment Bank (EIB) and European Commission (EU) will provide a total of EUR 1 billion in loans through seven Turkish banks (Akbank, Denizbank, Finansbank, Garanti, Isbank, Vakifbank, Yapikredi) for on-lending to private sector borrowers, for financing mid-size investments in renewable energy, waste-to-energy and industrial energy efficiency (MIDSEFF).

What's more, BIS fairly offers a target change for adapting the upgrades of capital adequacy system especially in ICAAP. BIS points that Turkey has early-adopted the implementation recommending further discussions for a reconsideration of the target capital adequacy ratio, as stated before. While the Assessment Team is confident that the Turkish regulation is compliant with the Pillar 2 standard, the team notes that its implementation is still at a relatively early stage in Turkey. As the BRSA and the banks build up further experience with ICAAP, the team recommends further discussing with the BRSA the effective implementation of the Pillar 2 regime during a future RCAP assessment. That would also allow the interaction, if any, between the Pillar 2 regime and the target capital ratio to be reconsidered. In addition, regulations do not allow signposting within the disclosures, and require that all disclosures are audited. These two measures may enhance the ease of use, comparability, and accuracy of data reported by Turkish banks. When a bank's capital adequacy ratio falls below its internal capital requirement ratio (calculated according to the ICAAP framework), the bank shall promptly submit to the BRSA an action plan that will satisfy the internal capital requirement ratio. This plan enters into practice once approved by the BRSA. At the end of the period foreseen in the plan, a new ICAAP report is prepared and results of the action plan are submitted to the BRSA (BIS, 2016a).

Still, resonsideration of target ratio in the banking system, awareness of reforms with cultural understanding and education are crucially important for the adoption of Basel accords, no matter how hard to implement advanced solutions like ICAAP, organizations and initiatives in order to prosper both energy market and financial environment that is so needed. But first of all, Turkey needs to have a revision of economic outlook by rating firms to a more stable and predictable domestic political and security environment and implementation of reforms that address structural deficiencies in the economy.

FUTURE RESEARCH DIRECTIONS

Basel III, IV, and More?

Global trends in financial markets are changing our perception of financial risks. Some risks, such as operational, business and systemic risks are now becoming relatively more important. It is evitable that institutions change in response to these trends that the need for consolidated risk reporting in large complex banking organisations introduces a new challenge and risk aggregation properly accounts for dependencies between risk factors (Alexander, 2003).

As the global risks and crises continue to increase, the emphasis and evolution of banking regulations and risk management implementations will certainly be upgraded. Basel III or even IV and maybe more will replace the current legislations in time. This section is a hypothetical study on the future of financing mechanisms in risky energy projects. The future research of the study depends upon policy-makers, awareness of risk management and maintenance of banking supervision.

Over time, as management scientists and economists state that 'good risk management' will evolve towards, simply, 'good management'. Risk control will be based on a business model which focuses on

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

the net costs and benefits to the entire organization; risk management decisions will be based on utility functions that properly reflect the risk tolerance of the organization – and, assuming risk tolerance differs across organizations, an heterogeneous population of risk managers may co-exist in stable equilibrium (Alexander, 2003).

Also this section highlights the long road for Turkey on the way to modernize energy market and financial environment to prosper risky projects. The roadblocks to higher performing clean energy technology are not just challenges of engineering design but are also limited by scientific understanding. Innovation relies on contributions from basic research to bridge major gaps in our understanding of the phenomena that limit efficiency, performance, or lifetime of the materials or chemistries of these sustainable energy technologies (US Department of Energy, 2008). But beyond that, energy market needs a solid financial environment justified with the upgraded risk management implementations. Financial environment can only be provided by a strong banking system that is supervised by a legal authority monitors the current economic and financial conditions globally and nationally for taking precautions.

For instance, despite high electricity prices (among the highest in Europe) demand is growing faster in residential and commercial sector more than tripling (in the past years) and is expected to double in 15 years until 2025 (EBRD, 2010b). Therefore, risk culture and awareness of risk management must be raised in private sector as well as banking for a healthy system nurturing all parties that adopt regulations like Basel III, IV and more even advanced guidelines like ICAAP without shocks in order to provide investment and even foreign direct investment with favourable financial solutions leading to cheap energy to everyone.

The purpose of Basel II-III risk implementations is to create an international standard that banking regulators can use when creating regulations about how much capital banks need to put aside to guard against the types of financial and operational risks banks face. Basel III is a response to prevent the weaknesses in the Basel II framework where it will lead tightening the risk management approach (Okay, 2014). Basel III could tighten banks' provision of long-term finance or result in increased interest rates. Either of these changes and tightened capital and liquidity requirements are likely to limit the amount of capital available for renewable energy financing from banks in the future. Together, these are threats to renewable energy deployment because limited financing may prevent the energy projects (Narbel, 2013).

In a number of areas, the Turkish rules go beyond the minimum Basel standards. Especially, the structure and binding nature of prudential regulations in Turkey are outlined in greater detail in the RCAP assessment report on the Turkish risk-based capital requirements for banks. Although these elements provide for a more rigorous implementation of the Basel framework in some aspects, they have not been taken into account for the assessment of compliance under the RCAP methodology as per the agreed assessment methodology (BIS, 2016b).

According to the Tenth Development Plan covering the period 2014-2018 includes the goal of boosting domestic savings, as the most reliable and lasting financing source; directing the growing domestic savings to productive investments; and reducing extravagancy, with a view to ensuring a high and stable growth dynamic. In this scope the BRSA has been assigned as the authority responsible for containing the growth in consumer loans through macro-prudential measures, and raising the share of commercial loans in total loans through differentiation of loan costs and other encouraging and discouraging measures (BRSA, 2014).

By the way as stated before, Basel III is expected to be implemented globally between 2013 and 2019 (BIS, 2013). But the 2019 deadline can be suspended to another date because of a global economic and

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

financial change as the risks and uncertainty rise in the world. And as for Turkey, the priority nowadays will be national security and stability. Therefore, implementations regarding the banking sector might be suspended for the short run. Afterall, ICAAP was planned to be launched in 2014 but was postponed to 2016 (BRSA, 2014).

CONCLUSION

Despite the high regulatory performance, capital adequacy and stability after the adoption of Basel accords, the Turkish banking sector is under pressure preparing for the requirements of Basel III framework. Banks in Turkey are headed for the preparation of ICAAP which is only one change but still comprehensive process that can have large effects in a complex system leading to results even in the energy market. Challenge in adopting ICAAP can be an additional barrier standing in the way to the development of energy market, whereas the Turkish banks already found it difficult to follow up high capital adequacy. At the same time, BIS announced that Turkey has early-adopted the implementation recommending further discussions for a reconsideration of the target capital adequacy ratio. It is expected that BIS and BRSA shall together identify an accurate target for capital adequacy in order to provide an adoptable ICAAP in Turkey which will directly influence and improve energy market, in the end.

But nowadays, the major priority is to eliminate the political and security concerns regarding the coup attempt of 15th July 2016 in Turkey. The government blissfully took back control after the failed coup attempt. However, it caused detrimental effects on the economic and financial well-being. The cost of coup attempt is estimated as $ 100 billion according to Trade Ministry of Turkey. Therefore, it is urgent to control the welfare of the economy rather than the necessity of the ongoing structural state anyway.

Besides, the Turkish government declared a state of emergency to conduct the necessary measures preserving stability. Although, Turkish economy remain calm after the coup attempt, the credit rating firms' approaches seem somehow reserved, highlighting political and financial risks. Reforms regarding the banking sector might be suspended for the short run in order to regain stability and national security. After recapturing factory defaults of stability and regular economic activity, government should attain reforms that provide a favourable environment both for the energy market and financial services and proceed with the banking implementations and ICAAP with no worry of all parties.

KEY TERMS AND DEFINITIONS

Banking Regulation: Legal measures and restrictions for banks designed to improve the effectiveness and stability in the banking sector.

Basel: Basel Committee on Banking Supervision in Europe declares recommendations on banking regulation and issued the Basel accords called Basel I, Basel II and Basel III. The accords are widely accepted in the world banking industry.

BRSA: Banking Regulation and Supervision Agency in Turkey that is addressed as a legal authority to improve effectiveness in regulation and supervision of the banking sector.

Energy Finance: Financial solutions for renewable energy, efficient energy projects and technologies in the energy market.

Energy Market: All public and private enterprises that involve in the energy industry working for production and sale of energy.

Energy Projects: Investments of all sources of renewables, clean and creative energy saving solutions and technologies.

ICAAP: Internal Capital Adequacy Assessment Process is a banking guideline that is issued by Basel II.

Risk Management: Understanding, assessment and mitigation of risks in order to prevent financial loss and uncertainty especially in financial services and banking.

Turkey: Turkey is a country located between Europe and Asia.

ENDNOTE

[1] This route is attractive to many players as a way to diversify supply to markets. The ongoing privatization process also offers interesting opportunities for energy investors (EBRD, 2010b).

Chapter 71
Sustainable Consumption Trends in the World in the Context of Green Economy and Sustainability

Recep Tayyip Erdogan University, Turkey

Durmuş Çağrı Yıldırım
Namık Kemal University, Turkey

Ayfer Gedikli
Istanbul Medeniyet University, Turkey

ABSTRACT

Nowadays, sustainable growth and development are main economic policies for the countries all over the world. Decreasing natural resources, deepening environmental pollution and global warming problems are red alert of our planet. Every single country on the earth has the responsibility to protect our planet. So, increasing environmental awareness caused new tendencies in consumer behaviors. Countries aim not to pollute or harm the environment while improving their economic performance and life quality by green economy. Besides, by sustainable consumption, it is aimed to support personal sustainable development. In this context, sustainable consumption trends and the reflections of green economy applications in the world will be discussed in this chapter. In addition, developed countries and developing countries will be compared with each other through results of global ecological footprint.

INTRODUCTION

Harmful and careless human exploitation of the natural environment has caused massive pollution. Since the unplanned expenditure of natural resources has occurred rapidly, the problem of sustainability problem has developed into one of the world's most crucial issues (Barr "& Gilg, 2006). When the nations of the world tried to find alternative ways to protect economic growth and sustainability, they realized a crucial fact: improvement and development must be sustainable.

Development, however, had widely-varied meaning for each nation in each time period. Though the definition varied, development always included not only economic features, but also non-economic features, such as the quality of life. In fact, a growth that is harmful for the environment and the ecological system cannot be sustainable (Meadows et al., 1972).

The history of sustainable development is relatively new, stemming from the early 1970s. Sustainable development and the creation of a clean and unspoiled natural environment took on importance only after the foundation of the United Nations Environment Programme (UNEP). This event marked the first time for the world's nations to mention *"ecological balance"* and *"the future of humanity"* at the United Nations Conference on the Human Environment, which was held during 5-6 June, 1972 in Stockholm (Johnson, 2012).

In 1980, The World Conservation Strategy (IUCN) introduced the idea of sustainable development and emphasized the challenges of integrating development and the environment, as well as the responsibility of conserving natural resources for the coming generations. However, The World Conservation Strategy was not successful enough in its environmental strategies. More specifically, the strategy could not explain conservation strategies in a suitable matter to influence economic policies or how misguided economic policies might harm the environment.

Following this effort, the World Commission on Environment and Development (WCED, also known as *The Brundtland Commission*), created by the UN as a result of a General Assembly resolution in 1985, published *Our Common Future* in 1987. The report mentioned sustainable development as a tool of economic policy. The report emphasized sustainable development: "development that meets the needs of the present without compromising the ability of future generations to meet their own needs" (WCED, 1987). The Brundtland Report defined the relationship among population growth policies, poverty eradication, technology, and distribution of goods harvested from natural to explain sustainable development. The report also emphasized the growing role of developing countries in improving and restructuring the environment. The report suggested that these countries improve their development policies, taking into consideration long-term growth with sustainable natural resources. More specifically, the report's intent was to achieve economic development for the global economy: satisfying the needs of the present generation without harming the next generation's resources.' (Republic of Turkey, Ministry of Foreign Affairs, 2015).

Toward the end of the 1980s, environmental awareness increased, thanks to these reports and the meetings of those commissions who created the reports. In 1988, according to Pearce et al. (2012), the environment was the second-most important issue to the world's political leaders at 93%, right behind unemployment, which ranked highest, at 98%. After these issues, price stability followed with 90%, arms limitation at 85%, agricultural surplus at 70%, a single European market at 63%, European political unification at 57%, and EC expansion to include Turkey at 27% (Pearce, Markandya & Barbier, 2012).

In the 1992 United Nations Conference on Environment and Development (UNCED) held in Rio de Janeiro, Brazil, sustainable development took on importance both for global and for national policies. In two decades, many developments had taken place to tackle this issue, but most countries had not implemented much of the agenda. Most of the countries found it difficult to apply the UNCED decisions.

To improve their sustainable development agenda, the United Nations developed two broad themes during the United Nations Conference on Sustainable Development, in 2012 (UNCSD, or Rio+20): an institutional framework for sustainable development and a green economy as it contributes to the eradication of poverty (Puppim de Olivera, 2012). In the Rio+20 summit, a green economy was described as a key component of sustainable development since it contributes to poverty eradication, food safety,

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

sound water management, universal access to energy services, ocean management, improving resilience, disaster preparedness, public health, and human resource development (Great Britain: Parliament: House of Commons Environmental Audit Committee, 2012:12).

Though it sounds noble, this development was not a huge step forward. Many environmentalists considered it a trade-off between sustainable development and environmental protection on one side, and economic development on the other. Despite the fact that many improvements on sustainable development had occurred all around the world, those improvements were still too weak to satisfy expectations. Furthermore, an excessive expenditure of natural resources brought about irreversible losses of the environment, particularly in biodiversity. After all these losses, the only thing that can be done is to save and protect the rest of the vulnerable population which is yet unspoiled.

The issue, then, that countries should take into consideration regarding sustainable development is to set sustainable economical and poverty eradication policies which have reversible and less-harmful impact on the environment and on biodiversity. To achieve a sustainable and inclusive economic development process with almost no trade-off will be difficult indeed. Furthermore, since there has been only weak institutional support for these policies until now, few improvements have been observed all over the world (Puppim de Olivera, 2012). The world, therefore, has a long way to go. To ensure sustainable development with fair income distribution on a global level, powerful international institutions will be needed on various levels. Existing institutions must also change their policies and put sustainable development on their agenda (Puppim de Olivera, 2012).

In this chapter, we will examine sustainable consumption together with the implications of a green economy. We will propose a holistic perspective for sustainable consumption alongside a green economy on a global level. According to the purpose of this chapter, we will answer the following research questions in a three basic parts using the conceptual research method:

- What is a green economy?
- How has the concept of a green economy developed historically on a global level?
- What does sustainable consumption mean?
- What are the main trends of sustainable consumption in the world?
- What is the result of an ecological footprint for developed and developing countries?
- How can we evaluate the indicators of a green economy parallel to sustainable consumption?

THE FIRST STEP FOR SUSTAINABILITY: A GREEN ECONOMY

In today's environmental politics, the countries that try to set targets and to implement sustainable development confront the term "green economy." That term was first used in the paper "Blueprint for Sustainable Economy," prepared by David Pearce, Anil Markandya and Ed Barbier at the London Environment Economics Centre in 1989. The United Nations Environment Program (UNEP) defined a green economy as "one that results in improved human well-being and social equity, while significantly reducing environmental risks and ecological scarcities" (United Nations, 2010). In other words, a green economy has a structure covering private and public investments which target increases in employment and income while decreasing carbon emission and pollution. The investments should also improve productivity without any trade-off on biodiversity and the ecosystem (UNEP, 2011). In brief, a green economy is a must for sustainable development.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Alternative philosophies to those which propose that a green economy will best solve the world's economic and ecological problems include environmental economics, ecological economics, ecosocialism and ecofeminism. The following table illustrates how these philosophies differ from that of green economics:

As illustrated in Table 1, there are links between these different strands of economic philosophies that give importance to the environment in different ways. By searching the footprints of these economic philosophies, it can be said that green economists have a different orientation than other schools of thought, such as those who espouse ecofeminist and ecosocialist points of view. More specifically, green economists engage in studies which allow them to undertake straightforward comparisons between the land available and the demands on the resources. The components of a green economy can be summarized as follows (State of California EDD, 2010:11):

- Generating and storing renewable energy: goods and services with alternative energy usage such as wind, solar energy, biofuel, biomass and geothermal.
- Recycling used materials: cooperation between consumers and producers in both preferring recycling goods and running recycling or wastewater factories.
- Energy efficient production, distribution, construction and maintenance.
- Education and improving awareness.
- Natural and sustainable production.

The target for launching a green economy is to develop the economy and increase investments while increasing environmental quality and social coverage. To reach such a target, it is critical to set the objectives which are necessary for private and public investments, as well as those covering broader environmental and social criteria. Furthermore, the basic indicators that are related to the economical performance, such as the gross domestic product (GDP), should be arranged with respect to pollution, depletion of resources, decrease in ecosystem services, and the loss of natural capital for the poor (UNEP, 2011).

In 2009, the UN General Assembly decided to arrange a 2012 summit to celebrate the 20th anniversary of the first Rio World Summit (1992). The summit was to be called "Rio+20" and would also take place in Rio de Janeiro. The two basic topics for Rio +20 were "Green Economy in the Context of Sustainable Development and Poverty Eradication" and "International Framework for Sustainable Development." With these topics taking central stage, a green economy would then be ensconced firmly in international policy agenda. Today, it is an inevitable necessity to analyze the relationship between a green economy and sustainable development (UNEP, 2011).

Table 1. Alternative economic and environmental philosophies

Economic Philosophy	How It Differs From Green Economics
Environmental economics	Based on a conventional economic paradigm, a numerical approach, gives less importance to values
Ecological economics	Based on a unified discipline of ecology and economics, gives less importance to spiritual values
Ecosocialism	Emphasizes equality but supports materialism
Ecofeminism	More theoretical than policy-driven. Although it shares principles and values, it covers a limited area.

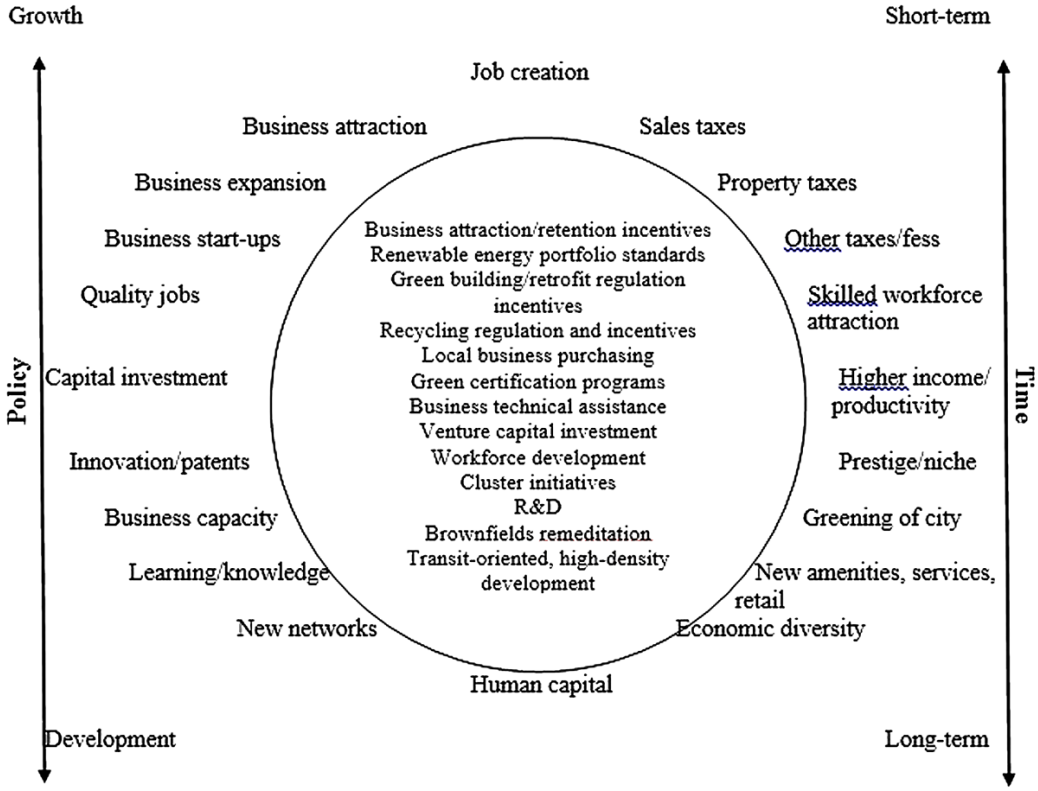
According to the European Environment Agency (EEA) Report (2009), with increases in income for people who are from European Union (EU) member countries, the people's level of consumption also increased. In other words, there is an increasing trend toward consumption among EU consumers. This increase was supported by the nations' business firms (EEA Report, 2009). On the other hand, with respect to the population growth in these countries, they have basic differences. In terms of consumption trends, the consumers' attitudes are not sustainable, since around 15 tonnes per capita of material were used for production to satisfy European consumers. Until 2020, this amount will be increased by one quarter. Parallel to this situation, waste in the EU will increase despite an increase in recycling and a decrease in landfills. For sustainable development and for improving the quality of life for its people, the EU also recognized the importance of sustainability for both consumption and production (EEA Report, 2009:36-37). With respect to sustainable development, the EU included Sustainable Development Strategies (SDS) in the *Review of the EU* in July 2009. The EU emphasized SDS strategies, and the member countries decided to combine SDS policies with the other policies in 2007. The EU also set targets for the years up to and including 2010. The basic issues were as follows (European Commission, 2013):

- Controlling climate changes and improving clean energy.
- Sustainable consumption and production.
- Sustainable transportation.
- Protection of natural resources.
- Improving public health.
- Social inclusion, eradication of poverty.
- Controlling migration.
- Challenges of SDS.

Although sustainable development had been on the political leaders' agenda since 1997, in June 2001 with setting SDSs in the EU, the issue became more crucial.

The green sector, however, is still relatively small in scale. In 2010, for the green economy, the estimated value of products and services was $2 trillion (2.7 percent of the global GDP) while profit was $530 billion. Nearly 10 million people were employed in the green sector worldwide. If we look at the separate countries (Porfiriev, 2013:5-6), we will observe the following:



- The green economy generates more than $600 billion (4.2 percent of the GDP) with three million people in the USA employed in this sector.
- In Japan, the green economy generates 3.4 percent of the GDP with 1.5 million people employed in this sector.
- In the EU, the green economy generates 2.5 percent of the GDP with 3.4 million people employed in this sector.
- In Germany, 4.8 percent of the GDP comes from the green economy (the country is one of the most important eco-friendly product exporters in the world. For example, the country sells 12 percent of the world's climate control equipment).
- The UK gets $240 billion from the green economy, comprising 8.8 percent of its GDP. This rate was the highest in the entire world during 2009.

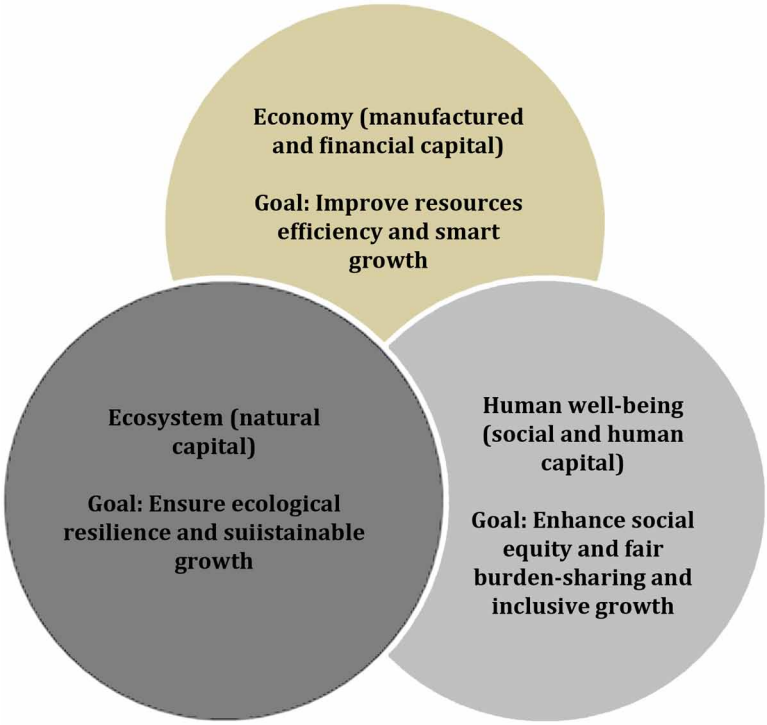
Figure 1 illustrates common development goals among the world's nations. On the growth side, the common goals are job creation, as well as expanding and growing businesses, thus expanding the tax base (Chapple, 2008:4-5). At this point, sustainable development should be differentiated from sustainable growth. Although they are different subjects, they are interconnected. If a society does not improve its real income per head, that society will have difficulty in developing. If the other aspects are ignored, but just income per capita and growth are considered, that economy will, too, not be considered as a developing economy.



Also, while a nation's economy is developing, growth should not be ignored. So rational economic development, together with an acceptable economic growth may be a solution of the development-growth dilemma (Pearce, Markandya & Barbier, 2012:30). Then it is important to follow proper economic growth with environmental protection. In other words, sustainable development does not mean sacrificing a nation's economic growth for improving the environment. Therefore, the main goal is to prepare the future of a sustainable environment without greater sacrifices to the nation's economic growth (Pearce, Markandya & Barbier, 2012:31). As illustrated in Figure 2, there must be a combination of three basic targets. The goal of an economy should be sustainable growth partnered with protecting resources and caring for the well-being of its citizens.

Figure 1. Common economic development goals
Source: Chapple, 2008:5.

Figure 2. The green economy concept in the context of sustainable development
Source: European Environment Agency (EEA), 2011:10.

More specifically, a green economy targets the improvement of human well-being and social equity while reducing environmental risks and ecological scarcities. In other words, a green economy is more resource-efficient, has a lower carbon footprint, and is more socially inclusive. A green economy is a combination of economic growth and economical sustainability accompanied by progress in social development. Thus environmental protections and development should be organized in a way that the result will be a win in both areas. That win-win solution handled with a willing role in delivering the economically viable products, processes, technologies and services, will help a nation transition to a green economy.

It is a fact that natural resources and green capital are the basic drivers of globalization. Although today technical innovation is the major target, natural capital is the physical basis for wealth. Green capital and globalization brought with it complex legal principles and laws about using resources, access to resources, and benefit sharing. At different organizations such as Rio+20, a large number of state and non-state actors consolidated their power to create a new economic era. With large natural resource reserves and their growing populations who are ready to consume, emerging countries such as China, India, Brazil, and South Africa engineer their economic growth. Their way of economic growth may differ from and even conflict with the green economy and sustainable development model created by the developed countries. Although the basic targets of emerging countries are growth and industrial development, social equality cannot be neglected. Social equality becomes a reality by distributing a nation's resources equally.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

The interdependence of countries requires cooperative solutions for the governance of natural resources (Blanco & Razzaque, 2012:3-4). When countries realize the importance of sustainable development and the environment, they can become prosperous. Many of those who have become prosperous enacted stimulus packages taking those two factors into consideration.

SUPPORTING A GREEN ECONOMY: GREEN PRODUCTS, GREEN CONSUMERS, AND SUSTAINABLE CONSUMPTION

According to the EEA Report (2009), with the income increase for people who are from EU member countries, their consumption level also increased. In other words, there is a trend towards increased consumption among citizens of EU member countries. This increase has been confirmed by the nations' firms (EEA Report, 2009). Hyper-consumption, however, without regard for natural resources and ecological balance has brought humanity to the brink of ecological disaster. In terms of their consumption trends, the attitudes of the consumers are not sustainable, since around 15 tonnes per capita of material were used for production to satisfy European consumers. Until 2020, this amount will be increased by one quarter. Parallel to this situation, waste in the EU will increase despite increased recycling and less use of landfills.

To boost sustainable development and to improve the quality of life, the EU recognized the importance of sustainability for both consumption and production (EEA Report, 2009:36-37). The European Environmental Agency (EEA, 2011) gave an explanation for what would constitute a balance of growth with environmental and sustainable development concerns. Furthermore, cities all over the world are also realizing the importance of consumption-driven economic development by adopting three green policies: green standards and regulations for energy use, green building incentives and environmentally preferable purchasing. These strategies may help build a green economy if they are mandatory.

In addition, building awareness among citizens and corporations is another important aspect of these strategies. They also result in economic development by building expertise in technologies such as green building operation and energy use evaluation. R&D's and education are other parts of these strategies. Supporting green innovation and developing new markets for green products are additional strategies that can lead toward the goal of a green economy. Similarly, a solar panel installation tax credit is another way of promoting green strategies (Chapple, 2008:3).

It was seen that "green economy" targets of large world economies promoting sustainable development on a macro level were not effective enough on consumer behaviors on the micro level, since the overwhelmingly unsustainable level of consumption stands as the basic obstacle blocking sustainable development. Despite the fact that producers use nonpolluting technologies and production systems with the support of the nations' green policies, all these attempts must be supported by consumer behavior (Peattie, 2010). In this context, sustainable consumer behavior should become widespread in order to be successful in building a green economy and in maintaining sustainable development policies. In the context of sustainable development, consumer groups who are environmentally aware may change their consumption habits on the micro level by changing the products they formerly bought to more environmentally friendly ones.

Thus, consumer behavior regarding their demands should be dependent not only on satisfying personal needs and wants, but also on ethics: conserving resources, reducing waste and improving society (Young et al, 2010). Sustainable consumption should be done in a way that while satisfying personal

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

needs, one should take into consideration that those goods should be produced by consuming as few of nature's resources as possible and harming the environment as little as possible (OECD, 2002).

There is indeed historical precedent for such changes in consumer behavior. Sustainable consumer behaviors actually go back to the 1960s, when this type of consumption was considered as "waking up." In the 1970s, sustainable consumption was marked by consumers' desire to protect the environment, while in the 1980s, consumers began to realize that without a change in their behavior, the earth had only "limited time' left. In the 1990s, environmentally friendly consumer behavior was regarded to give consumers "power in [the] market." This movement improved as the years went by from the 1960s to the 1990s (Kalafatis et al, 1999:42).

The first academic research on sustainable consumption was conducted in the 1970s and 1980s. What we now know as sustainable consumption was then usually defined as "decreasing consumption and non-excessive consumption" (Follows & Jobber, 2000:724). Although the term "sustainable consumption" was first heard during the protests of green consumer activists in the 1980s, widespread usage of this term started with the United Nations Conference on Environment and Development (UNCED) in Rio de Janerio in the 1990s. With the advent of the 2000s, the "green product" concept became popular both among consumers and producers. Firms that could predict the improving market share of green products changed their products and production channels accordingly (Candan & Yıldırım, 2013).

Sustainable consumption can reach its highest point with increased environmental sensitivity on the part of producers. If "consuming less (Jackson, 2005)" becomes a habit for ordinary consumers, this habit will bring with it a new attitude to buy environmentally friendly products. Basic needs, of course, must be satisfied whenever necessary. Consumers also need to be able to find these products in the market. At this point, the production of environmentally sensitive products is crucial for sustainable consumption (Mowen, 1993). Even though consumers care about environment, if they cannot find the goods they need in the market, they will have to purchase less environmentally friendly goods. Thus, environmentally sensitive products must be ready for purchase and easy to find in the market.

Generally, less-polluting products are considered as environmentally sensitive products (Ottman, 1993). Additionally, recyclable non-polluting goods which consume natural resources at a lower rate than others are also considered as environmentally sensitive products (Shamdasani et al, 1993:488). Environmentally sensitive products can be in many categories such as food, textile, electronics, etc. For example, if an electronic device is environmentally friendly, it must save energy. Similarly, an environmentally sensitive agricultural product must be organic, with recyclable packaging (Dangelico & Pujari, 2010).

The basic properties of environmentally sensitive products and services are as follows (Moisander, 2007:405):

- They should not be harmful to human beings or animals.
- There should not be pollution during production, consumption and disposal.
- Energy consumption should be low during production, consumption and disposal.
- The product should not cause unnecessary waste due to excessive packaging or short wear life.
- The product should not cause excessive usage.
- The production process must not harm or animals.
- Products should not contain materials that harm the animals or the environment.

According to the Organisation for Economic Co-operation and Development (OECD) (2009), environmentally sensitive products are ones which have less or limited harmful effects on air, water, and

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

other natural resources (Lin & Huang, 2012:11). The products that are considered as environmentally friendly may be sometimes confusing for consumers. Therefore, the environmental benefits of these products should be defined clearly.

Certification, then, can be a good way to categorize products as "green." Otherwise, consumers may be confronted with "green marketing myopia." Green marketing myopia means that environmentally sensitive consumers may be cheated by producers who sell their products as if they are environmentally sensitive, when in fact they are not. If there are no legal controls on labeling, markets became full of fake "environmentally friendly" products (Ottman et al, 2006). For this reason, certification is crucial.

Actually, there already exist several green certifications to protect both producers' and consumers' rights. Green certification is the process of preparing a generalized standardization by using a variety of science-based methods (Green Building Alliance (GBA), 2013). Today, there are many green certifications. The most popular ones are as follows (Vierra, 2014):

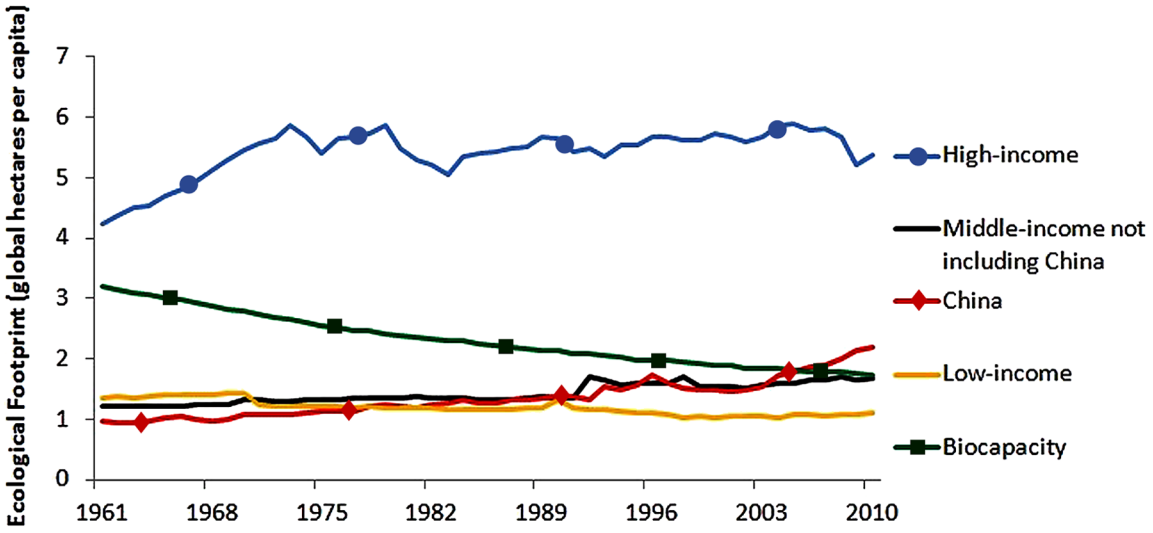
- **Energy Star:** Energy-consuming products.
- **WaterSense:** Showerheads, toilets, faucets, urinals, and valves.
- **Forest Stewardship Council:** Forests and forestry products.
- **Scientific Material Content Certification:** A wide range of products (i.e. carpets, textiles, wood products, insulation, and more).
- **Green Seal:** Covers a wide range of products (paints, adhesives, lamps, electric chillers, windows, window films, occupancy sensors).
- **Cradle to Cradle:** Covers a wide range of products (metals, fibers, dyes, plastics).
- **Greenguard:** Indoor air quality with a focus on children and schools.

Many studies have concluded that consumers who prefer to buy green products have a high regard for the environment. Furthermore, "green consumers" have a higher sensitivity for environmental protections (Young et al., 2010; Schultz & Zelezny, 1999; Karp, 1996; Dietz et al., 2002; Hedlund, 2011; Thogersen & Grunert-Beckmann, 1997; Şener & Hazer, 2008; Thogersen & Grunert-Beckmann, 1997; Poortinga et al., 2004; Vermeir & Verbeke, 2008). Green consumers make a bigger effort to find environmentally sensitive products. Most of them are willing to take on the added cost burden of purchasing such products (Straughan & Roberts, 1999; Laroche et al., 2001; Young et al., 2010). If there is a question about the product's carbon footprint, though, this may affect the consumers negatively.

In addition, there is an important reason for the consumers to choose environmentally sensitive products or not: price-quality equilibrium (Lin & Huang, 2012). Because of this issue, producers should be careful about quality-performance-price equilibrium (D'Souza et al, 2007).

It should also be kept in mind that one of the most important obstacles to sustainable consumption is unsustainable consumer behavior and preferences (Peattie, 2010). Purchasing preferences and consuming behaviors of households may affect the environment in a negative or positive way in the long run, depending on their choices (OECD, 2002:3). Therefore, the number of green consumers and green products should be increased, since this may result in more widespread awareness of sustainable consumption and an increasing application of green economic policies.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use



SUSTAINABLE CONSUMPTION TRENDS AND THE WORLD'S ECOLOGICAL FOOTPRINT

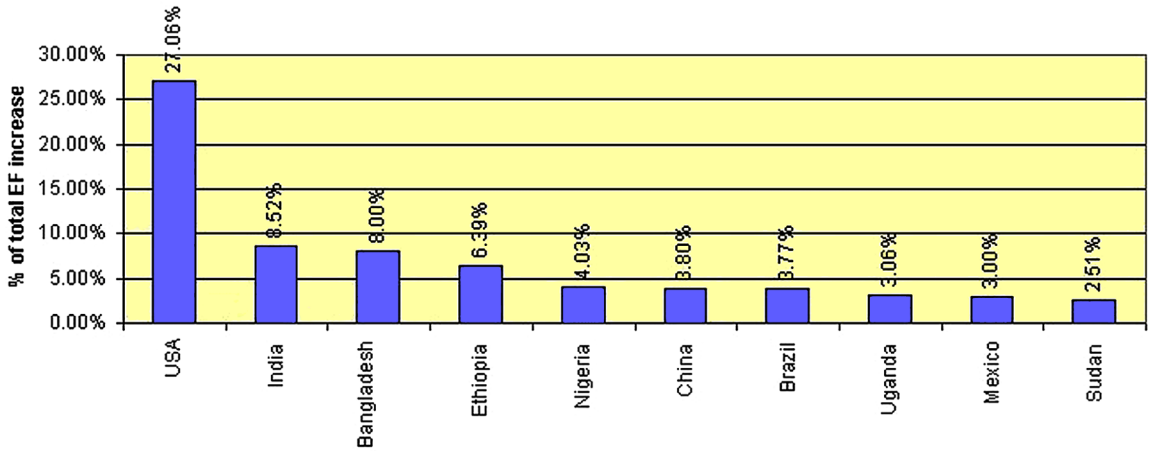
For more than 40 years, demand exceeded actual need. The ecological footprints of the world's nations show the consequences of this disastrous situation (World Wildlife Fund (WWF) Report, 2014). An ecological footprint for consumption can be defined as: "independently from the geographical region which provides the natural resources, renewable resources are those that are used to produce consumable production for people and societies." An ecological footprint for production can be defined as: "the usage of a certain country or geographical region's biological capacity" (WWF, 2012).

To analyze the total consumption and ecological footprint of the earth, the WWF calculated each of the world's countries' ecological footprint per capita, their average expenditure of goods and services per capita, as well as the correlation between these data and local natural resources to satisfy these needs. The results showed that the highest footprints were mostly in 25 high-income countries that have the highest carbon release into the atmosphere (WWF Report, 2014). According to the scenario created by the UN, "if the increase in population and consumption trends continues as it was without changing; in the 2030s, to satisfy the needs of humanity we will need two earths." (Global Footprint Network, 2015a).

In Figure 3, the ecological footprint per capita in different country groups for 1961-2010 is given. According to the figure, higher-income countries had much higher ecological footprints than middle- and lower-income countries. Furthermore, global biocapacity hectares per capita has decreased dramatically and steadily from 3.2 in 1961 to almost 1.5 in 2010. In other words, global biocapacity per capita lost half of its value in 40 years. This drop is explained with the higher increase in world population as compared to its biocapacity productivity (Global Footprint Network, 2015a).

Figure 3. Ecological footprint per capita in high-, middle- and low-income countries
Source: Global Footprint Network, 2015b.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use



More specifically, National Footprint Accounts (2010) revealed the National Ecological Footprint and Biocapacity for 2007. According to the study, ecological footprints of consumption are different for high-income, middle-income and low-income countries. The average ecological footprint for high-income countries was 6.1 in 2007. For middle- and low-income countries, however, the ecological footprint was only 2.0 and 1.2, respectively. The high-income countries were the USA, Canada, Oceania, and the European countries; low-income countries were African, Asian, Latin American and the Caribbean countries. The highest scores belonged to the US and Canada, while the lowest score belonged to African and Asian countries (Global Footprint Network, 2015b).

According to Global Footprint Network data, after the global financial crisis in 2008, high-income countries' average demand on nature decreased sharply. Despite this decrease, their footprints were still more than three times those of middle-income countries and almost five times those of low-income countries (Global Footprint Network, 2015b). Furthermore, in a few high-income countries, the per capita footprint started to rise in 2010, since governments provided economic stimulus packages worth billions of dollars to help stimulate their economies. During that time, however, middle- and low-income countries' per capita ecological footprint stayed almost the same (National Footprint Accounts, 2014).

In Figure 4, the top ten countries which contribute to the global ecological footprint increase and to the percentage of the world's total ecological footprint for the period from 2008 to 2050 period are estimated. According to the figure, the USA will have the highest increase in its ecological footprint with 27.06%. India follows the USA with a rate of 8.52%. While Bangladesh has 8%, Ethiopia has 6.39%, China and Brazil have near-identical scores at 3.8% and 3.77%, respectively.

Despite the fact that economic growth provides an increasing level of welfare in nations and in people, such growth will drain scarce natural resources. On the other hand, with the growing global trend toward the middle class, the trend of conspicuous consumption may cause potential side effects and obstacles to sustainable development. If these obstacles are overcome, though, sustainable development will be even more successful (World Business Council for Sustainable Development (WBCSD), 2008). By considering the effects of hyper consumption, countries must take care to reduce their ecological footprint to promote improvements in sustainable development. As the preferences of households may

Figure 4. Top 10 contributors to the global ecological footprint increase 2008-2050
Source: Population, Consumption, and our Ecological Footprint, 2015.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

change the consumption patterns of their countries, it may be a good idea to start at the household level. Changing consumption patterns of households is crucial in order not to exceed the limits of the earth's biological capacity.

At this point, consumer behaviors and purchasing habits should be changed. Production firms should support sustainable production.

To change consumers' purchasing patterns, many countries began targeted projects. Those projects target consumers to improve their environmental sensitivity and to give them more information that will empower them to choose environmentally sensitive products. For example, PERL (The Partnership of Education and Research about Responsible Living), Carrotmob, and Nudging—all projects to educate consumers—have gone worldwide in their scope. Furthermore, Sustainable Connections (United States), LivingSmart (Australia), The 10:10 (the United Kingdom), Slow Food (Italy), and Eco-Action Points (Japan) have introduced regional projects to stimulate environmental sensitivity (United Nations, 2010).

Several countries have also funded research to analyze consumers' sensitivity to and tendency to purchase green products. For example, GMS/Deloitte (2009) commissioned a survey to categorize US consumers according to their green purchasing behaviors. They created five green clusters: "committed, proactive, influenced, unsure, and aware." 6498 shoppers were included in the survey. According to the answers, 54% of the questionnaires were from consumers who were more aware of green products and were ready to buy these products. For the committed participants, it was important to buy green products. For the other groups, though, buying green products had little importance. For consumers unaware of environmental concerns, green products do not have any priority. Furthermore, consumers who are unaware of environmental concerns choose green products only as a last choice. In the survey, the purchase rate of green products was analyzed for many product categories. Respondents preferred green products by 33% for groceries, by 28% for household cleaners, by 19% for paper products, by 12% for meat, fish, and poultry, by 11% for health and beauty, by 11% for pet products, and by 8% for electronics. The preference rate for purchasing green textiles, however, was low, at only 3% (GMA & Deloitte, 2009).

Similarly, National Geographic and Globe Scan surveyed sustainable consumer behaviors in different countries in 2008 and 2010. According to their results, there is an increasing trend toward sustainable consumption. These surveys created an index named "Greendex" and calculated the Greendex score for each country. The highest scores were given to the emerging countries. The consumers with the highest awareness of sustainable consumption were located in India, Brazil, China, Mexico, Argentina, Russia, Hungary, South Korea, Sweden, Spain, Australia, Germany, Japan, the UK, France, Canada, and the USA. The restriction of those studies were the number of people that participated in the survey, since only 17,000 participants were questioned in total. As the number of participants was limited, the concluding idea cannot represent whole countries (National Geographic & GlobeScan, 2010).

Parallel to these results, according to Euromonitor International Global Consumer Trends Survey (2013), the sustainable consumption trend has increased all over the world. 16,300 participants and nine major developed and emerging markets were included in the survey. Participants were asked to answer the questions via the Internet. More than half of the participants in Germany, the UK, Russia, China, France, USA, Japan, Brazil, and India indicated that they check if a product is environmentally sensitive or not before they purchase it (Kasriel-Alexander, 2014).

The EU Commission conducted a similar survey in December 2012 to analyze the consumption patterns towards environmentally sensitive products. Twenty-seven countries and 25,568 people participated in the survey (Belgium, Czech Republic, Bulgaria, Denmark, Estonia, Greece, Spain, France, Ireland,

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Italy, Republic of Cyprus, Lithuania, Latvia, Luxembourg, Hungary, Malta, The Netherlands, Austria, Poland, Portugal, Romania, Slovenia, Slovakia, Finland, Sweden, and the United Kingdom). Fifteen percent of the participants indicated that they never prefer environmentally sensitive products, 26 percent indicated that they often prefer green products, and 54 percent of the participants indicated that they sometimes buy green products. Ninety-five percent of the participants agreed to use green products to protect the environment (European Commission, 2013).

According to the National Geographic and Globe Scan Greendex research results (2014), consumers' sensitivity from 18 countries (Brazil, Argentina, South Africa, Australia, South Korea, Japan, China, India, Russia, Hungary, Sweden, Canada, USA, Mexico, Germany, Great Britain, France, and Spain) increased as time went by. The survey had been done annually since 2012. According to the survey results, there is an increasing level of environmental sensitivity in 11 countries. The participants also confessed that they felt guilty when they harm the environment. They were also aware of global warming and its disastrous effects on humanity. In addition, they complained about the lack of governmental and industrial protections for the environment.

On the other hand, though, in most of the countries, consumers' sensitivity towards green products and preferring them to purchase has decreased since 2012. The basic reason for that decrease was weak promotional campaigns for green products. The tendency to purchase green products was mostly in developed countries (National Geographic & Globe Scan, 2014).

Finally, Sustainable Academy and Schneider Electric conducted a study on "Green Consumption" in Turkey in 2012. 1334 participants, all over the age of 15, were included in the survey. According to the results, just 13 percent of the participants always prefer green products. The participants complained about their lack of knowledge about green products. Additionally, the high prices of green products were considered as the biggest hindrance for consumers who might have otherwise purchased such products. Demographically, females, high income groups, and people with higher levels of education preferred green products (Sustainability Academy and Schneider Electric, 2012).

As expressed in these surveys, most of the consumers were unhappy with environmental pollution. Although they believe that sustainable consumption is very important, almost half of the participants neglected consuming green products. Therefore, to increase the sustainable consumption trend, people should be convinced to buy green goods. In other words, there must be a correlation between the intent to purchase green products and the actual purchase of sustainable products.

According to the Geographic and Globe Scan (2009) results, the Greendex score was 43.7 for the USA, while India scored 59.5. The top scores went to developing countries such as India, Brazil and China, Argentina, and South Korea. Japan, the USA, and Canada received the lowest scores. The survey results emphasized that the decreasing cost of the products and the increasing concern for the environment motivated the consumers in passing years (UNEP, 2010:28). It should be noted that the developed countries should do more for the earth and improve their green policies to protect the environment and the future of humanity. In addition, the consumer trends of middle class people in developing countries can be changed to become more environmentally sensitive by policies and promotional campaigns that educate and motivate consumers about the benefits of green products.

While developing countries launch strategies and policies to encourage growth of a green economy, their success must be examined as time goes by. We must wait for a while since existing research does not have enough data to determine the level of success. Despite the fact that the ecological footprint is low in developing countries, one must take into consideration that people have lower purchasing power in those countries since their income level is low.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

There is also a correlation between the Human Development Index and the sustainable footprint of every developing country (WWF Report, 2014:19). Similarly, in the Ewing et al. (2010) "Ecological Footprint Atlas 2010" research, the authors emphasized the correlation between the Human Development Index and the ecological footprint. In the study, the correlation between the Human Development Index and the ecological footprint was analyzed for 1980, 1990, 2000, and in 2007 for African, Asian, European, North American, Latin American, Oceanian and Caribbean countries. According to the results, there was not much change in passing years. The Human Development Index and ecological footprint rates were high for European countries, while those variables were low for African and Asian countries (Ewing et al., 2010).

CONCLUSION

According to most studies, developed countries have higher ecological footprints than middle- and lower-income countries. Also, as economical power and growth increase, environmental pollution also increase. In the last decade, there have been many conferences and meetings on renewable energy, green consumption, and controlling environment pollution in order to leave a livable earth to the next generations. Decreasing fossil fuels, using renewable or solar energy, green packaging, as well as increasing productivity and biocapacity are all worthy efforts to help create a sustainable world. All these efforts, however, are far behind the work it will take to reach sustainability. Furthermore, there are many obstacles and costs that nations must overcome to initiate sustainable development. In addition, the developing countries which have great enthusiasm about development and growth may have difficulty if they ignore the sustainability of natural resources. Even though these countries choose development and growth policies, they must also care for their natural resources and for the future of humanity.

For a sustainable world, the countries should first take on the responsibility of building a green economy; secondly, the people should take on the responsibility of sustainable consumption. Any policy created to further the green economy should be supported by the individuals living in that nation. Making the goal to create a green economy a team effort should boost the health of the environment and decrease consumption.

KEY TERMS AND DEFINITIONS

Ecological Footprint: A indicator that shows the quantity of waste that people generate while they meet their daily needs.

Green Consumer: A type of consumer who buys green products such as ecological, organic or energy-saving products and therefore consumes fewer natural resources.

Green Economy: A economic policy to create sustainable growth while protecting the environment and promoting social justice.

Green Product: A product that consumers prefer because it helps to protect the environment during the manufacture, use, and disposal of the product. Generally organic, ecological, recyclable, and energy-saving products are called green products.

Sustainability: A lifelong skill that provides daily needs for the current generation while protecting the next generation's needs.

Sustainable Consumption: A type of consumer behavior that promotes buying green, ecological or energy-saving products or consuming less to protect the environment and natural resources.

Chapter 72
Modern Optimization Algorithms and Applications in Solar Photovoltaic Engineering

Igor Tyukhov

Hegazy Rezk
Minia University, Egypt

Pandian Vasant
Universiti Teknologi PETRONAS, Malaysia

ABSTRACT

This chapter is devoted to main tendencies of optimization in photovoltaic (PV) engineering showing the main trends in modern energy transition - the changes in the composition (structure) of primary energy supply, the gradual shift from a traditional (mainly based on fossil fuels) energy to a new stage based on renewable energy systems from history to current stage and to future. The concrete examples (case studies) of optimization PV systems in different concepts of using from power electronics (particularly maximum power point tracking optimization) to implementing geographic information system (GIS) are considered. The chapter shows the gradual shifting optimization from specific quite narrow areas to the new stages of optimization of the very complex energy systems (actually smart grids) based on photovoltaics and also other renewable energy sources and GIS.

INTRODUCTION

All processes in surrounding material world and life on Earth are driven by energy. Vaclav Smil, author of many books on energy, wrote: "…energy's role in world history seems to be a natural proposition, with history seen as a quest for increased complexity made possible by mastering higher energy flows" (Smil V., 2004). This may be because of an extraordinary difficulty and exceptional nature of the coming energy transition—but, given the enormous challenges of ushering in a post-fossil world, it may also

be because of the possibility of an unprecedented and persistent commitment to a rapid change (Smil V., 2010).

Any process can be analyzed in terms of its underlying energy conversions; any object, as well as any bit of information, can be valued for its energy content and for its potential contribution to future energy transformations (Smil V., 2008).

Energy and information are including in the infrastructure of whole activity of modern humankind. Energy and communicative revolutions are the main driving forces in the human development. Education and information are also connecting by very strong relationship. Very often these technologies are considered separately. It is totally incorrect and inappropriate. Table 1 shows roughly the main steps of appearing the new energy, communicational and educational technologies.

Before the industrial revolution, our energy needs were modest. The level of development civilization is characterized by the rate of liberation from nature influences. The history of civilization and liberation from nature influences is the history of new types of energy conquest.

This work is stimulated by the modern trends or diffusion in developing the most important sphere of humankind activity – energy and new computer technologies. Last decades traditional electrical power industry, which basic principles were formed more than hundred years ago, is changing and transforming very fast.

Table 1. Energy, communicative and educational revolutions

Years Ago (Very Approximately)	Communicative and Educational Revolutions	Energy Revolutions	Stages of Development
10^6	Oral communication through language	Conquer of fire, biomass	Forming human society based on additional to biological type energy sources Renewable energy – first stage Exchange information between people
10^5	Picture and symbol communication	Solar energy, animal energy	
10^4	Writing (from internal biological memory to external recorded memory)	Wind and hydro energy (from muscles to machines)	
10^3	Book printing, forming of scientific systems Forming schools and universities	Mechanical energy, Thermal energy (coal, oil, gas)	Using fossil fuels (accumulating solar energy) Human civilization, scientific and technology revolutions
10^2	System of education Mass media, radio, TV	Steam energy, electrical energy, atomic energy	
10^1	Computers, Internet, MOOC	Photovoltaic revolution	Current technology revolution (informatization, robotization, artificial intelligence) Extra planetary activity
Now	Practically total interconnectivity Satellite communication Mobile communication Mass open education	Smart grids, Energy mixt Decentralized energy Space technologies	
Near future	Global earth and near space communication Internet of things Big data technology	Mixt of traditional energy and renewable energy – second stage, new sources of energy Thermonuclear energy Global energy system	Energy and information everywhere Moon and Mars exploitation
Future	Trends of dominating distributed energy and information networks integrating by smart technologies Global technologies and Internet of everything including energy, artificial intelligence		Solar energy for the future of mankind
Far future	Widen areal of mankind from Earth to near space		

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

We are now in the period of a transition as a process of successful technical and infrastructural innovation. Energy transitions can be also studied as specific subsets of two more general processes of technical innovation and resource substitution. Transition from an energy supply dominated by nuclear and fossil fuels to a world relying mostly on non-fossil fuels and generating electricity by harnessing renewable energy flows is thus definitely desirable and, given the finite nature of fossil resources (Smil, V., 2010).

Any anthropogenic energy system—that is any arrangement whereby the humans use the Earth's resources to improve the human species chances of surviving and to enhancing their quality of life (and, less admirably, also to increase their individual and collective power and to dominate, and to conquer and destroy others biological species)—has three fundamental components: natural energy sources, their conversions, and a variety of specific uses of the available energy flows.

Technological and social developments of humankind have been well supported by the discovery of new sources of energy and its proper application in day-to-day life. Since the first installation of electricity grids more than 100 years ago, our society has been driven by this convenient source of energy. Most of this electric energy is produced from fossil-fired power generation plants using carbon-based fuels, such as gasoline in the transportation industry. Burning of fuel looks like burning fire on the dawn of humankind in spite we have already now many technologies direct converting fuel energy into electricity (fuel cells), heat into electricity (thermo-elements), solar radiation into electricity (solar cells) and others.

In today's modern era, however, demands development of new and more efficient technologies for next-generation electrical grids and shifting of the focus of power generation to cleaner and carbon-free sources. Both the exhausting of carbon-based fossil fuels and environmental pollution created by the burning of fossil fuels are responsible for this desirable shift power engineering to so called green energy sources. Possible sources of such clean and renewable energy are solar, nuclear, wind, geothermal energy and many others. It is worth mentioning here that the world consumes less energy in one year than the amount of energy Earth surface receive from sunlight in one hour (13 terawatts).

Solar energy represents one of the most significant energy solutions to avoid and even to eradicate our addiction to oil.

1. SOLAR ENERGY, PHOTOVOLTAICS

Solar cells are devices that directly convert solar radiation into electricity by photovoltaic effect. Let us start from the early beginning of photovoltaics. In 1839 French scientist Edmond Becquerel discovers the photovoltaic effect while experimenting with an electrolytic cell made up of two metal electrodes placed in an electricity-conducting solution—electricity-generation increased when exposed to light.

At the beginning of 1930th one of the greatest Russian scholar A. F. Ioffe concentrated on semiconductor physics and formulated many important practical tasks of direct converting solar energy. In result it was created the world level school of semiconductor physics, which further lead to elaborating the most efficient solar cells on heterostructures (Strebkov, D. S., 2005).

It seems obvious that capturing solar energy is going to be the main trend for the last few decades. In line with this expectation, research on solar cell science and technology has taken a huge jump in recent years. Since the first demonstration of the solar cell in 1954 by Bell Laboratories, much progress has been made in this field. The initial more or less practical solar cell by Bell was a silicon p-n junction cell.

In 1960, solar cells were essentially unique, handmade, cost approximately $1000 per peak Watt of power and were used almost exclusively for space applications. In 1970, cells were manufactured in

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

batch processes, cost approximately $100 per peak Watt, were primarily used in space applications, but were making an entry into standalone applications.

In 1980, larger quantities of solar cells were produced in larger batch processes, cost approximately $10 per peak Watt, saw significant terrestrial applications (primarily stand-alone, remote devices), and began to be used for grid connected residential applications.

Today, different varieties of solar cells are being studied including amorphous silicon, microcrystalline silicon, polycrystalline silicon, cadmium telluride, copper indium selenide/sulfide, organic/polymer, dye-sensitized solar cells and many others. Actually three generations are considered in the book (M.A. Green, 2006) and many new concepts are appearing now

In spite the practically modern silicone cell dates back to 1954 and was developed at Bell Labs, it should be mentioned the first silicon solar cell was made entirely by accident in early 1940 when Russell Ohl, a researcher at Bell telephone Laboratories in New Jersey, made an important discovery. When he shone a flashlight onto a piece of silicon he was studying, the needle of the voltmeter connected across jumped to a surprisingly large reading.

Today, we are on the threshold of continuous-process manufacturing and photovoltaic modules are beginning to be purchased (in large orders) for approximately four dollars per peak Watt. In the United States, there are several thousand (mostly very small) residential systems and a few central power stations in operation or under development—primarily in California. In addition, there is a rapidly growing market for photovoltaic consumer products such as watches, calculators, radios, televisions, battery rechargers, and so on.

As our conventional source of energy—fossil fuel—rapidly depletes, the search for alternative energy sources has become an integral issue in modern industrialized society. Unavoidably, the world's energy demands and cost will rise. To keep pace with these demands, unlimited energy sources must be researched and optimized. The rapid depletion of non-renewable fossil resources will not continue, since it is now or soon will be technically and economically feasible to supply all of man's need from the most abundant energy source of all, the sun. [Green energies and the environment]

The predicted world energy demand will reach 28 TW by 2050 and 46 TW by 2100. The deployment of solar cells as a source of electricity will have to expand to a scale of tens of peak terawatts in order to become a noticeable source of energy in the future (Coby S.Tao, 2011), that is why even natural resource limitations to terawatt-scale solar cells are considered now and possible solutions are discussed (Tyukhov, 2012).

Solar photovoltaics (PV) have been growing exponentially since 2007, doubling in capacity every two years. This means that annual installation rates have mushroomed from less than 4GW in 2007 to 42GW in 2014 – a more than ten-fold increase in just seven years (Green, J, 2014).

2. DIFFERENT MPPT TECHNIQUES FOR OPTIMIZATION PHOTOVOLTAIC SYSTEMS

PV generation systems have two major problems: the conversion efficiency of electric power generation is low, and the amount of electric power generated by solar arrays changes continuously with weather conditions (Berrera et al., 2009; Sreekanth et al., 2012). Moreover, because of nonlinear I-V and P-V characteristics of PV systems, their output power is always changing with weather conditions, i.e., solar radiation, atmospheric temperature and also nature of load connected (Fangrui et al., 2008; Emad et al.,

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

2010). Maximum power point tracking (MPPT) is essential as there is a probable mismatch between the load characteristics and the maximum power points (MPPs) of the PV module in order to ensure optimal utilization of solar cells (Xiao et al., 2004; Ashish et al., 2007). Using of MPPT leads to reduce the cost of energy generated by PV panels (Hohm et al., 2000).

2.1 Conventional MPPT Under Uniform Insolation

A large number of techniques have been proposed for tracking the MPP of PV systems. There are many techniques available in the literature such as fractional open-circuit voltage and short-circuit current (Fangrui et al., 2008), the Artificial Neural Network (ANN) technique (El Sayed, 2013), and the Fuzzy Logic control (Eltamaly, 2010; Eltamaly et al., 2010). Also, it was demonstrated in (Ibrahim et al., 1999) technique to track the maximum power using look-up table in the microcomputer. Another common approach is to use the array power as the feedback. The popular tracking methods based on this approach are widely adopted in PV power systems (Faranda et al., 2008) which include but not limited to, perturb and observe method (P&O) (Koutroulis et al., 2001; Ioan et al., 2013), the incremental conductance method (INC) (Xiao et al., 2004; Esram et al., 2007) and the hill climbing method (HC) (Weidong et al., 2004). These techniques are widely applied in the MPPT controllers due to their simplicity and easy implementation.

2.1.1 Hill Climbing (HC) Technique

The advantage of the hill climbing MPPT technique is its simplicity. It uses the duty cycle of boost converter as the judging parameter when the task of the maximum power point tracking is implemented. When the condition $dP/dD = 0$ is accomplished, it represents that the maximum power point has been tracked (Xiao et al., 2004). The flow diagram of the HC algorithm is shown in Figure 1. The duty cycle in every sampling period is determined by the comparison of the power at present time and previous time. If the incremental power $dP > 0$, the duty cycle should be increased in order to make $dD > 0$. If $dP < 0$, the duty cycle is then reduced to make $dD < 0$. The main problem associated with this technique is because of the tradeoff between the stability of the system in constant radiation period and lack of fast response in rapidly changing radiation. The constant radiation period needs very small value of change in duty cycle, ΔD to prevent high oscillation of power around the maximum power point which reduces the energy captured from PV. On the other hand, the rapidly changing radiation needs higher value of duty cycle for fast tracking the maximum power. HC technique has been simulated in the PSIM software package as shown in Figure 2.

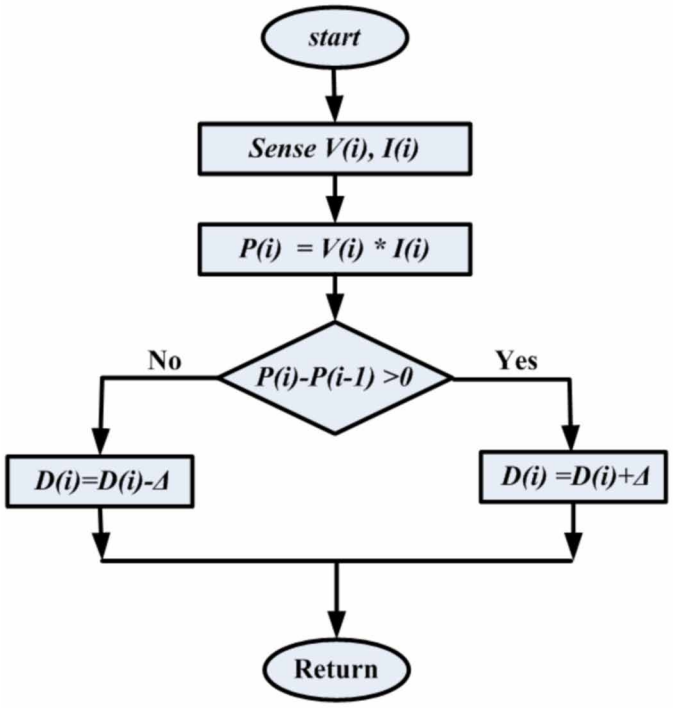
Where; ZOH is zero-order hold block; 1/Z is unit delay block (a unit delay block delays the input by one sampling period); and Sign is sign function block (The output of the sign function block is the sign of the input. When the input is positive, the output is 1. When the input is 0, the output is 0. When the input is negative, the output is -1.)

2.1.2 Incremental Conductance (INC) Technique

Among all the MPPT strategies, the incremental conductance technique is widely used due to the high tracking accuracy at steady state and good adaptability to the rapidly changing atmospheric conditions (Fangrui et al., 2008). This technique employs the slope of the PV array power characteristics to track

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. State flow chart of HC MPPT technique



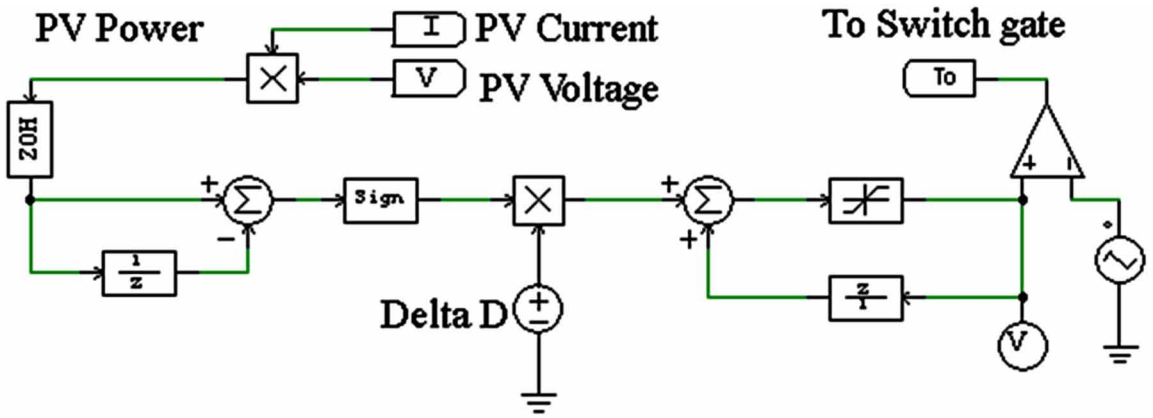


Figure 2. HC MPPT Control Technique using PSIM Software

MPP. The slope of the PV array power curve is zero at the MPP, positive for values of output voltage smaller than the voltage at MPP, and negative for values of the output voltage greater than the voltage at MPP. The derivative of the PV module power is given as in (1), and the resultant equation for the error e is as in (2) (Abouobaida et al., 2012; Emad et al., 2011; Chen et al., 2014).

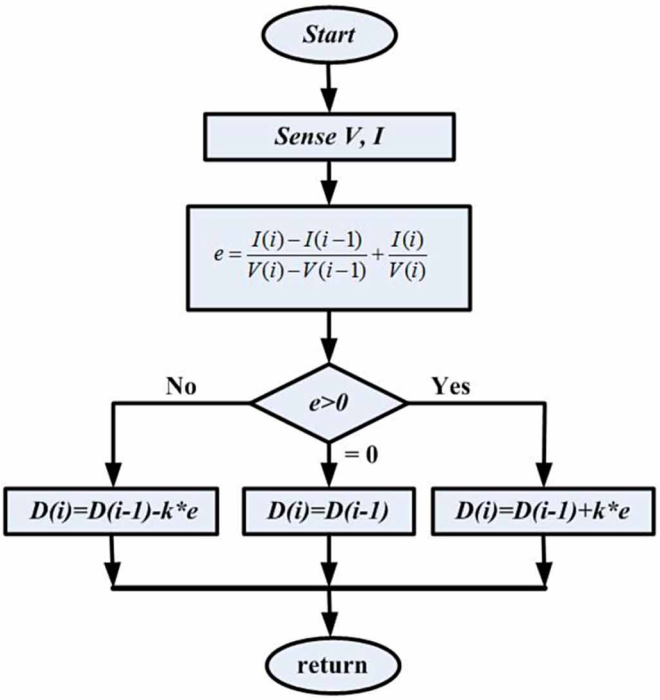
$$\frac{dP}{dV} = \frac{d(V \times I)}{dV} = I + V\frac{dI}{dV} = 0 \tag{1}$$

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Also,

$$\frac{dI}{dV}+\frac{I}{V}=\frac{I(i)\text{ - }I(i-1)}{V(i)\text{ - }V(i-1)}+\frac{I(i)}{V(i)}=0\ e=\frac{I(i)-I(i-1)}{V(i)-V(i-1)}+\frac{I(i)}{V(i)} \tag{2}$$

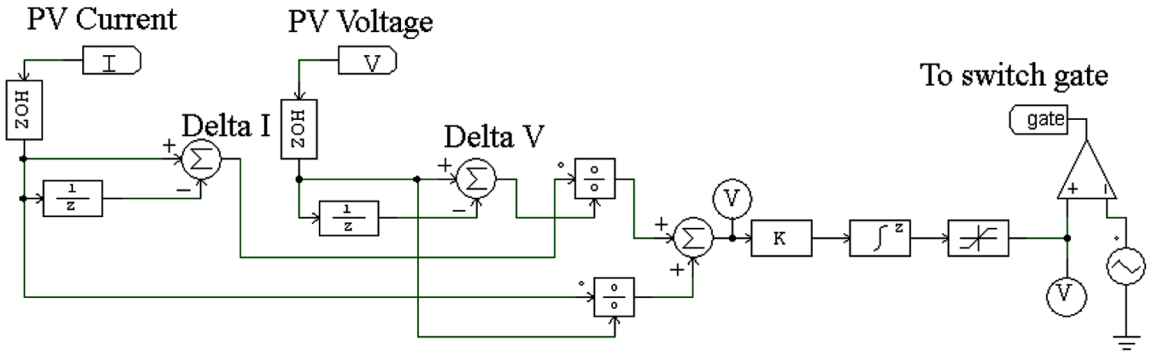
Therefore tracking the MPP requires the following procedure as shown in Figure 3. It can be implemented by a simple discrete integrator with the error signal e as the input, and a scaling factor k. The function of the scaling factor k is to adapt the error signal e to a proper range before the integral compensator. As the operating point approaches the MPP, the error signal e becomes smaller, resulting in an adaptive and smooth tracking (Abouobaida et al., 2012).



To improve, both, the MPPT speed and accuracy simultaneously a modified dynamic change in step size for INC is introduced (Fangrui et al., 2008). This technique improves the performance of INC technique but at a cost of increased complexity of the control system.

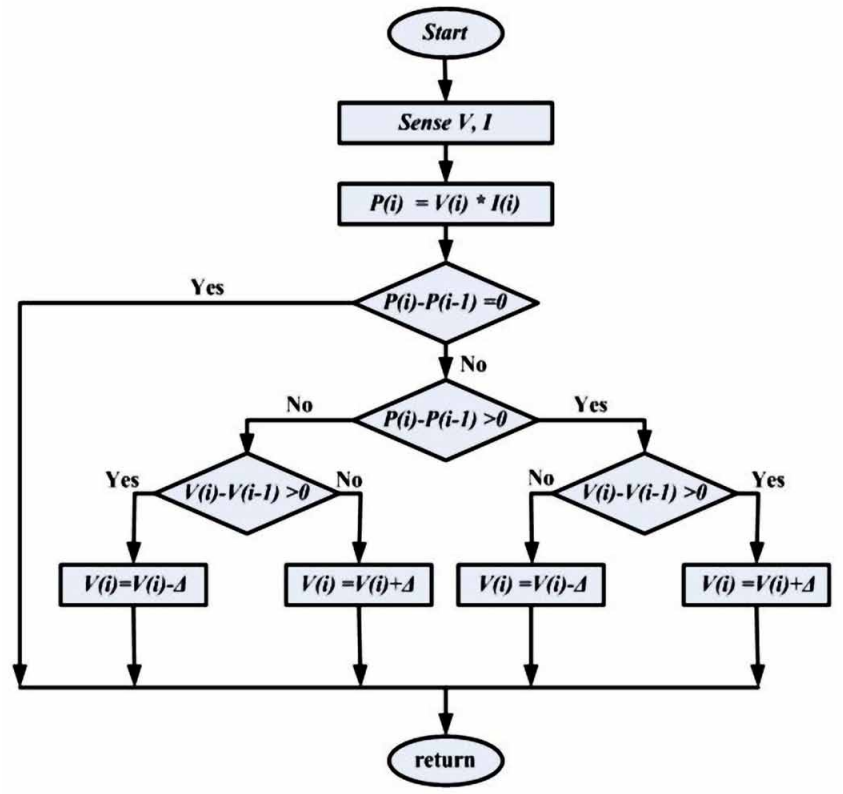
INC technique was simulated in the PSIM software package as shown in Figure 4.

2.1.3. Perturb and Observe (P&O) Technique



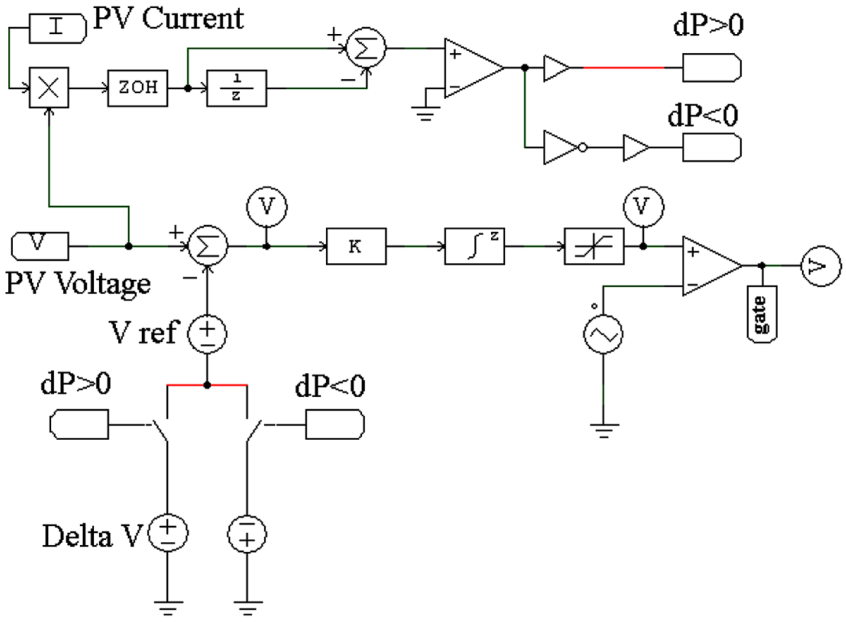
P&O is the most frequently used technique to track the maximum power due to its simple structure (Ioan et al., 2013). This technique operates by periodically perturbing the PV module terminal voltage and comparing the PV output power with that of the previous perturbation cycle (Faranda et al., 2008). As

Figure 3. State-flow chart of INC MPPT technique



EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. INC MPPT Control Technique using PSIM Software



shown in Figure 5 if the PV module operating voltage changes and power increases the control system moves the operating point in that direction; otherwise the operating point is moved in the opposite direction. The flowchart of this technique is shown in Figure 5. PSIM software package has been used to simulate this technique as shown in Figure 6. A common problem in this technique is that the PV module terminal voltage is perturbed every MPPT cycle; therefore when the MPP is reached, the output power oscillates around the maximum, resulting in power loss in the PV system. To remedy this problem, a modified P&O technique has been introduced in (Al-Diab et al., 2010) by multiplying the change in the

Figure 5. State flowchart of P&O MPPT technique

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 6. P&O MPPT control technique using PSIM software

duty cycle by dynamic constant depending on the previous change in the extracted power as shown in (1). Another technique (Amrouch et al., 2007) used ANN to predict this multiplying constant. These techniques increase the complexity of the system and may cause more oscillations in stable weather conditions.

2.1.4. Fuzzy Logic Controller (FLC) Technique for PV MPPT

FLC has been introduced in many researches as in (Gounden et al., 2009; Ben Salah et al., 2008; Altasa et al., 2008; Khaehintung et al., 2004; Karlis et al., 2007; Veerachary et al., 2003; Rajesh et al., 2014) to force the PV to work around MPP. FLCs have the advantages of working with imprecise inputs, not needing an accurate mathematical model, and handling nonlinearity. The details of using FLC in MPPT of PV system is shown in (Eltamaly, 2010). The error signal can be calculated as shown in (3). The value of ΔE is calculated as shown in (4). The model of the proposed system has been simulated in co-simulation between PSIM and Simulink software packages. The idea behind using co-simulation is the easy simulation of FLC in Simulink and power circuit in PSIM.

$$E\left(n\right)=\frac{P\left(i\right)-p\left(i-1\right)}{V\left(i\right)-V\left(i-1\right)} \tag{3}$$

$$\Delta E\left(i\right)=E\left(i\right)-E\left(i-1\right) \tag{4}$$

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

The detailed logic, theory and implementation of this model can be found in (Eltamaly, 2010) and (Eltamaly et al., 2010). The output power from the PV system and the voltage are used to determine the E and ΔE based on (4) and (5). The inputs to a FLC are usually E and ΔE. The range of E and ΔE are fixed judiciously based on trial and error. These variables are expressed in terms of linguistic variables or labels such as PB (Positive Big), PM (Positive Medium), PS (Positive Small), ZE (Zero), NS (Negative Small), NM (Negative Medium), NB (Negative Big) using basic fuzzy subset. Each of these acronyms is described by mathematical membership functions, MF as shown in Figure 7. Once E and ΔE calculated and converted to the linguistic variables based on MF, the FLC output, which is typically a change in duty cycle, ΔD of the power converter can be looked up in a rule base given in Table 2. A triangular membership function can be used for both inputs and output variables, as it can easily be implemented on the digital control system. The linguistic variables assigned to ΔD for the different combinations of E and ΔE are based on the power converter being used and also on the knowledge of the user.

These linguistic variables of input and output MFs are then compared to a set of pre-designed values during aggregation stage. The proper choice of If-then rules or Fuzzy inference is essential for the appropriate response of the FLC system. The inference used in this work is tabulated in Table 2. Some researches proportionate these variables to only five fuzzy subset functions as in (Eltamaly et al., 2010). Table 2 can be translated into 49 fuzzy rules IF-THEN rules to describe the knowledge of control as follows;

R_{25} : *if E is NM and* ΔE *is PS the* ΔD *is NS*

R_{63} : *if E is PM and* ΔE *is NS the* ΔD *is PS*

…..

R_{51} : *if E is PS and* ΔE *is NB the* ΔD *is NM*

Defuzzification is for converting the fuzzy subset of control form inference back to values. As the plant usually required a nonfuzzy value of control, a defuzzification stage is needed. Defuzzificaion for this system is the height method. The height method is both very simple and very fast method. The height defuzzification method in a system of rules by formally given by (5):

$$\Delta D = \left(\sum_{k=1}^{m} c(k) * W_k \right) / \sum_{k=1}^{n} W_k \tag{5}$$

where

ΔD = change of duty cycle
$c(k)$ = peak value of each output
W_k = height of rule *k*.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

In the defuzzification stage, FLC output is converted from a linguistic variable to a numerical variable. This provides an analog signal which is ΔD of the boost converter. This value is subtracted from previous value of D to get its new value.

PSIM model showing the calculating E and ΔE and the inputs to Simulink is shown in Figure 8. The simulation model showing the output signal from FLC in Simulink to PSIM and the switching circuit that control the switch is shown in Figure 9. The simulation model of the proposed system in Simulink is shown in Figure 10. Where; SLINK1 is the name that used in Simulink for the input to PSIM part of simulation

2.2. Soft Computing MPPT Under Partial Shading Conditions

PV system comprises multiple modules interconnected in series and in parallel to create a system with the desired rating. Therefore, the probability for occurring partially shaded condition (PSC) is extremely high. PSC is a phenomenon which is taken place when a part or the whole PV module receives a non-uniform irradiance (Ahmed and Salam, 2014). Ideally, the PV system should be installed in a shade free location. However, it is usually installed in urban and sub-urban areas and PV modules are subjected to partially shadow which is caused by clouds, trees due to wind, neighboring buildings and utilities. Under this condition, the power against voltage (*P–V*) characteristics of PV system exhibits multiple local peaks and one global peak which is required to be tracked, this phenomena reduces the effectiveness of conventional maximum power point tracking (MPPT) techniques (Liu et al., 2012; Sarvi et al., 2015). Large efficient conventional MPPT techniques have been proposed to track maximum power point (MPP)

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 10. Simulink simulation model of FLC MPPT

to improve the conversion efficiency of a PV system under uniform solar irradiance (Ma J. et al., 2013). These techniques include hill climbing, incremental conductance, fuzzy logic control (FLC), perturb & observe, and neural network (Liu et al., 2012; Tey et al., 2014). However, these techniques are highly efficient in tracking the MPP under uniform irradiance, fully illuminated system, where there is only single MPP that exists in the P–V curve, while they are not suitable for tracking the global MPP under PSC (Sarvi et al., 2015) and the efficiency of the PV system decreases (Tey et al., 2014). The idea of using global MPPT based on meta-heuristic optimization techniques algorithms such as genetic algorithms (GAs), Ant Colony Systems (ACS), Artificial Bee Colony (ABC), Artificial Immune Systems (AIS) and particle swarm optimization (PSO) have been presented in (Tey et al., 2014; Sundareswaran et al., 2014; Sundareswaran et al., 2015; Tajuddin et al., 2011). A global MPPT based on cuckoo search algorithm for PV system under PSC has been presented in (Ahmed and Salam, 2014); the authors exploit the significance of the Lévy flight to speed up the algorithm for reaching the global MPP. A modified PSO–MPPT has been presented in (Ishaqu et al., 2012) to minimize the steady state oscillation generated by unstable environmental conditions like change in solar irradiance, change in load and partial shading of PV system. Various extra coefficients have been added to conventional PSO to speed its performance in tracking the global power extracted from the PV system (Daraban et al., 2013); the disadvantage of adding these extra parameters is increasing the algorithm time consumption. A genetic optimization algorithm has been used to determine neuron numbers in multilayer perceptron neural network (ANN) (Kulaksız et al., 2012). A technique based on artificial bee colony has been proposed in (Kinattingal et al., 2015) for global MPP tracking in a PV power generation system. A new MPPT algorithm based on a colony of fireflies for quickly tracking global MPP in partially shaded A PV array has been presented in (Sundareswaran et al., 2014). The tracking procedure consists of positioning the fireflies in the possible solution space and based on the PV power output, the flies move to promised regions (Sundareswaran et al., 2014). An algorithm combines PSO and *P&O* for tracking the global MPP for the PV system has

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

been proposed in (Sundareswaran et al., 2013). Varying step size decreased response time and oscillations around the MPP. Ideal size for ANN structure with five neurons in hidden layer was obtained. In (Paraskevadaki et al., 2011) the effect of partial shading on PV module has been analyzed; additionally, a mathematical formula to calculate the shadow effect on the main electrical characteristic of PV module and the MPP of voltage and current has been provided. Modified Differential evolution technique (Tajuddin et al., 2011) able to deal with large and rapid fluctuations of solar irradiance and reached the global MPP under various PS conditions. Average efficiency of 99.6% was attained during tests of partial-shading conditions. Proposed Ant colony optimization (ACO)-based MPPT technique (Besheer et al., 2012) uses heuristic algorithm to find global MPP with simpler control system and low cost. Simulations verified that the technique was successful and robust to various shading patterns. A method for tracking the global MPP of PV system based on the measurements of the PV array open-circuit voltage has been presented in (Lei et al., 2011) while the method described in (Kazmi et al., 2009) is dependent on the solar radiation or PV array short circuit current. A two stage method to track the global MPP of the shaded PV system has been developed in (Kobayashi et al., 2006). In the first one the point of operation moves nearest to the global MPP and in the second one it converges to the actual global MPP.

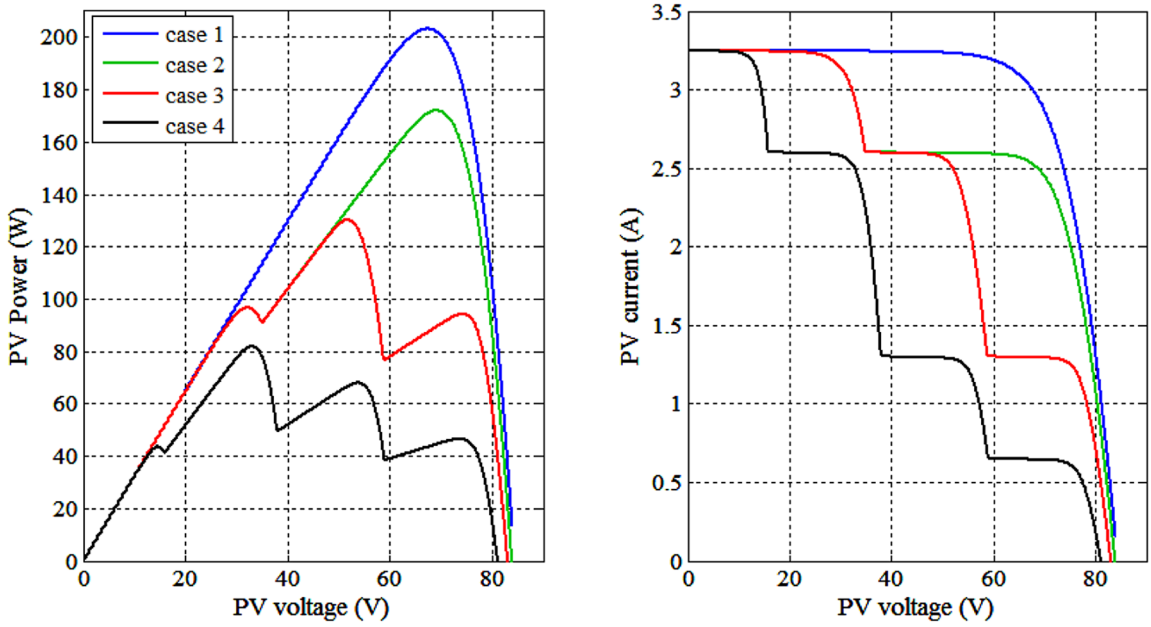
PV cell is an electrical device that converts the energy of light directly into electricity through the PV effect. They are connected in series and parallel to step up the voltage and current of PV module respectively. PV cell has a complex relationship between solar irradiance, temperature, and the load; so it exhibits a nonlinear output efficiency characteristic known as the P–V curve. Therefore, MPPT techniques should be developed in PV systems in order to maximize the output power (Chen et al., 2014; Rezk et al., 2015). Normally, numbers of PV modules are connected in series and parallel to form a PV array and the total output power is the combination of the power generated from each PV module. PSC is a common phenomenon occurred due to the shadows of buildings and clouds. If there is one or more of the PV modules are partially shaded, the shaded PV modules will consume the power generated by the rest of the PV modules and dissipates heat and cause hot spots (Tey et al., 2014; Chen et al., 2014). Under this condition, the current available in series-connected PV modules is limited by the current of the shaded PV module. This can be avoided by using bypass diodes which are placed in parallel with each PV module. The bypass diodes are reversing biased and have no impact under normal conditions (Tey et al., 2014). On the other hand, they are forward biased and carry the current instead of the PV module under shadowing effect. Figure 11 shows the power against voltage and the current against voltage curves of PV system, respectively, under different cases of PSC. This condition is given by four PV modules connected in series with solar irradiances as shown in Table 3.

Table 3. Different partial shading patterns

Shadow Pattern	First PV Module G_1, w/m^2	Second PV Module G_2, w/m^2	Third PV Module G_3,w/m^2	Fourth PV Module G_4, w/m^2
Case 1	1000	1000	1000	1000
Case 2	1000	1000	800	800
Case 3	1000	1000	800	400
Case 4	1000	800	400	200

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

From Figure 11 it can be seen that, the *I–V* curve under PSC have multiple steps, while the P–V curve has multiple peaks. Also, the number of peaks is equal to the number of different irradiance levels incident on the PV modules.



2.2.1. PSO–Based Tracker

PSO is a population–based evolutionary technique that has been recently used for global MPPT under PSC (Sarvi et al., 2015). It was inspired by the behavior of birds, which comprise a swarm of particles, and each particle suggests a candidate solution by exchange the information obtained in their respective search process to find the best solution (Boutasseta, 2012). These particles move in the search-space according to simple mathematical relation, exploiting their position and velocity. The position of the particle is affected by the agent position, which suggests the best solution through the current particles (local best), Pbest, as well as the best solution suggested through the entire population (global best), Gbest. In this work, the particle swarm position is defined as the duty cycle of the DC/DC boost converter, and the fitness value evaluation function is taken as the PV system output power. The particle position di is updated by the following relation;

$$d_i^{k+1} = d_i^k + v_i^{k+1} \tag{6}$$

where the velocity component v_i represents the step size at iteration k+1 and is calculated by using the following expression:

Figure 11. Power against voltage and current against voltage curves of PV system under uniform irradiance and different partial shading patterns

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

$$v_i^{k+1} = wv_i^k + c_1 r_1 \left(P_{best} - d_i^k\right) + c_2 r_2 \left(G_{best} - d_i^k\right) \tag{7}$$

where *w* is the inertial weight, c1 and c2 are the acceleration coefficients, r1 and r2 are random values that belong to the interval of [0, 1], Pbest is the best position of particle i, and Gbest is the best position in the entire population (Mirhassaniet et al., 2015). A basic problem with the conventional PSO can be traced to its random nature. It can be seen that the last two terms in (2) is totally dependent on random numbers. The modified velocity equation by (Ishaque and Salam, 2013) can be written as the following;

$$v_i^{k+1} = wv_i^k + P_{best} + G_{best} - 2d_i^k \tag{8}$$

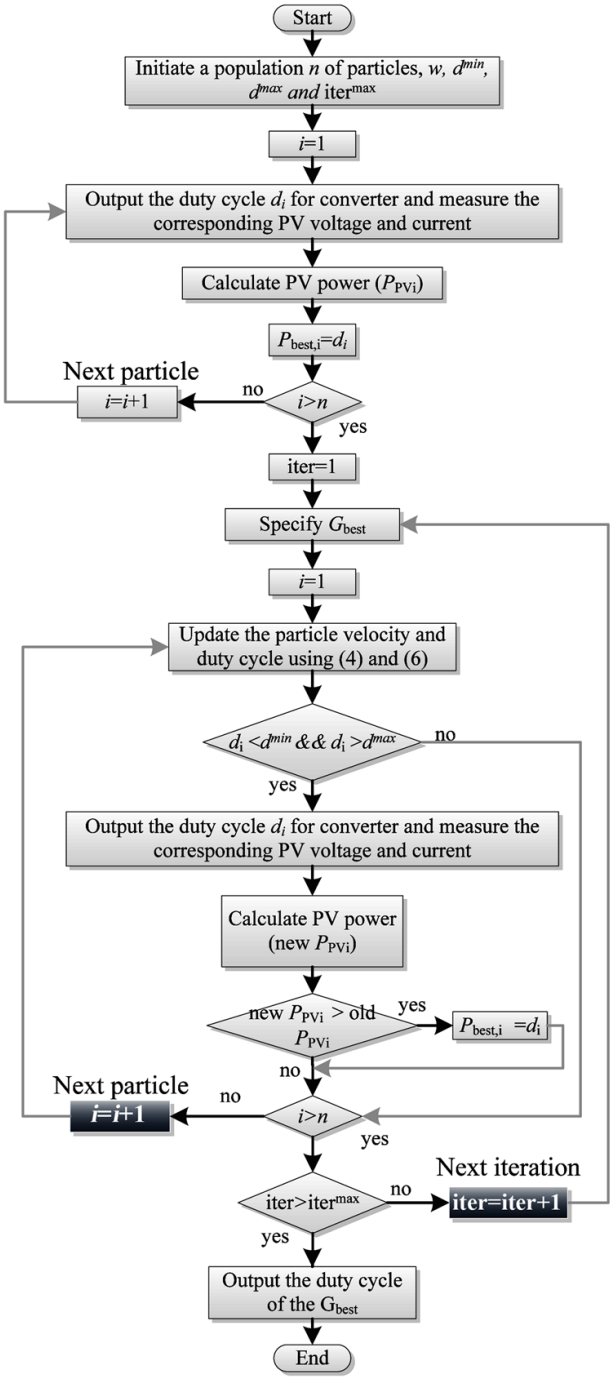


Figure 12 shows the flowchart for searching mechanism by PSO–based tracker. Using a larger number of particles result in more accurate MPP tracking even under complicated shading patterns. However, a larger number of particles also lead to longer computation time. Therefore, a tradeoff should be made to ensure good tracking speed and accuracy. Firstly appropriate variables have to be selected for the search. The total number of particles is defined as n, in this work; the particles are defined as the duty cycles of boost converter. The particles can be placed on fixed position or be placed in the space randomly. The generated samples are applied to the PV system and the corresponding PV voltage and current are measured. These values used to calculate the PV power (fitness value) of particle i. If the current power of particle i is better than the best fitness value in history p_{best}, set current power as the new best fitness of particle i. Then, choose the particle with the best fitness value of all the particles as the G_{best}. After evaluation of all particles, the velocity and position of each particle in the swarm should be updated using (1) and (3). Finally, if the maximum number of iterations is reached, the algorithm will stop and give the obtained G_{best} solution, which represents the optimum value of the duty cycle corresponding to global MPP (Liu et al., 2012).

2.2.2. Teaching-Learning Based Optimization (TLBO)

TLBO is proposed by Reo and Patel in 2010 (Rao and Patel, 2013) It is a population based technique that uses a population of candidate solutions to proceed to the optimal solution (Rao et al., 2015). TLBO simulates the traditional teaching-learning process of a classical school. A group of n students is considered the population and different subjects offered to the students are analogous with the different design variable of the optimization problem. The results of students are analogous to the fitness values of the optimization problem. The best solution in the entire population is considered as the teacher (Rao and Patel, 2013). The teacher tries to improve the individuals by changing the during the teacher and student phases, where an individual is only replaced if his new solution is better than his previous one. The process of TELBO is divided into two stages. During the first stage, called teacher phase, a teacher imports knowledge directly to his students. During the second stage, called student stage, a student may learn with help of fellow students. Overall, how much knowledge is transferred to a student does not only depend on his teacher but also on interaction amongst students through peer teaching (Cerpinsek et al., 2012). The process of TLBO can be summarized as follow:

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 12. Flowchart for searching mechanism by PSO–based tracker

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

In the teacher phase, a teacher conveys knowledge among the students and makes an effort to increase the mean result if the class (Rao and Patel, 2013). A good teacher is one who brings his students up to his level in terms of knowledge. But in practice this is not possible and a teacher can only move the mean of the class up to some extent depending on the capability of the students (Rao et al., 2015).

Suppose there is one subject (design variable) offered to n number of students. In this work the student represented by the duty cycle of boost converter di and the fitness value represented by the PV output power. At any iteration *i*, $d_{\text{i,mean}}$, is the mean value of the students. Since a teacher is the most experienced and knowledgeable person on a subject, the best student who is identified as a teacher for that iteration i. the teacher will put maximum effort into increasing the knowledge level of the whole class, but students will gain knowledge according to quality of teaching delivered by a teacher. The existing solution is updated in the teacher phase according to the difference between the value of the teacher di,best and the mean value of the students $d_{\text{i,mean}}$ as follows:

$$d_{i+1} = d_i + r\left(d_{i,best} - T_F d_{i,mean}\right), \tag{9}$$

where $d_{\text{i+1}}$ is the updated value of d_{i}. Accept $d_{\text{i+1}}$ if it gives a better function value. All the accepted function values at the end of the teacher phase are maintained, and these values become the input to the student phase (Rao and Patel, 2013). T_{f} is a teaching factor that decides the value of mean to be changed, and r is a random number in the range [0 1]. The value of T_{f} can be either 1 or 2.

In the student phase, TLBO simulates the learning of the students through interaction among themselves by discussing and interacting. A student will learn new information if the other students have more knowledge than him (Rao and Patel, 2013). During this phase, one student d_{x} tries to improve his knowledge by peer learning from arbitrary student d_{y}. In the case that d_{y} is better than d_{x}, d_{x} move toward d_{y} according to (10). Otherwise, it is moved away from d_{y} according (11).

$$d_{new} = d_x + r\left(d_y - d_x\right) \text{if } P_{\text{pv}}(d_y) > P_{\text{pv}}(d_x) \tag{10}$$

$$d_{new} = d_x + r\left(d_x - d_y\right) \text{if } P_{\text{pv}}(d_x) > P_{\text{pv}}(d_y) \tag{11}$$

If student d_{new} performs better by following Eq (10) and (11), he will be accepted into the next iteration. The algorithm will continue its iterations until reaching maximum number of iterations (Cerpinsek et al., 2012).

The searching mechanism by TLBO–based trackers as fellow; firstly appropriate variables have to be selected for the search. The total number of learners is defined as n, in the current work; the learners are defined as the duty cycles of boost converter. The initial duty cycles (learners) are applied to the PV system and the corresponding PV voltage and current are measured. These values used to calculate the PV power (fitness value) of each learner *i*. Then, choose the learner with the best fitness value of all the learners as the teacher. After evaluation of all learners, the duty cycle is updated in the teacher phase according to (9). Afterwards, select randomly any two learners and update the duty cycle according (10) and (11). These steps are executed for a certain number of iterations until the all nests reach at the best solution which represents the optimum duty cycle corresponding to global MPP.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

2.2.3. Differential Evolution (DE) Based Tracker

DE, which is proposed by Storn and Price, is one of the best population based techniques used for global optimization because of its simplicity and efficiency. Basically, a population of n particle is required in DE and little iteration needed to reach the optimal solution. The algorithm starts with an initial random population and implements mutation, crossover, and selection operations to update the population during the evolution toward the optimum solution (Tey et al., 2012; Salam and Saad, 2013). It implements mutation and crossover processes to yield a trial vector dui for each target vector. Thereafter, a selection operation is executed between the trial vector and the target vector. There are several mutation strategies, each of which is suited for obtaining particular results. The one used in this work is called DE/best/bin. The mutation, crossover and selection operations of this DE algorithm are explained as follow.

The duty cycle of boost converter is used as a target vector and the PV power as the fitness function. The target vectors are distributed on fixed positions with equal distance ranging over their corresponding feasible limits [d_{min}, d_{max}]. The initial population of duty cycles is send to the boost converter. Next, the fitness function values of population are evaluated by measuring PV system current and voltage correspond to each target vector. The measured current and voltage are then used to calculate the PV system power pi which is used as fitness function. After the initialization step finished, the highest PV power is selected as P_{best} and corresponding duty cycle di is saved as the best one D_{best}. Next, two different population members are randomly selected. The, a mutation factor F is used to weight the difference between the selected target vector and the weighted difference is added into the best duty cycle to generate mutated particle or so called donor vector d_{vi}. The mutation process is given by (Tey et al., 2012; Salam and Saad, 2013);

$$dv_i = D_{best} + F \times (d_{r_1} - d_{r_2}) \tag{12}$$

where indexes r_1, and r_2 represent mutually different integers that are randomly generated over [1, n], and F is the scaling factor.

In this work, if a one component of a mutant vector violates the boundary constraint, this component is reset as follows:

$$du_i = \begin{cases} du_i = d_{\max} & \rightarrow \quad \text{if } du_i \text{ greater than } d_{\max} \\ du_i = d_{\min} & \rightarrow \quad \text{if } du_i \text{ smaller than } d_{\min} \end{cases} \tag{13}$$

After the mutation process, the trail vector dui is generated by making use of a binomial crossover operation on the target vector di and the mutant vector d_{vi}. The condition used in crossover process is described as the following;

$$du_i = \begin{cases} dv_i & \text{if } rand \le C_r \\ di \end{cases} \tag{14}$$

Cr is the crossover control parameter in rang of [0 1]

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

After crossover, the selection stage is reach. It is conducted by comparing the target vector di against the trial vector d_{ui}. Each trial vector dui is assessed through PV system and P_{ui} have to be measured. However, the value of dui may remain as d_i after crossover and P_{ui} is also equal to P_i. Therefore, only the P_{ui} which does not have the same duty cycle as P_i measured again from the input of boost converter. This process helps to reduce the searching time. When all values of the P_{ui} are obtained, it is compared to P_i. From comparison, the duty cycle which corresponds to higher value of power is used as the next target vector according to the following;

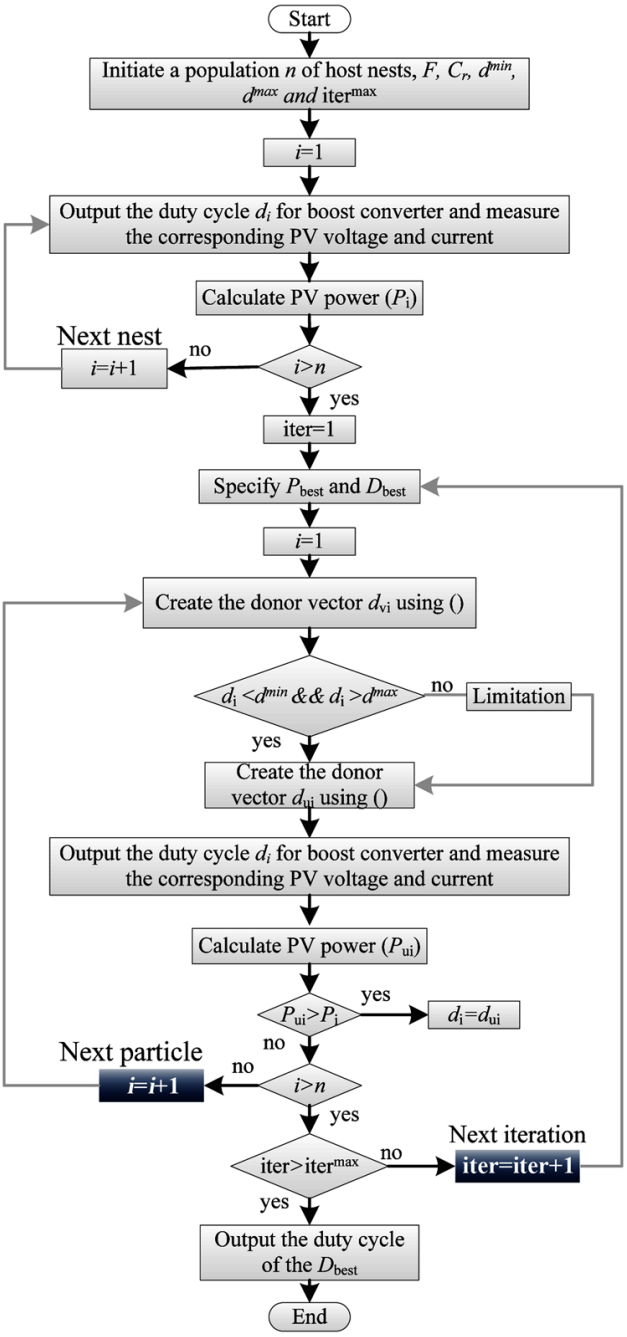
$$d_{i+1} = \begin{cases} du_i & \text{if } f(du_i) \geq f(d_i) \\ di & \text{otherwise.} \end{cases} \tag{15}$$

The iterations are carried out until a termination condition is met. The searching mechanism of DE-based tracker is shown in Figure 13.

2.2.4. Cuckoo Search Based MPPT Technique

Cuckoo Search represents a new optimization meta-heuristic technique recently developed by Yang and Deb (Yang and S. Deb, 2009). The key mechanism in cuckoo breeding is brood parasitism. This is the act of laying eggs in the nests owned by other birds, which may or may not be of the same species. There are three types of brood parasitism, which are termed intraspecific, cooperative and nest takeover (Payne et al., 2005). If the host bird discovers the cuckoo egg in her nest, it may destroy the egg or abandon the nest and build a new one elsewhere. In order to increase the probability of having a new cuckoo and reduce of abandoning eggs by host birds, cuckoos use several strategies such as imitating the colors and patterns and devolving the capacity of cuckoo to mimic the call of host bird to gain access to more feeding opportunity. The model described in (Yang and S. Deb, 2009) has been based on three proposed rules which are;

1. Each cuckoo lays one egg at a time and deposits it into a random nest,
2. The best nests contain the highest quality eggs pass to the next generation,
3. The number of host nests is fixed and there is always a probability that the cuckoo egg is discovered by the host. If an egg is discovered, the host bird throws it out of the nest.



One of the most powerful features of CS is the use of Lévy flights to generate new eggs. A Lévy flight is a random walk, characterized by a series of instantaneous laeps generated by a probability density function. Mathematically, a Lévy flight is a random walk where step sizes are extracted from Lévy distribution according to a power law as follows:

$$Lévy\left(\beta\right) = l^{-\beta} \tag{16}$$

where l is the length of flight and $1< \beta <3$. New eggs are provided by performing a Lévy flight from a randomly selected egg. The new egg is then represented by the coordinates reached at the end of the flight. A coefficient α is used to control the size of the Lévy flight. When a Lévy step is generated, it is

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 13. Flowchart for searching mechanism by DE-based tracker

first multiplied by α before it is used to generate a new egg. There are important controlling parameter to be adjusted; the fraction of eggs to be abandoned in each generation. In this work, the fraction of eggs to be discarded $p_a = 0.25$ were used, as suggested by (Yang and S. Deb, 2009). The proposed strategy in this work is that finding the optimum duty cycle of boost converter corresponding to global MPP under different partial shading patterns. Therefore the duty cycle is used as a variable to be searched,

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

independent variable. The PV output power is used as the fitness function, objective function. According the Lévy flight, the duty cycle is updated based on the following relation (Yang and S. Deb, 2009):

$$d_i^{k+1} = d_i^k + \alpha \oplus Lévy\left(\beta\right) \approx d_i^k + k_{\text{Lévy}} \times \left(\frac{u}{\left|v\right|^{1/\beta}}\right)\left(d_{best}^k - d_i^k\right) \tag{17}$$

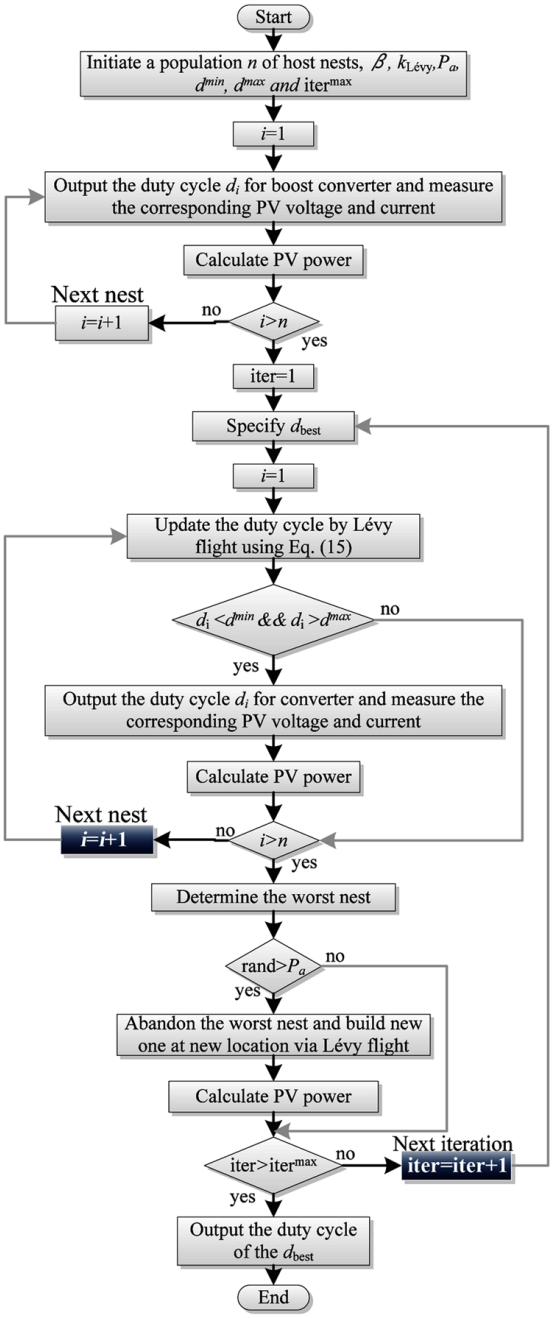
where β=1.5, kLévy is the Lévy multiplying coefficient (selected as 0.1), *u* and *v* are determined from the normal distribution curves.

$$u \approx N\left(0, \sigma_u^{\,2}\right) \quad and \quad v \approx N\left(0, \sigma_v^{\,2}\right) \tag{18}$$

where the variable σu and σv are defined as follows:

$$\sigma_u = \left(\frac{\Gamma\left(1+\beta\right) \times \sin\left(\pi \times \beta/2\right)}{\Gamma\left(\frac{1+\beta}{2}\right) \times \beta \times 2^{\frac{(\beta-1)}{2}}}\right)^{1/\beta} \quad and \quad \sigma_v = 1 \tag{19}$$

Based on the above mentioned rules, the searching mechanism for CS–based tracker can be summarized in Figure 13. Considering fixed numbers of the host nests (*n*) initially population is generated as a duty cycle of boost converter d_i=d_1, d_2,…,d_n. The duty cycles are applied in the PV system and corresponding PV voltage and current are measured. The measured PV voltage and current are then used to calculate the PV power which used as the fitness function. The duty cycle corresponding to the maximum value among the fitnesses is considered as the current best nest (d_{best}). Then Lévy flight is performed and new nests are generated as in (9). New fitnesses values are tested through the PV system. Afterwards, the worst nest is randomly destroyed with a probability Pa, this process emulates the behavior of the host bird discovering the cuckoo's eggs and destroying them. The new nest is replaced the destroyed one via Lévy flight, then the PV power is measured and the current best the current best nest is selected. These steps are executed for a certain number of iterations until the all nests reach at the best solution which represents the optimum duty cycle corresponding to global MPP.



2.3. Summary

Judging by the amount of recent work, it can be concluded that the MPPT is still a very active research area. There are rooms for improvement, particularly when dealing with partial shading conditions. For uniform insolation, there is an increasing trend in combining the conventional methods with soft computing techniques.

As for the partial shading, it appears that the EA methods are the most promising. The PSO, which has a very similar structure to HC has proven to be a viable option. However, there are still potential

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 14. Flowchart for searching mechanism by CS-based tracker

areas of concerns for EA, particularly the selection of appropriate evolutionary control parameters such as population size, mutation factor etc. This may be resolved with the assistance of other optimization technique such as ANN. There is also a need to consider the viability of EA methods when it comes to real time implementation. The way forward is to find an effective method such that the search space

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

can be narrowed, so that the computational time is reduced. Furthermore, there are several more EA techniques, which are yet to be exploited fully, for example the differential evolution (DE) and TLBO.

3. SOLAR ENERGY AND RENEWABLE ENERGY

For reliable energy supply using only PV systems is unpractical because of needs too much accumulating equipment. More practical solution especially for decentralized electricity energy supply is using combination of renewable energy different types. Renewable energy (REN) is defined as energy that is produced by stable or intermittent natural energy currents - such as sunlight, wind, rain, waves, tides, and geothermal heat—that are naturally replenished within a time span of a few years (Lund H., 2010). Henrik Lund even asks: how can society convert to 100 percent renewable energy?

Hundred percent of renewable power is foundation for next step of human evolution. The time has come to abolish the combustion of coal, oil and gas for energy generation worldwide, along with the nuclear power threat (Peter Droege, 2009).

The main unpleasant features of renewable energy are low density, space distribution and time intermittence.

Decentralized electricity generation and fluctuating availability pose a challenge on grid stability. This section provides understanding of interaction between PV and other REN systems. Optimization of combined renewable energy sources (different types of converters) for standalone electrical power supply is an important practical task.

The use of renewable energy sources (RES) for autonomous power supply is characterized with a number of features that must be considered when specific systems are creating and designing. The low energy density of renewable energy flows, their variability over time, on the one hand, and the non-uniformity of the load curve the consumers on the other, requires the use of additional equipment - energy storage devices and "smart" devices with the appropriate software and hardware for control income and outcome energy. Energy storage compensates unevenness between energy generation and energy consumption by storing it in periods of surplus energy and energy from in deficit moments. However, accumulating system increases the cost of energy supplying, despite the lack of fuel in the total expenses for such systems. So, the effective way to solve this problem is the combined use of renewable energy sources.

The combined use of the different renewable energy sources allows compensating the intermittent character of RES, to reduce the capacity of the accumulating system units, and, consequently, reduce its cost. However, due to territorial inequity of energy currents from RES, different equipment performances, and variable demands of energy consumers, the optimal configuration of the autonomous power supply combined system (in terms of its economy) is not the same for different places (geographical positions) of operation. The developed methodology and software package allow determining the optimal structure and parameters of the combined power system taking into account all the above factors. The system of computer mathematical package MATLAB with the block of visual simulation Simulink has been developed and used for finding the optimal configuration of the system combination for specific geographic locations.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

3.1. Outline of a Case Study

Simultaneous using of multiple energy sources allows to compensate uneven coming of renewable energy, which, in turn, can significantly reduce the capacity of the generating units, as well as storage capacity in such systems and, consequently, reduce their cost.

Planning and designing of such systems should also take into account the uneven territorial distribution of renewable energy resources. Thus, the problem of determining the optimal structure and parameters of the autonomous power supply combined system (APSCS) from renewable energy sources (APSCS-RES) with the real geographical and climatic conditions, characteristics of the equipment using and the characteristics of the energy consumer, including the expected variable graphics power consumption is arising. In this case, the optimality criterion must be the minimum cost of the system generating electricity.

In the example of a particular case, we consider the solution of the optimization problem for a system that can use only three renewable energy currents: solar, wind and small watercourse. Choice of data sources due to the possibility of increasing the reliability of uninterrupted power supply consumer as micro-hydro which is a relatively stable source of energy, and the installation of photovoltaic (PV) with a wind power unit (WPU) which help each other due to the synergistic effect. Moreover the existence of such sources as the sun and the wind is wide available and small streams flowing in abundance across the expanses of many countries. This result allows applying this methodology to solve optimization problems with a wide range of sources, as well as the relatively stable sources can be considered as geothermal, biomass and others.

3.2. Software Elaborating for Case Study

The solution of described problems is obtained by means of modern specialized software - computer systems Mathematics (CSM). The package MATLAB with visual simulation Simulink was chosen for this system, which is implemented software system that determines the optimal structure and parameters APSCS on the basis of three renewable energy: solar, wind, micro-hydro, taking into account the actual climatic and geographical conditions, characteristics of the equipment used and the characteristics of the consumer, including the expected variable graphics of electric power consumption, according to the criterion of the minimum system cost.

The developed complex consists of two interrelated parts:

- Sub-programs created in the m-file MATLAB;
- Mathematical models APSCS-RES created in Simulink.

The first part determines the optimal composition and preliminary parameters APSCS-RES, which are calculated on the basis of average values from the generalized expressions, and some dependencies are not taken into account, because the variability in the time is very difficult to express by the simple means. Accordingly, in the second stage there is a need to simulate the operation APSCS-RES throughout the calculating period: to analyze its operation, verify the optimal parameters, make corrections and adjustments. Moreover, the simulation can accurately determine the coefficients of power plants usage that characterize the climate conditions in selected areas and time characteristics of the equipment in order to solve the optimization problem.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

The methodology developed in the first part of the software package implements the principle that determines the optimal structure and parameters APSCS-RES. The unknown parameters are the power of installed plants based on renewable energy sources $N_{\text{res}}^{\text{inst}}$ and storage capacity $C_{\text{ab}}^{\text{inst}}$ according to their type and their size range. From the available n unknown variables (corresponding to the standard size range) a certain amount of ξ (ξ <n) must enter in the optimal solution. In this case, each target variable (discrete value) corresponds to a binary variable δi. Thus, if as a result of solving the problem δi = 1, the variable and, therefore, appropriate that variable setting of the standard series, is part of the optimal solution, if δi = 0, then no.

Taking into account that the optimality criterion, i.e. extreme value of the objective function is a minimum cost, the objective function takes the following form:

$$\begin{aligned}
&c_{\text{pv}} \cdot N_{\text{pv1}}^{\text{inst}} \cdot \delta_{1} + c_{\text{pv}} \cdot N_{\text{pv2}}^{\text{inst}} \cdot \delta_{2} + \ldots + c_{\text{pv}} \cdot N_{\text{pv}\,l}^{\text{inst}} \cdot \delta_{l} \\
&+c_{\text{wind}} \cdot N_{\text{wind1}}^{\text{inst}} \cdot \delta_{l+1} + c_{\text{wind2}} \cdot N_{\text{wind2}}^{\text{inst}} \cdot \delta_{l+2} + \ldots + c_{\text{wind}} \cdot N_{\text{wind}\,g}^{\text{inst}} \cdot \delta_{l+g} \\
&+c_{\text{hydro}} \cdot N_{\text{hydro1}}^{\text{inst}} \cdot \delta_{l+g+1} + c_{\text{hydro}} \cdot N_{\text{hydro}\,2}^{\text{inst}} \cdot \delta_{l+g+2} + \ldots + c_{\text{hydro}} \cdot N_{\text{hydro}\,p}^{\text{inst}} \cdot \delta_{l+g+p} \\
&+c_{ab} \cdot C_{\text{ab1}}^{\text{inst}} \cdot \delta_{l+g+p+1} + c_{ab} \cdot C_{\text{ab}\,2}^{\text{inst}} \cdot \delta_{l+g+p+2} + \ldots \\
&+c_{ab} \cdot C_{abf}^{\text{inst}} \cdot \delta_{l+g+p+f=n} \rightarrow \min
\end{aligned} \tag{20}$$

where,

c_{wind} , c_{hydro}: the specific cost for installed capacity in Watts for PV, wind turbines and micro hydro respectively, rub/W;

c_{ab}: unit cost of installed capacity accumulating battery at a voltage U_{ab}^{nom} for the entire life of the APSCS-RES, rub. / A • h;

$N_{\text{pv1}}^{\text{inst}}, N_{\text{pv2}}^{\text{inst}}, \ldots N_{\text{wind}\,l}^{\text{inst}}$, $N_{\text{wind1}}^{\text{inst}}, N_{\text{wind2}}^{\text{inst}}, \ldots N_{\text{wind}\,g}^{\text{inst}}$, $N_{\text{hydro1}}^{\text{inst}}, N_{\text{hydro}\,2}^{\text{inst}}, \ldots N_{hydrop}^{\text{inst}}$: installed capacity of PV, wind turbines and micro-hydro, respectively, in W;

$C_{\text{ab}\,1}^{\text{inst}}, C_{\text{ab}\,2}^{\text{inst}}, \ldots C_{\text{ab}\,f}^{\text{inst}}$: accumulator battery (AB) installed capacity at a nominal voltage U_{ab}^{nom}, A•h;

$\delta_{1}, \delta_{2} \ldots \delta_{l}$, $\delta_{l+1}, \delta_{l+2}, \delta_{l+g}$, $\delta_{l+g+p+1}, \delta_{l+g+p+2}, \delta_{l+g+p+f=n}$: binary variables corresponding number of standard sizes PV, wind turbines, micro-hydro and AB, respectively.

For determining the unit cost of AB during the life time of APSCS-RES the number of substitutions is taking into account produced during this time, due to the limited number of charge-discharge cycles

$$k_{\text{ab}}^{\text{sub}} = \frac{T_{\text{APSCS-RES}}^{\exp l}}{\left(\text{Q}_{\text{ab}}^{\text{u.r.p.}} \,/\, \text{Q}_{A.B}^{\text{u.r.}}\right)}, \tag{21}$$

where

$T_{APSCS-RES}^{\exp l}$: the life APSCS-RES years (we took in calculations 20 years);

$\text{Q}_{\text{ab}}^{\text{cdd.}}$: the number of charge-discharge cycles at a given depth of discharge;

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

$Q_{\text{ab}}^{\text{cd.}}$: the number of charge-discharge cycles, the average for the year (in the calculations is equal to 365, in average one full cycle per day).

In this case, the unit cost of AB, determined during its life APSCS-RES is found by the following expression:

$$c_{\text{ab}} = c'_{\text{ab}} \cdot k_{\text{ab}}^{\text{sub}} , \tag{22}$$

where c'_{ab} : the unit cost of battery at a voltage U_{ab}^{nom}, rub. / A • h.

The system of restrictions is a condition to ensure uninterrupted power supply to consumers. This is the equation of energy balance, made up for the average daily hours for each calendar month of the accounting period (years):

$$\begin{aligned}
&k_{pv}^{fac}(\Delta t_i^j)\cdot N_{\text{pv 1}}^{\text{inst}}\cdot k_n\cdot\delta_1\cdot\Delta t_i^j + k_{pv}^{inst}(\Delta t_i^j)\cdot N_{\text{pv 2}}^{\text{inst}}\cdot k_n\cdot\delta_2\cdot\Delta t_i^j + \dots\\
&+k_{pv}^{inst}(\Delta t_i^j)\cdot N_{\text{pv }l}^{\text{inst}}\cdot k_n\cdot\delta_l\cdot\Delta t_i^j + k_{wind}^{inst}(\Delta t_i^j)\cdot N_{\text{wind 1}}^{\text{inst}}\cdot k_n\cdot\delta_{l+1}\cdot\Delta t_i^j +\\
&+k_{wind}^{inst}(\Delta t_i^j)\cdot N_{\text{wind 2}}^{\text{inst}}\cdot k_n\cdot\delta_{l+2}\cdot\Delta t_i^j + \dots + k_{wind}^{inst}(\Delta t_i^j)\cdot N_{\text{wind }g}^{\text{inst}}\cdot k_n\cdot\delta_{l+g}\cdot\Delta t_i^j +\\
&+k_{hydro}^{inst}(\Delta t_i^j)\cdot N_{\text{hydro 1}}^{\text{inst}}\cdot k_n\cdot\delta_{l+g+1}\cdot\Delta t_i^j + k_{hydro}^{inst}(\Delta t_i^j)\cdot N_{\text{hydro 2}}^{\text{inst}}\cdot k_n\cdot\delta_{l+g+2}\cdot\Delta t_i^j + \dots,\\
&+k_{hydro}^{inst}(\Delta t_i^j)\cdot N_{\text{hydro}p}^{\text{inst}}\cdot k_n\cdot\delta_{l+g+p}\cdot\Delta t_i^j + k_{ab}^{inst}(\Delta t_i^j)\cdot C_{\text{ab 1}}^{\text{inst}}\cdot U_{ab}^{nom}\cdot k_n\cdot\delta_{l+g+p+1} +\\
&+k_{ab}^{inst}(\Delta t_i^j)\cdot C_{\text{ab 2}}^{\text{inst}}\cdot U_{ab}^{nom}\cdot k_n\cdot\delta_{l+g+p+2} + \dots\\
&+k_{ab}^{inst}(\Delta t_i^j)\cdot C_{\text{ab }f}^{\text{inst}}\cdot U_{ab}^{nom}\cdot k_n\cdot\delta_{l+g+p+f=n} \geq W_H(\Delta t_i^j)
\end{aligned} \tag{23}$$

where

$k_{pv}^{fac}(\Delta t_i^j)$, $k_{wind}^{fac}(\Delta t_i^j)$, $k_{hydro}^{fac}(\Delta t_i^j)$: the capacity factors PV, wind turbines and micro-hydro, respectively, for an interval of time;

$k_{ab}^{fac}(\Delta t_i^j)$: coefficient of AB during the time interval Δt_i^j;

$k_l = 0,93$: the coefficient of losses of energy conversion system;

Δt_i^j: a time interval corresponding to the i-th hour diurnal (i = 1,2 ... 24) j-th month (j = 1,2 ... 12) Δt_i^j h;

$W_{gp}(\Delta t_i^j)$: the amount of electrical energy required for guaranteed power consumers during the interval Δt_i^j W • h:

$$W_{gp}(\Delta t_i^j) = N_{\text{cons}}^{\text{av}}(\Delta t_i^j)/k_n\cdot\Delta t_i^j + N_{\text{on}}^{\text{av}}(\Delta t_i^j)\cdot\Delta t_i^j + N_1^{\text{av}}(\Delta t_i^j)\cdot\Delta t_i^j \tag{24}$$

where

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

$N_{\text{cons}}^{\text{av}}(\Delta t_i^j)$: the average amount of power consumers during the interval Δt_i^j, W (defined by schedule of consumer load);

$N_{\text{on}}^{\text{av}}(\Delta t_i^j)$: average value of the power of their own needs in a time interval Δt_i^j, W;

$N_{\text{l}}^{\text{av}}\ (\Delta t_i^j)$: the average power loss in the system during the interval Δt_i^j, W.

It should be noted that the utilization rate of energy discharge coefficient $k_{ab}^{fac}(\Delta t_i^j)$ corresponds to the $k_{ab}^{fac}(\Delta t_i^j)$ AB and it cannot be larger than the coefficient of the depth of discharge $k_{ab}^{dd.}$ (to take into account equal to 0.6), as in this case, during the hours of AB discharged more than adopted by the depth of discharge.

Total number of constraints from i = 24 and j = 12 is 12 • 24 = 288.

Utilization rates for each time interval determined on the basis of climatic and geographical conditions and the characteristics of the selected areas of the; $N_{\text{wind1}}^{\text{inst}}, N_{\text{w inf 2}}^{\text{inst}}, \ldots N_{\text{wind } g}^{\text{inst}}$; $N_{\text{hydro 1}}^{\text{inst}}, N_{\text{hydro 2}}^{\text{inst}}, \ldots N_{\text{hydro } p}^{\text{inst}}$ equipment used by a mathematical model of the system.

$C_{\text{ab 1}}^{\text{inst}}, C_{\text{ab 2}}^{\text{inst}}, \ldots C_{\text{ab } f}^{\text{CAB}}$: limitations of the capability of the equipment used, the following:

$$\delta_1 + \delta_2 + \ldots + \delta_l \le 1,$$

$$\delta_{l+1} + \delta_{l+2} + \ldots + \delta_{l+g} \le 1,$$

$$\delta_{l+g+1} + \delta_{l+g+2} + \ldots + \delta_{l+g+p} \le 1 \tag{25}$$

$$\delta_{l+g+p+1} + \delta_{l+g+p+2} + \ldots + \delta_{l+g+p+f=n} \le 1.$$

The first line corresponds to the standard size range of the PV, the second - of wind turbines, the third - the micro-hydro, and the fourth - the battery. This is possible quantity of facilities which can be selected from the corresponding range of power alone.

The boundary conditions are not recorded because the possible values of discrete variables are given, and the values of binary variables can only be 0 or 1.

With such a formalization of the optimization problem one cannot guarantee the accuracy of the results, because they do not take into account certain factors.

First, the ratio of depth of discharge (energy) AB depending on the desired energy outputted and determines the discharge capacity of the battery.

Second, inaccurate representation of AB in (23) as an independent energy source to consider introducing additional constraints arising from the fact that AB is a source of energy, the development of which is directly dependent on the production of generating units based on renewable energy. Thus, the average annual production power plants based on renewable energy must exceed the required annual average load factor taking into account the losses of electric energy for compensation. However, it is difficult to estimate accurately the amount of energy to be compensated. Thus, due to the above factors,

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

the solution of the optimization problem by classical methods of linear programming results are not very accurate results, so the composition and parameters APSCS-RES determined by successive iterations.

The proposed method of calculation is to step through the energy balance equations created for the average daily hours for each calendar month of the accounting period (23) with the accumulation of ($-C_{\text{ab}}^{T} \cdot U_{ab}^{nom}$) and generation ($+C_{\text{ab}}^{T} \cdot U_{ab}^{nom}$) energy by AB:

$$\begin{aligned} &k_{pv}^{fac}(\Delta t_i^j) \cdot N_{\text{pv}}^{\text{inst}} \cdot k_l \cdot \Delta t_i^j + k_{wind}^{fac}(\Delta t_i^j) \cdot N_{\text{wind}}^{\text{inst}} \cdot k_l \cdot \Delta t_i^j + \\ &+k_{\Gamma}^{ucn}(\Delta t_i^j) \cdot N_{\Gamma}^{\text{ycT}} \cdot k_l \cdot \Delta t_i^j \pm C_{\text{ab}}^{\text{B}}(\Delta t_i^j) \cdot U_{ab}^{nom} \cdot k_l \geq W_H(\Delta t_i^j) \end{aligned} \tag{26}$$

where

$$+C_{\text{ab}}^{\text{B}}(\Delta t_i^j) \cdot U_{ab}^{nom} = k_{ab}^{disch}(\Delta t_i^j) \cdot C_{\text{ab}}^{\text{ac}}(\Delta t_{i-1}^j) \cdot k_{ab}^{changC}(\Delta t_i^j) \cdot U_{ab}^{nom},$$

$$-C_{\text{ab}}^{\text{B}}(\Delta t_i^j) \cdot U_{ab}^{nom} = k_{ab}^{ch} \cdot C_{ab}^{inst} \cdot U_{ab}^{nom} \cdot \eta_{ab} \tag{27}$$

where $C_{\text{ab}}^{\text{ac}}(\Delta t_{i-1}^j)$: energy accumulated in the previous time by AB, defined in the previous step as:

$$C_{\text{ab}}^{\text{ac}}(\Delta t_{i-1}^j) = \pm C_{\text{ab}}^{\text{B}}(\Delta t_{i-1}^j) + C_{\text{ab}}^{\text{ac}}(\Delta t_{i-2}^j) \tag{28}$$

$k_{ab}^{changC}(\Delta t_i^j)$: coefficient characterizing changes in battery capacity based on the current discharge current is determined by the coefficient of discharge $k_{ab}^{disch}(\Delta t_i^j)$, which in turn is determined based on the required power compensation;

$k_{ab}^{ch}(\Delta t_i^j)$: coefficient characterizing the nominal charging current AB;

η_{ab}: efficiency of the batteries.

Since usually only efficiency of charge-discharge cycle is available it is counted only once during charging.

When checking each step takes into account the total amount of energy that can accumulate over the AB Δt_i^j:

$$\left| \sum_{i,j=1}^{288} \pm C_{\text{ab}}^{\text{B}} \cdot U_{ab}^{nom} \right| \leq C_{\text{ab}}^{\text{inst}} \cdot U_{ab}^{nom} \cdot k_{ab}^{\text{dd}} \tag{29}$$

where k_{ab}^{dd}: the coefficient of the depth of discharge of batteries.

Verification is required for all possible combinations of APSCS-RES with specified standard series equipment is used in it.

The second part of the software system, which determines the usage settings and adjusts the composition and parameters of APSCS-RES, a mathematical model and the modeling process is the means of

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

APSCS-RES under different operating conditions. The model is based on the principle of hierarchy; it is a basic block, in groups (subsystems) are functionally related units within the subsystems of the first level, second level are subsystems, etc.

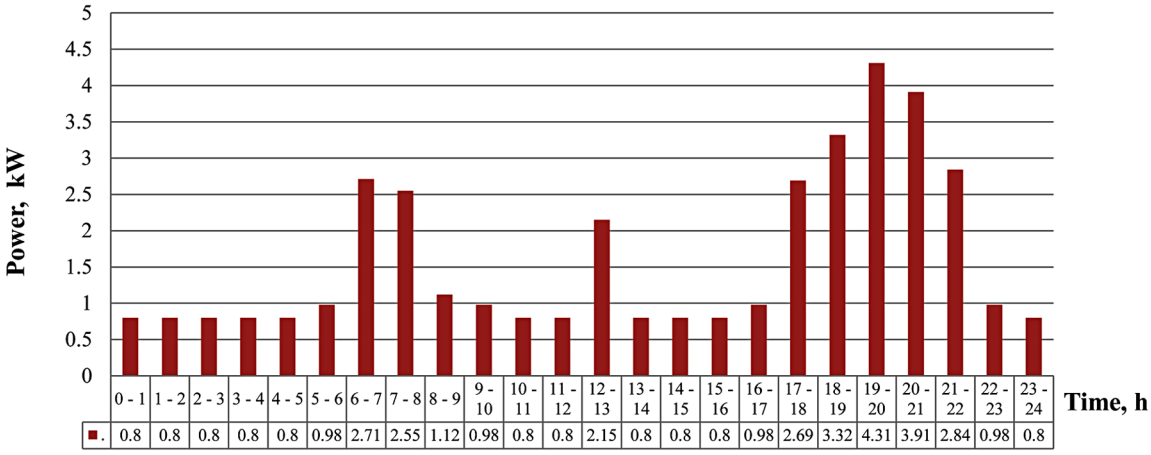
Using the background information that characterizes the real climatic and geographical conditions of operation, the corresponding blocks in the model, the data are generated determining the flow of renewable energy (solar, wind and Small River). Credibility is defined as the quantity of data characterizing renewable resources, and data characterizing the unequal distribution of them in time, given how predictable patterns (day, night), and random factors (cloudy, windless days, hours). The other model blocks directly characterize the functioning process APSCS-renewable energy sources and define the characteristics of the equipment used, and especially the consumer, based on graphs of consumption of electrical energy.

The simulated time of working RES APSCS, due to the frequency of recurrence of renewable energy resources, is equal to one year and is divided into n = 8760 time slots (Δt_i) with a duration of one hour. Detailed description of the mathematical model is presented in paper by Simakin V.V. (Simakin V.V., 2011).

3.3. Calculation Procedure of Concrete Example and Results

The following describes the basic procedures and procedures developed complex.

1. The data relating to the renewable energy equipment and consumer are entered. The energy flows inherent to renewable energy sources are generated and the work APSCS-RES is simulated under these conditions with the help of the mathematical model of the system. Power generating devices are set equal to 1 kW, capacity AB - arbitrary. The simulation determines the values of the capacity factor of power plants APSCS-RES ($k_{pv}^{fac}(\Delta t_i^j)$, $k_{wind}^{fac}(\Delta t_i^j)$, $k_{hydro}^{fac}(\Delta t_i^j)$) and the amount of electrical energy needed to power consumer ($W_H(\Delta t_i^j)$) at different time intervals.
2. The variants of configurations of APSCS-RES are defined to meet the certain conditions of operation, distributed in order of increasing cost, and prefound the optimum composition and parameters of the system.
3. It checks received at the second stage of options APSCS-RES until a configuration satisfying the demand of 100% coverage of the load.



Once the final result is displayed that allows you to get a lot of additional information that characterizes the work of APSCS-RES, as well as a look at the overall picture of the system, evaluate its operation to a new qualitative level.

The effectiveness of the use of combined power from those in the example of renewable energy sources has been evaluated for several case study in the CIS with the help of the developed software system.

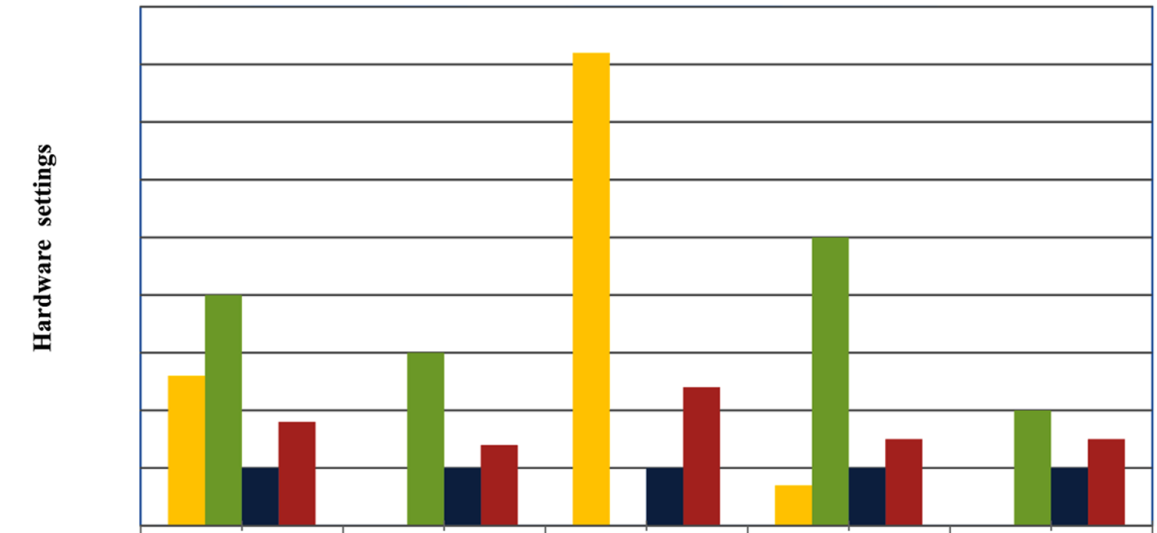
Fife geographic locations were taken for analysis: Sochi, Makhachkala, Bishkek (formerly Frunze, Kyrgyzstan), p. Ust-Kokshov (Altai), p South Kuril (Far East). Four rural houses modern buildings were selected as a consumer to which electricity from APSCS-RES is provided by Practical guidance (Practical guidance, 2008). The area of each house equals 300-360 m^2, daily consumption - 8,15 kW • h. Respectively a graph of the total daily load equal to, 32.6 kW • h is shown at Figure 15. According to the guidelines for the design of power supply agriculture (Guidance, 1981) the load factor was used:

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 15. Daily energy consumption diagram (consumer load)

winter - 1, spring - 0.8; summer - 0.7; autumn - 0.9 in the seasonal distribution. Type of equipment used in APSCS-RES PV consisting of fixed PV modules optimally oriented to the south, vertical-axis wind turbine type, micro-hydro sleeve-type. Two types of AB considered: with lead-acid and lithium-iron-phosphate.

Specific costs of power units generated by renewable-energy installations APSCS were assumed: cpv = 110 rub/W; cwind = 100 rub/W; cwind = 75 rub/W, cAB la = 206 rub/A • h, cAB LiFePh = 280 rub/A • h (UAB = 12 V), which corresponds to the real market values presently. Parameters of power electronics: $k_p = 0,93$ The parameters for lead-acid AB: $k_{ab}^{ch} = 0,2 \times C$, $\eta_{ab} = 0,8$, $k_{ab}^{dd} = 0,6$ for the lithium-iron-phosphate $k_{ab}^{ch} = 0,5 \times C$, $\eta_{ab} = 0,94$, $k_{ab}^{dd} = 0,77$.



Optimization parameters APSCS-RES defined for the five selected geographical locations are shown in Figure 16. Contingent resources of water flow were selected based on the fact that the available head and flow of water can get through micro-hydro power of 1 kW. Because the energy generated by the micro-hydro is the cheapest, its capacity is determined in all cases, the maximum available. However, the energy generated by the micro-hydro is not enough to cover the load of the consumer and requires additional sources, which in the case of the city of Makhachkala and part of the South Kuril were wind turbines, in the case of Bishkek - PV, while in Sochi with. Ust-Kokshov are optimal, given the micro-hydro, and wind turbines, and PV.

The optimal configuration study was carried out while the limiting sources were used on the example of the city Sochi (Figure 17). It is evidently that the combined use of renewable energy allows to reduce the installed power plants. If to look at the total cost of power plants (Figure 17 column 1, 6, 7, 8), the most expensive it will be for electric power through wind turbines and significantly less if use the PV. Combination PV allows reducing costs by a factor of 2.2 compared with only wind turbine and 1.6 as compared with PV. Their combined use with a micro-hydro can have a 2-fold more reduction in the costs of power plants for electric power consumers in the district of Sochi.

If to analyze the total cost of power plants in the five selected points (Figure 18 column 1 - 5) the most cost-effective electricity will be to consumers in Makhachkala and in the South Kuril village. And in the second case, power supply, despite a slightly lower utilization rate of wind turbines, their more

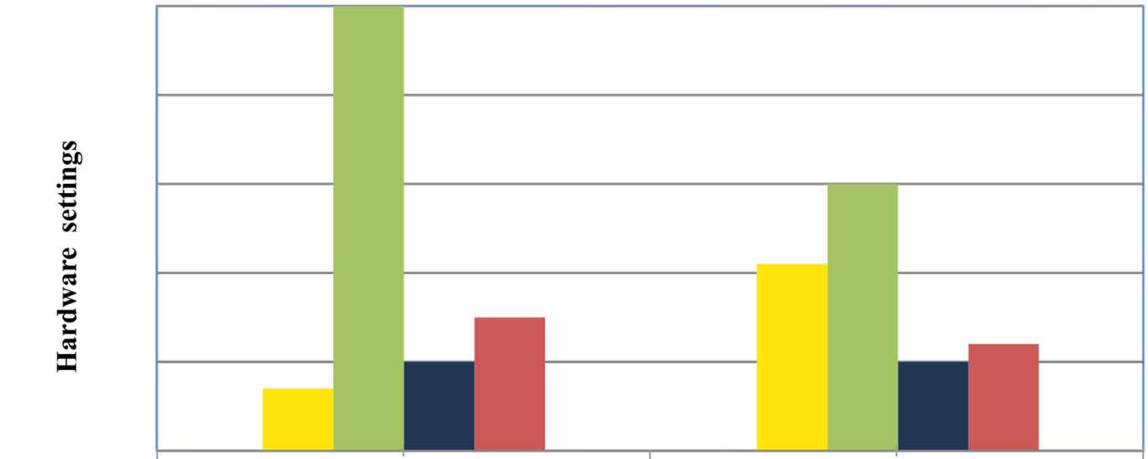
Figure 18. The total cost of power plants based on APSCS-RES under different operating conditions

profitable because of the best time distribution according to production of electrical energy by wind turbines and consumption generated energy.

The effect of seasonal factor of the load on the optimal configuration APSCS-RES was investigated on the example of Ust-Koksha village (Figure 19). For given the seasonal load factors in Ust-Koksha, along with a micro-hydro, the predominance of the wind turbines power is optimal, due to the coincidence of the seasonal increase in the load and generation of wind turbines. In the case where the load is not changing by season and throughout the year is constant, the optimal capacity of wind turbines and PV are comparable.

All results are presented for APSCS-RES using lithium-iron-phosphate AB, as the total cost of renewable energy power plants and AB in this case were 34% less in comparison with the use of more traditional for lead-acid AB. Thus, the superiority of lithium AB is already significantly in the field of power engineering, and without regard to their weight and size.



3.4. Summary

The technique and software package that allows any user to determine the optimal parameters of the combined systems of autonomous power supply using only renewable energy sources such as solar, wind and water. Results of optimization studies, conducted with the help of the program complex showed a significant dependence of the optimal structure and parameters APSCS-RES on many factors, which should certainly be taken into account when designing such systems.

For example, the Sochi shows how, under certain conditions the combined use of power plants based on renewable energy profitable. Combination PV multiplier to reduce costs by a factor of 2.2 compared with only wind turbine and 1.6 times as compared with a photomultiplier. Their combined use with a

micro-hydro can have a 2-fold reduction in the costs of power plants for electric power consumers in the district of Sochi.

So, fluctuating and intermittent renewable energy production should be coordinated with the combination of RES, and also the size of the energy demand must be adjusted to the realistic amount of potential renewable sources. The implementation of 100 percent renewable energy systems is challenging task with the next step to integrate RES into existing energy systems on the large scale.

4. OPTIMIZATION OF GLOBAL-LOCAL MONITORING AND IMPLEMENTING CLIMATE-WEATHER CONDITIONS FOR SOLAR ENERGY

The main objective of this section is to describe activity associated with high technologies of real-time monitoring of the Earth surface and solar energy conversion. Geographic Information Systems (GIS) are currently being used to analyze the potential for producing electricity from renewable energy sources. Making decisions based on meteorological-geographical data is basic to human thinking nowadays. A geographic information system is a technological tool for comprehending geography and making intelligent decisions. Faced with grim predictions of energy supply and consumption, humankind is responding with tremendous efforts to capture and cultivate renewable resources (GIS for Renewable Energy, 2010).

Solar energy systems are becoming more widespread, cheaper and more efficient each year. At the same time, it is not very evident and clear what kind of solar energy system is most suitable for the concrete geographical location and weather-climatic conditions, what output parameters and characteristics concrete solar energy system will perform in real situations.

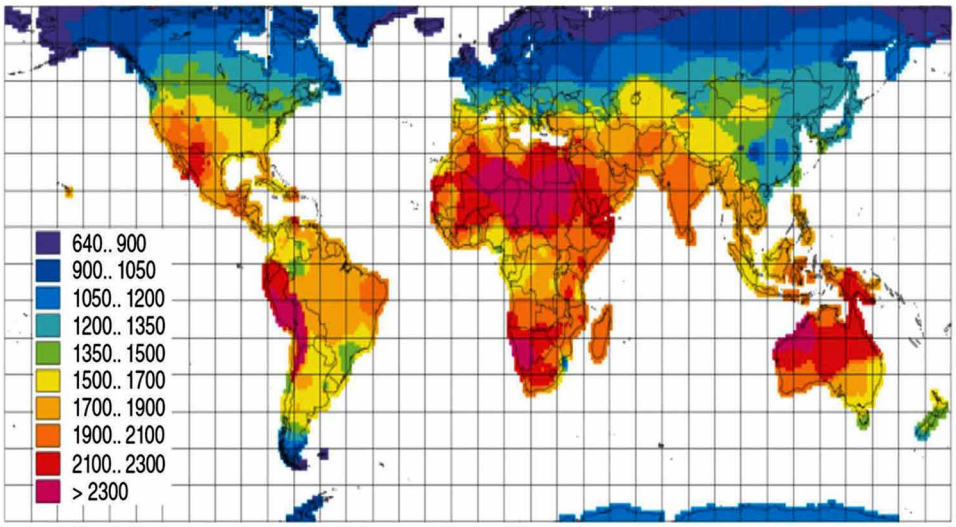
EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

4.1. A Case Study: Global-Local Monitoring of Climate-Weather Conditions for Solar Energy

A concept of global-local monitoring of climate-weather conditions for solar energy was developed firstly in (Tyukhov, 2012). A data acquisition system has designed and implemented with facilities for monitoring meteorological data and solar radiation. The system, using photovoltaic monitoring equipment and hardware–software complex "Kosmos–3M", was developed for taking images of the Earth from National Oceanic and Atmospheric Administration (NOAA) satellites and for handling these images, analyzing many important geographical and meteorological parameters for forecasting of incoming solar radiation. With the help of the proposed monitoring system it is possible to study not only weather but also climatic aspects using solar energy in case of long-term collecting data at least during 10–30 years.

According to Renewables 2013 Global Status Report, renewable energy markets, industries and policy frameworks have evolved rapidly in recent years (Renewables 2013 Global Status Report, 2013). Solar photovoltaic (PV) stands out as having undergone one of the greatest technological developments. It offers the greatest potential for being competitive in the market (Trillo-Montero D., 2014, European Photovoltaic Industry Association (EPIA), 2013). PV market saw strong year, with total global operating capacity reaching the 100 GW in 2012. On the other hand the concentrating solar thermal power (CSP) market continued to advance in 2012, with total global capacity up more than 60% to about 2550 MW. The Middle East and North Africa region saw significant new developments in 2012 as the Egyptian Solar Plan, approved in July 2012, setting a target for 2800 MW of thermal CSP and 700 MW of solar PV by 2027 (Renewables 2013 Global Status Report, 2013). Europe is still the world leader in PV electricity generation, and for the second year running it has been the largest new source of installed generation (European Photovoltaic Industry Association (EPIA), 2013). In markets outside Europe, such as China, Japan or the USA, the percentage of installed power is still very small compared with their enormous potential. Moreover, there are large parts of Africa, Middle East, Southeast Asia or Latin America where this type of installations is only beginning now to be developed (Trillo-Montero D., 2014).

PV applications in developing countries have the potential to become a major force for social and economic development. Many isolated sites are not yet connected to the conventional electrical grid and face severe problems of water for domestic consumption and irrigation purposes (Benghanema M, 1999). Egypt and Russia are situated among the countries, which are better placed for the utilization of solar energy.



Egypt has a high solar radiation intensity—the annual global solar radiation of over 2000 kWh/m^2: areas appear in red or pink (see Figure 20, including Egypt) (Rezk, H, 2013, Dousoky, G.M., 2010). Moreover, Egypt has large areas of low-cost land. It has been estimated that Russia's gross potential for solar energy is 2.3 trillion tce. The regions with the best solar radiation potential are the North Caucasus, the Black Sea and the Caspian Sea areas, and southern parts of Siberia and the Far East. This potential is largely unused, although the possibilities for off-grid solar energy or hybrid applications in remote areas are huge (Strebkov D., 2000, Energy in Russia, 2013). Prediction of the solar radiation coming onto the earth's surface at the given geographical location, depending on the cloudiness, is particularly very important when large solar power plants are used as energy sources for power supply, giving a significant contribution to the power grid system based on conventional sources (Tyukhov, I, 2009, Tyukhov, I., Vignola. F., 2008). Knowing the arrival of solar radiation will allow for planning of system operators of grids. Many factors like cloudiness, atmospheric transmissivity, latitude and orientation of the Earth relative to the Sun, time of day, slope and the surface orientation determine the spatial and

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

temporal distribution of the aspect of solar radiation on a surface. At the same time, the availability of solar radiation data from meteorological stations is more restricted, for example, than for precipitation and temperature. Solar resource assessment is a significant input for a wide range of different solar system applications. Solar radiation assessment is the most important for operational purposes of the big solar plants working in combination with the utilities. The aim of this paper was to design and develop a software application that enables users to perform an automated analysis of data from the monitoring of photovoltaic systems. This application integrates data from all devices which are already in operation such as environmental sensors and meters, and which record information on typical PV installations (Trillo-Montero D., 2014).

Solar radiation and other environmental parameters are needed in the design of solar systems; it is difficult to obtain these data for remote areas (Mukaro, R, 1999). Developing new technologies aimed at solving the world's energy and climate change challenges, and environmental problem demand young people with a good background in solar energy (Tyukhov, I, Schakhramanyan M, 2008). Satellite imagery is widely used to study and solve problems in many industries, including the assessment of natural resources of the Earth, mapping, forestry and agriculture, etc. Currently, analysis and collection of meteorological data mainly benefited from surface, upper-air, radar and satellite observations. Remote sensing by satellites allows quickly covering large areas of capturing Earth images, and provides acceptable accuracy and high visibility materials (Kasyanov, O.V., 2014). Analysis and short-term forecasting of atmospheric processes on successive series of satellite images of the clouds to identify the characteristic features of the evolution of cloud structures and the direction of their movement were considered in (Bespalov, D.P., 2011). Authors (Chubarova N.Y., 2008) measured the arrival of natural ultraviolet radiation under actual cloud conditions and the absence of clouds. Study of theoretical and experimental methods of forecasting and evaluation of solar radiation as a function of cloud resource space monitoring the earth's surface are also studied in (Hammer, A, 1999, Lorenz, E, 2012, Vignola, 2012).

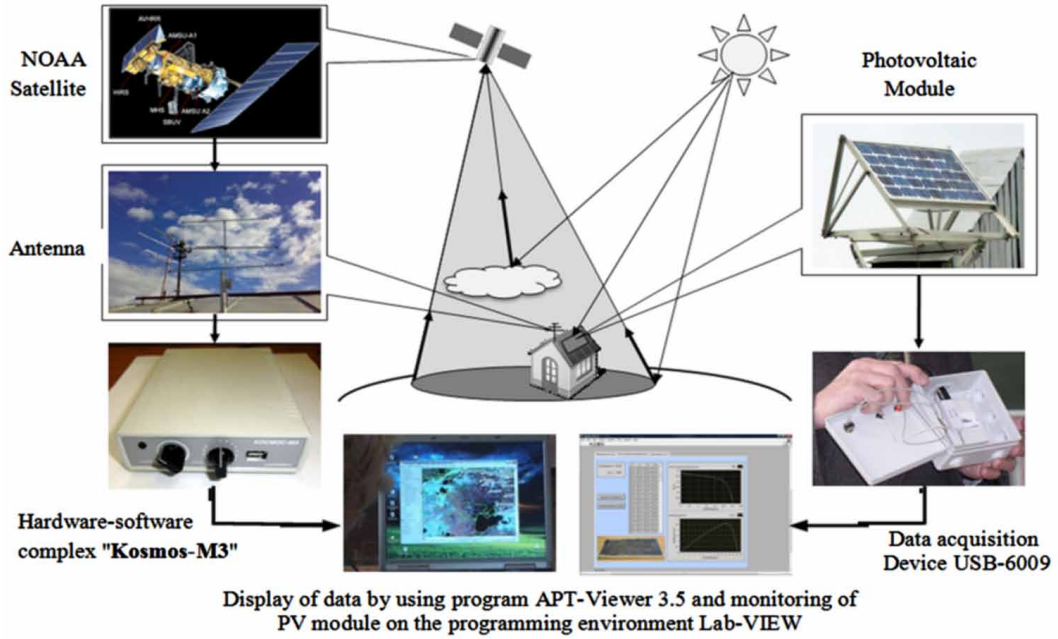
4.2. Components and Principle of Operation of Space Monitoring System

In the current manuscript, a computer-based data-acquisition system for monitoring both meteorological data and photovoltaic solar radiation is discussed. Data-acquisition system allows observing current incoming radiation and observing cloud motion using space technology; with this, one is able to predict cloudy or sunny sky and to make forecast for any solar application.

A block diagram of the proposed system is shown in Figure 21. The collected data are processed, displayed on the monitor and stored in the personal computer using the Lab-VIEW software and program APT Viewer 3.5. Lab-VIEW provides an easy-to-use graphical environment that permits the system operators to process easily the collected data, using complex data-processing algorithms, without detailed knowledge of the data acquisition system design like in (Koutroulis, E, 2003). The system shown in Figure 21 consists of solar photovoltaic module "FSM-25" installed on the roof of a University of Mechanical Engineering, Moscow (Umech), data acquisition device USB-6009 with output on a computer and software, developed in the graphical programming environment Lab-VIEW. The structure of devices and software for receiving and processing satellite images includes hardware-software complex "Kosmos-M3", which includes an antenna mounted on the roof of an Umech university, a receiver and program APT Viewer 3.5.



PV module FSM-25 is made of 35 multi-crystalline silicon solar cells in series and provides 26.7W of nominal maximum power at 1000W/m^2 and 25 °C (standard conditions). The installed PV module in the monitoring system is based on the silicone gel lamination technology. A new encapsulant developed at the All Russian Research Institute for Electrification of Agriculture (VIESH) was used in an attempt to increase the service life time of the module. The main factor determining the operational life of PV modules is the encapsulation material (encapsulant). Encapsulant is a protective material completely enveloping and isolating the photovoltaic cells from moisture, heat and mechanical damage and providing good optical contact between the surface of the PV cells and the protective outer coating. Silicone gel encapsulant allows better stress relaxation during thermal cycling of PV panels, compared to traditional solid EVA encapsulant. Silicone gel laminated PV panel with power reduction about 15% over 50 years service life is possible because of strongly reduced corrosiveness of solar cells in modules by silicone gel. Corrosiveness of solar cells is the main source of failures in EVA laminated PV panel (Poulek, V., 2012).

Typically, fixed (nonadjustable) PV arrays should be tilted toward south by an angle equal to the latitude of the array's location to capture the most year round solar energy. If the PV array is mounted with a tilt angle equal to the site latitude, it is perpendicular to the sun twice a year (on each equinox date) and very close to perpendicular for the weeks before and after the equinox; this makes the array perpendicular to the sun's position in the sky for the greatest number of hours throughout the year (Goswami, D.Y., 2000).

A satellite receiver and software were elaborated for demonstrating how GIS systems can be used, particularly for solar engineering projects. Complex consists of satellite antenna mounted at the roof of Umech, receiver of satellite signal and software of processing aerospace images of the Earth (Figure 21, left part). Software of the receiving complex "Kosmos–M3" is able to determine the temperature of underlying surface at any point of the image obtained; to measure distance from one point to another with regards the Earth's geometry; to determine surface area; selection of map layer and so on, to have real time images within interval 2–4-h interval. With the help of this complex it is possible to study the climatic aspects of solar energy if to collect data at least during 10–30 years.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 21. Schematic diagram of the hardware proposed data acquisition system

In general A hardware/software complex, Kosmos–M3 is designed under the supervision of Prof. M. Schakhramanyan for receiving Earth images transmitted from the National Oceanic and Atmospheric Administration (NOAA) series polar orbiting satellites (NOAA-12, NOAA-14, NOAA-15 and NOAA-17), and the Meteor satellites, in Automatic Picture Transmission (APT) format at a frequency of 137MHz (Tyukhov, I., Vignola. F., 2008). Kosmos–M3 is a portable, relatively inexpensive tool. It was designed to receive and process images of Earth sent by satellites in real time. These systems are quite useful for introducing certain modern technologies. Images can be received without payment of a fee, helping to minimize the expense involved in research cost in this subject matter. Basic capabilities of the multifaceted "Kosmos–3M" system include: receiving signal from NOAA satellites; digital processing of space images with geographical fixing, superposition of maps of cities and coordinate grid; finding of geographical coordinates at any point of space image; finding of temperature of underlying surface at given points; finding of albedo (reflection coefficient) at any point of space image; finding of upper boundary of clouds (cloudiness); forecasting of dangerous weather phenomena; defining wind fields in cyclones; precipitations forecast; measuring distances between given points; measuring surfaces (areas) and forming of electronic library of images of the Earth. Work is underway to use the "Kosmos–3M" cloudiness images to estimate the incident solar radiation values for evaluating terrestrial solar energy performance in real time. Such kind of system would have a wide variety of uses from the classroom to the field (Tyukhov, I, Schakhramanyan, M, Strebkov, D, 2009).

Solar radiation is scattered and absorbed by Earth's atmosphere and is reflected from the Earth's surface and clouds. Reflected light carries information about the properties of the underlying surface area and, particularly, about underlying clouds. This radiation is collected by the satellite receiver system and is transformed into an electrical signal and transmitted to an antenna for further processing (Figure 21 left part). Swath width is about 3000 km, and the spatial resolution of the image 4 km. There are

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

tradeoffs related to data volume and spatial resolution. Our working experience showed that the swath width is quite big to see the whole picture (all cloudy and non-cloudy areas in a region) and quite small spatial resolution to see how clouds move on a specific place with enough accuracy. The higher resolution will complicate saving and analyze big numerical data for climatic investigations during long time of collecting information. Images of good quality with a single satellite can be captured 3–4 times a day. During receiving the image, the trajectory of the satellite in the web portal can be watched as shown in Figure 22 (Real time satellite tracking and prediction, 2012).

Table 4 shows an example of more detailed parameters on the image pixel by pixel. Thus, this system allows for local monitoring of incoming solar radiation and global monitoring of climatic conditions in real time. APT Viewer 3.5 program allows to monitor meteorological phenomena such as the appearance or disappearance of cyclones and anticyclones, wind speed and direction, temperature change of the land and water surfaces, temperature and height of cloud top forecast rainfall, cloud species, etc. as shown in Figure 23 (Shakhramanyan, M.A., 2009).

4.3. Monitoring Weather-Climatic Conditions and Data Processing

Solar radiation was monitored in real time, by measuring electrical energy generated by the photovoltaic solar module. Then this information compares with information received from satellites.

Predicting the incident solar radiation on the earth's surface in cloudy conditions is particularly important when large solar power plants are used as sources for power generating in order to allow for planning of power energy system operation.

PV module short-circuit current is the current when the voltage across the PV module is zero (i.e. when PV module is short circuited). This current is due to the generation and collection of light-generated carriers. For an ideal PV module at most moderate resistive loss mechanisms, the short-circuit current and the photocurrent are identical. Therefore, the short-circuit current is the largest current which may be drawn from the PV module. At normal levels of solar radiation, the short-circuit current can be considered equivalent to photocurrent, i.e. proportional to the solar radiation G (W/m^2). But this may result in some deviation from the experimental result, so a power law having exponent α to account for the non-linear affect that the photocurrent depends on. PV module short-circuit current is not strongly temperature dependent. It tends to increase slightly with the increase of the module temperature.

For the purposes of PV module performance, modeling this variation can be considered negligible. Then, the short-circuit current can be simply calculated by (Zhou, W., 2007):

$$I_{sc} = I_{sc0}\left(\frac{G}{G_0}\right)^{\alpha} \tag{30}$$

where I_{sc0} is the short-circuit current of the PV module under the standard solar radiation G_0; while I_{sc} is the short-circuit current of the PV module under the solar irradiance G; α is the exponent responsible for all the non-linear effects that the photocurrent depends on.

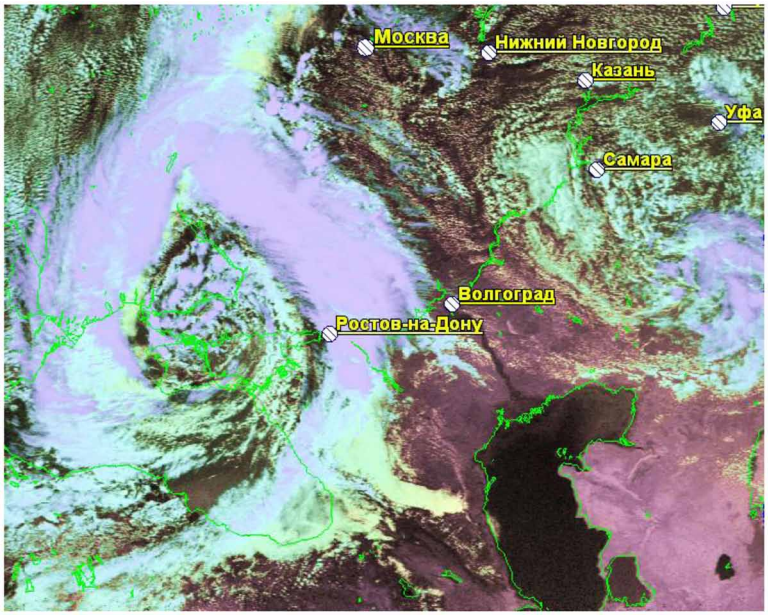
From (1) it can be concluded that the solar radiation can be estimated by the following equation;

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 22. Satellite trajectory observation

$$G = G_0 \left(\frac{I_{sc}}{I_{sc0}} \right)^{\frac{1}{\alpha}} \tag{31}$$

The proposed monitoring system allows us to measure PV short circuit current and solar radiation. The data are transmitted and stored in a computer through data acquisition device USB-6009. The monitoring variables are processed and displayed in the computer screen using virtual instruments developed with Lab-VIEW in the real-time interface system (Forero, N, 2006). Figure 23 shows a computer interface used to display monitoring data of short circuit current and solar radiation. A print screen for monitored solar radiation is shown in Figure 24.



Simultaneously, the space image receiver allows to record information from satellite about weather conditions on the earth surface. Program APT Viewer allows monitoring the actual state of the weather situation, including the state of the atmosphere, the presence or absence of clouds on radio brightness parameters laid down in the program and settlement functions. In addition, it can be used “Cloud Atlas” to study the more properties of cloud cover (Bespalov, D.P., 2011).

4.3.1. Study the Effect of Clouds on Incident Solar Radiation

The recorded solar radiation from monitoring system can be compared to the pixel value of satellite image. This can provide ground true data for testing solar radiation derived from the satellite data (Tyukhov, I, Schakhramanyan, M, Strebkov, D, 2009). Figure 25 shows incident solar radiation and NOAA 15 satellite image taken at 16:46 in clear weather.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 4. The pixels of different underlying surfaces in the picture and their parameters

The image from the satellite NOAA 18						
Pixels from image Meteo parameters						
Underlying surface	Cloud			Water	Earth	
AVHRR-2	16,13%	42,33%	9,93%	0,63%	0,63%	8,50%
AVHRR-4	– 51,14°C	– 20,28°C	– 1,74°C	8,38°C	26,85°C	16,09°C
Cloud top height	10 km	4 km	1 km	–	–	–
Precipitation 90’	9 mm	1 mm	–	–	–	–
The size of hail (clouds)	4 mm	–	–	–	–	–
The size of hail (land)	–	–	–	–	–	–

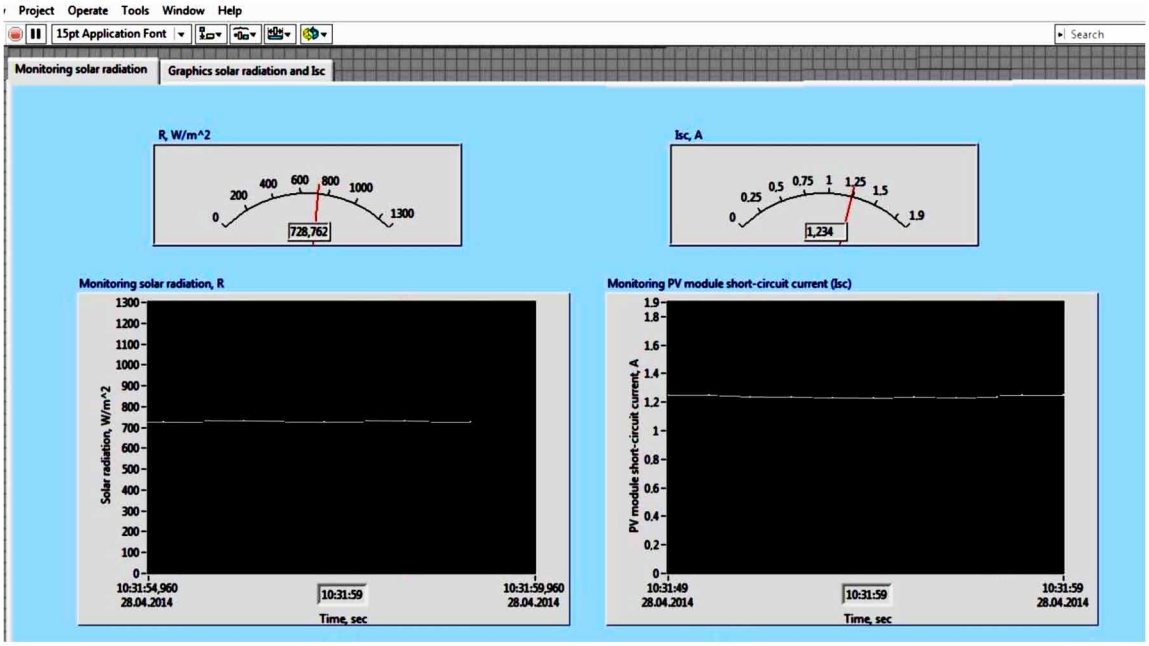
Notes: AVHRR-2 (Advanced Very High Resolution Radiometer): for surface albedo the 2nd spectral channel is used; AVHRR-4 —for surface temperature the 4th spectral channel is used; “precipitation 90” is an indicator of the average total amount of convective precipitation that may fall out in 90 min.

The measurements carried out in one of the sunny days. Due to the fact that in the absence of clouds demonstrable change between multiple images is not significant, there is shown only one satellite image recorded on the afternoon of the same day. From the shown figure it can be clearly seen that, solar radiation curve varies smoothly, reaching its peak at noon. On the other hand it can be seen some fluctuations on the curve, and these fluctuations are caused by various factors: the absorption and the scattering of dust, dry air molecules, a selective absorption of water vapor, carbon dioxide, etc.

Figure 26 shows the experimental measurement of solar radiation at cloudy weather. From the showed figure it can be seen that the values of incident solar radiation decrease with the time. There are also three satellite images at different intervals in time. First half of the day due to the variability of thickness of cloud layers there are sudden changes in availability of solar radiation; it changes from 278

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 23. Computer interface to display the PV module short circuit current and solar radiation



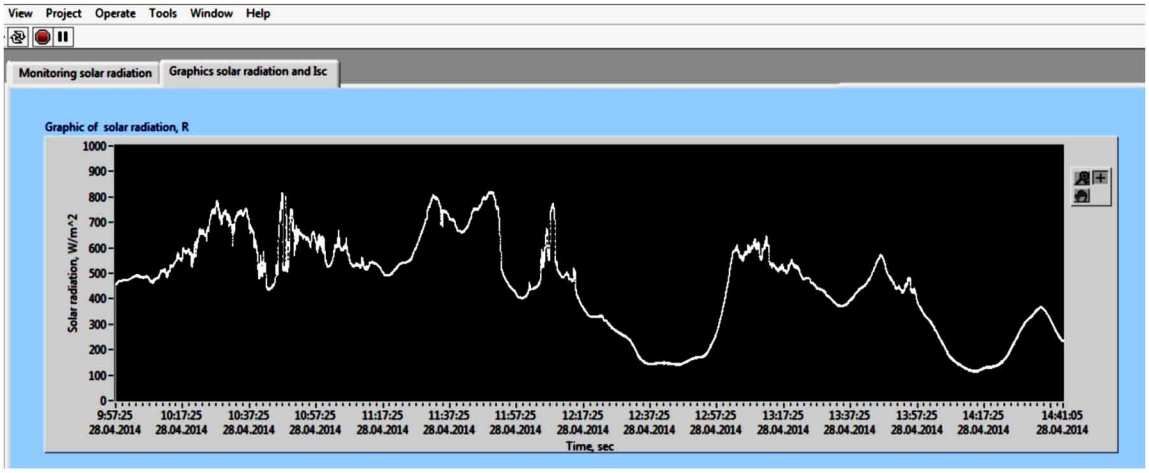


Figure 24. Monitoring solar radiation in specific day

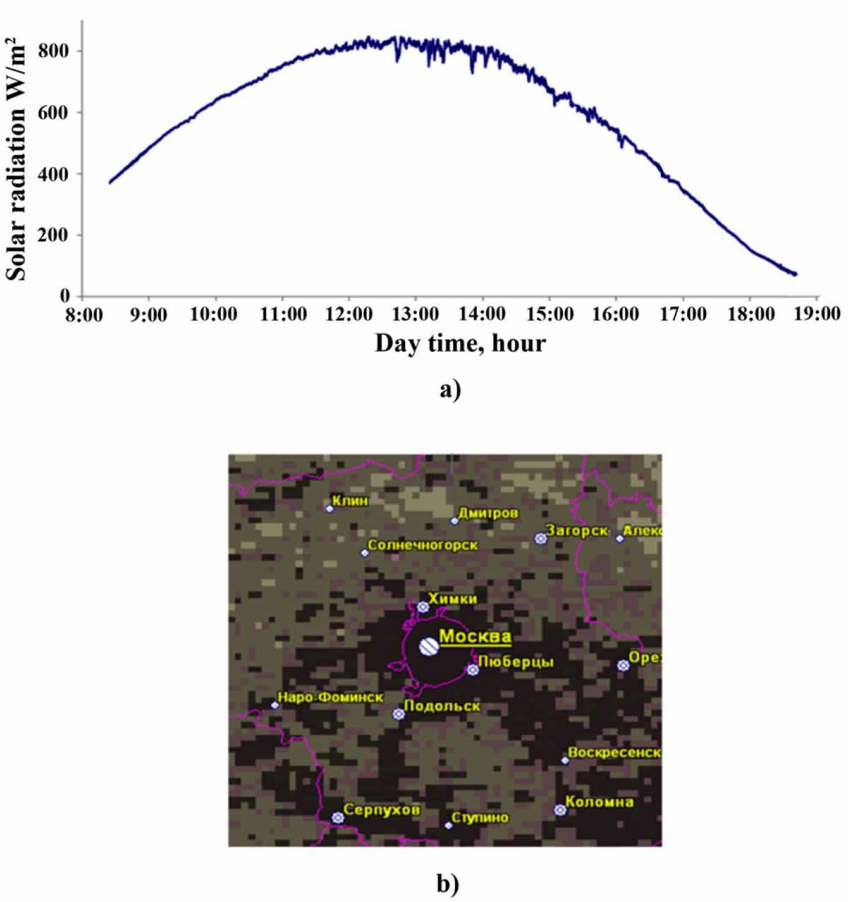


to 784W/m^2. Furthermore due to the appearance of dense layers of cloud, the solar radiation decreased and changed from 114 to 84 W/m^2.

4.3.2. Observing and Forecasting the Movement of Clouds

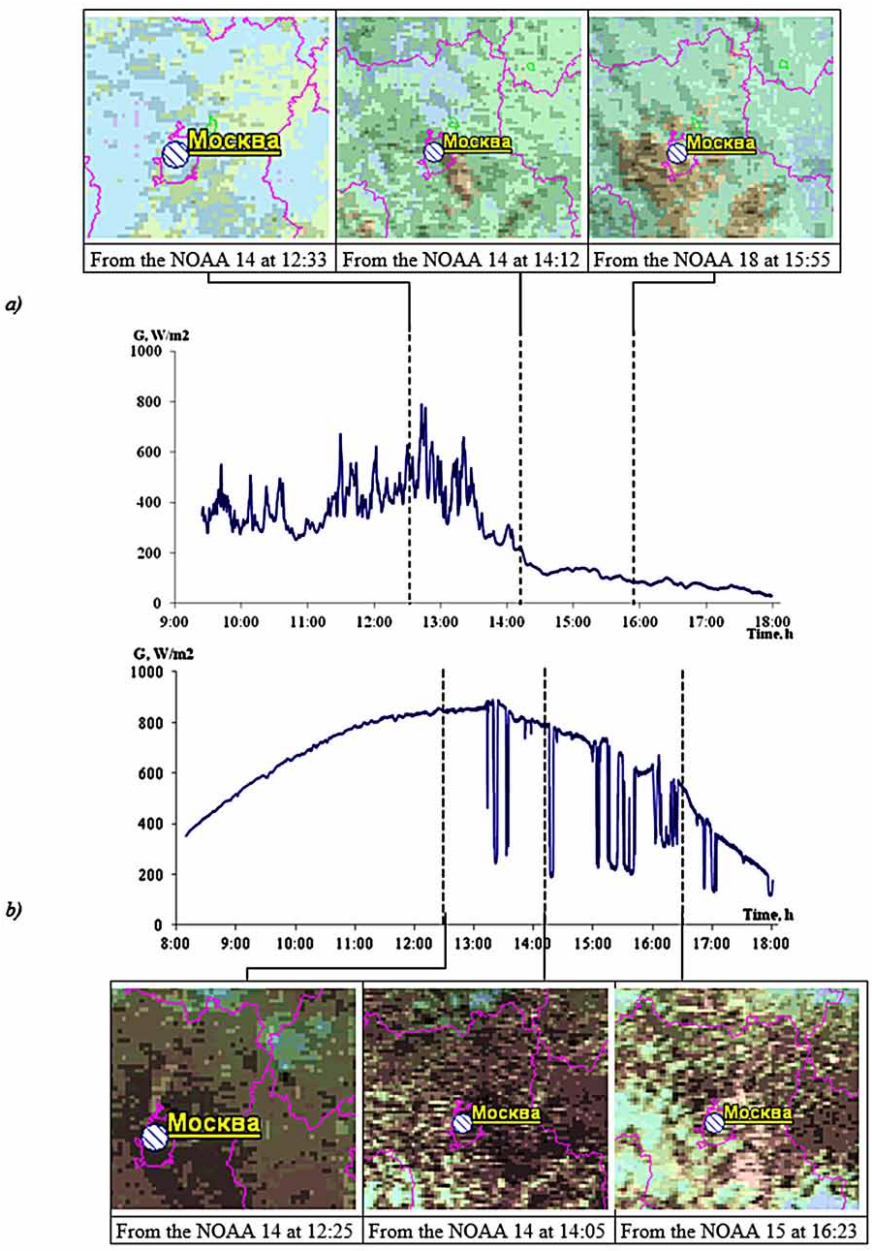
Predicting the incident solar radiation on the earth's surface in cloudy conditions is particularly important when large solar power plants are used as sources for power in order to allow for planning of system

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 25. a) Incident solar radiation and b) NOAA 15 satellite image taken at 16:46 in clear weather in Moscow

operation. Considering Figure 26b it can be seen that, there is a clear cloudless weather until 13:00 at afternoon and then the weather changes to cloudy skies, which clearly illustrate the solar radiation curve advent of periodic dips. The process of cloud formations in the current site and the gradual movement of other clouds from different sides are shown in the following figure.

Figure 27 shows that four satellites images were taken during one specific day from two meteorological satellites at different time intervals and elevation angles of the satellites relative to the horizon.



The results of measurement are shown in Table 5. Considering Figure 27 it can be seen the movement of the clouds, also directed towards the movement of wind, as forecast.

4.3.3. Three-Dimensional Modeling and Visualization of Clouds

Constructing a three-dimensional model of clouds and modeling of incident direct solar radiation in three-dimensional modeling software package allows to analyze not only the actual state, but also to obtain predictive information about cloud cover impact on solar power plants. The prediction and study of cloud cover impact on the incident direct solar radiation are particularly needed for concentrated

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 26. Measured solar radiation and satellite images, taken in: a) clear cloudy overcast and b) variable cloudy weather in Moscow

solar power plants. Satellite images of the earth surface give a visual picture about the state of the cloud in the region under study. However, in case of partial cloud, using only satellite images is not able to determine the cloud cover impact on the incident direct solar radiation on specifically selected area or point on the earth's surface. This is due to the fact that the cloud shading may vary depending on the area, height and thickness of clouds, the location and angle of the sun above the horizon. For further information about cloud shadow modeling the incident solar radiation is needed, taking into account

4	14:05	105	27.4	13.1	

the velocity of cloud movement. Using three-dimensional (3D) modeling with aid Google Sketch Up program is considered the best way for simulating sunlight. Figure 28 shows the transformation steps of the satellite image into three-dimensional model. The height of the cloud layers and the temperature of the underlying surface are shown in Figure 28.

After receiving the necessary data on the size and exact location on the cloud space image, a three dimensional model is developed over the map. After that, by enabling the “Shadows” date and time are configured to accurately simulate the arrival of direct solar radiation and shadow clouds are considered in exactly the specified time. Figure 29 shows the result of converting a satellite image from the cloud space image into a three-dimensional model.

4.4. Summary

An efficient solar monitoring system of meteorological data, photovoltaic solar radiation which enable forecasting sunny and cloudy hours, has been designed and implemented. The new type of PV modules with improved service life time was used because of reduced corrosiveness by using silicone gel laminated. This type of modules is a good candidate for long-term collecting data. By using simple Google Sketch Up program, a three-dimensional model of clouds has been constructed. Also, the height of the cloud layers and the temperature of the underlying surface have been determined for accurate forecasting of sunny or cloudy weather. The described technology and approach is useful not only for research but also for educational purposes because non-expensive components are involved. With the help of the proposed monitoring system, it is possible to study the climatic aspects of solar energy after long-term collecting data for many years. In future PV systems will be aggregating with other renewable systems and GIS systems designed for optimal collecting and distributing electrical power nets according the consumer demand.

CONCLUSION

The history of human civilization should be considered as the progressive development of new energy sources, their associated conversion technologies and info-communicative infrastructure. Solar energy is the best among the most infinitely available clean sources and photovoltaic conversion is the most appropriate direct conversion solar radiation into electricity.

Great progress in the development of solar cells design and technology allows creating practical PV systems. Optimization of PV systems was analyzed from the point of view of maximum power point tracking technologies (MPPT). The comprehensive comparison of different MPPT techniques for photovoltaic systems was carried out.

The optimization of renewable energy systems demands of combination of energy sources, accumulation and consumption. The case study of elaborated technique and software package allows any user to determine the optimal parameters of the combined systems of autonomous power supply using only renewable energy sources such as solar, wind and water. It was shown that fluctuating and intermittent renewable energy production can be coordinated with the combination of RES, and also the size of the energy demand can be adjusted to the realistic amount of potential renewable sources.

Renewable energy systems using information from GIS systems demands optimization of energy systems taking into account all renewable energy currents at real time regime. The case study of solar monitoring system of meteorological data, photovoltaic solar radiation which enable forecasting sunny and cloudy hours, has been designed and implemented.

It is extraordinary difficulty and exceptional nature of the coming energy transition—but, given the enormous challenges of ushering in a post-fossil world, it may also be because of the possibility of an unprecedented and persistent commitment to a rapid change (Smil, V., 2010).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

A general approaching to the challenging task of the implementation of 100 percent renewable energy systems with the next step to integrate RES into existing and future smart energy systems on the large scale were described. A modern concept of smart grid includes a variety of operational and energy measures and systems including smart meters, smart appliances, renewable energy resources, and energy efficiency resources. Electronic power conditioning and control of the production, distribution and consumption infrastructure are important aspects of the smart grid.

Chapter 73
The Application of Crowdfunding to the Energy Sector

Chiara Candelise
Bocconi University, Italy

ABSTRACT

Crowdfunding in energy begins as a response to reduced investments (both governmental and private) into the transition to decarbonized energy systems and to the spread of innovative business models and approaches conductive of greater participation of citizens and communities in distributed renewable energy projects. This chapter presents results of a worldwide overview of the use of crowdfunding in the energy industry. Evidence gathered from available energy crowdfunding platforms highlight a very new, but quite dynamic sector. The crowdfunding tool has been applied in most of its forms, ranging from peer-to-business lending to pure donation, with strong environmental and social mission and the explicit aim of increasing participation of citizens in sustainable energy investment. Evidence also shows that, despite maintaining their environmental and clean energy focus, some energy platforms have begun to move from niche, grass root initiatives into larger projects and collaboration with energy private sector and institutional finance.

INTRODUCTION

This chapter provides an overview and analysis of the development of crowdfunding within the energy industry. It looks into the trends and dynamics of this emerging sector and presents results of a worldwide review of energy crowdfunding platforms. It aims at providing a better understanding of the application of this innovative financing tool to the energy industry and of its performance to date. It intends to provide a reference analysis to policy makers, regulators as well as finance, industry and general public stakeholders about the state of the art of this emerging sector.

ENABLING FACTORS

One of the drivers behind the growth and spread of crowdfunding worldwide has been the reduced access to capital to citizens and firms for new investments due to the financial crisis and restricted access to credit since the second half of the 2000s. Indeed, crowdfunding platforms have begun to spread around the world in 2008, along with other emerging alternative finance instruments outside the traditional banking sector, including mini bonds, social impact bonds, microcredit, impact investing. A similar trend has affected the energy sector, with the financial crisis impacting on investments in energy projects and infrastructures. In particular, both governmental and private investments in sustainable transition have been decreasing (Geels, 2013), despite the growing need for financial resources to support clean energy projects in response to climate change reduction policies and strategies. Thus, as in other sectors, crowdfunding in energy could be seen as an answer to the need to mobilize financial resources, and support the transition toward cleaner energy systems.

Another important enabling driver to the use of crowdfunding in the energy industry is the strong transformation undergoing in the sector since the late 90s. The restructuring and liberalisation of the industry has allowed the entry of new stakeholders in the energy markets. Contextually, climate change mitigation strategies and the need to decarbonize energy systems by increasing the proportion of renewable distributed generation and reducing energy use through the implementation of energy efficiency measures has set the basis for a shift in the energy system paradigm, from a centralized "top-down" system to decentralized generation, a "bottom-up" system. An immediate difference between the two paradigms is the role of the energy end user, who in a decentralized generation system could become both investor and generator. The modularity of renewable energy projects has allowed smaller size investments (than centralized generation plants) and the entrance in the energy market of new generators and investors (including citizens, local authorities, small firms) previously set outside of the industry mainly dominated by large energy companies (Kempener et al., 2015). This trend has been particularly evident for small/medium scale renewables and energy efficiency measures which have generally higher transaction costs (and comparatively low equity return rates) which makes them less appealing for large companies. In addition, large companies often lack for experience with small scale projects and can have split incentives: decentralized generation and energy efficiency can have a negative competitive impact on their core business. These changing scenarios have thus left space for the entrance of new and smaller players in the energy industry.

The transition to clean energy systems is challenging the role of old generators and utilities' business models. In Europe the share of renewables with dispatch priority in electricity markets in increasing which, in conjunction with post crisis reduction in electricity demand and fossil fuel generation overcapacity, has led to a reduction in wholesale prices and in the profitability of utility owned conventional power plants. Utilities are losing money on their electricity generation core business and gradually reducing their role of investors in energy systems.

Such transformation of the energy industry is also seen in the financial market. Utilities and large energy companies were traditionally seen as low risk investments by institutional finance (large investors, pension funds) as they operated in a regulated and stable market. However, the changing paradigm in the energy sector has seen the entrance of new players in the energy finance market and the development of new financing instruments, such as green bonds issued by development banks, corporate investors and municipalities or yieldcos (publically traded companies formed to own power plants and pass revenues to investors as dividends) (Frankfurt School-UNEP & BNEF, 2015). Utilities weight in the finance mar-

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

ket decreasing, top 20 energy utilities were worth in 20013 less than half of 2008 value (of around €1 trillion) and have been the worst-performing sector in the Morgan Stanley index of global share prices (Gray et al., 2015; The Economist, 2013).

Nonetheless, much of the transition to decarbonized energy systems has been led by major investors and large companies, but smaller players as well as citizens and local communities are increasingly playing an active role in delivering clean energy investments. Decentralised energy is now part of governments' and societies' 'localism' agenda, as citizens, communities, firms, local authorities and other public sector organizations can become energy producers and not only 'passive' users of a service delivered. As such, they could fully harness benefits and incomes originating from energy investments implemented in their premises and territory. Indeed, the last decade has seen the increasing development of community energy and shared ownership approaches for investments in the energy sector worldwide (ILO, 2013, van der Schoor and Scholtens, 2015, Yildiz, 2014). These approaches are new business models and structures conductive of greater participation of citizens and communities in energy projects, as such are a form of democratization of energy investments and policy. However, it has been pointed out how such community led scheme are often under-resourced (Seyfang et al., 2014) and lacking of sufficient access to finance to scale up activities (Phimister & Roberts, 2012). Crowdfunding, which aggregate financial resources, people and potential investors on specific energy projects have the potential to expand the applicability and the scope of such type of approaches. It can guarantee additional source of funding, where conventional financing channels do not always deliver, through participatory approaches and enabling the possibility of reaching a higher number of potential investors thanks to the communication power of internet and social networks.

Through crowdfunding platforms, a company, a local authority or a community developing a renewable generation plant or an energy efficiency measure can not only raise capital but also involve citizens and other stakeholders in the investment, allowing them to invest, become shareholders and benefit from the return on the investment itself (according to the type of crowdfunding model adopted - see Section 2.2). Crowdfunding platforms allow people to invest even small amount of money on energy projects and proponents of projects to get access to a large audience of potential investors. It thus provides the possibility to those interested in investing in clean energy, but without suitable conditions (e.g. lack of sufficient capital or of a suitable area to develop the project) to directly contribute to CO_2 emissions reduction and benefit from the returns on the investment. In some cases, also thanks to its communication and public engagement potential, could help in gathering financial resources to support investments less suited for traditional project financing (such as smaller size investments or projects aiming at delivering long-term solutions such as regeneration, social housing or generation in remote areas).

Indeed, crowdfunding is an interesting financing tool for the energy sector and there exist several active platforms worldwide 'vertically' focused on the sector, which are already proving to be a powerful method to raise capital in particular for renewable energy projects.

A WORLDWIDE REVIEW OF THE SECTOR

This section presents results of a worldwide overview and analysis of crowdfunding development within the energy industry to date and of the initial results and trends coming out of this new and dynamic sector.

Energy crowdfunding platforms have been searched for and selected through analysis of online grey literature (McCann, 2013; Renewable Energy Crowdunding Conference, 2014; Solarplaza, 2014a, 2015,

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

2014b) and systematic web browsing running Boolean keyword searches for the terms 'energy', 'renewables', 'crowdfunding', 'community shares, 'equity', 'solar', 'wind', 'biomass', 'energy efficiency', 'shared ownership' . The platforms identified and included in the review have at least one project focused on energy and, if not active yet, express clear focus on the energy sector in their mission.

Such systematic review has allowed identifying forty two energy related platforms worldwide. Through close reading of all published projects on each active platform (i.e. the published material on each project web page) a data base of 389 energy crowdfunding campaigns has been created, accounting for several variables including: project name; location; technology type; opening and closing date of the offer; target and amount of money raised; type of investment offered; returns guaranteed. Data have been gathered up to October 2015.

A New, but Dynamic Sector

The application of crowdfunding to the energy sector has been relatively recent, within the short lifetime of the crowdfunding sector itself which appeared as a wide phenomenon around 2008 when platforms such as Indigogo or Kickstarter (IndieGoGo, n.d.; Kickstarter, n.d.) have been launched. Table 1 lists the forty-two platforms searched for and identified worldwide. Apart from the pioneering experience of the German platform GreenVesting in the 2009, the first relevant platforms and campaigns have begun to appear in 2012 (the non-energy specific platforms such as Milaap and Microgenius despite being launched in 2010 and 2011 have both been publishing energy related projects only in 2015). Since then the number of initiatives and platforms have been increasing overtime. By July 2015 twenty-nine energy crowdfunding platforms were active with projects online and thirteen new platforms were in the pipeline.

Table 1. Platforms overview: country, launch date, and technology focus

Platform	Country	Launch	Platform Focus	Technology Focus
GreenVesting	Germany	2009	Renewables	Solar
Milaap	India	2010	General	Solar
Microgenius	United Kingdom	2011	General	Mix
Lumo	France	2012	Renewables	Mix
Crowdener.gy	Germany	2012	Renewables	Solar
WindCentrale	Netherlands	2012	Renewables	Wind
Greencrowd	Netherlands	2012	Renewables	Mix
Abundance Generation	United Kindom	2012	Renewables	Mix
SunFunder	USA/Tanzania	2012	Renewables	Solar
Bettervest	Germany	2013	Renewables and energy efficiency	Mix (Mostly Energy Efficiency)
Econeers	Germany	2013	Renewables	Mix
GreenXmoney	Germany	2013	Renewables	Mix
We share Solar	Netherlands	2013	Renewables	Solar

Table 1. Continued

Platform	Country	Launch	Platform Focus	Technology Focus
Trillion Fund	United Kingdom	2013	Renewables	Mix
Collective Sun	USA	2013	Renewables	Solar
Divvy	USA	2013	Renewables	Mix
Mosaic	USA	2013	Renewables	Solar
Village Power	USA	2013	Renewables	Mix
Enerfip	France	2014	Renewables	Mix
Lendosphere	France	2014	Renewables	Mix
LeihDeinerUmweltGeld	Germany	2014	Renewables	Mix
Duurzaaminvesteren	Netherlands	2014	Renewables	Mix
Veolis	Switzerland	2014	General	Mix
Solar Schools	United Kingdom	2014	Renewables	Solar
Clean Reach	USA	2014	Renewables	Ocean Energy
Re-Volv	USA	2014	Renewables	Solar
Coopernico	Portugal	2015	Renewables	Mix
GridShare	USA	2015	Renewables	Mix
Citizenergy	Europe	Non active	Renewables	Mix
Joukon Voima	Finland	Non active	Renewables	Mix
Crowd2win	France	Non active	Renewables	Mix
Benoolend	France	Non active	Renewables	Solar for rural electrification
Babyloan/Total	France	Non active	General	Rural electrification
GreenCrowding	Germany	Non active	Renewables	Mix
Ecomill	Italy	Non active	Renewables	Mix
Fundera	Italy	Non active	Renewables	Mix
Trine	Sweden	Non active	Renewables	Solar for rural electrification
Crowdgeneration	United Kingdom	Non active	Renewables	All
EnergyDonwell	United Kingdom	Non active	Renewables	Mix
Palmetto Direct	United Kingdom	Non active	Renewables	Mix
CrowdEnergy	USA	Non active	Renewables	Ocean Energy

Note: 'Launch' is the online launch date of the first energy project on the platform, despite several platforms have been reported to be conceived couple of years before the date of launch of the first campaign. Unique exceptions in the list are Milaap and Microgenius General platforms: platform launch date is reported, but their first energy related campaigns have been launched in 2015.

Europe, in particular Germany, United Kingdom and the Netherlands have been the initiators of the sector in 2012, with USA following in 2013 and currently hosting the highest number of energy related platforms (Table 2).

Crowdfunding in the energy sector is currently associated with and serves only clean energy investments, with most of the platforms specifically focused on renewable energy (the few non-thematic platforms listed in Table 1 have also published renewable energy projects). Platforms generally offer investments

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Number of platforms per country

	USA	Germany	United Kingdom	Netherlands	France	Switzerland	Portugal	Italy	Finland	Sweden	India

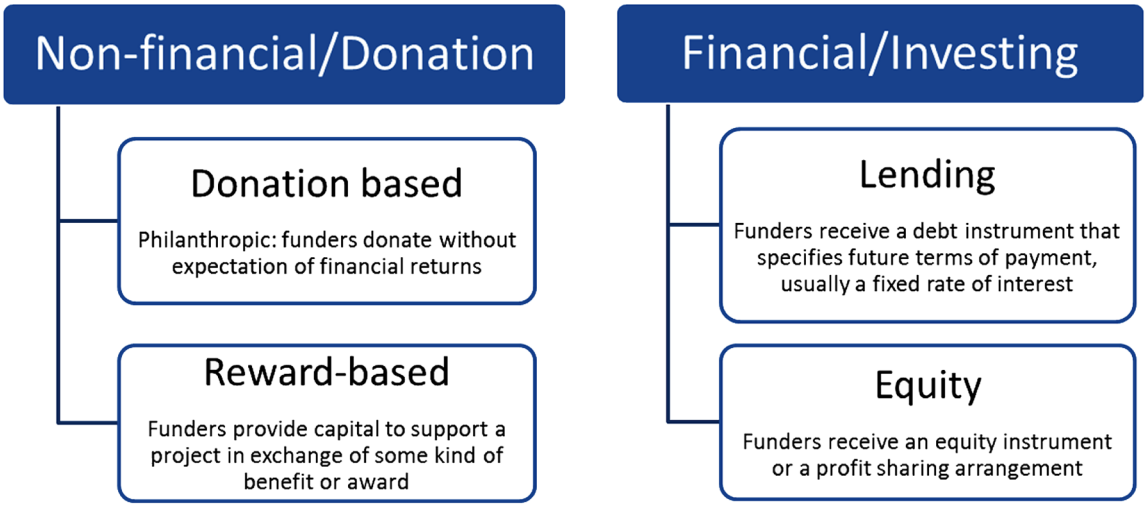
Forthcoming platforms	1	1	3	-	3	-	-	2	1	1	-

in renewables energy projects from a mix of technologies, including solar photovoltaics, wind, biomass, hydropower and, in some cases, in energy technologies startups or energy related technological research and development projects. Investments in energy efficiency projects are much less common, apart from one German platform, Bettervest, which is almost totally concentrated on them. Some platforms are instead focused on a specific renewable technology, usually structuring their project scouting and communication strategy explicitly targeted on the renewable technology chosen. Clear examples are We Share Solar or Windcentrale in the Netherland, Mosaic and Sun Funder in the USA or Solar Schools in the United Kingdom whose respective descriptive slogans are as follows:

- "The Windcentrale enables households to produce their own sustainable energy with their own wind turbine" (Reitsma, 2014);
- "We are a crowdfunding platform for collective solar-energy initiatives", We Share Solar website (WeShareSolar, n.d.);
- "Turn sunshine into savings" or "The simplest home solar loans", Mosaic website (Mosaic, n.d.);
- "Financing solar beyond the grid", Sunfunder website (SunFunder, n.d.);
- "Powered by sunshine, funded by everyone", Solar Schools website (Solar Schools, n.d.).

How Are Different Crowdfunding Models Applied?

The landscape of renewable energy platforms is still fragmented, the concept of crowdfunding in energy is not a commonplace and platforms differ among themselves in particular in terms of the crowdfunding model chosen.



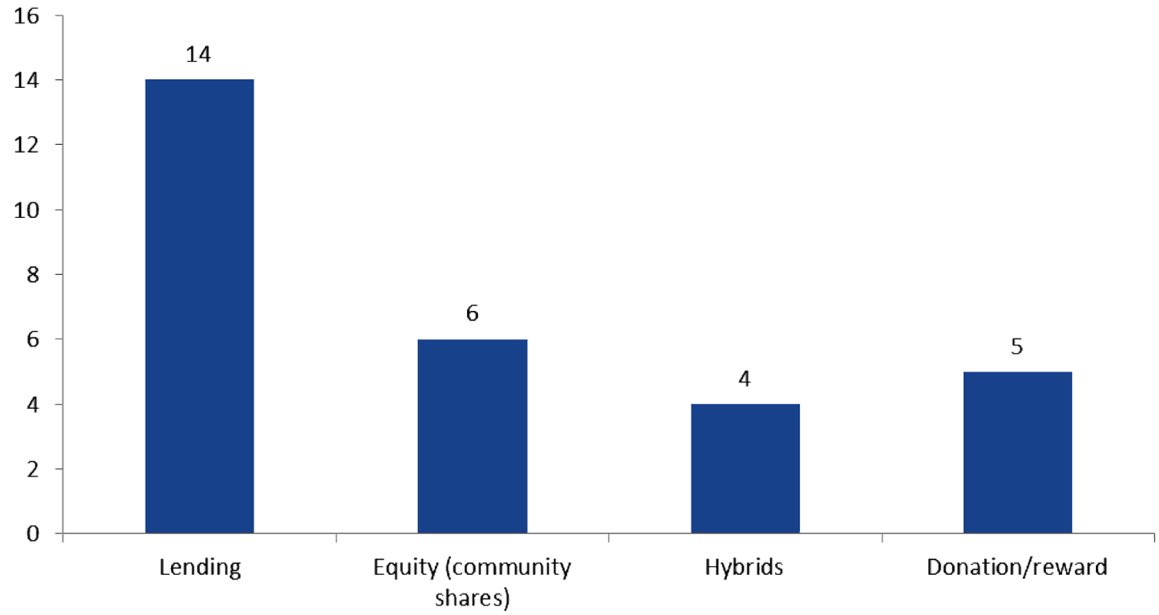
There exists several types of crowdfunding models and several classifications have been produced by previous contributions (EU Commission, 2014; Massolution, 2015; Pais et al., 2014; World Bank, 2013). For the purpose of this review and analysis crowdfunding platforms are grouped in two overarching categories (Figure 1), which differentiate themselves on the basis of the relationship between those who provide financial resources and those that receive the funds (i.e. recipients):

1. Non-financial or donation crowdfunding, where individuals' contributions are not associated with a financial return and;
2. Financial or investing crowdfunding, where financial instruments are sold in relation to companies assets and/or financial performance.

Non-financial crowdfunding can be pure calls for *donations* which are given without expectation of any financial returns or benefit, thus relying on altruistic motives. Typical donation campaigns are

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Overview of major crowdfunding models
Source: Author's elaboration.
Note: Other, less common models are recently gaining traction: 1. Hybrid models, platforms offering one or more crowdfunding models on a single platform; 2. Royalty-based model, where investors receive a royalty interest derived from intellectual property of the fundraising company.



run for charitable or public interest causes. Another form of non-financial crowdfunding is the *reward based* model where individuals provide capital to support a project in exchange for some kind of benefit or award; such award could also be the product that will be produced with the capital collected (typical examples are musicians who raise funds to record an album in exchange of the copy of the album once released). Reward based crowdfunding has also been used extensively by businesses or innovators, often as a tool to assess demand for a new potential product or service by raising on crowdfunding platforms capital for pilot design and production. The main financial crowdfunding models are *lending* and *equity based* crowdfunding. With lending crowdfunding funders receive a debt instrument that specifies future terms of payment, usually a fixed rate of interest. Lending platforms can be peer-to-peer (i.e. lending among individuals) or peer-to-business (i.e. lending to support a business activity). With equity crowdfunding funders receive an equity instrument or a profit sharing arrangement. In this case the returns on the investment are dependent on the company's performance, thus potentially higher than the case of lending, but also accompanied with a higher risk.

In practice there are several variations of these basic models, but it is useful to use such categories to give a picture of how the crowdfunding tool has been applied to date within the energy sector. Over 80% of the active platforms are financial/investing platforms (twenty-four out of twenty 29 – see Table 3) with the remaining 20% dedicated to non-financial/donation models (Figure 2). Of the financial ones a good majority have adopted some sort of declination of the lending model (14 out of 24), some the equity/community share model (6 out of 24) and the remaining have adopted an hybrid model allowing investors to choose among different types of investing options (debt instruments, bonds, company equity or shares in local cooperatives).

But let's have a closer look: Tables 3 and 4 show how the twenty-nine active energy crowdfunding platforms are differentiated across models.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Number of energy crowdfunding platforms per model
Source: Author's elaboration

The *lending platforms* in this context are all 'peer to business' meaning that, according to the definition above, some money is lent through the platform by the investor to support an energy related business or activity. Investments in renewable energy projects (and in few cases in energy efficiency projects) are solicited online by the platform providing the investor with a debt instrument which is then repaid and remunerated over time as a function of the revenues generated by the project. Payments of revenues are often administered by the platform itself which, in this case, acts as a sort of financial intermediary between the project developers and the wider investors (e.g. Abundance Generation, We Share Solar, Mosaic). In some cases, the remuneration is variable as a function of the revenues accruing from the sale of the electricity generated by the renewable project, which vary due to both the fluctuations in the generation itself (e.g. solar, wind are intermittent and variable renewable power) and the variability of electricity selling price. In other cases the remuneration guaranteed is fixed.

All lending platforms' mission and communication strategy emphasize the ethical and environmental dimension of the initiative; a quick browsing of slogans on platforms' websites provides the best evidence for it:

- "Investments that build a better world", Abundance Generation (Adundance Investment, n.d.)
- "Working together for a better future. Crowdfunding for energy efficiency and green technologies", (Econeers, n.d.)
- "Enerfip, la plateforme de financement participatif pour la transition énergétique", Enerfip (n.d.)

However, some platforms have a stronger ethical/social connotation, either in the type of investments they offer or/and in the way they structure investors' involvement and returns. To give some examples:

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 3. Financial active platforms

Financial			
Platform	**Model**	**Investor's Benefit**	**Country**
Abundance Generation	Lending	% of revenue of profit generated by the projects	United Kingdom
DuurzaamInvesteren	Lending	% of revenue of profit generated by the projects	Netherlands
Econeers	Lending	% of revenue of profit generated by the projects	Germany
GreenVesting	Lending	% of revenue of profit generated by the projects	Germany
Lumo	Lending	% of revenue of profit generated by the projects, plus use of the electricity generated	France
Mosaic	Lending	% of revenue of profit generated by the projects	USA
We share Solar	Lending	% of revenue of profit generated by the projects	Netherlands
Lendosphere	Lending	% of revenue of profit generated by the projects (higher % returns for investors living in the project area)	France
Enerfip	Lending	% of revenue of profit generated by the projects	France
Bettervest	Lending	% of revenue of profit generated by the projects	Germany
GreenXmoney	Lending	% of revenue of profit generated by the projects	Germany
LeihDeinerUmweltGeld	Lending	% of revenue of profit generated by the projects	Germany
Collective Sun	Lending (for no profit projects)	% of revenue of profit generated by the projects	USA
SunFunder	Lending (for rural electrification)	% of revenue of profit generated by the projects	USA/Tanzania
Crowdener.gy	Equity (Community Shares)	Financial returns proportional to the share owned	Germany
Gen Community	Equity (Community Shares)	Financial returns proportional to the share owned, plus surplus income reinvested in the community	United Kingdom
Microgenius	Equity (Community Shares)	Financial returns proportional to the share owned	United Kingdom
WindCentrale	Equity (Community Shares)	Financial returns proportional to the share owned, plus use of the electricity generated	Netherlands
Village Power	Equity (Community Shares)	Financial returns proportional to the share owned	USA
Coopernico	Equity (Community Shares)	Financial returns proportional to the share owned	Portugal
Trillion Fund	Hyprid (Lending, Equity, Community Shares)	Returns vary in accordance to the financial tool chosen (bonds, community shares, equity, funds)	United Kingdom
Greencrowd	Hybrid (Lending, Equity)	Returns vary in accordance to the financial tool chosen (loan or quity)	Netherlands
Veolis	Hybrid (Lending, Reward)	Benefits vary: % of the revenue of profit generated by the projects (Lending) or rewards provided (Reward)	Switzerland
GridShare	Hybrid (Lending, Equity, Reward)	Benefits vary: % of the revenue of profit generated by the projects (Lending) or rewards provided (Reward)	USA

- Collective Sun mainly supports solar projects development for non-profit entities, such as schools, churches, community centres and so on;
- SunFunder's mission is to unlock solar energy in emerging and developing countries to improve access to energy and rural electrification;

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 4. Non-financial platforms

Non-Financial			
Platform	**Model**	**Investor's Benefit**	**Country**
Milaap	Lending (for social value projects)	Loan without interests or repayment – high social value project	India
Re-Volv	Donation (plus Revolving Fund)	No monetary returns for investors. The lease payments are reinvested in a revolving fund, the Solar Seed Fund, to further finance community-based solar projects	USA
Clean Reach	Donation	No monetary returns for investors. Money collected are used for testing new technologies and organize thematic events	USA
Solar Schools	Donation	No monetary returns for investors. Money collected are used by a charity to install photovoltaic plants on UK schools	United Kingdom
Divvy	Donation/Reward	No monetary returns. Rewards provided	USA

- Lendosphere offers higher returns to investors living in the area of the project, thus emphasizing the importance of the involvement local community in the project.

The *equity crowdfunding* platforms active in the energy sector generally offer a form of *community shares*, usually for investments in renewables projects: investors give money in exchange of shares of the legal entity making a specific investment (usually a company or a cooperative), as such benefiting from returns on the investment itself through dividend payments and acquiring rights to participate to the legal entity activities (which vary according to the form of the legal entity, e.g. generally higher in the case of cooperatives (SpaceTec Capital Partners, 2014)). In the case of renewable generation and energy efficiency revenues accrue respectively from the sale of the electricity produced and the savings on the electricity bills.

Most of these platforms have a strong focus on community based projects, with a strong geographical characterization and with the explicit aim of increasing and improving the participation of local communities and citizens in the renewable energy investments accruing in their territories. Platforms such as Gen Community, Microgenius, WindCentrale, Village Power and Crowdener.gy explicitly shape their mission as well as scout and structure their projects in order to empower communities by offering them a stake and voting rights in the legal entities (usually cooperatives) making the renewable energy investment. Gen Community's projects also encompass a sort of revolving fund[1] which allow to reinvest surplus income from the project into other activities of community interest. WindCentrale also offers to investors the use of the electricity generated by the wind farms thanks to a partnership with an energy supplier (Reitsma, 2014).

Finally *hybrid platforms* allow investors to choose among different types of investing options: debt instruments, bonds, company equity or shares in local cooperatives. Each of the four hybrid platforms listed have its own peculiarity. Veolis is a lending platform, which has also launched some reward based campaigns to support energy technologies startups or energy related R&D activities. Greencrowd is also structured as a lending platform, mainly raising from online investors loan to finance the construction phase of renewable energy projects; however, it also offers equity instruments to finance initial development costs and/or to fund the equity component of a renewable investment funded through project financing. In this context equity is offered as a higher risk but higher return investment. Grid share of-

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

fers a combination of loan, equity and reward, within the same projects. However, from the evidence presented online it is difficult to gauge whether the platforms is fully operational as very limited money has been raised to date and none of the projects has been funded. Trillion Fund instead looks as a successful case of hybrid platforms (see also Section 2.3). On Trillion Fund investors can browse among several types of investments, including:

- **Lending instruments:** Things such as bonds and funds (issued respectively by renewable energy company or investment funds) and direct loan to renewable energy projects.
- **Community Shares:** Shares in co-operatives or firms serving a community purpose.
- **Equity Investments:** Trillion Fund is the first platform to have launched a pure equity crowdfunding campaign, offering shares to capitalize Triodos Renewables, a renewable energy company developing projects across the UK.

In this case the platform acts as an intermediary, thus being responsible only for the crowdfunding campaign; payments of returns to the investment are then managed autonomously by the proponent of the project i.e. company, cooperative or investment fund.

Five of the active platforms are *non-financial/donation* (Table 4), four of which are strongly socially oriented, providing renewable energy projects to communities and no-profit in their respective countries, and one aiming at raising funds to support technological development in ocean energy (Clean Reach).

How Have Energy Crowdfunding Platforms Performed to Date?

Such high variability of crowdfunding models adopted raises the question of how have the different platforms performed to date. Is there a model more successful than another? What is the success rate of the projects? Is success affected by the returns offered and/or by other factors such as e.g. the ethical/social mission of the projects? Let's begin by looking at the evidence gathered on projects published to date by each active platform (data summarized in Table 5). Platforms performances differ quite substantially, in terms of both number of projects and amount of money raised. This is certainly an indication of how young and fragmented this sector still is. However, it is possible to highlight some initial trends out of the gathered evidence.

When data are aggregated by country, focusing on the most active in the sector (Table 6), United Kingdom stand out as the market leader, in terms of number of projects and money raised (both total amount raised and average project size). This is not surprising, considering United Kingdom leadership in the wider European crowdfunding market (accounting for market share of over 74% (Wadrop et al., 2015)). Netherland follows, with the next highest figures in terms of money raised, then USA and Germany whose numbers fall in a similar range.

Table 7 instead presents data aggregated by crowdfunding model. Lending platforms have been publishing the highest number of projects to date, which could have been expected considering they account for about 60% of the active platforms. However, equity/community shares and hybrids platforms seem to have better performed in terms of money raised (both total amount and average project size). Average returns offered to investors are comparable between lending and hybrid platforms and slightly higher for equity/community shares projects (which is again expected, as usually equity is remunerated at higher rates than debt). Thus, these data seem to show that despite lending platforms are the mostly implemented, they tend to attract smaller size projects and raise lower amount of money overall.

Notes:

1. Success rate is the percentage of the published projects which get successfully funded.

2. Money raised figure is the result of the sum of money raised in each single project published online. The survey thus assume that figures published by platforms for each project are accurate and factual.

3. Money raised figures for Mosaic and WindCentrale are taken from websites and grey literature, as information and data of specific projects is not available online.

4. Trillion Fund figure for money raised presented is conservative as three successful 'Fund' projects are not added to the figure as data not available online.

Table 6. Performance by country

Country	Number of Projects	Money Raised €	Average Raised per Project €	Average Returns by Country	Number of Platforms
France	23	1,691,990	73,565	4.21%	3
Germany	87	11,148,740	128,146	5.53%	6
USA	98	12,406,537	126,597	6.29%	8
Netherlands	49	20,364,614	415,604	5.58%	4
United Kingdom	121	118,234,845	977,147	7.36%	5

Table 7. Performance by crowdfunding model

Model	Number of Projects	Number of Funded Projects	Money Raised €	Average Raised per Project €	Average Returns
Lending	203	153	37,179,291	243,002	5.39%
Equity (community shares)	38	31	22,740,049	733,550	7.00%
Hybrids	66	53	104,325,206	1,968,400	5.34%
Donation/reward	93	58	814,883	14,050	-

Note: 'Number of projects' figure for Hybrid platforms does not include three Trillion Fund successful 'Fund' projects for which data on amount of money raised is not available online.

However, a closer look reveals that the data presented above are strongly affected by the performance of two specific platforms: Trillion Fund in the United Kingdom and WindCentrale in the Netherlands. Indeed, Trillion Fund significantly outperforms to at least an order of magnitude all other energy crowdfunding platforms across the world (Table 5), thus being the main contributor of United Kingdom leadership in the sector. Similarly, WindCentrale is the largest platform in the Netherlands and the second biggest in Europe (Table 8), comparable only to Abundance Generation (second biggest platform in the United Kingdom - Table 5).

Moreover, disaggregating Trillion Fund performance data across their different project types (Table 9) it is quite striking to notice how the majority of the money has been raised through their lending projects, i.e. loans and funds issued by renewable energy company or investment funds. Average returns for such type of investments are also higher than average lending platforms returns (just above 5%).

Moving Trillion Fund lending projects from the hybrid model group to the lending one (Table 10) leads to very different results than above in terms of energy crowdfunding models' performances: lend-

Table 8. WindCentrale performance

WindCentrale	
Money raised €	14,300,000
Number of projects	9
Average return	3-8%
Average raised per project €	1,588,889

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Table 9. Trillion fund performance, by project type

Trillion Fund	Equity	Community Shares	Loan	Fund
Money raised €	4,747,208	6,972,470	34,017,910	56,358,206
Number of projects	1	9	13	3
Average return	9.5	5.29%	7.34%	15.13%
Average raised per project €	4,747,208	774,719	2,616,762	18,786,069

Note: Successful 'Fund' projects are in reality six, but three have not been included as data on amount of money raised is not available online.

Table 10. Performance by crowdfunding model – accounting for Trillion Fund lending projects

Model	Number of Projects	Money Raised €	Average Raised per Project €	Average Returns
Lending (with Trillion Fund's lending projects)	219	127,555,407	768,406	9.29%
Equity (community shares)	38	22,740,049	733,550	7.00%
Hybrids (no Trillion Fund's lending projects)	40	13,949,090	348,727	4.58%
Donation/reward	93	814,883	14,050	-

ing model is not only the more frequently applied by energy crowdfunding platforms, but it's also the best performing. Table 10 clearly shows how lending projects have been the highest in numbers, raised the largest amount of money (over 75% of the total raised to date) and for largest average project size. Returns offered are also the highest, although the 9.29% figure in Table 10 is slightly biased upper ward by the Trillion Fund's average returns to funds of 15.13%, without which average returns would stay around 6% (thus still slightly lower than equity/community shares' returns).

Compared to the financial platforms, donation/reward initiatives have raised much less money, but for a good number of projects overall. They sit in a fairly different category. In this contexts crowdfunding campaigns are smaller in size than in financial platforms as they are generally used to raise funds for rather small renewable energy projects, such as small/medium solar energy plants on schools roofs or solar for rural electrification projects (e.g. in the case of Milaap, the currently open campaigns would finance solar lamps for women empowerment in India and have set targets between a min of 80$ and a maximum of 250$).

The most successful of these platforms, e.g. Milaap (15 projects published in the first month of activity, August 2015) and Solar School (65 published projects, 53 of which successfully funded), offer very homogenous and replicable projects (i.e. solar lamps in the case of Milaap; solar projects on schools roofs mobilizing the interest of parents, local businesses, former students and wider local community in the case of Solar Schools) which allows them to raise money from a high number of similar small projects.

How Does It Compare With the Wider Crowdfunding Sector?

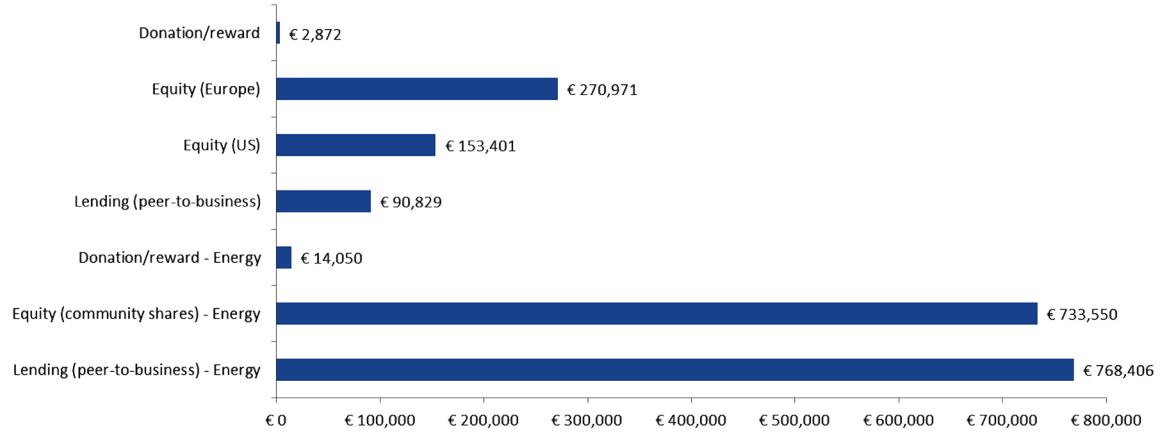
Overall the energy crowdfunding sector has raised about €165millions since 2012, which accounts for only 0,75% of the crowdfunding funding volume cumulated worldwide roughly over the same period of

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

time (i.e. almost €23billions) (Massolution, 2015). However, it is interesting to notice that, despite being a still quite small market, the size of energy crowdfunding campaigns is almost double than the average wider worldwide crowdfunding (Figure 3). And this pattern is consistent across all models.

Moreover, the energy crowdfunding campaigns are also on average more successful. Figure 4 shows much higher success rates[2] for energy crowdfunding projects than wider crowdfunding averages, and across all models. The only exception is lending based campaigns showing the highest success rate

Figure 3. Comparing average crowdfunding campaign size, by model
Source: Author's elaboration, (Massolution, 2015).



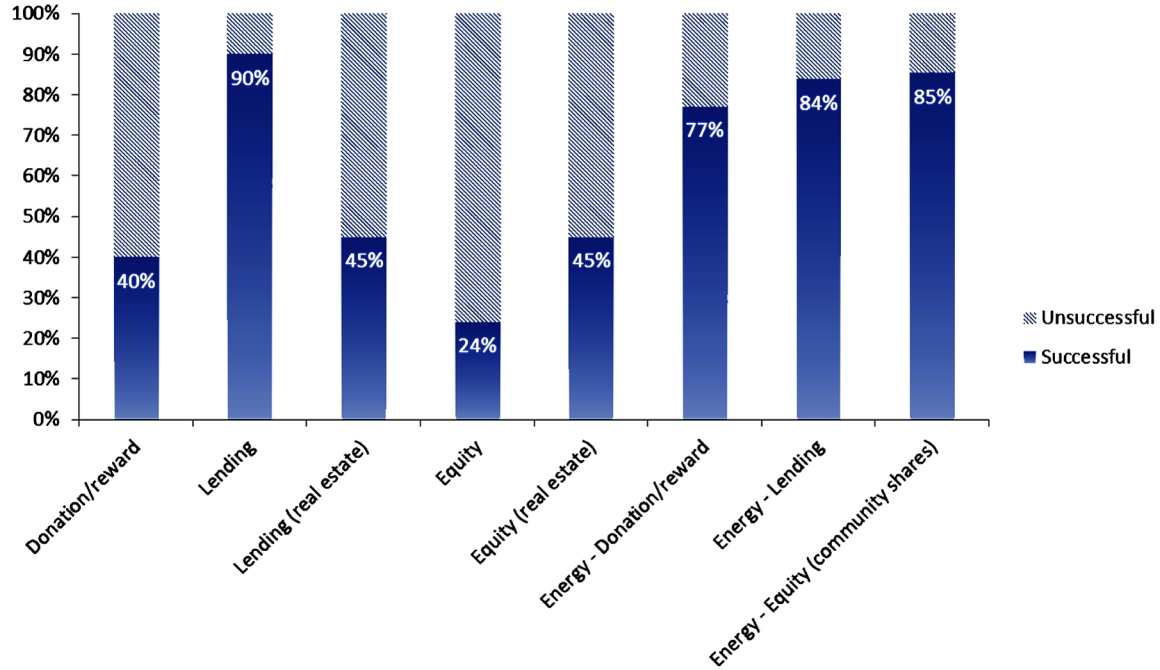


Figure 4. Comparing average success rate, by model
Source: Author's elaboration, (Massolution, 2015).

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

(around 90% and above), mainly due to the popularity of peer-to-peer microloans (which have the highest success rate across all campaigns). However, the peer-to-peer microloan model has not been used in the energy sector to date, thus such figure is not directly comparable with the success rate of lending projects in the energy sector, which are instead peer-to-business. When lending in the real estate market (which is instead peer-to-business) is taken as a more realistic benchmark, energy crowdfunding sector still outperform the average global trend. Similarly, donation/reward and equity/community shares projects are also very successful in the energy sector. Success rate of the latter is particularly striking if compared with wider equity projects success rate (which is expectable due to the fact that they tend to be focused on innovative start-up businesses offering highly risky and volatile returns) and, even more striking, with equity projects in the real estate sector (which is instead characterized by less risky investment with relatively stable and foreseeable returns, such as the energy sector). A discussion of some of the potential drivers of such higher success rate are presented in Section 4.

SHAPING INVESTMENT DECISIONS

The review has highlighted how all energy crowdfunding platforms are characterized by a clear environmental and social mission both in the type of projects they publish and in their wider communication strategy. Some lending platforms have explicit focus on projects in developing countries for rural electrification or renewable projects for not-for-profit, and equity/community shares platforms emphasise the community and local nature of the investments they offer.

Indeed, crowdfunding in energy not only is mainly focused on clean and sustainable energy investments, but, as also previously noted, has also flourished within in a wider process of democratization of the energy sector, which has seen the development of several community energy and energy cooperative initiative across Europe and USA in particular (Kunze & Becker, 2014, ILO, 2013). These new approaches for renewable energy deployment bring forward forms of shared ownership of energy assets with the aim of maximising localization of economic returns and increasing communities' participation. Thus it would seem that the environmental, social/ethical and participatory characteristics of the investment are at least some of the drivers behind the decision to invest from the general public and the communities interested by the energy project (in particular in the case of community shares). However, this is definitely not the only driver. Most of the platforms are financial models, thus offering quite interesting monetary returns on the investments, on average in the 4% to 7% range.

It would be interesting to explore more in details what are the drivers behind investment decisions in energy crowdfunding as well as the investors' profiles. Which type of people and investors tend to approach investments on energy crowdfunding platforms? Are more the social and environmental commitments or the financial returns driving investment decisions? Unfortunately, data on investors profile and behaviour are owned by platforms under strict privacy controls and the sector is relatively young, thus publicly available analysis on this topic is still limited.

However, some initial evidence can be drawn from experience shared by some platforms. An analysis from a leading UK energy crowdfunding platform (Abundance Generation) points out that about 34% of their target investors are the so called 'ethical investors' (those that actively consider the impact of their investment activities, thus motivated by the 'green value' of the investment), but over 50% are 'financial planners' (experienced investors, who plan for their financial futures, thus less motivated by the sustainability cause and more by the returns on the investment and the possibility to choose among additional

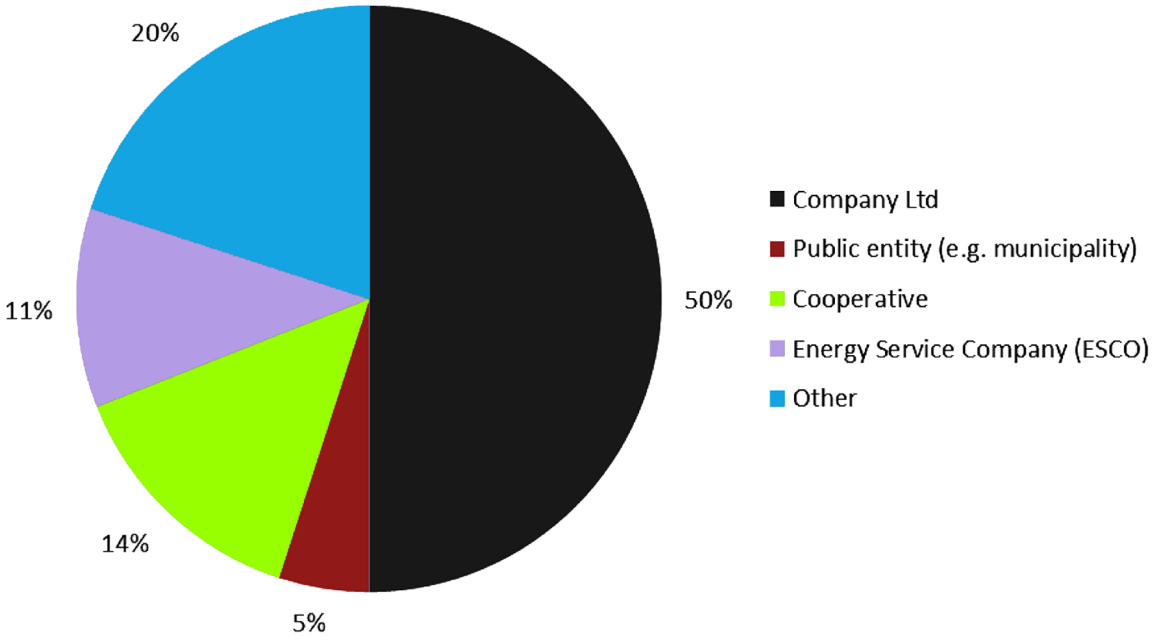
EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

and novel investment options) (Abundance Generation, 2014). This UK experience seems to indicate that returns on the investments play a considerable role in making energy crowdfunding investments attractive. On the other hand, at the recent Energy Crowdfunding Conference (London, 5th November 2015) several platforms' representatives (among those Trine and Lendosphere) have emphasized the importance of communicating social and environmental impacts of investments to acquire investors and guarantee high success rates to their projects (Energy Crowdfunding Conference, 2015). Lendosphere also stated the success of their strategy of offering higher returns to people geographically closer to the project, which has to date allowed them to raise about 50% of the money among local people (Blais, 2015).

TRENDS: LOOKING INTO THE FUTURE

The analysis of the evidence gathered on energy crowdfunding platforms pictures a very new, but quite dynamic sector. The crowdfunding tool has been applied in most of its forms, ranging from peer-to-business lending to pure donation platforms. The strong environmental mission is a common place, with all platforms focusing on clean energy projects and most of them explicitly shaping their project scouting and communication strategy emphasising the ethical dimension of the initiative.

Indeed, the use of crowdfunding in the energy sector has begun as a fairly niche application to grass root and community energy projects, with the explicit aim of increasing participation of citizens in renewable energy investment. First ground-breaking campaigns are those launched by platforms such as WindCentrale (Netherlands), which in 2013 managed to raise €1.3 million in less than 13 hours from 1700 households in the Netherlands to finance a community owned wind turbine (Reitsma, 2014, Bayar, 2013); or Abundance Generation (United Kingdom), which is allowing citizens to invest in solar or wind plants with as little as £5 investment since 2012 (Abundance Generation, 2014). More recently platforms such as Lendhosphere (France), LeihDeinerUmweltGeld (Germany), DuurzaamInvesteren (Netherlands) or Village Power (USA) have managed to successfully raise millions of euros in renewable energy projects with explicit community and local focus.



This local and social connotation is probably one of main elements guaranteeing higher success rate to energy crowdfunding campaigns than worldwide averages, in particular when compared to potentially less locally and socially characterized businesses such as real estate, where the driver to invest is likely to mainly be the financial returns offered. Evidence shows that funding from local population is more easily raised, and potentially lower returns is counterbalanced by the possibility of being involved in the project with some sort of participation or control rights (Yildiz, 2014; Dóci & Vasileiadou, 2015).

Evidence from forthcoming platforms also seems to indicate that the social and ethical advocacy of energy crowdfunding platforms will continue to drive the sector. The 2015 has seen the entry into the energy sector of the Indian micro lending platform Milaap as well as the announcement of several new platforms focused on raising funds for rural electrification projects in developing countries.

However, evidence presented in previous sections also shows how energy crowdfunding platforms, while maintaining their environmental and clean energy focus, have already been moving from niche, grass root initiatives into larger projects and collaboration with energy private sector and institutional finance. Results from a recent European survey among projects proponents (Figure 5) highlight how the majority of projects have been developed by private sector stakeholders, either limited companies or energy service companies (Klaes, 2015). In other words, crowdfunding has been used by energy project developers to finance new investments in the sector, despite with a participatory and shared ownership

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 5. Company structure of projects proponents
Source: Author's elaboration, (Klaes, 2015).

approach. The case of Trillion Fund is a clear indication of this trend: structured finance instruments such as energy loans and funds coming along community shares on the same platforms.

Thus, how is the energy crowdfunding sector likely to develop in the future? What are the potential conditions to scaling up? Are larger companies, institutional investors and finance going to play a role in the future, along with locally sourced and community energy projects?

More generally crowdfunding, despite beginning as a grass root phenomenon, it has quickly scaled up and moved into financing innovation and providing seed capital for innovators and startups, raising money in the billion euros range and being increasingly used by established businesses to finance growth and expansion activities (Lehner, 2013; Mollick, 2014). The energy sector is already showing signs of similar trend: from small/medium locally characterized energy projects to larger projects, from energy cooperatives to private sector led campaigns often launched to support the expansion of renewable energy companies rather than single projects (in particular in the United Kingdom). Trillion Fund performance to date highlights the important role of structured finance and more institutional investors for scaling up the sector: over 50% of the total funding volume of worldwide energy crowdfunding sector (about €165 millions) has been raised only by 16 loan and fund campaigns launched by Trillion Fund in the last couple of years. Whether grass root, community approaches will coexists with more structured finance instruments in the scaling up of the sector is an open question to which we will get an answer only in the years to come.

On the other hand, utilities are in need of developing new business models as a response to the ongoing energy sector transition which is challenging their historical role of market makers and leaders. Could crowdfunding become an interesting tool for utilities or large energy companies?

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Some platforms are already collaborating with energy utilities as for example WindCentrale (which is partnering with the utility Greenchoice in order to offer to investors the use of the electricity generated by the wind turbine they own (Reitsma, 2014)) or Lendosphere (which had developed a project in partnership with Électricité de France (EDF) (Blais, 2015). Moreover, crowdfunding platforms are generally perceived to be a more democratic form of financing (Lehner, 2013), so they could for example become a tool for improving utilities' public image and accountability with final energy end users (i.e. their clients) or to fund (fully or partially) projects in their core business activities through a democratic, empowering and engaging financing tool. Indeed, crowdfunding, beside its primary role (of financing projects) has a strong marketing and communication function, which can favour its use by institutional actors, corporate and large companies in the energy sector for public advocacy and marketing activities. Some examples have already started to appear, as the recently announced partnership between the French oil company Total and the crowdfunding platform Babyloan to develop a crowdfunding platform dedicated to access to energy in developing countries (Total, 2015). As above, only the years to come will tell us whether such type of initiatives will be well received by the general public and will actually successfully become new business models for energy utilities and large energy companies along with other community led and bottom up approaches.

In conclusion, crowdfunding in energy is a novel sector, with large room from innovation, testing and standardization of business models (both for platforms themselves and projects launched on them). It is a highly innovative sector characterized by flexible and dynamic firm structures to keep the pace with fast market developments. Initially developed as a socio-technical practice in a niche, it is already showing signs of scaling up and is turning into a new business model, which can help in fostering and scaling up sustainable solutions in the future (Bocken et al., 2014, Vasileiadou et al.).

Chapter 74
CSR Strategies in Emerging Markets:
Socially Responsible Decision Making Processes and Business Practices for Sustainability

Claudia Ogrean
"Lucian Blaga" University of Sibiu, Romania

Mihaela Herciu
"Lucian Blaga" University of Sibiu, Romania

ABSTRACT

The purpose of the chapter is to emphasize on the roles of businesses – as an effective (sustainable) development agent in emerging markets, on one hand, and of their CSR strategies – as an efficient sustainable development tool, on the other hand, in order to identify valuable business practices able to lead the emerging markets towards sustainability – through socially responsible decision making processes at business level. Having in the fore-ground the ideas of sustainability (which basically is a macro-economic concern) and responsibility (and especially its micro-economic correspondent that usually embraces the form of CSR), it will try to discover the general and specific features of the business models that capitalize the best the synergy between the social responsibility of business and the ensuring of sustainability in emerging markets.

INTRODUCTION

Generally speaking, businesses do not exist per se. They exist and operate in order to fulfill social needs (by delivering goods and services), and this is happening as long as they properly meet these needs. Basically, this kind of (socially responsible) behavior would be necessary and sufficient to ensure the sustainable development in emerging markets. But the reality of business is far from being so simple:

DOI: 10.4018/978-1-5225-3817-2.ch074

shareholder value is still overrated, and the practice of CSR (as concern towards sustainability) is still in the shadow of profits (on the expense of sustainability itself). Ultimately, this kind of a zero-sum game is prejudicial not 'only' for sustainability, but also, on the long run, for businesses themselves – in terms of losing their legitimacy and, eventually, diminishing of their profits (Werther Jr, & Chandler, 2010).

Nevertheless, some encouraging good news have to be considered in order to draw the entire picture of the relationships between businesses and society as they are nowadays: research directions such as stakeholder relations management (Steurer, Langer, Konrad, & Martinuzzi, 2005); theories such as the bottom of the pyramid (Prahalad, 2006) and the business case for CSR (Carroll, & Shabana, 2010); concepts such as shared value (Porter, & Kramer, 2011); or even new business models that have emerged from these concepts and theories (Michelini, & Fiorentino, 2012). All (and each one) of these breakthroughs, if considered, will enable businesses to take the lead on breaking the vicious circle of unsustainability – by reinforcing their relationships with the society while gaining competitive advantage (Porter, & Kramer, 2006).

These shifts are particularly significant and worthy to be considered in the case of emerging markets and their businesses – forasmuch as they do not consider sustainability concerns and practices in terms of additional costs for businesses (which are rather difficult to be found and hardly to be justified in terms of effectiveness and efficiency), but as essential endeavors and tools leading to a never ending virtuous circle of sustainable competitiveness and development for both businesses and the society.

Having this broad approaching perspective in mind when arguing about both the reasons (to exist) and the purposes (to succeed) of businesses, there are some comforting premises which allow and favor an eventually bet on both businesses as an effective sustainable development agent and strategic CSR as an efficient sustainable development tool in emerging markets:

- Needs (in general) have the vocation of being synchronically unlimited and diachronically evolving (as the human kind is developing itself), forcing businesses to accordingly adjust their actions and behaviors in order to successfully survive;
- Each business is (more or less consciously) a network of internal and external networks, which is defined and governed by all the features and principles of complexity, including: co-evolution with the environment, linkages, contagions, self-organization, and the butterfly effect (Ramalingam, et al., 2008);
- The assumption (resulted from the extrapolation of the recent dynamics and trends registered by the emerging markets so far) that *over the next two decades, most of the world's growth is expected to occur in today's emerging markets* (Cavusgil, Ghauri, & Akcal, 2012);
- The real, significant and specific sustainability related problems, challenges and dilemmas that the emerging markets confront and try to deal with (Khanna, & Palepu, 2013);
- The relatively recent, but increasingly powerful concerns regarding the sustainable development, coming from academia, as well as from national and international bodies, and asking for sustaining nature, life support and community while developing people, economy and society (UN, 2013);
- The strong connections between sustainable development – as (national and) global desiderate – and CSR – as business practice that brings together, into a unique and contextually different framework, the economic, legal, ethical and philanthropic responsibilities of business (Johnson, 2012);

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

- The growing pressure towards CSR reporting (of the economic, social and environmental impacts of business), transparency and accountability – coming from a variety of global actors and stakeholders: consumer groups, NGOs, formal and informal supranational structures and so on;
- The efforts, actions and concrete steps that both academia (Urip, 2010) and businesses (Pfitzer, Bockstette, & Stamp, 2013) have made towards integrating CSR into the business core in emerging markets.

All of the aforementioned dynamics and shifts are happening because *we live in a small world, where everything is linked to everything else* (Barabasi, & Frangos, 2002), and each agent is *competing with everyone from everywhere for everything* (Sirkin, Hemerling, & Bhattacharya, 2008). This kind of 'small world' could represent either the biggest opportunity or the highest risk for the emerging markets and their businesses (SMEs and MNEs as well) – which are all looking for sustainable development and competitiveness. On the other hand, it is well known that emerging markets have, all and each one of them, idiosyncratic features and development patterns, which are, in the same time, cause and effect of/for specific problems, dilemmas and constraints, and ask for particular approaches, strategies and solutions at business level (Kearney, 2012).

However, no matter the particular situation of each emerging market and/or business within it, the challenges of sustainable development – within the complex and networked global economy of nowadays – are forcing businesses to reconsider their strategies and business models in order to successfully survive. In this light, a systemic CSR approach could be the best solution businesses can come with. It will enable businesses to reveal themselves as effective (sustainable) development agent, by leveraging their potential through CSR strategies – acting, at their turn, as an efficient sustainable development tool.

Therefore, the chapter will argue the case for CSR strategies as socially responsible decision making processes and business practices for sustainability in emerging markets; accordingly, the chapter discusses the following main objectives:

- To outline the overall context of businesses in emerging markets – defined by the urge for sustainable development, and to place businesses – and their specific needs for CSR-related strategies – within it;
- To argue that the complex and networked global economy of nowadays defines the most appropriate framework for businesses in emerging markets in order to integrate CSR into their core strategy – while emphasizing the need for a co-evolutionary approach;
- To identify the particular challenges and opportunities of CSR and their vocation to determine strengths and/or weaknesses for businesses and their decision making processes in emerging markets;
- To develop a SWOT analysis, followed by possible solutions and strategies (resulted from the analysis of good practices in the field) – able to determine a critical mass of businesses toward integrating CSR into the business core and eventually to give direction to such a generalized behavior.

The new realities, dynamics and trends that characterize the global system in its search for sustainability, on one hand, and the (particular) challenges that emerging markets and their businesses have to confront with, as increasingly significant actors on the ever-changing global arena, on the other hand, highlight the importance of the topic this chapter covers. By taking an integrative and interdisciplinary

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

approach (which is not exhaustive, but comprehensive), the chapter will try to fill a gap in the literature by enlarging the perspective – up to the complex and networked global economy, and the role of businesses in emerging markets, while offering significant insights – on the SWOT analysis, possible solutions and CSR strategies in emerging markets.

BACKGROUND

Since the Bruntland Report (1987) – arguing for development which *meets the needs of the present without compromising the ability of future generations to meet their own needs* (UN, 1987), sustainability has undeniable become a common presence on the global agenda. Although basically everyone (academics, politicians, non-governmental organizations, national states and international bodies) admits that the concept of sustainable development *strongly links environmental and socio-economic issues* (Hopwood, Mellor, & O'Brien, 2005), it is also true that *the expression 'sustainable development' has been used in a variety of ways, depending on whether it is employed in an academic context or that of planning, business or environmental policy* (Redclift, 2005).

But one thing is for sure now: the challenges of sustainability, as global concern towards a desirable 'end' of all humankind endeavors, have transformed all the global actors and each one of them into (consciously or not) global stakeholders, with different (and most often contradictory) needs and expectations, on one hand, pressures and influences towards satisfying these claims, on another hand (Carroll, 2004). In this context, responsibility seems to be the best answer businesses could give to these challenges (Waddock, Bodwell, & Graves, 2002), while local, specific practices are the most suitable 'means' in order to meet them (Oliveira, 2012). This kind of *think globally, and act locally* approach – integrating the concept of responsibility into the practice of business strategy – would be both a contribution to the broad sustainability imperative, and a solution for particular sustainability related issues, emphasizing on the role of responsible business.

However, during the last few decades, the relationships between responsibility and business have raised a lot of questions and controversies about what businesses are responsible for, and to whom, leading academia to different answers and arguments. Thus, Davis (1973) discussed about *the case for and against business assumption of social responsibilities*; Langtry (1994) analyzed *stakeholders and the moral responsibilities of business*; Utting (2000) argued about *business responsibility for sustainable development*; Whetten, Rands, & Godfrey (2002) questioned on *what are the responsibilities of business to society*; and Friedman (2007) argued that *the social responsibility of business is to increase its profits*. In the same time, different theories and (recommendations for) business practices have been developed, in order to achieve the responsible business desideratum: *stakeholder theory* (Donaldson, & Preston, 1995) and *stakeholder management* (Hillman, & Keim, 2001), the *triple bottom line* (Elkington, 1998), *the sustainable/holistic firm* (Knez-Riedl, & Mulej, 2008), the *social business* (Yunus, 2007), or the *ethical and socially responsible management* (Davidson, Wood, & Griffin, 2009), and so on.

Within this framework, corporate social responsibility (CSR) is the most common concept and practice which translate sustainable development at business level – because *CSR refers broadly to actions that business and corporations voluntarily undertake both to promote social and environmental goals and to minimize any potential social and environmental costs associated with their business activities* (Clapp, & Rowlands, 2014, p. 42). The strategic dimension of CSR is increasingly embraced and promoted by

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

academia (Orlitzky, Siegel, & Waldman, 2011) – as it stands for *the incorporation of a holistic CSR perspective within a firm strategic planning and core operations so that the firm is managed in the interests of a broad set of stakeholders to achieve maximum economic and social value over the medium to long term* (Werther Jr, & Chandler, 2010, p. xiii). Accordingly, CSR (related) strategies could be conceptualized as (genuine and/or questionable – in terms of their motives) socially responsible decision making processes and business practices for sustainability.

Therefore, an abundant literature has been developed in the field of CSR, trying: to define the concept and its internal components (Garriga, & Melé, 2004; Dahlsrud, 2008); to argue for and/or against CSR (Campbell, 2007; Argandoña, 2012); to guide the business behavior towards CSR (Carroll, 1991; Young, & Makhija, 2014); to measure the impact CSR has – on the business itself and on different stakeholders (Peloza, & Shang, 2011; Epstein, & Buhovac, 2014); and to predict the future of CSR (Robins, 2005; Lee, 2008).

The abovementioned breakthroughs were both cause and result of/for new developments as regards the relationships between business and society, allowing for new business models to emerge and grow. For instance, Stubbs, & Cocklin (2008) have researched on *conceptualizing a "sustainability business model"*, while Birkin, Polesie, & Lewis (2009) argued for *a new business model for sustainable development*, and Varey, & Storbacka (2011) have sketched a *business model design for sustainable society*. But, unfortunately, they failed to entirely transform the business landscape. Therefore, besides the responsible business, the 'dark side' of the 'irresponsible' business still exists – some call it *corporate social irresponsibility* (Clark, & Grantham, 2012), while others argue about *irresponsible management practices* (Tyagi, & Vasiljeviene, 2013) or emphasize on *grey areas: irresponsible corporations and reputational dynamics* (Jackson et al., 2014) – and asks for more (theoretical) exploration, in order to properly (and practically) address to it, through consistent and articulated responsible strategies at business level.

The picture becomes more complicated when referring to the case of CSR strategies in emerging markets. Although a growing body of relevant and valuable studies has appeared (mainly) in the last decade (Baskin, 2006; Li, et al., 2010; Su, Peng, Tan, & Cheung, 2014), both the literature and the practice in the field of CSR strategies in emerging markets are younger, on one hand, while the solutions seem to be more diversified and less cohesive, on the other hand. This situation is due to a variety of reasons, such as: different approaching angles (authors and/or practitioners coming from different cultural backgrounds, valorizing their own knowledge and expertise and emphasizing on a specific theory when doing that), and different contexts (with specific needs and concerns, regulations, access to resources, perceptions on and behaviors towards CSR). That is why a closer and deeper look, in order to eventually identify both the proximate genus and the specific difference in terms of CSR strategies in emerging markets is more than necessary.

Accordingly, the study will progressively address the following problems and research questions: (1). the changing global (economic) environment – more and more characterized by complexity and interdependencies – which asks for new approaches as concern the relationships between businesses and society, based on co-evolution and symbiosis; (2). the impact that the complex and global economy has on the emerging market economies, and especially on the role of businesses in emerging markets – considering their search for both development and sustainability; (3). a SWOT analysis, followed by possible solutions and CSR related strategies in emerging market economies – in order to identify best practices, able to serve as behavioral guidance.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

The Complex and Networked Global Economy

Both sustainability (as continuous and never-ending desired outcome of all humankind endeavors) and responsibility (as permanent and context-related feature that has to define each agent's behavior) need to be placed and considered, in order to be properly achieved, within the general evolution framework that conditions them. As the process of (economic) globalization – which defined (with its cohorts of goods and bads, pros and cons) the last half of the twentieth century – has offered the fertile ground for the sustainability issue to sprout and become a global concern, the complex and networked global economy of nowadays sets new coordinates – in terms of opportunities and threats as well – for responsibility to occur.

Undoubtedly, *globalization is one of the most used, but also one of the most* mis*used and one of the most* conf*used, words around today* (Dicken, 2007, p. 3). Beyond all the theories and controversies that surround it (Held, & McGrew, 2007; Jones, 2010), and generally speaking, *globalization is a process that encompasses the causes, course, and consequences of transnational and transcultural integration of human and non-human activities* (Al-Rodhan, & Stoudmann, 2006). Very generous in their nature and expression, *the transformative powers of globalization reach deeply into all dimensions of contemporary social life* (Steger, 2013, p. xii): economic, political, cultural and ecological. As defining feature and major dimension of the globalization process, the *economic globalization refers to the increasing interdependence of world economies as a result of the growing scale of cross-border trade of commodities and services, flow of international capital and wide and rapid spread of technologies* (Shangquan, 2000); it also is the fuel which powers the engine of today's complex and networked global economy.

According to Maznevski, Steger, & Amann (2007) there are *four major sources of complexity that interact together to create today's environment: diversity, interdependence, ambiguity* and *flux*. In other words, myriads of different actors (individuals, on one hand, and all types of structures, on the other hand: companies, states, international bodies, interest groups) are playing their roles on the global arena, by continuously interacting with each other while constantly looking for information that is both abundant (generally) and rare (if talking in terms of relevance) in order to successfully survive; and all these premises change permanently – adding more complexity to the environment.

Therefore, *our economy, especially the global economy, is a complex system* (Homer-Dixon, 2011), proving all the properties Homer-Dixon (2011) claims to characterize such an entity: (a). *many components* – considering all the small-to-global companies that operate around the world; (b). *a high degree of connectivity between components* – the even existence of each company depends on a lot of connections with its stakeholders (suppliers, clients, employees, to name just a few of them); (c). *thermodynamically open* – each company evolves as a network of networks with variable architecture, never knowing exactly where it starts and where it ends in terms of its boundaries; (d). *information, matter and energy* – which are continuously flowing and fueling the system, in order to keep it vivid; (e). *nonlinear behavior* – as opposed to mechanical systems, the global economy as a complex system develops 'irrational behaviors', demonstrating that the butterfly effect not only works for meteorology; (f). *emergence* – the existence and evolution of the global economic system is more / different than its parts, developing a trajectory of its own – as 'nonlinear' and/or unpredictable result of all the above-mentioned features.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Both the global environment – placed under the auspices of complexity, which characterizes *the behavior of macroscopic collections of such units that are endowed with the potential to evolve in time* (Coveney, & Highfield, 1995, p. 7) – and the global economy – which can be seen as a *complex network, whose nodes are companies and whose links represent the various economic and financial ties connecting them* (Barabasi, & Frangos, 2002) – are now defined by the presence and behavior of businesses as complex adaptive systems. They *are composed by a diversity of agents that interact with each other, mutually affect each other, and in so doing generate novel, emergent behavior for the system as a whole. The system is constantly adapting to the conditions around it, and over time it evolves* (Lewin, 2000, p. 198). In conclusion, the idea of symbiosis and co-evolution with the environment is crucial for businesses to survive because, *in today's fast-changing business environment, companies will survive only if they are able constantly to adapt and evolve through operating optimally as a complex adaptive system* (Lewin, 2000, p. 198).

The Overall Context and the Role of Businesses in Emerging Markets

In addition to the emphasizing on a new, *evolutionary* (economic) *perspective* (Boschma, & Martin, 2007), the *new economic geography* (Krugman, 2011) of globalization literarily *reshapes economic geography* (Rigg, et al., 2009), if considering the dynamics that the global economy has registered during the last few decades and the current trends it develops. *Today we increasingly recognize that nothing happens in isolation. Most events and phenomena are connected, caused by, and interacting with a huge number of other pieces of a complex universal puzzle* (Barabasi and Frangos, 2002, p. 7); then, *we look forward and see a new era emerging. (…) a different kind of environment, in which business flows in every direction. (…) Western business orthodoxy entwines with eastern business philosophy and creates a whole new mind-set that embraces profit and competition as well as sustainability and collaboration* (Sirkin, Hemerling, & Bhattacharya, 2008, pp. 1-2).

Under these circumstances, and because *sustainable development itself is a global vision* (Schmidheiny, 1992, p. xxi), the global challenges to sustainable development – which *have been driven by a broad set of "megatrends", such as changing demographic profiles, changing economic and social dynamics, advancements in technology and trends towards environmental deterioration* (United Nations, 2013) – ask for unanimous concern and concerted actions, able to integrate its economic, social and environmental dimensions. On the other hand, corporate responsibility – which *fundamentally (…) has to do with corporations fulfilling their obligations to society in ways that reflect a social contract between business and society* (Smith, Bhattacharya, Vogel, & Levine, 2010, p. 6) – *has gone global* (Smith, Bhattacharya, Vogel, & Levine, 2010, p. 1), while being *one of the ways that companies and others have used to navigate the new terrain associated with globalization that is not necessarily good or bad, but simply different from preceding eras* (Blowfield, Murray, 2011, pp. 110-111). Therefore, as the world is neither flat (Friedman, 2003) nor curved (Smick, 2008), but rather complex (Porter, & Derry, 2012), CSR strategies – as socially responsible decision making processes and business practices for sustainability – should be characterized by the same logic (in terms of determinants, features, behaviors and impacts) of complexity.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Within this framework, academia generally acknowledges and proclaims that *the rise of emerging markets – their emergence after more than 200 years of being relatively minor players in the global economy – is causing one of the most significant shifts in the global economic and geopolitical structure since the beginning of the industrial revolution* (Ciravegna, Fitzgerald, & Kundu, 2013, p. 1). Having *firms and states* as *major shapers*, this global shift has led to *a multi-polar, kaleidoscopic global economy* (Dicken, 2003) – defined and dominated by:

- The multiplying of the global centers of power and of their determinants, both diachronically (from states to firms – and especially multinational companies) and synchronically (from 'center' – the old Triad, to 'periphery' – the new emerging markets), within a business environment characterized by multi-polarity (Falk, 2009; Layne, 2012);
- The emergence and development of multinationals from emerging markets (Goldstein, 2009; and the rise of new global giants from emerging markets (Ghemawat, & Hout, 2008);
- New approaches and strategies at firm level (domestic and multinational companies as well, originated and/or hosted in/by emerging markets) – aiming for (global) competitiveness by valorizing the new – internal and external – dynamics and trends (Hoskisson, Eden, Lau, & Wright, 2000; Pillania, 2009).

Although the definition and the content of the term are still subjects to debates – for both researchers (Ciravegna, Fitzgerald, & Kundu, 2013) and international institutions (The World Bank, The International Monetary Fund) – it is generally recognized that the emerging markets possess some *core characteristics* that distinguish them from other countries – *(1). they are dynamic economies; (2). their institutional environments were buffeted in the 1990s by a contagious tidal wave of policy shocks (liberalization, privatization, deregulation); and (3). they suffer from missing or weak market-based institutions, particularly in terms of property rights and legal infrastructure* (Mendoza, & Irmak, 2008, pp. 333-334). By taking a dynamic and evolutionary perspective, Kvint (2010) goes even further, and identifies 45 *major characteristics that all EMCs* (emerging-market countries) *have, had, or will have at some stage during their process of economic maturation and development* (Kvint, 2010, p. 82).

It is also true that the emerging markets category is far from being homogenous, as the literature emphasizes on the fact that they *differ in many manners: size; political, regulatory, and legal regimes; the role of governments; economic reforms and industry structure transformation* (Luo, 2002, pp. 7-8), which leaded to the reality that *the overall improvement in the fundamentals of EMEs masks a great dispersion regarding most of the benchmark indicators (notably GDP growth, inflation, balance of payments, foreign currency reserves and public* finances) (Odonnat, & Rahmouni, 2006).

Given the emerging markets common characteristics, on one hand, and their idiosyncratic features and development paths, on the other hand, academia recommends that *businesses still need to distinguish emerging markets – collectively from developed markets and individually from each other* (Khanna, & Palepu, 2013, p. 3). Therefore, as relatively new – but very vigorous – entrants on the global arena as players that count and decisively contribute to the reshaping of the global economic architecture (Dicken, 2003; Ravenhill, 2014), the emerging market economies are confronted with the transformative realities of nowadays, on one hand, while struggling with particular challenges of their own (common and / or different), on the other hand. As recent studies and reports have revealed, although *after decades of stalled and even regressed convergence, emerging markets* (EMs) *started closing the income gap with*

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

advanced economies in the last decade (Cubeddu, et al., 2014), they also *face growing domestic vulnerabilities along with a heightened sensitivity to global conditions* (International Monetary Fund, 2014).

SWOT ANALYSIS, POSSIBLE SOLUTIONS AND CSR STRATEGIES IN EMERGING MARKETS

The increasing pressures towards sustainability and responsibility – coming from myriads of global stakeholders concerned about the impact of the (rather irresponsible as concern CSR) business models and business practices dominating in emerging markets (Rettab, Brik, & Mellahi, 2009; Reimann, Ehrgott, Kaufmann, & Carter, 2012) – force the companies (both domestic or multinational, originated from or hosted by an emerging market) to take the issue of CSR (and especially the CSR strategies) in emerging markets more and more seriously. Therefore, the (generic) SWOT analysis – undertaken prior to proposing and developing a CSR strategy at firm level – might serve as a valuable instrument able to offer significant insights on the internal and external determinants of CSR strategies in emerging markets, as well as possible guidance regarding effective and efficient behaviors.

Although both the emerging markets and their firms are quite different, some general aspects have to be taken into account when considering (both the idea and the formulation of) a CSR strategy:

- It is based on the internal and external audits of the firm – developed in accordance with: the strategic management approach (David, 2011), a combined strategic management approach with a stakeholder approach (Freeman, 2010) and/or a stakeholder approach of CSR (Jamali, 2008);
- These combined internal and external audits lead to specific lists of:
  - Strengths and weaknesses – coming from within the firm (either domestic or multinational – originated from / or hosted by an emerging market) and determining CSR strategies in emerging markets as socially responsible business practices;
  - Opportunities and threats – raised by the external environment (at global level and at national – emerging market – level) – and determining CSR strategies in emerging markets as business practices for sustainability.

Therefore, performing such a SWOT analysis will imply for each company a unique interpretation of the internal and external forces shaping its riverbed of evolution, and will generate a unique integration – looking for the best suited CSR strategy, able to deliver a symbiosis of the stakeholders needs, expectations and interests while maintaining the company on the competitiveness map – of the following:

- The impact of *globalization on different* (internal and external) *stakeholder groups*: *shareholders; consumers; suppliers and competitors; civil society; government and regulation* (Crane, & Matten, 2010, p. 25);
- The *characteristics of emerging markets and the opportunities they create: markets and culture are demanding; there are high rates of emigration to the developed world; markets are fragmented; populations are youthful and growing; there is limited income and space; infrastructure is weak; technology is underdeveloped; distribution channels are weak; markets are changing rapidly* (Mahajan, & Banga, 2005);

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

- The *business challenges* – emphasizing on *the importance of good corporate governance and CSR* – determined by *globalization: more demanding consumers, competitive differentiation, emergence of NGOs, complexity of market and environment, government policy and regulation, tightening margins, converge and consolidation, the importance of developing human resources, competition in capability* (Urip, 2010, p. 4);
- The new insights that firm related approaches bring to support the (internal and external) environmental assessment:
  - The resource-based view of the firm – looking for the capitalizing of: *resources, dynamic capabilities and knowledge; corporate governance; management buy-outs and venture capital financing; institutional environment; entrepreneurship*, and, particularly, *a uniquely ethical culture* (Barney, Wright, & Ketchen, 2001), in order to reach a *sustained competitive advantage* (Barney, & Clark, 2007);
  - The value-chain analysis – bringing together *key elements* such as *barriers to entry and rent; governance; and systemic efficiency* – within a process *which includes the whole cycle of the organization, production and delivery of products from inception to use and recycling* in a manner consistent with the idea that *it is not so much a matter of whether to participate in global processes, but how to do so in a way which provides sustainable income growth for poor people and for poor countries* (Kaplinsky, 2000);
  - The CSR view of the firm – which, starting from the hypothesis that *a firm's level of CSR will depend on its size, level of diversification, research and development, advertising, government sales, consumer income, labor market conditions, and stage in the industry life cycle*, emphasizes on the idea that *there is an "ideal" level of CSR, which managers can determine via cost-benefit analysis* (McWilliams, & Siegel, 2001).

The solutions that academia brings to the problem of CSR strategies – aiming to transform the company into a sustainable development agent while operating on the basis of CSR as a sustainable development tool – are quite diverse (some of them more realistic, as opposed to quite idealistic others), and may be divided into general and specific (emerging markets based) ones.

Within the first category, the *sustainable business*, based on the concept and practice of the *triple bottom line* (profit, people, and planet) is one of the most known and referred to. As Elkington (2004) argued, *in the simplest terms, the TBL agenda focuses corporations not just on the economic value that they add, but also on the environmental and social value that they add – or destroy*. Considering their different stages *along the evolutionary path to a chrysalis economy*, the author insists on the fact that *the key to developing environmental policies that facilitate the transition to sustainability is to understand that the roles of government need to be different in relation to the four different types of corporation* (Elkington, 2004).

More than that, Porter and Kramer (2011) claim that *companies must take the lead in bringing business and society back together* (…and …) *the solution lies in the principle of shared value, which involves creating economic value in a way that also creates value for society by addressing its needs and challenges*. This would be possible through: *reconceiving products and markets, redefining productivity in the value chain* (in terms of *energy use and logistics*, *resource use, procurement, distribution, employee productivity, location*), *and building supportive industry clusters at the company's locations* (Porter, & Kramer, 2011), and by being aware and valorizing the fact that each one of these actions has a leverage effect on the others, and on the entire company.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Yunus (2007), on the other hand, makes a distinction between two types of businesses – based on the CSR approach they embrace: (a). companies promoting a "*weak CSR*" *credo*: *do not harm to people or the planet (unless that means sacrificing profit)* – category which refers to businesses which *avoid selling defective goods, dumping factory wastes into rivers or landfills, or bribing government officials*; (b). companies promoting a *"strong CSR" credo*: *do good for people and the planet (as long as you can do so without sacrificing profit)* – category which refers to businesses which *may work to develop green products and practices, provide educational opportunities and health plans for their employees, and support initiatives to bring transparency and fairness to government regulation of business* (Yunus, 2007, pp. 15-16). But, rather pessimistic about the transformative power of CSR on the entire business landscape, he comes with the solution of *social business* – which is developed *to pursue specific social goals,* as opposed to the *profit-maximizing businesses* (Yunus, 2007).

Taking a broader view, Young (2003) advocates for *reconciling private interest with the public good* – based on the fact that *the enterprise is not self-contained and self-sufficient but, rather, is importantly dependent on inputs controlled by others. It must please others in order to prosper. That service is a moral activity, subordinating self to what is beyond the self* (Young, 2003, p. 3). Therefore, the solution he comes with is the *moral capitalism*, considered to be *the most appropriate means by which our modern, global human civilization can empower people and enrich their lives materially and spiritually* (Young, 2003, p. 1).

When specifically addressing the case of CSR in emerging markets, academia generally insists on: (a). aspects such as *context and consequences dependency* (Halme, Roome, & Dobers, 2009) – arguing that *CSR should be seen as a local, not a universal, concept. The historical and national context of communities, especially their corporate and societal governance frameworks and business-society relations, impact on how CSR may be practiced in these areas.* (Zhang, 2008); (b). the main particular concern such an endeavor should pursue – considering that *a real contribution to the society will happen only when this is enabled to have its own sustainable development. The empowerment of people through providing them the capability of developing their own instruments of income should be the ultimate objective of a responsible corporate* (Pelle, 2007, p. 172).

Regarding the particular case of those positioned at *the bottom of the pyramid* – category that encompasses more than four billion people living on less than two American dollars per day (Prahalad, 2006) – theory insists on a perspective shift, leading to a symbiotic development. Thus, *if we stop thinking of the poor as victims or as a burden and start recognizing them as resilient and creative entrepreneurs and value-conscious consumers, a whole new world of opportunity will open up*, based on *an approach that involves partnering with them to innovate and achieve sustainable win-win scenarios where the poor are actively engaged and, at the same time, the companies providing products and services to them are profitable* (Prahalad, 2006, pp. 1-3).

Given this discussion framework, the CSR strategies that companies embrace in emerging markets are, at theirs turn, quite different. However, some general *aspects related to the formulation of corporate social strategy* could be mentioned: *(a). market opportunities; (b) resources; (c) corporate values; (d) structure of industry; (e) stakeholders; (f) CSR alignment to core business; and (g) the social impact of corporation competitiveness* (Sousa Filho, Wanderley, Gómez, & Farache, 2010); in the same time, some particular business models integrating CSR strategies could be noticed in the case of both multinationals – hosted by / or originated in an emerging market – and local companies.

Thus, as concerns the MNEs hosted by emerging markets and their CSR strategy, studies generally revealed that:

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

- *Global MNEs face a clear choice. They can (…) manage local and global CSR issues on a case-by-case analysis of the pressures for integration and responsiveness surrounding each issue: in short, they can become 'transnational' in their CSR strategy. Alternatively, they can ignore local subtleties and nuances in their CSR agenda, with the attendant risks* (Husted, & Allen, 2006);
- More attention should be paid to the *politics, corruption, and corporate social responsibility lenses on the multinational enterprise* and *the potential linkages across* them – because MNEs *operate in multiple countries and institutional environments throughout the world. As local residents, they must respond to local rules and institutions, adapt to diverse socio-economic conditions, and respond to multiple stakeholders* (Rodriguez, Siegel, Hillman, & Eden, 2006);
- *A comprehensive CSR strategic framework must include key components for MNEs (…): (1). to define a CSR mission reflecting corporate values and objectives; (2). to assess existing programs, codes of conducts, guidelines, standards (…) and reflect how they can be included into policy and decision-making; (3). to develop a CSR strategy based on the above; (4). to gather a team of international leaders, reflecting the diversity of the organization in charge of implementing and monitoring the process; (5). to get feedback from employees, governmental and non-governmental institutions about the positive impacts and/or limitations of implemented policies; (6). to review compliance mechanisms and performance requirements.* (Lévy, 2007).

On the other hand, as regards the MNEs originated in emerging markets, they develop particular business models and CSR strategy – by specifically addressing the opportunities and challenges they face in their home countries, while leveraging their idiosyncratic strengths. Regardless of their country of origin, the development paths they pursue, and/or the generic umbrella that covers them – *southern multinationals* (Battat, & Aykut, 2005), *emerging economies' multinationals (*Salehizadeh, 2007), *global latinas* (Casanova, 2009), *global players from India* (Taylor, & Nölke, 2010), *non-triad multinationals* (Nölke, & Taylor, 2010), *Chinese multinationals* (Hobdari, Sinani, Papanastassiou, & Pearce, 2010), *emerging Russian multinational companies* (Filippov, 2012) and so on – the emerging market multinationals are not only sensitive to CSR concerns, but they sometimes take over leadership regarding CSR development within their countries of origin (Torres-Baumgarten, & Yucetepe, 2009).

As Deutsche Gesellschaft für Internationale Zusammenarbeit (2011) argues:

these companies do more than just provide good jobs to many thousands of people in emerging and developing economies. They also: (a). nurture a professional class that commands higher wages and can spur further development in the public, cultural and educational arenas; (b). provide business opportunities for the vendors, small businesses and entrepreneurs from which they source; (c). create innovations that boost productivity and drive sustainable national economic growth; (d). bring profits home and contribute to the tax base so that governments can sponsor development across the socioeconomic spectrum.

More than that, the emerging market multinationals have the vocation of spreading their beneficial influence beyond economic development, towards human development, through:

(a). discovering and serving new markets, potentially growing revenue and profits – and at the same time address unsatisfied needs; (b). creating disruptive innovations in products, processes and business models that are well received not only in their home countries, but also in host markets; (c). improving the business environment so they can operate more effectively – and at the same time addressing de-

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

velopment goals such as building infrastructure, combating disease, and educating local populations; (d). engaging in a policy dialogue, and at the same time bolstering their reputation with civic leaders nationally and globally; (e). building their brands in the minds of consumers concerned about social responsibility. (GIZ, 2011)

The analysis of the CSR strategies in the case of domestic (emerging market) companies also indicates practices which respond, through particular actions, to local contexts and expectations, by reconciling businesses and society. But, as the emerging markets are quite different between them, so are their approaches towards CSR – in terms of motivators, actions/behaviors, impacts and reporting/communicating (Vives, 2006; Rivera, 2010; Katamba, Katamba, Zipfel, Haag, & Tushabomwe-Kazooba, 2012; Chahal, Mishra, Raina, & Soni, 2014).

SOLUTIONS AND RECOMMENDATIONS

Due to a variety of reasons – such as solely pursuit of (quick) profits and a myopic interpretation of the CSR paradigm (exclusively in terms of additional costs for business) – and against the background of no serious scrutiny (which favored the lack of businesses' accountability and transparency) – CSR strategies have been rather a peripheral concern for businesses in emerging markets until recently. But, under the auspices that define the new dynamics of both the global (economic) system and the understandings of the CSR paradigm, a series of quite influential determinants – coming from academia, regulatory bodies and different (formal/informal, as well as national/international) pressure groups – has brought the issue into the spotlight of the businesses' core strategy.

Thus, a growing body of (increasingly refined) proofs and evidences has emerged in order to build the case for CSR strategies in emerging markets, emphasizing on both business and country-related effects and positive impacts. So, the arguments on favor of *how corporate social responsibility pays off* in terms of *strategic benefits* for companies (Burke, & Logsdon, 1996), were complimented by those referring to how CSR is *supporting the business case* in terms of *the long-run benefits for companies* – through: *cost savings, enhanced staff loyalty, improved government relations, innovation and learning, enhanced reputation, consumer response* (Luetkenhorst, 2004); and all of the above-mentioned arguments were circumscribed by those related to how *collective corporate social responsibility (CSR) activities amongst various corporations and its stakeholders could contribute to the microeconomic development of a developing country through sustainable benefit to all* (Urip, 2010, p. xiii).

Consequently, despite the fact that, *unfortunately, the majority of companies still see such concepts as sustainability and social responsibility as pursuits that only the rich can afford* (Handy, 2002), the reality reveals that *today, a growing number of creative new business models (..) demonstrate that social and environmental purposes do not have to be sacrificed for profits, and that profits do not have to be sacrificed for social and environmental purposes. Rather than conflicting, the two purposes can mutually reinforce each other. Even better, these innovative, purpose-driven business models can become a source of competitive advantage* (Osterwalder, & Pigneur, 2011). This kind of 'open minded' search for (sustainable) competitive advantage – that only a strategic approach of CSR can provide – would be able to break the vicious circle of unsustainability that surrounds the emerging markets and their businesses, by unleashing the latent potential of contingent creativity and capitalizing on it, for the mutual benefit of all the stakeholders.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

The concept of *strategic corporate social responsibility* should be transposed into business models which reveal a *business strategy that is integrated with core business objectives and core competencies to create business value and positive social/environmental value, and is embedded in day-to-day business culture and operations* (McElhaney, 2007). This kind of simultaneously short and long-term perspective, which equally encompasses daily routines and overall goals, while contributing to the sustainability of both the emerging markets and their businesses, can only be achieved if (long-term) socially responsible decision making processes are operationalized through (short-term) business practices for sustainability.

In this way, strategic corporate social responsibility could serve *as a tool for managing the current situation and helping firms overcome the consequences of the crisis* that was partially caused by *the lack of CSR* itself (Fernández-Feijóo Souto, 2009); more than that, it could help moving businesses forward, towards: (1). higher competitiveness – if considering that *firms who better understand their social responsibilities and who begin to more adequately explore how they can build CSR into strategy are likely to reap the rewards of improved competitive positions in the future, to the benefit of their shareholders, but also to the benefit of society at large* (Galbreath, 2009); (2). expanding and deepening the *CSR boundaries* – if considering that in the case of *emerging or transitional societies, transnational corporations (TNCs) can find themselves the catalyst for legal or conceptual reform* (Mullerat, 2010, p.4). By playing such a role, businesses can contribute to the overall development of the emerging markets, while helping them to climb on the ladder of responsibility and sustainability.

Certainly, such an approach will not be an easy way for businesses in emerging markets, especially if taking into account: (a). the institutional and regulatory voids that still define emerging markets – allowing businesses to act irresponsible without being scrutinized and/or punished for their behaviors; (b). the discretionary dimension that usually characterizes CSR – which makes other than economic values and 'bottom lines' to be easily overlooked and/or ignored; (c). the urge for economic development on the basis of 'no matter' how – which justifies, against the background of no penalties, almost any kind of profit; (d). the lack, until now, of an indubitable proof of a direct causal link between CSR and financial performance – even though different empirical studies have directly, as well as indirectly demonstrated the correlations between those two; (e) the knowledge gap that characterizes both the theory and the practice in the field of strategic CSR – encapsulating all the above.

But it could be the only way for the emerging markets (and their businesses) in order to overcome the sustainability (economic-social-environmental) gaps and to meet the challenges of the complex and networked economy of nowadays. And this is especially true if considering the new age – *of responsibility* – and stage of business responsibility – *systemic CSR* – which is about to emerge, according to Visser (2011). Following *the ages of: greed, philanthropy, marketing and management – characterized by: defensive CSR, charitable CSR, promotional CSR, and strategic CSR* respectively – *systemic CSR* represents a step forward for business (thinking and action) and could become a benchmark for the companies from emerging markets, because it *focuses its activities on identifying and tackling the root causes of our present unsustainability and irresponsibility, typically through innovating business models, revolutionizing their processes, products and services and lobbying for progressive national and international polices* (Visser, 2011).

Therefore, the ideas of co-evolution (with the environment) and symbiosis (between stakeholders' needs and expectations) – considered in terms of both premises and consequences – should accompany any strategic endeavor. They would help businesses to properly asses their (internal and external) environment and to define their most appropriate systemic CSR approach accordingly. As a growing number of businesses will embrace this approach, the interdependencies (between the global stakeholders) will

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

multiply and strengthen, while the overall 'sustainability outcome' will (exponentially) be rising. The 'best fitted' businesses will be able to take the lead in terms of competitiveness, while the others will be left behind. Therefore, due to sustainability related reasons will be essential that a critical mass of businesses to make the move towards integrating systemic CSR into their core business. Thus, the challenges of development and sustainability (as moving targets for the emerging markets and their businesses) will get their best answers, enabling emerging markets to catch-up – on one hand, and businesses to be competitive – on the other hand. And the virtuous circle will be continued…

FUTURE RESEARCH DIRECTIONS

The topic of the chapter is at the same time broad and deep, as well as uneven and controversial, therefore it could not be entirely covered. Moreover, it opens new perspectives and research directions in relationship with the generic topic of the book – which deserve to get a closer look and to be thoroughly explored. In this light, some of the future research directions might envisage: firstly, practical case studies for particular contexts – countries and companies – in order to emphasize on the models for good practice in the field of CSR in emerging markets and to extract similarities and differences that define such behaviors; secondly, developing of a flexible strategic model – integrating various inputs and able to generate different CSR strategies, based on particular situations and scenarios and integrating the results of a relevant number of case studies; thirdly, determining of an 'flexible' equilibrium point – in terms of costs versus benefits of different CSR strategies – as result of a comprehensive analysis and serving as decision criterion when developing a CSR strategy; and fourthly, designing, implementing, and evaluating a CSR strategy into an emerging market (Romania) – in accordance with all the above-mentioned, and taking into account the challenges of responsibility and sustainability, on one hand, and of the complex and networked global economy, on the other hand.

CONCLUSION

The chapter brings new insights on the thorny and controversial issue of CSR strategies in emerging markets, insisting on the need for responsibility at firm level, which, in turn, will have the vocation of leading towards sustainability at broader levels (from national to global). Such a view on the relationship between business and society will enable firms in emerging markets to operate as sustainable development agents, while their CSR strategies will act as sustainable development tools, contributing in the same time to a systemic (and long-term) reconciliation of interests between business and society.

The multilevel (firm - country - global), multidisciplinary (management - strategic management - international business) and multifaceted (internal and external global stakeholders) approach of the chapter has revealed the main characteristics that define the challenging (and continuously changing) context of business in emerging markets: the complex and networked global economy of nowadays, the increasing role of the emerging markets on the global arena, the specific internal and external challenges emerging markets and their companies (local and/or multinationals) face, and the growing pressures toward corporate social responsibility coming from different stakeholders. All and each one of the above represent genuine and valuable cues that need to be properly considered and optimally valorized by companies in emerging markets when designing and implementing their best suited CSR strategy.

EBSCOhost - printed on 2/13/2023 6:06 AM via . All use subject to https://www.ebsco.com/terms-of-use

Both theory and practice offer recommendations and/or solutions for good practices in the field, but this is not enough – given the great diversity of particular situations. Each business in emerging market has to identify and pursue its own development path while defining and building its own relationships with the society through its CSR strategy. More than that, in search for (global) sustainable competitiveness, it should synergistically integrate the new concepts and practices that have recently emerged – such as *shared value* and *systemic CSR* – into its business core; but this would be a long and difficult process, which asks for a paradigm shift as regards the idea of business itself.

In conclusion, the study has developed a general discussion framework – placed under the auspices of the complex, networked global economy, where each business is a complex adaptive system which has to operate in co-evolution with the environment – on the issue of CSR strategies in emerging markets – by covering from both sides (and through multiple lens) the relationships between (responsible) business and (sustainable) society, while opening new lines of debates and new directions for future research.
