On the other hand, firms that implement CSV strategies involves social and environmental issues into core business model and strategies, and enable the society, such as local people or social organizations, to be their partners for cross-sector collaboration. Cross-sector collaborations form in order to address social or environmental issues (Alvord, Brown, & Letts, 2004; Murphy & Bendell, 1999). Co-created value includes a wide range of benefits for all stakeholders such as access to new knowledge, increase financial or natural resources, improve legitimacy, reputation, and customer perceptions which lead to competitive advantages of firms; preserve the environment, support and develop local people, and relieve social and environmental issues. Corporate, social, and environmental value is co-created in a sustainable way. Furthermore, customers are also involved in this social and environmental activities. CSV strategies enable the firm to reinforce the mutual interdependencies between the value co-created for its customers, society and the environment as well as the value captured for itself. Ideally, the more value the firm can create for its customers, society, and the environment, the higher the value it captures for itself (Abdelkafi & Täuscher, 2016). Consequently, socio-environmental value, which is the mediating effect, is co-created and enhance the normal social and environmental value. Simultaneously, customers are offered co-produced value propositions of economic and non-economic value propositions. Economic value propositions refer to purchased products or services. Non-economic value propositions refer to self-fulfillment and pride for making social contributions. These value propositions amplify customer value. The practice also provides new opportunities for value creation to increase corporate value. The amplified and long-term value co-creation of every stakeholder facilitates the sustainable development,

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

performance, and loyalty which eventually lead to economic, social, and environmental sustainability. Overall, this value-based model distinguishes a transitional view of CSR and CSV strategies using value co-creation and collaboration approaches for the economic, social, and environmental sustainability for the firm, society, and the environment. The active engagement with society will ultimately create synergistic value for all and gain the sustainability.

A CASE STUDY

Introduction to Socialgiver

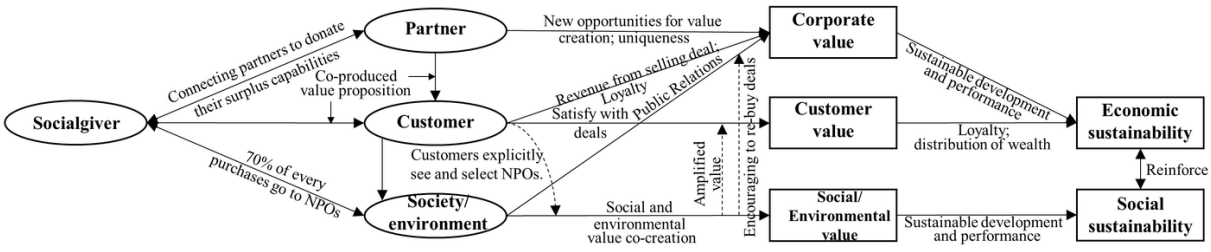
www.socialgiver.com is an online deal website based in Thailand that virtually connects profit organizations such as restaurants and hotels, non-profit organizations (NPOs) that support social and environmental issues, and customers in ways that have significant and sustainable economic, social, and the environmental impact. Socialgiver is both a shopping website and charity website that simultaneously aims to promote a comfortable lifestyle and social consciousness. The purposes of Socialgiver include (1) to convert spare service capacity from the service sector into social progress, thereby making the entire sector more sustainable, (2) to provide funding for social and environmental projects through sales of services pledged by its partner businesses and to connect those projects with donors, and (3) to improve the sustainability of its partners and social projects. Socialgiver acts as an intermediary connecting business partner, social projects, and customers. It is responsible for deciding and managing value propositions, determining the discount rate, and setting an appropriate price for services. It also validates its partners and social projects in order to protect customers' rights and privacy. The information displayed on its web page is to assure customers and eliminate bias against services providers and social organizations.

Implementing CSV Strategies

Socialgiver implements the CSV strategies that aimed to create shared value together with its partners, society, and customers. Socialgiver aims to change the surplus service capacities of for profit-organizations that currently do not generate any benefits such as unfilled rooms in a hotel and unsold tickets into funding for social and environmental projects of NPOs by engaging customers. First, Socialgiver connects and persuades business partners to donate their surplus products or service capacities of businesses for charity purposes, which later turn into their CSR activities. Seventy percent of every purchase go to NPOs, while the rest is for covering the operating costs of Socialgiver.

Socialgiver allows customers to explicitly see and involve in firms' social and environmental activities by letting customers select projects from NPOs for their donation. From this interaction, customers help to co-create social and environmental value for society and the environment. At the same time, these value also positively influences customer and corporate value. It encourages customers to re-use the services from Socialgiver, leading to the economic sustainability. Long-term social and environmental value co-creation leads to social and environmental sustainability. Sustainability can be achieved in CSV but not in traditional CSR since sustainability refers to sustainable value co-creation from the strategic alliances among the firm, consumers, business and non-business players such as society and the environment in ethically, responsibly and innovatively creating socio-economic and environmental gains. Cross-sector

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use



alliances between firms and NPOs are explicitly formed to address social and environmental issues, which appear in the business model of Socialgiver. CSV strategy of Socialgiver is illustrated in Figure 2.

DISCUSSION

The traditional perspective of CSR was associated with corporate philanthropy and legitimacy practices, which usurped firms' resources. Therefore, this concept is not a suitable approach that contributes corporate, social, and environmental sustainability. CSR has been for defined in terms of creating solely social benefits and not explicitly exposing the economic aspect of business engagement in social and environmental issues which aims to gain the legal benefits (Wójcik, 2015). Therefore, the concept of CSV was introduced to address this issue by re-conceptualizing the roles of business in the society and offering a solution focusing on value co-creation and sustainability. CSV guides the thinking about the relationship between business, society, and the environment and aimed at changing how the core business operates, business model, and strategies. It aims to create new opportunities for new value creation instead of being forced by external factors such as legitimacy and stakeholder pressure, a firm is motivated internally to pursue shared value creation to achieve sustainability.

The CSV strategies emphasize co-created value and cross-sector collaboration as the hidden keys for sustainability since working together with local people or social organizations enable deep understanding of local context, constraints and barriers (London, 2007), and enhance corporate value. Simultaneously, sustainable social and environmental value is co-created. Understanding and integrating with the local communities enables the creation of what the literature calls social embeddedness or native capability which in turn leads to a sustainable competitive advantage for the firm and thus the creation of economic, social and ecological value (London, 2007; Rosca et al., 2016). According to Porter and Kramer (2011), a collaboration between for-profit and non-profit organizations is one of the strong signs that creating shared value is possible. For a firm, the starting point for creating this kind of shared value is to identify all the societal needs, benefits, and harms that are or could be embodied in the firm's products or services. An ongoing exploration of societal needs will lead companies to discover new opportunities for differentiation and repositioning in traditional markets, and to recognize the potential of new markets they previously overlooked (Porter & Kramer, 2011). From the sustainability-oriented perspective, integrating economic, environmental, and social value is important for a holistic view of sustainability (Joyce & Paquin, 2016). Moreover, consumer participation and engagement also play a major role in trust and legitimacy that could impact for sustainability.

Figure 2. CSV strategy of Socialgiver

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Sustainability can be achieved in CSV but not in traditional CSR since sustainability refers to sustainable value co-creation from the strategic alliances among the firm, consumers, business and non-business players such as society and the environment in ethically, responsibly and innovatively creating socio-economic and environmental gains.

IMPLICATIONS, LIMITATIONS, AND FUTURE STUDIES

This study contributes to sustainability and business literature by investigating insights into the differences between CSR and CSV from the sustainability-oriented viewpoint and strengthening the importance of social involvement that undertaken in practice. The findings present the movement from abstract to concrete concept into a theoretical model. The CSV concept is still in its nascent stage and its relationship with the CSR umbrella term has not been consistently explained. They are overlapped. This study contributes to theory development and supported by a case study and seeks to delineate a borderline between the notions of CSR and CSV from value and sustainability points of view. Findings would also allow managers to better understand the opportunities for creating sustainability from CSR and CSV practices as well as the characteristics of the implementation based on the value co-creation and cross-sector collaboration approaches.

This research is not without limitations. Our results need to be viewed in the light of limitations, which can provide potential directions for future research. First, this conceptual paper could not have featured all the contributions that are related to CSR's value-driven notions. Second, the analysis of CSV in this study was focused mainly on external stakeholders, which CSV covers both internal and external stakeholders. A holistic view would provide more insights and complete views which would help to distinguish from tradition CSR and provide a better understanding on how it facilitates the economic, social, and environmental sustainability.

Chapter 63
Assessing the Maturity of Green IT Adoption Within the Philippine Manufacturing Industry

Alexander A. Hernandez
Technological Institute of the Philippines Manila, Philippines

ABSTRACT

Green IT is the sustainable use of computing resources in organizations with minimal or no impact on the environment. The role of Green IT is recognized to achieve sustainability in organizations. This study presents the extent of Green IT adoption in a developing country. This study used GIT maturity model to assess the overall level of Green IT maturity among manufacturing organizations. The results suggest that participants recognized Green IT, however, a low level of maturity is found within the manufacturing organizations. To further Green IT adoption in organizations, practical and research implications are presented.

INTRODUCTION

Green IT (GIT) is a resource-efficient consumption strategy through the utilization and operation of IT infrastructures and implementation of associated policies aiming to enhance business and environment sustainability. GIT is recognized for its potential in driving organizations towards reducing business footprint while achieving performance with a lesser impact on the environment (Loeser et al., 2017). Hence, GIT is for greener business activities, efficiency, and conservation of resources. Previous studies have recognized the benefits of GIT to sustain firms' competitiveness. First, cost reduction is one of the emphasis of GIT adoption benefits in organizations to remain sustainable with regard to business operations. GIT lowers business costs for complying with environmental regulations compared with

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

competitors who still do traditional way of business which only focus on economic benefits (Ramaya et al., 2013; Gholami et al., 2017a), requires relatively less material and resources during the product design and manufacturing stages (Savita et al., 2016), and lower operational costs (Chugh et al., 2016). Second, the adoption of GIT enhances corporate reputation within the business community and to its stakeholders. GIT improves corporate image of firms as compared with their competitors (Hba et al., 2016), perceived by customers as environmentally responsible (Chuang & Huang, 2016), and favored by shareholders due to their good GIT reputation (Ainin et al., 2016). Third, green innovation as a benefit of GIT aims to make the firms more capable of spurring environmental research and development (Gholami et al., 2016b), enhances environmental management systems (Hoang et al., 2016), and green innovation as compared with major competitors (Hanelt et al., 2016). Hence, GIT can drive green innovation, foster environmental stewardship to improve corporate image and reputation, and cost reduction within business operations.

Despite, the growing benefits of GIT in organizations, there is little work that investigates Green IT adoption in developing countries, such as the Philippines. First, most of these studies have been conducted in developed countries in which Green IT has been progressing enormously using various frameworks, and strategies and research on GIT in the social enterprise are relatively scarce (Coffey et al., 2013). Thongmak (2013) analyzed GIT frameworks in the literature, however, most of these were implemented in developed countries; thus, a proposed sustainable ICT framework for developing countries is discussed. Similarly, Bokolo (2016) found that GIT is more proliferated in IT organizations in developed countries. Thus, this study offers new insights on GIT in a developing country perspective. Second, developed countries are proactively underway of assessing their current level of Green IT maturity and readiness for a more effective propagation of improvement efforts aiming to achieve resource-efficient and low carbon economy guided by a comprehensive GIT strategy. Therefore, a handful of work has been done to initially understand the level of maturity of GIT in organizations in developing economies, such as the Philippines. Seuring and Gold (2013) and de Sousa Jabbour (2014) notes that there are few studies on developing countries exploring the maturity of GIT adoption in the manufacturing industry. Similarly, Ateetanan and Usanavasin (2015) investigated the level of GIT adoption in the government agencies in a developing country using Green IT Maturity Model and found a lower level of adoption. Hence, there is a need to explore GIT maturity in a developing country perspective further. Third, most studies in GIT adoption explored on the factors, antecedents, and drivers to adoption of GIT using well-known Information Systems (IS) theories (Deng & Ji, 2015; Dezdar, 2017), however, few studies attempt to investigate on the level maturity of GIT in manufacturing sector, which greatly contributes to global carbon footprint and degradation of environment (Giret et al., 2015). Thus, this gap in the literature with regards to GIT use in the manufacturing industry is addressed and extends prior empirical findings on GIT adoption maturity in organizations.

Therefore, a study that explores the level of GIT in maturity in developing countries could further insights on its current status, experience, issues, and challenges. To this end, this research aims to assess the level of Green IT maturity within the Philippines manufacturing industry. Hence, this research not only assists policy makers and implementers to further the uptake of GIT within organizations, however, consider GIT as a strategic approach to green growth especially for developing countries and global firms aiming to harness the potential of GIT for economic and environmental sustainability.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

LITERATURE REVIEW

Green IT Benefits

Previous studies suggest some benefits of GIT adoption covering reduction of carbon footprint, optimized business processes, and resource-efficient consumption, and greener end of life management.

First, in the area of reducing carbon footprint, Gholami et al. (2013) found in the study of senior IT managers in the manufacturing and service sector that GIT adoption resulted in a reduction of carbon footprint. Similarly, managers of small and medium enterprises (SME) have agreed that GIT achieved reduction of emissions (Dick et al., 2011; Ramaya et al., 2013). For example, a study on using energy-efficient data center solutions resulted in a major decrease in carbon emissions through real-time monitoring systems (Lee & Zomaya, 2012; Beloglazov et al., 2012). Likewise, intelligent lighting systems helped organizations to reduce their carbon emissions by thirty-five percent (Wang et al., 2012; Nguyen & Aiello, 2013). Hence, GIT adoption through a variety of energy-efficient solutions further reduces carbon emissions of organizations.

Second, business process optimization is also a major concern of organizations to eliminate or minimize duplication information in work processes, making procedures more simplified and systemized (Nowak et al., 2010). For instance, fully integrated business systems could result in better data tracking, expansion of utilization, and enhanced data integration among major work procedures of the organizations (Houy et al., 2010). Business workflows systems used by organizations integrated to a private sector, and agencies reduce inefficiencies and redundancies, likewise, allows better (Vom Brocke, & Seidel, 2012).

Third, efficient resource consumption remains a major priority for organizations slowly adopting to GIT. Beloglazov and Buyya (2010) found that virtualization technologies assist in reducing the number of IT infrastructures deployed by organizations, covering data centers, servers, and other associated equipment. For instance, desktop virtualization has been used and expanded in organizations with automated power management solutions (Younge & Von Laszewski, 2010; Papagianni et al., 2013). Resource efficiency is also translated through many office automation tools such as print management solutions to control printing of unnecessary files and documents, which could be transmitted in digital form (Park et al., 2012; Ateetanan & Usanavasin, 2015). Thus, increasing the resource consumption management on various business activities. Banister et al. (2007) suggest that telecommuting work practice offers new mechanisms to prevent additional travel costs, and footprint while enhancing productivity and efficiency of employees. For instance, some studies presented the benefits of adopting to communication systems allowing multinational companies to promote better collaboration (Ruth, 2011) while reducing the need for travelling of employees from overseas locations and offices, therefore, reducing gas, oil, and other associated natural resources consumption (Schwartz et al., 2010; Hernandez et al., 2016).

Fourth, organizations also strive to enhance end of life management in variety of strategies such as waste reduction schemes (Winkler, 2011; Choudhary & Seth, 2011), 3R (reduce, reuse, recycle) activities (Eltayeb et al., 2011) and improving product designs and throughput for a longer product life span (Dangelico, & Pujari, 2010), and better material recovery, and disposal strategies promoting take-back programs (Sarkis et al., 2010) for employees to increase participation, awareness, and education on the impacts of electronic wastes to the environment (Molla et al., 2014). Park et al. (2012) found that 3R program was an effective approach to encourage organizations to monitor IT asset gradually, replacement of inefficient equipment, convert reused and recycled equipment to monetary benefits. Similarly, Diabat et al. (2013) suggest that capacitating organizations on reusing and recovering schemes for IT equipment

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

offer monetary benefits through material recovery and take-back programs. Dwivedy and Mittal (2013) found that take-back schemes remain relevant approach in enhancing recycling performance and reduction of waste. Thus, it also assists organizations in improving environmental compliance certifications (Arimura et al., 2011).

Generally, GIT benefits were translated in measurable actions by organizations through resource-efficient consumption and preservation.

Green IT Adoption Strategies

The previous section presents the benefits of GIT adoption. More importantly, the literature suggests some strategies to assist organizations in achieving the GIT adoption benefits. Bokolo and Noraini (2015) suggest the strategic approach to GIT through the incorporation of "green" indicators on design, manufacturing, usage, and disposal activities. These variations can result in the resource-efficient design of computing solutions and equipment (Naumann et al., 2011), advanced data center management systems (Molla & Cooper, 2014), and environment-friendly end of life management practices (Ninlawan et al., 2010). Moreover, this domain is appropriate in choosing ecologically compliant and proactive measures to sustainable reproduction and pollution prevention benefits (Dao et al., 2011).

Previous studies suggest GIT metrics by starting from a setting of GIT agenda, conceptualization of operational goals, and development of assessment, and evaluations tools for an efficient GIT adoption (Molla et al., 2011;). Murusegan and Gangadharan (2012) similarly proposes enterprise GIT strategies through a multi-level approach covering strategic, deep green, and incremental tactical solutions. Also, the literature describes eco-efficiency, eco-effectiveness, and eco-collaboration as realization of GIT as strategy (Loeser et al., 2017) provided that energy-efficiency, cost reduction, savings, preservation of natural resource, disposal activities, and stakeholders collaboration serves as eco-goals to further the benefits of GIT adoption within organizations (Zhang & Liang, 2012; Cai et al., 2013).

Green IT Maturity Model

Initially, GIT benefits were achieved through some of the strategies discussed in the previous section. Also, it is significant to explore on the maturity level to understand the extent of GIT adoption in organizations.

A number of GIT maturity models were developed. However, there were varying conditions to which these models were used and adopted by prior studies. First, Accenture developed a green maturity model for assessing the GIT maturity of organizations and proposes a strategy to enhance green performance. The model has five major areas of evaluation with 300 indicators comprising of work practice, office environment, data center, procurement and corporate citizenship (Hersch & Bonecutter, 2008). Second, the British government co-developed with Gartner a GIT scorecard aiming to assess the level of GIT maturity of various government offices. The GIT scorecard was developed assist decision-makers in reducing the impact of ICT on the environment. Also, it was developed and utilized complementing the Sustainable Operations targets, piloted with eight government agencies and the local government of Scotland (Cabinet of the UK, 2008). Third, Korea's National Information Agency (NIA) developed the GIT Maturity Model Integration (GMMI) to assess the state of and support GIT to design a GIT roadmap and action plan. The GMMI consists of 5 areas involving data center, work practice, office environment, corporate citizenship, and procurement with stages of maturity model consisting six stages

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

(0 to 5) for each indicator. An indicator-specific weight is applied to calculate the overall score (Park et al., 2012). Fourthly, Royal Melbourne Institute of Technology with Australia Connection Research developed the GIT readiness index to measure the GIT maturity level among Australian firms. The study was participated by 200 Australian firms, and measured by using 36 indicators in 5 areas such as end user, enterprise, enablement, life cycle, and metrics. Fifthly, Infosys proposed a GIT maturity model to assess the adoption of GIT services, and ranked firms' green maturity and evaluate efforts towards greener future. The major constructs include data center and facilities, end user computing, asset life-cycle, IT service management, and people practices (Desai & Bhatia, 2011). Sixthly, APECTEL through the NSTDA Academy, National Science and Technology Development Agency, Thailand, developed a GIT maturity model assessing the areas of (1) knowledge and awareness, (2) policy and strategy, (3), management techniques, and (4) implementation and development (NSTDA, 2011).

Previous studies suggest that among these models, the Korea's National Information Agency GIT maturity model was the most comprehensive as it highlights both management and technical aspects with a strong emphasis on five areas of GIT. The model was used in some of the assessment studies available in the literature (Park et al., 2012, Ateetanan and Usanavasin; 2015).

Overview of the Philippines Manufacturing Industry

As of 2012, the total manufacturing companies in the Philippines was at an average of 25,064 with different business activities supporting local and international customers (Aldaba, 2014). Moreover, the manufacturing sector continued to grow due to the increased production demands and growing economies. From 2011 to 2015, the manufacturing sector posted PHP 738 Billion in gross valued reaching its 2.7 trillion Gross Value Added (GVA) and growing at an average of 7.3% annually (Batungbacal, 2016). More importantly, the manufacturing sector labor market and productivity increased by 4.9% (Official Gazette, 2015). The steady increase in the manufacturing sector is attributed to the foreign direct investments, and the numerous expansions and projects in the past six years (Philippine Statistics Authority, 2016). To date, the manufacturing sector encourages partnership with government agencies and academe to harness research and development (Department of Trade and Industry, 2016), co-develop industry champions and participate in environmental programs. More recently, the manufacturing sector embarked to greener business activities such as GIT as one of the focus areas for rapid growth and sustainability (Gutterer, 2015). More specifically, the professional association and organization on manufacturing sector developed GIT roadmap and strategy together with the design of guidelines on its implementation (Steigerwald, 2015). Overall, through GIT, the manufacturing sector contributes to achieving a more sustainable business and environment.

METHODOLOGY

Participants

This research covered five manufacturing and eight service locations in Region 4 and National Capital Region, as these sites were considered economic zone centers in the Philippines. This study was participated by senior IT Managers and Heads with existent background and implementation of Green IT

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

adoption practices within their organizations. Table 1 presents the profile of survey respondents. Respondents came from the manufacturing sector. Majority of the respondents held senior management positions, and connected with these positions for more than one year.

Instrument

This study used the survey instrument from Park et al. (2012) Green IT Maturity Model (GMMI) with validated measurements by experts, available in Green IT adoption studies and literature. The survey instrument includes five major constructs in assessing the maturity of Green IT adoption: (a) data centers, (b) office environment, (c) work practice, (d) procurement, and (e) corporate citizenship, a total of 54 survey items were measured and operationalized. The data center constructs consisted 15 items, office environment has 15 items, work practice covered 16 items, procurement consisted nine items, and corporate citizenship with nine items. Table 2 presents the summary of survey constructs and items.

Park et al. (2012) and National Information Agency of Korea (NIA) proposed a level of Green IT maturity with six stages of maturity for each indicator as presented in Table 3.

Data Collection

An email was initially sent to the companies asking their participation in the study. Consequently, another email containing the survey link was provided to companies who confirmed their participation in the survey. There were some companies who did not participate in this study. However, a total of 387 companies answered and completed the questionnaire. The survey was distributed from November 2016 to February 2017. After a couple of months of data gathering, all responses were considered for analysis.

Table 1. Profile of respondents

	Frequency	Percentage
Position		
President / CEO	57	14.73
General Manager / CIO	125	32.29
MIS Director / Manager	115	29.72
IT Head	90	23.26
Time in the Position		
5 years or less	183	47.29
6-10 years	128	33.07
10 years or more	76	19.64
Size		
Small and medium	267	69
Large	120	31

Table 2. Constructs and measures

Area	Item	Assessment Indicators
Data Center Shared computing capacity including servers, storage and networks	**Server Assets**	When developing information systems and introducing new servers in your operating environment, does your company consider server virtualization as a basic implementation method?
		To proactively manage the floor space occupied by idle servers, does your company use orchestration tools in all environments?
		Does your company collect data on the use of server instances across all your assets, manage related indicators and conduct optimization activities based on this information?
		Do you company practice intelligent refreshing in servers in all environments to improve their operation efficiency?
		Are all servers in your company optimized based on their performance efficiency and highly efficient in terms of power supply?
	Support Infrastructure	Have your network storages in data centers been integrated to create a single-storage network?
		Does your company collect data on the use of storage equipment on all your assets and develop and manage related indicators?
		Have your networks been converged (voice/data, fixed/wireless) to reduce the number of switches needed in your data centers?
		Is your intelligent power allocation equipment installed in the LAC within the data centers and is linked with monitoring systems?
		Are backup software programs within your organization integrated into a single platform so that they may be used for company-wide backup and restoration?
	Physical Equipment	Is power usage monitored in real time in your company, and is monitored by each section or unit?
		Is the lighting system in your data centers designed with energy efficiency in mind?
		Was energy efficiency considered in the design of your data centers?
		Is the control of temperature and moisture in your data centers automated, and is the control system effective?
		Is your company conducting a data center rationalization program to minimize the number of data centers?
Office Environment Computing resources within an office environment, including desktop and laptop computers, printers and mobile devices	**PC**	Have screensavers been disabled in all display devices so that they go into power saving mode?
		Are all IT equipment in your office controlled by a central power management system?
		Have desktops been replaced by lower-power laptop computers in your company where possible?
		Have your company's desktop units been replaced by thin client solutions where possible?
		Are there rules in your company, requiring employees to shut off power to all unused PCs and IT devices, and a management system to monitor compliance?
	Printers	Are multifunction devices functioning at the same time as a printer, fax machine, scanner and a photocopier used in your company, instead of separate devices?
		Is there support for a virtual fax service for all users in your company, and is its use widespread?
		Are all printers in your company installed with a toner saving solution?
		Are all printers in your company configured so that power is automatically shut off during night hours and weekends?
		Do you have an integrated print management service in your organization to reduce unnecessary printed materials?
	Office Equipment	Do you have wireless network access in your organization to reduce the use of fixed-line networks?
		Is there an intelligent lighting system in all offices of your organization?
		Is the lighting system in your organization energy-efficient?
		Is temperature in your offices controlled by a building control system, and is your company continuously improving the energy efficiency of the heating system?
		Is the power supply to printers in your organization shut off during weekends and night hours?

Table 2. Continued

Area	Item	Assessment Indicators
Work Practice The way an IT organization and its members work, including the organizational structure and processes	**Applications**	Can all employees in your company conduct their basic tasks through an electronic approval system or a web interface?
		Are emails or electronic signatures accepted in your company as a valid method for approving or authorizing processes?
		Does your company have and use an electronic payment/settlement system to settle transactions with customers or vendors?
		Does you company have an internet-based sales channel?
		Does your company use an e-billing system to issue paperless customer invoices (or payment receipts)?
		Is your company conducting an application rationalization program to reduce the size of the application portfolio and achieve a company-wide standardized architecture?
		Are organizational processes in your company being thoroughly reviewed and continuously improved in order to reduce the number of tasks performed?
		Does your organization have a single, consolidated tool for communicating internal messages? (email, MSN, Skype, voicemail, fax)
	Operation	Is a video conference system in place and in use, in your company, to minimize travel needs?
		Is your IT unit capable of supporting teleworkforce and mobile workforces through remote support services? (ex. IT support via remote control)
		Does your company provide support tools and office space for telecommuting, and encourage telecommuting by employees?
	Management	Is green IT education provided to employees in your company, on a regular basis?
		Does your company conduct analysis on the environmental impact of its activities, concerning all business cases?
		Does a charge-back mechanism for services provided by the IT unit exist in your company, and if so, is it appropriately managed?
		Does a model for charging back carbon costs to units and projects exist and are improvement activities carried out based on the charge-back model, in your company?
		Does your organization have a green leadership program in place, along with well-defined rules and a management system? Also, is your organization carrying out a green agenda?
Procurement The process through which companies procure and purchase equipment and services	**Asset Management**	Is the lifecycle of IT assets efficiency managed under your company's asset management policy?
		Are all asset purchase activities and power consumption tracked by a centrally-managed configuration management database (CMDB) and included in the audit process?
		Is your company's configuration management database (CMDB) linked to its service catalog?
	Captical Costs	When selecting standard hardware solutions, is the energy efficiency of IT assets, including energy star certification, a key consideration?
		When selecting an asset, does your company consider carbon emissions at the vendor's side, resulting from manufacturing, transportation and disposal processes, and has there been improvement in this area?
		Does your company have rules requiring compliance with environmental regulations, including the EU Restriction of Hazardous Substance (RoHS) Directive and the Waste Electrical and Electronic Equipment (WEEE) Directive, and are the rules enforced?
	Operating Costs	Does your company use a smart logistics system for product delivery? (ex. single packages, single pickup, etc.)
		Does your company have a utility management process in place to minimize the use of consumables?
		Does your company have rules requiring the purchase of office supplies made with recycled/environment-friendly materials, and is encouraging compliance with these rules?

Table 2. Continued

Area	Item	Assessment Indicators
Corporate Citizenship The method of interaction between an IT organization and the local or global community	**Waste Disposal**	Does your company conduct analysis on items that are sold or discarded, for instance, to define and classify hazardous substances?
		Does your company have incentive and information programs for reducing IT-related waste production, and are these programs conducted effectively?
		Are all items audited before they are discarded, and has continuous improvement been made in terms of reduction of the environmental impact of your company's activities?
		Are wastewater and waste heat produced from offices and IT resources re-used in your company?
	Recycling/ Re-use	Does your company have rules and processes in place for reusing computers and other internal assets by donating them or changing their intended use, and are these rules and processes effectively implemented?
		Are consumables like batteries and printer cartridges recycled or re-used in your company?
	Waste Reduction	Does your company have set practices for its employees to participate in environmental movements, and has there been a continuous participation in environmental movements?
		Does your company use smart redundancy techniques to reduce the number of physical apparatuses?
		Does your company encourage electronic distribution of product or company brochures to customers and vendors?

Table 3. Levels of maturity

Level	Description
0: Incomplete	Although a process is in place, it is not used, and efforts to draw actual benefits from it are insufficient.
1: Initial	The process is not at all or poorly documented, and tends to be modified depending on the user or event.
2: Repeatable	Although the process manual or instructions are far from clear or complete, they, nevertheless, are helpful in maintaining existing practices.
3: Defined	A clearly-established process exists, and the process has improved over time.
4: Managed	The process is carried out using statistical, Quantitative techniques, and it is possible to predict quantitative values.
5: Optimized	There is a quantitative process improvement goal, and the process has been continuously improved to reflect the business goals.

ANALYSIS OF RESULTS

This section presents the results of the study in Tables 4-8. The following parts discuss the major constructs and their corresponding results based on analyzed survey results.

For data center, organizations considered introducing energy-efficiency in the design of data centers (AVE = 2.9) and made backup software available for organization-wide backup and restoration activity (AVE = 3.1). On the other hand, organizations have lower consideration in managing orchestration tools to enhance the use of floor space for idle servers (AVE = 1.5), and limited practice has been devoted in adopting intelligent refreshing in servers to enhance operational efficiency (AVE = 2.1).

In terms of the office environment, the organizations had utilized multi-function equipment with features to print, scan, fax and photocopy documents within the organizations (AVE = 3.7). Also, the organizations considered using toner saving solutions to reduce costs (AVE = 3.3). However, there were limited guidelines requiring employees to shut down unused computers and other devices, and management

		Are all servers in your company optimized based on their performance efficiency and highly efficient in terms of power supply?	
	Support Infrastructure	Have your network storages in data centers been integrated to create a single-storage network?	2.8
		Does your company collect data on the use of storage equipment on all your assets and develop and manage related indicators?	2.5
		Have your networks been converged (voice/data, fixed/wireless) to reduce the number of switches needed in your data centers?	2.7
		Is your intelligent power allocation equipment installed in the LAC within the data centers and is linked with monitoring systems?	2.6
		Are backup software programs within your organization integrated into a single platform so that they may be used for company-wide backup and restoration?	3.1
	Physical Equipment	Is power usage monitored in real time in your company, and is monitored by each section or unit?	2.6
		Is the lighting system in your data centers designed with energy efficiency in mind?	2.7
		Was energy efficiency considered in the design of your data centers?	2.9
		Is the control of temperature and moisture in your data centers automated, and is the control system effective?	2.5
		Is your company conducting a data center rationalization program to minimize the number of data centers?	2.6

systems to ensure the compliance (AVE = 1.3). Moreover, there was limited implementation of intelligent lighting systems within the organizations, as an approach to reducing power and energy consumption.

For work practice, the respondents elicited that electronic approval systems and applications were made available to allow employing to perform their basic functions (AVE = 4.1) and related tasks. Moreover, the respondents agreed that paperless invoicing systems were utilized (AVE = 3.9) to reduce associated costs. However, the respondents pointed that there was limited green leadership program available, with policies and guidelines, management strategy, and green programme encouraging participation of all employees with the organizations (AVE = 1.0) as well as limited Green IT education (AVE = 1.2) was provided to recognize its benefits, outcomes, and implications towards individual and corporate-wide culture.

In terms of procurement, the respondents agreed that their organizations continue to make IT asset management efficient (AVE = 3.5) by ensuring that a management policy is in place, to further its

		Is the lighting system in your organization energy-efficient?	2.0
		Is temperature in your offices controlled by a building control system, and is your company continuously improving the energy efficiency of the heating system?	2.8
		Is the power supply to printers in your organization shut off during weekends and night hours?	3.0

implementation, monitoring, and improvement activities. Also, smart logistics systems are recognized as a critical approach to reducing the carbon footprint of transport when deliveries of products to their customers (AVE = 3.1). However, most of the respondents agreed that their little consideration on looking at the carbon emissions by vendors during the product design, development, transport, and end of life management (AVE = 1.0). Also, limited policies are in place requiring the organizations to comply with environmental regulations, lacks monitoring, and continuous enhancement by considering international standards (AVE = 1.4).

For corporate citizenship, the organizations have established environmental programs and practices to enhance participation of employees (AVE = 3.5). Also, the respondents agreed that electronic brochures were distributed to customers to become familiar with the organizations' products and services (AVE = 3.1). However, the respondents agreed that reusing wastewater and waste heat from offices and IT resources were not widely implemented (AVE = 1.1) as well as reusing or recycling consumables to reduce waste disposal (AVE = 1.7).

		Does a model for charging back carbon costs to units and projects exist and are improvement activities carried out based on the charge-back model, in your company?	1.3
		Does your organization have a green leadership program in place, along with well-defined rules and a management system? Also, is your organization carrying out a green agenda?	1.0

DISCUSSION

The results of the survey revealed that organizations within the manufacturing industry had initiated Green IT practices (see Table 9). However, further recognition, research, and implementations should be taken into consideration to harness the benefits of Green IT and reduce business processes impacts to the environment. For data center, newly developed and advanced energy-efficient solutions should be in place to reduce energy consumption and operational costs of data center and related equipment. With regard to enhancing the office environment, although improvements are being made to enhance efficiency

Table 9. Summary of Green IT areas

Area	Average
Data Center	2.57
Office Environment	2.41
Work Practice	2.65
Procurement	2.02
Corporate Citizenship	2.34
Overall Average	2.39

and energy consumption, IT equipment is not sufficiently used to enhance the working environment of organizations. In the area of work practice, the organizations had higher scores among all other Green IT areas in terms of the efficient utilization of software applications and mobile work practices. However, concerns were pointed on the limited Green IT education, leadership and programs, and placing practices on carbon charge-back systems. The organizations also received had lower results regarding procurement, and requires enhancement in procurement activities covering purchasing, recycling, reuse, and disposal processes. Also, the results revealed the organizations had established corporate citizenship programs, effective processes are in place for waste disposal, recycling and reusing, and waste reduction, however, small practices were made to enhance reuse of consumables and deal with wastes discarded and recoverability.

Recommendations for Improvement

The organizations should establish Green IT vision, and framework to propagate green growth, structured processes, and management approach coupled with informatization methods from the initial phase of planning and deployment. More specifically, the organizations should increase the awareness on reducing business footprint and related emissions. Establishing a structured approach to measure, monitor, and analyze business footprint is needed while supporting mechanisms should be in place to slowly increase the awareness and education of the employees within organizations. Also, by recognizing that Green IT performance is necessary to achieve long-term sustainability, an institutionalization of performance management systems incorporating Green IT could further actions, training, and education in all aspects of its implementation.

In the area of institutionalizing Green IT practices, the organizations should further design effective and efficient processes in deploying software applications and encourage telecommuting activities to reduce transport footprint and related costs. Optimization of business procedures could further minimize associated costs. Reviewing and simplification of work procedures and its integration with existing main business processes should be considered to reducing duplicate information. Also, integrated communication systems and mobile office practices should be in place to promote better collaboration, participation, and major reduction of traveling footprint.

Concerning office environment, the organizations should assess and utilize energy-efficient IT equipment and devices. The use of automated power management systems should be in place as well

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

as expand the desktop virtualization utilization in office environments. The organizations should also consider introducing print management solutions as company-wide implementation in conjunction with an efficient toner management solution, reducing printing consumptions and further the adoption of paperless business activities. Also, the organizations should introduce the use of intelligent lighting systems, highly efficient heating and air-conditioning technology in a centralized and controlled facility. Likewise, assessing the potential of moving to a green certified building, office environment and facility would allow provisions for natural lighting systems and access to advanced facility management solutions. Hence, it could allow continuous measurement of power consumption and savings.

In the area of IT procurement, the organizations should assess and enhance existing policies about the purchase and use of energy-efficient and environment-friendly IT infrastructure and its associated equipment, and consider advanced energy-efficiency management solutions. Procedures should be in place to effectively monitor IT lifecycle management along with measuring its efficiency and introducing integrated data resource management systems for IT assets and end of life management. Detailed implementation guidelines on 4R (reuse, reduce, recycle, recover) practices could further end of life management practices within the organizations as well as placing more rigorous rules in using consumables. Moreover, consideration and assessment activities are needed to look at suppliers' procurement activities, participation in environment programs and the establishment of performance management could further assist organizations in monitoring carbon footprint associated with procurement life cycle.

Regarding data center operations, the organizations should take actions on establishing guidelines and management systems that optimize the allocation of data resources. Further consideration on server virtualization should be slowly extended to all the key aspects of business operations. Also, using efficient storage solutions, recovery and backup systems could result in efficient data management while introducing converge network, connectivity, and utilization of wireless network, as well as real-time power and energy monitoring solutions, are needed, and enhancing the physical setup and space of data centers to allow constant evaluation and optimization of energy use.

To further corporate citizenship, organizations should consider monitoring waste disposal activities, continuous IT asset audits including discarded items, recycled and reused resources, and a mechanism to manage items that are sold. Top management should also explore on establishing regular recycling and reuse programs for employees and encourage participation to environment programs could further increase awareness and education. Rewards and incentives systems should be in place to recognize employees' efforts in helping the organizations to reduce its business footprint are highly recommended.

Overall, a strategic strategy recommendation is needed to further the update of Green IT in the manufacturing industry in the Philippines. As the Philippine government recently participated in the Paris agreement on reducing per country carbon footprint and environmental protection programs, it is necessary to take the following steps (a) establishing a national committee on introducing green growth and Green IT policies, implementation guidelines, performance, and monitoring systems; (b) structuring and creating stringent policies and regulatory programs aiming to promote Green IT procurement across industries, and require enterprise level Green IT agenda with its long–term strategy; (c) establishing an education, awareness and promotion programs through Green IT capacity building and training with rewards and awards systems; (d) setting up a support systems through technical assistance, financial budget allocation, and collaborations with social enterprises aiming to further environment sustainability through green growth.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

CONCLUSION

This study is an initial attempt to explore, assess and understand Green IT maturity within the Philippine manufacturing industry. The results indicate that there is likely lower level of Green IT maturity. Thus, Green IT is highly recommended. A Green IT framework and structure are needed for systematic management and further the update of Green IT within organizations. An emphasis on Green IT efforts, programs, and initiatives requires adopting newly developed advanced technologies to manage environment-friendly resources efficiently. Therefore, the Philippine government requires further efforts to enhance Green IT performance across industries. Developed countries all over the world have been proactively making efforts to introduce and adopt greener processes within their society, thus, assessing the Green IT maturity is the initial step towards building a green society.

Despite the contributions of this research, it is not free from limitations, thus, this study considers research possibilities to contribute to Green IT adoption as key area of inquiry in the computing, environment, and sustainability discipline including (a) studies on exploring the motivational drivers, factors, and antecedents could further understanding of the decision-makers intent to adopt Green IT, more particularly in the developing countries, such as the Philippines, with its initial attempt to introduce Green IT through voluntary enterprise level programs and practices, future studies can offer new insights as to how decision-makers perceive corporate culture and environment as consideration in introducing Green IT within organizations. (b) conduct cross-industry maturity assessment studies to identify the laggards and mature adopters of Green IT, compare, and explore the issues and challenges experienced by various industries, and recommend a suitable framework that assists them in slowly enhancing the adoption of Green IT practices, and periodically monitor and evaluate the performance. (c) explore the potential roles of industry associations and social enterprises for collaborations and participation in promoting business and environment sustainability initiatives. It can further offer new knowledge on the level of involvement and acceptance of Green IT as a strategy to attain long term environmental protection and resource conservation; (d) and develop a Green IT maturity indicators and ranking systems for the Philippine government.

Chapter 64
Assessing the Green Supply Chain Management for the United Arab Emirates Construction Industry

Sreejith Balasubramanian
University of Wollongong – Dubai, UAE

Balan Sundarakani
University of Wollongong – Dubai, UAE

ABSTRACT

The United Arab Emirates (UAE) construction industry has been witnessing an unprecedented growth in the last two decades. As a result, the sector is facing a major challenge of reducing the carbon footprint and thus creating major concern for the governments and the environmental agencies in the UAE. The chapter discusses the role of Green Supply Chain Management (GSCM) in achieving sustainability in the UAE construction industry. The various stages of GSCM applicable to the construction industry are critically assessed along with green performance measures in achieving environmental, economic and operational performance. Finally, the chapter provides a list of recommendations that could be used by practitioners and policy makers in implementing and measuring sustainability practices in the construction industry.

INTRODUCTION

Environmental pollution and climate change are the main challenges faced by mankind in the 21st century. Increasing carbon emissions from the various stationary and non-stationary facilities are the main cause of global warming and rise in sea level. Hence the carbon footprint quantification, analysis and reduction are considered as the key to identification and mitigation of emissions in every industry. One of the main industries from a sustainability perspective is the construction sector. According to United Nations Environmental Program (UNEP, 2007) report, the construction sector is responsible for 30%

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

of the world greenhouse gas (GHG) emissions. The increased growth in construction industry has led to increased GHG emissions due to higher energy consumption, embodied emission from the production of steel, cement etc., and from the combustion of petrol and diesel from related transportation from construction activities. In addition, construction industry waste makes a significant percentage of the total waste generated in many cities around the world (Li and Zhang, 2012). Hence, there is an urgent need to reduce the environmental impacts of the sector, especially in developing economies like United Arab Emirates (UAE), where the construction is the main contributor of environmental emissions.

Background to the United Arab Emirates (UAE) Construction Sector

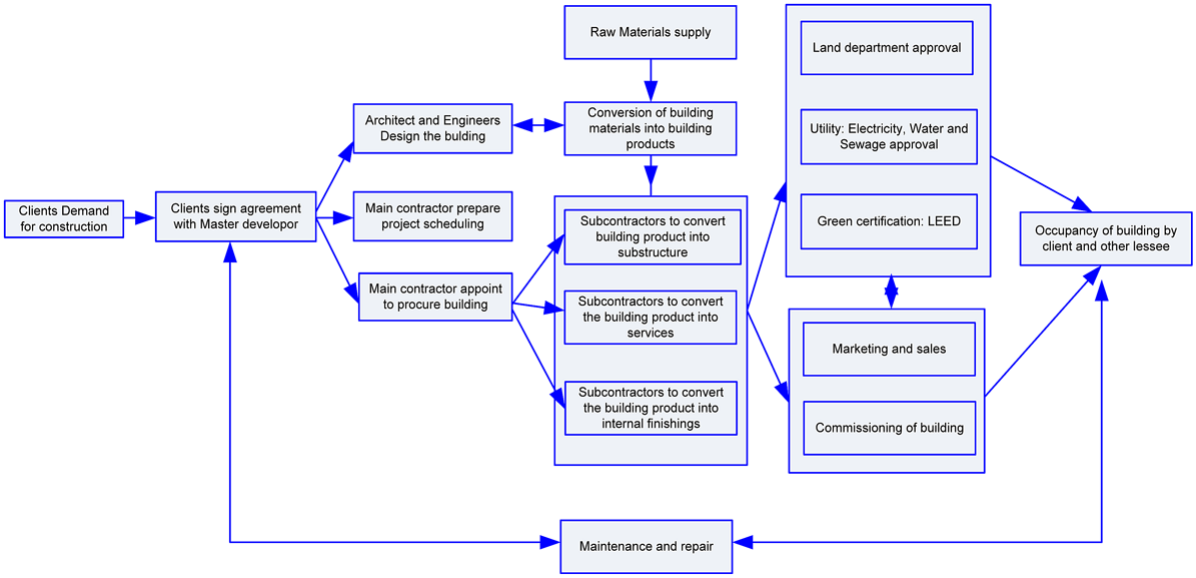
During the last decade, UAE has witnessed an unprecedented construction boom, in which the sector on average had grown 10-12 precent, and is the major contributor of environmental pollution. As of 2010, the total construction projects in UAE had an estimated worth of $958bn and is expected to grow by 9.6% annually between 2010 and 2014 (Deloitte Middle East, 2010). According to the 'UAE construction Industry Outlook (2012)' report, UAE accounted for nearly 20.3% of total construction industry in the Gulf Cooperation Council (GCC) having outpaced Saudi Arabia in 2008 in becoming the region's largest construction market. Even during the global financial recession (2009-2012), the sector managed to record strong growth and contributed approximately 8% to the country's GDP in 2009 to over 14% in 2012. Unfortunately, this unprecedented construction boom had largely contributed to UAE becoming one of the top countries in terms of per capita carbon emissions. UAE was ranked 4th, 6th and 1st place in terms of per capita carbon emission in the year 2006, 2008 and 2010 respectively (World Bank Report, 2012), with per capita carbon emission estimated at 22.6 metric tons in 2010. As a result, there is increasing pressure on UAE by global environmental bodies to cut down carbon emissions and per capita energy spending.

Green Initiatives in the United Arab Emirates (UAE) Construction Sector

Due to growing international pressure, UAE government has taken number of green initiatives to promote sustainability in the build environment. For e.g., Abu Dhabi Urban planning Council in 2010 introduced 'Pearl Rating System' a framework for sustainable design and construction in which consideration and documentation of sustainability aspects of new buildings is mandatory. Dubai Electricity and Water Authority (DEWA, 2011) announced the green building guidelines which covers aspects such as site selection, usage of construction materials, waste management and indoor environment quality. The World Energy Forum 2012 and World Future Energy Summit 2013 were hosted by UAE in a bid to create awareness and promote sustainable living in the UAE. These are already some evidences of the green projects in the UAE construction sector. For example, Masdar City is the world's first planned carbon neutral city located in the city of Abu Dhabi. However, these ad-hoc government initiatives and projects alone are not sufficient to green the UAE construction sector. To green the UAE construction sector, the sector needs to be looked at from a holistic perspective. The concept of GSCM, which offers a holistic approach, can be applied for greening the UAE construction sector.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Evolution of Green Supply Chain Management (GSCM)



From a supply chain standpoint of view to ensure future generations will have resources, we need to look into the supply chain and understand its implications on the environment. The environmental impacts of supply chain process have been an issue for many years. Traditionally supply chain management focused primarily on time, quality and cost. Supply chain management (SCM) has been viewed as process where raw materials are converted into final products, then delivered to the end customer (Beamon, 1999). However, in the mid 1990's as SCM evolved, practices such as just-in-time (JIT), lean supply chain, total quality management (TQM), are adopted by organizations to enhance the operational efficiency of the supply chain. However, increasing concern of environmental issues has led to number of independent studies on eco-friendly design (Chandra, 1991), life cycle analysis (Penev, 1995), waste management (Roy & Whelan, 1992), green manufacturing (Van & Salomon, 1997; Guide & Srivastava, 1998), green transportation (Gendreau & Dejax, 1993) and reverse logistics (Kelly & Silver, 1989; Pohlen & Farris, 1992) and together played a pivotal role in the evolution of GSCM, to counter the environmental impacts of supply chain processes in an organization. Having said, GSCM is not the only term used by researchers and practitioners. A review of recent literature in sustainability shows that supply chain environmental management (SCEM), sustainable supply chain management (SSCM), environmental supply chain management (ESCM) are used and often interchangeably. However, a closer investigation revealed that related concepts such as SSCM and ESCM are broader and incorporates the social dimension of sustainability, while GSCM primarily focuses on the environmental dimension along with operational and economic dimensions. The scope of the book chapter is narrowed to GSCM to focus on the environmental issues of construction. According to (Srivastava, 2007), GSCM can be defined as ''Integrating environmental thinking into supply chain management, including product design, material sourcing and selection, manufacturing processes, delivery of the final product to the consumers as well as end-of-life management of the product after its useful life'' (p.12)

Importance of Green Supply Chain Management (GSCM) in the United Arab Emirates (UAE) Construction Sector

The environmental considerations are under looked and often neglected by firms in the UAE construction sector. A typical UAE construction supply chain is shown in Figure 1. Typically the construction project is awarded to a main contractor by the client/developer. Habitually, neither the main contractor nor the suppliers are involved in the planning or design stage of the construction supply chain. Developer hires the consultant and architect for the master planning and design and then hires the main contractor who will be responsible for the entire construction and commissioning of the building. The potential of GSCM in the UAE construction industry is enormous. An end to end GSCM can reduce emission across all stages of the supply chain. Support of all the stakeholders is required to implement GSCM. For instance, developer requirement for green buildings will be conceptualized by the architect in the form of green building design. The requirements of the green building design is tendered and awarded to the main contractor, who takes the responsibility to implement the green project. The main contractor should possess the sufficient knowledge of GSCM to implement as per tender specification. Moreover, the other activities undertaken by the main contractors such as project scheduling can forecast the op-

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. A typical UAE construction supply network

erational improvement resulting from implementing GSCM. However, the integration of GSCM into the construction sector is a complex undertaking. This chapter attempts to integrate the various aspects of GSCM in the UAE construction sector.

Methodology

Due to the limited number studies in green supply chain management (GSCM) in construction, a systematic evaluation of existing literature GSCM from other sectors which has witnessed considerable research in GSCM over the last decade was executed to synthesise the various GSCM aspects relevant to the United Arab Emirates (UAE) construction industry. A comprehensive understanding of the UAE construction sector is achieved through industry and government reports, published company annual reports and newsletters along with number of discussions with industry experts. The findings from the literature collated the various aspects of GSCM that is necessary for the implementation of GSCM for the UAE construction sector. The various GSCM aspects identified include factors that influence construction firms to implement GSCM practices (drivers), the various green supply chain stages for greening the construction sector, environmental, economic and operational benefits of GSCM and challenges faced by the sector in implementing GSCM. The rest of chapter discusses the various aspects of GSCM in detail.

POTENTIAL DRIVING FACTORS TO THE ADOPTION OF GREEN SUPPLY CHAIN MANAGEMENT (GSCM) IN THE UNITED ARAB EMIRATES (UAE)

Driving factors of GSCM adoption for firms include both internal and external factors.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Internal Drivers

Internal drivers are forces that arise within the organization. The various internal drivers in the adoption of GSCM are as follows;

Commitment to Improve Environmental Performance

Environmental performance is considered as a major agenda in the company policy Similar to corporate social responsibility, corporate environmental responsibility is considered by firms to reduce the adverse environmental impacts of their activities (Simpson et al., 2007). However, the extend of commitment depends on the environmental values of the founder or owner (Wycherley, 1999) and support and involvement of top management (Min & Galle, 2001).

Desire to Achieve Economic Benefits

Commitment to GSCM may not be driven by environmental responsibility or regulatory compliance. Increasing number for firms has identified it as a potential management strategy to achieve economic benefits. Previous studies have identified that green practices can lead to cost reduction and savings (Dhanda & Hill, 2005; Fassoula, 2005; Richey et al., 2005).

Improve Corporate Brand Image

Adopting GSCM can improve the corporate brand image resulting in increased market share by winning new projects (Francesco & Fabio, 2010). Recent studies show that firms are using GSCM as a springboard to reach environmental conscious customers (Faisal, 2012). Wycherley (1999) identified the benefits of improved corporate brand image in the case of Body Shop International, one of the early adopters of GSCM.

To Achieve Competitive Advantage

A proactive GSCM strategy can be used by firms to differentiate themselves from their competitors (Rao & Holt 2005). Competitive advantage can be in the form of cost reductions, preferential treatment and subsidies from government and for securing stakeholder approval in environmental projects (Faisal, 2012). To extend of competitive advantage will be more in the region where GSCM is still at infancy stage (Francesco & Fabio, 2010).

Improving Supply Chain Efficiency

In additional to improvement in cost reduction and brand image, organizations are prompted to implement GSCM practices to improve supply chain efficiency. Previous studies such as Lippman (2001) and Lee (2008) identified that adoption of GSCM practices leads to reduction in cycle time and cost, and improved quality. In addition, it can lead to decreased inventory level and improved capacity utilization (Zhu et al., 2005; Zhu et al., 2008).

Table 1 summarizes the various internal drivers of GSCM and its relevance to the United Arab Emirates (UAE) construction sector.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

External Drivers

External drivers are external pressures faced by the firms to implement GSCM. The various external drivers in the adoption of GSCM are as follows;

Government Regulation and Legislation

In GSCM, the role of government and legislation plays a vital role. This is considered as the mother of all drivers and leaves no option for a firm but to comply with it or exit the market. Numerous studies have identified government regulation and legislation as the main driver of GSCM (Beamon, 1999; Hall, 2001; Min & Galle, 2001; Zhu & Sarkis, 2006; Walker et al., 2008; Schneiderman; 2009),

Client Pressure

Environmental commitment of client/developer can drive firms to implement GSCM practices. For instance in the construction sector, environmental commitment of the developer can influence contractors, which in turn can influence sub-contractors and suppliers. Hence the pressure is typically exerted from top to bottom in the supply chain (Walton et al., 1998; Handfield et al., 1997; Hall, 2001). Similarly, studies have shown that large clients can influence small and medium stakeholders in the supply chain to implement GSCM practices (Chen, 2010; Lee, 2008).

Consumer Pressure

Consumer behaviour studies in 1990's found that consumers are increasingly aware of the environmental impact of the products they consume (Roberts, 1996). The individual consumer's belief that they can contribute to environmental causes have led to environmental purchases (Berry & Rondinelli, 1998; Buckholz, 1991). Berns et al. (2009) found that consumer concern about sustainability is a significant driver for firms to adopt GSCM. Lo & Leung (2000) identified the increasing environmental awareness of young customers.

Table 2 summarizes the various external drivers of GSCM and its relevance to the United Arab Emirates (UAE) construction sector.

Table 1. Internal drivers of GSCM relevant to UAE construction sector

Drivers of GSCM	Implications to UAE Construction Sector
1. Commitment to improve environmental performance	Incorporating sustainability strategy as a part of organizational strategy
2. Achieve economic benefits	Substantial opportunities to reduce construction costs through reduction in energy, water, materials and through waste management and recycling
3. Improve corporate brand image and hence winning new contacts.	Improve corporate brand image and hence attract foreign investments and buyers.
4. Proactive approach to achieve competitive advantage	Differentiation for companies in the highly competitive UAE construction market
5. Improving supply chain efficiency.	Improve construction productivity, reduce project time, improve quality in the fast paced UAE construction sector

Table 2. External drivers of GSCM relevant to UAE construction Industry

Drivers of GSCM	Implications to the UAE Construction Industry
1. Government regulation and legislation	Compliance to green design guidelines and regulation
2. Client pressure	To meet the environmental requirements in the tender documentation
3. Consumer Pressure	Customer desire for green buildings

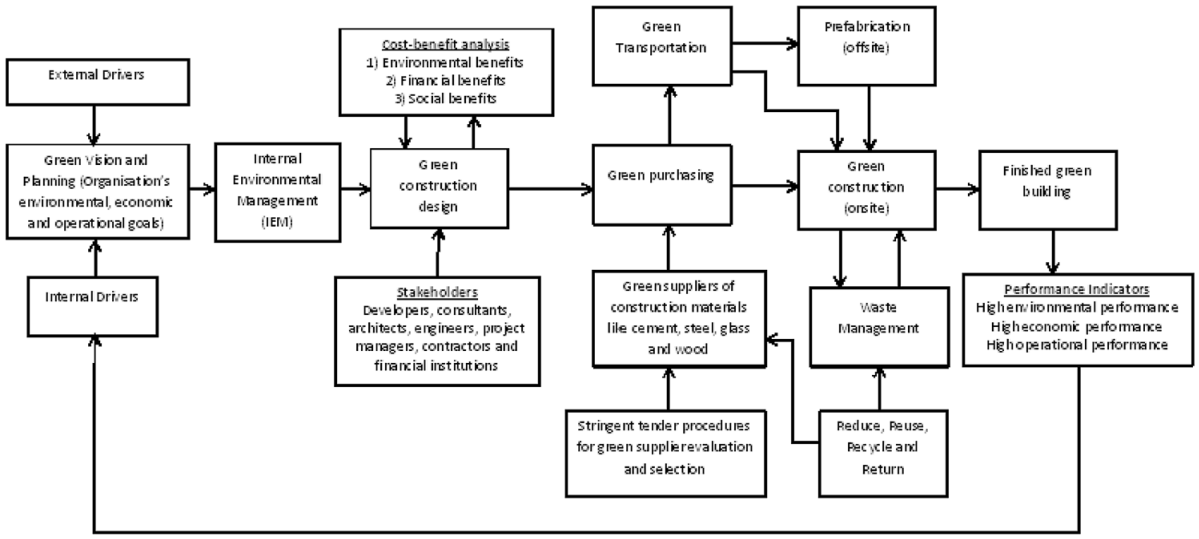
PROPOSED GREEN SUPPLY CHAIN MANGEMENT (GSCM) STAGES APPLICABLE TO THE UNITED ARAB EMIRATES (UAE) CONSTRUCTION INDUSTRY

Reduction in carbon emission can be achieved from all functional stages of the construction supply chain such as design, purchasing and construction. Therefore for greening the construction sector, it is necessary to green the various phases of the integrated supply chain. The proposed stages identified from the literature include green design, green purchasing, green distribution and green construction (offsite and onsite) and waste management. However, extend of implementation of these supply chain phases depends on the internal and external driving forces as explained in detail in the previous section. Depending on the influence of these drivers, GSCM strategy is adopted organizationally and is reflected in the firm's vision and mission. However, prior to implementation of supply chain practices such as green design and green construction, firms have to ensure they have the necessary internal environment such as environmental management systems (EMS) and ISO 14001 implementation to efficiently implement supply chain practices. Organizations also have to conduct cost benefit analysis on the benefits and costs associated with the implementation of GSCM practices. Performance measurement post implementation will enable organizations to re-assess the cost-benefit analysis for continuous improvement.

Figure 2 shows the designed green supply chain applicable to the United Arab Emirates (UAE) construction sector. Figure 2 is developed by integrating the various GSCM stages indentified from the literature to the UAE construction supply chain as identified in Figure 1.

The various GSCM practices are explained in detail in the following section.

Internal Environmental Management (IEM)



IEM is the practice of developing green supply chain management as a strategic organizational imperative through commitment and support from senior and mid-level managers (Zhu et al., 2008). IEM is a prerequisite for all the GSCM practices and should be part of the overall strategy for the successful implementation of GSCM practices (Murray, 2000). Earlier studies have also shown that management commitment to environmental strategy is necessary to implement GSCM (Byrne & Deeb, 1993; Klassen & McLaughlin, 1993). However, it was Zhu et al., (2008) who defined IEM and validated the factors with IEM.

The identified factors for IEM are:

- Cooperation, commitment and communication between top management, senior and middle managers for GSCM.
- Implementation of EMS and ISO14001 certification.

Figure 2. Green supply chain stages applicable to the UAE construction sector

- Environmental compliance auditing programs.
- Cross-functional integration for environmental improvement.

Green Design

Green design refers to environmental conscious design of products and services (Fiksel, 1996). It considers design issues associated with carbon emission, waste management and environmental pollutions. Srivastava (2007) identified life cycle analysis (LCA) is critical in green design concept. Green design includes low material consumption design, selection of environmentally friendly materials, and substitution of hazardous material (Gungor & Gupta, 1999; Tibben-Lembke, 2002). However recent literatures incorporate design of products for reuse and recycle (Zhu et al., 2008). Green-design requires that manufacturers design products that minimize consumption of materials and energy, that facilitate the reuse, recycle, and recovery of component materials and parts, and that avoids or reduces the use of hazardous products within the manufacturing process (Zhu et al., 2008).

Identified factors for green design are:

- Design of products for reduced consumption of material energy.
- Design of products for reuse, recycle, and recovery of material and/or component parts.
- Selection of environmentally-friendly raw materials with low embodied energy.
- Substitution of environmentally hazardous materials.

For the construction sector, implementing green building design requires attention from the conceptual stage of the building design. It could utilize innovative technology and architectural concepts to incorporate design features to reduce material use, promote low energy consumption materials, promote recycled materials such as recycled concrete, wood, steel and plastic, promote end of life recovery of materials, promote alternative source of energy like solar or wind energy, site selection for construction,

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

efficient floor space utilization, energy efficient lighting and cooling technology, reduction in the use of hazardous materials, use of onsite water and solid waste treatment, proper ventilation, promote usage of precast or offsite manufactured materials in controlled environment to reduce onsite construction etc. An effective green building design shall consider the construction phase, operational phase, maintenance and renovation phase and end of life demolition and recovery.

Some of the relevant practices in green building design are:

- Shape and orientation of the building.
- Reducing primary heat losses through the building envelope.
- Reduced cooling loads.
- Introducing energy saving measures and energy creation systems.

Green Purchasing

Green purchasing is important aspect of GSCM. It addresses the requirement of green design. Green purchasing in GSCM is more than mere supplier selection. It involves stringent supplier environmental assessment criteria, environmental audit of suppliers, information and knowledge sharing with suppliers such as trainings and seminars to develop their own environmental programs such as ISO 14001 to improve environmental performance of suppliers (Min & Galle, 1997; Rao, 2004; Rao & Holt, 2005; Zhu et al, 2005; 2007; 2008)

Identified practices in green purchasing relevant to the construction sector are:

- Suppliers environmental assessment as prequalification criteria.
- Guiding suppliers to set up their own environmental programs such as Suppliers' ISO14000 certification.
- Environmental audit for suppliers' internal management.
- Providing design specification to suppliers that include environmental specifications for purchases.
- Bringing together suppliers in the same industry to share their know-how and problems.
- Urging and pressuring suppliers to take environmental actions.
- Information and knowledge sharing to suppliers.

Construction firms in UAE should monitor and evaluate the environmental performance of suppliers. In addition, sharing design specifications to suppliers in advance and urging suppliers to consider environmental actions can improve the environmental performance of the supply chain. Construction firms can also cooperate with suppliers for the purpose of developing products that are environmentally sustainable.

Green Distribution

Green distribution typically consists of green packaging and green transportation. Both the factors are interconnected as green packaging have a direct impact on transportation. Green packaging involves reducing the size, shape and weight of packaging, and the use of environmentally friendly materials. It can be defined as a way to package products that minimizes impact to the environment (Kassaye, 2001).

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

In addition, green packaging is the easiest and foremost practice an organization can adopt in GSCM (Shi & Kane, 1996). By switching to green packaging, organizations will allow their products to gain public image (Kassaye, 2001). Ho et al. (2009) identified green packaging can reduce material usage, improve space utilization and reduce the handling time. Green transportation is the use of environmentally-friendly transportation system such as type and mode of transport such as sea, land and air transport and use of alternative fuel vehicles.

The identified factors for green distribution are:

- Reduced size of packaging.
- Use of environmental friendly packaging materials.
- Better shape for space utilization and handling.
- Use of environmentally friendly mode of transport options.
- Use of alternative fuel options.

Green Construction

Green construction means using sustainable principles and technology in the construction process such as cleaner technologies and automation in the construction process. The other green construction practices include on site usage of energy efficient vehicles and machineries, offsite fabrication of materials in a controlled environment to reduce construction waste and energy usage and use of project management techniques in the construction process to achieve efficiency in the construction process. In addition, having skilled labourers increases the efficiency of the construction process and enables reduction in construction waste. Further, practices such as onsite segregation of construction waste, re-use and recycling can further improve the performance of onsite construction.

Waste Management

It is an important aspect of GSCM. In the UK, construction and demolition waste contributed to 47.6 million tonnes in (UK Gov, 2010). In the US according to EPA (2003), 170 million tonnes of waste have been generated. The UAE is not far behind and is considered as the biggest producers of per capita construction waste in the world behind US. The construction industry in the UAE contributes to 75% of the total waste in the country (UAE Interact, 2007). The construction waste generated in the UAE in 2007 is 27.7 million tonnes compared to 10.6 million tonnes in 2006 (Alkhafaf, 2008). The figures indicates construction waste minimization is very important to reduce emissions and in promoting sustainable development. The Building Research Establishment (1978) defined waste as the 'difference between material ordered and those placed for fixing on building projects'. However waste generation from construction activities is much complex and therefore understanding the source of waste is important to minimize it. Research by (Rounce, 1998; Ekanayake & Ofori, 2000; Keys et al., 2000; Ekanayake & Ofori, 2004; El-Sayegh, 2008) identified improper design as the major cause of construction waste. The labour intensive nature of the construction activity implies, unskilled labourers employed in the construction contribute to excessive waste generation. Lingard et al. (2000) defined the origins of construction waste as procurement, handling, operations and culture.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

GREEN PERFORMANCE MEASURES

GSCM management strives to achieve environmental, economic and operational performance. Although environmental performance is the important aspect of GSCM, the latter two are equally important to achieve business performance and act as intrinsic motivators for firms for adopting GSCM and to stay competitive in the industry. However in most cases, the extend of environmental, economic and operational performance achieved is not measured. Hence, performance measurement is an important aspect of GSCM for continuous improvement, to justify investment in GSCM, to publish the measures in annual reports and to benchmark with peers and industry average.

Environmental Performance Measures

Zhu et al. (2008) defined environmental performance in GSCM as the ability to reduce air emissions, effluent waste, and solid wastes and the ability to decrease consumption of hazardous and toxic materials. The key environmental performance indicators relevant to construction sector identified from the literature and its implication to United Arab Emirates (UAE) construction sector are given in Table 3.

Economic Performance

Economic performance is important for organizations adopting GSCM. From a management perspective, economic performance represents yield of the profit. For evaluating economic performance in GSCM, this study identified direct benefits such as the decrease of cost for energy consumption, material purchasing, waste treatment, and waste disposal (Zhu et al., 2007; 2008). However, GSCM economic performance also include indirect long term benefits such as new market opportunities, increase product price, increased profit margin, increased sales and market share and improved corporate image (Rao, 2002; Rao & Holt, 2005). The key environmental performance indicators and its implication to UAE construction sector are given in Table 4.

Table 3. Environmental performance measures relevant to UAE construction industry

Environmental Performance	Implications to UAE Construction Industry
1. Reduction in energy consumption	Reduction in electricity consumption, reduction in fuel consumption, reduction in embodied energy of materials etc.
2. Reduction in raw materials	Reduction in raw material consumption such as steel, glass, cement etc.
3. Reduction in solid and effluent waste	Reduction in solid and effluent waste during construction site preparation and onsite construction activities.
4. Reduction in air emissions	Reduction in greenhouse gas emission (GHG) due to onsite construction activities and transportation
5. Reduction in water consumptions	Reduction in water consumption during the construction process
6. Reduction in consumption of hazardous/harmful/toxic materials	Reduction in the use of hazardous materials like lead and sulphate based paints and adhesives
7. Decrease in frequency of environmental accidents	Reduction in environmental accidents like fire, breakage of underground pipes, leakage of hazardous materials etc.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Operational Performance

Operational performance is the foundation of the traditional supply chain. It is imperative that GSCM adoption should not compromise the operational performance of the supply chain. Operational performance of GSCM is identical to operational performance measurement of any supply chain and includes overall efficiency of the supply chain, quality improvement, productivity improvement and asset utilization. Studies by (Ru-Jen et al., 2011; Sang et al., 2012) indicates GSCM can improve cycle time and reduce project duration along with increase in value to customer. The key operational performance indicators are given in Table 5.

POTENTIAL GREEN SUPPLY CHAIN MANAGEMENT (GSCM) CHALLENGES PERCEIVED BY THE CONSTRUCTION INDUSTRY IN THE UNITED ARAB EMIRATES (UAE)

Although there are factors prompting organizations to adopt GSCM, the implementation of GSCM is not easy as firms have to overcome number of challenges. The challenges would be much higher for developing economies like UAE, where GSCM is still at infancy stage. Identifying and overcoming the challenges are key for the sector to overcome the status quo and to implement GSCM. Similar to drivers, challenges faced by firms can be classified as internal and external challenges.

Internal Challenges

Internal challenges are challenges faced within the organization. The identified internal challenges relevant to the construction sector are;

Table 4. Economic performance measures relevant to UAE construction industry

Economic Performance	Implications to UAE Construction Industry
1. Increase in sales and market share	Increase in the sales of green building projects, Increase in market share through entry to new foreign markets and new environmental conscious buyers.
2. Increase in product price	Higher rent or selling price for buildings
3. Increase in profit margin	Overall increase in profit from green projects.
5. Cost savings - Decrease of cost for energy consumption - Decrease of fee for waste treatment - Decrease of fee for waste discharge - Decrease of fine for environmental accidents - Decrease of cost for materials purchasing	Overall reduction in cost in the construction supply chain through reduction in energy, material consumption and waste. Reduction in fines from environmental accidents.

Table 5. Operational performance measures relevant to UAE construction industry

Operational Performance	Implications to UAE Construction Industry
1. Improvement in overall efficiency of the supply chain	Measuring the improvement in the overall efficiency of the construction supply chain
2. Improvement in quality	Improvement in the quality of the construction process
3. Improvement in productivity	Improvement in the productivity of the construction process
4. Improvement in cycle time	Reduction in transportation time for inbound and outbound logistics
5. Reduction in project completion time	Reduction in the construction project handover time.
6. Increased value to customer	Return on investments for the customer through reduced operational cost, reduction, improved indoor air quality, improved safety etc.
7. Improved asset utilization	Optimization of construction resources, reduction in inventory etc.

Source: Rao (2002), Rao and Holt (2005), Ru-Jen et al. (2011), Sang et al. (2012)

Lack of Knowledge, Training, and Awareness of GSCM

Studies have acknowledged that lack of knowledge and training (Cooper et al., 2000; Bowen et al., 2001), lack of experience (Yu Lin & Hui, 2008) are all important challenges to overcome for the adoption of GSCM. Rettab and Ben (2008) identified lack of knowledge as the primary inhibitor of organizations in UAE for adopting GSCM. Balasubramanian (2012) identified lack of knowledge and experience as an important inhibitor for GSCM in the UAE construction industry.

Lack of Top Management Commitment

Lack of top management support and commitment is one of the main challenges of GSCM. Zhu and Sarkis (2007) identified the importance of top management in the implementation of GSCM practices. Similarly, Ravi & Shankar (2005) mentioned the importance of continuous support from top management for organization wide implementation of GSCM strategy. Balasubramanian (2012) identified lack of top management support as one of the challenges faced by the UAE construction sector.

Fear of High Initial Investment

Many organizations carry the conception that huge investment is required for implementing GSCM practices. In addition, companies are aware for the fact that implementation of GSCM will not deliver immediate financial benefits, and hence many companies are reluctant to invest on GSCM (Nidumolu et al., 2009). For instance, green materials tend to be more expensive and increase the product's overall cost (Koplin et al, 2007; Hoffman, 2008). Several studies have identified high cost as the major challenge faced by organizations (Min & Galle, 2001; Alkhidir & Zailani, 2009).

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Lack of Environmental Management Systems, ISO 14001, and Information Technology

An efficient environmental management system (EMS) is necessary for implementing GSCM. EMS promotes communication and knowledge sharing between clients, designers, suppliers and contractors. Balasubramanian (2012) identified lack of EMS leads to lack of understanding among stakeholders. EMS certified with ISO 14001 is very important for firms moving towards sustainability. Toshi et al. (2011) identified a positive relationship between Japanese firm's ISO 14001 certification and GSCM practices and found that ISO 14001 significantly promotes GSCM activities. Studies have found that it is difficult to implement GSCM without a proper environmental management system (Stevels, 2002). Similarly, information technology supports collaborative supply chain processes and enhances supply chain performance (Rogers et al., 1998). An advanced information and technology system is necessary for supporting the GSCM during various stages of product life cycle. It can be useful for product development programs encompassing the design for environment, recovery and reuse. Efficient information systems are needed for tracking and tracing the returns of product, linking with the previous sales (Ravi & Shankar, 2005). It is required to handle information's flows associated with both forward and backward flow of materials and other resources to manage green supply chain efficiently (AlKhidir & Zailani, 2009). Construction sector being traditionally a backward industry with poor IT infrastructure vis-à-vis other sectors, is one of the reasons for its poor environmental performance.

Lack of Sustainable Organizational Culture

Sustainable culture within the organisation is important for GSCM. Long term sustainable vision, informal and improved internal communication enable organizations to adopt green practices (Yu Lin & Hui Ho, 2008). Training and awareness are important for achieving successful implementation of GSCM in any organization (Ravi & Shankar, 2005). Management may encourage employees to learn green information and may provide rewards for green employees (Hsu & Hu, 2008). This is relevant for the UAE construction sector, considering the fact that UAE is relatively new to the concept of green.

Resistance to Change

Adopting and implementing GSCM involves change in the normal business processes, re-aligning the responsibilities, learning new technologies like ISO 14001, etc. Organizations and employees resist these changes and new technology adoption. Previous studies have identified in their research 'resistance to change' as a major challenge for environmental innovation such as GSCM (Hosseini, 2007; Hsu et al., 2008; Digalwar et al., 2004). The identified internal challenges and its relevance to the UAE constructions sector are provided in Table 6.

Table 6 summarizes the various internal challenges of GSCM and its implication to the UAE construction industry.

External Challenges

External challenges are outside industry challenges faced by the organization. The identified external challenges relevant to the construction sector are;

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 6. Internal GSCM challenges relevant to UAE construction sector

Internal Challenges of GSCM	Implications to UAE Construction Industry
1. Lack of knowledge and awareness of GSCM	Government and the industry should conduct GSCM trainings and awareness sessions, conferences and seminars to improve knowledge and awareness of stakeholders in the construction
2. Lack of top management commitment	Government and the industry should recognize leaders in GSCM and would encourage GSCM commitment among other industry leaders
3. Fear of high investment cost.	Perceived high initial investment in the construction sector for green practices
5. Lack of EMS and IT infrastructure	Government regulations and leading clients should make it mandatory for all construction firms to implement EMS and to have a standard IT infrastructure requirements
7. Lack of sustainable organizational culture	Top management and HR department should create a sustainable culture to adopt the concept of GSCM at all employee levels

Lack of Government Support

Lack of government support can hinder the adoption of GSCM. There is increasing need for government to provide industry friendly policies to promote GSCM rather than mandating firms to adopt GSCM. Government should facilitate a win-win situation of GSCM adopters by providing incentives, preferential treatment, best practices awards, and recognition for sustainable leaders and organizations. Lack of these can discourage firms in adopting GSCM. Presently in the UAE construction sector there is little support from government. Numerous studies have highlighted the importance for government support for GSCM (Hosseini, 2007; Hsu et al., 2008; Mudgal et al., 2009; Mudgal et al., 2010; Srivastava, 2007)

Lack of Skilled Professionals

GSCM requires skilled professionals both inside the organization as well as throughout the supply chain. Skilled professionals can adapt to the changes quickly, learn new technologies, share ideas and solve environmental problems (Yu Lin & Hui Ho, 2008). Balasubramanian (2012) identified lack of skilled professionals as an important inhibitor of GSCM in the UAE construction sector.

Lack of Trust and Commitment of Suppliers

Trust and commitment of suppliers play an important role in GSCM. Previous studies have identified lack of commitment and trust as the major challenges facing firms to implement GSCM practices (Wycherley, 1999; Walker et al., 2008). Lack of trust and commitment of suppliers is also a challenge for the construction sector, because of the one off nature of the construction projects.

Perceived Lack of Demand for Sustainable Solutions

Customers demand for low prices. Considering the financial crisis of 2008 and afterwards, there is lack of demand for sustainable solutions as customer are not willing to pay more for sustainable solutions. Orsato (2006) identified customer desire for low prices can lead to lack of sustainable practices. Bala-

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

subramanian (2012) identified the lack of demand as a major inhibitor to the adoption of GSCM in the UAE construction sector.

Table 7 summarizes the various external challenges of GSCM and its implication to the UAE construction industry.

The various aspects of GSCM relevant to the construction sector is discussed. Although, more empirical investigation is required to obtain more insights on the various aspects discussed, the chapter provides an initial investigation into the potential GSCM aspects that is relevant for the UAE construction sector.

KEY TAKE AWAY POINTS FOR PRACTITIONERS

The following questions are important for practitioners while implementing GSCM.

Does Adoption of GSCM Improve Economic Performance?

The social responsibility of any business is to be profitable. Economic performance is important for organizations to sustain in the competitive environment. Before adopting GSCM, organizations much do a cost-benefit analysis to understand the financial benefits of GSCM along with achieving environmental and operational benefits. Analysis such as life cycle assessment (LCA), total cost of ownership (TCO) etc. are key to the implementation of GSCM. If the answer is 'Yes' then it's a win-win situation for the environment and business. Most cases organizations having sustainable vision often settle for trade-off between environmental and economic performance.

Is Profitability the Only Concern of SCM?

This may be the case in the past; however the present and future supply chain needs to fulfil the requirements or regulations of governments, NGO or sometimes customers. So achieving environmental performance and social performance is important to sustain business. So organizations need to implement environmental measures to stay competitive in the business, hence profitability is not the only concern of SCM. Implementing GSCM is no longer an option but a must in the future.

Table 7. External GSCM challenges relevant to UAE construction sector

Internal Challenges of GSCM	Implications to UAE Construction Industry
1. Lack of government support.	Government should provide support in the form of preferential treatment, incentives, subsidies and best practices award to encourage adoption of GSCM
2. Lack of skilled professionals.	Organizations should attract skilled green professionals from around the world and retain them to implement GSCM
3.Lack of trust and commitment of suppliers	Construction stakeholders should focus on having long term relationships with suppliers
4. Perceived lack of demand for sustainable solutions.	Construction industry should clearly articulate the benefits of green buildings and hence customers will be willing to pay higher for green buildings

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Are You Measuring the Environmental, Economic, and Operational Performance of the Supply Chain?

Measuring the performance of the supply chain is important in closing the loop of the supply chain. Implementing GSCM is a continuous process and it requires performance measures to understand the weak links in the supply chain in order to improve the performance. Key performance indicators are important for the successful implementation of GSCM. Green balanced score measures would probably an alternative method organisation can use to measure their Return on Assets (ROA).

Which Organizational Strategy Would You Choose? Proactive or Reactive Strategy?

Proactive organizations will have strong sustainable vision with environmental leaders having the confidence to adopt GSCM. These organizations often have strong financial and human resource capabilities. Proactive organizations will try to achieve first mover benefits, preferential treatment and government incentives and also try to improve the operational efficiency of the supply chain. Hence these companies have long term vision to improve their economic and environmental performance. They will also incorporate necessary internal environmental management changes to implement GSCM practices.

Reactive organizations respond to government rules and regulations, compliance to client specifications, stakeholder pressure and competition to improve their environmental performance. The implement GSCM to achieve minimum compliance with no long term vision. From a government perspective, a balance should be kept to promote proactive GSCM practices such as incentives and subsidies and at the same time tighten the rules and regulations to ensure organizations consider GSCM in their organizational strategy.

For implementing GSCM, integrating GSCM practices with construction industry practices is the best way to move forward. Similarly different industry requires different GSCM approaches. All the stakeholders should be incorporated and study should focus on the end to end supply chain.

CONCLUSION

As the construction sector grows, we are depleting more and more natural resources and in the process harming the environment. It is important that we look into sustainable management practices such as GSCM to reduce the environment impact of the construction sector. Considering the fact that GSCM in construction is still at infancy, present study will significantly contribute to filling the knowledge gap of GSCM in the United Arab Emirates (UAE) constructions sector and for construction sector in general. Some of the significant contributions of the study include identifying the potential drivers and challenges faced by the construction industry in the UAE and in general for implementing GSCM. The various stages in the supply chain for reducing the environmental impacts is identified such as design, purchasing, transportation and onsite and offsite construction. The importance of having an internal environmental management (IEM) for implementing GSCM is identified. Finally, performance measures namely environmental, economic and operational is identified to assess the performance improvement post GSCM implementation. However, considering the fact that present study is largely derived from the literature, the various aspects identified are more indicative than conclusive. Hence, more studies

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

and empirical research is required to validate the various aspects identified in the study. Future studies can also focus on identifying the difference in GSCM implementation among the various construction stakeholders such as developers, consultants, architects, main contractor, subcontractor, and suppliers. Stakeholder analysis is important to ensure all stakeholders are coherent in implementing GSCM. Further, future studies can use case studies on large companies that have implemented GSCM practices to find evidence on the improvement in performance. Such empirical evidence is critical for imparting confidence among construction stakeholders to engage in GSCM.

Chapter 65
Evaluation of Financial and Economic Effects on Green Supply Chain Management With Multi-Criteria Decision-Making Approach:
Evidence From Companies Listed in BIST

ABSTRACT

This chapter aims to analyze the financial and economic effects on green supply chain management of the food and beverages industry. For the research purpose, the fuzzy DEMATEL and fuzzy MOORA methods are used for the integrated model construction. The main stages of the green supply chain are considered as the dimensions and the selected performance measures are listed as a set of criteria for each dimension. Accordingly, 21 food and beverage companies listed in Istanbul Stock Exchange (BIST) are employed to measure the performance of green supply chain processes. It is concluded that low pollution is the most important criterion whereas alternatives has the least weight. Reverse logistic is also second most significant criterion which means that these companies give importance to reduce their costs. It is also found out that there is not a certain correlation between green supply chain management performances with the profitability of the firms. However, it can be seen that bigger firms have higher green supply chain management performance than the smaller firms.

INTRODUCTION

The interconnectedness of customer satisfaction and firm performance make green supply chain management (GSCM) as one of the most discussed and analyzed topics during the last decade. The foremost reasons behind the popularity of GSCM are the increase in the environmental awareness (Sari, 2017), the share of logistic costs in the finished products (Nikbakhsh, 2009), meeting stakeholder needs (Srivastava, 2007) and social sustainability (Fahimnia et. al., 2015). Also, these motives refer to the driving forces to adopt GSCM practices for competitive superiority. Moreover for firms, institutional pressures like ISO4001 certification indicate environmental management as a strategic issue for both economic and environmental performance (Diabat and Govindan, 2011). Thereby, greening through environmental standards is a factor of market success (Min and Galle, 1997) by enhancing competitiveness, resource productivity and innovation (Porter and van der Linde, 1995).

Through globalization, firms' coordination in the supply chains turns out to be the most critical business success factor (Lambert et. al., 1998). As a consequence, the management philosophy that starts with logistics management evolving to GSCM is an outcome of global markets and "globalization of supply" (Mentzer et. al., 2001:2). Besides globalization of supply, GSCM develops for predicting, minimizing and preventing environmental harms given by supply chain operations (Beamon, 1999; Sari, 2017). Thereby as an attempt to form an ecological nature for an organization, green supply chains (GSC) refers to "developed and advanced form of traditional supply chains with a special aim of reducing the environmental harm given during a product's life cycle" (Mishra et.al, 2017:86). Parallel to these, GSCM comprises elements of both corporate environmental management and supply chain management (Srivastava, 2007; Laari et. al., 2017). In line with this thinking, GSCM consists of numerous R activities (e.g. reduce, re-use, and recycle) (Sirvastara, 2007). These R activities provide firms to coordinate their purchasing, production and distribution processes in an environmentally-friendly manner for a better economic, ecological, operational, and social performance (Geng et. al., 2017).

Therefore, it is of paramount importance to determine the key factors of GSCM and measure GSCM performance in terms of these components. Concordantly, the current study aims (1) to present a literature review of determinants of GSCM, (2) to examine key components of green supply chain management and develop a multidimensional model for GSCM performance (3) to test the model through fuzzy-based decision making methodology, (4) to show which dimensions and criteria are more critical for a sustainable GSCM performance (5) help decision makers and researchers develop appropriate guidelines for GSCM success.

In line with these given aims, the paper continues with relevant literature on GSCM, its dimensions and its effects on firm performance. Following literature, the research methodology and the application of this methodology on 21 Food and Beverage companies listed in Istanbul Stock Exchange is discussed. Finally, the findings together with future implications are given.

THEORETICAL BACKGROUND

Supply Chain Management

As a management philosophy, supply chain management (SCM) has evolved from logistics management with a claim to enlarge the boundaries of the traditional understanding of logistics. Standing from this

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

stance, SCM is defined by the Council of Logistics Management in 1986 as "the process of planning, implementing, and controlling the efficient, cost-effective flow and storage of raw materials, in-process inventory, finished goods, and related information flow from point-of-origin to point-of-consumption for the purpose of conforming to customer requirements" (Lambert and Cooper, 2000:67). The definition of the Council of Logistics Management directs two important points. The first is to incorporate business operations with the support of external firms in the supply chain and the second is to involve customers to these operations for an understanding of customer needs (Cooper et. al., 1997).

Besides being a management philosophy, the supply chain is also evaluated as a process through which the flow of information starts from suppliers and ends with customers. Parallel to this approach, a supply chain is the dynamic network of firms that exchanges information, money or materials for production (Jain et. al., 2009) and as a network of firms, a supply chain generally includes suppliers, manufacturers, distributors, retailers and customers. Thereby, the main objective of supply chain management (SCM) "is to provide right product to the right customers at the right cost, right time, right quality, right form and right quantity" (Chin et. al., 2015). Also managing the supply chain includes integrating "key business processes from end-user through original suppliers that provide products, services, and information that add value for customers and other stakeholders" (Lambert et. al., 1998).

Similarly to successfully implement SCM, all firms in the chain are to be interconnected by embracing a process approach and organizing functions as key processes for their operations (Lambert et. al., 1998). More to that, SCM that designs each key process to meet customer requirements aims to minimize costs, enhance customer satisfaction and have a competitive advantage (Mentzer et. al., 2001). To reach these objectives, the perspective of being "green" has recently added to the activities of SCM. Therefore, procurement, manufacturing, distribution and logistics activities are reorganized and extended with an environmentally-conscious attitude.

Green Supply Chain Management

GSCM can be defined as "the sum of green purchasing, green manufacturing and material management, green distribution and marketing, and reverse logistics" (Mishra et. al. 2017: 86). As the definition clearly points out GSCM combines economic, social and environmental goals within its scope (Kafa et. al. 2013). One of the critical key terms for GSCM success is sustainability (Dubey et. al., 2015) and hence, being green is mostly associated with being "sustainable" (Baines et. al., 2012). The business sustainability covers meeting current and future economic, social and environmental demands in a proactive manner for future success. That's to say, being sustainable means that operations are conducted regarding current and future needs of people and nature. Concordantly, the sustainability vision is mentioned within Triple Bottom Line (3BL) framework that determines "organizational and societal success through the three Ps of people, planet and profit" (Baines et. al., 2012:60).

Generally, firms adopt GSCM practices in three manners (Agi and Nishant, 2017). The first one is related with market based pressures and includes adopting voluntary proactive strategies to improve corporate brand, meet environmental regulations, influence customers and hence to have a competitive superiority over others in the market (Agi and Nishant, 2017). The second is associated with legal, governmental regulations set for environment. And the third manner emerges as a result of customer or supply chain partners' needs for environment sensitive products or processes.

For being sustainable, GSCM covers all business partners and GSCM efficiency can't be attained only to the lead company. In line with this, GSCM is to form the synergetic bond between partners and

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

has to assure all partners' success together with increased environmental/economic performance and competitiveness (Rao and Holt, 2005). Therefore, to keep their business operations green, each partner in the chain has to be aware that GSCM practices would enhance their economic performance. The reducing costs, increasing profits and the synergetic cooperation of suppliers in decision making processes are the main drivers for adopting GSCM practices in the chain (Rao and Holt, 2005).

Additionally, numerous studies point out that adopting GSCM practices positively influences performance of companies. For instance, better environmental and operational performance is achieved if green perspective is carried on from production to recycling (Jabbour et. al., 2015). Environmental performance is an outcome of environmental management (Albertini, 2015), while operational performance is the degree to meet customer needs. Current consumers are becoming more environmentally conscious and more inclined to buy environmentally-friendly products. Within this framework, GSCM practices influence consumers' approach to the firm and its products; and in return increase the firm's competitiveness and economic performance (Andiç et. al., 2012). Consequently, making the supply chain "green" reduces the harms given to the environment, and affirms the environmentally-friendly image that can respond to the needs of today's environmentally concerned consumers.

Determinants of Green Supply Chain Management

Researchers have given remarkable attention to determine the main elements of GSCM. The first thing to be noticed in the related literature is that much of the studies categorize determinants of GSCM as internal and external factors (Sarkis, 2003). Internal GSCM practices refer to firm's environmentally-friendly activities (Azevedo et. al., 2011). On the other hand, external elements take a strategic stance because organizations act based on actors and changes in their environment (Mintzberg, 1994). From the perspective of GSCM, partners in the supply chain and the level of greenness in their operations come to the fore as critical factors of GSCM success. External GSCM activities also include environmental monitoring and environmental collaboration (Vachon and Klassen, 2006). Environmental monitoring is related with supplier and material selection; whereas environmental collaboration is associated with helping suppliers' to develop their environmental qualifications (Vachon and Klassen, 2006). More to that, institutional norms (Zhu et. al. 2007; Sarkis et. al. 2011) like governmental regulations and customer requirements (Laosirihongthong et. al., 2013) can be regarded as other significant external elements for adopting GSCM practices. To the numerous studies, influence of institutional pressures is closely related with market dynamics and governmental regulations (Srivastava, 2007; Laosirihongthong et. al., 2013). A proper example can be the widely adoption of ISO 14001 because of customer pressure (Vachon 2007).

To prove these forces empirically, numerous studies are conducted. For instance, Laosirihongthong et. al. (2013) proved that legislation and regulation is the most important driving force for GSCM implementation by Thai manufacturers. On the other hand besides government regulations, Kafa et. al. (2013) determine stakeholder pressures, economic interests, and ecological interests of firms as important forces of GSCM practices. Among the studies on GSCM performance factors, Sarkis (2003) takes product life cycle, operational life cycle, performance measures, and environmentally influential organizational policy elements for GSCM achievement. Moreover, Sarkis (2003) also highlights the importance of combining organizational processes like reduce or reuse both with all the supply chain activities and the product life cycle. Similarly, Zhu and Sarkis (2004) determine internal environmental management, external GSCM, investment recovery, and eco-design as critical GSCM practices to have a sustainable environmental and economic performance. Following that studies, Zhu et. al. (2008) analyze variables

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

to measure GSCM practices as internal environmental management, green purchasing, eco-design, cooperation with customers and investment recovery.

In their study on the critical factors influencing the adoption of GSC practices in Chinese firms, Lin and Ho (2011) classify the determinants of GSCM as technological, organizational and environmental. The technological factors include "relative advantage, compatibility, complexity", organizational factors are "organizational supports, quality human resources, company size" and "customer pressures, regulatory pressures, government supports, environmental uncertainty" are the environmental factors (2011:69). Following Lin and Ho (2011), Kuei et. al. (2015) also show evidence that relative advantage, quality of human resources, and customer pressure are positively related to the green practice adoption for focal firms; on the other hand, customer demands, and regulation are significant factors for sustainability for upstream firms.

A recent study by Dubey et. al. (2015:74-5) lists these factors as enablers of GSCM: a. total quality management implementations, b. a strong supplier relationship management with a focus on being 'cleaner' and 'greener" c. green technology adoption for efficiency in GSCM processes, d. institutional pressures such as ISO 14001 certification, e. top management commitment and practices for green supply chain, f. reduction in carbon emissions (RCE) for a better environmental performance, g. customer relationship management managing for sustainability, h. increase in market share as a symbol for customer loyalty and i. increase in profitability as a result of "focus on R's as reduction, reuse, reselling, repair, recycling, and reverse logistics".

Along with these studies, Wu and Chang (2015) focus on dimensions of supplier management, product recycling, organization involvement and life cycle management through a case study conducted on electrical and electronic industries in Taiwan. The study results show that organization involvement dimension that includes factors as green design, top management support, environmental policy, cross-function integration, manpower involvement, effective communication platform within companies and with suppliers, establishing an environmental risk management system for GSCM, supplier evaluation and selection is the most critical dimension in GSCM. Among these factors, top management support and environmental policy for GSCM are found out to be the two critical factors in organization involvement.

Questioning the factors for implementing GSCM practices, Agi and Nashart (2017) specify 19 factors and categorize these 19 factors into two groups as organizational factors and inter-organizational factors. Organizational factors refer to structural features, organizational processes and activities (e.g. use of information technology, capabilities of purchasing department, size of the company, functional integration, top management commitment, employees' education and training), while inter-organizational factors represent the relationships, activities and processes in the supply chain (e.g. cooperation and support from SC partners, information and knowledge sharing with SC partners, assessing and monitoring supplier performance and practicing supplier selection, trustful relationships with SC partners).

Besides these studies, it can be stated that GSCM covers many operational dimensions extending traditional supply chain management with an environmental perspective through material selection, manufacturing processes, delivery of the products including reverse logistics, and the recovery of the product by recycling or res-using after it concludes its life cycle (Srivastava, 2007). All these processes are interrelated and work in accordance for improved GSCM performance. For instance, selection process is closely related with recovery process as selection of an environmentally-friendly material would also refer that this material would easily be recycled (Mishra et. al., 2012). Following previous studies, the current research's dimensions and criteria based on GSCM functions can be seen at Table 1.

Table 1. Proposed dimensions and criteria of green supply chain management

Dimensions	Criteria	Supported Literature
Material Selection	**Sustainability**	Almeida et. al. (2017), Zhu and He (2017), Min and Galle (1997), Rao and Holt (2005), Zhang et. al. (2017)
	Low Pollution	Franzoni (2011), Khoshnava et. al. (2016), Sun et. al. (2017)
Manufacturing	**Reduced Energy**	Bhattacharya et. al. (2015), Tao et. al. (2016), Kucukvar et. al. (2016), Hsu et. al. (2013)
	Clean Technology	Klassen and Whybark, (1999), Vachon (2007), Baines et. al. (2012)
	Reduce Waste	Harveni et. al. (2005), Deif (2011), Islam et. al. (2017)
Distribution	**Combined Transport**	Bukold (1993), Jensen et. al. (2001), Jensen (2008), Martinsen and Björklund (2012)
	Alternatives	Onat et. al. (2015), Mierlo et. al. (2017), Doll et. al. (2017)
	Reverse Logistics	Sarkis (2003), New and Westbrook (2004), Wells and Seitz, (2005), Mishra et. al. (2012), Ayvaz et. al. (2015)
Recovery	**Recycling**	Johnson and Wang (1995), Mishra et. al. (2012), Misni and Lee (2017)
	Reuse	Thierry et. al. (1995), Kriwet et. al. (1995), Ferrer (1997), Krikke et. al. (1999)

The details of the dimensions will be explained in the following sections together with a discussion on the application of Turkish food and beverages firms listed in Istanbul Stock Exchange.

DECISION MAKING IN GSCM

Material Selection

Ecologically responsive material selection, also called as sustainable material selection (Zhang et. al., 2017), aims to select suitable materials for a product to reduce environmental damages given in operations (Tao et. al. 2016). GSCM literature points out product design and product life-cycle as two significant factors related with the material selection and production process (Srivastava, 2007). The use of resources, production style, transportation and distribution of products can differ through their life cycles. From the GSCM point of view, life-cycle evaluation is critical as it includes the decision-making process related with which materials to be used at the beginning of the production process to the disposal or recycle processes (Almeida, 2017; Srivastava, 2007; Akkucuk, 2016).

Business sustainability refers to administrating business operations with the concern for well-being of society, economy and environment (Hassini et. al., 2012). From the perspective of sustainability, purchasing green material would enhance the reduction of waste material (Rao and Holt, 2005) and hence firms are developing environment oriented purchasing strategies to supply their materials from partners that would produce environmentally-friendly materials (Min and Galle, 1997). Therefore, through adopting a proactive approach at the product design by design environmentally-friendly products would inhibit most of the harm a product can give to the environment (Büyüközkan and Çifci, 2012). Moreover at the beginning of purchasing, firms should consider the disposal of given materials for minimizing waste and hazardous material (Walker et. al., 2008). For instance, firms like Coca-Cola, PepsiCo adopted green packaging programs by introducing recyclable and reusable packages (Min and Galle, 1997). Thereby,

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

it is of paramount importance for firms to take environment into consideration when buying materials and designing packaging (Min and Galle, 1997). More to these, selecting the appropriate material would help to take precautions against climate change and pollution. For instance, especially for the construction firms, selecting green materials would minimize the indoor pollution which can influence the life quality to a highest degree (Franzoni, 2011; Khoshnava et. al., 2016; Sun et. al., 2017).

Manufacturing

The main reasons behind adopting environmentally sensitive manufacturing are to enhance production efficiency, to reduce pollution or carbon footprint through advanced technologies and to conform to national or international legislations (Bhattacharya et. al., 2015). In line with these targets, the clean (sometimes called as lean) manufacturing can be described as "a modern manufacturing mode that takes into consideration resource consumption and the environmental impact" (He et. al. 2007). Manufacturing, itself, is a waste generation process and hereby greening the manufacturing is to minimize or to eliminate every kind of waste (Hervani et. al. 2005; Akkucuk, 2015). Moreover, energy consumption is one of the biggest concerns for production processes and sustainable manufacturing refers to low-carbon and efficient use of energy (Kucukvar et. al., 201&). Using renewable energy like biomass or hydropower power instead of fossil fuels can be an example in this context to increase the sustainability, reduce the energy and carbon emissions and thereby reduce the total costs.

The main purpose of a cleaner production is to have sustainable development by minimizing the hazardous effects on the environment. From this perspective, the classical perspective to green manufacturing was to minimize pollution through pollution control technologies through 70s (Baines et. al., 2012). In the following decade, a more proactive approach was adopted through clean technologies that focus on efficient use of energy through resource control at the source (Vachon, 2007). Therefore, to minimize the use of energy and other resource consumption through using clean technologies requires a proactive manufacturing approach. Thereby, this approach consists of production processes with little or no waste or pollution through less resource consumption and less cost (Deif, 2011). Environmentally- friendly manufacturing also includes re-manufacturing and lean manufacturing with a target of minimizing wastes and environmental pollution through using clean technologies and not using hazardous materials during manufacturing (Islam et. al., 2017).

Distribution

Distribution refers to packaging, transportation and logistics activities (Rao and Holt, 2005). For greening distribution, firms can redesign their logistic network and plan the network for ecological development (Wu and Dunn, 1995). The main concerns for green distribution is to "reduce transportation costs and the amount of CO_2 emissions, product distribution time from manufacturers to retailers of products and to increase the levels of delivery rate" for customer satisfaction and sustainable development (Mohammed and Wang, 2017).Thereby, environmentally-responsible logistics refers to "fewer movements, less material handling, shorter travel distances, more direct deliveries and better space utilization" (Kim and Min, 2011). Also, route planning, fuel reduction (Mishra et. al., 2012), fewer transports, better space utilization (Sarkis, 1999) are among the factors for planning transportation, storage and inventory or material handling with decreased costs.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Transportation in the supply chain has been the process with the highest impacts on the environment (Wu and Dunn, 1995; Pazirandeh and Jafari, 2013) as it is accountable for up to 30% of global greenhouse gases due to excessive use of fossil fuels (Doll et. al., 2017). From the perspective of GSCM, logistics managers can plan transportation routes and modes in order to have fewer trips and use less fossil fuels from a variety of distribution options. For instance, to minimize the carbon emissions released alternative transportation modes are being used (e.g. using rail and shipping inland waterway transport (IWT) and short sear shipping (SSS) instead of road (Doll et. al., 2017). Further, using bio fuels and renewable energy, modern vehicles with less emission, more direct transports with well-planned routines are the main tools for sustainable distribution (Martinsen and Björklund, 2012). Additionally, combined transport, using more than one transport mode, has attracted the attention to prevent truck emissions (Bukold, 1993) and it becomes a noteworthy distribution method overlapping society's environmental sensibilities with firms' environmental strategies (Jensen, 2008).

Another dimension of distribution is reverse logistics referring to transporting used products back to the firm for re-manufacturing. Hence, reverse logistics is mainly related with recovery processes together with waste management and it is critical for creating value for products used or harmed (Afshari et. al., 2014; Gencer and Akkucuk, 2016). The reverse logistics is also closely related with the closed loop supply chain as the main idea in the loop is to return all the scrap, returns or unusable materials back to the traditional production process including both reverse and forward supply chains so as to minimize the use of natural resources and eliminate the waste (Wells and Seitz, 2005).

Recovery

Green manufacturing differs from the classical production thinking in its approach to the post-delivery of the goods and the green recovery process of goods delivered both in the market and the environment (Srinivas, 2014). Similarly, organizations adopting green manufacturing have already selected environmentally-friendly materials and used clean technologies for manufacturing processes but they also consider recovery or reuse of their products that would benefit planet, people and profit.

As the final step in the supply chain, recovery process can be defined as a combination of remanufacture, re-use and recycle (Johnson and Wang, 1995). Re-use can have various forms as direct re-use, repair, recycling, and remanufacturing (Thierry et. al., 1995). Moreover, re-use can be applied to assemblies, components and materials (Ferrer 1997; Krikke et. al. 1999; Kriwet et. al. 1995). Another important recovery operation is re-cycling and it is the process of producing new raw material from wastes (Misni and Lee, 2017). Further, if the returned product has no option of remanufactured then it is recycled. Similar to re-use, recycling process works with two principles of maximizing the resource use and minimizing the costs of the process (Mishra et. al., 2012). Consequently, recycling not only reduces costs and greenhouse gas emissions, but it also helps to minimize the use of environmental and organizational resources.

Turkish Green Supply Chain Management Practices

In 2016 Environmental Performance Index (EPI) that ranks countries on protection of human health and protection of ecosystems, Finland with its carbon-neutral society claim is ranked at the top of the list followed by Sweden, Denmark, and Slovenia. On the other side of the list, Somalia appears as the last country in the list (180th) and before Somalia comes Eritrea, Madagascar, Niger, and Afghanistan. In the

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

list, Turkey is ranked 99 among 180 countries and its place in EPI indicates that Turkey has a mediocre performance and has to improve its ecological performance to reach its European counterparts. Additionally, another report, "Trends in Global CO_2 emissions: 2016 Report" (Oliver et. al. 2016), indicates that Turkey's greenhouse gas (GHG) emissions as CO_2 equivalent were 360 million tons in 2015 where China and United States had 10,720 and 5,180 million tons, respectively.

Though having a large emerging market, Turkey has been recently got engaged in environmental issues, and lately become ecologically responsive to these issues' criticality for sustainability of organizations and society. Parallel to European Union candidacy and compliance to the union's environmental acquis, Turkey has introduced new legislations and institutional practices as National Environmental Action Plan (NEAP) (European Environment Agency, 2016). For instance, Turkey is required to implement the EU waste electric and electronic equipment directive for EU candidacy (WEEE Directive', 2002/96/EC). However, in the case of electric waste, authorities (e.g. World Bank) suggest that Turkey has to form its own national standards and regulations that would support international standards for green operations.

When regionally examined, it is recorded that Turkish regional manufacturing is responsible for approximately 40–60% of total Turkey's carbon emissions (Kucukvar et. al., 2016). In the country scope, 99.8% of Turkish business environment consists of small and medium-sized Enterprises (SMEs) and these SMEs are accountable for nearly 70 percent of all industrial pollution (Agan et. al., 2013). Some industries are determined as more polluting sectors as food and beverages, textiles and metal products based on water and energy consumption, the amount of hazardous waste generated, and greenhouse gases (GHGs) emissions (Aksoy and Gonel,2015).

To both business environments and academic circles in Turkey, GSCM refers to a new management approach that becomes recently salient (Büyüközkan and Vardaroğlu, 2008; Camgöz-Akdağ and Aksoy, 2014). Therefore, the academic interest in GSCM practices in Turkey is limited with a dearth of studies and is still in the preliminary stage. These few studies are worth mentioning for understanding the motives and barriers of GSCM practices developing in the country. For example, a study conducted by Andiç et. al. (2012) on the forces affecting GSCM practices in Turkey, find out customer demand as the most influential driver for GSCM practices. Confirming Andiç et. al. (2012), Tatoglu et. al. (2015) find out that stakeholder pressures as the most important dimension of corporate environmental policies followed by environmental management practices, and the dimension of sources of greenhouse gas emissions is found out to be less influential factor. Agan et. al. (2013) within a sample of 500 SMEs, examined SMEs' environmental processes (disposal, reduction, recycling, design) on firm performance. The study findings prove that the most influential driver for GSCM practices for Turkish SMEs is expected benefits and soft performance expectations like image, reputation, and brand. Also, SMEs with ISO 14001 certification are found out to have better performance related with environmental processes, while disposal, design. Further, SMEs with environmental management systems are also found to have better performances. Based on their findings, Agan et. al. (2013) offer cooperation between firms in the supply chain as a critical factor to cope with pollution besides the government forced regulations. Similar to Agan et. al.'s study (2013), Sabegh et. al. (2016) on their research on inter-organizational relations and their influences on GSCM practices show that manufacturing and logistics firms have different perceptions related with GSCM and hence they need cooperation and some experiences to fully adopt GSCM premises (Sabegh et. al., 2016).

Besides all these factors related with the newly adopted GSCM, studies point some barriers for Turkish firms. The awareness and knowledge of environmental issues is still lacking both in the society and industry basis that foster the thinking that GSCM is a cost center rather than a profitability source

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

(Andiç et. al., 2012; Saridoğan, 2012). In line with this thinking, firms also don't indulge in research and development activities that would enhance their environmental performance. Together with these, the inefficiency of governmental penalties and control on waste management and related operations or on the recording of carbon footprint of operations are the other factors that result in misguided actions.

Therefore inferred from the previous studies, it is suggested that GSCM practices in Turkish food and beverages industry, one of the most polluting sectors, requires attention and as to the knowledge of authors there is no study analyzing the GSCM performance determinants for the industry.

Turkish Food and Beverages Industry

According to the information given at the website of The Republic of Turkey Prime Ministry Investment Support and Promotion Agency (ISPAT), Turkey is the world's 7th largest agricultural producer and 6.1 percent of the country's GDP in 2016 is created by agriculture and food industry. Also, the overall GDP provided by agriculture and food industry "increased 40 percent from 2002 to 2016 and will be predicted as USD 52.3 billion in 2016. Globally, Turkey exported 1,781 kinds of agricultural products to more than 190 countries in 2016, accounting for an export volume of USD 16.9 billion" (http://www.invest.gov.tr/en-US/theagency/Pages/OurServices.aspx: 06.08.2017).

According to Business Monitor International's Turkey Food and Beverages Report (2017), Turkey has a promising long-term consumer market and the largest firm is Nestlé whereas PepsiCo, Mondelez, The Coca-Cola Company, Mars, and AB InBev are among the top 10 food and beverage companies in the country. Besides these firms, Anadolu Efes, Danone, Çaykur, Pınar Su are the top beverage firms. More to that, trends of processed foods and growing health consciousness are started to be felt in the sector. The report (2017:15) signals that growth is expected in the industry especially due to "youthful demographics, rising incomes and increased participation of women in the labor force". On the opposite side of the coin, inflation rates, the depreciation in the national monetary unit, geographical location and international relations in terms of exporting (e.g. Russia) appear as negative factors for the development of food industry, and increasing taxes with falling tourism arrivals are hindrances for beverages.

Parallel to these, according to "National Greenhouse Gas Inventory Report:1990-2014" prepared by Turkish statistical institute, food processing, beverages and tobacco were evaluated together and as a category's share of GHG emissions as CO_2 eq.in the Turkish manufacturing industry is 7.2% in 2014 while it was at its peak with 8.3% in 1990. Also to the report, the changes of emissions in the industry is attained to emissions in this sector is due to increasing electricity produced by auto producer together with increasing consumption in solid and liquid fuels.

Food and beverages industry covers use of fertilizers, herbicides and pesticides in farming techniques as well as water pollution, packaging types as factors that cam impede or enhance the hazards given by the industry to the environment (Jackson and Singh, 2015). According to the studies, the environmental hazards by food and beverages can be categorized into three groups (Davies and Konisky, 2000; Wang et. al., 2013). The first group addresses the "environmental impacts of the services given by restaurants including energy consumption, solid waste generation, air emissions, water emissions, food safety-foodborne diseases, and refrigerants" (Wang et. al., 2013:86). The second group implies the impacts caused by downstream actors in the chain as suppliers, manufacturers and farms. Lastly, the downstream harms caused by other businesses and consumers (e.g. using too much napkins). Therefore, excessive use of energy, water, food, and detergents is among the main causes of pollution and a hindrance to

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

sustainability in food and beverages industry (Wang et. al., 2013). However, as mentioned before, Turkish agriculture and food industry generally consists of SMEs (Seyfettinoğlu, 2016; BIM, 2007) that don't have the required budget and motivation to invest highly in research and development activities to increase the value created through their supply chains. Consequently, all these make GSCM practices and environmental management in food and beverages industry critical.

METHODOLOGY

Experts are appointed and annual reports and related news are considered to provide the linguistic assessment regarding the companies. Proposed dimensions and criteria are illustrated in the following table.

Fuzzy DEMATEL

DEMATEL method refers to the first letters of "The Decision-Making Trial and Evaluation Laboratory". This method was developed by Geneva Research Institute within the scope of Science and Human Relations Program. This program was performed for the periods between 1972 and 1976. DEMATEL method is mainly used to give decisions in a very complex situation (Shieh et. al., 2010). In other words, this method aims to rank the alternatives according to their importance. In addition to this situation, it is also very beneficial to identify cause and effect relationship among the criteria. In this situation, the criteria, which influence others very much, belong to cause criteria group. On the other side, the criteria are included in effect criteria group if they are affected by others. The main reason is that these criteria have lower importance in comparison with others. When the opinions of the experts are linguistic, in such a case, fuzzy DEMATEL method is taken into the consideration. The steps of this method are detailed as following (Tseng, 2009).

Step 1: The goal of the situation is identified. In other words, the purpose of the decision to solve the problem is determined.

Step 2: The criteria is defined for evaluation. These criteria aim to analyze causal relationship. In addition to this situation, fuzzy linguistic scale is also determined. This scale helps to solve uncertainty conditions by considering following aspects.

- No
- Low
- Medium
- High
- Very High

Step 3: Decision makers evaluate the criteria. In this situation, the number of the experts who share their opinions is referred to "p". Furthermore, "Ž" shows fuzzy matrixes obtained according to the views of these experts. The details of average fuzzy matrix are given below. In this matrix, $\check{Z}_{ij} = (l_{ij}, m_{ij}, u_{ij})$ refers to the triangular fuzzy numbers (Dinçer et. al., 2017).

$$\breve{Z} = \frac{\breve{Z}^1 \oplus \breve{Z}^2 \oplus \ldots \oplus \breve{Z}^p}{p}$$

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

$$\breve{Z} = \begin{bmatrix} 0 & \cdots & \breve{Z}_{1n} \\ \vdots & \ddots & \vdots \\ \breve{Z}_{n1} & \cdots & 0 \end{bmatrix}$$

Step 4: The direct relation fuzzy matrix is normalized. The details of this matrix and equations used in the calculation process are emphasized as following.

$$\bar{\mathrm{X}} = \begin{bmatrix} \bar{\mathrm{X}}_{11} & \cdots & \bar{\mathrm{X}}_{1n} \\ \vdots & \ddots & \vdots \\ \bar{\mathrm{X}}_{n1} & \cdots & \bar{\mathrm{X}}_{nn} \end{bmatrix}$$

$$\bar{\mathrm{X}}_{ij} = \frac{\breve{Z}_{ij}}{r}\left(\frac{\mathrm{l}_{ij}}{r}, \frac{\mathrm{m}_{ij}}{r}, \frac{\mathrm{u}_{ij}}{r}\right)$$

$$r = max_{1 \le i \le n}\left(\sum_{j=i}^{n} u_{ij}\right)$$

Step 5: Total relation fuzzy matrix is calculated as below.

$$\mathrm{d} = \begin{bmatrix} \breve{\mathrm{t}}_{11} & \cdots & \breve{\mathrm{t}}_{1n} \\ \vdots & \ddots & \vdots \\ \breve{\mathrm{t}}_{n1} & \cdots & \breve{\mathrm{t}}_{nn} \end{bmatrix}$$

$\breve{\mathrm{t}}_{ij} = (\mathrm{l}''_{ij}, \mathrm{m}''_{ij}, \mathrm{u}''_{ij})$

$$l''_{ij} = X_l \times \left(1 - X_l\right)^{-1}$$

$$m''_{ij} = X_m \times \left(1 - X_m\right)^{-1}$$

$$u''_{ij} = X_u \times \left(1 - X_u\right)^{-1}$$

In this calculation, following matrixes are used.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

$$X_l = \begin{bmatrix} 0 & \cdots & \mathrm{l}'_{1n} \\ \vdots & \ddots & \vdots \\ \mathrm{l}'_{n1} & \cdots & 0 \end{bmatrix} \qquad X_m = \begin{bmatrix} 0 & \cdots & \mathrm{m}'_{1n} \\ \vdots & \ddots & \vdots \\ \mathrm{m}'_{n1} & \cdots & 0 \end{bmatrix} \qquad X_u = \begin{bmatrix} 0 & \cdots & \mathrm{u}'_{1n} \\ \vdots & \ddots & \vdots \\ \mathrm{u}'_{n1} & \cdots & 0 \end{bmatrix}$$

Step 6: $\left(\breve{D}_i + \breve{R}_i\right)^{def}$ and $\left(\breve{D}_i + \breve{R}_i\right)^{def}$ are calculated. In this process, fuzzy numbers become defuzzied and the following matrix is obtained.

$$\mathrm{d}^{def} = \begin{bmatrix} \breve{\mathrm{t}}_{11}^{def} & \cdots & \breve{\mathrm{t}}_{1n}^{def} \\ \vdots & \ddots & \vdots \\ \breve{\mathrm{t}}_{n1}^{def} & \cdots & \breve{\mathrm{t}}_{nn}^{def} \end{bmatrix}$$

Some studies in which DEMATEL method is used are detailed on Table 2.

As it can be seen from Table 2, most of the studies, which considers MOORA method, are related to selecting the best alternative. For example, Mirmousa and Dehnavi (2016) made a study to select the

Table 2. Featured studies with DEMATEL approach

Authors	Scope	Results
Mirmousa and Dehnavi (2016)	Iran	The financial stability index is the most significant criterion to select the best supplier.
Büyüközkan and Güleryüz (2016)	Turkey	They created a model which is very helpful to select the most efficient renewable energy resources.
Supeeket et. al. (2016)	Thailand	It is understood that completeness of treatment is the most important aspect to evaluate hospital supply chain performance.
Su et. al. (2016)	Taiwan	Recycling and reusing are important factors for selecting the suppliers.
Gigovic et. al. (2016)	Serbia	They developed a model which can evaluate the sites for ecotourism development in Serbia.
Psndey and Kumar (2017)	Literature Review	They updated the model of Chou and others that was developed in 2012 which is related to the evaluation of criteria for human resource management.
Song and Cao (2017)	Case Study	They proposed a product and service model which can identify the weights of each requirement.
Sharma et. al. (2017)	Literature Review	They created a system for flying aerial vehicles which decreases the delays about 25%.
Büyüközkan et. al. (2017)	Turkey	They developed a model which makes an evaluation to select the best CRM partners.
George-Ufot et. al. (2017)	Nigeria	Corruption, theft and inadequate planning are the critical factors that affect electricity consumption.
Luthra et. al. (2017)	India	Government regulations play a very critical role for sustainable production and consumption system.
Tooranloo et. al. (2017)	Iran	Environmental factors are the most significant issues for the success of sustainable human resource management.
Tsai (2018)	China	Compensation, promotion and supervisors are significant influencing factors in order to improve the job satisfaction of R&D personnel.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

best supplier in Iranian market. They reached the conclusion that the financial stability index is the most important criterion for this purpose. Similar to this study, Su et. al. (2016) also made an analysis for Taiwan and identified that recycling and reusing are the most significant factors for supplier selection. In addition, Büyüközkan et. al. (2017) proposed a model that makes an evaluation to select the best CRM partners. Moreover, Büyüközkan and Güleryüz (2016) developed a model for Turkey to select the most efficient renewable energy resources.

Furthermore, it can also be seen that some studies focused on the evaluation of the performance. For instance, Supeeket et. al. (2016) made a study to evaluate the supply chain performance for hospital in Thailand. According to the results of this analysis, it is defined that completeness of treatment is the most important aspect for this situation. Additionally, Psndey and Kumar (2017) tried to make evaluation for human resource management. Similar to this study, Tooranloo et. al. (2017) also focused on human resource management and identified that environmental factors are the most significant issues for this situation.

Moreover, it is understood that some other studies aimed to determine the influencing factors of some issues. For example, George-Ufot et. al. (2017) made an analysis for Nigeria to identify the determinants of electricity consumption. They reached a conclusion that corruption, theft and inadequate planning are the most critical factors. In addition to this study, Luthra et. al. (2017) tried to understand the factors affect production and consumption system in India. They defined that government regulations play an essential role. Tsai (2018) also focused on the determinants of job satisfaction of R&D personnel in China. It was identified that compensation, promotion and supervisors are significant influencing factors for this aspect.

Fuzzy MOORA

MOORA method refers to the Multi-Objective Optimization on the basis of Ratio Analysis. It was developed by Brauers and Zavadskas in 2006. It is a decision making technique which depends on the ratio analysis. In other words, it makes an optimization to solve the complex problems by considering some limitations (Brauers and Zavadskas, 2006). MOORA method has many advantages in comparison with other approaches. First of all, it takes shorter time to make analysis by using MOORA method. In addition to this situation, it is very simple to implement MOORA method. The steps of this method are explained below (Dinçer, 2015).

Step 1: Fuzzy decision matrix is created. Within this framework, various alternatives are considered in this matrix which is shown below. In this matrix, "X_{ij}" refers to the value of the criterion i for alternative j. Additionally, "X_{ij}^{l}", "X_{ij}^{m}", "X_{ij}^{n}" represent lower, middle and upper values.

$$X_{ij} = \begin{bmatrix} (X_{11}^{\ l}, X_{11}^{\ m}, X_{11}^{\ n}) & \cdots & (X_{1n}^{\ l}, X_{1n}^{\ m}, X_{1n}^{\ n}) \\ \vdots & \ddots & \vdots \\ (X_{m1}^{\ l}, X_{m1}^{\ m}, X_{m1}^{\ n}) & \cdots & (X_{mn}^{\ l}, X_{mn}^{\ m}, X_{mn}^{\ n}) \end{bmatrix}$$

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Step 2: The matrix is normalized. In order to achieve this objective, following matrix is taken into the consideration. In this equation, X_{ij} shows the normalized value of criterion i for alternative j. On the other side, all alternatives are stated on the denominator (Karande and Chakraborty, 2012).

$$r_{ij}^{l} = \frac{X_{ij}^{\ l}}{\sqrt{\sum_{j=1}^{m} (X_{ij}^{\ l})^2 + (X_{ij}^{\ m})^2 + (X_{ij}^{\ n})^2}}$$

$$r_{ij}^{m} = \frac{X_{ij}^{\ m}}{\sqrt{\sum_{j=1}^{m} (X_{ij}^{\ l})^2 + (X_{ij}^{\ m})^2 + (X_{ij}^{\ n})^2}}$$

$$r_{ij}^{n} = \frac{X_{ij}^{\ n}}{\sqrt{\sum_{j=1}^{m} (X_{ij}^{\ l})^2 + (X_{ij}^{\ m})^2 + (X_{ij}^{\ n})^2}}$$

Step 3: Weighted results of the alternatives are identified by considering the importance of them. This process is detailed below.

$$v_{ij}^{l} = W_j r_{ij}^{\ l}$$

$$v_{ij}^{m} = W_j r_{ij}^{\ m}$$

$$v_{ij}^{n} = W_j r_{ij}^{\ n}$$

Step 4: Ratings of beneficial and non-beneficial criteria are determined. On the following 6 equations, first three represent beneficial criteria whereas the last three show non-beneficial criteria.

$$S_i^{+l} = \sum_{j=1}^{n} v_{ij}^{\ l}$$

$$S_i^{+m} = \sum_{j=1}^{n} v_{ij}^{\ m}$$

$$S_i^{+n} = \sum_{j=1}^{n} v_{ij}^{\ n}$$

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

$$S_i^{-l} = \sum_{j=1}^{n} v_{ij}^{\ l}$$

$$S_i^{-m} = \sum_{j=1}^{n} v_{ij}^{\ m}$$

$$S_i^{-n} = \sum_{j=1}^{n} v_{ij}^{\ n}$$

Step 5: Overall performance index (Si) is calculated. The details are given on the following equation.

$$S_i\left(S_i^{+},S_i^{-}\right) = \sqrt{\frac{1}{3}\left[\left(S_i^{+l} - S_i^{-l}\right)^2 + \left(S_i^{+m} - S_i^{-m}\right)^2 + \left(S_i^{+n} - S_i^{-n}\right)^2\right]}$$

Step 6: Alternatives are listed as according to their performance results.

MOORA is so popular in the literature that many researchers used this method in their analysis. Some of these works are demonstrated in Table 3.

Table 3. Featured studies with MOORA approach

Authors	Scope	Results
Karande and Chakraborty (2012)	Case Study	They created a method to select the most efficient materials.
Patel and Manilya (2015)	Case Study	With respect to the selection the optimal value of the output, both MOORA and ANP method work effectively.
Akkaya et. al. (2015)	Turkey	They concluded that technology, software/informatics and finance are most commonly preferred sectors for industrial engineering.
Gupta and Singh (2016)	India	They developed a method to rank the criteria which may influence service quality of the retailers.
Dinçer et. al. (2016)	Turkey	There is a positive relationship between the size and the performance of Turkish banks
Matawale et. al. (2016)	India	They developed a methodology in order to select the best supplier in agile supply chain.
Gupta et. al. (2017)	India	A new method was developed with the aim of measuring and evaluating the strategies related to data distribution.
Dinçer et. al. (2017)	European Union	They reached the conclusion that the airline companies, which have profitability and efficiency, are more successful.
Mavi et. al. (2017)	Iran	Quality, health, safety and recycling are the most significant factors with respect to the logistic provider selection.
Bircan et. al. (2017)	Turkey	CO_2 emission, price and luggage volume are very critical factors so as to select a rent a car firm.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 3 shows that MOORA method is mainly used to select the best alternative. For example, Dinçer et. al. (2016) tried to evaluate the performance of deposit banks in Turkey. They reached a conclusion that there is a positive relationship between the size and the performance of Turkish banks. In addition to this study, Matawale et. al. (2016) proposed a method in order to select the best supplier in India. Moreover, Mavi et. al. (2017) focused on the best logistic provider selection in Iran. They identified that quality, health, safety and recycling are the most significant factors.

Furthermore, Bircan et. al. (2017) tried to select the best rent a car firm in Turkey. They reached a conclusion that CO2 emission, price and luggage volume are very critical factors for this aspect. Dinçer et. al. (2017) also aimed to evaluate the performance of European airline companies. They determined that the airline companies, which have profitability and efficiency, are more successful in comparison with others. Gupta et. al. (2017) also focused on developing a new method in order to measure and evaluate the strategies related to data distribution. Akkaya et. al. (2015) also used MOORA method to select the best sectors for industrial engineering and concluded that technology, software/informatics and finance are most commonly preferred sectors.

AN APPLICATION ON BIST

The purpose of the study is to analyze the multidimensional points of the green supply chain management using a fuzzy-based decision making methodology. For this purpose, the fuzzy DEMATEL and fuzzy MOORA methods have been used for the integrated model construction. The main stages of the green supply chain have been considered as the dimensions and the selected performance measures have been listed a set of criteria for each dimension. Accordingly, 21 Food and Beverage companies listed in Istanbul Stock Exchange have been employed to measure the performance of green supply chain processes. Experts have been appointed and annual reports and related news have been considered to provide the linguistic assessment regarding the companies. The financial situation of these 21 firms as of 2016 is shared on Table 4.

The application initiates by defining the multi-criteria decision-making problem to construct the dimensions and criteria of green supply chain management for the companies listed in the BIST food beverage index as seen in Table 1. Decision makers have been appointed to determine the linguistic evaluations for each criterion and the firm. The proposed model has been defined for ranking the alternative firms.

Accordingly, the Fuzzy DEMATEL and Fuzzy MOORA methods have been integrated for the novel hybrid decision making approach. The methodology begins by constructing the direct fuzzy relation matrix provided from the decision-making group. The second step continues by the initial and normalized direct-relation fuzzy matrix respectively. At the following stage of the Fuzzy DEMATEL, the total influence matrix and the total-relation fuzzy matrix have been employed to attain the crisp values. The final step of the fuzzy DEMATEL has been defined by the defuzzied total-relation matrix to determine the weights of the key components of green supply chain management. The results have been presented in Table 5-8.

Linguistic scales have been appointed for each criterion by using No influence (N), Low influence (L), Medium influence (M), High influence (H), Very high influence (VH) and the scales have been

Table 4. Basic financial information of selected firms

Firm	Total Assets (TL)	Total Profit or Loss (TL)	Return on Assets
A1	294,042,194	15,227,319	0.052
A2	153,483,677	981,801	0.006
A3	1,110,737,612	62,415,065	0.056
A4	691,466,792	64,700,560	0.094
A5	546,963,372	59,689,181	0.109
A6	551,870,110	-8,606,371	-0.016
A7	604,820,268	-73,770,826	-0.122
A8	107,858,304	-6,246,356	-0.058
A9	207,835,834	-10,644,729	-0.051
A10	29,670,032	-832,007	-0.028
A11	111,557,216	-6,447,353	-0.058
A12	25,628,559	-40,055	-0.002
A13	52,345,285	61,502	0.001
A14	568,647,893	14,796,725	0.026
A15	94,206,031	3,068,840	0.033
A16	933,593,147	60,019,544	0.064
A17	10,455,946	22,391	0.002
A18	86,709,590	9,887,534	0.114
A19	1,285,558	236,890	0.184
A20	5,526,188,949	242,004,730	0.044
A21	205,912,354	-21,421,595	-0.104

converted to the triangular fuzzy numbers to evaluate the relative importance of the criteria (Uygun et al. 2015). The evaluation results can be seen in Table 5.

Initial direct-relation fuzzy matrix has been normalized in table 5.

Table 7 represents the total influence matrix using the crisp matrices.

Table 8 illustrates the total cause and effects of the criteria between each other with the defuzzied values. The results show that C2 is the most important factor in the green supply chain management while C7 has the least weight in the criteria. However, C9 influences the other criteria most dominantly as C7 is the most influenced factor among the criteria.

The second phase of the integrated model continues with the Fuzzy MOORA method. Firstly, the linguistic scales have been appointed for each firm and the fuzzy decision matrix has been provided in table 9. And then, the weighted normalized values have been calculated to attain the overall ratings of beneficial and non-beneficial criteria for each firm.

The final ranking results are presented in table 10.

Table 10 demonstrates that A21 is the best firm while A2 has the worst performance in BIST food beverage index according to the key components of the green supply chain management.

DISCUSSION AND CONCLUSION

Environmental pollution is a crucial concept in the world especially in the last years. Within this scope, it can be said that some companies increase this pollution because of their operations. On the other side, there are also some groups which announce the importance of environmental pollution. Nowadays, it can be observed that consciousness of most of the companies regarding the pollution increased. They focus on green supply chain management activities to contribute to the solution of this problem.

Indeed, green supply chain management activities have many economic and the financial advantages to these companies. First of all, by applying the activities, such as recycling, reuse and reverse logistic, they can have a chance to reduce their costs. In addition to this advantage, companies can also increase the image in the eyes of the customers by adopting some green supply chain management activities like low pollution, clean technology and reduce waste. Since customers prefer these companies due to these factors, they can increase their revenues.

This study aims to evaluate financial and economic effects on green supply chain management. Within this framework, 21 different companies listed in BIST food beverage index are taken into the consideration. In addition to this situation, the fuzzy DEMATEL and fuzzy MOORA methods are used to achieve this objective. Moreover, by analyzing similar studies in the literature, 10 different criteria are identified which may show the performance of green supply chain management.

In the analysis process, first of all, the importance of these 10 criteria is determined with the help of fuzzy DEMATEL method. As a result of this analysis, it is identified that “low pollution” is the most important criterion for these companies. On the other side, the criterion of “alternatives” has the least weight. This condition gives information that food and beverage companies mainly focus on saving their image in the public eye. The main reason behind this situation is that they can be more preferred by the customers while having an image that does not pollute the environment.

According to the results of fuzzy MOORA analysis, it is defined that there is not a strict correlation between the profitability of the companies and green supply chain management performance. For example, A21 has the highest performance with respect to the green supply chain management. However,

A20	0,0583	3
A21	0,0608	1

it has a significant loss in 2016. On the other side, it can also be said that bigger firms have higher green supply chain management performance than the smaller firms. For instance, the companies, which have the highest total assets value, are ranked as the third, fourth and sixth position. Nevertheless, A10 and A19 are the companies that have low green supply chain management performance and lower size in comparison with other firms.

KEY TERMS AND DEFINITIONS

Clean Technology: It means the technology that does not cause any harmful effects to the environment.

Globalization: It is the process in which there is a free movement of goods among different countries.

Green Supply Chain Management: It refers to the consciousness of the companies with respect to the environmental issues.

Recycling: It refers to the process of converting waste to the new objects that can be used again.

Return on Asset (ROA): It is calculated by dividing net profit to total assets. It shows how profitable a company is.

Reverse Logistics: It shows the role of the logistic in reusing, recycling, and reducing waste.

This research was previously published in the Handbook of Research on Supply Chain Management for Sustainable Development edited by Ulas Akkucuk, pages 144-175, copyright year 2018 by Business Science Reference (an imprint of IGI Global).

Chapter 66
Survey of State-of-Art in Green Cloud Computing

Sanjay P. Ahuja
University of North Florida, USA

Karthika Muthiah
University of North Florida, USA

ABSTRACT

Cloud computing is witnessing tremendous growth at one time when climate change and reducing emissions from energy use is gaining attention. With the growth of the cloud, however, comes an increase in demand for energy. There is growing global awareness about reducing greenhouse gas emissions and healthy environments. Green computing in general aims to reduce the consumption of energy and carbon emission and also to recycle and reuse the energy usage in a beneficial and efficient way. Energy consumption is a bottleneck in internet computing technology. Green cloud computing related technology arose as an improvement to cloud computing. Cloud data centers consume inordinate amounts of energy and have significant CO2 emissions as they have a huge network of servers. Furthermore, these data centers are tightly linked to provide high performance services, outsourcing and sharing resources to multiple users through the internet. This paper gives an overview about green cloud computing and its evolution, surveys related work, discusses associated integrated green cloud architecture – Green Cloud Framework, innovations, and technologies, and highlights future work and challenges that need to be addressed to sustain an eco-friendly cloud computing environment that is poised for significant growth.

1. INTRODUCTION

To know what Green Cloud Computing is let's split the words and understand the meaning of each word. The word "Green" implies living friendly to the environment and contributing towards maintaining ecological balance and preserving the planet and its natural resources. The word "Cloud" is used as an analogy for network of servers accessible over the internet that provides a service to its users. So green cloud computing refers to use of computers and relevant resources in an environmentally responsible manner through implementing energy efficient computer systems and their peripherals (Rouse, 2010).

It is known that global warming emitting greenhouse gases and other toxic gases are harmful to mankind and the environment. Moreover, human activities like burning of coal, natural gas and oil causes emission of more greenhouse gases results in change in climate and average temperature of the atmosphere. On the other hand, IT technology keeps advancing and is extensively used globally due to the tremendous growth of the internet in the past decades. Industries like medical, telecommunication, business, and financial are predominantly dependent on applications that are developed and serviced by information technology systems.

The demand for internet bandwidth has been accelerated by the advent cloud computing technology. Cloud computing is helpful in providing services like software, infrastructure, and platform to its clients in an efficient manner. The cloud computing network provides a shared infrastructure which includes large data centers to store and service the client's data. Energy consumption is the key concern in distributed cloud computing systems. This cloud's cooling system consumes more energy and power and results in major energy costs and high carbon emission.

It makes sense to save energy and recycle or reuse as much as possible for the wellness and preservation of the environment. Lot of research is going on in every field to make the environment pure and healthy. Safety measures have also been taken by many organizations to support eco-friendly environment. Nowadays industries and companies in various fields like science and technology, medical, manufacturing, research etc. have started transforming their innovations and developments towards green technology. Because of the utilization of inordinate amount of energy in cloud computing, it has become a necessity to find a way for reducing energy consumption and promote reusability. Green cloud computing technology has evolved to fill this need.

Green cloud computing aims in reducing energy utilization and promote a sustainable and eco-friendly environment in cloud computing field. This paper discusses how green cloud computing plays a vital role in reducing energy usage and carbon-di-oxide emissions in the cloud data-center setting.

The remaining sections in the paper are organized as follows, Section 2 will discuss about the introduction to cloud computing technology Section 2.1 is about green cloud computing and section 2.2 is its relevant terminologies. Section 3 is about Literature Survey. Section 4 describes about the list of organizations that supports Green Cloud Technology. Sections 5, 6, 7 and 8 will discuss about the study of the latest architecture – Integrated Green Cloud Computing, simulators, and algorithms of green cloud computing technology, benchmarks and the challenges it faces towards sustainability in environment. Lastly, Section 9 will discuss the conclusion and future work that can be done to improve this technology to a greater extent.

2. CLOUD COMPUTING

The ideas and concepts behind cloud computing have existed for many years. It was started in 1950's along with mainframe computing. In the 1970's virtualization concept was created in which one or more operating systems can execute simultaneously in an isolated environment. In the early 1990's, telecommunication companies were offering virtualized private network services to its users. In the late 1990's the term "cloud" signifies the computing space among provider and end user. Later on the cloud providers like salesforce.com, amazon.com, Google gained the major internet marketplace and proved the power of cloud computing to the real world.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

According to United States National Institute of Standards and Technology, Cloud Computing is defined as "A model for enabling convenient, on-demand network access to a shared pool of configurable computing resources (e.g., networks, servers, storage, applications, and services) that can be rapidly provisioned and released with minimal management effort or service provider interaction". Cloud computing is used in one's personal as well as business life. It is widely used by major corporations like Amazon, Google, IBM, Sun, Cisco, Oracle etc., Social networking websites, email services, backup services, banking and financial services, health care and governmental agencies all use cloud computing.

Cloud computing is offered as different types of services like Software as a Service is commonly represented as SaaS, where the end user applications run on a set of pooled hardware resources and are accessed over the network; Platform as a Service is commonly represented as PaaS, a set of application components is offered by the service providers are used by developers put together into applications; Infrastructure as a Service is commonly represented as IaaS which subcontract the equipment that comprises of hardware, servers, storage, and networking components to support operations.

Cloud computing systems are characterized by on request self -service computing capabilities, wide network access on different platforms, multi-tenant model to serve multiple customers with hardware and simulated resources that are dynamically allocated and reallocated based on customer request, elasticity to scale up or down the services, and automatically optimized and which control the resource usage through measured service capability. Many IT companies and global brands like Amazon, Facebook, and Google are rapidly transforming their way of work, communication, sharing pictures, watching television, listening music to "cloud" systems in order to benefit the great services cloud offers. The cloud development and investment scale is very significant and it is been estimated that almost a 50-fold growth in digital data by 2020 and almost half a trillion in investment in the future years, all these are evident to generate and nourish our need for abundant access to endless information from our computers, laptops and mobile devices, rapidly (Cook, 2012).

2.1. Green Cloud Computing

The cloud data center consists of thousands of servers to store and manage the rapidly growing data and these consume tremendous amount of electricity equivalent to the electricity consumption of nearly 180,000 homes. For example, the datacenters in Amazon on a 3-year amortization-schedule estimated to be about 53% of the total budget on cost and operation payment of the servers, 42% on energy related costs, approximately 19% through power usage and cooling infrastructure and amortized over a 15 year period estimated to be about 23% on cooling infrastructure (Hamilton, 2009). Thus, we need to increase energy efficiency in cloud data centers to contribute to greater environmental sustainability. With the advent of Green Cloud technology it is possible to achieve better energy efficient and eco-friendly environment.

Green cloud computing is facing lot of challenges these days and research is going on in at various levels to attain energy efficiency and reduce power consumption in cloud computing architecture. The application level (SaaS) is focused on deploying the software on accurate infrastructure to ensure it executed efficiently, less energy consumption and good performance on many platform and hardware. The infrastructure level is focused on planning and resource management to reduce the workload that execute the user applications of active resources. Virtualization technique plays a vital role in this level.

At the datacenter level, many fine practices are proposed to improve efficiency by building energy effective datacenters. Many best practices has been recommended to improve efficiency from electrical to processor level of individual device (Garg and Buyya, 2012). It includes constructing the data center

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

by selecting a smart location, cooling systems to consume only 33.33% of overall energy consumption, power efficient servers and processors to be deployed in the datacenter and to design energy efficient power supply unit. At the monitoring/metering level, to construct a power model to determine the energy consumed by a particular device and to reduce the consumption. Green Grid proposed two metrics called Datacenter Infrastructure Efficiency (DciE) and Power Usage Effectiveness (PUE) (Rawson et al., 2008) to measure efficiency and improve performance of the datacenter's. At the network infrastructure level, the focus is on either node level or infrastructure level to achieve energy efficiency.

2.2. Relevant Terminology

This section lists the common terminology used in cloud or green cloud computing technology.

- **Computer Recycling:** A process in which equipment is broken into smaller pieces to recycle back the computer components easily. Recycling components include leaded glass from the cathode ray tubes, gold, copper, silver, tin ores and wires.
- **Green Computing:** It aims in reducing the usage of hazardous materials in computers, lower the energy consumption, maximize the new computers output, and recycle older computer parts to keep them out from landfills.
- **Electronic Waste:** It consists of discarded computer / electrical equipment. These wastes need to be recycled as they are harmful to environment.
- **Hibernate:** It is a feature of the operating system where the RAM is written to non-volatile storage before system power is turned off. The system can be restored without any break with exactly the programs that was left as before to work. Hibernating and restoring from hibernation is usually faster than normal system shutdown and reboot.

3. RELATED WORK: LITERATURE SURVEY

Saurabh et al in (2012) discuss that to achieve energy efficiency a detailed analysis on cloud related to their power efficiency is required and how these solutions draws a conclusion that directs to enable green cloud computing. Green cloud computing was enabled to provide solution to network contribution via Green Cloud Architecture which considers user's and provider's aspect to make green. In this architecture the greenest cloud provider is selected through a middleware green broker to service user's request. The framework's efficiency is validated using 5 policies including Greedy Minimum Carbon Emission, Minimum and Minimum Carbon Emission, Green Maximum Profit, Maximum Profit Maximum Profit and Minimizing Carbon Emission and Maximizing Profit and proved to be efficient with carbon emission. It is inferred that green policies reduces almost 20% of carbon emission and the usage of energy efficient solutions benefits both users and cloud providers. The paper concludes towards future direction to make green cloud reality with still many technological solutions like designing software at various levels, understanding the existing datacenter's cooling, power designs, energy consumption and resource utilization, design complete resulted in planning and resource provisioning for applications, and emerging technologies do not bring irreversible change and threat to human health society are required.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Qilin et al in (2011) discusses about finding a unifying abstraction in managing the tasks of hardware abstraction, resource allocation and operating system that needs energy awareness being integrated. Three major things approached in green networking are Re-engineering is to design more energy efficient components in network architecture. Dynamic adaptation aims in modulating the capacities of network device resources. The third approach Sleeping/Standby is used to select the idle portions to minimal standby mode and wake it up whenever necessary in the network. The paper concludes that in future many issues like metrics, benchmarking standards, green data and abstraction layers control; redundant devices support and management; virtualization and equipment in networks all requires investigation.

Mazedur et al in (2013) addresses and classifies the energy saving issues and challenges in mobile clouds and computing, reviews the current research techniques and outputs, examines their strengths and weaknesses, and identifies open issues for future research. The energy consumption issue during computation task is addressed by offloading computation to cloud and derive the amount of energy saved. In ad-hoc mobile cloud framework only small portion of task is executed locally and remaining is delegated to nearby mobile which already runs the same task. The cellular data rates are monitored periodically at a chosen interval in order to minimize the significant usage of device energy. Catnap, an energy saving strategy accumulates the small intervals between packets to form large intervals when the device is sent to sleep mode without changing packets actual delivery time. EnaCloud approach uses energy aware heuristic algorithm to generate the application assignment and schemes scheduling in response to workload entry and exit, and alter the events size. The paper concludes that technology only focus on specific issues from one perspective and lacks saving energy with well-defined frameworks and solutions to address diverse green computing issues and needs in mobile clouds. The future research focus is on developing an innovative energy-saving infrastructure based on real-time analysis and intelligent decision-making.

4. ORGANIZATIONS

This section lists some of the organizations that help in regulating green computing in today's worldwide markets.

- **TCO Certification:** A series of accreditations and principles fixed up and maintained by TCO Development. These accreditations refer to monitors and high standards for computer equipment's, mobile phones, furniture's and additional electrical office tools.
- **Climate Savers Computing Initiative:** It comes under non-profit organization (NPO) consisting of customers, businesses, and other maintenance organizations are helpful in refining power efficiency, consuming less energy, and promoting smart technologies in computers.
- **Green Computing Impact Organization (GCIO):** It is a non-profit organization to support end clients and more responsibility towards environment with their products. It provides special services in auditing to help their users.
- **Green Electronics Council:** On the basis of 28-point criteria, different systems and components are evaluated to measure the efficiency of the product and its attributes.

5. INTEGRATED GREEN CLOUD COMPUTING ARCHITECTURE

The Green Cloud Framework was proposed as an integrated solution with the intention to reduce energy consumption in green clouds. Cloud is made green by considering users and providers aspect. With the help of green broker middleware, the software type cloud service request is submitted by the users. The greenest cloud provider is selected by the middleware broker to service user's request. The services are registered by cloud providers as green offers which need the access time for least carbon emission to a public directory and time being retrieved by green broker.

By using different cloud services and carbon emission directory, the present energy parameters status are received by green brokers (Kawade and Kapse, 2013). The entire data associated to energy efficiency is maintained in Carbon Emission Directory which also includes Power Usage Effectiveness (PUE), network cost, cooling efficiency for datacenters, and emission rate of carbon in electricity. The carbon discharge value is calculated for all cloud providers and the service with the least value is selected by Green Broker and buys it as a representative of users.

To make the requested service "Green" the complete energy utilization and efficiency of each cloud provider that depends on carbon emission directory and green providers components are kept track by Green Cloud Framework. In the cloud providers aspect each cloud layer should be conscious about "green" and in user's aspect serving a user is a crucial role where the cloud services are selected and monitored on the basis of Quality of Service (QoS) requirements by Green Broker to ensure minimum carbon emission.

It becomes essential to ideal and amount the efficiency of energy design, operation and software deployment on behalf of SaaS service level providers. While serving users, only the least figure of copies of user private data should be retained by energy proficient storage. At the PaaS platform service level the developed applications should confirm wide energy efficiency in system by addition of energy profiling tools like JouleSort, a scale to measure vital energy to do external sort. The IaaS infrastructure service level providers offers both infrastructure and other support services and plays an important part in accomplishment of green architecture. They design various green offers and incentives to users using the service throughout the off-peak hours of energy efficiency.

6. STUDY ON GREEN CLOUD SIMULATORS

These simulators were developed in recent years to make cloud data centers energy efficient. This study discusses the features of different energy efficient green cloud simulators available namely, GreenCloud, iCanCloud, CloudSim and Cloud Reports.

The *GreenCloud Simulator* is an extension to packet-level network simulator Ns2 and offers a finely tuned energy consumption model by the elements like server, switches and links of the data center. The user demands need to be satisfied by transforming the received power to computing work. Server element uses varied job scheduling mechanisms extending from simplest round-robin to advanced Dynamic Voltage and Frequency Scaling and DNS supported, preset processing power limit and memory or storage resources size to implement single core nodes. The execution of workload is performed by delivering the load to one of the computing servers through interconnection fabric in an appropriate way using switches and links elements of data center. Each workload object execution requires the computational and communicational components for its successful completion. The comparison study done on differ-

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

ent data center architecture based on setup composed of 1536 computing nodes employed energy-aware "green" scheduling policy for the incoming workloads arrived in exponentially distributed time intervals (Kliazovich et al., 2010). The policy aimed at grouping the workload together on a least possible set of computing servers allowing idle servers to be put into sleep. The dynamic shutdown showed effective result on both servers and switches energy efficiency.

iCanCloud is a new simulator with features such as elasticity, performance and scalability of cloud infrastructures. It is made based on the following design principles: target to conduct large experiments from literature, offers stretchy and wholly modifiable universal hypervisor for incorporating any cloud brokering rule, creation of instance type replica's as delivered by cloud setup, and lastly, it has a user-friendly GUI for organizing and initiating simulations (Nunez et al., 2012).

CloudSim is a popular simulator for cloud parameters, free and open source software based on Java code library. It provides the features like, an autonomous platform for service brokers, provisioning policies and model large-scale clouds; support and maintenance for simulation of computing environments and network connections; ability for simulation of combined cloud environment and experimentation studies linked to Cloud-Bursts and spontaneous application scaling (Calheiros et al., 2010).

CloudReports, a realistic tool to simulate scattered computing settings created using Cloud Computing pattern which uses CloudSim's simulation engine and offers easy access of graphical user interface, providing report information and design of extension plugin (Gupta, 2013).

7. STUDY ON GREEN CLOUD ALGORITHMS

This section lists some of the algorithm studied related with green cloud computing.

- *Green Genetic Algorithm* is a search heuristic based on genetic operations used for generating solutions to optimization and search problems. Two algorithms Critical Path Genetic Algorithm to minimize total execution time and Task Duplication Genetic Algorithm to deal with load balance satisfaction and to overcome communication overhead was developed. The Improved Genetic Algorithm was developed to make use of the computing resources to complete the tasks in shorter time period and reduced costs. It includes chromosome encoding and decoding, production of the initial population, fitness function, and genetic operations: selection, crossover and mutation (Nirubah and John, 2014).
- *Improved Clonal Selection Algorithm (ICSA)* will regulate the complete distribution of resources. As a pre-process, relationships are mapped into binary codes as a set of initial population X (0) and every individual i.e., antibody represent a binary series of characters of bits among tasks and resources. The length of the bits is used to get solution for the problem. The resource allocation process in ICSA evaluates the attraction of each antibody and the one with higher attraction is taken for subsequent generation. The selected antibodies are multiplied and replicated in the current population and then executed to mutation operation which produces a mutant individual. By this way, the worst antibodies are replaced best antibodies from the clonal library (Shu et al., 2014).
- *Green Scheduling Algorithm* used neural network predictor to address the shortage of energy problem and global climate change. It uses four different running modes namely, optimal, conventional, prediction and prediction plus 20% additional servers mode to predict the future load demand.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Six new algorithms, namely Shortest Task First for Computer with Minimum Energy and Random Computer, Longest Task First for Computer with Minimum Energy and Random Computer, Random Task for Computer with Minimum Energy and Random Computer are developed to reduce the pollution and lower energy consumption.

Two traditional heuristic task scheduling algorithms - Shortest and Longest Task First for Computer with Minimal Energy First with Maximum Speeds and two new green task scheduling algorithms – Shortest and Longest Task First for Computer with Minimum Energy First with Speed Adjustment are evolved to minimize energy consumption in multi-task scheduling problem. Six energy-efficient task scheduling algorithms with continuous speeds, discrete speeds and hybrid algorithms are developed to conserve maximum energy (Nirubah and John, 2014).

- *Green Algorithm* is an effective way used for short and long terms to consolidate the tasks to manage clouds. In short term, the volume flux is handled by decreasing the live resources count and inordinate to a power saving mode or switching off systematically and in long term, cloud providers create an improved model to facilitate power and resources to lower the burden due to excess of provisioning. The two energy conscious algorithms used in power management are Maximum Utilization, and Energy and Task Consolidation (Yamini, 2012).

8. BENCHMARKS

This section lists the benchmarks used in green cloud computing that are helpful to make the cloud performance easy.

Perfkit is a living benchmark framework intended to develop through cloud technology variations and measures the latest workloads and makes knowledgeable decisions that matches infrastructure needs. New design tools, patterns and providers arise to keep it up-to-date (Google Cloud Platform Performance Team, 2015).

Grid'5000 similar to a benchmark is a large-scale, versatile test bed used to perform research experiments focusing on parallel and distributed computing which includes Cloud, High-Performance Computing (HPC), and Big Data (Grid'5000).

9. CONCLUSION AND FUTURE WORK

Cloud Computing has made tremendous impact to how business and companies leverage on computing technology. Green Computing has been evolving and makes amends on improving technology. There have been innovations, changes in architecture, simulators and other energy-efficient algorithms that are trying to help computing environment friendly. Green Cloud is one such, where it makes cloud computing friendly to our ecosystem.

The future of Green cloud is still evolving, with more work towards green computing and efficient algorithms. Green cloud is not a distant reach, new techniques will come out which is not only energy efficient but also efficient carbon emission usage. Cloud providers should reduce the demand of electricity in clouds and shift to using renewable energy sources for servicing.

Chapter 67
Looking Good and Thinking Green:
Can Green Personal Care Products Be Promoted?

Gauri Joshi
Symbiosis Centre for Management and Human Resource Development (SCMHRD), India

Gurudas Nulkar
Symbiosis Centre for Management and Human Resource Development (SCMHRD), India

ABSTRACT

The purpose of this paper is to determine the extent of environmental concern among consumers while purchasing personal care products. This paper also examines the role of consumer's willingness to pay for environmentally friendly products while making green purchase. It also tests if willingness to pay can be predicted based on certain product attributes. An exploratory factor analysis was carried out to develop the conceptual framework and based on which a questionnaire was designed. Primary data was collected from 300 respondents, women working in Information technology sector between the age group 25-45. The results show that there is high amount of environmental awareness among the consumers. However due to lack of proper and reliable information exchange between the manufacturers and the consumers this awareness does not materialize in green purchase behavior. Consumer's willingness to pay extra for ecolabeled product is dependent on the product reliability and appeal. Hence ecolabeled products stand a chance to be selected if they are appealing and reliable.

1. INTRODUCTION

The personal care products category (PCP) in India is rapidly growing. Over the last a few years, it has witnessed a 12 percent growth (Walkers, 2013). Products which once targeted higher income consumers are increasingly accessible to lower economic segments. C.K. Prahlad's call for serving the bottom of the pyramid has spawned several innovations; a notable one is the single serve sachet, which helped

companies reach out to the poor and create an environmental menace with the lack of proper disposal of the sachets (Nulkar, 2016). The PCP market includes large multinational and domestic players who have since, widened their product ranges to accommodate new market segments. In the euphoria of rapidly growing markets and increasing competitive intensity, the environmental impacts of PCP cannot be ignored. Like other products, they impact the environment in the entire life cycle consuming resources, creating waste and emissions during production, distribution and consumption and increasing the carbon and water footprints. Even as regulation and competitive pressures drive companies to improve their performance within their premises, overuse of resources and waste generated in consumption is not controlled and urban waste is turning out to be one of India's biggest problems. Moreover, consumers are often unaware of environmental impacts of the products they buy (Kennedy, Beckley, McFarlane, & Nadeau, 2009) which makes them overlook the environmental costs of their purchases. In this situation, it is imperative to promote green behavior in consumers of PCP category.

Product labels have been considered useful in this quest. Labels are used to convey specific attributes of the product that may be overlooked by consumers (Koos, 2011). Similarly, they can display environmental information about the product. This is increasingly seen in durables, especially those which consume energy during use. Environmental certifications and marking systems have evolved in many countries, which can be placed on product labels. Unfortunately, Indian industry lacks sophisticated labeling norms and has a weak enforcement regime. Unscrupulous sellers can get away with deceitful information. In 1991 the Ministry of Environment and Forests (MoEF) introduced 'Ecomark' scheme of labeling for environment-friendly products, however, this does not have a wide industry acceptance.

The authors conducted an exploratory study to examine factors which can influence green purchase behavior in consumers during purchase of personal care products. The role of ecolabels in this category was also studied. This paper presents the results of the study conducted on 300 women consumers and 35 retailers of PCP in Pune, India. This research is intended to assist in development of a more comprehensive study on PCP and ecolabeling. In the paper the term ecolabel is used to denote the information displayed on products about environmental impacts in their life cycle. The word 'green' is used to denote the environmental considerations.

2. LITERATURE REVIEW

Growing awareness of environmental problems and increasing media coverage have prompted many firms to take up greener practices. Studies show increasing consumer awareness and concern of the environmental impacts of the products they buy, and this manifests in growing purchases of environmentally friendly products across markets (AMF do Paco. & Raposo, 2009). Consumer's environmental concern is not easily translated into pro-environmental behaviour, so individuals holding strong beliefs that their environmental conscious behaviour will result in positive outcome are more likely to engage themselves in such behaviour in support of their concern for the environment (Sharma & Bansal, 2013).

Akwa (2009) suggests that women are significant actors in natural resource management and major contributors to environment rehabilitation and conservation. Studies also show that women are generally more willing to pay a premium for a green-product (Blend & Van Ravenswaay, 1999) (Loureiro & Lotade, 2005), (Loureiro M., 2003), (Loureiro, Mittelhammer, & McCluskey, 2002), (Brécard, Hlaimi B., Lucas S., Salladarré F., & Y., 2009). However, Lee (2011) argued that the environmental awareness of consumers affects environmental friendly behavior. To differentiate green products from others, it

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

is then important to communicate environmental information of the product to consumers. Moreover, terminology is not clearly defined and "recyclable", "eco-friendly", "environmentally safe" could mean different things to different manufacturers (Borin, Cerf, & Krishnan, 2011).

Studies have examined awareness, attitude, cultural background and situational factors to explain green purchase behavior in consumers. Bray et al (2011) note that despite environmental concerns and positive attitude of consumers towards sustainability and green products, market share of green products remains at about 3% of the entire market. Green purchase behavior forms a complex form of ethical decision-making behavior (Joshi & Rahman, 2015). Individual values and concerns for health, safety and pleasure specifically affected green food purchase behavior (Cerjak, Mesic, Kopic, Kovacic, & Markovina, 2010). Tsarkiridou et al (2008) found habit to be an important obstacle to green purchasing, which makes it difficult to change behavior. Another challenge is posed by the lack of trust consumers have on green claims and confusion among green characteristics (Joshi & Rahman, 2015).

Nelson (1978) suggests that an environmentally conscious consumer may be held back if she lacks sufficient knowledge on intended purchase and environmental labels are gaining importance as a tool for identification of green products (D'Souza, Taghian, & and Lamb, 2006).

Our concepts about price shape an expectation, which then biases our experience and our purchasing behaviour (Plassmann, 2008).

The increased concern of consumers towards the environment is reflected by their willingness to pay relatively higher prices for products that have been produced in an environmentally friendly manner. This increased willingness to pay provides a positive incentive for producers to choose techniques that minimize the adverse effects on the environment and improve the quality of final products (A. K. Basu., N. H. Chau., & U. Grote., 2003) In the Indian context there are few studies published on understanding the female consumer's willingness to pay for eco-labeled personal care products. The present study uses the Product Reliability which in this paper is an aggregate of Government certification, fixed vendor and Superior quality of product and Label Appeal which is an aggregate of the label design and the advertisement of the labeled product as predicting variables to predict the willingness to pay for an ecolabeled product.

Eco labels include claims like 'recyclable', 'eco-friendly', and 'recycled content' so as to catch attention of consumers that are looking for ways in which they could reduce adverse impacts to environment through purchasing decisions (Sinha, 2014). Ecolabels convey more than just functional properties of products. Scholl (2006) suggests that the symbolic values of a product can be more decisive, and ecolabels play an important role in this. Ecolabels can hold a variety of information and the quality of an ecolabel depends on the standards it selects (CSI, 2010). Moisander (2007) discusses the role of ecolabels in reducing controversial and dubious ecological information and how they could simplify decision making for consumers (Thøgersen, Jørgensen, & Sandager, 2012). Several studies have been undertaken on ecolabels (Gallastegui, 2002) (D'Souza, Taghian, & Lamb, 2006). Many researchers agree that ecolabels can influence consumers to take an informed purchase decision (Sherman, 2012) and are considered important to improve consumer's trust in a firm's environmental claims (Thøgersen, 2002) (Commission of the European Communities, 2007).

One category of ecolabel literature talks on relevance to buyers and sellers while another discusses third party eco-certifications and its market implications. An accepted definition of ecolabel is by Global ecolabeling network (GEN) - 'A label which identifies overall environmental preference of a product (i.e. good or service) within a product category based on life cycle considerations'. Rex (2007) considers it a tool for consumers to facilitate decision making during choice of environmentally friendly products.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Horne (2009) discusses the role of appropriate label information in sustainable purchasing. The large number of symbols and marking add to consumer's difficulty in assessing the comparable advantages of different products. Additionally, labels could be incomplete in terms of comprehensive environmental disclosure. Even as the social cost of purchase is not a high priority for many consumers, they could be persuaded to make an environmentally better choice through ecolabels.

However, some studies show a lack of trust among consumers on the information provided while some may not understand environmental information on the ecolabels. This leads to confusion or even negative reactions towards ecolabels (Hamilton & Zimmerman, 2006). Few studies show evidence of a variety and sheer number of eco-certifications and labels leading to consumer confusion (Leire, 2005). Moreover, it is often difficult to identify with accuracy the true attributes of product environmental impacts, the credibility of the ecolabeling process is important to facilitate consumer choices of green products (Mason, 2006). Some of the early generations of ecolabeled products were associated with lower quality products and some consumers might still associate ecolabels with lower quality products and be reluctant to purchase them (Gallastegui, 2002) (Peattie & Crane, 2005). Teisl (2008) suggests that the success of an ecolabel depends on its ability to present the information in such a way so that the consumer absorbs it. One study suggests that consumer's growing preference to ecolabeled products could give sellers a competitive advantage and an incentive to develop more environmentally friendly products (Grankvist, Dahlstrand, & Biel, 2004).

Third party eco-certifications, often given by non-producing organizations, have been studied in many countries. They suggest that there is growing acceptance of such certifications since they offer an independent validation of the producers' claims (Ibanez & Grolleau, 2008) (Cason & Gangadharan, 2002). In India Eco-Mark was launched in 1991. However, this has not met expected success (Mehta, 2007). Unlike category specific labels, the Eco-mark can be used for wide range of product categories from paper, pulp to leather to detergents to personal care products like soaps. Food and personal care items are low-involvement products which entails minimal effort and consideration before a purchase decision. Hence we need to check for the success of the ecolabeling scheme for such products; especially considering that the personal care products business is nearly $950 billion market and expected to treble by 2020.

3. MATERIALS AND METHODS

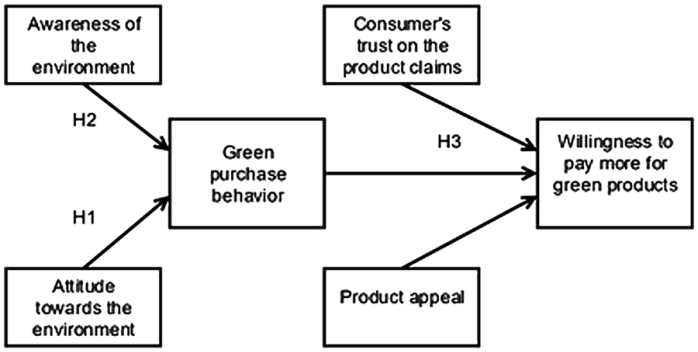
We first examined empirical research from various countries, to identify factors affecting green behavior among consumers. This was followed by exploratory interviews with consumers and retailers of PCP in Pune. Based on this, a conceptual model was developed which proposed factors affecting green purchase behavior and their relationship. A detailed questionnaire was developed with a web based survey application. This was administered online and in paper and pen format to over 450 respondents living in Pashan, Bavdhan, Aundh and Hinjewadi suburbs of Pune city. Respondents were working women between ages 20 to 45 and employed in the information technology sector in Pune. Sampling methods employed were simple random using internet lists, convenient samples and snowballing. 300 valid responses were analyzed. For selection of retailers, random and convenience sampling methods were used. In-depth interviews were conducted with 35 retailers. This comprised of chemists, vanity store owners and grocery store owners but did not include organized retailers like D-Mart, Big Bazar and others.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

3.1. Objectives, Conceptual Framework and Hypotheses

Although many studies on consumers' green purchase intentions in the PCP category are published from developed countries, very few from India were available. Most Indian research focuses on organic food or healthcare products. This study was developed with two primary objectives: (i) to examine factors which affect the green purchase behavior of consumers in personal care products and (ii) to study the role of ecolabels on consumers' purchase behavior. Urban working women are important target segments for PCP. Based on previous studies, we identified factors and studied them within Indian working women. Additionally, the environmental awareness, attitudes and behavior of respondents helped understand the environmental considerations in purchase of PCP.

3.2. Conceptual Framework



The conceptual framework (Figure 1) depicts the research variables and proposes relationships between them.

Corresponding to the objectives we propose the following hypotheses:

H1: Green purchase behavior is dependent on the consumer's attitude towards the environment.
H2: Green purchase behavior is dependent on the consumer's environmental awareness.
H3: Consumer's trust on the product and its appeal will result in a higher willingness to pay more for green products.

The questionnaire opened with relevant demographic questions and questions on leisure activities, shopping frequency and preferences. The construct '*Attitude towards environment'* was operationalized by classifying attitudes based on responses to questions on personal care products and the environment, recycling and on willingness to pay for environmentally friendly products. The respondent's '*Awareness of environmental issues'* was measured through questions on ecolabels, environmental terms and respondents' understanding of the impact of personal care products on the environment. One set of questions pertained to the extent of information sought during the purchase, her awareness and perceptions of ecolabeling and factors which might influence respondents to choose eco-labeled PCP.

Figure 1. Conceptual framework

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

4. RESULTS AND DISCUSSIONS

The research focused on the personal care product category. A list of the sub-categories is shown in Table 1. The demographic profile of the respondents is shown in Table 2.

The responses were clubbed into the two age groups - Age group 1 for respondents from 20 to 35 and Age group 2 for those over 35 years. 79.7% of the respondents fell in Age group 1 and 20% in Age group 2. 64% of all respondents earn up to INR 50,000 per month, which indicates that they are in early stages of their careers. To group the respondents according to their activities and interests, we conducted an exploratory factor analysis (EFA). The reliability test on this set of questions yielded Cronbach's alpha of 0.706. The EFA came up with four groups which were named as Multiactive, Self-engaged, Relaxed, TV addicts.

The respondents' 'Awareness of environmental issues' was measured through a set of questions and the responses were given marks. The total marks were termed as the Awareness Score. Due to a high variance in this score, three groups were made representing three levels of environmental awareness – high, medium and low. The number of respondents in each Awareness level is shown in Table 3.

Table 1. List of personal care product categories in this study

Soaps
Hair care
Skin care
Oral care
Baby and child care
Men's grooming
Cosmetics

Table 2. Demographic profile of respondents

Sr. No.	Characteristic	Category	Frequency	Percent
1	Age	20 to 35 years	239	79.7
		Over 35 years	60	20
2	Monthly income	Upto 50,000	191	63.7
		50 to 100,000	55	18.3
		100,000 and above	37	12.3

Table 3. Level of environmental awareness among respondents

Level of Environmental Awareness	Number of Respondents	Percent of Respondents
Low	73	24.3
Medium	53	17.7
High	174	58.0
Total	300	100.0

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Considering the educational and other demographic similarities in the respondents, the high incidence of environmental awareness was expected.

In the same manner, the Attitude Score was computed from the set of questions measuring the respondents' attitude. The scores were clubbed into negative, indifferent and positive Attitude Type. The frequencies are shown in Table 4.

The majority of respondents (63%) demonstrated an indifferent attitude, which is surprising, since 58% had high environmental awareness. Our review of other studies suggested that this could be due to a low trust that consumers have on environmental information, certifications and on the lack of accepted definitions of green products.

To test if the Attitude and Awareness levels are independent of each other a Fisher Exact Chi Square test was conducted. The test showed a significant dependence of the two variables (p=0.006). Table 5 shows the test results.

74.4% of the respondents with a positive attitude had a high awareness. This suggests a need to improve consumer awareness and one way to do this is displaying environmental information on the product label. Such information is found on some product categories in India, however, not in the PCP category. There is also a need to communicate the benefits of purchasing ecolabeled products through various mediums of communication.

4.1. Green Behavior

We asked the respondents their shopping preferences in sub-categories. The sub-categories included deodorants, sunscreen lotions, moisturizer and body wash, hair care products, colour cosmetics, oral care products and baby products. From the responses the 'Green Behavior Score' was computed for the respondent. These scores ranged from -17 to +20. Based on their z values the scores were clubbed into three 'Shades of Green Behavior' - Brown, Grey and Green (Table 6). A 'brown' consumer would have neither sought nor purchased ecolabeled PCP in any of the categories'; a 'grey' consumer may have

Table 4. Respondents' attitude towards the environment

Attitude Type	Number of Respondents	Percent of Respondents
Negative	68	22.7
Indifferent	189	63
Positive	43	14.3
Total	300	100.0

Table 5. Correlation between the level of environmental awareness and attitude of respondents

		Level of environmental Awareness			
		Low	Medium	High	Total
Attitude	Negative	33.8%	23.5%	42.6%	100%
	Indifferent	21.7%	18.5%	59.8%	100%

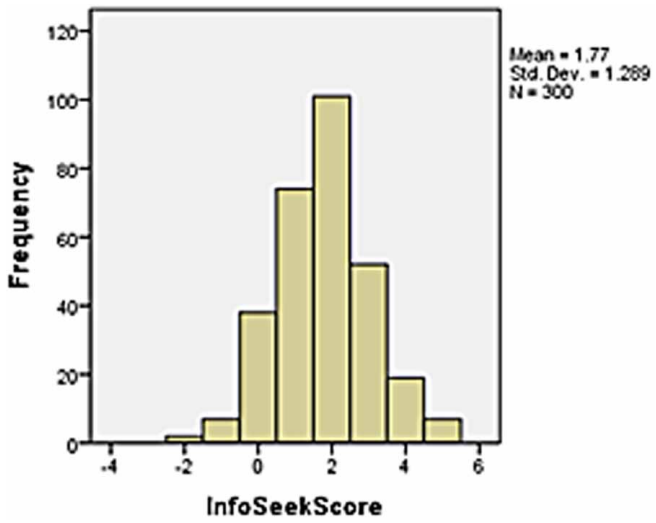
Table 6. Shades of green behaviours among respondents

Shade of Green Behavior	Brown	Grey	Green	Total
Number of respondents	44	89	167	300
Percent of respondents	14.7%	29.7%	55.7%	100%

sometime bought one or more of the ecolabeled PCP category products and a 'green' would have bought and searched for ecolabeled products.



In our study, a large number of consumers demonstrated green behavior (55.7%). Considering the earlier finding, it is possible that consumers may have inadvertently chosen greener products. This suggests that at least some environment considerations in the PCP can improve the value of the product in some way which is important to consumers. For example, consumers perceive herbal products as more health friendly. This finding can be an important reason for companies improve their environmental performance and to educate consumers on those aspects of their products.

4.2. Do Consumers Seek Environmental Information During Purchase of PCP?

To answer this, we asked questions about the respondent's search for information in the purchase process. The questions checked how often respondents read the label information and what information they read. The responses were scored into an InfoSeek Score. The scores ranged from -2 to 6 (see Figure 2).

The skew of the histogram indicates that consumers seek environmental information during these purchases. This was supported by responses from retailers who said that consumers generally read product labels during purchase. This finding places importance on the role of labels in conveying the information sought as well as emphasizes that retailers should have knowledgeable and sales persons at the counters who can help consumers interpret the ecolabels. This will increase the chances of sale of ecolabeled products (Pandey & Khare, 2015).

Figure 2. Scores

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

4.3. Is the Green Purchase Behavior Dependent on the Information Sought by Consumer in the Buying Process?

To understand this, we carried out a parametric ANOVA to see if the mean InfoSeek Score was different in the three groups of Shade of Green behavior. The ANOVA showed a highly significant difference in the mean scores in Brown, Grey and Green behavior groups. This suggests that consumers who exhibit a green behavior have a higher tendency to seek information on the product. This could explain the increase in the market share of organic personal care products category in India, which mention 'organic' on their labels. Product information, in addition to manufacturer's information and product usage form a part of Secondary benefit which women seek to satisfy while making purchase decision related to personal care products (Sundari & Murugan, 2011).

4.4. What Drives Consumers' Willingness to Pay a Premium for Ecolabeled PCP?

To understand consumer's willingness to pay extra for an eco-labeled product, we conducted a factor analysis by grouping items from Q.23. The questions comprised of options influencing the purchase of ecolabeled personal care products. The factor analysis yielded 5 factors which were grouped under two sub headings of 'Product Reliability' and 'Product Appeal'. Three variables - buying from a known vendor, presence of independent certifications on labels and the quality of the product being bought were grouped under 'Product Reliability'. The other two variables - well designed label and advertisement of ecolabeled products, were grouped under 'Product appeal'. A regression equation was formed with 'Willingness to pay extra' as the dependent variable and 'Product reliability' and 'Product appeal' as independent variables. The relation between 'Product reliability' and 'Willingness to pay' is significant with a B value of 0.166. Similarly, the relation between 'Product appeal' and 'Willingness to pay' is also significant with a B value 0.146. The regression equation explains an overall variance of 26% (Table 7). This suggests that there are other factors apart from 'Product reliability' and 'Product appeal' which influence the willingness to pay extra for eco-labeled products and worth studying further. This supports the third hypothesis made in the conceptual framework - *Consumer's trust on the product and its appeal will result in a higher willingness to pay more for green products.*

A further analysis on the responses on 'Willingness to Pay' more for ecolabeled PCP yields four categories of respondents - not willing to pay more, unsure if they would pay more, willing to pay up

Table 7. Regression between Prodrel and ProdAppeal

Model		Unstandardized Coefficients		Standardized Coefficients	t	Sig.	95.0% Confidence Interval for B	
		B	Std. Error	Beta			Lower Bound	Upper Bound
1	(Constant)	.867	.266		3.261	.001	.344	1.390
	Q24_Prodrel	.166	.022	.395	7.717	.000	.124	.209
	Q25_ProdAppeal	.146	.028	.268	5.235	.000	.091	.201

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

to 10% and willing to pay over 10% for eco-labeled PCP (Table 8 and 9). The results showed a high percent of respondents (58%) were willing to pay up to 10% more. On the other hand, just 11.3% were unwilling to pay anything more for eco-labeled PCP. This makes an argument in favor of improving product ecolabeling.

4.5. Testing the Hypotheses

In the conceptual framework we proposed the first hypothesis as - *Green purchase behavior is defendant on the consumer's attitude towards the environment.* To test this, we performed an ANOVA on the Attitude scores by factoring the Shade of Green behavior. The test showed a highly significant difference between the mean attitude scores between each shade of green. A post-hoc test showed no significant difference in the mean scores of grey and brown, but a highly significant difference between green and brown and green and grey. The test accepts the hypothesis.

The second hypothesis proposed is - *Green purchase behavior is dependent on the consumer's environmental awareness.*

To test this, we conducted the non-parametric ANOVA (Kruskal Wallis) between the Awareness scores of the respondents and the Shade of Green behavior. The test showed a significant difference in the mean Awareness scores between the three Shades of Green. The post-hoc Mann Whitney test was carried out on each pair, yielding the following results:

1. Between the Brown and Grey Shades of Green Behavior, there is no difference in the mean awareness scores;
2. Between the Brown and Green highly there is a significant difference in the mean awareness scores;
3. Between the Grey and Green there is a highly significant difference in the mean awareness scores.

Table 8. Willingness to pay more for green products

	Number of Respondents	Percent
Not willing to pay more	34	11.4
Not sure	74	24.8
Willing to pay up to 10% more	173	58.1
Willing to pay up to 20% more	17	5.7
Total	298	100.0

Table 9. Summary statistics for predictor variables

Variable Name	Description	Scaled Values	Mean	Std Deviation
Product Reliability	If a PCP is selected from the same vendor with Govt validated label and is of superior quality	(1,5)	9.05	3.00
Product Appeal	If a PCP is based on label attractiveness and Advertising	(1,5)	6.25	2.03

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

These relations suggest the possibility of improving green behavior by conveying more information to buyers. The information conveyed needs to be made directly relevant to the kind of product the consumer is intending to purchase. This could be trickier since no manufacturer would like to highlight the synthetic substances used in their products. A stronger policy regulation needs to be in place to control the malpractices.

4.6. Qualitative Responses

In addition to the questionnaire data, qualitative data was also collected from female respondents working in Information technology sector and the chemists and retailers stocking personal care products.

The female respondents were questioned on their personal background, the mode of transportation used by them to commute to the place of work, the manner in which they carried food to their workplace, their usage of disposables in the routine life and their inclination towards organic food and on the personal care product they used.

It was observed that out of a group of 35 female respondents, 60% preferred to travel by company transport, 20% preferred purchasing organic vegetables and fruits and a majority of them (70%) preferred using disposable items while hosting family functions. This suggests that on the one hand the respondents are demonstrating pro-environmentally behavior, they probably compensate its impact by indulging in non-ecofriendly practices like using disposable items. This also indicates the changing lifestyle of urban working women where convenience is preferred over functionality. Most of them preferred the branded personal care products (57%) while 31% preferred to use either home-made remedies or herbal products from well-known brands like Patanjali, Lotus Herbal and Himalaya. This indicates the increased exposure of working women to branded personal care products. In addition, it also emphasizes the trend of consumer's increasing consciousness about their looks. This further suggests that if marketed properly with the right communication strategies, ecolabeled products can get a foothold into the current market.

We also interviewed chemists, retailers and vanity store owners who stocked PCP. This was done to understand their awareness of eco labeled products. Out of 21 chemists interviewed, 80% were unaware of eco labeled products. This finding is quiet surprising as chemists are generally qualified individuals with a degree in pharmacy science. Though they stocked most of the personal care products, they did not recommend a product unless asked by the customer. The recommendations were not on eco-friendliness of a product. Since retail product margins are strong drivers to push product sales for retailers, conventional products may be paying retailers more than ecolabeled products. This could be altered by incentivizing pharmacists to increase the sale of ecolabeled personal care products.

5. CONCLUSION

The 2014 Greendex survey has shown that the top scoring consumers of this survey belong to the developing countries like India and China. Our research corroborates these findings as they show a high percent of Indian consumers displaying green behavior, possibly inadvertently, in the purchase of PCP. Moreover, PCP buyers showed a high awareness of environmental impact of their purchase. A large number of respondents are willing to pay extra to purchase ecolabeled personal care products. This aligns to consumers' correlation of price and quality, where a higher price corresponds to higher quality (Solomon M. R., 2006). The willingness to pay more suggests that PCP consumers perceive a similar relation

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

between price and quality. Correlations between awareness, attitude and green behavior are similar to findings from other countries and support the results of studies in other countries.

PCP consumers seeking green products consciously searched for environment related information on the product labels. This is a key consumer characteristic for marketers. This is a positive change as it will encourage producers, manufacturers and the Government agents involved to increase the standard of environmental products or services (Gallastegui, 2002). Unfortunately, our research does not support the findings from developed economies that there is a growing incidence of ecolabeling. We did not find any significant labeling in the PCP category in the Indian market. However, the findings from our research significantly favor ecolabeling and their ability to convey environmental information which can help marketers realize better prices. This can be looked upon as an opportunity to increase awareness through better labeling schemes and thus increasing the demand for environmentally friendly personal care products. We suggest that some existing ecolabels can be simplified to better communicate with non-buyers of ecolabeled products, especially since Tversky & Kahnemann (1981) study shows that negative information receives greater attention in consumers.

Some studies suggest that retailers have a prominent role in promoting green products and influencing consumers (Grunert, 2011). However, our study showed low awareness among various retailers and lack of interest in promoting green products. Most of retailers promoted products based on the margins they received and their popularity in the market. The retailers themselves were not highly educated to understand the gravity of the environmental issues. Moreover, there is confusion between herbal and ecolabeled products. Marketers need to consider this while launching green products. Product training and visual merchandise needs to be developed to improve retailer-consumer communication. Additionally, product labels can convey health benefits. Stricter law on product labeling especially for personal care products have to be enforced in order to avoid 'green washing' by PCP companies.

5.1. Limitations

The limitations of this research paper are it has considered only women working in Information technology sector and not any working women. The sample size of 300 is relatively small and may not represent the population of PCP buyers. In addition to this it has not considered the exact interpretation of an ecolabeled personal care product from these women. This was meant to be an exploratory study to further develop an in depth research with a larger sample.

ABSTRACT

This paper proposes a comprehensive framework of the individual factors that influence organizational decision-makers to adopt Green information systems (IS), based on a review of psychological theories and empirical studies on Green IS and technology adoption. The objectives of this paper are, firstly, to explain that the adoption of Green IS by managers is directly influenced by their intention, which is assumed to be influenced by their attitude towards Green IS, subjective norms, perceived behavioral control and personal norms. In the framework, attitude towards Green IS is influenced by managers' positive and negative affect in response to Green IS. The findings of this study show that subjective norms are reflected from three sources containing primary, secondary and work referents. Perceived behavioral control includes self-efficacy, monetary cost–benefit assessment and the ethical climate of the organization. Personal norms are influenced by awareness of consequences, ascription of responsibilities and

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

personal values including self-transcendence and self-enhancement. Secondly, the paper aims to assess the importance of the individual factors that influence the organizational decision-makers to adopt Green IS. Accordingly, the Technique for Order of Preference by Similarity to Ideal Solution (TOPSIS) is applied to rank the importance of the factors incorporated in the proposed framework. The data for this study is collected by conducting an online survey through a structured questionnaire-based instrument comprising 5-point Likert-type scales. The findings of this study contribute to the Green IS literature by improving the decision-making process in IS adoption for the purpose of environmental sustainability enhancement. It is hoped that the proposed model would help to clarify the relative importance of the psychological and socio-demographic factors influencing the adoption of Green IS by organizational decision-makers.

INTRODUCTION

Due to the fragile balance of the future of our ecosystem and society, sustainability issues are paramount and corporations, governments and cross-national bodies are turning their attention to the question of "how we can make the world a better place" (Malhotra et al., 2013). Sustainability is a complex term which encompasses issues related to the environment, economy and society. Simply, sustainability refers to conservation deployment and the responsible use of resources. According to the United Nations Report of the World Commission on Environment and Development (the Brundtland Report), sustainable development is "development that meets the needs of the present without compromising the ability of future generations to meet their own needs" (Commission, 1987). Recently, the focus of environmental concerns has changed from the local scale to the global scale, and has become the top concern of organizations, governments, non-governmental organizations and consumers (Dedrick, 2010; Kuo and Dick, 2010). As policies regarding environmental sustainability have been developed, and rules and legislation have been established, it was natural that organizations would focus more on their sustainable practices (Bansal, 2005; Zeleny, 2010).

Environmental sustainability has gained significant interest among researchers from different disciplines such as management (as evidenced in special issues of the Academy of Management Review in 1995 and Academy of Management Journal in 2000), and in other disciplines through some specialized journals such as Journal of Environmental Management, Journal of Industrial Ecology and Journal of Social Issues. The role which can be played by information technology (IT)[1] and information systems (IS)[2] in such endeavors has been neglected by researchers with few exceptions (see Pavlou and Fygenson, 2006 for a summary). The impact of IT and IS on the environment was considered in the special issue of Management Information Systems Quarterly (MISQ) in 2010/2011 on IS and environmental sustainability. Following this special issue, researchers focused on identifying the relationship between IT/IS and the environment, with this relationship found to be a complex one because of the two order effects of IT on the environment (Elliot, 2011; Malhotra et al., 2013). The first order refers to the negative impact of IT production, use and disposal on the environment. This perspective considers IT as part of the problem (Dedrick, 2010; Molla and Abareshi, 2012). Making IT product, use and disposal more environmentally friendly and greener is referred as Green IT (Dedrick, 2010; Molla, 2013; Molla and Abareshi, 2012; Ryoo and Koo, 2013). The second order effect refers to the positive impact of IT

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

on the environment which considers IT as part of the solution. Utilizing IT to make business processes and activities greener is known as IT for Green or Green IS (Dedrick, 2010; Molla, 2013; Sarkis et al., 2013; Watson et al., 2010).

Green IT and Green IS are still in their infancy and have just begun to be understood and implemented by organizations (Grant and Marshburn, 2014). The majority of Green IT and Green IS studies are focused on the introduction of the research agenda (e.g., Elliot, 2011; Esfahani et al., 2015b; Jenkin et al., 2011; Melville, 2010; Watson et al., 2010), and theoretically and empirically explaining the drivers and consequences of adopting organizational Green IT and Green IS initiatives (e.g., Bose and Luo, 2011; Chen et al., 2011; Molla and Abareshi, 2012). Despite the importance of organizational Green motivations, actions and factors that influence the adoption of these initiatives, they only tell part of the story (Molla et al., 2014). These studies have expanded our knowledge regarding the macro level-factors influencing the adoption of Green IS (Esfahani et al., 2015a; Esfahani et al., 2015b). For environmental sustainability and climate change issues which are complex problems, besides the organizational factors, there is a need to identify and understand the individual drivers and actions (Hasan and Dwyer, 2010) of managers and other decision-makers within the corporation who have the power to impact the direction and degree of environmental initiatives (Al-Khatib et al., 1995; Molla et al., 2014; Shafer, 2008; Trevino, 1986). The focus of the present study is on Green IS.

The pursuit of environmental sustainability in an organization should be the responsibility of everyone regardless of their position because of its complexity (Molla et al., 2014), while the urgency of the issues and the capacity for taking action would vary significantly. The adoption and implementation of organizational Green initiatives is not solely driven by commercial imperatives (Hemingway and Maclagan, 2004), but could also be associated with the environmental beliefs and attitudes of managers. Knowledge regarding the environmental beliefs of managers and their actions towards environmental sustainability, together with the factors which contribute to their beliefs and action formation, could be utilized to define the strategies that encourage individuals and groups to engage more in Green behaviors, and to facilitate the implementation of organizational Green IS initiatives and strategies (Molla et al., 2014).

Furthermore, organizational researchers like Starik and Rands (1995) proposed that "there is much to be gained by studying what guides managers' and other employees' sustainability-oriented decisions and behaviors" (as cited in Flannery and May, 2000). We also believe that in order to understand what organizations must do to become ecologically sustainable (e.g. Green IS adoption), it is crucial that we understand the decision intention of managers as they encounter the environmentally sensitive dilemmas.

Although some studies have shed light on the psychological factors in the adoption of Green IS, they have been limited to a set of psychological factors and did not embrace an encyclopedic set of key factors influencing the adoption of Green IS. As Trevino (1986) postulated, most managers "will look outside themselves for cues about what is right (appropriate) behavior and what is wrong (inappropriate) behavior". Understanding what key psychological factors influence the adoption of Green IS initiatives would interest managers as they intend to promote environmentally and ethically sound decision-making. Furthermore, as stated by Collins (1989), "ethical issues are often complex because in many instances, the trade-off is not between generating a harm or benefit, but between degrees of harms or benefits to company and/or stakeholder"; thus, the combination of psychological factors would be necessary to help and prepare decision-makers to make such difficult decisions.

To the best of the authors' knowledge, no such comprehensive framework for the adoption of Green IS has yet been proposed. The purpose of this paper is to develop a framework for the adoption of Green IS

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

initiatives by organizations to improve the social and/or environmental conditions. Thus, in comparison with the research efforts found in the literature, our work has a number of differences. In this research:

- A comprehensive set of psychological factors influencing the managers' intention to adopt Green IS has been integrated;
- The goal-frame of morality is included in the model, as it has been neglected in the Green IS-related literature;
- Following the upper echelons theory stating the importance of individual characteristics in the ethical decision-making process, the influences of socio-demographic factors of managers including age, gender and education level have been considered;
- Since Green IS is a new concept, measuring the actual behavior of managers regarding the adoption of Green IS is difficult. Hence, in this research, the impacts of identified factors on the adoption behavior are mediated through intention, which is the most significant predictor of actual behavior;
- The influence of identified factors in the proposed framework on the adoption behavior has been ranked based on their importance from the experts' perspective utilizing the Technique for Order of Preference by Similarity to Ideal Solution (TOPSIS).

We first elaborate the concepts of sustainability, ecological sustainability and Green IS. Next, based on goal-framing theory we discuss the motives and their underlying psychological frameworks that influence behavior in favor or against the adoption of Green IS. Subsequently, we clarify the factors that indirectly impact the decision-making process of managers to adopt Green IS initiatives. Then, the comprehensive framework, constituting the psychological factors that directly and indirectly influence the managers' decision to adopt Green IS, is presented. The applied methodology and the data collection strategy are discussed. Finally, the conclusions and contributions of the study are presented in the last section.

SUSTAINABILITY, ECOLOGICAL SUSTAINABILITY, AND GREEN IS

In this section, the terms "sustainability", "ecological sustainability" and "Green IS" are conceptualized.

Sustainability

Sustainability is a complex and partially developed concept (Mulvihill and Milan, 2007). The term was popularized in the Brundtland Report which defined it as "development that meets the needs of the present world, without compromising the ability of future generations to meet their own needs" (Commission, 1987). Traditionally, the single bottom-line measurement of success for organizations is the generation of profit, known as the creation of value for stakeholders (Friedman and Allen, 1970). Economic sustainability, which is the sustainable generation of profit, is pursued by many corporations, particularly the large ones. The opportunities for improving market share, profitability and competitiveness have enticed organizations to solely focus on their economic sustainability. However, only short-term success can be achieved through this single-minded economic sustainability. In order to achieve long-term success, organizations need to satisfy economic, social and ecological sustainability simultaneously (Dyllick and Hockerts, 2002). The ultimate goal of organizations is constituted by satisfying the three interdependent

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

dimensions of the "triple-bottom line" (Elkington, 1997), namely, economic sustainability, social sustainability and ecological sustainability.

Ecological Sustainability

Ecological sustainability refers to "the ability of one or more entities, either individually or collectively, to exist and thrive (either unchanged or in evolved forms) for lengthy timeframes, in such a manner that the existence and flourishing of other collectivities of entities is permitted at related levels and in related systems" (Starik and Rands, 1995). Natural resources have been long taken for granted and their preservation and sustainability are unlikely to be high on organizational agendas. Due to the lack of serious foreseeable economic impact in the future, societies and the natural environment have been ignored in organizational decision-making processes (Chen et al., 2008). All human activities such as agriculture, forestry and manufacturing rely on the natural environment (Starik and Rands, 1995). Hence, ecological sustainability should have the higher priority in organizational decision-making than economic sustainable development (Starik and Rands, 1995). The natural environment should be added to the list of organizational assets to ensure the long-term viability of the firm (Hart, 1995).

Green IS

Due to the compelling problem of ecological deterioration, the relationship between IS and environmental sustainability has attracted growing attention (Elliot, 2011; Melville, 2010; Watson et al., 2010). Related to environmental sustainability, IS applications abound for the purpose of good citizenship or to alleviate the detrimental effects of value chain activities. As stated by Malhotra et al. (2013), an example of these environmentally responsible IS applications is a large technology company's launch of an IS application to raise awareness regarding the climate and energy use and to drive engagement. Another example, provided by Musbah (2010), is related to a logistics company that gathered and analyzed route information on trucks, and was successful in increasing safety, lowering emissions and cutting maintenance. This IS application complemented the company's software package to recommend the most sustainable routes to drivers to deliver their packages, resulting in the reduction of gas usage by three million gallons and CO2 emission by 32,000 metric tons (Malhotra et al., 2013). Strategically, the deployment of IS applications for environmental sustainability allows organizations to proactively transform their business processes to benefit the society economically and ecologically.

Melville (2010) defined IS for environmental sustainability as "IS-enabled organizational practices and processes that improve environmental and economic performance" which is referred to as "Green IS". Green IS refers "to the development and use of information systems to support or enable environmental sustainability initiatives and, thus, tends to have an indirect and positive impact" (Jenkin et al., 2011). Overall, Green IS refers to strategically investing, deploying and using IS to mitigate the detrimental impacts of organizational activities on the natural environment.

GOAL-FRAMING THEORY

In psychology and sociology it is assumed that people have different views on a given situation, and these views define how people behave in that situation. So, among other things, the behavior of an individual

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

in a given situation depends on the "definition of the situation" (Lindenberg and Steg, 2007). The goal "frame", which is the way of processing information by people in a given situation and acting upon it, has been identified as the main determinant of how people look to the given situation (Lindenberg and Steg, 2007). By changing the goal, the perception of people regarding the given situation will also change. The perceptions of individuals based on the goal-frame, and their behaviors, are the basics of goal-framing theory which has emerged from different sources but is strongly influenced by research in cognitive social psychology on the influence of goal-frames on cognitive processes (Lindenberg, 2001; Lindenberg and Steg, 2007). Based on the study by Lindenberg and Steg (2007), the central idea of this theory is that "goals govern or frame what people attend to, what knowledge and attitudes become cognitively most accessible, how people evaluate various aspects of the situation, and what alternatives are being considered".

Lindenberg and Steg (2007) identified three main goals which are also highly related to environmental behavior. These goals are the hedonic goal "to feel better right now", the gain goal "to guard and improve one's resources" and the normative goal "to act appropriately". When a gain goal is activated, the choice of an individual is based on giving weights to factors such as the costs, benefits and risks of different options, and the individual will select an option with the highest gain against the lowest costs or risks. When a normative goal is activated, the choice of the individual from different options is based on moral evaluation, which is what is supposed to be the best in that situation. When a hedonic goal is activated, the choice of the individual is based on what feels better. When it comes to technologies related to environmental sustainability, individuals can base their adoption on: 1) the accumulation of costs, benefits and risks, 2) moral evaluation, depending on the extent to which the technology has a positive or negative effect on the environment or society, and 3) feelings, whether positive or negative, such as feelings of satisfaction, joy fear, or anger (Huijts et al., 2012).

Based on Lindenberg and Steg (2007), these three goal-frames coincide with popular theories and models in environmental psychology, which typically focus on one motivation only. The three goal-frames together with their coinciding theories are elaborated in following sections.

Gain-Goal Frame and Theory of Planned Behavior

When the focal goal-frame is gain, individuals are sensitive to changes to their personal property and resources. The time horizon of this goal-frame is medium- or long-term and the criterion for the realization of this goal-frame is the improvement of or prevention from a decrease in one's property and resources (Lindenberg, 2001; Lindenberg and Steg, 2007). In this goal-frame, individuals are sensitive regarding incentive information such as benefits, costs and risks especially in terms of scarce resources such as money, time and status (Lindenberg and Steg, 2007).

Among the social psychology theories of behaviors, the theory of planned behavior (TPB) (Ajzen, 1991; Ajzen and Madden, 1986) utilizes a rational-choice framework and self-interest deliberation to explain pro-environmental behavior and is likely to be particularly relevant when gain goals are focal (Lindenberg and Steg, 2007; López-Mosquera and Sánchez, 2012; Steg et al., 2014). TPB is a well-researched model that has been proven to predict behavior across a variety of contexts and settings (Pavlou and Fygenson, 2006),, and as a general model is used to explain most human behaviors (Ajzen, 1991). In TPB, behavioral intention depends on three factors: (1) attitudes, defined as "learned predisposition to respond in a consistently favorable or unfavorable manner with respect to a given object" (Fishbein and Ajzen, 1975), (2) subjective norms, which refer to individuals' perceived social pressures to perform or

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

not to perform a specific behavior, and (3) perceived behavioral control, which refers to the individuals' perceived ease or difficulty in performing a particular behavior.

Green IS Attitude

Attitude refers to the degree to which an individual assesses a behavior as favorable or unfavorable (Fishbein and Ajzen, 1975). According to Gholami et al. (2013), attitude is an affective characteristic of an organization's decision-makers which measures the extent to which they are aware of and interested in Green IS. Organizations' decision-makers (i.e. senior managers) play an important role in conveying the strategic importance of Green IS across the organization and in making resource allocations (Gholami et al., 2013). . In particular, the positive attitude of organizations' decision-makers is necessary for Green IS to be adopted successfully (Butler, 2011; Gholami et al., 2013). Empirical studies have proven that attitude is a strong predictor of intention to adopt IT (Hsu and Chiu, 2004; Taylor and Todd, 1995) and Green IS use (Kranz and Picot, 2011, 2012; Rivis et al., 2009).

Subjective Norms

The behaviors of humans do not happen in a vacuum environment, but are embedded within a social context, so they are susceptible to interactions with the social environment (Kranz and Picot, 2011, 2012). Several theories in different disciplines such as social psychology (e.g., Fulk et al., 1987), behavioral research (e.g., Fishbein and Ajzen, 1975), and innovation diffusion (e.g., Venkatesh et al., 2003) highlight the impact of social influence. In studies related to technology adoption, however, social influence has only the subordinate role because of its uncertain psychometric properties (Davis et al., 1989) and contradicting results (e.g., Pavlou and Fygenson, 2006; Venkatesh and Morris, 2000). Based on TPB, most of these studies measured the social influence factor by a single item. Armitage and Conner (2001) suggest that the poor performance of subjective norms in different studies is because of its single-item scale measurement; they believe a multi-item scale measurement would be more reliable. Following empirical studies (e.g., Brown and Venkatesh, 2005; Venkatesh et al., 2003) influential others are grouped into primary sources, secondary sources, and workplace referents. The influence of primary sources is "the extent to which members of social network influence one another's behavior" (in this case, family and friends), the influence of secondary sources is "the extent to which information from TV, newspaper, and other secondary sources influence behavior", and the influence of workplace referents is "the extent to which coworkers influence behavior" (Venkatesh and Morris, 2000; Venkatesh et al., 2003).

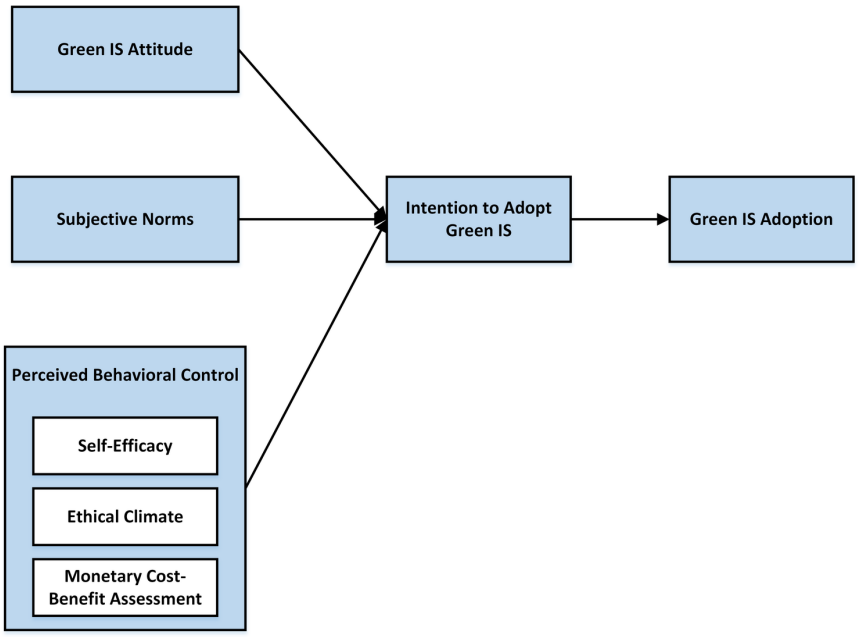
Perceived Behavioral Control

Ajzen differentiated between internal and external perceived behavioral controls, and defined internal control factors as "individual dispositional factors and include the amount of information a person has, along with the person's skills, abilities, emotions, and compulsions concerning a specific behavior" (Ajzen, 1988). External control factors are situational issues outside the individual. Ajzen and Madden (1986) asserted that "these factors determine the extent to which circumstances facilitate or interfere with the performance of the behavior". Following the empirical studies (e.g., Flannery and May, 2000; Papagiannakis and Lioukas, 2012), we distinguish between the internal control factor of self-efficacy and the two external control factors of monetary cost-benefit assessment and ethical climate of the organiza-

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

tion. Self-efficacy (i.e. the belief or conviction that one has the capability to perform a specific behavior (Bandura, 1997)) is a prominent construct in social psychology. As Bandura (1997) stated, self-efficacy refers to a person's expectancy about whether he/she can perform the specific behavior successfully. She argued that self-efficacy influence individuals' decisions and choices, because they engage and put more efforts in tasks that they believe they can successfully perform. The adoption and diffusion of environmental initiatives highly depend on the budget allocation and process prioritization of the corporation (Phillips and e Costa, 2007) and the associated cost-benefit assessment (Weber, 2008). As suggested by Papagiannakis and Lioukas (2012), when the assessment is purely based on monetary issues, "it does not embrace the philosophy of environmental proactiveness". While the costs can be measured easily, the benefits such as customer attraction or the improved image of the corporation cannot be measured without additional information. While the acquisition of such information is often considered too costly, the misestimation of the overall assessment (King and Lenox, 2002) may lead managers to invest in costly environmental practices. The importance of studying organizational decision-makers and their context is established in the literature (Trevino, 1986) and (Tetlock, 1985), because "both individuals and small groups of individuals are constrained by the norms, procedures, and resources of the institutions in which they live and work" (Tetlock, 1985). As proposed by Wimbush and Shepard (1994), the factor which mostly causes individuals to behave unethically is the instrumental climate. In an ethical climate based on the instrumental dimension, "organizational members look out for their own self-interest, first and foremost, to the exclusion of the interest of others who may be affected (even adversely) by their decisions" (Wimbush and Shepard, 1994).

TPB has been applied in various studies to investigate the environmental behavior and intention of individuals both within and outside organizations (e.g., Bernardi, 1994; Bernath and Roschewitz, 2008; De Groot and Steg, 2007; Flannery and May, 2000). Most importantly, this theory has been applied as a bridge between the managers' characteristics and the organizations' environmental behaviors (e.g., Flannery and May, 1994; Flannery and May, 2000; Papagiannakis and Lioukas, 2012; Sharma and Sharma, 2011). From the empirical studies (e.g., Flannery and May, 2000; Papagiannakis and Lioukas, 2012), it can be thus concluded that attitudes towards Green IS, subjective norms and self-efficacy positively influence the managers' intention to adopt Green IS initiatives, while the monetary cost–benefit assessment and ethical climate (instrumental) of the organization negatively impact their intention to adopt Green IS initiatives. A summary of the TPB adapted for the context of Green IS adoption is depicted in Figure 1.



Normative Goal-Frame and Value-Belief-Norm Theory

Following the activation of the normative goal-frame, all related sub-goals linked to appropriateness are also activated. This goal-frame makes individuals sensitive regarding what they think that they should do. This makes the aspects of the situation normative in that the individual is sensitive both to what he or she "should" do according to self or others, and sensitive to observing what other people are doing (Lindenberg, 2001; Lindenberg and Steg, 2007). In the environmental context, the normative goal-frame means acting pro-environmentally without considering costs or benefits (Lindenberg and Steg, 2007) and this goal-frame is stronger when people are aware of environmental problems.

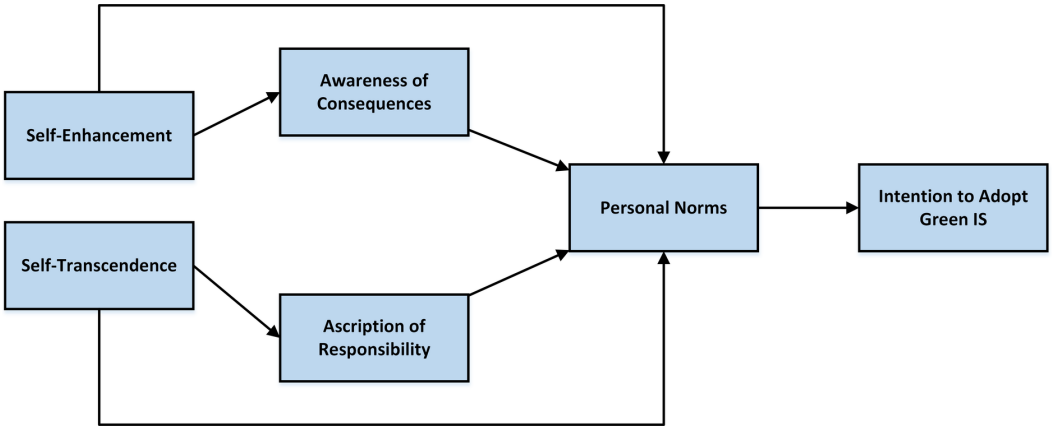
Normative goals are the key factors of Schwartz's norm activation theory (Schwartz, 1977) which explains how moral motivations impact on behavior. The central idea of this theory is that, by activation of personally moral norms, the pro-social behaviors are influenced. There are two pre-conditions for the

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Theory of planned behavior adapted to Green IS adoption

activation of personal norms: 1) awareness of consequences (i.e. "the individual must be aware that her action has consequences for the welfare of others"), and 2) ascription of responsibility (i.e. "the individual must feel a personal responsibility to undertake that action") (Schwartz, 1968, 1977). Schwartz (1977) explains that, in an action situation, norms are constructed based on a set of values related to the taken action. In the literature on the application of norm activation theory in pro-environmental action, altruism (or concerns toward other human beings) is considered as a value orientation that is relevant for norm construction in the context of environmental behavior. However, Stern (1999) argues that besides the personal norms based on altruistic values towards other human beings, norms based on self-interest and altruism towards non-human species are also guiding the individual's pro-environmental behavior. The idea of guiding pro-environmental action through these three value orientations further resulted in the development of the value–belief–norm (VBN) theory by Stern (1999). The VBN theory postulates that the relationship between values and actual behaviors is affected by more factors than the specific environmental attitudes. These factors are: (i) fundamental values, (ii) behavior-specific beliefs, and (iii) personal moral norms that guide the individual's actions. Within VBN theory, various individually held values have been identified that affect individuals' beliefs and norms and consequently their actual behavior (Jansson et al., 2010). The values most related to activating individuals' pro-environmental beliefs and norms and thus influencing their Green behaviors have been found to be altruistic, biospheric, egoistic (De Groot and Steg, 2008; Hansla et al., 2008; Stern, 1999), and hedonic values (Steg et al., 2014; Steg et al., 2012). Altruistic and biospheric values (also known as self-transcendence) have generally been found to have a positive relation with environmental beliefs and norms and subsequently with pro-environmental behaviors, while egoistic and hedonic values (also known as self-enhancement) have been found to have negative influences on pro-environmental behaviors (De Groot and Steg, 2007, 2008; Nordlund and Garvill, 2003; Steg et al., 2014).

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use



In conjunction with VBN theory, different types of beliefs have been found to influence individuals to behave pro-environmentally. Following norm activation theory (Schwartz, 1977) and further VBN (Stern, 2000), it can thus be concluded that if organizational decision-makers are aware of the environmental consequences (the first pre-condition for the activation of personal norms) of their organizational activities, whether general or specific, and ascribe responsibility (AR – the second pre-condition for the activation of personal norms) to themselves to take preventive actions, their pro-environmental norms will be developed with a high potential to impact their actual behavior (Bamberg and Schmidt, 2003; Stern, 2000), in which there would be the adoption of Green IS. While attitudes reflect cognitive beliefs about the behavior in question, perceived behavioral control reflects beliefs about the degree of determination, and social norms reflect the beliefs of important others, personal norms provide the moral "coloring" of the decision-making process. However, the integration stage is the intention which is generated immediately before the behavioral decision is made (Klöckner and Blöbaum, 2010). It has also already been shown that a personal norm towards taking action is the most important predictor of intention to act pro-socially and pro-environmentally (Huijts et al., 2013); likewise, the study by De Groot and Steg (2010) regarding the adoption of nuclear energy technologies showed that the intention is strongly influenced by personal norms. Managers' awareness of consequences and ascription of responsibility influence their intention to adopt Green IS via their personal norms (see Figure 2).

Hedonic Goal-Frame and Theories on Affect

Based on Lindenberg and Steg (2007), when the hedonic goal-frame is activated, it eventually improves the feeling of an individual in a specific situation (e.g. avoiding efforts, avoiding negative thoughts, seeking direct pleasure or improving self-esteem). The time horizon of this goal-frame is short, and the improvement in the individual's feelings is its goal realization. Individuals who are in the hedonic goal-frame are sensitive to what makes their feelings, mood and pleasure better or worse (Lindenberg and Steg, 2007) . In this goal-frame, individuals are sensitive to factors such as mood, energy level (tired or energetic) and social atmosphere, with these factors playing the central role in theories on affect.

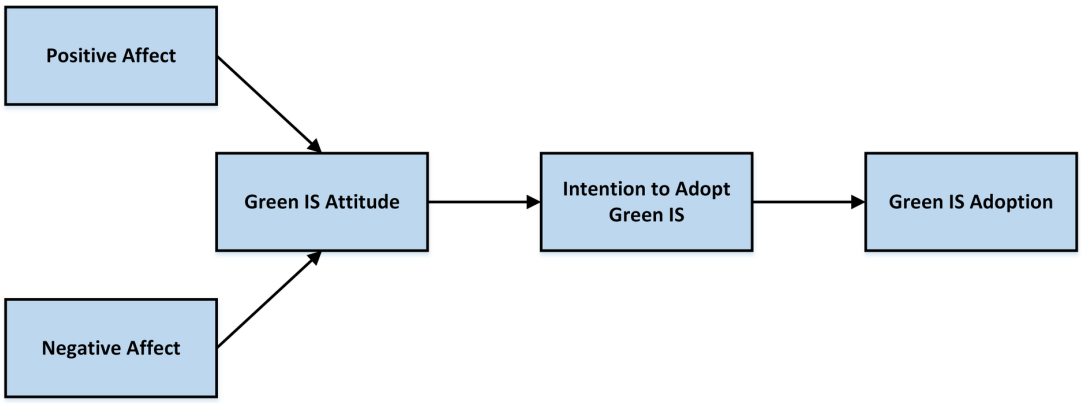
Vallerand et al. (1992) asserted that people who act pro-environmentally because it makes them pleased and satisfied are more likely to engage in pro-environmental behaviors, compared to the situation

Figure 2. Value-belief-norm theory adapted to Green IS adoption

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

where they act morally or follow pro-environmental norms especially when the behavior is relatively difficult. In the studies by Nilsson and Küller (2000) and Steg (2005) it was found that individuals who were emotionally attached to car-use for commuting drove more frequently than the individuals who were not emotionally attached to their cars and were more predicted by affect than instrumental motives. Emotional reactions to environmental problems also appear to be related to pro-environmental behaviors (Lindenberg and Steg, 2007). For example, as Grob (1995) postulated, the more intense the reaction of individuals to environmental degradation emotionally, the more they will engage in pro-environmental behaviors. In addition, it has been found that emotional affinity is positively related to conservation behavior (Kals and Maes, 2002).

Different studies (e.g., Bechara et al., 1994; Bechara et al., 1997) suggest that decision-making without affect is at "best impractical" and at "worst impossible". According to Djamasbi et al. (2009), affect "guides rationality by helping individuals to focus on a manageable subset of possibilities that look right or feel right". People who are in their positive affective state access more positive thoughts in their memory and hence tend to focus more on favorable and positive aspects of the situation, while on the other hand, people who are in the negative affective state are focusing more on the unfavorable aspects of the situation and tend to be more critical towards the situation (Djamasbi et al., 2009).



Various studies have investigated whether affective responses positively influence attitude and behavior (Loewenstein and Lerner, 2003) ; for example, studies related to risk perception (Taylor-Gooby and Zinn, 2006) and marketing (Erevelles, 1998). Following Ajzen (2001), affect can directly influence attitude; or following TPB (Ajzen, 1991), affect can indirectly influence intention. This suggests that attitude is both rooted in perceived costs, benefits and risks (cognitions) and affect (Ajzen, 2001) in which attitude is defined as "an evaluative integration of cognitions and affect experienced in relation to an object" (Crano and Prislin, 2006). In empirical studies (e.g., Cropanzano et al., 2003; Midden and Huijts, 2009; Peters and Slovic, 1996) it has been shown that positive affect (such as pride, happiness or satisfaction) and negative affect (such as fear, worries or anger) are related to each other but are distinct factors while both factors independently predict attitude. In studies related to the acceptance and adoption of energy technologies (e.g., Midden and Huijts, 2009; Montijn-Dorgelo and Midden, 2008; Peters and Slovic, 2007), affect has been found to influence evaluation of the technologies. Regarding the adoption of Green IS, it is then likely that senior managers in a positive mood will focus more on the helpful and beneficial aspects of Green IS, while those who are in a negative mood will focus more on those aspects of Green IS that are not favorable (Djamasbi et al., 2009) . Hence, we propose that positive and negative affect influence the attitudes of managers towards Green IS and indirectly their intention (see Figure 3).

THE INFLUENCE OF DEMOGRAPHIC FACTORS

In the IS literature it has been proved that socio-demographic variables such as age, gender, education level and working experience are critical in understanding how individuals make decisions regarding the adoption of technologies (Venkatesh et al., 2003). In the business ethics literature, the importance of these variables on individuals' ethical decision-making has been proven (Craft, 2013; Ford and Richardson, 1994; Lehnert et al., 2014; Loewenstein and Lerner, 2003; O'Fallon and Butterfield, 2005). In the literature, it has been identified that people who behave more ethically and are more ecologically responsible are female (Abeliotis et al., 2010; Cagle and Baucus, 2006), older (Brouthers et al., 2008; Eweje and Brunton, 2010; Krambia-Kapardis and Zopiatis, 2008), and well-educated (do Paço et al.,

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Integration of affect and attitude influencing intention to adopt Green IS

2009). Thus, we surmise that the managers' demography such as age, gender and education level can influence their decision-making process to adopt Green IS.

Age

The potential relationship between age and ethical decision-making has been investigated by many researchers in the business ethics literature (Cagle and Baucus, 2006). Mixed results have been reported regarding the influence of age on ethical decision-making. Some state that age is positively correlated with ethical decision-making (Nill et al., 2004), while others found an insignificant relationship between age and ethical decision-making (Marta et al., 2004). In the cognitive development approach adopted by Rest and Barnett (1986), they asserted that people are less likely to behave unethically as they gain an understanding of their position in society. In the empirical studies regarding ethical behaviors it is reported that older people tend to behave more ethically than younger ones (Brouthers et al., 2008; Eweje and Brunton, 2010; Krambia-Kapardis and Zopiatis, 2008).

A number of researchers have investigated the relationship between age and environmental sustainability commitment. Some scholars have reported a significant correlation between age and environmentalism (Jain and Kaur, 2006; Tilikidou, 2007). For example, Jain and Kaur (2006) reported that frugality and a conservative lifestyle were associated with older age. Tilikidou (2007) reported that people aged 55–60 tended to engage in more pro-environmental purchasing behaviors, while individuals aged 25–35 showed strong but unstable concern. Abeliotis et al. (2010) suggested that there is a positive link between individuals' age and pro-environmental behavior, finding that as age increases, the engagement in pro-environmental activities like "reduce, reuse, recycle" also increases. In the field of Green IT, Molla et al. (2014) reported a significant correlation between age and pro-environmental IT practices, and they found that young IT professionals tended to practice IT pro-environmentally.

Gender

A factor which is heavily researched in empirical studies on ethical decision-making is gender (Ford and Richardson, 1994; Lehnert et al., 2014; Loe et al., 2000; O'Fallon and Butterfield, 2005). The gender

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

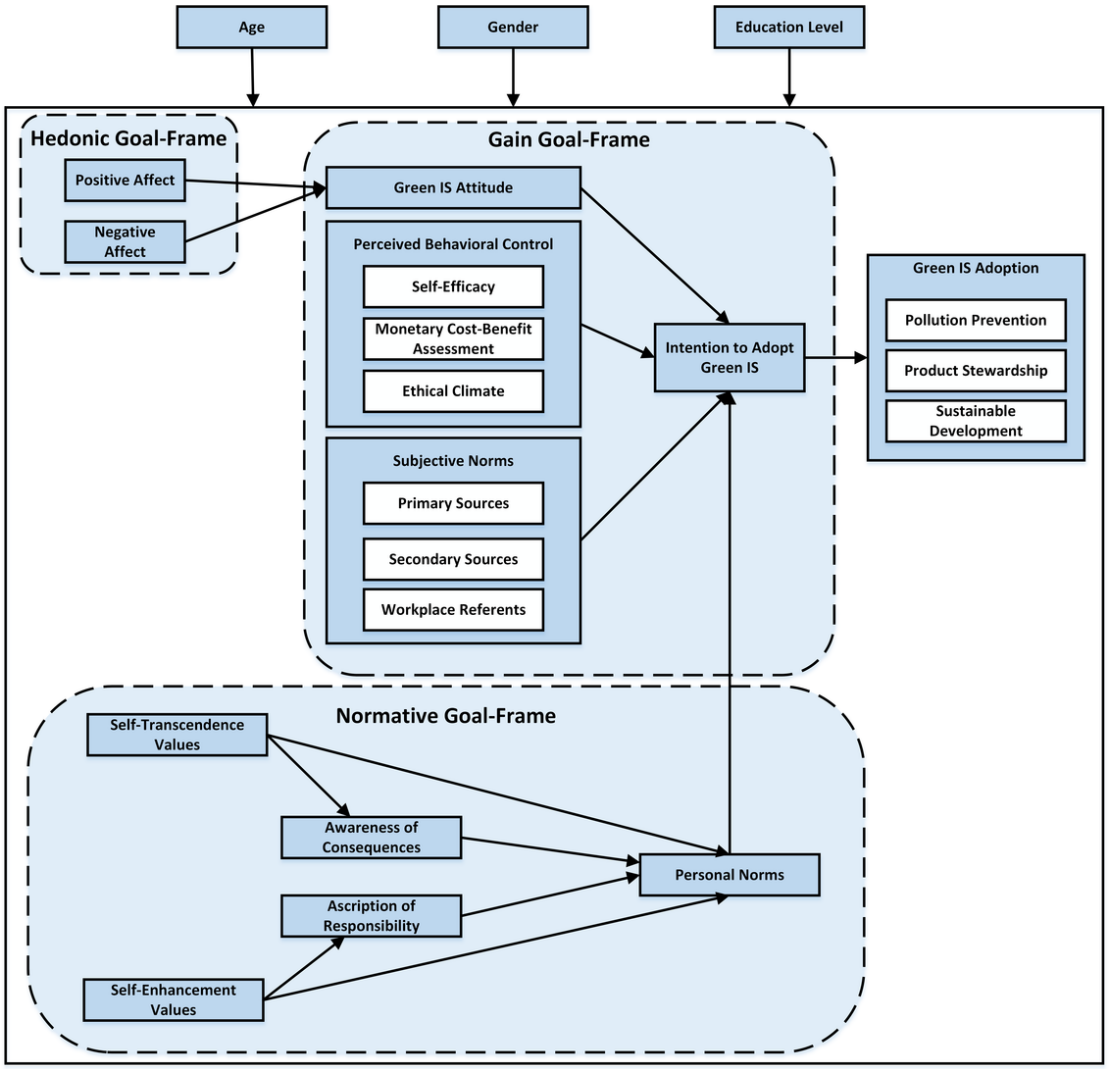
social theory (Gilligan, 1982) argues that males and females have different ethical behaviors because of differences in their socialization. It asserts that females tend to maintain relationships and emphasize the needs of others, while males engage in socialization according to fairness and equity. Furthermore, the ethical studies within the IS literature report that males are more likely to engage in ethical behaviors than females (Gattiker and Kelley, 1999; Kreie and Cronan, 1998; Loch and Conger, 1996; Solomon and O'Brien, 1990), while Moores and Chang (2006) reported that there were no difference between males and females regarding ethical behaviors.

Likewise, in the environmental psychology literature, mixed results are reported about the relationship between gender and pro-environmental behaviors. For example, Schultz et al. (1995) reported that gender does not predict attitude towards the environment. Further, it has been reported that there is no difference between males and females regarding committed environmentalism (Jain and Kaur, 2006), or the opinions regarding the seriousness of climate change or engaging in "reduce, reuse, recycle" activities (Abeliotis et al., 2010). However, some researchers have reported a significant difference in pro-environmental behaviors because of gender difference. For example, Iyer and Kashyap (2007) reported that females have "more favorable attitudes towards the environment and recycling and were more likely to engage in environmentally friendly and recycling behaviors" than males. Further, Ngo et al. (2009) reported that females pay more attention to greenhouse gas reduction activities than males, with women found to be more likely than men "to characterize global climate change as the most important environmental issue" (Abeliotis et al., 2010). Regarding pro-environmental IT practices and Green IT behaviors, Molla et al. (2014) reported the better behavior of males than females; however, in their model, there were no differences in the path coefficient between males and females.

Education Level

The correlation between ethical decision-making and the educational level of individuals has been studied in the literature related to business ethics. The results regarding the influence of education level on ethical decision-making are mixed, with some scholars reporting the significant influence of educational level while others arguing the insignificant impact of educational level on the ethical decision-making process (Musbah, 2010).

In the literature related to environmental psychology, a large number of studies have investigated the influence of education on environmental consciousness. However, the results that are reported are inconclusive. Although some studies have reported a negative correlation between education level and pro-environmental behaviors, most scholars have reported a significant positive relationship between the individuals' education level and their pro-environmental behaviors (do Paço et al., 2009; Rowlands et al., 2003; Tilikidou, 2007). Regarding pro-environmental IT practices and Green IT behaviors, Molla et al. (2014) reported that the IT professionals with undergraduate-level education or below tended more towards the pro-environmental practice of IT.



Following the above discussion on the influence of age, gender and education level on the adoption of Green IS, we suggest that these factors impact the whole decision-making process of managers towards the adoption of Green IS rather than specific factors or relationships.

There are various information technologies that enable an organization to practice Green IS including collaborative technologies such as telepresence and video-conferencing, carbon emission management systems and energy informatics systems. Green IS organizations also implement policies on the organi-

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

zation's use of IS for managing their emissions, energy and other assets (Gholami et al., 2013). Based on Chen et al. (2011) and Gholami et al. (2013), the adoption of Green IS by an organization can be assessed through the extent to which IS is embedded in its pollution prevention (i.e. "reducing overall emissions, waste and hazardous materials"), product stewardship (i.e. "enhancing the environmental friendliness of upstream and downstream supply chain management"), and sustainable development (i.e. "transforming business operations"). Hence, we suggest that the goal-framing of firms' managers together with their demographic characteristics influence the adoption of Green IS for the purposes of pollution prevention, product stewardship and sustainable development (see Figure 4).

Figure 4. The integrated framework of psychological factors influencing the organizational Green IS adoption

THE COMPREHENSIVE GREEN IS ADOPTION FRAMEWORK

Based on the psychological theories and the empirical studies on Green IS and IT adoption discussed above, we propose the comprehensive Green IS adoption framework as depicted in Figure 4.

METHODOLOGY

TOPSIS Method

TOPSIS was first developed by Yoon (1980) and is one of the well-known classical multiple criteria decision-making (MCDM) methods (Jajimoggala et al., 2010). Several objectives are achieved by MCDM, in which it provides a structured approach to determine the overall preferences among alternatives (Agha et al., 2014; Jajimoggala et al., 2011). TOPSIS can be used with both normal numbers and fuzzy numbers. It has been widely used in dealing with MCDM problems (Yazdani and Graeml, 2014). It makes full use of attribute information, provides a cardinal ranking of alternatives, and does not require attribute preferences to be independent. To apply this technique, attribute values must be numeric, monotonically increasing or decreasing, and have commensurable units. The procedure of the TOPSIS method consists of the following steps (Hwang and Yoon, 1981):

Given a set of alternatives, $A = \{A_i \mid i = 1,...,n\}$ and a set of criteria, $C = \{C_j \mid j = 1,...,m\}$ where:

$$X = \{\tilde{x}_{ij} \mid i = 1,...,n; j = 1,...,m\}$$

denotes the set of ratings and $\tilde{W} = \{\tilde{w}_j \mid j = 1,...,m\}$ is the set of weights. The first step of TOPSIS is to calculate normalized ratings by:

$$\tilde{r}_{ij}(\boldsymbol{x}) = \frac{\tilde{x}_{ij}}{\sqrt{\sum_{i=1}^{n} \tilde{x}_{ij}^2}},\ i = 1,\cdots,n;\ j = 1,\cdots,m \tag{1}$$

and then to calculate the weighted normalized ratings by:

$$\tilde{v}_{ij}(x) = \tilde{w}_j \tilde{r}_{ij}(x),\ i = 1,\cdots,n;\ j = 1,\cdots,m \tag{2}$$

Next the positive ideal point (PIS) and the negative ideal point (NIS) are derived as:

$$PIS = \tilde{A}^+$$
$$= \{\tilde{v}_1^+(x), \tilde{v}_2^+(x), \cdots, \tilde{v}_j^+(x), \cdots, \tilde{v}_m^+(x)\}$$

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

$$= \{(\max_i \tilde{v}_{ij}(x) \mid j \in J_1),$$
$$(\min_i \tilde{v}_{ij}(x) \mid j \in J_2) \mid i = 1,\cdots,n\}$$

$$NIS = \tilde{A}^-$$
$$= \{\tilde{v}_1^-(x), \tilde{v}_2^-(x), \cdots, \tilde{v}_j^-(x), \cdots, \tilde{v}_m^-(x)\}$$

$$= \{(\min_i \tilde{v}_{ij}(x) \mid j \in J_1),$$
$$(\max_i \tilde{v}_{ij}(x) \mid j \in J_2) \mid i = 1,\cdots,n\} \tag{3}$$

where J_1 *and* J_2 are the benefit and the cost attributes, respectively. Similar to the crisp situation, the following step is to calculate the separation from the PIS and the NIS between the alternatives. The separation values can also be measured using the Euclidean distance given as:

$$\tilde{S}_i^+ = \sqrt{\sum_{j=1}^{m} [\tilde{v}_{ij}(x) - \tilde{v}_j^+(x)]^2}, i = 1,\cdots,n \tag{4}$$

$$\tilde{S}_i^- = \sqrt{\sum_{j=1}^{m} [\tilde{v}_{ij}(x) - \tilde{v}_j^-(x)]^2}, i = 1,\cdots,n \tag{5}$$

$$\max\{\tilde{v}_{ij}(x)\} - \tilde{v}_j^+(x)$$
$$= \min\{\tilde{v}_{ij}(x)\} - \tilde{v}_j^-(x) = 0 \tag{6}$$

Next, the similarities to the PIS is given as:

$$C_i^* = D(S_i^-) \Big/ [D(S_i^+) + D(S_i^-)], \ i = 1,\cdots,n \tag{7}$$

where:

$$C_i^* \in [0,1] \ \forall i = 1,\cdots,n \tag{8}$$

Finally, the preferred orders are ranked according to C_i^* in descending order to choose the best alternatives.

Calculation of the Entropy Weight Vector

Information entropy is an uncertainty measure in information theory. Using the entropy method, objective weights are calculated.

Objective weights of the objective ratios can be determined by Shannon's entropy concept (Shannon, 2001). In this research, the concept of entropy is applied to determine the criteria weight. According to Shi-fei and Zhong-zhi (2005) and Zeleny and Cochrane (1982), entropy is a term in information theory, also known as the average amount of information. The criteria weights are calculated by the entropy method. According to the degree of index dispersion, the weight of all indicators is calculated by information entropy. The entropy method is highly reliable and can be easily adopted in information measurement (Zou et al., 2005).

Formally, the entropy method begins with a normalization process using the values of matrix $N = (n_{ij})_{n\times m}$ (n alternatives and m indicators) by the following specific formulation (Hwang and Yoon, 1981):

$$n_{ij} = r_{ij} / \sum_{i=1}^{n} r_{ij} \tag{9}$$

The following equation calculates entropy measure of every index:

$$\begin{aligned} E_j &= -K\sum_{i=1}^{n}\left[n_{ij}\ln(n_{ij})\right] \forall_j = 1,2,...m \\ K &= \frac{1}{\ln(n)} \end{aligned} \tag{10}$$

The degree of divergence dj of the intrinsic information for each criterion C (j= 1, 2, …, n) may be calculated as:

$$d_j = 1 - E_j \tag{11}$$

The value d_j represents the inherent contrast intensity of cj. The higher the dj, the more important the criterion cj is for the problem. The objective weight for each criterion can be obtained. Accordingly, the normalized weights of indexes can be calculated as:

$$W_j = \frac{d_j}{\sum_{k=1}^{m} d_k} \tag{12}$$

Since E_j is less than or equal to one, the entropy weights are therefore always positive.

Table 1. Profile of survey respondents

Gender	%	Age	%	Academic Rank	%	Number of Publications	%
Male	73	< 25	0	PhD (ongoing)	9	1-3	26
Female	27	25 – 34	17	Lecturer	13	3-5	22
		35 – 44	24	Senior lecturer	18	5-10	50
		44 – 55	26	Associate Professor	55	> 10	2
		55 – 65	23	Professor	5		
		> 65	10				

Data Collection and Analysis

The data for this study was collected by conducting an online survey through a structured questionnaire-based instrument comprising a 5-point Likert-type scale. The respondents were asked to indicate the importance (from 1 'not at all important' to 5 'very important') of each factor in influencing the behavior of managers to adopt Green IS.

This research instrument was addressed only to experts in the field of IS and preferably those with knowledge of Green IS. To that aim, using the Association for Information Systems database, which is the basket of IS-related journals and conference proceedings, we extracted the list of scholars who had published papers in the scope of incorporating IS and environmental sustainability issues (including Green IT and Green IS). The list contained the details of 113 scholars meeting the desired attributes.

Invitation to participate in the survey, together with an explanation about the research and a web link to the online survey questionnaire, was sent to all the listed scholars through an email. We followed up on the initial invitation with four reminders. After two weeks, 50 scholars had completed the survey. Respondents had a variety of positions in the field of IS. Almost 91 percent of respondents held a lecturing position in their affiliated institution and IS department. The majority of respondents were male (73 percent), held Associate Professor title (55 percent), were within the age of 34–65 (73 percent), and had 5 to 10 publications in the field of Green IT or Green IS (50 percent). A summary of the demographic background and profile of the respondents is provided in Table 1.

After data collection, we applied the TOPSIS technique to rank the factors in each group which influence Green IS adoption. Using the entropy method, objective weights were calculated and finally the ranks of all 15 Green IS adoption factors were calculated. Accordingly, the positive ideal and negative ideal (using Equation 3) and the final ranks (using Equation 7) are presented in Table 2 and Table 3, respectively. The calculated entropy measures of every index using Equations (10)–(12) are presented in matrix W (see Box 1).

Table 2. Positive ideal and negative ideal

Max V_{i1}	**Max V_{i2}**	**Max V_{i3}**	**Max V_{i4}**	**Max V_{i5}**
0.3429	0.529	3.559	8.529	8.411

Table 3. The final ranks of all 15 factors for green IS adoption

Factor	$D(S_i^-) / [D(S_i^+) + D(S_i^-)]$	Rank of Factor
Secondary Sources	0.451	15
Negative Affect	0.455	14
Primary Sources	0.463	13
Ethical Climate	0.472	12
Work Referents	0.508	11
Self-Enhancement	0.552	10
Positive Affect	0.561	9
Self-Efficacy	0.561	8
Ascription of Responsibility	0.582	7
Self-Transcendence	0.595	6
Awareness of Consequences	0.612	5
Monetary Cost-Benefit Assessment	0.665	4
Attitude	0.676	3
Personal Norm	0.721	2
Intention	0.741	1

[1] IT: devices which store, process and transmit information

[2] IS: cooperating set of people, processes and information technologies to support individual, organizational and societal goals

Box 1. Calculated entropy measures

$$w_1 = 0.048,\ w_2 = 0.185, w_3 = 0.221, w_4 = 0.379 \text{ and } w_5 = 0.165 \Rightarrow W = \begin{bmatrix} 0.0048 & 0 & 0 & 0 & 0 \\ 0 & 0.185 & 0 & 0 & 0 \\ 0 & 0 & 0.221 & 0 & 0 \\ 0 & 0 & 0 & 0.379 & 0 \\ 0 & 0 & 0 & 0 & 0.165 \end{bmatrix}$$

According to the ranking presented in Table 2, the first five ranks (using a threshold value greater than 0.6) belong to awareness of consequences (0.612), monetary cost–benefit assessment (0.665), attitude (0.676), personal norm (0.721) and intention (0.741).

DISCUSSION

IT has made significant impact on our lives (Amrollahi et al., 2013, Ghapanchi and Aurum, 2012, Zarei and Ghapanchi, 2008, Ghapanchi et al., 2012b, Ghapanchi et al., 2011, (Ghanbarzadeh et al., 2014, Najaftorkaman et al., 2014, Ghapanchi and Aurum, 2011). Many studies to date have been directed on various effects of IT in a wide variety of fields (Merati et al., 2012, Ghapanchi, 2013, Khosravi et al.,

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

2012, Ghapanchi and Aurum, 2011b, Amrollahi et al., 2014, Ghapanchi et al., 2014, Rezvani et al., 2012, Ghapanchi et al., 2010, Ghapanchi et al., 2012a). Several of such studies have reported positive impact of technology on various aspects of businesses (e.g. Zarei et al., 2013; Atlikhan et al., 2013; Purarjomandlangrudi et al., 2014; Talaei-Khoei et al., 2014; Vichitvanichphong et al., 2013; Ghapanchi et al., 2008; Ghapanchi et al., 2013; Ghapanchi, 2015).

By developing the comprehensive framework comprising the factors that influence the adoption of Green IS and by analyzing the model utilizing the TOPSIS technique and the data collected from 50 experts in the field of IS, some findings of previous studies on the importance of factors in adopting organizational eco-innovations and pro-environmental IT practices were confirmed. The results of the TOPSIS analysis revealed that the intention to adopt Green IS gained the first rank among the other factors regarding the importance of its influence on adoption behavior (0.741). This is in line with the theory of reasoned action (Fishbein and Ajzen, 1975) which postulates that the immediate predictor of actual behavior is the behavioral intention. Furthermore, behavior has been hypothesized as a function of a willingness to perform a behavior, which is intention. In the technology adoption in the literature, it is already asserted that the intention to act is a better predictor of the actual behavior than just merely evaluating the technology (Ajzen, 1991; Armitage and Conner, 2001). Huijts et al. (2013) asserted that by studying the intention, policy-makers can benefit from the early knowledge of how individuals will respond prior to the actual observable behavior.

Another important variable, sitting in the second place in the ranking list, is the personal norm. The ranking of this factor (with the value of 0.721) reflects the fact that individuals with the feeling of a moral obligation to engage in pro-environmental behaviors have a greater intention to practice Green IS initiatives. This supports the findings from previous studies that the most important predictor of intention and behavior to act pro-socially and pro-environmentally is the individual's personal norm (Andersson et al., 2005; Huijts et al., 2013; Jansson, 2011; Jansson et al., 2010; Jansson et al., 2011; Stern, 2000).

The third important factor in the list is the managers' attitude toward Green IS (0.676). Attitude, referring to the degree to which an individual assesses a behavior as favorable or unfavorable (Fishbein and Ajzen, 1975), plays a significant role in individuals' decisions to engage in a specific behavior. In a study on the factors that influence the senior managers' decision to adopt Green IS, Gholami et al. (2013) reported that the possibility of adopting Green IS initiatives among the managers with a positive attitude towards Green IS was higher than among the ones with less positive or even negative attitudes. The significant impact of attitude on the decision-making process of individuals to adopt IT (Hsu and Chiu, 2004; Taylor and Todd, 1995) and practice pro-environmental behaviors (Papagiannakis and Lioukas, 2012) has already been reported in the literature, and the findings of this study echo the results obtained by previous scholars.

The decisions of managers to adopt innovations for their firms are mostly based on rational choices, which are the trade-offs amidst costs, benefits and the risks of diffusing new technology and applying it to the business processes of the organizational activities. The fourth important factor on the list from the point of view of the experts and based on the results retrieved from the TOPSIS analysis is the assessment of cost and benefit (with the weight of 0.665). Economic motivations and outcomes are often the focus of the strategic decision-making literature (Flannery and May, 2000; Ilinitch and Wicks, 1996). However, in environmental proactiveness studies it has been reported that monetary cost–benefit assessment negatively influences the behavior of managers. It means that, the more that managers base their cost–benefit assessment on monetary criteria, the less they will integrate environmental initiatives

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

in their business processes (Bansal and Roth, 2000; Flannery and May, 2000). These findings indicate the importance of financial costs and benefits on the decision-making process of managers and further suggest that organizational researchers should examine the role played by monetary cost–benefit assessment in ethical and environmental decision-making.

Based on the TOPSIS analysis, the fifth important factor influencing the decision-making process of managers towards the adoption of Green IS is their awareness regarding the detrimental effects of their behavior on the natural environment. Various studies have investigated the impact of awareness of consequences on engaging in pro-environmental behaviors. Jansson et al. (2011) reported that the intention of individuals to adopt eco-innovations can be largely explained by their awareness of consequences. Furthermore, Gholami et al. (2013) asserted that the managers who attach a high degree of importance to the immediate consequences of behavior to the environment are more likely to integrate Green IS initiatives into their business processes. Hence, the results of this study reflect and support the results reported by other scholars from various disciplines.

Abovementioned are the first five important factors that influence managers to adopt Green IS based on the data retrieved from the experts and analyzed by the TOPSIS technique with the threshold of 0.6. Besides these five factors, the other factors including self-transcendence, ascription of responsibility, self-efficacy, positive affect, self-enhancement and work referents were placed within the ranking values of 0.5 and 0.6. The last four items, which are ethical climate, primary source, negative affect and secondary source, had the ranking values of 0.4 to 0.5. The dichotomizing of factors based on their ranking values helps organizational researchers to prioritize their focus in studying factors that influence the decision-making process of managers to practice Green IS initiatives in the business processes. In summary, it is believed that the intention of managers to adopt Green IS, their personal moral obligation to engage in pro-environmental behaviors, their attitude towards Green IS, financial considerations, and awareness of detrimental consequences of their behaviors are the key factors in influencing their behavior to integrate environmental practices in their organizations. Other factors regardless of their lower importance rankings should not be overlooked by researchers.

CONCLUSION

In this paper, we proposed a comprehensive framework to understand the factors that influence the firms' decision-makers to adopt Green IS initiatives. To conclude the proposed model, the literature was reviewed from various disciplines and fields including IS, environmental psychology and social psychology. The dependent variable in the model is the intention to adopt Green IS which is the most significant predictor of actual behavior. The model comprehends the psychological factors related to: (1) evaluating the Green IS initiatives themselves, (2) taking action in favor or against Green IS, and (3) morality influencing the intention to adopt Green IS.

The framework assumes that the managers' intention to adopt Green IS initiatives is based on the three relevant goal-frames (see goal-framing theory), which are the gain, moral and hedonic goal-frames. Gain motives are perfectly reflected in TPB, while the moral motives are assumed in VBN theory. These two theories are integrated in the proposed framework. In the model, hedonic goals are modeled as the predictors of attitude which are assumed in a large body of studies on affect.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

The variables that directly or indirectly predict the managers' intention to adopt Green IS have been identified as: positive affect, negative affect, attitude, perceived behavioral control (including self-efficacy, monetary cost–benefit assessment and ethical climate), subjective norms (including primary sources, secondary sources, and work referents), self-transcendence values, self-enhancement values, awareness of consequences, ascription of responsibilities, personal norms, age, gender and education level. The casual paths between the factors in the model were all based on the reviewed empirical studies in the corresponding literature. The variables of age, gender and education level were assumed to influence several factors and relationships, and were, hence, depicted to impact the whole proposed model.

The influence of each factor on the adoption behavior has been analyzed based on their level of importance. To do so, the data was collected from the IS experts and scholars through a 5-point Likert scale online questionnaire. To analyze the data, we applied TOPSIS, which is a multi-criteria decision analysis method for ranking the factors based on their importance in influencing the behavior. Results from the TOPSIS analysis supported the previous studies in the literature and reflected the experts' insights into the most important factors impacting the decision-making process of managers regarding Green IS adoption. From the perspective of the experts, intention, personal norm, attitude, monetary cost–benefit assessment and awareness of consequences were the five most important constructs influencing the behavior of managers. This study aimed to provide insights organizational researchers investigating the factors impacting the behavior of decision-makers to practice pro-environmental initiatives in corporations. Furthermore, corporations aiming at enhancing environmental sustainability would achieve better outcomes if they screen candidates for environmental management positions on the basis of their pro-environmental behavior. As Trevino (1986) postulated that "most managers will look outside themselves for cues about what is right (appropriate) behavior and what is wrong (inappropriate) behavior", the findings of this study would interest managers as they are intended to promote environmentally and ethically sound decision-making. As stated by Collins (1989), "ethical issues are often complex because in many instances, the trade-off is not between generating a harm or benefit, but between degrees of harms or benefits to company and/or stakeholder"; thus, the combination of ethics, ecological educations and explicit behavioral guidelines would be necessary to help and prepare decision-makers to make such difficult decisions. Finally, by integrating the individual factors and issues into organizational ethics and environmental behavior models, researchers may begin to understand the process of judgments and decision-making of our society's most influential decision-makers – the individuals who through their daily decisions within organizations contribute to the sustainability of the natural environment.

The framework is specifically proposed for Green IS adoption; however, it also can be used to study the adoption of Green IT, which focuses on mitigating the detrimental effects of IT on the environment. We limited the model to psychological and socio-demographic factors. Other factors may influence managers to adopt Green IS in their firms such as mimetic pressures, coercive pressures and normative pressures. These factors may influence the intention of managers to adopt Green IS through the variables in the model rather than directly. We hope the proposed model would help to clarify the relative importance of the psychological and socio-demographic factors influencing the adoption of Green IS by organizational decision-makers.

The casual order of the relationships between factors in the model has been investigated in the literature and has been the subject of debate in various empirical studies. The proposed framework (as illustrated in Figure 4) is based on the relationships dominantly investigated and suggested in the literature. For future studies, an appropriate research design would be needed to elucidate or strengthen the causality

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

of relationships, such as empirical and longitudinal studies. Furthermore, the variables in the framework are investigated in relation to Green IS as general technology acceptance or pro-environmental behavior. Hence, it would be worthwhile to use the framework to study specific Green IS initiatives as the technological aspects vary among different initiatives.

ACKNOWLEDGMENT

The authors would like to thank the anonymous reviewers for their helpful and constructive comments that greatly contributed to improving the final version of the paper. They would also like to thank the Editors for their generous comments and support during the review process.

Chapter 69
Meaning of Green for 3PL Companies

Pervin Ersoy
Yaşar University, Turkey

ABSTRACT

In today's competitive environment managing green, becoming environmentally friendly and sustainable has become main topic for all industries and companies. Therefore, in this chapter it will be addressed how green logistics solutions and practices can help companies to increase their performance with specific practices, cases and results from Turkey's 3PL service providers' side. This chapter will discuss why being green is important for 3PL companies and the benefits of being green from the business and environment side with current data and real life examples. The main purpose of this chapter is to shed light on green performance indicators and to identify benefits of being green for 3PL companies in Turkey.

INTRODUCTION

The growth of economy and globalization have increased the usage of energy and other sources. In a rapidly changing and developing world, environmental and social issues have become more important for managing businesses and industries (Luthra, et al., 2011). Green sustainability and corporate responsibility have started to play an important role in companies and managers' strategic decisions and plans (Lee, 2009) in recent years.

In the parallel of these developments and usage environmental issues, carbon emissions, solid waste disposals, and environmental pollution have become main topic for all industries.

Greening the supply chain is a new topic for many industries for managing their logistics activities in 21th century (Zhu et al., 2008a). Thus, companies try to find new tools or ways for being first innovator in the market.

As known the firm's activities directly threaten the environment with carbon dioxide and carbon monoxide emission through the transportation, production or packaging activities. Managing environmental problems effectively has become strategic and vital issues for many companies in recent years (Diabat and Govindan, 2011). Environmental concerns which has directly impact on company's supply

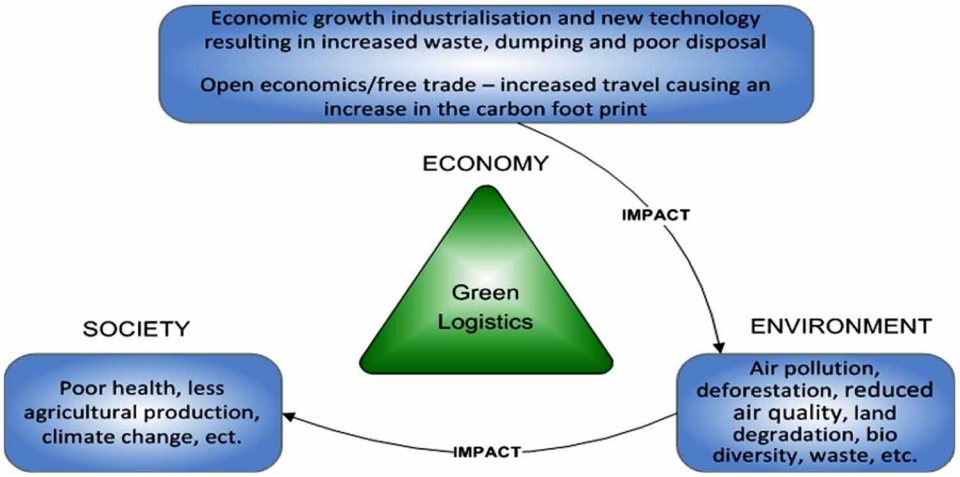
chain activities and performance have widely started to implement company's business processes (Zhu, et. al., 2016). It has been an enhancing interest on reducing wastes and company's disposals during the corporate activities (Melnyk et al., 2003).

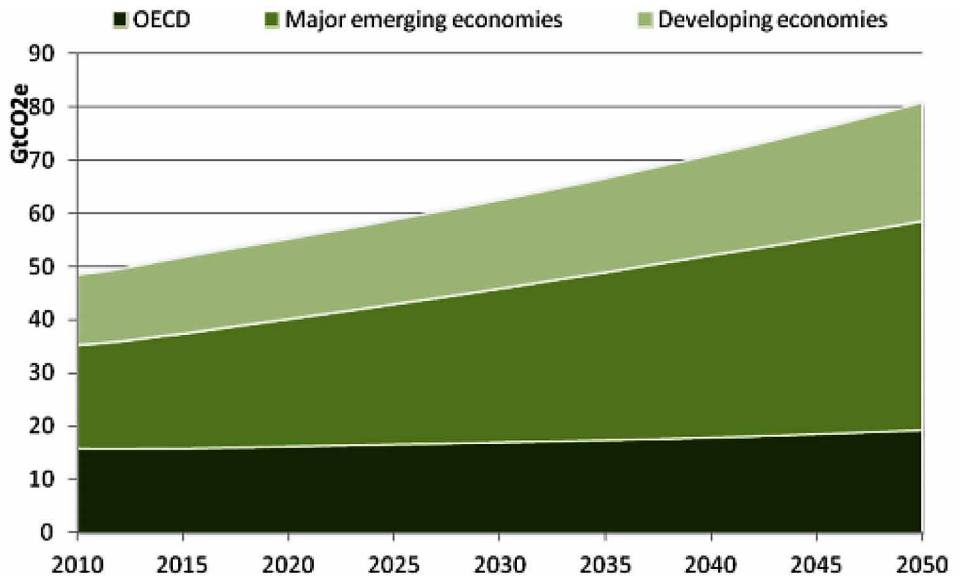
Companies have started to deal with these increasing environmental changes (Gil-Saura et al., 2009) with green solutions. Therefore, green has become current year's trend for economic, social and environmental sustainability (as shown in Figure 1).



Developed and developing countries have started to adapt environmental solutions to their policies (Mathiyazhagan et al., 2015), likewise all countries have begun to adapt environmentally friendly formulas to their policies to reduce the impact of pollutions, hazardous gases or chemicals, solid wastes, etc. In today's changing and developing world has increased the importance of green and protecting environment.

As seen in Figure 2, scientists and decision makers emphasize that developing countries are facing with intensive carbon dioxide emissions. Although today most developing countries contribute only minor shares to global greenhouse gas (GHG) emissions compared to the OECD and major emerging economies (OECD Report, 2012), like Turkey. Therefore, greening, green thinking, going green and green solutions have become important issues for all members, companies and also countries.

Greening means putting environmental values into each step of the processes. Essentially it can be said that being green means being environmentally friendly in each phases of processes. Companies are increasingly becoming responsible of environmental concerns and environmental issues with increased importance of being green. Therefore, environmental issues have become popular concerning factor in the last decades for the supply chain activities. Due to the increasing recognition towards green issues, firms have started to adapt green supply chain strategies to their business policies. Kurien and Qureshi (2012) emphasized that; "Green Supply Chain Management (GSCM) has become an important strategy for companies to gain profit and market advantages by reducing the environmental risks and improving efficiency".



Today many researchers and managers interested in green business, green environment, green logistics and also green supply chain management (GSCM) not only for corporate social responsibility but also gaining sustainable competitive advantage and strengthening company's corporate image. Thus, green

Figure 1. Components of green logistics

policies and being environmentally friendly have become key issues for many types and sizes of companies in the world. There are many theories in the literature that support these ideas. The main theories are Resourced Based View, Resourced Based Theory, Natural Resource Based View, Complexity Theory and Social Network Theory. Resourced Based View (RBV) theory implies that using environmental tools for managing company's activities can help companies to gain competitive advantages (Barney, 1991; Zhu et. al., 2005). Wernerfelt (1984) emphasized that Resourced Based View is a useful tool for investigating effects of green practices on supply chain performance. Natural Resource Based View (NRBV) highlights, using natural sources for managing company's process can help companies to increase their efficiency, environmental operational and financial performance (Zhu and Sarkis, 2004, Zhu et al., 2005). In the Complexity Theory, being responsive and sensitive to the environmental problems with adapting these solutions firm's system is important (Crozier and Thoenig, 1976). Social Network Theory is a suitable theory for helping and understanding sustainable developments (Connelly, 2011).

GREENING THE SUPPLY CHAINS

The cross-disciplinary field of green supply chain management has been growing in the recent years both in the academia and industry field (Sarkis, et al., 2011). The increasing importance of environmental issues have increased integrating green solutions into supply chain activities. In the traditional supply chain, the flow of materials and information is recti lineal and from one to another. In addition, the responsibility of the being green or environmentally friendly belongs to only limited partner or partners (Emmett & Sood, 2010). However, in the green supply chain the responsibility of protecting green and being environmentally friendly belongs to all members of the chain (Emmett and Sood, 2010). The vital

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

role of green supply chain management is to reduce company's bad environmental impact and increase company's financial performance with sustainability (Chin et al., 2015).

Green Supply Chain (GSC) can be described as the integration of green solution for each step of supply chain processes from raw material to consumer or end product. Although the traditional supply chain only focuses on the process and delivery, green supply chain concentrates on environment, environmental solutions and quality of living conditions during the process and delivery. Adding green component to the supply chain refers to integration of supply chain and environment (Srivastava, 2007). Green Supply Chain Management is the integration of green thinking into all supply chain processes (Chin, et al., 2015). Green supply Chain Management (GSCM) is an improvement tool for process and products development with environmental regulations and requirements (Hsu & Hu, 2008).

The main purpose of green supply chain management is to reduce traditional supply chain's environmental risks and impacts (Guo and Tsai, 2015). The purpose of being green is to minimize the negative impact of firms and their supply chains on the natural environment (Mollenkopf et al., 2010). Green supply chain practices represent the environmentally friendly image of products, process, systems and technologies (Vachon and Klassen, 2006).

This process ranges from green product design to product returns (reverse logistics activities) (Perotti et al., 2012). There are many different green supply chain definitions in the literature, the most commonly used definition was made by Srivastava (2007) as:

Integrating environmental thinking into supply chain management, including product design, material sourcing and selection, manufacturing processes, delivery of the final product to the consumers as well as end-of-life management of the product after its useful life.

Green supply chain means using green solutions in each step of the supply chain. Green supply chain management includes whole processes from product design to recycling. These processes include green design, green materials, manufacturing, green purchasing, green production, environmental performance evaluation and reverse logistics (Zhu and Sarkis, 2004; Hervani et al., 2005; Srivastava, 2007).

The ingredients of green supply chain can be listed as follows: green supply, green transportation, green purchasing and procurement, green distribution, green manufacturing, green warehousing, and green building, green packaging-eco labeling, green marketing and reverse logistics. Green supply; means providing goods and materials with noticing environmental qualifications like ISO 14000 (environmental standards). Green transportation; implies environmentally friendly vehicles in each step of transportation like using electrical vehicles during the transportation process or using eco-friendly equipment's and fuels. Green purchasing and procurement; refers to procurement and purchasing of products and services that have a reduced effect on human's health and the environment when compared with competing products or services that serve the same purpose (https://financial.ucsc.edu/Pages/Purchasing_GreenPurchasing.aspx#green). Green Products; are reusable or recyclable, as opposed to disposable, made with renewable energy, or contain a significant percentage of recycled post-consumer waste (https://finance.vanderbilt.edu/procurement/procurement/green.shtml). Green distribution; means designing distribution process more efficiently with thinking all parameters (warehouses, distribution centers, retailers) and finding optimum solution with transfer process. Green manufacturing; is an integrated approach to the reduction and elimination of all waste streams associated with the design, manufacture, use and/or disposal of products and materials (Handfield et al., 1997). Green warehousing and Green building/sustainable constructions; using eco-friendly equipment like pallets, forklifts in the warehousing and also designing

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

warehouses with less energy consumption (like solar energy usage windows, warehouses, etc.). The aim of these buildings is using energy, water and other resources efficiently for reducing waste, pollution, etc. Green packaging-eco labeling; implies re-usable or re-cycle packages for reducing environmental impact of packaging. Green marketing; is most frequently associated with the greening of the different aspects of traditional marketing. This generally involves the production of "green" products for sale to "green" consumers who are admonished to recycle the waste from their consumption (Kilbourne, 1998). Reverse logistics; is the process of planning, implementing and controlling the efficient, effective inbound flow, inspection and disposition of returned products and related information for the purpose of recovering value (Srivastava, 2007). Green supply chain processes like green purchasing, green packaging, green manufacturing, etc. can help companies to improve their performance (Green, et. al. 2012).

Integrating environmental management practices into all the supply chain processes to be greener help companies to be competitive in the market (Rao and Holt, 2005). In addition, some researches emphasized that greening activities increase business' profit and market share (Seman et. al. 2012).

The major differences between traditional supply chain and green supply chain can be listed as follows (as shown in Table 1).

In the next part the importance and benefits of being green will be discussed from the third part logistics providers' side with Turkey cases.

THE IMPORTANCE OF BEING GREEN ON FIRM'S PERFORMANCE

Performance and performance indicators are very important for companies especially supply chain firms for measuring their effectiveness and efficiency. Beamon (1999) enhanced that performance tools which include resource measures, output measures and flexibility used for measuring supply chain performance. Key Performance Indicator (KPI) is the another indicator for measuring company's performance. KPI shows actually that company achieved their purposes, goals and objectives or not. Some of the performance indicators that used for measuring supply chain performance are; on time delivery, zero defects,

Table 1. Differences between traditional supply chain and green supply chain

	Traditional Supply Chain	Green Supply Chain
Focus	The main focuses of the traditional supply chains are product, process, capital and information flows. Logistics, marketing, purchasing, distribution, demand forecasting, order fulfillment, customer services, coordination and adding value to the partners and customers are main topic of traditional supply chains. In the traditional supply chains, each member of the chain individually may focus on green like reduction of carbon emission or being environmentally friendly.	The main focuses of the green supply chains are environment, human, energy, waste disposal, and recycling. Green and environmental solutions, green purchasing, green logistics, reverse logistics, green marketing, green packaging, eco labelling and sustainability are main topics of green supply chains. In the green supply chains, all the members of the supply chains responsible to be environmentally friendly and protect environment from raw materials to the end users in each step of processes.
Aims	The aim of traditional supply chain is increasing coordination between partners/members and gaining competitive advantage in the market.	The aim of green supply chain is reducing the impact of wastes, disposals, etc. and protecting environment. Increasing firm's performance and financial performance for taking competitive advantage in the market with increasing company's reputation.
Benefits	Traditional supply chain provides coordination and control between partners. It can help to increase visibility and share information between partners.	Green Supply Chain can help companies to enhance their green image, customer loyalty, positive image, reputation, economic and environmental sustainability.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

customer satisfaction, quality of goods and services, accident ratios, etc. The main goals of supply chain performance indicators are increasing on time delivery, product and service quality, flexibility, value, product/process innovation, information flow, cash flow, response and reducing wastes. Supply chain performance measurement tools are substantial for companies to achieve sustainable competitive advantage (Lee, 2002).

Green Supply Chain Management (GSM) can help companies to develop "win-win" strategies to increase profit, efficiency and market share with reducing environmental risks and their impacts (Van Hoek, 1999). The aim of green supply chain solutions is to improve whole supply chain performance with natural environmental solutions. These solutions divide into 3 performance categories as environmental (reducing air emission, waste, harmful gasses, toxic, etc.), economic (reducing energy consumption, environmental accidents, cost for purchasing materials etc.) and operational (increasing on time delivery, product quality, improving capacity utilization) performance (Zhu, et. al. 2007). There are different studies that emphasize being green or using environmental solution for supply chain processes can help companies to increase companies' performance (Zhu, et.al., 2005). Other researches show that the degree of green supplier assessment and green collaboration has direct impact on company's environmental performance and these performance impact company's purchasing performance positively (Large and Thomsen, 2011; Chiou et al., 2011). Another research emphasis that innovative green solutions (like product, process or material innovation) can help companies to take competitive advantages (Chiou et al., 2011). Chen (2008) emphasized that company's core competences directly affected company's green innovative performance and green images positively. Green supply chain activities/practices improve energy, water and cost saving (Chin et al., 2015).

These studies show that green supply chain solutions can help companies to reduce air pollution, wastes, toxic materials, environmental accidents, scrap rates, energy usage, etc. Actually, many researches and researchers argued that green supply chain solutions can help companies to increase corporate image, product image, employee satisfaction, customer loyalty/satisfaction, brand image/reputation and better relations with customers and partners (Eltayeb et al., 2011; Testa & Iraldo, 2010; Xie and Breen, 2012).

The advantages of green and importance of being green from the Turkey's 3PL service providers' side will be discussed in the next section.

LOGISTICS SERVICE PROVIDERS' GREEN LOGISTICS SOLUTIONS IN TURKEY

There are still limited studies about Green Supply Chain Management activities in developing countries (Seman et al., 2012). This study aims to show the benefits of green logistics solutions form the 3PL service provider's perspective in Turkey. Especially Turkey's major 3PL service providers will be analyzed in this section.

Karagülle (2012) emphasized that fuel consumption and carbon emissions are major dimensions for green logistics activities. Therefore, in this research 3PL service providers' carbon emission reduction and diesel savings were analyzed. To find and measure these dimensions ISO 14001 standards used for evaluating 3PL service providers' green practices. ISO 14001 certificate is the International Standard for Environmental Management Systems (EMS). ISO 14001 is the principal management system standard which specifies the requirements for the formulation and maintenance of an EMS. EMS helps to control company's environmental aspects, reduce impacts and ensure legal compliance (https://www.nqa.com/

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

en-gb/certification/standards/iso-14001-2004). Therefore, Turkey's major logistics service providers divided according to their ISO 14000/14001 certificates.

In this research the sampling selected from the major logistics firms who have ISO 14000/14001 certificates exactly in Turkey. The major logistics service providers who have ISO 14000/14001, etc. certificate are shown in Table 2.

According to Table 2, it was selected only 3PL service providers who have ISO 14000/14001 certificates in Turkey. Therefore, firstly DHL and CEVA were excepted from the sampling. After that other five 3PL service providers' websites were analyzed due to the lack of information about company's green logistics activities for measuring green performance Borusan Logistics and Arkas Logistics also were excepted form the sampling. Therefore, only Ekol Logistics, Omsan Logistics and Mars Logistics' green logistics performance were analyzed in this study. These companies web sites were examined for obtaining much more data and statistics that related to company's green logistics activities. In this process, firstly it was sent questions that related to company's green logistics activities to all the 3PL providers for getting real information about their green logistics activities. Some companies sent a report about their green logistics activities, some of them sent web site links to get information and some of them gave only brief information about their green policies via e-mail and phone. 3PL service provider's green logistics solutions were obtained from face to face meetings, via e-mails and also company's sustainability reports.

Company's green solution capabilities were analyzed according to questions that related to the company's green logistics activities, impact of green solutions to company's performance, carbon emission calculation, carbon footprint calculation, company's green policy, their carbon emissions, etc.

EKOL

Ekol is listed among the pioneering suppliers of integrated logistics services in Turkey and Europe with its distribution centers in Turkey and offices in Germany, Italy, Greece, Ukraine, Bosnia and Romania. Today; Ekol achieved a combined structure to offer 3PL integrated logistics services globally, offering tailor made solutions for variety of customer expectations. Ekol is aware that protecting the nature and the environment is among its most fundamental and vital duties.Therefore, Ekol has adopted the motto "logistics for a better world" for its business operations. This motto is an indication of how Ekol places importance on developing environmental awareness. In that respect, it is extremely attentive to the issue of Green Logistics which covers the industry's environmental implementations (Ekol, 2016).

Table 2. 3PL Service providers who have ISO 14001 certificate in Turkey

3PL Firms	Types of Certificate
Ekol Logistics	ISO 14064-1 Greenhouse Gas Inventory GOLD level "Sustainable Logistics Certificate"
Borusan Logistics	14001
Omsan Logistics	ISO 14001
Mars Logistics	ISO 14001, ISO 14064-1
DHL	ISO 14001 (International Level, not specifically in Turkey)
Ceva Logistics	ISO 14001 (earn this standard only Czech Republic, Slovakia and Hungary, not specifically in Turkey)

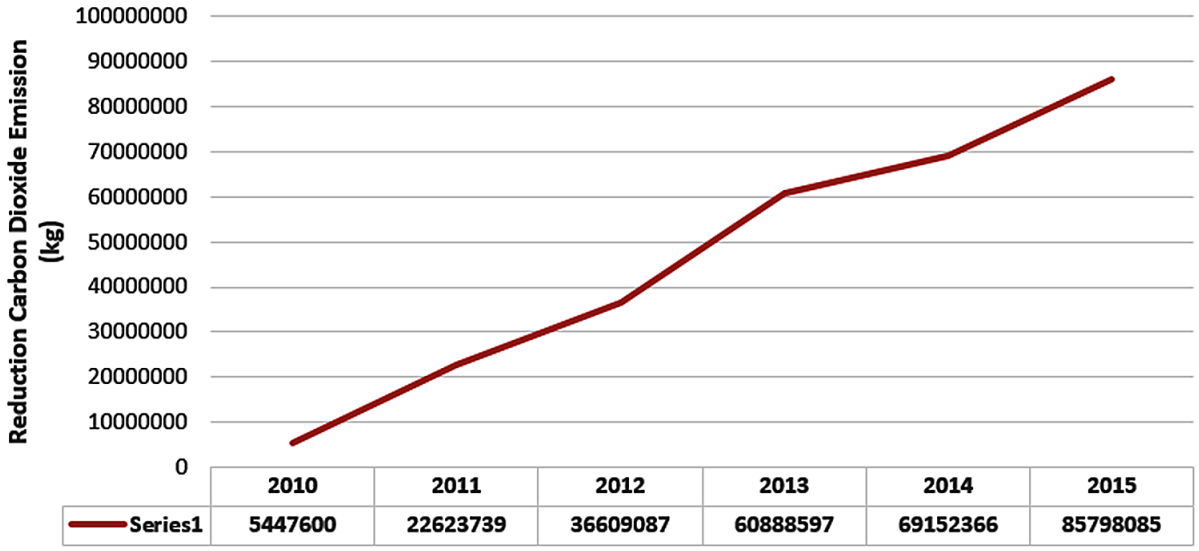
EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Ekol reduces the mileage on road with its intermodal solution created by combining railroad, land and maritime transportation and minimizes the carbon dioxide, hydrocarbon, particle and nitrogen emission. With this environmentalist approach, Ekol Logistics aims to leave a better world for the next generations (Source: http://www.ekol.com/en/at-a-glance/facts/environmental-data).

Ekol Logistics reduced their carbon emissions 1475% during the last five years (from 2010 to 2015). At the same time, they reduced their diesel consumptions 510,1%. These statistics are shown in Figure 3 and Figure 4.

Ekol logistics is the best company for applying green logistics activities to their processes. Ekol's green logistics activities and their impact on company performance were shown in the figures:

Figure 3. Reduction of carbon dioxide emission (2010-2015)



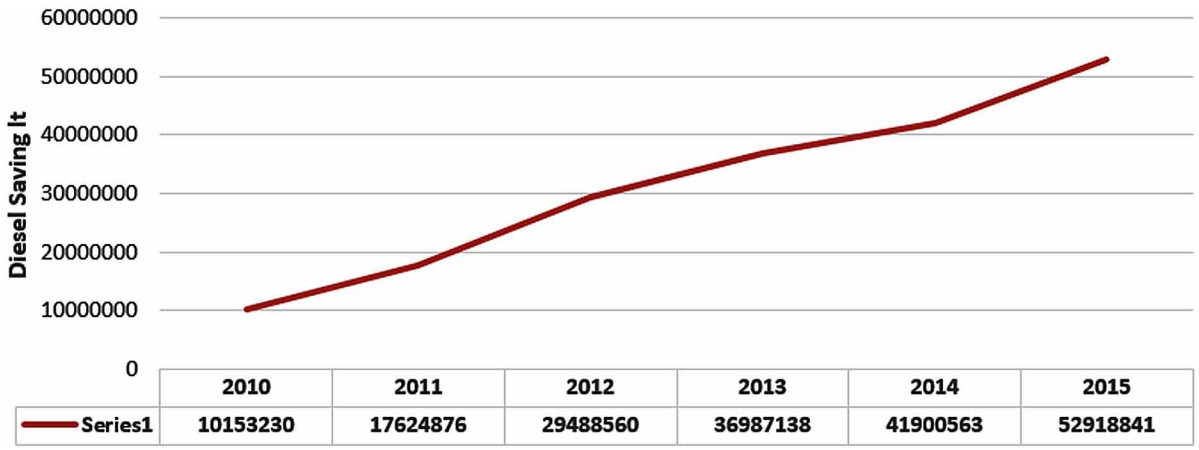


Figure 4. Diesel saving (2010-2015)

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3 and Figure 4 show that using environmentally friendly vehicles and equipment can help companies to reduce diesel consumption and diesel cost. In other words, these activities can help Ekol Logistics to save diesel, save energy and reduce diesel cots.

EKOL Case

What Is Eco-Performance?

Eco Performance defines the effective integration of ecological, economical and social engagement of a company and its representation of individual responsibility for the realization and sustainability of successful road freight transportation.

The term "Eco" combines the words "Economy" and "Ecology". Eco Performance Award assesses the services of the companies, which will serve as a model for the sustainability in transportation sector.

Ekol, often making an impression with its operations to protect environment, is the winner of 2012 Eco Performance Award.

European Eco Performance Awards, organized by St. Gallen University and sponsored by DKV Euro Service, are granted following an assessment of the companies' environmental conscience against the economic business model and measuring the levels of its implementation.

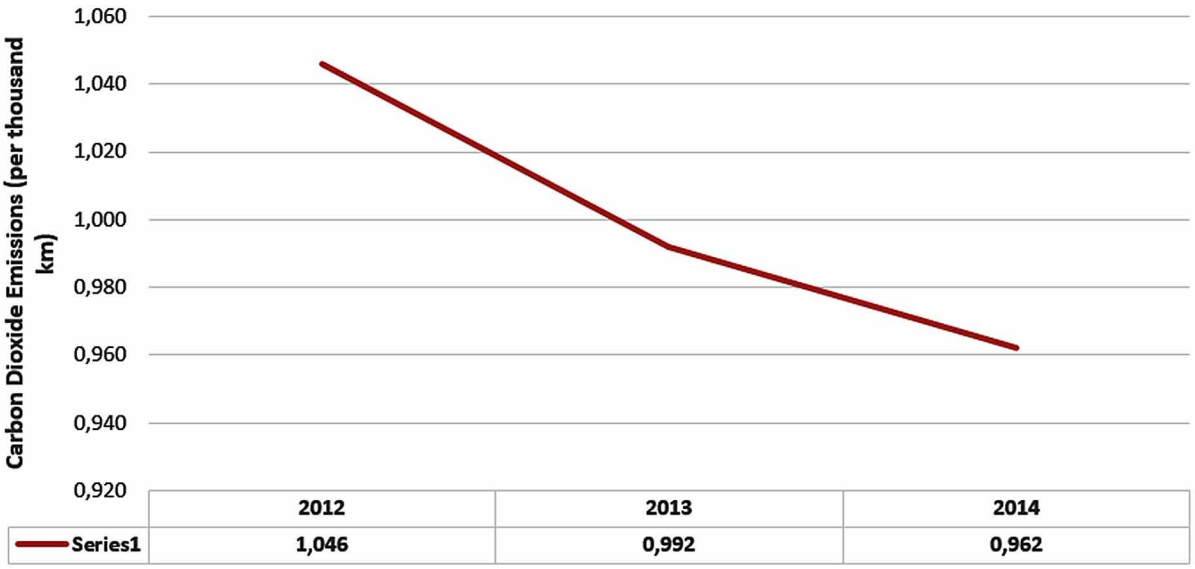
With a fleet of more than 2000 vehicles, Ekol competed in the category of large scale corporations and was assessed in 3 areas; economic success, environment and social responsibility by the jury.

In the scale of economic success that is assessed in terms of effective service and efficient work process; criteria such as operating in various markets, work capacity, international locations and total cost optimization were taken into consideration.

Ekol has been assessed on the basis of its contribution to environment in terms of efficient fleet, use of telematics, intermodal solutions, reduction of carbon dioxide emission, and cooperation with suppliers, advanced tracking devices, fuel consumption and use of Euro 5 compliant vehicles.

In its approach to social responsibility; Ekol has been assessed on the basis of its education, corporate culture, social activities, motivation and awarding criteria.[1]

OMSAN



OMSAN established as a subsidiary of OYAK in 1978, OMSAN offers flexible solutions to customers. OMSAN integrates Domestic and International Land, Sea, Air and Rail Transportation, Bonded and Non-Bonded Warehouse Services as well as Home and Office Logistics services for leading enterprises of various industries, primarily including automotive, iron and steel, cement-construction, fuel oil, textile, retail, food and communication (Omsan, 2016).

Omsan has built its transportation strategy to reduce carbon emission and energy consumptions. In parallel with this strategy the company has reduced their carbon emission and fuel consumptions 7,36% from 2012 to 2014 per 1,000 kilometers. Omsan also achieved energy savings success with night deliveries options. Omsan reduced their fuel consumption and carbon emissions 2% with this new delivery strategy. (The statistics are shown in Figure 5).

According to company's real data statistics and their annual reports, it can be said that green logistics activities can help companies to reduce the impact of carbon dioxide emission and diesel consump-

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 5. Reduction of carbon dioxide emission (2012-2014)

tion. For this reason, reduction of diesel consumption can help companies to reduce their fuel cost and increase their profit.

OMSAN Case

OMSAN acknowledges the impact of its policies and practices in the field of environmental management on its sustainability performance; it carries out responsible processes going beyond legal requirements. OMSAN identifies environmental risks and design practices that manage them; it both minimizes its environmental footprint and achieves significant economic advantages through concrete practical results such as fuel savings, material efficiency and accident free trips.

OMSAN aims to enhance the environmental awareness of its largest stakeholder network, primarily its employees, through practices it conducts under the headings of Energy Management and Waste and Water Management. OMSAN does not limit its sustainability performance to its organization and it performs measurement and reporting practices encompassing all its value chain. OMSAN achieves its environmental sustainability objectives, which it has constituted with the understanding of preserving global resources and leaving behind a clean world to future generations, through internationally acclaimed systems and standards; it continually improves its performance in this area.

Energy Management

OMSAN makes a tremendous effort to create innovatory and leading solutions in the field of combating climate change, it implements active energy and emission management practices as a responsible logistics company. Not remaining limited to its own organization, it also includes its suppliers in measurement and reporting practices in the field of energy and emission; OMSAN continuously improves its performance in these areas.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

OMSAN manages its internal energy consumption, which includes the energy consumed in its facilities, and the fuel consumption of its self-owned fleet and company vehicles, through practices where it primarily encourages conscious personnel behavior and ensures the development of its technological infrastructure; it minimizes its environmental footprint thanks to innovative solutions OMSAN realizes and fleets renewal practices. It manages its external energy consumption, which is generated by the fuel consumption of its supplier fleet and the personnel shuttle services, with the same sensitivity; it limits the environmental impacts of its supplier fleet through environmentalist vehicle choices at purchasing and fuel saving trainings it provides to drivers, while it controls the fuel consumption of personnel shuttles through efficient route planning practices.

In the reporting period, the energy consumption level of its self-owned fleet was realized as 303,339 GJ, indicating a 24% decrease compared to the last period. In the same period, the amount of energy consumed in its facilities was realized as 14,149 GJ with a 15% reduction compared to the last period. Its energy consumption outside of the organization, which is comprised of its supplier fleet and outsourced services, was realized as 513,841 GJ with an approximately 40% decrease.

Since the year 2012 when it puts into use the Safe and Economic Driving Simulator, it provides efficient driving technique trainings to drivers in its self-owned fleet. Through efficient vehicle use it achieves fuel savings as well as significant reductions in its greenhouse gas emission values. Since the date when the simulator was put into use it has achieved a 7.4% reduction in the fuel consumption rate and greenhouse gas emission of its self-owned fleet.

During the reporting period, the emission intensity rate of its self-owned fleet was realized as 0.969 ton CO2e/1,000 km, with a 2.4% improvement compared to the previous period.

Night Deliveries

OMSAN minimizes the negative impacts of traffic and contribute to the safety and environmental sustainability of cities with night deliveries it conducts as part of its storage and distribution operations. Thanks to the deliveries it makes use of empty road capacities, it reduces energy consumption and carbon emissions, and it enhances driving safety. OMSAN makes an average of 72 night deliveries with its vehicles monthly, thereby consuming 2% less fuel and achieving emission reduction.

In order to ensure energy efficiency in its plants and to minimize the greenhouse gas emissions caused by its operations, it relies on Green IT practices and its environment friendly facility practices; it continuously improves its performance in this field through the controls it provides and the environmental impact targets it puts forth. OMSAN uses LED armatures for external lighting and warehouse interiors which need constant illumination, as well as all its recently constructed plants, it makes use of motion sensors in shared spaces. OMSAN operates 90% of its servers in virtual environments; in its warehouse operations it utilizes 'thin clients' which consume less electricity than PCs.

As a logistics company, it makes significant investments to increase the share of railway and marine transportation in its service portfolio, it actualizes practices that will minimize its environmental footprint in this way. As of the reporting period, maritime transportation and railroad transportation constitute 32% and 2% of its total sales income respectively.

Intermodal Practice in Finished Vehicle Logistics

As part of the intermodal transport project put into use during the reporting period, OMSAN started to use the railroad for the distance between Pitesti and Port of Constanta and marine for the distance be-

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

tween Constanta and Derince ports, for the automotive import transportations from Romania to Turkey. With the project, it has carried 19,487 automobiles in the year 2014 and it has reduced the total distance it covers by land by 2.2 million.

Environmental Trainings

OMSAN regards the environmental awareness of its employees and the behavioral changes in practice as a significant opportunity to reduce the environmental impacts of its operations; it aims to enhance its environmental awareness with the trainings it provides. It provides several trainings to its white collar and blue collar employees including the requirements of ISO 14001:2005 Environmental Management System which the OMSAN adopts. It offers trainings aimed at increasing driving competences to its drivers as well as other companies' drivers working in the industry with the Safe and Economic Driving Simulator it has designed. In the reporting period, it has provided 642 man*hour environmental training for its administrative employees and blue collar employees. During the same period, it has provided 1,427 man*hour training to its drivers and 345 man*hour training to sector drivers, as part of the simulator trainings.

Waste and Water Management

OMSAN is thinking of ways to minimize natural resource use in all its operations and it implements practices that will prevent waste generation at the source. It evaluates prospects of recycling and reuses in its waste management processes whereby it deals with wastes according to its type, amount, impact time, environmental impacts, sensitivity of the receiving medium, elimination challenges and costs and it generate solutions; it seeks the help of expert and licensed institutions in this matter.

It classifies the waste coming from offices and the field according to its types in colored containers at Recycling and Waste Stations located in its facilities, it performs its delivery to relevant institutions for recycling or elimination at intervals identified in the" Waste Field Management Instructions". It encourages all its departments to put the waste paper and other safe wastes generated in the offices to the recycle bins located at the offices, it ensures that household wastes that are not suitable for recycling are picked up by municipality vehicles and eliminated at municipality facilities. It conducts the processes of storing, stacking and delivering hazardous wastes according to" Hazardous Waste Instructions"; it sends those hazardous wastes that cannot be recovered to licensed waste elimination facilities to be eliminated.

In the reporting period, it has sent 100% of the nonhazardous wastes generated by its activities to recycling via authorized institutions.

It makes use of its Green IT practices at its facilities and it implements practices that will minimize wastes at the source. With the central printer system integrated with employee cards, it allows for taking printouts only by swiping an employee card at the printer, thereby preventing unnecessary paper use. In this regard, it has achieved 7% paper savings in the reporting period.

In the reporting period, the amount of nonhazardous wastes generated by its operations improved by 7.5% compared to the last period and was realized as 48,870 kg, whereas the amount of hazardous materials improved by 22% and was realized as 30,238 kg.

With the practice started in its Tuzla plant in 2013, it repairs the pallets used in warehouse operations and reuse them, thereby achieving material efficiency. With the technological improvement it realized in the same year, it ensures cardboard recovery in the operations of its specific customers. OMSAN uses

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

its customers' materials efficiently, generating added value for them. The rates of reused pallets in the relevant location were 17% in 2013 and 48% in 2014, whereas the rates of recovered cardboard were realized as 58% in 2013 and 52% in the reporting period.

It works as the only authorized company in the processes of collection, transport and delivery of the practice of collecting waste oils conducted by Petroleum Industry Association (PETDER) within the scope of the Regulations for the Control of Waste Oils. It collects waste oils on behalf of PETDER from service and public terminals and carry them to recycling, elimination or cement facilities, performing an important environmental protection activity. In the reporting period it has collected 17,750 tons of waste motor oil from 6,500 waste oil producers across Turkey. The amount of the waste oil collected in 2014 would have polluted 17.75 billion meter squares of water. This quantity amounts to the annual water need of 84 million people and 15% of all underground and aboveground consumable water potential of Turkey.

By the nature of its business, it conducts non-water intensive operations; it manages its performance in this field on the basis of compliance with legal regulations and savings in personal use. It meets the infrastructural requirements for water to be used efficiently at its facilities, it guarantees that legal values are not exceeded by performing periodical analyses of the waters it discharges, and it ensures efficient water usage through controls that it conducts and water usage targets it follow.

It uses photoelectric armature and pulverized outlet nozzles at all the toilets and showers in its facilities, thereby preventing unnecessary water usage. It collects rain water and assures its reuse through 400 m3 reservoirs located in its Tuzla and Cevizli facilities. It plans to tighten its controls in the next period in order to reduce water usage and to perform the measurement and reporting of reused waters starting from 2015. While there are no water resources that are negatively affected by its operations; it has reduced its water usage rate by 9% as against the last period and realized it as 18,120 m3 through its practices in the reporting period.

OMSAN Logistics does not have an operation field in regions under protection and regions with high biodiversity not under protection, nor does it have a significant operational impact on these fields.

Safe Transport

It handles the transport of various products ranging from retail logistics to hazardous cargo transportation, to industrial material delivery to finished vehicle logistics. It carries out security practices that combine its sector experience with its integrated management systems. It conducts operations that will guarantee environmental and social safety; it carries out safe and environmentally sensitive transportation processes through the right equipment and conscious drivers as an exemplary corporate citizen.

OMSAN organizes regular meetings with its drivers in its regions of operation to remind them about the issues of health, security and environment; it makes announcements concerning using seasonable tires, driver fatigue, safe driving according to weather and road conditions, and equipment that must be kept in the vehicle. It provides extensive safety trainings for all its drivers as part of the Safe and Economic Driving Simulator and it organizes operation-specific trainings for its drivers carrying hazardous materials.

It ensures that its drivers dress suitably for fuel transportation and use antistatic, cotton, long sleeved uniforms, hydrocarbon resistant safety shoes, special fuel resistant valve and solvent gloves, barrettes, protective glasses for fuel vapor and reflective vests for night drives; it installs reflective safety belt pillows on the safety belts in order to ensure the control of safety belt use. It conducts road risk analyses through vehicle tracking systems; it supports its drivers about choosing the safe route.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

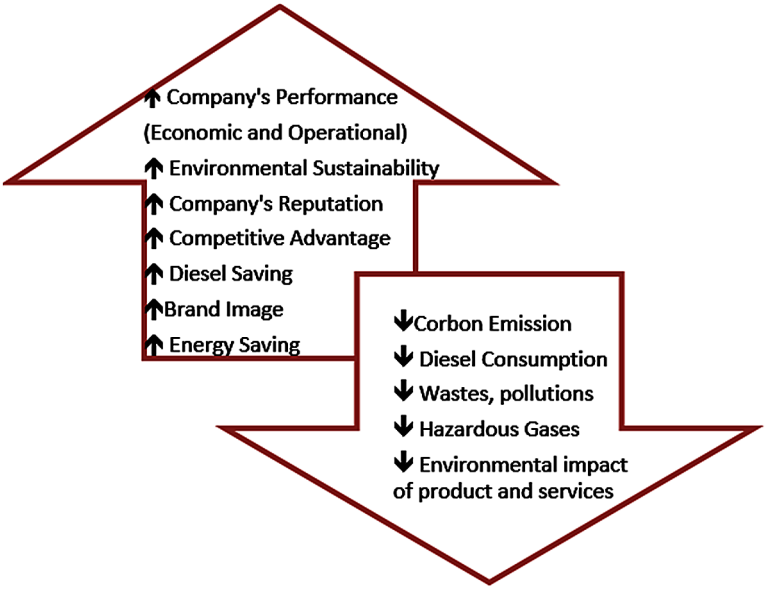
It has completed the Safety Management System audits realized by TOTAL Oil Turkey among all its suppliers on October 23rd & 24th, 2014. The audits were conducted according to a total of 13 evaluation criteria; training of managers and employees, emergency preparedness, recognition and communication in health, safety and environment issues, planned control and maintenance operations. It received full points in all the phases of the audits after a challenging evaluation process and were evaluated to be Level 4, which is the highest security level.[2]

MARS

Mars Logistics is a group company that incorporates International Transportation Storage Distribution, Air and Maritime Cargo, Insurance and Logistics companies and provides all logistics services perfectly. Mars Logistics attach importance to certify its modern logistics services with the quality standards on the journey of quality that started in 1998 and became the first company that was awarded ISO 9002 Quality Assurance Certificate in the industry together with its warehouse in the same year. Then, the company started to make revisions in ISO 9001:2000 in 2003 and in ISO 9001:2008 in 2009. It started Total Quality Management works in 2000 and ensured that this philosophy is adopted in the company. As Mars Logistics that is a member of the National Quality Movement, it started ISO 14001 / OHSAS 18001 works in 2008 and ISO 14001 Environment / OHSAS 18001 Occupational Health and Safety Management Systems standard. Company's, first priority is to provide the best service in line with "Customer-Oriented" vision and Omsan awarded ISO 10002 "Customer Satisfaction" and ISO 27001 Information Security certificates in 2013. In 2014, the company awarded validation certificate and certified our environmental sensitivity according to ISO 14064-1 Greenhouse Emissions Calculation standard (Mars,2016).

Mars has started to calculate its carbon emission since 2013. Therefore, there aren't any carbon foot print calculation in their websites and annual reports. The sustainability report (2013 is the latest one) emphasized that their main focus topics are reducing carbon emissions, waste management, energy and water consumptions.

To sum up all, the benefits of green logistics activities can be summarized as shown in Figure 6.



MARS Logistics Case

Sustainability aims at conveying resources to next generations. To achieve this, it guides us about what it should do in economic, environmental and social aspects by considering any current requirements. Even if the first thing that comes to mind when it is said 'sustainability' is protection of the environment, sustainability should be considered in economic and social aspects in order to define it correctly.

- **Environmental Sustainability:** It manages its environmental effects in terms of power efficiency, reduction of CO2 emissions and waste management. It tries to prefer renewable sources when it selects power sources. It measures its power consumption and determine what needs to be done to reduce its power consumption. In this scope, Mars reviews both its operational processes and support activities. It pays utmost attention to protect the environment when it selects the sources

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 6. Benefits of green logistics activities

it uses for lighting and heating purposes, equipment that it uses at its logistics hubs and transportation modes and trucks that it presents to its customers. It is crucial for its business partners that it cooperate in the field of waste management operate in accordance with legal and other requirements.

- **Economic Sustainability:** Mars determined the components of its economic sustainability as operational efficiency and customer satisfaction. Operational efficiency is also critical to maintain customer satisfaction for Mars Logistics. With operational efficiency, it aims to reduce costs and ensure that all its sources are used at optimum level. It utilizes technology to render its operations sustainable. With its ERP applications and investments for trucks and warehouses, it offers services to meet requirements of its customers. It reviews its activities and implements improvement activities to render customer satisfaction sustainable.
- **Social Sustainability:** Mars contributions to the society, satisfaction of its employees and their health and safety constitutes the foundation of its social sustainability. It directs its social investments to the projects that will support professional trainings and increase employment in its sector.

More than 9 thousand organizations in the world and more than 90 organizations in Turkey have so far prepared and shared a report on sustainability activities with their stakeholders* (GRI Sustainability Disclosure Database 2016 March data). It was the first sustainability report that was certified by GRI in the Turkish logistics industry. With its second report, it became one of the first 10 companies in Turkey that published a report at the level GRI A+. It will increase and maintain its business concept that is sensitive to the environment and to the future of the world based on its preferences and projects and also with the support of all its stakeholders.[3]

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

CONCLUSION

The main topic of today's competitive environment is managing green, becoming environmentally friendly and sustainable for all industries and companies. This chapter addresses how green logistics practices can help companies to increase their performance via green solutions with specific practices, cases and results from Turkey's 3PL service providers' side.

In this section the advantages and benefits of being green was discussed from the 3PL service providers' side both business and environment side with current data and real life examples. The main purpose of this discussion is to shed light on green performance indicators and identifying benefits of the being greening for 3PL companies in Turkey.

According to feedbacks from the managers or directors the benefits and advantages of being green can be summarized as follows. These solutions were reported according to 3PL service providers' annual reports, websites statistics and companies' feedbacks. The hypotheses and results of hypotheses can be summarized as shown in Table 3.

The hypothesis and research questions provide some further directions for 3PL companies and managers to cope with problems that related to environmental issues with green and being green view point.

According to real data and current statistics of the 3PL service providers in Turkey the benefits of the green solutions can be summarized like below:

- Green supply chain and logistics activities have positive impact on financial performance with reducing fuel consumption (diesel saving).
- Green solutions are important for companies to reduce environmental risks and risks of legal actions and financial sanctions of environmental disasters.
- In addition, positive financial performance with reducing costs can help companies to increase company's efficiency, service and product quality.
- Green logistics activities can help to protect environment and increase sustainability with reducing carbon-dioxide emissions as shown above the tables.
- Green logistics activities have positive impact on brand image and customer loyalty.

Table 3. Summary of benefits of green logistics activities

Hypotheses	Supporting Method/s	Result
H1: Green supply chain solutions have positive impact on 3PL companies' performance (company performance)	Supported with statistics	✓
H2: Green supply chain can help 3PL companies to reduce air pollution (environmental performance).	Supported with statistics	✓
H3: Green supply chain can help 3PL companies to reduce wastes, toxic materials (environmental performance).	Supported with statistics	✓
H4: Green supply chain can help 3PL companies to reduce energy usage (company and environmental performance).	Supported with statistics	✓
H5: Green supply chain solutions have positive impact on 3PL companies' reputation (company performance).	Supported face to face meetings	✓

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

As for future research, these carbon emissions data can be compared with developed countries or these research can be applied for other industries for finding their carbon emission reduction data and industry's green performance can be benchmarked. In addition, country's carbon emission activities and their success stories can be another research for green topics.

CASES

DHL Case

Green Logistics Solutions

Climate change is one of the greatest challenges facing our generation. Increasingly authorities and consumers expect business to calculate, account for and reduce their emissions.

Carbon accounting is a new science and there is no single way of doing it. With DHL's broad range of green products and services, DHL's GoGreen program can guide you through the processes you'll need to optimize and offset your greenhouse gas emissions. Reliably, conveniently, and with full transparency.

Greening your supply chain can reduce your costs significantly, not to mention help you prepare for key legislation on carbon emissions already in force in several countries.[4]

GoGreen Program: Deutsche Post DHL Group

The transport sector, which also encompasses the logistics industry, is responsible for 23% of the world's energy-related greenhouse gas emissions. As the world's largest logistics service provider, DHL has a special obligation to minimize the negative impact of our business on the environment. At the same time, its stakeholders, including its customers, increasingly expect from DHL to fulfill this obligation.

GoGreen, its Group-wide environmental protection program, is how it act on its responsibility. The main focus of GoGreen is to avoid, reduce and, when necessary, give its customers the chance to offset, greenhouse gas emissions (primarily CO_2). These emissions account for the logistics industry's largest negative impact on the environment.

DHL measures greenhouse gas emissions using standardized procedures, which it continuously adapts and optimizes. This allows it to identify potential efficiency gains and, as a next step, implement the necessary carbon efficiency measures.

DHL develops and deploys innovative technologies across its fleets, offices and facilities. It is making the transition to alternative fuels, optimizing the carbon efficiency of its networks and routes, and increasing environmental awareness among its employees around the world.

It prioritizes this wide-ranging list of measures based on two core principles. First, it focusses its effort on the measures that promise the biggest efficiency gains. Second, it strives to reduce energy and fuel consumption before turning to alternative energy and fuel sources, including alternative fuels.

The Shared Value proposition plays an important role in all of its environmental protection activities. Shared Value means that its contributions to environmental protection and society also enhance the success of its business. In this way, its diverse carbon efficiency measures and portfolio of GOGREEN products and services not only benefit society and the environment, but also create added value for its customers, strengthening its market position.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

GoGreen addresses other environmental factors in addition to greenhouse gas emissions. These include natural resource consumption (e.g. water and paper) as well as local air pollutants and noise pollution. DHL works to continuously reduce the negative environmental impact of its business activities by addressing these areas as well.[5]

CEVA Case

In 2014 CEVA further developed its customers CO2 reporting capability to provide CO2 measurement for the customers' supply chains across a range of transport modes. Carbon emissions are recorded for each air and ocean transaction and calculated automatically in the different types of standards, including GHG, DEFRA and EN16258. Customers have access to emission data related to their logistics operations and can request CEVA to work with them on additional calculations for transparency purposes.

CEVA provides its customers with:

- Dashboards with monthly and quarterly results;
- Standardized reports with agreed-upon measured results.

If needed, they can request CEVA to work with them on additional calculations for transparency purposes.

Carbon Dioxide (CO2): Carbon dioxide is the primary greenhouse gas emitted through human activities. The CO2 accounted for is for more than 80% greenhouse gas emissions from human activities. The main human activity that emits CO2 is the combustion of fossil fuels (coal, natural gas and oil) for energy and transportation, although certain industrial processes and land-use changes also emit CO_2.

The main sources of CO2 emissions are described below.

- **Electricity:** Electricity is a significant source of energy and is used to power homes, businesses and industry. More than 33% of the global amount of man-made emissions, the combustion of fossil fuels to generate electricity is the largest single source of CO_2.
- **Transportation:** The combustion of fossil fuels such as gasoline and diesel to transport people and goods is the second largest source of CO2 emissions of the CO2 emissions with about 30%. This category includes transportation sources such as highway vehicles, air travel, marine transportation and rail.
- **Industry:** Many industrial processes emit CO2 through fossil fuel combustion. Fossil fuel combustion in various industrial processes accounted for about 10% of the total CO2 emissions worldwide. Note that many industrial processes also use electricity and therefore indirectly cause the emissions from the electricity production.

CEVA'S Eco-Sustainable Facilities

Eco-Sustainable Logistics Hubs in Italy

CEVA Italy is aggressively reducing its ecological footprint through new measure and adjustments in its 121 warehouses. Some of the results are:

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

- **Recycled Materials:** 85% of total waste produced.
- **Source of Electricity:** 100% hydroelectric.
- **Electricity Saved:** ≈30%.
- **High-Frequency Battery Chargers:** €200/300 yearly saving per unit Italian operations have built and modified 10 warehouses with state-of-the-art solar panels generating in total 18,980 MWh per annum, reducing CO2 emissions by 10,000 tons per year and producing enough power for more than 6,700 households.

CEVA Dubai: LEED Gold Certification

CEVA maintained the LEED Gold certification of its CEVA facility in Dubai (ref. CEVA 4 Unit-1) in 2014, amongst others by managing:

- 6% reduction in electricity consumption in comparison to 2013.
- 11.3% reduction in water consumption in comparison to 2013.

The warehouse is fitted with an efficient lighting system which uses a combination of motion sensors to optimize the lighting inside the warehouse. The exterior lighting is powered by solar panels.

Environment: What CEVA Has Achieved Sustainability in Fleet Performance

In the United States, CEVA continued its commitment to the Environmental Protection Agency's SmartWay Excellence program in 2014. CEVA was a recipient of the EPA's SmartWay Excellence award in 2013, given to the top one percent of supply chain environmental achievers. The award is the EPA's highest recognition for demonstrated leadership in the movement of goods via freight transport. In 2014, the CEVA fleet performed about 4% better on average than the competition, saving more than 5,100 tons in CO2 emissions.

In 2014, CEVA rolled out a major fleet investment program within the UK.

The investment - worth US$ 20 million - added 120 tractor units, 40 rigid vehicles and 180 new trailers to CEVA's UK ground transport fleet. All of the vehicles have telematics and the rigid vehicles will have a load restraint system to enable use across multiple CEVA operations. CEVA and its customers will also benefit from some weight-saving enhancements to the trailers which increase their carrying capacity to 29.2 tons. The telematics will measure, monitor and continually improve the behavior of its drivers in terms of safety and efficiency. The innovations in sustainability, efficiency and environmental credentials are calculated to reduce carbon dioxide emissions by 6,000 tons in 2014.

Environment: What CEVA Has Achieved Sustainability in Driver Behavior

UK: Truck driver training for top performance in the UK, every CEVA truck driver is trained in road safety and has a handbook to consult to operate their truck in compliance with CEVA's health, safety and environmental standards. The training includes information about personal protective equipment, personal accident reporting procedures, environmental impact, safe manual handling, truck driver delivery guidelines, quality, driver duties and responsibilities, environmental and awareness training, safe

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

and fuel efficient driving, spillage training and waste management training. The results of the course are impressive with savings of 2,234 tons in CO2 emissions, a reduction in vehicle wear and tear and a rise in driver retention.

In Italy, CEVA organized a training course developed specifically for truck drivers. Through the training, CEVA achieved two main goals: 1. Improve the safety and prevent accidents and risks 2. Improve awareness with regards to fuel consumption and the environment. The training combines theory and practical lessons focused on fuel consumption and greenhouse gas reduction. The lessons learned can dramatically reduce the impact of transport on environment. CEVA estimates the following savings to be realized:

- **Drive at Optimal Speed:** 10-15% fuel consumption
- **Minimize the Use of Air Conditioning:** 10/15% fuel consumption
- **Remove Unnecessary Weight:** 5-8% fuel consumption
- **Check the Tire Pressure:** 3-4% fuel consumption.[6]

BRIEF SUMMARY OF TURKEY CARBON EMISSION REPORT

Scientists and decision makers agree that climate change is the biggest problem ever faced by humankind. Parties to the United Nations Framework Convention on Climate Change (UNFCCC), including 195 contracting states and the European Union, will meet in Paris in December 2015 and negotiate the new climate agreement that is expected to replace the Kyoto Protocol after 2020 (The Kyoto Protocol is an international treaty which extends the 1992 United Nations Framework Convention on Climate Change (UNFCCC) that commits State Parties to reduce greenhouse gas emissions, based on the premise that (a) global warming exists and (b) human-made CO2 emissions have caused it. The Kyoto Protocol was adopted in Kyoto, Japan, on 11 December 1997 and entered into force on 16 February 2005. There are currently 192 parties (Canada withdrew effective December 2012) to the Protocol. The Kyoto Protocol implemented the objective of the UNFCCC to fight global warming by reducing greenhouse gas concentrations in the atmosphere to "a level that would prevent dangerous anthropogenic interference with the climate system" The Protocol is based on the principle of common but differentiated responsibilities: it puts the obligation to reduce current emissions on developed countries on the basis that they are historically responsible for the current levels of greenhouse gases in the atmosphere.).

This study identified Turkey's share in the remaining carbon budget based on "minimum historical responsibility" and "maximum development needs". Projections suggest that Turkey's CO2 emissions, which amounted to 363 MtCO2 in 2013, will reach 851 MtCO2 by 2030 under high growth scenarios, and 659 MtCO2 by the same year under realistic growth scenarios. Low Carbon Development Pathways and Priorities for Turkey report shows the impact of CO2 emissions on climate change and causes that related to CO2 emissions in Turkey. In this part it will be mentioned only transportation part for more information please visit http://ipc.sabanciuniv.edu/en/wp-content/uploads/2015/11/Low-Carbon-Report1.pdf

Transport: According to 2013 figures, CO2 emissions generated by the transport sector constitute 18.6% of Turkey's total CO2 emissions. After electricity generation, transport is the largest contributor to CO2 emissions.40 Land vehicles account for 90% of transport-generated emissions in Turkey.41 A recent study on Turkey's emission reduction potential proves that an increased fuel efficiency in transport (through the adoption of the 2025 target of 35.9 km/l and the 2030 target of 47.5 km/l for cars

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 4. Annual CO2 emission projections under climate policy package and alternative scenarios

Sectoral Shares in CO2 Emissions (%-Percent)	1990	1995	2000	2005	2010	2011	2012	2013
Fuel combustion in electricity generation (%)	21.99	25.12	28.43	28.49	31.37	31.97	32.66	31.25
Fuel combustion in industry (%)	21.91	20.82	27.77	28.43	18.58	16.68	17.64	17.07
Fuel combustion in transport (%)	16.99	17.89	14.72	14.20	13.64	13.74	16.68	18.61
Fuel combustion in buildings (%)	19.37	18.23	14.60	13.90	19.83	20.49	16.47	15.23
Mineral products manufacturing (%)	9.62	10.24	8.19	8.80	10.36	10.76	10.50	11.37
Metal products manufacturing (%)	8.78	6.55	5.42	5.26	5.48	5.40	5.15	5.63
Other* (%)	1.36	1.14	0.87	0.93	0.74	0.96	0.91	0.84

* "Other" includes CO2 emissions generated by waste, agriculture, non-energy use of fuels and solvents, chemical industry, and leakage CO2 emissions in energy use.

Source: TurkStat, Greenhouse Gas Emissions Inventory, 2013 http://ipc.sabanciuniv.edu/en/wp-content/uploads/2015/11/Low-Carbon-Report1.pdf

registered for the first time, which is an issue under discussion in the EU now) could lead to a decline in GHG emissions by 15 to 19 MtCO2e by 2020, and 50 to 88 MtCO2e (million ton CO2 equivalent) by 2030.42 A further emission reduction may be achieved by transforming the transport infrastructure, and by promoting railroad and maritime transportation rather than land transportation.

Priority Sectors for Climate Change Mitigation

The share of carbon dioxide (CO2) in Turkey's total GHG emissions expanded from 70% to 80% over the period of 1990-2013. Among CO2 sources, the highest growth occurred in the use of fossil fuels for electricity generation. CO2 emissions from electricity generation have risen by 236% since 1990, and the sector's share in total CO2 emissions has increased from 22% to 31%. Besides the electricity sector, the following sectors are the other main contributors to CO2 emissions:

- **Transport:** The period of 1990-2013 witnessed a 159% increase in transport generated CO2 emissions, and thus the share of transport in CO2 emissions rose from 17% to 18.6%.
- **Energy Use in Industry:** CO2 emissions generated by energy use in the industry sector rose by 84% over the period of 1990-2013.
- **Emissions from Industrial Processes:** Process emissions generated by mineral products industry increased by 179%, and those generated by metal products industry by 51%.

Chapter 70
Green Marketing Strategies and Marketing Performance: The Case of Turkey

Serkan Kılıç
Uludağ University, Turkey

Erkan Özdemir
Uludag University, Turkey

ABSTRACT

Businesses have increasingly paid more attention to the production and marketing of green products. The aim of this study is to establish the marketing mix (4P) strategies that businesses pursuit for their green products and examine the effects of green product, green pricing, green marketing channel and green marketing communication strategies on the marketing performance. The results of the present study are particularly important in terms of shaping the marketing mix strategies of businesses that have already implemented/will implement the production and marketing of green products. The research data were collected by the web based questionnaire method from 258 businesses that operated in Turkey. SPSS 18.0 and AMOS 17.0 softwares were used to conduct the analysis. As a result of multiple regression analysis, it was found that green pricing and green marketing communication strategies had a significant effect on the marketing performance.

INTRODUCTION

Today when environmental interests and awareness of the consumers have come to increase, more and more consumers have started to demand environmentally friendly products and services from the businesses. In addition to the businesses that emphasize the environmental issues, the businesses that have noticed the environmental demands and preferences of the consumers have tended to develop and implement green marketing strategies (Agrawal & Das, 2013) both during the manufacturing processes and in their marketing approaches (Alsmadi, 2007). This particular trend plays various roles such as the creation of legal regulations related to environment, awareness-rising in terms of the costs and the lack of natural resources, increase in the demands by the community and stakeholders and the activities of

the pressure groups (Jones, Clarke-Hill, Comfort, & Hillier, 2008). In other words, it is possible to say that businesses turn to green marketing for reasons such as government pressure, cost issue, competitive pressure, increase consumer base, subsidies from government and social responsibility (Pawar & Kamble, 2016). Currently, green marketing strategy is a very important issue and if businesses think that they are responsible for long term, they will be able to use this strategy very effectively. The sustainable marketing strategy, which is an important strategy, is also a requirement in ensuring the consumer confidence.

Green marketing is comprised of activities that are designed to satisfy the wants and needs of the individuals, and have minimal detrimental effect on the natural environment (Nair & Menon, 2008). Green marketing is defined as "the holistic management process responsible for identifying, anticipating and satisfying the requirements of customers and society in a profitable and sustainable way" (El Dief & Font, 2010, p. 158). This definition emphasizes the significance of market orientation in the process of environmental marketing (Nair & Menon, 2008). From the perspective of macro marketing, Mitchell et al. (2010), on the other hand, recommended the sustainable market orientation and emphasized its importance. Terms such as environmental marketing, ecological marketing and sustainable marketing are used to mean the same as green marketing (Garg, 2015). These concepts reflect an environmental approach from the perspective of marketing. However, sustainable marketing represents an integrative approach that emphasizes environmental (green marketing), social value (social marketing) and economic / financial issues in the development of marketing strategies (Bridges & Wilhelm, 2008). While social marketing, on the one hand, includes the green marketing and sustainable marketing issues such as environmental pollution, nutritional aspects of products and consumer health, it also includes other social issues such as reducing smoking and excessive alcohol consumption in general, demotivating the use of harmful drugs, and increasing the public prosperity. Social marketing campaigns are aimed at changing people's consciousness, values, actions or behaviors in a positive manner (Kotler & Keller, 2012, p. 638). Although sustainable marketing currently focuses on consumers and their needs, it includes the consumers of next generation and meeting their needs (Seretny & Seretny, 2012). From this point of view, it can be said that responsive and proactive market orientations (Narver, Slater, & MacLachlan, 2004; Atuahene-Gima, Slater, & Olson, 2005; Tsai, Chou, & Kuo, 2008; Li, Lin, & Chu, 2008; Zhang & Duan, 2010; Zhang & Duan, 2010a; Bodlaj, 2010; Bodlaj, Coenders, & Zabkar, 2012; Yannopoulos, Auh, & Menguc, 2012; Oswald, Brettel, & Engelen, 2012) are closely related to sustainable marketing. Within the framework of sustainable marketing, environmental marketing or green marketing strategy signifies that consumers' needs are met not only through the commercialization of green products and services, but also through making the systems and processes green (Fraj-Andrés, Martínez-Salinas, & Matute-Vallejo, 2009b). The concept of sustainable production (Ali & Suleiman, 2016) can also be considered at this point.

The concept and scope of green marketing, in general, is quite comprehensive within the field of marketing. In this sense, green marketing is not only limited to the communication policies of the operator, but is also associated with all the functional areas of marketing. Furthermore, green marketing should be seen as a philosophy guiding all actions of the business, not just a series of procedures, activities and techniques for the design and commercialization of green products. Green marketing philosophy can be expressed as a way of understanding the exchange relationships that go beyond the current needs of consumers and take into account the social interests of protecting the natural environment (Chamorro & Bañegil, 2006). In this respect, the environmental marketing strategy includes decisions at the operational and functional levels. With the commercialization strategies at the business level, the competitive position of the business develops. Functional strategy, on the other hand, manages the planning and processing

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

procedures between different functions such as marketing and research and development. Businesses should demonstrate environmental proactive behavior. Therefore, businesses can have competitive advantages such as cost minimization, quality improvement, and social image enhancement by reducing the consumption of raw materials and energy resources by environmental management and can pursue more profitable marketing opportunities by targeting the ecological consumer segments (Fraj-Andrés et al., 2009b). In addition, the sectors that produce environmentally-friendly products balancing the technical features, price acceptability and compliance with environmental protection (Pap, Ham, & Turalija, 2015) can be financially supported by the state (Garg, 2015). Tax exemptions may be provided to importers, exporters and green businesses for green applications (Ali & Ahmad, 2012).

When the studies in the literature are examined, though rare, the sustainable and green marketing concept and system (Murphy, 2005; Singh & Pandey, 2012; Paramod, 2016; Antony & Pakutharivu, 2016; Nair & Menon, 2008; Pawar & Kamble, 2016; Phalke & Ranade, 2016) green labeling (Chamorro & Bañegil, 2006), design of environmentally sustainable products (Diego-Mas, Poveda-Bautista, & Alcaide-Marzal, 2016), sustainable production (Ali & Suleiman, 2016), green marketing strategies (Banerjee, Iyer, & Kashyap, 2003; Ginsberg & Bloom, 2004; Fraj-Andrés, Martínez-Salinas, & Matute-Vallejo, 2009a; Leonidou, Katsikeas, & Morgan, 2013; Garg, 2015; Pap et al., 2015; Rastogi & Khan, 2015; Villarino & Font, 2015), sustainable market orientation (Mitchell, Wooliscroft, & Higham, 2010) were investigated by different researchers.

Green marketing strategies and the performance relationship were also addressed in various studies (Chen, Lai, & Wen, 2006; Fraj, Martínez, & Matute, 2011; Leonidou et al., 2013; Fraj-Andrés et al., 2009b). In one of those studies, Chen et al. (2006) found that green product and process innovation of businesses had a positive impact on the performance. Fraj-Andrés et al. (2009b) also found that environmental marketing affected the operational and commercial performance of businesses. In a similar study, Fraj et al. (2011) suggested that the environment-oriented businesses had more superior operational and marketing performance. Leonidou et al. (2013) concluded that green products and green distribution had significant effects on the product-market performance. Wu and Lin (2016) investigated the influence of green marketing strategies on business performance and found that green marketing strategies improved the business performance. Al Khattab and As'ad (2015) found that the elements of the green supply chain management "internal environmental management, green purchasing, green information systems, cooperation with customers, eco-design and packaging, and investment recovery" practices affected the environmental-based marketing performance. Richey et al. (2014) also found that the environmental focus of businesses did not lead to superior performance without the support of senior management.

The businesses that wish to make a difference in the minds of consumers position themselves as socially responsible and environmentally with their advertising activities and competitive prices. Green marketing is comprised of aims such as eliminating the concept of waste rather than getting rid of it, developing the concept of product consistent with the environmental commitment, offering value for money to the consumers by enabling to reflect the true costs of the product, and possessing environmental awareness and converting it into profit (Alsmadi, 2007). In line with these aims, the businesses create their marketing strategies and put them into practice. However, it has become an intriguing issue especially for the businesses that have tended to be involved in green marketing whether the green marketing strategies are effective on the marketing performance of the businesses. This issue is even more important especially in the countries where the adoption of the green marketing philosophy is still an ongoing issue.

The aim of this chapter is to review the relevant literature regarding the green marketing and investigate the effects of green marketing strategies of the businesses operating in various sectors in Turkey on

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

their marketing performances. The study aims to investigate and analyze which factors of the marketing mix (4P) will have an impact on the marketing performance of the businesses. Based on the findings to be obtained, recommendations will be offered to the businesses. This paper is structured as follows: Firstly, the existing literature regarding the green marketing strategies and marketing performance are reviewed. Secondly, the research methodology and the results are shown. Next, conclusions are drawn and the limitations of the research are discussed. Finally, some suggestions for future research are made.

LITERATURE REVIEW

Green Marketing Strategies

Businesses can develop green marketing strategies by focusing on 3Rs (Reduce, Reuse, and Recycle) that help green consumption (Alsmadi, 2007; Phalke & Ranade, 2016) and they can become a green business in three ways such as value-addition processes (firm level), management systems (firm level) and/or products (product level) (Prakash, 2002). First of all, the green consumer segments should be identified and consumers' wants / needs should be investigated. As the number of consumers interested in the environment increase, it is observed that the businesses also turn to these target markets (Singh & Pandey, 2012). Demand for green products should be assessed at this point. If consumers demand green products and are willing to pay more for these products, the consumer-oriented businesses should focus on developing environmentally friendly products and adopting the environmental standards (Bhaskaran, Polonsky, Cary, & Fernandez, 2006).

Green consumer segments, on the other hand, can be classified as true blue greens, greenback greens, sprouts, grousers and basic browns (Ginsberg & Bloom, 2004). The importance of value, consequential belief and sense of responsibility are the main factors that affect the consumer behavior towards green products (Shao, Taisch, & Mier, 2017). Green marketing involves the promotion of environmentally safe and useful products. This, in turn, includes the development of ecologically safe products, recyclable packaging, green marketing channels, green promotional efforts and green labeling (Bati, 2016). However, businesses should create green marketing strategies that are appropriate for themselves. Ginsberg and Bloom (2004), according to marketing mix elements, defined these strategies as the lean green strategy, the defensive green strategy, the shaded green strategy, and the extreme green strategy. At this point, businesses should identify the green marketing as a long-term investment with long-term benefits (Garg, 2015) and change their attitudes to "think green, think clean, and think eco-friendly" (Pawar & Kamble, 2016, p. 154). Green marketing strategies can be examined according to four components of marketing mix such as product, price, distribution and promotion. These components are discussed below.

Green Product Strategies

The green products can be identified as naturally grown, recyclable, biodegradable, reusable, containing natural ingredients, recycled contents and nontoxic chemicals; do not harm or pollute the environment; have eco-friendly packaging i.e. reusable and refillable containers (Phalke & Ranade, 2016). Green product characteristics are also related with the manufacturer's production processes, policies and practices, and the social and ecological nature of the product material. It is especially important to integrate ecological characteristics with the concept of quality in the new product development process (Pap et al., 2015).

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

The green product strategy requires the businesses to emphasize such subjects as easily recyclable products, products using renewable energy sources such as rechargeable batteries, solar powered machines, recyclable packaging, non-destructive products such as organic foods and materials used throughout the production process, consumed energy and packaging regulations (Alsmadi, 2007). Thanks to the businesses that are interested in these issues, automobiles can be designed with alternative energy sources and furniture can be produced with recyclable materials (Murphy, 2005). For instance, Nike used less glue and recycled materials during the production of Air Jordan XX3 shoes (Leonidou et al., 2013).

Green products can be classified as simple, extended and completely green products (Chamorro & Bañegil, 2006). The ISO 14000 environmental management system helps to improve the environmental performance of the products of the businesses with environmental labeling and instruction standards (Bridges & Wilhelm, 2008). Environmentally conscious consumers also rely on green labels as an indicator of green characteristics (Suki, Suki, & Azman, 2016) and use less packaging (Pinto, Nique, Herter, & Borges, 2016). Packaging is important in terms of attracting attention, enabling effective communication and having a critical role in the decision-making process. For instance, in his study, Jerzyk (2016) examined what the consumers expected of the ecological messages in the packaging of products, the characteristics of sustainable packaging in consumer behavior, and how the consumers made the purchasing decisions based on sustainable packaging. Accordingly, packaging design should be environmentally friendly; emphasizing the nature of the product, or the design process should consider sustainable development principles.

Green Pricing Strategies

In connection with the subject of pricing, some green products can be extra costly for the consumers. Therefore, the environmental characteristics of the products may cause the price of the products to be higher. Nevertheless, in many cases green products can be developed at low cost due to the cost savings associated with materials, energy and even processes in comparison to the non-green products and can be sold at a lower price (Alsmadi, 2007). For instance, the 3M firm has publicly introduced the "Pollution Prevention Pays" program in recent years and obtained significant savings from this program (Murphy, 2005). However, this may not be true for every sector. Many businesses consider that the green policies are expensive and they usually set the price of green products higher (Prakash, 2002). Consumers may want to pay higher prices for products if they perceive that the products offer them higher value (such as higher performance, function, design, visual quality and taste) or the products have environmental characteristics (Antony & Pakutharivu, 2016; Rastogi & Khan, 2015). It has also been observed that consumers can pay 5% to 10% more for environmentally friendly products (Kostadinova, 2016; Bati, 2016). It is also seen that when green products with the same value and quality as non-green products are offered to consumers, they may purchase the green products (Kostadinova, 2016).

Green Marketing Channels

In terms of distribution, businesses want their consumers to easily reach their green products. This position must be consistent with the image the business wants to have and distinguish it from its competitors. For this purpose, in-store promotional activities, visual presentations or recyclable materials that emphasize environmentalism and other benefits can be used (Antony & Pakutharivu, 2016). In other words, the fact that channel members have the image of being environmentally committed in the market,

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

and focusing on recycling or re-using will help green marketing practices (Alsmadi, 2007). Regarding the distribution issue, "reverse channel" issue such as investment costs and transportation costs should also be addressed (Murphy, 2005).

Green Marketing Communication

Sustainable communication has two main points: The first one is to raise awareness on the target consumers by specifying how the product will meet consumer needs and the effects related to economic, social and environmental issues; and the second one is to make the necessary communication about the operations and activities with the stakeholders (Villarino & Font, 2015). The target audience should be reached through the convincing environmental messages and communication strategies. In this sense, there are three types of green advertising. Firstly, advertisements should focus on the relationship between a product / service and the biophysical environment; secondly, advertisements contribute to creating a green lifestyle by highlighting a product or service; finally, advertisements should demonstrate the image that the business has environmental responsibility (Singh & Pandey, 2012, p. 28).

The reliability of the message in green communication is very important. Consumers must trust the content of the advertising message. For this reason, in many cases green advertising should be supported by some government agencies and environmentalists in the community (Alsmadi, 2007; Diego-Mas et al., 2016). It is very important for the businesses with regards to promotion to use ecological messages in the advertisements, educate consumers with special programs and cooperate with environmental organizations in the context of green marketing (Fraj-Andrés et al., 2009b). One of the most important obstacles before the purchase of eco-friendly products is the gap between consumers' product-related expectations and perceptions. Information about the sustainability of the product should be presented to the consumers in the purchasing process (Shao et al., 2017). For instance, the Timberland irm has presented its Green Index rating system to the customers to communicate the effect of each product on the environment (Leonidou et al., 2013).

Businesses can sell green shopping bags under the green environment capital by reducing the use of plastic bags (Antony & Pakutharivu, 2016). Businesses can educate the consumers about green marketing by emphasizing the importance of protecting the environment, the ways of protecting the natural environment, the benefits of protecting the environment and the damages of anti-environmental practices in their advertisements (Ali & Ahmad, 2012). They also maintain eco-friendly communications on their websites (Murphy, 2005). It is important for consumers to recommend environmentally friendly products to one another in the development of environmentally friendly behavior. At this point, word of mouth marketing is effective. Social networks such as Facebook and Twitter can also be used for effective communication (Lee, 2008; Ali & Ahmad, 2012). Green marketing communication, which is a requirement for sustainable development, is an important factor in ensuring the consumer confidence (Garg, 2015).

Marketing Performance

Performance defines the number of new-products, the sales percentage of new-products and the frequency of new products offered relative to competitors by a business (Atuahene-Gima, 2005). New-product performance is to be achieved based on the level of organizational aims in areas such as new-product profitability, sales and market share (Yang & Liu, 2006). Marketing performance characterizes the effectiveness of marketing function used to meet the needs of customers and the expectations of the com-

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

munity. Marketing performance is considered as the important consequence of green marketing strategies of businesses (Fraj et al., 2011, p. 343). Marketing performance measurement provides performance feedback to the businesses regarding the results of marketing efforts (Clark, Abela, & Ambler, 2006) and can be measured with objective criteria such as profitability, sales growth, and market share (Hacioglu & Gök, 2013), and with subjective criteria based on personal opinions such as consumer satisfaction and employee satisfaction. Performance is also evaluated from the perspective of sales, profitability, and consumer awareness, attitudes, commitment and satisfaction by comparison with the competitors (Erdil & Kitapçı, 2007; Ambler, Kokkinaki, & Puntoni, 2004; Lamberti & Noci, 2010; Beukes & Van Wyk, 2016).

When the literature on green marketing is examined, it is seen that the measurement criteria of performance in the measurement of marketing and / or business performance have been addressed in relation to different issues (Fraj-Andrés et al. 2009a; Fraj et al., 2011; Wu and Lin, 2016, Al Khattab, & As'ad, 2015; Leonidou et al., 2013; Richey, Musgrove, Gillison, & Gabler, 2014). The marketing performance criteria are used not just in assessing the results of the operations of the businesses; at the same time, they are used in the strategic decisions and applications of the businesses (Hacioglu & Gök, 2013). Therefore, addressing the objective and subjective marketing performance criteria together may provide more meaningful results. Marketing performance is measured and evaluated from the perspective of objective and subjective criteria in this chapter. Objective scale items are sales growth, market share, level of customer retention (Fraj-Andrés et al. 2009a; Leonidou et al., 2013) and subjective scale items are customer satisfaction, brand image of products, success of the new products offered to the market, level of adoption between businesses' offers and the market expectations (Fraj-Andrés et al. 2009a; Fraj et al., 2011).

Businesses can meet the environmentalist expectations of consumers through specific abilities and resources by focusing on the expectations of the market. Thanks to the development of environmental marketing programs or strategies, some marketing benefits such as better commercial brand image, more satisfied and loyal customers, and removing the negative image can be enabled. Eventually, environmentalist responsibility can generate positive relations in the mind of individuals, develop positive attitudes towards the business and its brands and enhance the perception of consumers about the product quality. Finally, the green marketing strategies enable the optimization of marketing performance of businesses and this contributes to the increase in economic performance (Fraj et al., 2011). Consequently, it is proposed that green marketing strategies have a positive effect on businesses' marketing performances. Following this idea, four hypotheses are stated:

H1: Green product strategy has a positive effect on marketing performance.
H2: Green pricing strategy has a positive effect on marketing performance.
H3: Green marketing channel strategy has a positive effect on marketing performance.
H4: Green marketing communication strategy has a positive effect on marketing performance.

METHODOLOGY

Purpose

The purpose of this paper is to determine the effects of green marketing strategies on marketing performance of businesses. The basic research problem is to determine which strategies have significant effects on marketing performance. Hence, multiple regression analysis was used to fulfill this purpose. AMOS 17.0 software was used to conduct the fitness analysis of research model and SPSS 18.0 software was used to conduct the multiple regression analysis.

Sampling and Data Collection

There is no perfect listing of green businesses that can be used for sampling in Turkey. For this reason, it was decided to reach to Turkish Exporters Assembly (TIM). As the sampling framework, it was decided by the researchers that it would be appropriate to conduct the study on the businesses registered in this assembly thought to implement green marketing applications. Therefore, the judgement sampling method was used in this study. Turkish Exporters Assembly (TIM) is the roof organization of the exporting businesses in Turkey. There are 13 exporting associations under this roof organization. For the study, initially, the exporters' assembly was contacted with. A web-based questionnaire was used in the study. For the study, a link containing the questionnaire form was intermittently sent twice to the registered members of this assembly. However, nearly half of the sent emails bounced back due to various reasons. Totally, 258 businesses replied to the questionnaire.

Questionnaire

Firstly, a literature review was conducted to determine the green marketing strategies and marketing performance. A total of 29 items were found. Secondly, 15 businesses were interviewed to check these factors related to the strategies of green marketing. Seven items were assumed to represent marketing performance and the other twenty two items describe green marketing strategies. All respondents were asked to evaluate the green marketing strategies by using a 5-point Likert scale (1= not at all important, 2= not important, 3= Neutral, 4= important, 5= very important). Marketing performance items were evaluated by using a 5-point Likert scale (1= Not very satisfied, 2= Not Satisfied, 3= Neutral, 4= Satisfied, 5= very satisfied).

RESULTS

Participants' Characteristics

The respondents consisted of owners (42.8%) and managers (57.2%) of the businesses. The participants of the study were composed of 78.3% males and 21.7% females. When the education levels of business owners and managers are examined, it is seen that 2.3% had elementary school degrees, 14.3% high school degrees, 58.9% undergraduate degrees and 24.4% post-graduate degrees. The participants of the

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

study can be divided into 5 groups in terms of experience: Those with 1-5 years of experience, (13.6%), with 6-10 years of experience (12.8%), with 11-15 years of experience (18.6%), with 16-20 years of experience (18.6%) and finally those with 21 years or more experience (36.4%). Sizes of the participant businesses were classified into four groups: 69.7% were small-sized businesses (1-49 employees) 21.7% medium-sized businesses (50-249 employees), and 8.5% large-sized businesses (250 and more employees).

Measures

- **Marketing Performance Scale:** This scale was adopted from Fraj-Andrés et al. (2009a), Fraj et al. (2011) and Leonidou et al. (2013). Marketing performance scale had seven items. Reliability was (Cronbach alpha) 0.882. Validity results indicated a good fit as shown in Table 1. In the literature, the accepted values of these indices were χ^2 / df ≤ 3; GFI $\geq .90$; CFI $\geq .90$; $0.05 \leq$ RMSEA ≤ 0.08 (Baumgartner & Homburg, 1996; Iacobucci, 2010; Weston & Gore, 2006). Scale items were; sales growth, market share, customer satisfaction, level of customer retention, brand image of products, success of the new products offered to the market, level of adoption between businesses' offers and the market expectations.
- **Green Marketing Strategies Scale:** This scale was adopted from Fraj-Andrés et al. (2009a), Banerjee et al. (2003) and Leonidou et al. (2013). Green marketing strategies scale had twenty-two items. The reliability of green marketing strategies items was 0.958, no items were dropped from the list to increase Cronbach alpha. Then, an exploratory factor analysis was conducted to identify the main groups. The Kaiser-Meyer-Olkin (KMO) measure of sampling adequacy was 0.93, which suggested that the data were suitable for factor analysis. Initially, using a scree plot test to determine the factor number, four factors were identified and therefore extracted, accounting for 73.75% of the variance with varimax rotation. As a result, four main factors were maintained in the exploratory factor analysis. Common method bias was examined using Harman's one factor test and was found to be a non-issue in this study. Consequently, the green marketing strategies scale consisted of four main factors and 22 sub-items in total and the factor loadings were strong. Four first- order factor model (correlated) had a good model fit as shown in Table 2. The results of the confirmatory factor analysis showed a good fit.

Table 1. Fit Indices

χ^2 / df	p-value	CFI	GFI	AGFI	RMSEA	RMR
1.32	0.264	0.99	0.99	0.95	0.03	0.008

Table 2. The Fitness Analysis of Model

χ^2 / df	p-value	CFI	GFI	AGFI	RMSEA	RMR
1.74	0.001	0.97	0.90	0.86	0.054	0.08

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

These factors can be included to the regression analysis. Factor 1 (Green marketing communication) included six items. Factor 2 (Green product strategies) included six items. Factor 3 (Green marketing channels) included six items. Factor 4 (Green pricing) included four items as shown in Table 3.

Research Model

Based on the literature, a research model showing four research hypotheses for empirical testing is shown in Figure 1.

To test the hypotheses, a multiple regression analysis was conducted. Inter-correlations of variables can be seen in table 4. Normality assumption was tested for using the normal probability plot and scatter plot tables to ensure that the score distributions were normal and linear. All variables were distributed as normal according to P-P plot and scatter plot. There was also no evidence of multicollinearity among the independent variables according to inter-correlations and variance inflation factor that did not exceed 5.0 (in this study VIF was found at 1.85 and 3.72 level for each construct).

Table 5 presents the results for the multiple regression analysis for each of the four green marketing strategy factors of businesses on marketing performance. The regression coefficients, p values for the significance of the relationships and the associated coefficients of determination were reported. The sign and the statistical significance, rather than the magnitude, of each regression coefficient were of primary interest here. For each of the green marketing strategy measures, the final model p value, the model R^2, the independent variables entered in the model, their beta coefficients and the p values for the independent variables were listed.

Two factors were significant at $p < 0.05$ and two independent variables did not meet this significance level. Multiple regression analysis showed that green pricing strategy ($\beta = -.161$, $p < 0.05$) and green marketing communication ($\beta = .303$, $p < 0.05$) factors had a positive effect on marketing performance at a significance level of 0.05. Green product strategy and green marketing channel factors did not have a significant effect on marketing performance. As a result, H2 and H4 hypotheses were accepted, but H1 and H3 hypotheses were rejected.

CONCLUSION AND MANAGERIAL IMPLICATIONS

This study focused on the effects of the green marketing strategies on marketing performance of businesses. The research was conducted with the businesses which were the members of Turkish Exporters Assembly and the basic research problem was to determine which green marketing strategies had a significant effect on marketing performance. Although some studies were conducted on green products in Turkey (Daştan & Gürler, 2016; Tayfun & Öçlü, 2016), little attention was given to the green marketing strategies of Turkish businesses. The findings of this study will give valuable insights to businesses to learn the effects of manufacturing these products on marketing performance. It was found that two main green marketing strategy (green pricing strategy and green marketing communication strategy) factors had a significant effect on marketing performance. This result is not compatible with the results of the study conducted by Leonidou et al. (2013) in England. In their study, Leonidou et al. (2013) concluded that green products and green distribution had significant effects on the product-market performance. It is possible to think that this different result might be due to the different sampling in both studies. Especially the fact that the income capita per consumer in a developing country like Turkey is low in

Table 3. Exploratory Factor Analysis Results

The Statements of Green Marketing Strategies	Green Marketing Communication	Green Product	Green Marketing Channels	Green Pricing
Emphasizing the responsibility regarding the protection of the environment in the business communications	.825			
Informing the customers and institutions about the environmental efforts/management of the business in the promotions	.804			
Supporting or sponsoring the environmental groups or activities	.787			
Efforts to minimize the negative effect of marketing promotions on the natural environment	.774			
Emphasizing the environmental aspect of products in the advertisements	.728			
While positioning the product characteristics and content in branding efforts, communicating the eco-friendly aspect of the product	.594			
Orientation towards eco-friendly product designs		.850		
Developing products with minimal negative effects to the environment		.821		
Pay attention to the content and the raw material of the products are friendly to the environment		.775		
Focusing on environmental benefits in the packaging and labelling decisions (such as ecological and clean materials)		.667		
Maintaining and increasing the recyclable content of product packaging for a long time		.655		
Using recyclable and reusable materials in the products		.546		
Encouraging the suppliers and distributers to establish and demonstrate environmental responsibility and obligations			.722	
Cooperating with the suppliers and distributors to develop eco-friendly marketing programs			.651	
Establishing clear / specific guidelines and specifications to monitor the reactions and environmental responsibilities of the channel members			.630	
Using reusable or recycled containers in logistics			.627	
Working as a team with the members of the channel to improve the product and packaging appropriate to the regulations after use			.599	
Cooperating with the members of the channel to take on responsibility aimed at protecting the environment			.571	
Evaluating the costs of eco-friendliness within the price of the product				.859
Setting higher prices for the eco-friendly versions of products				.804
Evaluating the benefits of eco-friendliness within the price of the product				. 792
Using pricing tactics (such as discounts and product return) to encourage end-users to take environmental actions (reuse and recycling)				.584
Explained variance %	53.41	9.16	6.04	5.14
Cronbach alpha	.934	.895	.918	.885

comparison to the developed countries may cause the price flexibility to be high. This particular result might be due to the fact that the consumers paid more attention to the price of eco-friendly products. At this point, the communication strategies of businesses also played an important role in specifying the price and eco-friendly characteristics of the products.

The fact that businesses are green oriented may provide the businesses with higher financial gains, market share and business performance, and help their abilities to increase. At this point, implementing the right green marketing strategies is a crucial factor for businesses in green competition. Consumers are inquisitive to know "the true" green businesses. Therefore, the green marketing strategies of businesses aimed at reluctant customers are critically important. In order to overcome the reluctance and skepticism of consumers, the businesses should focus on sustainable activities more, be more transparent and minimize the environmentally threatening wastes (Cronin, Smith, Gleim, Ramirez, & Martinez, 2011). Therefore, marketing managers should be more aware of the increasing environmental responsibility of businesses and implement the green marketing strategies in a way to secure their reliability from the perspective of shareholders without sacrificing the profitability (El Dief & Font, 2010). In fact, as also stated by Fraj et al. (2011), green marketing strategies contributed to the optimizations of businesses' marketing performance and enhanced their profitability by reducing the production costs. One of the most important results revealed by the present study was that environment-oriented businesses had more superior operational and marketing performance. Businesses should continuously improve their values that they offer to meet the mixed needs of consumers and consumer-oriented benchmarking approach should be adopted (Shamma & Hassan, 2013). Chen et al. (2006) also found that the green product and process innovation of businesses had a positive impact on the performance and competitive advantage. Banerjee et al. (2003), on the other hand, found that competitive advantage affected the environmental marketing strategies of businesses. In their study, Fraj-Andrés et al. (2009b) also found that environmental marketing affected the operational and commercial performance of businesses and this, in turn, was reflected on the economic results of the businesses. Environmental marketing positively influenced competitiveness of businesses and benefited them in gaining competitive advantage and product differentiation.

For the creating of marketing strategies, food safety, health information and environmental values should be emphasized. It is because, as Juwaheer et al. (2012) also stated, there is a relationship between the green marketing strategies of businesses and the purchasing decisions of consumers. For instance, Saba and Messina (2003) concluded in their study that consumers found the organic products healthier, more eco-friendly, more delicious and more nutritious in comparison to the traditional products. It is clearly observed that especially the health and environmental-related benefits (Gracia & Magistris, 2007) and economic benefits (Maniatis, 2016) are the most important factors in consumers' purchasing decisions of green and organic products. Accordingly, businesses should develop their green products considering their target markets, their characteristics and preferences of this market (Vernekar & Wadhwa, 2011). For instance, marketing managers should carefully consider all the information that the green consumers look at before purchasing the product and the factors that demonstrate the reliability of all information products (Maniatis, 2016).

Businesses should also adopt an appropriate pricing strategy for green products, considering the issues related to the quality and product category. In fact, Hughner et al. (2007) found that consumers integrated high price with high quality and taste. It should be aimed to protect the products from the chemicals and save the costs by using as few channel member as possible for the distribution of the green products. Offering the green products to consumers at more affordable or lower prices and through more

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

efficient distribution channels may increase the demand for green products. In the promotion of green products, businesses need to attend training courses and fairs in order to inform the consumers, implement promotional and advertising efforts, arrange the sections in the store together with the retailers to make it easy for the consumers to compare the green products, and organize in-store promotions of the green products and showcase them in the best possible way. In this respect, it is also important to provide the seller support in marketing the green products (Vernekar & Wadhwa, 2011). In this regard, Richter and Hempfling (2003) stated that organic products should be displayed on the shelves separately from the traditional products, so consumers should be able to find organic products more easily by showing them with different signs and colors in the product classification. Similarly, La Via and Nucifora (2002) also stated that consumers should be better informed about product certification and quality issues and that advertising should be regulated in such a way to increase the demand for organic products. In this regard, Tayfun and Öçlü (2016) also demonstrated that consumers received information about products' level of environmentalism more through advertisements.

Green marketing involves proactive activities in the management of business resources. For instance, it is possible to reduce consumption by designing and producing environmentally friendly products, using recyclable materials or by implementing efficient systems. The integration of environmental issues into distribution reduces the production costs of businesses by helping the economic and environmental objectives. For this reason, businesses can reduce their costs and improve their efficiency with some process-oriented activities such as eco-design, reverse logistics or by using the clean materials in their products and packaging, and clean transportation systems. For instance, they can improve their products and packaging with cheaper and alternative raw materials. Integrating the green values with marketing strategies will contribute to the development of corporate reputation and image as well as helping to use the resources effectively. All these affect the operational results of the businesses positively and enable the business to be more economical and have better performance results (Fraj et al., 2011).

LIMITATIONS AND DIRECTIONS FOR FUTURE RESEARCH

The present study has some limitations. Firstly, only the opinions of businesses' managers who were members of the Turkish Exporters Assembly were considered. In future studies, certain green product categories can be selected and consumers' reactions to the marketing applications of these green products can be investigated. Therefore, if the present study conducted on the businesses in different sectors is carried out on the businesses operating in the same sector, more in-depth results can be obtained. Another limitation is the analyses of data from only one country. In this context, a cross-cultural study might be conducted to analyze the structure of businesses and their reactions to environmental issues.

In future studies, it would be beneficial to consider the opinions of businesses about the green marketing strategies and make a comparison of the businesses according to their size and experiences. Again, in future studies, the effect of green marketing strategies on the marketing performance can be examined within the framework of a model together with the moderating effect of idle resources and competitive intensity.

KEY TERMS AND DEFINITIONS

Green Marketing: Green marketing is the marketing of products that satisfy the wants and needs of the consumers, and have minimal detrimental effect on the natural environment.

Green Marketing Mix: Green marketing mix can be defined as the creation of the traditional marketing mix, known as 4P, as being environmentally friendly.

Green Marketing Strategy: The Green Marketing Strategy is a set of marketing strategies that are environmentally friendly.

Marketing Performance: Marketing performance is marketing outputs compared to the determined marketing objectives of the businesses.

Strategy: Strategy is the way to reach the aims and objectives of the businesses in an uncertain environment.

Sustainable Marketing: Sustainable marketing is an integrative approach that emphasizes environmental, social value and economic issues in the development of marketing strategies.

Turkey: Turkey is a developing country with a democratic, secular, unitary, parliamentary republic and various cultural heritages in Eurasia.

Chapter 71
Identification of Contextual Relationship Among Collaboration, Cooperation, Coordination, and Innovative Green Procurement Practices

Surajit Bag
Tega Industries South Africa Pty Ltd, South Africa

ABSTRACT

Globally, every organization is focusing on minimizing the usage of scarce resources in production. The authors have used resource dependence theory (RDT) as the theoretical lens to develop the foundation of the chapter. RDT suggests that firms within the supply chain network should coordinate and collaborate to achieve superior performance. Under RDT, the most important assumption is that firms cannot be fully independent with regards to strategically critical resources for survival. The purpose of this chapter is to explain the contextual relationships between collaboration, coordination, cooperation, and innovative green procurement practices. Here, interpretive structural modeling (ISM) technique has been used to develop the SSIM matrix with the assistance from five experts based in the South African steel and engineering sectors. The ISM model depicts the contextual interrelationships that may help supply chain managers in quality decision making. The chapter concludes with managerial implications and directions of future research.

INTRODUCTION

In today's competitive era focal companies have supplier networks comprising of multi tier suppliers located in different countries and continents. The purpose of sourcing from both local and international suppliers is primarily to mitigate supply risks and gain costs benefits. Many past studies have reported about numerous big suppliers of reputed firms were actually involved in child labor practices, polluting the surrounding environment and not complying with local and international laws and regulations. There

are high risks involved in doing business with such suppliers who fails to adhere to the triple bottom line principles. Thus the concept of sustainability has gradually extended towards supplier networks and attracted attention of SCM researchers.

In this study we use Resource Dependence theory (RDT) as a theoretical lens for preparing the research foundation. RDT suggests that member firms within the supply chain should coordinate and collaborate to achieve superior performance. Under RDT the most important assumption is that firms cannot be fully independent with regards to strategically critical resources for survival (Sarkis et al., 2011).

Under Green procurement practices, the eco-design of products and materials recovery is outstanding organizational resources requiring partnership with key suppliers to extract performance benefits (Zhu et al., 2005). From the RDT viewpoint, customer and supplier relationships are important links for firms to reduce the uncertainty surrounding their operating environment (Carter & Rogers, 2008).

While establishing theoretical foundations for three Cs' and innovative green procurement practices, the following research question is proposed: Do Collaboration, Coordination and Cooperation create value in improving innovative green procurement practices of firm?

There are few brilliant studies available in the area of supplier relationship management, supplier integration and collaboration and has been discussed further to understand the breadth and depth of study available in the area of sustainable procurement.

Bag (2016b) studied the interrelationship between green strategy, supplier relationship management and supply chain performance. Important variables such as supplier integration, ethics, trust, culture and flexibility has been considered in the study to develop supplier relationship model. Green purchasing positively influences flexible systems which in turn reduces operational cost. Bag (2016c) also argued that flexible procurement systems is key to supply chain sustainability. In that study the important variables considered were supplier integration, supplier responsiveness and strategic sourcing. The findings suggest that manufacturing organizations having a strong sourcing policy successfully integrate suppliers. This helps to achieve greater level of flexibility and develops more innovative products successfully. It was also suggested that trust and collaborative efforts between buyers and suppliers improve delivery and product quality, which enhance customer satisfaction and considered as a right move towards sustainability.

In a recent study by Bag and Anand (2016) we find the importance of innovation leadership in cultivating sustainable supply chain practices of an organisation. One interesting finding from the study is that empowering junior managers and creating innovation culture among employees facilitate green practices.

The above studies are some of the recent exceptional work in the area of sustainable practices where different links has been examined. However, the missing link in all the past studies is the role of 3 Cs' in influencing innovative green procurement practices.

Firms mostly emphasizes on innovation for creating eco-friendly designs, reducing level of wastage and value addition. Firms apply different tools and techniques to measure performance of green practices which generally differ from the conventional practices.

Research Gaps

The research gaps which evolved from the review of literature have been presented here to further develop the research objectives for the present study.

Existing studies mainly focused on identifying green procurement drivers and barriers. There is lack of studies considering the soft dimensions of green procurement such as collaboration, coordination and cooperation and therefore require more research focus.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Although existing studies discussed about innovative approaches and its importance for environmental practices but there is hardly any study where scholars have argued that innovation and green procurement is intertwined together and has drawn our attention.

Thirdly, no existing study explains the contextual interrelationships between innovative green practices and the 3 Cs'. There are existing studies showing links between resource dependency theory and green practices (Cooper & Ellram, 1993; Carter & Carter, 1998; Buvik., 2001; Carter & Rogers, 2008; Zhu et al., 2008; Sarkis et al., 2011; Sarkis, 2012; Lee et al., 2012). However, there is a scope for further developing new theory and extending the knowledge base.

Research Objectives

Thorough review of literature has revealed the research gaps and provides direction for developing the following research objectives:

- To identify the contextual relationships between Collaboration, Cooperation, Coordination and innovative green procurement practices.
- To develop a conceptual model for sustainable supply management

The manuscript has been organized as follows. The next section describes the key constructs used in this study. Third section covers the research methodology followed by section four on analysis and discussion. Finally, the manuscript concludes with a discussion of managerial implications, unique contribution, limitations and suggested future research.

LITERATURE REVIEW

Here we have done review from selected articles which are suitable for our study and described the key constructs used in the study.

Collaboration

We argue in light with Attaran & Attaran, (2007) that trust building and ethical behavior is necessary to develop good business relationship with suppliers and integrate them with the buying organization system. This will ensure collaborative planning, accurate forecasting and replenishment which will provide greater level of visibility in uncertain times and flexibility in operations.

It is necessary to develop specialist suppliers and involve them in the green design stage for finalizing blueprint for remanufacturing and disassembly (Ayres et al., 1997; Charter & Gray, 2008; Subramoniam et al., 2009; Gunasekaran, & Spalanzani, 2012).

Vachon, (2007) suggested that environmental collaboration with suppliers is positively associated with greater investment in pollution prevention technologies. Previous seminal studies by Carter & Carter, (1998); Bowen et al., (2001); Vachon & Klassen, (2006) and Dubey et al., (2013) also suggest that buying organization environmental and logistical collaboration with suppliers positively influences adoption of green purchasing practices.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

The study by Eltayeb et al., (2011) and Green et al., (2012) also supports that environmental collaboration and monitoring practices among supply chain network partners' results to improved environmental performance and organizational performance.

However, the impact of commitment on green collaboration is mediated by purchasing capabilities (Large & Thomsen, 2011).

Cooperation

This construct selection is supported by the seminal work of Chen, (2005). It was suggested by Chen, (2005) that support and cooperation of suppliers is a prerequisite of green procurement implementation. Further Zhu et al., (2008) argued that cooperation with environmental concerns is important for successful green procurement programs. Such environmental programs cross all boundaries within and between organizations and therefore, cooperation from all functions are necessary for achieving the environmental goals. Also customer cooperation is required for meeting environmental goals such as cleaner production, greener packaging and green logistics.

Coordination

Carter and Carter, (1998) argued that coordination between buying and supplying organizations is critical for success of green procurement programs. The findings of Carter and Carter, (1998) have also been supported by recent studies conducted by Srivastava, (2007); Varnas et al., (2009); Yen and Yen, (2012); Zhu et al., (2012) and Swami & Shah, (2013).

Therefore, green purchasing actions will be facilitated through increased internal cross function coordination between operations, sales and design departments (Carr et al., 2008) and coordination with suppliers and downstream members of the supply chain (Yang & Zhang, 2012) which will result to enhanced management of process and products in the global network and reduce uncertainties in dynamic business environment (Foerstl et al., 2013).

Ryoo & Koo (2013) suggested that organization's green practices-IS alignment is having a positive effect on both green practices manufacturing coordination and green practices-marketing coordination.

Innovative Green Procurement

Innovation green procurement key dimensions include Innovation capability; ISO 14000 standards adoption; Environment, Health and Safety programs; Life Cycle assessment; SA 8000 adoption; Customer satisfaction; Supplier satisfaction and Better risk management.

Innovation capability is correlated to the way an organization manage innovation. World class organizations nurture this capability and enhance organization performance by developing new products and services (Lawson & Samson, 2001; Calantone et al., 2002). It was found that employee willingness to both donate and collect knowledge enable the firm to improve innovation capability (Lin, 2007). Further Liao et al., (2007) argued that absorptive capacity is the intervening factor between knowledge sharing and innovation capability.

ISO 14000 is the series of environmental management standards which are published by International Organization for Standardization. However, ISO 14001 is the most important standard and aims

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

at environment management system for any organization. ISO 14001 is based on the principle of Plan, Check, Do, Review and Improve cycle.

Environment, Health and Safety (EHS) programs are linked with green procurement actions because any procurement decisions directly influence the EHS program. Therefore, cross functional coordination, cooperation and both supplier and customer collaboration helps to smoothly run EHS programs.

Life Cycle assessment (LCA) approach can be used to check the design of any new component or assess the design of an existing product. This method is used to evaluate the environmental impact of a product from birth to its end. Green procurement includes LCA policy making which develop regulations on materials selection and usage for production and release in the environment. LCA involves comparing alternative raw material and change in manufacturing process to minimize environmental impact. It also compares resource use and pollution information with those of competitors. To make LCA process successful organization must train and educate designers, production engineers and buyers for better understanding of the subject matter.

Green procurement also involves SA 8000 adoption where buying organizations do not support any supplying organizations involved in child labor practices. SA8000 is set to embrace existing international agreements, including International Labour Organization conventions, the Universal Declaration on Human Rights, and the UN Convention on the Rights of the Child.

Green procurement is also found to enhance customer satisfaction and supplier satisfaction. It also helps organization to manage risks (Dubey et al., 2013).

Theoretical Perspectives on Collaboration, Cooperation, Coordination, and Innovative Green Procurement Practices

Let us understand particularly why the term "innovative green procurement practices" has been used for the study; the underlying reason is that any firm practicing green practices basically performs out of the box thinking, i.e. innovation. Firms are innovating using newer appaches to come out with eco-friendly designs, reduce wastage, reclaim, add value and also save costs. Firms use different tools and techniques to measure performance under green practices which differ from the traditional or standard practices. If we consider any world class firm practicing sustainable practices such as Apple, Dell, Ford and Toyota, we can see the approaches of individual firms are different from each other, although the ultimate objective is to save natural resources and reduce carbon footprint. Innovation and green practices is intertwined and no common or standard practice can yield the same result to every firm. The central concept is to innovate and come out with better ideas for sustainability. In this study resource dependence theory is used as a theoretical lens to further disseminate and enhance the existing knowledge base. It is interesting to note that resource scarcity can generate huge risks both internally and externally. Therefore, author felt the need to identify the interrelationships among innovative green practices and the internal (trust building, internal coordination) and external (supplier collaboration, supplier cooperation, customer cooperation and external coordination) dimensions. The present study will generate rich insight mainly for supply chain professionals involved in green practices. The findings will help in developing practical tools for green performance measurement.

Since natural resources are widely used, there are chances of resources becoming scarce and expensive to acquire. In that scenario firms need to innovative for sourcing alternate resources. Here firms deviate from the standard practices and adopts the best practices which enhance the brand image in the business world. As per RDT, scarcity can occur internally or externally (Leblebici et al., 1991). When

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

firms have unskilled manpower demonstrating poor cooperation and poor coordination may result in resource scarcity. Externally if the firm does not collaborate with customers and suppliers, then the firm might run out of resources and which generally becomes costlier to acquire at the last moment. Also the growth in demand for the eco designed product increase the demand of the resource. Scarcity of the input resource will lead to difficulty in manufacturing of the product. Competitive pressures also restrict firms in raising the prices of final products. The internal and external forces compound together and act on the firm. This is a burning problem for the firm and often results in unsuccessful green procurement practices and financial losses.

As per the NSF (2010) study, existing green initiatives have mainly focused on investment in new technology and developing energy saving equipment and facilities. Such initiatives are valuable but they tend to ignore the green production economics, interaction, and coordination where the flow of products to final customers engages multiple firms in long and complex supply chains. Therefore, the present study is necessary to bring out the richness of 3 C' and its importance in enhancing innovating green procurement practices in today's complex supply chain structure operating under uncertainty.

In this turbulent business scenario every supply chain practitioner is struggling to mitigate the risks. The level of uncertainty is more due to long and complex supply chains (Applequist et al., 2000; Juttner et al., 2003 and Kleindorfer and Saad, 2005). In this scenario, every supply chain practitioner spends their time majorly in aligning supply chain strategies with product uncertainties (Lee, 2002). The problem has aggravated with tight competition in the market and strict government regulations. This has raised the question of firm's sustainability and created difficulty to stay in the business (Walker, 2008; Wagner and Bode, 2008). To change the game and remain in business, supply chain practitioners innovated and shifted the focus towards triple bottom line concept and focusing on environmental, social and economic aspects of business sustainability (Carter and Rogers, 2008; Dubey & Bag, 2014; Dubey et al., 2015). Further they adopted green procurement practices where firms emphasize on reduction of wastage; material substitution through environmental sourcing of raw materials and reduce usage of hazardous materials. Basically green procurement focuses on life cycle thinking whereas the traditional procurement system used to focus only on costs (Kaiser et al., 2001). In response to the internal and external changes firms have instituted socially responsible buying process (Carter et al., 1998). Currently green procurement is considered as a noble approach to improve the performance of firms (Hamner & del Rosario 1998; Dubey et al., 2013; Dubey et al., 2014a). Green procurement is controlled by the internal and external forces and the balance between the two forces is necessary for successful green procurement practices. The internal forces are the forces within the firm and the external forces are basically supplier and customer pressures. From the internal viewpoint the team coordination and cross functional cooperation among members are necessary for running any projects successfully (Pinto and Pinto, 1990). The tasks and roles embedded in driving innovative green practices as well as rules and procedures to coordinate the project needs attention of members (Tjosvold, 1988; Hoegl et al., 2004). It is the responsibility of top management to cultivate effective communication, cooperation and trust to achieve rapid milestones in green procurement (Kerzner, 2013).

Also, it is essential to understand the external forces such as supplier pressures and customer pressures. The strict regulations drive firm to form an alliance with suppliers and integrating suppliers into environmental management practices. Green procurement demands environmentally conscious suppliers who have implemented ISO 14001. This necessitates firms in developing environmental policy and environmental supplier evaluation criteria (Green et al., 1996; Green et al., 1998; Chen, 2005; Zhu et al., 2005; Zhu & Sarkis, 2006; Zhu & Sarkis, 2007; ElTayeb et al., 2010; Dubey et al., 2013). Supplier

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

collaboration is an important component of green procurement. Collaborative strategies facilitate closer cooperation between buyer and supplier firms, provides flexibility in handling projects (Bowen et al., 2001). It was found that firms achieved greatest success in innovative green practices when suppliers are physically involved with buyer's plant and also when the buyer spend maximum time in the supplier's plant (Simpson and Power, 2005). In some of the earlier studies, researchers have used the term innovative practices under green procurement practices such as innovative packaging based on customers' willingness to buy biodegradable packages and they even discussed on green firms being innovative in their environmental practices and innovative approaches in managing waste at source. There is evidence in certain papers where discussions have been done on ways to bring innovative green products in the market (Green et al., 1996; Min & Galle., 1997; Min & Galle., 2001).

RESEARCH METHODS

Research design is the most critical step in any research study. The research design is different for both qualitative and quantitative approaches. Some of the seminal papers available in the area of qualitative research design under management sciences are (e.g., Eisenhardt, 1989; Eisenhardt & Graebner, 2007; Suering, 2008; Stock & Boyer, 2009). From existing literature, it is seen that case study research is the most popular technique under qualitative approach. Therefore, keeping in mind the qualitative approach for the present study we have several options for addressing the research objectives. But the author adopted the ISM methodology for identifying the contextual relationships between identified variables. The reason for adopting ISM methodology is basically to generate a robust model from the complex links and for which ISM is the perfect tool. The ISM methodology is interpretive from the fact that as the expert group decides whether one variable enhance other variable, therefore an overall structure is extracted from the relationships of the variables and is further validated using MICMAC analysis. ISM has gained popularity in the branch of supply chain management and the seminal work available are (Mandal & Deshmukh, 1994; Singh et al., 2003; Luthra et al., 2011; Pfohl et al., 2011; Shahabadkar, 2012; Sushil,2012; Attri et al., 2013; Bag & Anand, 2014a,b; Bag., 2014; Dubey et al., 2014b; Dubey & Singh, 2015).

We conducted literature review and identified 20 variables which were finally reduced to 15 based on the opinion of industry experts. The final fifteen and sources have been presented in Table 1.

ANALYSIS AND DISCUSSION

Interpretive Structural Modeling

Step 1: Developing the Structural Self Interaction Matrix

For developing structural self interaction matrix (SSIM) in Table 2, the below symbols have been used to denote the direction of relationships between variables (i and j):

V i lead to j but j does not lead to i
A i do not lead to j but j lead to i

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Final variables

Purpose	Element No.	Elements	Source
Innovative Green Procurement Practices	C1	Innovation capability	Bag, (2016a); Bag and Gupta, (2017)
	C2	ISO 14000 standards adoption	Dubey et al., (2013); Bag, (2016b)

X i lead to j and j lead to i
O i and j are unrelated to each other.

Step 2: Develop Reachability Matrix

The SSIM has been converted into a binary matrix, i.e., the rechability matrix (Table 3) by substituting V, A X and O by 1 and 0. The substitutions of '1' and '0' is done as below:

1. If the (i, j) entry in the SSIM is V, then the (i,j) entry in the rechability matrix becomes '1' and (j,i) entry becomes '0'
2. If the (i, j) entry in the SSIM is A, then the (i,j) entry in the rechability matrix becomes '0' and (j,i) entry becomes '1'
3. If the (i, j) entry in the SSIM is X, then the (i,j) entry in the rechability matrix becomes '1' and (j,i) entry also becomes '1'
4. If the (i, j) entry in the SSIM is O, then the (i,j) entry in the rechability matrix becomes '0' and (j,i) entry also becomes '0'

In this step the concept of transitivity is introduced so that some of the cells of the initial reachability matrix are filled by inference. Transitivity can be explained with the following example if element 'i' relates to element 'j' and element 'j' relates to element 'k', then transitivity implies element 'i' relates to element 'k'. Transitivity is the basic assumption in ISM and is always used in this modelling approach. It also helps in maintaining the conceptual consistency. The final reachability matrix will then consist of some entries from the pair-wise comparisons and some inferred entries. The transitivity concept is used to fill the gap, if any. Following the above rules, the initial reachability matrix is prepared. After incorporating the transitivity concept as described above, the final reachability matrix is obtained in Table 4.

Table 3. Initial reachability matrix

	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
1	1	0	0	0	0	1	0	1	0	0	0	0	1	0	0
2	1	1	1	1	1	1	1	1	0	0	0	0	0	0	0
3	1	0	1	1	1	1	1	1	0	0	0	0	0	0	0
4	1	0	0	1	0	1	1	1	0	0	0	0	0	0	0
5	0	1	1	0	1	1	1	0	0	0	0	0	0	0	0
6	0	0	0	0	0	1	1	0	0	0	0	0	1	0	0
7	1	0	0	0	0	1	1	1	0	0	0	1	0	0	0
8	0	0	0	0	1	1	0	1	0	0	0	0	0	0	0
9	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
10	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
11	1	1	1	1	1	1	1	1	0	0	1	0	0	0	0
12	1	1	1	1	1	1	0	1	0	0	1	1	0	0	0
13	0	1	1	1	1	0	1	1	0	0	1	1	1	0	0
14	1	1	1	1	1	1	1	1	0	0	1	1	1	1	0
15	1	1	1	1	1	1	1	1	0	0	1	1	1	1	1

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Step 3: Level Partition

The final reachability matrix obtained above in Table 4 is now partitioned into different levels. After the first iteration, the element classified to level 1 is discarded and the partitioning procedure is repeated on the remaining element to determine the level 2. These iterations are continued until the level of each variable has been determined.

Step 4: Diagraph

From the final reachability matrix and level partitions, the structural model is generated by means of nodes and lines of edges. If there is a relationship between the elements j and i, this is shown by an arrow which points from i to j. This graph is called digraph.

Step 5: Interpretive Structural Model

From the connective information shown in diagraph we further create the structural model. The particulars of elements are indicated in the respective boxes with indicated relations as designed in the digraph, thus obtaining the interpretive structural model for fifteen elements. The interpretive structural model shows the elements and their reachability to the higher level elements and provides a clear picture with an understanding of the inter-relationships among the elements.

Table 4. Final reachability matrix

MICMAC Analysis

MICMAC analysis Matrice d' Impacts croises multiplication appliqué and classment (cross-impact matrix multiplication applied to classification) is abbreviated as MICMAC. The objective of MICMAC analysis is to analyse the drive power and dependence power of variables. Based on the drive power and dependence power the variables have been classified into four sectors: autonomous variables, linkage variables, dependent and independent variables and presented in Figure 3.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Diagraph with significant transitive links

The results of MICMAC analysis has been presented in tabulated form (Table 12).

Based on the findings of MICMAC analysis we have drawn the conceptual model (refer figure 4) which shows the links between independent, linkage and dependent variables. This conceptual model is very unique in terms of coverage and will be useful for conducting structural equation modelling.

CONCLUSION

The paper is an unique attempt to uncover new links between collaboration, cooperation, coordination and innovative green procurement practices. This paper is an extension of the study conducted previously by Bag (2016a). Initially effort was given to describe the constructs in details followed by identification of associated elements. Further, interpretive structural modelling technique has been used to identify

the contextual relationships among all elements. The ISM resulted into development of a hierarchy of fifteen elements achieving seven different levels. The TISM diagraph shows the direct links and transitive links which will be useful for decision makers. We found that SA 8000 adoption; Customer satisfaction; Supplier satisfaction and Green supply chain risk management achieved the top level whereas Trust building and Ethical Behaviour achieved bottom level. Supply chain practitioners must aim at removing the bottlenecks at the bottom level for successful innovative green procurement programs.

We also focused on conducting the MICMAC analysis to understand the driving power and dependence power of all elements. It was found that four elements are actually acting as drivers such as Trust building, Ethical behaviour, External coordination and Internal coordination. From MICMAC analysis ten linkage variables emerged and finally we found that green supply chain risk management is the dependent variable. We have also drawn the conceptual model based on MICMAC analysis which will be useful for future empirical research. The findings corroborate with previous studies such as Dubey et al., (2013); Muduli et al., (2013) and Foerstl et al.2013. The findings as well support Resource Dependence theory and we can infer that Collaboration and Coordination is indeed very critical to drive the green procurement programs successfully and manage resources which ultimately results in mitigating the supply risks in the network.

Managerial Implications

The interesting part of this study is that we have considered all the soft dimensions which have so far lacked attention and focus from the supply chain researchers. The findings show that Coordination and Collaboration are basically the driving factors whereas Cooperation acts as a linkage factor. Therefore, supply chain practitioners must focus in improving these areas to achieve superior green procurement performance and ultimately manage green supply chain risks. Firms may focus on cross functional team building and regular review of activities to ensure that green procurement program is receiving full cooperation and support from suppliers and customers.

Unique Contributions, Limitations, and Future Research Directions

The current study is unique in terms of scope and coverage and attempted to bridge the gaps between practice and theory. Limitation in this study include small sample size (five experts opinion) used to develop the VAXO matrix. The limitations can be eliminated in future studies by involving larger sample size for data collection and statistically validate the model using structural equation modelling.

KEY TERMS AND DEFINITIONS

Green Supply Chain Risk Management: Companies adopting green supply chain programs face multiple challenges because of the dynamic nature of business environment, which exposes them to a series of risks and threats. The problems are aggravated by changes in customer demand patterns, supply crisis for environmentally friendly material, and competitor activities. Therefore, companies must develop appropriate strategies to reduce such uncertainties and mitigate risks. Companies focusing on good internal coordination, external coordination, and collaboration relationships may better manage the supply risks.

Innovative Green Procurement (IGP): IGP involves integrating the social, environmental, and economic perspectives in the supply network. IGP includes both the hard dimensions and soft dimensions. However, existing literature shows that less focus has been given to studying the unique IGP soft dimensions such as collaboration, cooperation, and coordination. These soft dimensions significantly influence the success of IGP and therefore must be considered while making any green procurement programs. IGP leads to development of innovative capability within the supply network and reduces supply chain risks.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Interpretive Structural Modelling (ISM): Interpretive structural modeling (ISM) is a method that transforms indistinct and inadequately articulated mental models of systems into visible, well-defined models helpful for many fields of research. The method is based on group or individual decision making and decides whether and how elements are related in the system. Interpretive structural modeling interprets the links in terms of the contextual relationship and the direction of the relationship for each pair of elements. This becomes the starting point of articulating the structure of any ill-defined system. At the final stage, it interprets the nodes of the diagraph in terms of the definition of respective elements so that a clear picture can be portrayed in terms of the relationships among the elements.

Chapter 72
Green Retailing: A New Paradigm in Supply Chain Management

Arnab Adhikari

ABSTRACT

Sustainable development with ecological protection has gained global significance across society because of continuing environmental degradation. It causes green supply-chain management to be an area of interest among researchers and practitioners. Existing literature related to green supply chain indicates that most of the scholarly works have been limited to the manufacturing context and retailing has not been paid enough attention. It signifies that integrating green policies into retail sector is a new potential area of research from academicians' and practitioners' point of view. This chapter discusses about the drivers, barriers, different dimensions, issues, existing environmental practices and policies adopted by leading retailers, future research avenues, different green polices adopted by various organizations and government bodies in the area of retailing. Thus it facilitates researchers, industry practitioners, policy makers to find the existing works, new research opportunities as well as to improve practices and policies.

INTRODUCTION

Over the last three decades, sustainable development with ecological protection has gained the global significance due to a number of factors like global warming, resource depletion, water pollution, carbon emission, soil erosion and so on. Previously, the environment has been highly affected by the firms' profit maximization objective without considering the environmental concerns and government's negligence about environmental policy. The world has experienced dire consequences of these myopic measures

several times. 'Bhopal disaster,' one of world's largest chemical industrial accidents in 1984, took around 5200 lives (Bhopal Gas Tragedy Information report). This tragic incident occurred due to the chemical gas leak from a pesticide plant in Bhopal managed by Union Carbide India Limited. The explosion at the Chernobyl nuclear power plant of former USSR in 1986 brought life threatening challenges to the civilization (IAEA report, 2006). The release of radioactive material from a nuclear reactor jeopardized the livelihood. In 2010, Oil spill in the Gulf of Mexico caused extensive damage to wildlife habitats (Gulf Oil Spill report). These catastrophes impel governments, organizations, different official bodies to pay attention in designing a suitable policy taking both economic development and environmental sustainability into account. An example of increasing level of green activities is presented in Figure 1 which depicts the growth of the global investment in renewable energy sources over the years (Eyraud & Clements, 2012).

Different nations and organizations have employed various policy measures to combat with environmental challenges. Several countries have adopted 'carbon trading' scheme to reduce emission. i.e. A regulatory mechanism where firms or countries buy and sell carbon permits (Lazarowicz, 2009). The programmes like "Pollution Prevention Pays" (3P) 3M and "Waste Reduction Always Pays" (WRAP) initiated by 3M and DOW, respectively indicate that the firms have recognized the importance of environmental friendly practices (Segerson and Miceli, 1998). Problems like resource marginalization, toxic waste overflow, increasing pollution level have become matters of concern for all the players within and outside the boundary of the supply chain. These circumstances inevitably give rise to the idea of green supply chain management. It emerges from environmental science and supply chain management. Srivastava (2007) defines green supply chain management as 'integrating environmental thinking into supply-chain management, including product design, material sourcing and selection, manufacturing processes, delivery of the final product to the consumers as well as end-of-life management of the product

Figure 1. Growth of global investment in renewable energy sources

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

after its useful life.' The scope of green supply chain management ranges from green purchasing of raw material to the design and the sale of green final product. The design of a green supply chain management encompasses the product design incorporating the environmental issues related to the product safety, pollution prevention, minimization of resource depletion, and waste management. Green procurement demonstrates the importance of raw material suppliers' adherence to the sustainable policies. These policies can be voluntary or imposed by the regulatory measures. Green manufacturing relates to the usage of the pollution free proper resource which will cause a minimum level of pollution and thus producing the environment friendly products.

Existing literature related to green supply chain indicates that most of the scholarly works have been limited to the manufacturing context whereas retailing has not been paid enough attention (Lai et al., 2010). Jones et al. (2008) opine that large retailers can play an instrumental role in environmental development in a supply chain. Adoption of greening policies helps a retailer to attract more environment-conscious end customers. Green retailing can be defined as an approach toward managing any retail business by incorporating sustainability focused practices and environmentally friendly processes. According to Juliet Norton (2010), green practices facilitates retailers to attract more customers as well as exploring new markets. Wiese et al. (2012) Support Juliet Norton's claim and state that green retailing can be an important building block of the marketing programme to portray a better image in customer's perception. It signifies that integrating green policies into the retail sector is going to be a potential area of research from academicians' and practitioners' point of view.

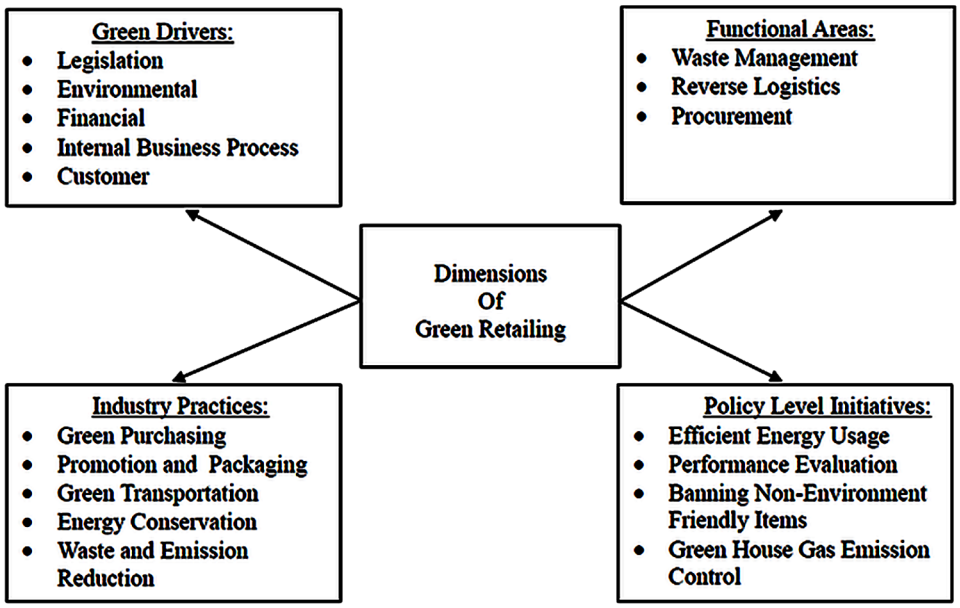
From the 1990s, many researchers came with different concepts, constructs, and solution approaches to deal with these problems. The companies have started to show their interest to maintain ecological balance by taking the initiatives like green purchasing, ISO implementation, eco-friendly production etc. Cairncross (1993) have brought about the idea of co-existence of industrial development and environmental security. Owen (1993) and Gupta (1995) advocate the value of integrating the environmental concerns in the business strategy by reasoning about the resource saving, waste elimination, productivity improvement.

The ideas behind reverse logistics and related market uncertainty, product speculation, return deposition are developed by Jahre (1995), Fleischmann et al. (1997) and many others. Fleischmann et al. (1997) describe the re-usage of the products from operations research perspective. Waste management, disposal option, proper disposal location selection is another area where many authors have come with different modeling solutions. Authors like Haastrup et al. (1998), Richter and Weber (2001), and Bloemhof-Ruwaard et al. (1995) use analytical techniques to minimize the waste; Dunn and El-Halwagi (1993) propose a methodology of the optimal design for the reused product. Teunter and Vlachos (2002) worked in the area of disposal option for the remanufacturable items. Walton et al. (1998) have shown the integration of suppliers in the construction of the green supply chain management.

This chapter describes the drivers, barriers, different dimensions, issues, methodologies used by scholars, future research avenues in the area of green retailing. Also, it presents existing environmental practices and policies adopted by leading retailers across the world. Besides, it demonstrates the different policies adopted by various organizations and government bodies. It also discusses the challenges related to the incorporation of the environmental friendly policies in the retailing. In addition, it highlights the opportunities associated with the green policies and justifies it with the existing industry practices. Thus it facilitates researchers, industry practitioners, and decision makers to find the existing works and new research opportunities, as well as to improve appropriate green practices and policies.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

The organization of this chapter is as follows: in Section 2, different aspects like drivers and functional aspects of green retailing are described. Section 3 discusses the prevalent industry practices in the context of green retailing. Section 4 deals with the greening policies adopted by large retailers. In section 5, the barriers that hinder the successful implementation of green policies along with associated opportunities are presented. The chapter concludes with discussing contributions and future research avenues.



METHODOLOGY

The extant literature on green retailing can be broadly classified into four broad areas. The first set of articles concentrates on different drivers for adopting greening policies by various firms. Following the approach of Mann et al. (2010), the drivers of green retailing can be categorized into five classes related to legislation, environmental, financial, internal business process, and customer. The second area focuses on the functionality or operational sides of green measures like waste management, green procurement, and reverse logistics. The third strand of literature looks into the prevalent industry practices and internal firm-level policies for greening. The fourth set of literature investigates the impact of governmental (federal or local) policies and statutory body decisions on sustainability measures adopted by various firms. Based on this classification, here, we propose a conceptual framework to facilitate the scholars and industry practitioners' understanding about the green retailing, given below (also see Figure 2).

Green Retailing Drivers

The green retailing drivers describe the stimuli behind the firms' adoption of greening policies in their retail domain. These drivers pave the way of integrating green retailing through either voluntary approach

Figure 2. Conceptual framework of green retailing

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

or contractual agreement. In a similar fashion with Mann et al. (2010), the drivers of green retailing can be categorized into following ways, as presented in Table 1.

Legislation Driver

The legislation is one of the primary drivers of green policy adopted by different firms. It compels the firms to integrate the environmental policies into their business strategy and operations. Diverse factors like public opinion, government intervention, lobbying by interest groups are mostly responsible for the introduction of various green related legislations. They can be in the form of government laws (Fleischmann et al., 1997) or imposition of environment standards for production processes like carbon emission. European Union (EU) has already employed an emissions trading system to bring down the emission level (Lazarowicz, 2009). According to Georgiadis and Vlachos (2004), suitable environmental policies like usage of recycled products give firms the monetary incentive and thus an impetus to incorporate the green business strategy.

Environmental Driver

Reduction of non-renewable processes (Chan, 2007), control in the usage of toxic materials, goal to bring down the pollutants in emission are the most common environmental concerns those have led to environment related green drives. Also, associating with a partner who employs green practice helps a firm to improve its eco-friendly public image (Grant, 2007). Apart from these, opportunity to capture the new market plays a crucial role in adopting environment drives of green policies by a firm. For an example, Seventh Generation, a cleaning product provider has gained competitive advantage through their eco-friendly product design (Klonsky, 2010).

Financial Driver

Adoption of sustainable measures helps a firm to reduce cost, improve performance efficiency, and exercise better control over her process related activities. Several scholars like Hicks et al. (2004), Krikke et al. (1998), Ketzenberg et al. (2006), Goldsby and Closs (2000) demonstrate that reduction of energy cost, waste, holding cost, shortage cost, and penalty cost is possible by incorporating the green

Table 1. Classification of green retailing drivers

Drivers	Internal	Legislation	Fleischmann et al. (1997) Georgiadis and Vlachos (2004)
		Environmental	Chan (2007)
	External	Financial	Hicks et al. (2004), Krikke et al.(1998) Ketzenberg et al. (2006) Goldsby and Closs (2000)
		Internal Business Process	Mann et al. (2010) Hervani et al. (2005)
		Customer	Vermeulen and Ras (2006)

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

practice. Thus improved financial performance is one of the main drivers for adopting green practices. According to a survey conducted by Boston Consulting group in 2013, 37% of the executives inform that their respective companies have become profitable due to the value addition caused by integrating green policies in the respective practices (Vanderbilt report, 2013).

Internal Business Process Driver

It is very critical for any firm to consider the internal business process drivers or operational activities while adopting green practices. Quality, system responsiveness, production, and product recovery rate can be improved through green practices. Adoption of internal control mechanisms for green measures is mostly cost and profit driven (Hervani et al., 2005). In the context of the cost reduction through green policies, Matt Kistler, the senior vice president of at Wal-Mart, commented that "*If this was not financially viable, a company such as ours would not be doing it*" (Bhanoo, 2010). Also, incorporating green policies into the existing practices brings more operational efficiency. Canon has shown the improvement of its process efficiency through successful implementation of green practices (Canon report).

Customer Driver

Because of increasing social awareness, social media influence, increasing education rate, customers are these days well informed about the importance of environment friendliness. Their attitude towards the ecological protection has created a significant impact on the supply chain. In case of customer driver, several aspects such as product quality, delivery reliability, and economic benefits from the reusable product play very significant role in the design of the green supply chain. Vermeulen and Ras (2006) point out that marketing communication play a crucial role for the firm to create an environmental concern image in the eyes of a customer. The eco initiatives adopted by the organizations like eBay, Starbucks, Google are well accepted by the consumers (usanfranonlinen report).

Waste Management

The presence of hazardous waste brings down the quality of life and causes significant environmental degradation (Beamon, 1999). Minimizing any form of waste at each level of the supply chain i.e. from manufacturing to retailing is a prerequisite for designing a sustainable, environmental friendly supply chain. The issues related to waste management (Giannikos, 1998) can be categorized into two classes: (a) pollution prevention and (b) disposal management. Existing literature indicates that pollution prevention focuses on devising the strategy to restrict the pollution at the source at every stage of supply chain (Newman & Newman, 1995); disposal management deals with minimizing the cost related to waste (Richter & Dobos, 1999).

Pollution Prevention

Pollution prevention (P2) is a strategy to prevent the creation of waste rather than managing it after generation (Gupta, 1995). The term 'pollution prevention' is introduced by 3M Company in 1976 and often it is known as 'Source Reduction' (SR) strategy (Srivastava, 2007). As per Hart (1995), a green

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

product strategy is 'path dependent' on pollution prevention and emission reduction. It is evident that Reduction of emission increases the performance efficiency of firms and provides them with a cost advantage. In the context of manufacturing industry, Hanna and Rocky Newman (1995) show the integration of pollution prevention focus in product design. Hart and Ahuja (1996) empirically demonstrate that preventive measures to reduce pollution help firms to increase their profit level and significant gain is earned by the firms with the highest emission levels. They show that there exists a lagged relationship between preventive measures (emissions reduction) and financial performance (return-on-equity). The environmental profile of a company influences her reputation as well as market value (Barth & McNichols, 1994; White, 1995).

Disposal Management

In the context of an urban waste management system, Haastrup et al. (1998) design a decision support system, to identify the appropriate disposal locations. Giannakos (1998) develops a multi-objective model to determine the transportation network and the disposal locations. In the context of the reverse logistics supply chain, Teunter and Vlachos (2002) analyze the importance of a disposal option for remanufacturable items. Often, legal regulations force firms to set up facilities for collecting hazardous waste, and thus force companies to act green (Kotzab et al., 2011). These services, a part of disposal management, create immediate additional costs to the firms though in the long run has positive it has positive effects on the economic and ecological bottom line. However, this positive correlation is contested among the scholars. Nakao et al. (2007) argue that there exists a positive relation between the financial and ecological sustainability. Clemens and Papadakis (2008) doubt such relation and Williander (2007) argue that this relationship cannot be established.

Green Reverse Logistics

According to Dowlatshahi (2000), reverse logistics is highly influenced by the environmental concerns, whether be it packaging regulation or consumer choice, Exploration of related literature reveals that there are a significant number of works focusing on assessment of existing environment friendly practices (Lenox et al., 2000; Scherpereel et al., 2001). In the context of reverse logistics and related network design, scholarly works demonstrate the design of network that will comprise the facility locations for product recovery, reuse, and recycle and identification of the appropriate transportation links to minimize the incurred cost (Fleischmann et al., 1997; Krikke et al., 1998). Flapper et al. (2005) conduct an extensive study on reverse logistics network of different industries comprising pharmaceuticals, electronics, breweries, photocopiers, automobiles, and so on.

As per Tibben-Lembke (2002), remanufacturing, reuse, suitable logistics network design can bring higher profitability to the firms. Hvozda (2015) comments that small businesses need to partner among its industry so that they can develop a global system of recovery; partnership brings more efficiency to the entire closed loop supply chain. Rechargeable Battery Recycling Corporation (RBRC) is one such an industry-funded recycling system; the company has collected more than 100 million pounds of batteries over its two decade long existence (Hvozda, 2015). The business of refurbished products is predicted to grow in the coming days (Hagerty and Glader, 2011). A recent survey suggests that the market for refurbished electronic items is expected to double in only a few years' time (Cummings, 2015). Online

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

retailers like Amazon, eBay, and Overstock have dedicated web-sections for selling refurbished devices. National retailers like Best Buy and GameStop are following the same trend. Hazen et al. (2011) use 'diffusion of innovation' and 'resource-advantage' theories to analyze consumer reactions to firms that implement green reverse logistics practices. Their empirical research shows that an adoption of such policies leads to increased customer loyalty toward the organization and it, in turn, leads to higher willingness to pay more for such firm's products. Next subsection describes the topics on green procurement in the context of the retail industry.

Green Procurement

Green procurement encompasses the topic of how a retailer can build a cooperative strategy with a supplier to integrate the greening policy in the upstream activities. It can be either voluntary or regulatory compliance. Johnson (1998) discusses the ecofriendly procurement strategies in case of reverse logistics value management. With the help of empirical study, Min and Galle (2001) investigates the environmental friendly purchasing strategies of US firms. A significant number of scholarly works describe how a retailer should employ the appropriate supplier evaluation criteria like ISO 14000, EFP evolution and many others for procurement to check whether the vendor is maintaining the environmental friendly practice in his production process (Walton et al., 1998; Kumar et al., 2012). All these studies suggest that it is desirable to encourage the suppliers for being environmentally responsible. Christiansen et al. (2003) present a six step green sourcing model where the authors have given stress on building an environmental conscious supplier base and appropriate green sourcing strategy. Kumar et al. (2012) show that the example of green sourcing strategy of Coca Cola and Apple. Apple made an agreement to those suppliers who are in compliance with the company's environmental policy and standard. Coca Cola has improved in the reduction of wastage of their inputs like water and energy. Walton et al. (1998) provide a summarized version of the supplier evaluation criteria as presented in Table 2.

INDUSTRY PRACTICES

This section represents the existing environmental friendly practices adopted by retailers. The investigation into the current practices of the retail industry indicates that leading retailers focus on mainly six issues for greening (Evans and Denney, 2009). They are presented in Table 3. These six aspects are discussed below in detail.

Table 2. Supplier evaluation criteria

Top Ten Environmental Supplier Evaluation Criteria			
1	Public disclosure of environmental record	6	ISO 14000 certification
2	Second-tier supplier EFP evaluation	7	Reverse logistics program
3	Hazardous waste management	8	EFP in product packaging
4	Toxic waste pollution management	9	ODS management
5	On EPA 17 hazardous material list for product labeling	10	Hazardous air emission management

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 3. Prevalent industry practices

Industry Practice	Policy Adopting Firm (Indicative List)	Scholarly Article
Green purchasing	Aeon, Carrefour	Duff (2007)
Promotion of green products and green packaging	Wal-Mart	Wilson (2008)
Green facility location design	IKEA	Field (2008)
Green Transportation	Tesco	Thompson (2007)
Energy conservation	Sears Holding Corporation Mark & Spencer	Piel (2009)
Waste and emission reduction	Coca Cola	Stribling (2007)

Green Purchasing

In the context of green purchasing, it is observed that firms like Aeon and Carrefour have designed assessment criteria to develop environmentally responsible supplier base. Home Depot Canada gives stress on promoting the eco-friendly product to the consumers by launching exchange programme. Wal-Mart has established a partnership with manufacturers like GE, Royal Philips, and Osram Sylvania as well as suppliers to tackle the environmental issues. For selecting the supplier, Fujitsu Japan considers the environmental friendliness of the raw material suppliers' process. In a similar fashion, According to the 'green plan' announced by Panasonic in 2010, there is an emphasis on selecting the partners who involve in the reduction of the environmental impacts (Panasonic report). Early adoption of green products like organic foods is attributed to the 'universalism values' of the consumers (Schwartz, 1992). In a mall-intercept based study, Thøgersen and Zhou (2012) investigate the motivating factors for early adoption of organic food in China. They find that the influence of social norms in the context of adopting green products is less. Consumers' purchasing pattern is strongly linked to the customers' beliefs about product's healthiness, taste, and environmental friendliness.

Green Product and Packaging

Mark and Spencer has become the first retailer of United Kingdom to become 'carbon neutral'; the retailer has aimed to increase its sales of organic food and drink by 2012 (Smithers, 2012). On the basis of strategic capabilities like pollution prevention, product stewardship, and sustainable development of a retailing firm, Lai et al. (2010) present three dimensions of green retailing:

1. Internal improvement based green retailing,
2. External coordination based green retailing, and
3. Supportive development based green retailing.

Focused promotional strategy for green products also results in better awareness among the end customers. Phau and Ong (2007) show that consumers respond positively to product-related promotions compared to cause-related promotions. Consumers also perceive any environmental claims to be credible if the same is attributed to the green brands than to the neutral brand. They adopt a survey based

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

mechanism to investigate consumers' response toward different environmental claims embedded in promotional messages. As per a consumer survey conducted in 2012, Procter and Gamble is the leading brand in green packaging (begreenpackaging report). The use of plant fiber trays in their operation is widely accepted. Tesco has shown a phenomenal performance in the reduction of carbon emission and in the removal of plastic packaging (Lai et al., 2010).

Green Facility Location

Organizations like IKEA have deviated from the standardized model for setting up the facility location and have taken the local environmental concerns into account for store design. By applying an evolutionary multi-objective algorithm, Harris et al. (2009) show that trade-off between environmental impact and cost impact of opening new stores/ depots would help human decision makers to choose facility location. In the context of carpet reuse, Louwers et al. (1999) suggest that it is possible to have economically viable logistics networks with due consideration for environmental factors; their model differs from conventional facility location allocation models on two accounts:

1. The design of reuse systems is a free choice of the locations of the preprocessing centers, and
2. Inclusion of depreciation costs.

The world's largest office products company Staples along with the City of Miami and MK Real Estate Group has designed Miami's first Leadership in Energy and Environmental Design (LEED) registered green retail building to achieve a sustainable living standard (Staples annual report). As per the report released by McGraw Hill Corporation in 2013, 65% of the retail owners have adopted extensive green approaches in their daily operational and maintenance activities (cdrecycler report).

Green Transportation

From the green transportation perspective, Tesco is giving more stress on shifting from railways and road transport to the water shipment. Edwards et al. (2009) compare the carbon footprints of conventional and online retailing of non-food items from a "last mile" perspective. Neither home delivery nor regular shopping habit has an absolute carbon footprint advantage. Through the analysis of various "last mile" scenarios, they show that the home delivery operation is likely to generate less carbon-di-oxide (CO_2) than the conventional shopping trip to brick and mortar store. A123 systems, Tesla Motors, Venture Vehicles are the leading transport companies who employ green technology in the respective transport design (Kanellos, 2008). Dell has shown the selection of proper transportation mode for the product delivery which can vary from "truck to rail, air to sea" (Dell report).

Energy Conservation

Sears Holding Corporation has designed the energy efficient rooftop units to conserve the energy. Large retailers are adopting measures for energy conservation. Marks & Spencer aims to make their UK operations carbon neutral by employing diverse strategies, such as a commitment to reduce energy use and to use green energy (Smithers, 2012). Since 2003, the firm has reduced carbon emissions by 30% per square foot in their UK stores and plans to reduce it by a further 25% (Thompson, 2007). The firm has

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

also opened 'eco stores'. Target's store and Fontana store use solar panels and skylights, respectively to reduce the use of electricity (Lai et al., 2010). In 2010, Walmart has put emphasis on energy efficiency based supplier selection and has successfully reduced 17.4 metric ton greenhouse gas emission by the end of 2014 (Walmart report, 2015).

Waste and Emission Reduction

As per the existing scholarly works, several factors like legal regulations, community group pressure, external stakeholders' influence, competitive advantage (Lai et al., 2010; Kotzab et al., 2011) propel the environmental concerns in the domain of retailing. On the other hand, high cost of disposal of hazardous materials, environmentally friendly materials and packaging, and fulfilling the requirements of customer organizations for environmentally friendly operations and processes, insufficient awareness of the importance of environmental protection among the consumers can be obstacle the way of implementation of greening policy (Wang et al., 2013). In order to successfully integrate the environmental friendly concerns in the supply chain practice, several recommendations like identification of waste reduction opportunities, government financial support for green initiatives, awareness of the importance of green operations and willingness to lead green initiatives in suppliers and retailers, awareness of consumers have been suggested in the existing scholarly works (Lai et al., 2010; Kotzab et al., 2011; Wang et al., 2013). To reduce the carbon emission along with waste, Timberland has introduced a special programme named 'Climate Strategy' in 2009 (Timberland report, 2009). Here Timberland has developed a cooperative plan with its partners to reduce climate impact due to the carbon emission in its footwear value chain.

POLICY LEVEL DECISIONS

In this section, we describe the different government level initiatives adopted to incorporate environment friendly regulatory measures into the existing retail practices. In United Kingdom, a Waste and Resources Action Programme with a budget of 8 million euro have been launched to facilitate the retailers reducing their production, storage and transportation costs and companies like Argos, Asda, Tesco, Co-op group, and Marks & Spencer have applied for it (Centre for Retail Research, 2007). In 2004 Tesco, as a part of greening policy adoption measure, re-launched its "Healthy Living Club" program; the program makes the customers aware of general health, weight loss and green and other organic products (Jones et al., 2005). European Union has implemented a set of regulations using EU packaging directive to minimize the waste material using '2007 regulations' and to promote energy conservation and reusability of packaging with the help of legislation 'essential requirements'. EU has also introduced Renewable Energy Directive (RED) programme in 2009 to enhance the usage of nonrenewable electricity sources (Moïsé and Steenblik, 2011). Recycling activities are encouraged among retailers with the help of WEEE directive and regulations. Tesco establishes an objective to reduce its carbon footprint (Lai et al., 2010). Metro Group has been organizing 'energy savings week' for motivating employees to lessen energy savings (Tang, 2012). In France, a general framework law named 'Grenelle 1' has been implemented to establish the government's environmental policies. Retailers' responsibility to inform the consumers about their ecofriendly policies is specified in 'Grenelle 2', the extension of the 'Grenelle 1' (Moïsé & Steenblik, 2011). To promote green procurement, Swiss Federal Procurement Commission (BKB) has devised a supplier selection policy where they include assessment of suppliers' environment friendly approach as

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

a criterion (BBL report). In Australia, South Australian government has introduced a scheme called The Retailer Energy Efficiency Scheme (REES) to engage energy retail giants for helping households and small business houses for the efficient usage of energy as well as reduction of the Greenhouse Gas emission. In New Zeland, programs like Envirostep and Carbonzero are launched to evaluate the environmental performance and greenhouse gas emission, respectively (Sustainability report, 2015). Canadian government have taken many initiatives like establishing multi-stakeholder National Packaging Task Force to devise appropriate policy measures for bringing down the environmental impact related to packaging, banning single-use plastic shopping bags, replacing plastic bags with biodegradable ones, launching a reusable bag pilot project in Ontario and so on(Green scape report, 2012). In the USA, environmental protection agency (EPA) has introduced Greenscapes programme to designed cost-efficient and environmentally friendly solutions for the preservation of natural resources, waste prevention, and pollution reduction(Green scape report, 2012). EPA has launched Renewable Transport Fuel Obligation Programme (RTFO) and National Renewable Fuel Standard Program (RFS programme) and transportation sector to increase the use of different bio fuels namely renewable biofuel, advanced biofuel, cellulosic biofuel, and biomass based biofuel instead of fossil fuels (Moïsé & Steenblik, 2011). Indian government's action plan related to the devising the appropriate regulatory measures help to increase the concern about green policies among retailers. They are also envisioning it as a tool of competitive advantage. For example, Re-feel a cartridge manufacturer has shown the way to enhance the customer base in both economic and environmental friendly way (Datar & Laghate, 2011).

BARRIERS AND BENEFITS

There are several factors that can hinder the successful implementation of greening strategies in the retail sector. According to Hazen et al. (2012), consumers attitude towards the products manufactured in green reverse logistics production process does not bring the optimistic picture to the retailers. Often, customers perceive these products to be inferior in terms of quality. Often stakeholders of the organizations show disinterest in incorporating the greening policies in the existing practices to get rid of the extra cost. It leaves a negative impact on all supply chain agents including retailers. Many a firms maintains a susceptible stance to the success and the long run effect of greening policies. In 2009, large Oil companies have opposed the US government's renewable 'green oil' initiative. In this context, Rex W. Tillerson, the chief executive of Exxon Mobil, said that "We don't oppose alternative energy sources and the development of those. But to hang the future of the country's energy on those alternatives alone belies reality of their size and scale" (Mouawad, 2009). From small retailers' perspective, lack of detailed information about the green practices adopted by the retail giants and absence of benchmark policy act as impediments for integrating ecofriendly approaches in their existing practices. Proper Implementation of environmental regulatory measures is another critical issue regarding this matter. Often, it is observed that strict legal action is not taken against the firms causing environmental pollutions.

The adoption of green policies in the retail sector has brought success to many organizations. The inclusion of environmental management system leads to improvement of financial performance, energy efficiency, waste reduction in case of many companies like Sainsbury, Calgary, Target, Walmart, Staples and many others (Greening retail report, 2006).1 In case of Sainsbury, electric usage is reduced by 12% that leads to the savings of $17000 per store. In a similar line, Calgary group has experienced savings of $57000 per year through reducing the electricity consumption and improving the energy efficiency.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Target has brought down its water usage by 7%. Walmart's fuel efficiency has increased from 6.5 gallons to 13 gallons per gallon. Staples achieves a saving of $4.5 million through the trashless packaging. Many other organizations like Kesko, Wholesale club emphasize on educating employees about the ecofriendly policies and reduction of natural resource usage through special programmes.

CONCLUSION

In this book chapter, at first we have demonstrated the background of green retailing along with its importance. Then we have presented a conceptual framework depicting the drivers, dimensions, industry practices, and government policy level initiatives. Next we have described each of the things mentioned above in detail. For drivers, we have identified that legislation, financial, environmental, internal, and customer driver act as most important stimuli for the green retailing domain. Then, we have described how green measures influence waste management, procurement, and reverse logistics. Next, we have provided a detailed representation of green practices adopted by several industrial organizations in different areas like procurement, packaging, designing the facility location, transportation, energy conservation, and waste reduction. Further, we delve into the government policies that facilitate the integration of environment friendly measures into the practices through regulations, initiatives, and new ventures. Next we demonstrate the challenges and opportunities associated with the green retailing with the help of real life examples. From future research avenue perspective, analytical modeling techniques employed to solve the problems in the domains like reverse logistics, transportation, waste minimization and facility location design can be an area of interest for both scholars and practitioners point of view. Country or organization specific empirical studies on the disposal management, supplier evaluation, and waste reduction can be useful for both academia and industry practices. Approaches regarding modification and proper implementation of the existing environmental friendly policy measures can be other opportunities for government officials.

The nature earth has been highly affected by many a myopic measures of human civilization. If these activities cannot be curbed down, extinction of flora and fauna will be endangered in near future. It may happen that the integration of the greening activities in existing practices will not be successful for some retailers. But we can hope that this green movement in retail industry will bring desirable sustainability of the system and a safe future to the human civilization.

KEY TERMS AND DEFINITIONS

Energy Conservation: Energy conservation refers to reduction in the amount of energy consumption for either a process or a system through rational usage, reducing the requirement of energy intensive services.

Green Packaging: Green packaging or sustainable packaging uses environmentally-sensitive manufacturing methods and recyclable and biodegradable materials for the purpose of product packaging, so that the package has low impact on the environment and the packaging process consumes minimum energy.

Green Procurement: Green procurement refers to the spending and investment policy adopted by a firm toward purchase of environmentally friendly products as well as services, selection of vendors and the setting of required environmental criteria.

Green Promotion: Green Promotion refers to the specific type of advertising that focuses on the promotion of sustainable policies, environmentally friendly operations, green packaging and environmental measures adopted by a firm.

Green Retailing: Green Retailing is an approach toward managing any retail business by incorporating sustainability focused practices and environmentally friendly processes.

Green Supply Chain: Green Supply Chain Management integrates eco-friendly aspects into conventional supply-chain management practices, in order to make the every activity of the value chain: designing, procurement, processes, final product delivery, and end-of-life product management, to become environmentally conducive.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Green Transportation: Green Transportation or Sustainable Transportation comprises of those modes of transportation that do not depend on diminishing natural resources like fossil fuels. These transportation modes rely on renewable energy sources. They also have very low impact on the environment as these modes produce minimal or no greenhouse gas emission.

Reverse Logistics: Reverse Logistics is defined as the flow of used or unwanted or surplus materials, goods (semi-finished or final), and equipment back to the manufacturer through her logistics chains or retailers for the purpose of recycling and reuse, or disposal or both.

Waste Management: Waste management includes generation, minimization, removal, transportation, and treatment of waste. It also looks into the aspects of recycling, reuse and disposal of residual parts of used products.

Chapter 73
A Review on Green Trust and Environmental Quality Awareness Affect Towards Environmental Attitude

Trianna Rosli
University Technology of Malaysia, Malaysia

Fauziah Sh. Ahmad
University Technology of Malaysia, Malaysia

ABSTRACT

There are literally thousands of the global warming and pollution issues affecting the living resources, habitats and residents of an ecosystem. The question is, do the issues affects consumers' environmental attitude? Although environmental awareness is gaining more ground among consumers, it is still not clear how this influence their cognitive thinking and consequently their action. The findings on this issue are still equivocal. There are also arguments that most consumers expect others to solve environmental issues which seems to be more of future concerns while they seek immediate gratification or short term personal satisfaction. To date, marketers are still struggling to convince consumers towards eco-products. Furthermore, green halo effect and greenwashing continues distorting buyers and caused them to be more skeptical. This chapter intends to consolidate the literature on green trust factors and environmental quality awareness and assess how these could stimulate environmental attitude.

INTRODUCTION

During the past decades, researchers from multidisciplinary areas relating to environmental studies recognized the importance knowledge and practices that can lead to more responsible ecological decisions and sustenance of environment. While advance nations have been more action oriented towards green and reported to take more initiatives to control and manage environmental issues (Otman, 2011), the developing nations including Malaysia are building up their stronger perceptions on the importance

to go green. Slowly it builds concerted effort to provide solutions to protect, develop and sustain the environment. The government as well as other responsible parties have been increasingly educating and undertaking the responsibility to enhance the nation's capacity in dealing with the environment issues. The consumption issues of natural resources such as water, energy as well as the protection of natural habitats and endangered species are making it more important for all individuals to practice green in their daily life. However, the national effort may not necessarily translated into a better green perceptions of customers.

However, in a different perspective, it is believed that conscious customers are socially performing daily decision making to minimize the impact of environmental burden and some voluntarily join the green movements to highlight the importance of being green. They even called themselves as 'green people' or more fashionably known as 'pro-environmentalist' (Ottman, 2011). Often, these environmentalist are not leaving the responsibility of environmental issues entirely on the government and businesses (Thøgersen, Jørgensen, & Sandager, 2012).

The environmental movement has extended into organization's practice that determines environmental performance. This includes higher environment standards to innovate and stimulate technology performance that affects companies' efficiency (Peng & Lin, 2009). The implementation of environmental regulations and development of environmental technology (improvement) are one of the critical factors in the organizations towards environmental performance. However, many firms are not capable of undertaking the green marketing strategies and integrating the green concept within all aspects of marketing routine (Ottman, 2011). The implementation of environment performance in the organization has proven such environment oriented practice can support customers to become greener practical within the company. It may not reflects individual's practice-related activities such as practicing product recycling at home or using the green product in the daily routine (Grimmer & Bingham, 2013).

Generally, people who are aware of the environmental problems tend to possess the environmental attitude, and it will translate into supporting or encouraging environment movements. Several research findings support that individuals who possess the environmental awareness have the tendency to perform the environmental behavior (Boztepe, 2012). Unfortunately, the past results seemed to be inconsistent. No matter how severe is the environmental degradation issues and people are expected to monitor lifestyles ethically, yet, there is an indication of poor green practice. People may take the environment for granted, as well as to some, leave for the others to solve the issue (Carrington, Neville, & Whitwell, 2010) because bio-gradable or green products may often cost more money and efforts (Markkula and Moisander, 2011). Customers are likely to seek personal gain (self-fulfillment) and satisfaction rather than a future outcome (Oliver, 2014). Furthermore, the reality in Malaysia shows the presence of a green idea in individual perspective but it is still limited (Goh & Wahid, 2014; Mei, Ling, & Piew, 2012; Ramli, 2009; Sinnappan et, 2011).

Based on Boztepe (2012), people behavior has a complex spectrum of habit, personality, and lifestyle. Hence, the attitude problem is rooted in customers' deep confusion on the green idea. Therefore, marketers are still struggling to change people behavior to be greener as well as to convince them on green consumption. Furthermore, it is difficult to overstate the effectiveness of the green initiatives and marketing strategy due to many possible constraints to make people going green.

The famous green constraints are known as green halo effect and greenwashing that are distorting the reality of green products. These restrictions are escalating the misconception and skeptical towards eco-label, claims, and advertising. Time to time, it has become a serious challenge for marketers to create a solid marketing strategy that will 'move' people towards being green.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Past literature has been discussed about people awareness and trust. However, the results still remain inconclusive to influence environmental attitude. Many initiatives by government bodies present the eco-labelling and advertisement, yet, how much people trust the green claims to actually persuading them to practice green in their daily activities? Although Malaysia has Environmental Performance Index to monitor how significant the performance of country's environment, but what are the perceptions of customers towards our environmental quality or development? How well the customers aware of the environmental issues and to what extend they will go about it? It is thus crucial to consolidate the literature on green trust and environmental quality awareness to bridge environmental attitude gap. Furthermore, an adaptation of the Theory of Reason Action; Three Paradigm Model as well as Trust-Based Situation Awareness Model would explain the potential relationship of the proposed constructs.

GREEN TRUST

Trust has numerous background from diverse disciplines including sociology, psychology, and economics. In psychology, trust "compromises the intention to accept the vulnerability based on positive expectations of the intentions or behavior of another" (Rousseau, Sitkin, Burt, & Camerer, 1998, p. 395).Two criteria in the definition, the first criteria relates to 'positive expectancy' from another individual. It explains the individual's belief towards another person will act in a manner that is responsible and integrity. The second criteria is related to 'accepting the vulnerability' where people will accept it with an open heart (willingly accept) of whatever outcomes.

Early researchers discussed the trust antecedent in the Commitment-Trust Theory where it is conceptualizing trust "as an existing when one party has confidence in an exchange partner's reliability and integrity" (Morgan and Hunt, 1994, p. 5). The definition is similar to another early study that claimed: "trust is defined as a willingness to rely on an exchange partner in whom one has confidence" (Moorman, Deshpande, and Zaltman, 1993, p. 82). Furthermore, it is suggested that positive trust could influence the relationship between partners. For instance, when a customer has high competence trust towards a service provider, it is presumed that the customer holds a high-performance expectation of the provider in the subsequence relationship exchange (Singh & Sirdeshmukh, 2000).

The popular example of green constraints are called a greenwashing and green halo. These terms are considered as marketing strategy or tactics to make customers feel safe in a placebo way.. The modern western 'greenwash' term started in the early 1970s when Earth Day began on April 22, 1970; the US government encouraged companies to advertise themselves as being friendly to the environment. During that green period, western public utilities spent 300 million dollars to portray themselves as a green company. A New York writer, Jay Westervelt who created the first term of greenwashing in 1986, wrote about environmental issues essay concerning hotel industry's practice of placing placards in each room promoting reuse of towels to 'save the environment.' Westervelt (1986) said, in most cases, no significant effort had contributed to reducing energy wastage, and companies claimed that they were green but demonstrated nonexistence cost reduction due to this practice. Therefore, the greenwash term used to describe the practice of businesses over claiming the environmental products or practice that cannot be validated. Hence, the false claims are broad misleading marketing tactics by dishonest companies which often result in suspicion about green claims (Parguel, Benoît-Moreau, & Larceneux, 2011; Self, Self, & Bell-Haynes, 2010).

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Green products are associated with the direct impact on the environment in every phase of the product's life-cycle, and this also serves vague promises that guaranteed by the profit-making companies. The exaggeration of the environmental value of their products will rise the suspicions which make customers distrust and hesitate to buy. Thus, such greenwash claims can damage and lead to confusion, skeptical as well as uncertainty towards the green products (Obermiller, Spangenberg, & MacLachlan, 2005; Tahir Albayrak et, 2011, Pomering and Johnson, 2009). As a result, it will potentially destroy the green market in the future (Kalafatis, Pollard, East, & Tsogas, 1999; Peattie, 1999; Polonsky & Rosenberger, 2001).

Another example of marketing strategy is called the Green Halo tactic; it is a cognitive bias that most companies influence their customers' feelings and thought about the characters of the products. For example, organization claim is to saving the world by driving a Prius, selling the organic beauty products and safe product made by bio-ingredients. This halo effects seems to give false feelings or thoughts of consumers that they are doing good for the society. Edward Thorndike who is a psychologist that named Halo Effect term which refers to a person who being perceived as having a halo when he or she influenced by products claims or branding. The University of Toronto shows that when people spend money on eco-friendly products, believe they earned 'moral credit' for saving the world.

Turnbull (2000) define the green consumer confusion as a 'customer failure' to develop a correct interpretation of green product's preference during their purchase decision process (Turnbull, Leek, & Ying, 2000). Therefore, the confusion and mistrust arise when companies fail to develop a real situation or give a misleading interpretation of a various aspect of their products during information decision making (Peattie, 1999; Turnbull et al., 2000). As a result, consumer's misunderstanding creates a confusion of the green market when the products are too similar, complex, ambiguous or too much of information of the products (Y.-S. Chen, 2007, 2009; Y.-S. Chen & Chang, 2012b; Mitchell & Papavassiliou, 1999; Turnbull et al., 2000). Hence, this will raise people suspicions and undermine their trust and eventually, this will stop them to purchase or consume green products again. (Singh & Sirdeshmukh, 2000). Even worse, they will tell their friends and influence them not to try or buy green products.

Therefore, an interesting extension study by Chen (2009) has developed antecedent in sustainability research, and coined the Green Trust term. This precursor serves customer's 'willingly to depends' on green products characteristic, attributes as well as advertising. Trust defines the trustworthy or an act of willingness to rely on products, service or brand based on beliefs or expectation resulting in its credibility, benevolence, and ability to its environmental performance (Schurr & Ozanne, 1985).

Adapt by Chen (2010); there are four items proposed as below:

1. Green product's environmental reputation is reliable.
2. Green product's performance is dependable.
3. Green product have assurance towards environment protection.
4. Green product's environmental claims are trustworthy.

ENVIRONMENTAL QUALITY AWARENESS

According to Han, Hsu, Lee, & Sheu (2011), environmental awareness is a positive attitude towards eco-friendly activities and encourages people to engage more frequently in ecological behaviors in their everyday life. Chen (2010) defines an individual with environmentally awareness has the environmen-

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

tally concerned attitude that can be described as the perception of self and the extent to which a person identifies him/herself to be an essential part of the environmental setting. Past result shows that the environmental quality issues have brought up the idea of being more exposed to efficiency and favorable attitude (Simmons & Widmar, 1990).

For many years, environmental awareness has received significant attention and extensive coverage of studies among academicians and practitioners (Bran, Radulescu, & Ioan, 2011; Grimmer & Bingham, 2013; Peng & Lin, 2009). According to philosophy science study, self-awareness is an effort "to describe consciousness in clear terms that develop awareness of the qualia drawn up by other networks" (Ferrari & Sternberg, 1998, p. 6). A person with environmental awareness practices energy saving, recycling, and efficiently consuming bio-gradable products; they are the individuals who acknowledge the importance of environment protection (Ottman, 2011).

There were extensive coverage studies on environmental awareness (Bran, Radulescu, & Ioan, 2011; Grimmer & Bingham, 2013; Peng & Lin, 2009). The environmental awareness can be associated with business success by communicating various products' ecology credibility and impact towards social and environment. Although, the early models were based on the linear progression of environmental awareness that hypothesized to influence pro-environmental behavior, yet, it was claimed that environmental awareness does not promote sustainable lifestyle efficiently (Hobson, 2001).

Unfortunately, in the case of Malaysia, there is discrepancy between individual's stated and actual behaviour. The commitment does not necessarily translated into pro-environmental behavior (Mat Said, Ahmadun, Hj. Paim, & Masud, 2003). Behavioral researchers argues that individual hardly change their behavior when their lifestyle is rooted deep in a social context (Jackson, 2005). Another study supported that awareness about a green product does not affect the purchasing green product decision (Suki, 2013). Hence, the question is, why environmental awareness is still not enough to influence environmental attitude?

In 2009, the introduction of Environmental Performance Index had become a favorite indicator which numerically marking the environmental performance of states policies and provides a ranking of the whole countries. Even so, EPI cannot provide feedback on the level of customers' sensitivity (Carrington et al., 2010). To date, there is no inclusive evidence on the study of environmental quality awareness (EQA) in Malaysia.

Environmental Quality Awareness defines as an acknowledgment the quality of environmental towards Human Health, Ecosystem Vitality and Socioeconomic Sustainability of the country (Trianna R, 2017). EQA investigates customers' awareness towards environmental quality and seeing to what extent the customers will receive a response in their lifestyle regarding human health, ecosystem vitality and socioeconomic sustainability of the country (Trianna R, 2017). It postulates to support the attitude/behavior gap issues, as well as structuring the solutions for the current ecological concerns in Malaysia. By considering this, the researcher proposed the environmental awareness quality could contribute towards the sustainability area of knowledge (Trianna, 2017). EQA will deliver four question items:

1. I am aware environmental burden can affect my health and ecosystem vitality.
2. I know that air and water quality may affect my health and ecosystem vitality.
3. I believe that water sanitation system is important to maintain a good health.
4. I am aware that open fire, transportation, and industrial hazardous waste can affect my health and ecosystem vitality.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

ENVIRONMENTAL ATTITUDE

Historically, people are worried about their health because the fear of losing the ability to sustain healthy life environment and they felt the environment has diluted by many unethical actions (J. Ottman, 2011). In social psychology research, the customer's attitudes have been continuously used to predict energy conservation and ecologically informed purchase which specifically focused on the relationship between environment attitudes as well as environmentally related behavior (Ajzen, 1991; Ajzen & Sexton, 1999).

Environment attitude refers to the individual's value judgment and it taps the person's cognitive assessment to participate in environmental-supportive behavior (Lee, 2008; Sinnappan et, 2011) in instances such as to ride public transport, recycling, or to get environmental products. However, supported by Carrington's study shown that most of the people expect others to solve on the environment issues (Carrington, Neville, & Whitwell, 2010). Furthermore, the deceiving cases about organizations that are trying to compete by claiming things that untrue. Therefore, it has been formed as customers' constraint to rely on and depends on green product's claims.

Many green attitudes constraints that evolved with people trust and awareness have restricted to influence them to behave environmentally. People are driven by the curiosity and added precaution to protect their health, and some of them are skeptical with the reputations of product manufacturers towards social and environment responsibility (Ottman, 2011).

Adding to this, customers are overwhelming with complex information on green products (Moisander, 2007). The increasing skeptical and confusion towards green claims would negatively influence green consumption (Y.-S. Chen, 2009; Y.-S. Chen & Chang, 2012a, 2012b, 2013; Walsh & Mitchell, 2010) as well as outperform the ability to act in a green way.

Hence, it is best to study the environmental quality awareness influence towards environmental attitude. The researcher will access Environmental Attitude antecedent as to gain the understanding about individual's belief. The proposed variable items are adapted from Sinnapan et al. (2011);

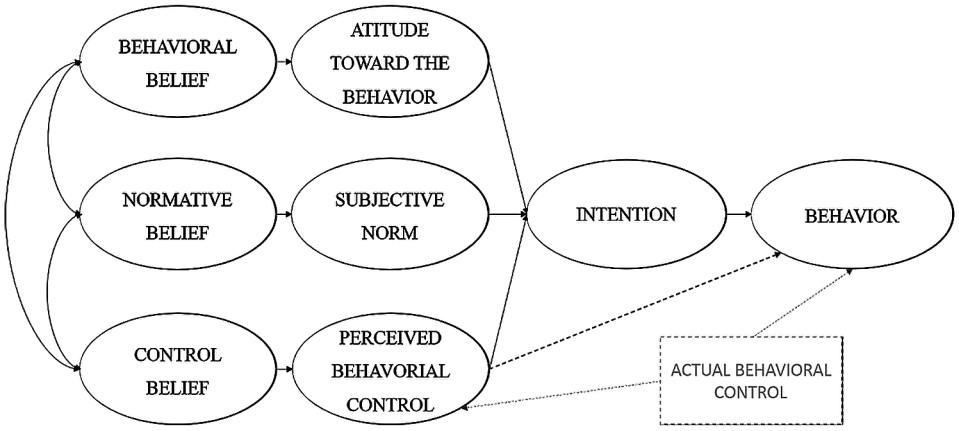
1. It is essential to promote green living in Malaysia.
2. I strongly agree Malaysia needs more environmental protection.
3. It is important to raise environmental awareness among Malaysia people.

THEORIES AND MODEL

As proposed by Theory of Reasoned Action (TRA), 'evaluation of outcome' constitutes the attitude of a person which lead to the behavior, by this mean, people must be observant to the consequence (Azjen, 2011). TRA theory suggests 'beliefs' are the novels that play the first role in human behavior (Figure 1). In another word, these beliefs guide the human behavior by three kinds of considerations, the first belief is about the consequences of the behavior, which is called behavioral beliefs. Then, a normative belief that defines as beliefs about the normative expectations of others. Followed by control beliefs, which constitutes the beliefs about factors that may facilitate that performance of the behavior (Ajzen, 2002). The theory delivers in-depth information on three salient beliefs are behavioral beliefs, normative beliefs and as well as control beliefs. These three salient beliefs that people who hold onto which considered principal determinants of individual's intention and action (Ajzen & Sexton, 1999).

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

According to this underpinning theory from Icek Ajzen, behavioral beliefs is predicted to influence attitudes towards the behavior, normative beliefs constitute the underlying determinants of subjective norm, and lastly, control beliefs provides the foundation perceptions of behavior control.



Meanwhile, Sterling's of Three Paradigm model (2009) also explains that the individual must have the ethical sensibility or consciousness through perception (seeing) and followed by the conception (understanding). Stephen Sterling (2009) suggested a critical understanding of pattern and the consequence will help a person to connect towards the subject. In the study of ecology learning, people need to have 'cognitive domain' (aware and understanding) and 'affective domain' (seeing, emotion, assumption, values), then people will have 'intentional domain' (doing or practical) in order to respond towards environmental issues. Correspond to futures expert Paul Raskin argues that "the shape of the global future rests with the reflexivity of human consciousness – the capacity to think critically about why we believe what we do – and then to think and act differently" (Raskin, 2008, p. 469). The Three paradigm model suggests that the people awareness is critical to shaping the people values and attitude.

Moreover, the addition of Environmental Performance Index (EPI) literature has shown that contents raw data (index) is insufficient which it does not play the part of taking account of customers' awareness or standpoint, nor it examines how well green practice as they exposed to the environmental performance (Alex de Shernin et, 2013). Hence, the theories and model support the relationship between green trust and environmental quality awareness towards the environmental attitude that will discuss further.

PROPOSED MODEL

In this chapter, the researcher proposed the Theory of Situation Awareness (SA) as a foundation for the model relationship. SA theory is a significant contributor to the "Quality of decision-making in complex, dynamically changing environments" (Aydoğan, Sharpanskykh, & Lo, 2014,p. 22). SA refers to knowing what is happening around oneself and generally, this theory is adapted in intelligent software agent and aviation organizations. The operational of SA model has been vigorously debated about two main

Figure 1. The theory of planned behavior. Organizational behavior and human decision processes.
Source: Ajzen (1975)

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

streams of the traditional information-processing approach of psychology versus ecological psychology. Based on Endsley (1995), the concept of situation awareness refers to the level of knowledge that an individual has of a situation and an operator's dynamic understanding of 'what is going on.'

A decision-making process developed by considering from what sources should be taken into the information fusion of making that particular decision. Therefore, an individual must be in somewhere to 'depend' on the information sources. Alas, the decision-making process may vary because the persons influenced by the source of information given and the degree of (un)certainty of information provided by this source. Hence, the person must determine to what extent of communicated or observed information contributes to the activation level to correspond or to decide (Aydoğan, Sharpanskykh, & Lo, 2014). Moreover, one of the major factors influencing both misuse and disuse is trust in automation (Parasuraman, Sheridan, & Wickens, 2008).

Therefore, this chapter adapted the model concept by R. Aydo˘gan et al. (2015) study which extended the SA theory in the study of an aircraft. This study integrated the interpersonal trust in the framework which previously SA Theory does not take it in the model range. The study suggested that the more person trusts the information source, the more it affects that person to make an assessment of the situation. Thereby, the ability examines of what kind information source should be taken into account and how well person aware of the situation is important in decision making.

The model noted that the choices or alternative would depend not only on the content of information but also on the trustworthiness of the information source is important to put into the consideration (Aydoğan et al., 2014). Thus, R. Aydo˘gan et al. (2015) proposed integrated model between SA which activated by communicated or observed information and the trust towards information sources affect decision maker's assessment of the situation.

R. Aydo˘gan et al. (2015) performed Endsley and Hoogendoorn's computational model of SA which manage to introduced agent-based situational awareness model incorporating trust to enable humanlike decision-making tools in the computational area. The finding proved that significant impact of trustworthiness of information sources had an effect on airline operation controller's situation awareness and implication on its decision-making.

Therefore, this chapter adapted Trust Based-Situation Awareness model by R. Aydo˘gan et al. (2015) that has extended the knowledge area by integrated the trust antecedent and stimulate in an airline's operation control domain case. This chapter aims to investigate the relationship between green trust and environmental quality awareness towards environmental attitude using the Trust Based-Situational Awareness model. Figure 2 shows a study by R. Aydo˘gan et al. (2015). Both are hypothesized that the independent variables are affecting the dependent variable (outcome).

Figure 3 showed the example of prior study and proposed green trust and environmental quality awareness towards environmental attitude. The first construct of green Trust discusses on the willingness of the people to depend on the marketing information sources, for instance, advertisements, eco-label, and claims. The second novel discusses the environmental quality awareness which explains about people's awareness is towards environmental quality to fit the environmental discipline study. Therefore, this chapter suggests that based on this adapted model, the integration of green trust and environmental quality awareness potentially affects environmental attitude. Therefore, it is postulated that when people trust towards information source and there is sufficient awareness towards environmental quality, it will lead them to have the environmental attitude.

CONCLUSION

Overall, the chapter explains the opportunity to strengthen the relationship between green trust and environmental awareness towards environmental attitude for future research. Furthermore, a discussion of Trust Based-Situational Awareness model has extended the EQA framework that proposed by Trianna R (2017). Hence, the future research could test the Planned Behavior theory to provide a necessity

bridge between green trust, environmental quality awareness and environmental attitude relationship in the framework.

As supported by Chen et al., (2009, 2010, 2013) behavioral study, people must trust the green claims, eco-label, characteristics and attributes to make them purchase green products. Hence, no matter how well perspective or attitude towards environmental, if the people are skeptical or confuse about green products, they will not be interested in purchasing green products (Y.-S. Chen, 2009, 2013; Y.-S. Chen & Chang, 2013; Walsh & Mitchell, 2010). Chen et al. (2013) who is developed green trust novel has tested in Taiwan and environmental awareness (Zsóka, 2005; Dunlap, Liere, Mertig, & Jones, 2000; Kollmuss & Agyeman, 2002; Connolly & Shaw, 2006; Chen, 2010; Han, Hsu, Lee, & Sheu, 2011; Boztepe, 2012) has tested in many Western countries, hence, the study should not be generalized and presented as a whole customer's behavior.

The differences of background and multi-culture of Malaysian people contributed different findings as compare to Western countries. The interaction between behavior, organizational factor and personal factors described in triadic reciprocal determinism (Bandura, 1986) which has multicultural society dominated by Malay, Chinese and Indian. Thus, the personality behavior possibly will influence by culture as Schein stated that "one can view personality and character as the accumulation of cultural learning that an individual has experienced in the family, the peer group, the school, the community and the occupation. In this sense, culture is within us as people and yet constantly evolving as we join and create new groups that eventually creates new cultures" (Shein, 2004, p. 8). In addition, environmental quality awareness (EQA) provides another spectrum of scale has contributed towards the sustainability area of knowledge. This chapter proposed environmental quality awareness variable that is assumed the person will make more initiatives to control and manage environmental issues. Hence, the research hypothesizes that if individuals are aware of environmental quality; it will translate it to their environmental attitude by supporting as well as encouraging environment movements.

Dunlap (2000), suggested that to understand any specific environmentally significant behavior requires empirical analysis and the roles of environmentalist tendencies are different from behavior, the actor and the context. Furthermore, "environmental intent and environmental impact are two separate things, theories explaining environmentalism are necessarily insufficient for understanding how to change environmentally significant behaviors" (Dunlap, Liere, Mertig, & Jones, 2000, p. 9). As a conclusion, Green Trust and Environmental Quality Awareness are hypothesized to affect an environmental attitude that further study, especially in developing country like Malaysia. Therefore, by assessing proposed model will extend the understanding of people trust to influence environmental attitude and to what extent of awareness towards environment quality that could influence them to gain environmental attitude as well as change social and lifestyle.

KEY TERMS AND DEFINITIONS

Eco-Label: A certification that provides the understanding of ecological benefits to the customers in the long run.

Environmental Attitude: An expression of psychological tendency between favor and un-favor towards things, situations, and people.

Environmental Performance Index: Global metrics for the environment that rank the countries' environmental performance of the human health protection and the protection of ecosystems.

Environmental Quality Awareness: Explains customers' awareness towards environmental quality that consists of three sustainable pillars which are environmental health, ecosystem vitality, and socio-economic sustainability.

Green Consumerism: Defined as the customers' purchasing habits towards environmentally friendly products and services.

Green People: Also called pro-environmentalists, these are people who belong to environment-society. These people are supporters of green or environmental movements whether political or ethical movements.

Green Products: Environmentally safe products that are safe, energy efficient and often have low maintenance requirements.

Green Purchasing Behavior: Spending on products that are beneficial to the environment.

Green Self-Efficacy: People's degree of involvement, effort and how long they will persist in facing the obstacles as well as aversive experiences.

Green Trust: Defined as the willingness to depend on a product or service based on the belief or expectation resulting from its credibility, benevolence, and ability about environmental performance.

Chapter 74
Sustainable Consumption and Green Marketing in Developing Countries:
Contemporary Perspective Using Nigeria and Kenya as Case Studies

Abiodun Elijah Obayelu
Federal University of Agriculture, Abeokuta, Nigeria

ABSTRACT

This chapter provides an insight into why Green Marketing (GM) and Sustainable Consumption (SC) of green products are subject of research and discussion in contemporary society. It analyzed the extent of GM in developing countries using cases of Nigeria and Kenya, factors influencing GM, the benefits of GM on the environment and firms, and the challenges. The study is both exploratory with the use of structured literature review of publications in peer reviewed academic journals on GM and SC, and empirical in nature. The findings on respondents rating of factors influencing green purchase behavior showed that concern for health and environment was considered as the most important in Nigeria, while in Kenya it was social awareness and value. For an effective GM and SC, government at all levels has a role of creating awareness to boost green knowledge through educative campaign programs and enforcing green agenda. Government can make regulations relating to GM and ensure SC by lowering the cost when compared to the conventional marketing

INTRODUCTION

Green, environmental and eco-marketing is fairly a new concept or philosophy in the modern marketing (Kassaye, 2001; Singh & Pandey, 2012) acting as a bridge connecting the corporate, environment and the consumers (Seth & Khan, 2015). The marketing concept emerged due to concerns over issues such as environmental degradation, global warming and the over-use of non-renewable resources (Hartmann

DOI: 10.4018/978-1-5225-7915-1.ch074

& Ibanez, 2006; Tanner & Kast, 2003). Green marketing (GM) is cognizant of making the world green (Shah, *et al.,* 2014) and is a part of the new marketing approaches, which do not just refocus, adjust or enhance existing marketing thinking and practice, but seek to challenge those approaches and provide a substantially different perspective (Ahmad, 2012). It provides the satisfaction consumer needs, wants, and desires in conjunction with the preservation and conservation of the natural environment (Sahu, 2012). GM is now part and parcel of the overall corporate strategy (Menon, 2013), an increasingly interesting research field, and a more viable and sustainable alternative to the conventional marketing (Singh, 2015). The society is becoming more concerned with the natural environment thereby making businesses begin to modify their behaviour as a response to the society's new concerns (Nandini, 2011). According to American Marketing Association (AMA, 2010), GM is the marketing of products that are presumed to be environmentally safe. As a golden rules of green marketing, the consumer must be aware of, and concerned about the issues that the firm's product attempts to address. It also educates the customers not only to let people know whatever the company is doing to protect the environment, but also a matter of letting them know why it matters; being genuine and transparent in green marketing campaign and reassure the buyers that the product performs the job and finally give the customers an opportunity to participate. Firms use GM in an attempt to address cost or profit related issues.

People are worried about sustainability-related issues than ever before by been more concerned about the environment (GIA, 2011). The perceived seriousness of environmental problems will therefore contribute to green purchasing behavior (Dagher & Itani, 2014). Influential customers want to do business with companies that have established their green credentials, so companies are launching hefty advertising and web campaigns, publishing extensively documented sustainability reports, cooperating with external sources to communicate transparently, and communicating their efforts internally (Choudhary & Gokarn, 2013). Marketers are now trying to use green marketing concept in developing their strategies to ensure sustainable development, thereby making GM to catch the attention of scholars and practitioners in developing countries. Marketing theory as applied to these issues remains relatively under-explored. Also, green marketing has been widely explored in developed nations of the world but appears to be at a distant dream in developing nation as studies on green marketing are conspicuously missing in the context of developing economies like India, Pakistan, Brazil, Russia, China and most Africa countries (Singh, 2015). The purpose of this study is to bridge this gap, and to advance our theoretical and empirical understanding of Sustainable consumption (SC) and GM in developing countries as a means of tackling problems associated with the impact of economic activity on the environment. This chapter therefore attempts to address the following objectives:

1. Provide a conceptual link between GM and SC;
2. Describes the status of green marketing in Nigeria and Kenya;
3. Assess respondents understanding and awareness of green products, and factors influencing GM in Kenya and Nigeria;
4. Explain reasons and strategies of using green marketing for sustainable development;
5. Analyze the basic challenges of green marketing in developing countries and
6. Suggest the possible ways of overcoming the challenges associated with green marketing and sustainable consumption.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

JUSTIFICATION OF THE PAPER

Many of the developing countries are more concerned with natural environment thereby making producers and marketer modify their behaviours in an endeavor to address the new concerns. Empirical evidences have shown that marketers are now incorporating green marketing strategies into many activities such as pricing (Kapelianis & Strachan, 1996); promotion (Davis, 1993); planning (McDaniel & Rylander, 1993); product and package design (Polonsky, *et al.,* 1997); distribution (Schlegelmilch & Robertson, 1995), retailing (Duff, 1990); customer segmentation (Balderjahn, 1988); strategic alliances (Stafford & Hartman, 1996); industrial marketing (Drumwright, 1994) and overall marketing strategy (Menon, 2013). Most green marketing literature is strongly based on the assumption that a consumer's environmental awareness is a pre-condition for green purchasing (Meyer, 2001). Public concerns over environmental deterioration in recent years have made marketers recognize the need, and value of green marketing. This chapter evaluates literature related to green marketing and sustainable consumption by digging deep into literature in this newly growing area, throw more light on the conceptual issues associated with green marketing and provide information on green consumer behavior. It also serves as a roadmap on how to organize green marketing effectively and sustainably, and intervention strategies undertaken by some developing countries to enhance green marketing and protection of consumers. The study is a tool for examining current practices in the green marketing arena, a guide for future practices that need comprehensive knowledge and direction and provide guidance for future researchers seeking to investigate corporate and market sustainable (green) development. Further, It will assist managerial audience looking for advice on how to launch or enhance green marketing efforts in Kenya, Nigeria of elsewhere, and contribute to the understanding of consumer motivations for purchasing green products. The findings will also contribute goal 12 of the new Sustainable Development Goals (SDGs) of ensuring sustainable consumption and production pattern by showing the status of the consumption of green products in the selected countries.

CONCEPTUALIZATION OF GREEN MARKETING AND SUSTAINABLE CONSUMPTION

Protection of environmental resources and developing social responsibility are very important for enterprises as well as customers and the government (Peattie & Peattie, 2009; Grinstien & Nisan, 2009). GM concept emerges from societal marketing (Kotler, 1999) introduced by the American Marketing Association (AMA) via a workshop on "Ecological Marketing" in 1975 (Zhu & Sarkis, 2015). Proceedings of the workshop resulted in one of the first books on green marketing entitled "Ecological Marketing" (Henion & Kinnear, 1976). The concept however became prominent in the late 1980s and early 1990s ((Laheri, 2014) as a result of valuable concerns for people and a healthy environment (Dodds, 2007). It is the primary segment of social marketing, because it covers the protection and preservation of the values necessary for survival, existence and development of man as a human being, reflecting the practical support for the implementation of the philosophy of sustainable development of mankind (Srinivasa, 2014).

The evolution of green marketing has three phases (Peattie, 2001). The first phase in 1980s was termed "Ecological" green marketing, and during this period all marketing activities were concerned at solving and providing remedies for environmental problems (Lee, 2008). The second phase in 1990s was termed "Environmental" green marketing and the focus shifted to clean technology that involved

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

designing of innovative new products, which take care of pollution and waste issues. GM in this phase was closely tied to issues of industrial ecology and environmental sustainability such as extended producers' liability, life-cycle analysis, material use and resource flows, and eco-efficiency (Singh & Pandey, 2012). The third phase is the "Sustainable" green marketing which marked a more radical approach to markets and marketing to meet the full environmental costs of production and consumption and create a sustainable economy. GM is rapidly growing, and is expected to get bigger in the years to come (Dangelico & Pujari, 2010).

In terms of definition, there is no universal definition of green marketing and its dimensions. For instance, GM has been described as an organization's efforts of designing, promoting, pricing and distributing products that will not harm the environment (Pride & Ferrell, 1993). While many people believe that green marketing refers solely to the promotion or advertising of products with environmental characteristics, especially in his buying decision (Panahi *et al.,* 2014). To Polonsky (2007), green marketing is a broader concept that can be applied to consumer goods and industrial goods and services. GM is view as strategies to promote products by employing environmental claims either about their attributes or about the systems, policies and processes of the firms that manufacture or sell them. It is also referred to as an initiative which primarily advocates sustainable development by incorporating activities such as product modification, change in production process, packaging, promotion and advertising (Polonsky, 2007) which Laheri (2014) referred to as green marketing strategies. All the activities are designed to generate and facilitate any exchange intended to satisfy human needs or wants, such that the satisfaction of these needs and wants occurs, with minimal detrimental impact on the natural environment (Sarkar, 2012; Laheri, 2014).

Further, GM is the adoption of environmentally friendly strategies that promote resource conservation in every stage of the value chain (Iweana, 2014). It is a marketing response to the design, production, packaging, use and disposal of product (Oyewole, 2011; Lampe & Gazda, 1995). Neeraja *et al.,* (2014) described green marketing to include all the marketing activities of the firm, starting from conceiving the product idea to the actual sale of the product, which are designed with the objective to either create a positive impact or reduce the negative impact of its products on the environment. GM is the process of selling products and/or services based on their environmental benefits or the marketing of products that are presumed to be environmentally safe (Meso & Wario, 2014). It is a holistic marketing concept where in the production, marketing, consumption and disposable of product and services happen in a manner that is less deterimental to the environment with growing awareness about the implication of global warming, non biodegradable solid waste, harmful impact of pollution etc (Katiyar & Katiyar, 2014). This study however considered GM as the process or art of creating awareness among consumers using competitive pricing, promotion and distribution strategies; which can be referred to as green marketing mix to facilitate uptake of products and services intended to satisfy human needs or wants with minimal detrimental impact on the natural environment.

GM is an emerging marketing strategy that includes a wide variety of tasks and activities like fair-trade practices, product modification, production process and packaging that are eco-friendly (Mishra & Sharma, 2008). GM includes greening products as well as greening firms and green products are those that are originally grown, recyclable, reusable and bio-degradable; products with natural ingredients; products containing recycled contents, non-toxic chemical products content under approved chemicals that do not harm and pollute the environment, products that will not be tested on animals and have eco-friendly packaging (Rath, 2013; Neeraja Rani *et al.,* 2014).

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

GM has three key components (Polonsky, 1994): (i) it is a subset of marketing; (ii) it evaluates both positive and negative activities; and (iii) it examines a range of environmental issues. A common element within the definition is the explicit inclusion of environmental awareness in marketing management. GM is an integration of environmental issues into corporate marketing strategy, especially the 4P's, and green consumerism (Zhu & Sarkis, 2015).

Sustainable development (SD) on the other hands is the form of development which aims at sustainable consumption (SC) and sustainable economic growth and tries to protect the environment. We can therefore say that sustainable consumption (SC) is a part of sustainable development (SD) and a prerequisite in the world-wide struggle against sustainability challenges such as climate change, famine or environmental pollution (Lorek & Fuchs, 2013). While SD is the maintenance of long-term economic, social and environmental capital, SC becomes the way of life (Saxena & Khandelwal, 2010).

SD can be conceptually broken into three constituent parts: environmental sustainability, economic sustainability and socio-political sustainability. Realizing the importance of people's concern for a healthy environment to live and preferring environmental friendly products and services to consume, marketers these days are trying to capitalize on the same to ensure sustainable growth and using these concepts in designing their strategies. Green marketing focuses on all marketing activities while protecting the environment. On the other hand sustainable development demands that the future generations inherit the natural environment in the same state or better as inherited by the previous generations. This calls for the protection and improvement of the environment. Therefore, sustainable development is a dependent variable of green marketing and other factors (Kinoti, 2011) (See Figure 1 for more details).

Based on Kinoti (2011) framework, certain differences can be drawn between GM and the conventional marketing (See Table 1).

METHODOLOGY

The study looks at SC and GM in developing countries where it is believe that both consumers and firms are becoming more and more conscious about the environment and also becoming socially responsible. The study is built on other past studies such as Olsen *et al.,* (2014) model on GM, Kotler, (2011) essay on GM and Kinoti (2011) framework of Green Marketing. In order to analyse consumer perceptions of

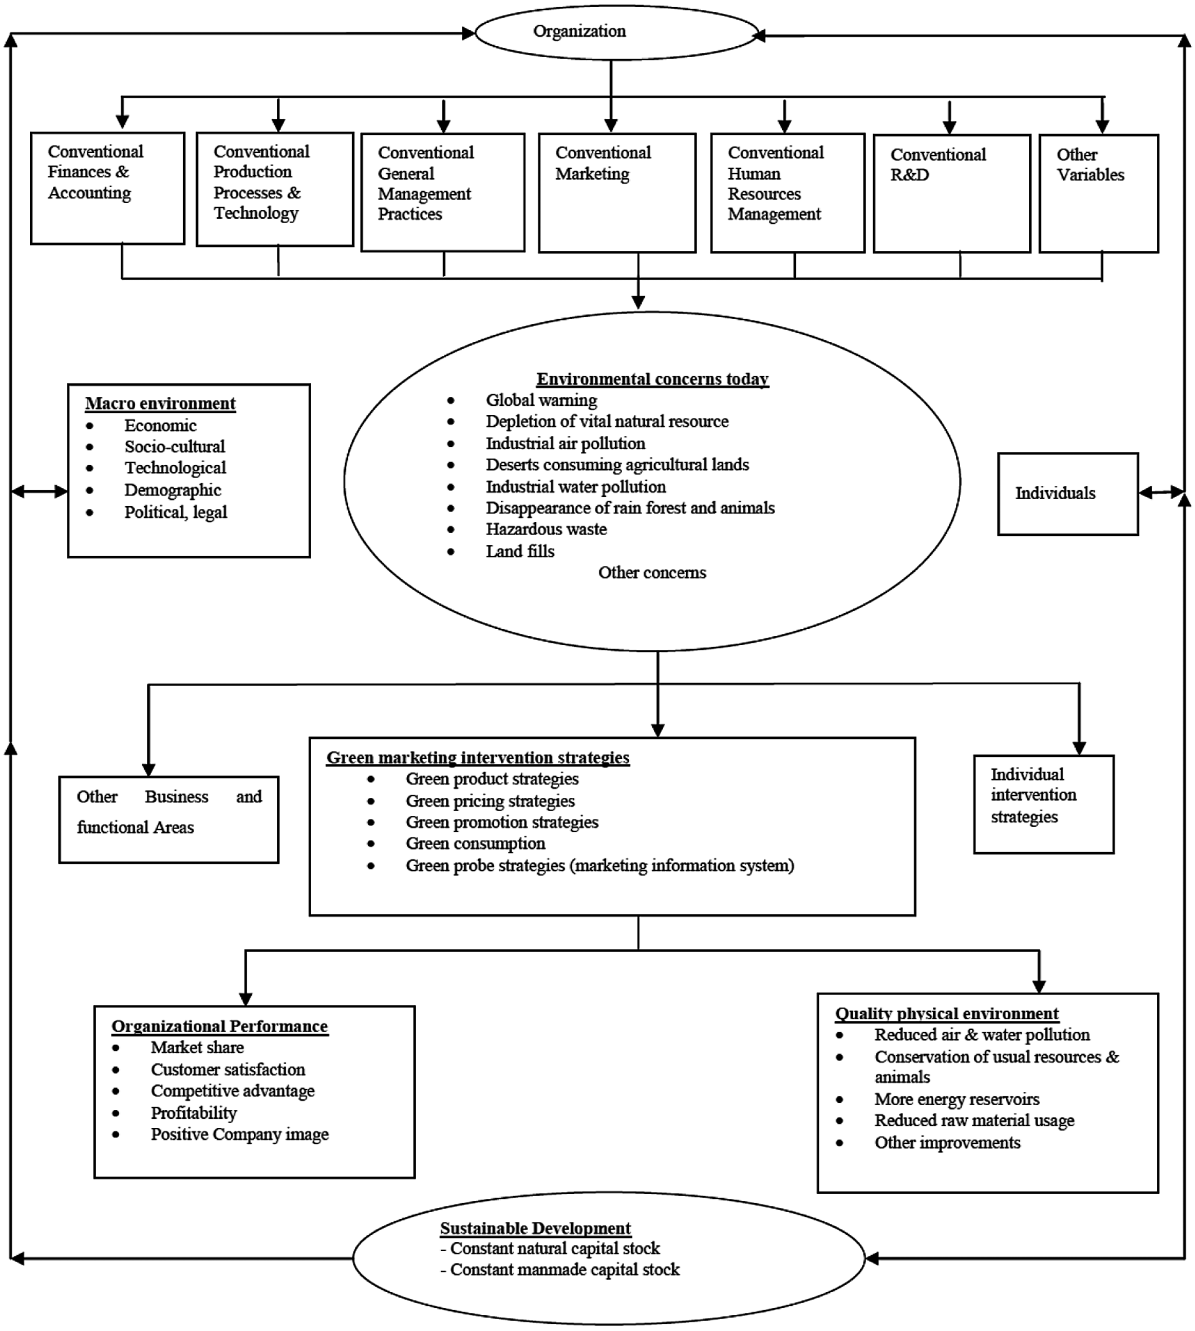

Table 1. Traditional/conventional marketing versus green marketing

Indicators	Traditional/Conventional Marketing	Green Marketing
Goals	Customer satisfaction (as customers)	Customer satisfaction (as humans)
	Accomplish traditional goals	Accomplish sustainable goals Eco-system compatibility
Decision making	Fragmented thinking	Integrated thinking
	Short term orientation	Long-term orientation
Ecological responsibility	Organization alone responsibility	Mutually responsibility
	No underpaid ecological costs	Full accounting of ecological cost
Focus	Tangible goods	Products as services

green products which Chris (2010) observed as unclear in many countries, this study complements findings from literature by conducting a pilot survey in Kenya and Nigeria, using the University students, making it both exploratory and empirical in nature. The study used a structured literature review of publications in peer reviewed academic journals on green marketing and sustainable consumption. By

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

structured literature we mean a systematic, explicit, and reproducible design for identifying, evaluating, and interpreting the existing body of recorded documents (Fink, 2013). The study employed case studies of Nigeria and Kenya by conducting a pilot survey of 50 selected University students each in Nigeria and Kenya using a convenient sampling technique. Some of the students in the selected institutions which were: the Federal University of Agriculture, Abeokuta, Ogun State in Nigeria and Jomo Kenyatta University of Agriculture and Technology, Kenya were interviewed in order to obtain some relevant information about their awareness and factors influencing their purchasing decision for green products. The University students were used as case study because their views on the subject on green products are believed to reveal the true status of green products in the two countries. Students are believed to be more up to date, and use more of green products. Information collected was analyzed using the simple descriptive statistics such as frequency table and a five points likert scale.

RESULTS AND DISCUSSION OF MAJOR FINDINGS

Reasons for Using Green Marketing and Strategies to Ensure Sustainable Consumption

While going green may be in fashion, it is still unclear to some people why firms are making these changes. Green purchasing behaviour can help achieve a sustainable environment (Dagher & Itani, 2014). As organizations are facing limited natural resources, they have to develop new or alternative ways of satisfying these unlimited wants using GM which make use of the limited resources, while satisfying individual and industrial consumers wants, as well as achieving the organization's objectives without causing any harm to the environment (Orange, 2010). GM strives to ensure that production, consumption and even disposal of products in a manner that is less harmful to the environment (Mohanasudaram, 2012). Everyone wants to create and establish sustainable businesses than ever before and GM has become the mainstream as consumers want something that can impact their lives and therefore want to take corrective measures to embrace sustainability effectively. Consumers patronize the products and their aims are to make sure the contribution is supporting sustainable environment and contribution the guiding of the climate change (Hartmann & Apaolaza-Ibáñez, 2006). Green marketing helps a business to become socially responsible, provide better products and improve working conditions (Seth & Khan, 2015). The importance of going green is to save the environment by reducing the hazardous wastage, sewage, deforestation and air pollution in order to preserve and conserve the limited resources for the future generation (Kinoti, 2011). Green products are less harmful to the environment, consume natural resources less, and help in saving time, money and effort (Hartmann & Ibanez, 2006; Papista & Krystallis, 2012). While GM helps at satisfying the needs and desires of the customers, it also keep the company responsible in maintaining long term social and environmental gains (Szuster 2008; Yildirim 2014). It gives alternative picture on different food consumption patterns and lifestyle and energy mixes that could close the gap between ecological footprint and biocapacity. All areas of our economy are affected by green marketing (Zulfiqar & Shafaat, 2015), GM leads not only to protection of the environment, but it also develops job opportunities and new market (Yazdanifard & Mercy, 2011).

According to Afande (2012), GM ensures sustained long term growth along with profitability; helps in accessing the new market and enjoying competitive advantage; assist companies to market their products and services keeping the environment aspects in mind. We can therefore conclude that GM helps at: (i)

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

changing people's consciousness to ecological-friendly lifestyle and consumption (ii) engage consumers in sustainable consumption through convincing examples. GM also helps to reduce waste by using raw materials and energy-saving products, thereby making marketing of green products a profitable venture that leads to a sustainable long-term growth (Ottman 1997; Gupta & Agarwal, 2012). Competitive advantage can also be enjoyed by the companies that are first to deploy their environmental innovation. There is also an increase in brand loyalty leading to increase in market share by the company beyond healthier and more fulfilled lives offered to consumers with a reduction in air and water pollution, and depletion of natural resources through green products (Olsen, 2014).

The Strategies of Green Marketing

There exists a substantial gap or disconnect between the stated pro-environmental beliefs and actual consumption behaviors of ostensibly green consumers (Davari & Strutton, 2014). To close this gap by green marketers requires green marketing mix strategies. GM strategies refer to product modification, changes to production process, and improvements in packaging with intent of reducing the detrimental impact on the environment (Laheri, 2014). To achieve that, green marketer uses the green marketing mix strategies which include developing green-based products, green logistics, green promotion, green pricing and green consumption. The strategies include; adoption of eco-marketing orientation as a business philosophy, government intervention, undertaking life-cycle analysis and teaming up for success (Ottman, 1999; Willum, 1998). While some companies employ the 4 Ps (product, price, promotion, and place) of marketing mix, some others have 7 Ps of marketing mix. Green marketing manipulates the four elements of the marketing mix to sell products and services offering superior environmental benefits in the form of reduced waste, increased energy efficiency, and/or decreased release of toxic emissions (Singh & Pandey, 2012).

- **Product:** The ecological objectives in planning products are to reduce resource consumption and pollution and to increase conservation of scarce resources. This strategy has not been well utilized in Nigeria with a lot of pollution and prevalent high level of destruction of scarce resources such as forest resources.
- **Price:** Price is a critical and important factor of green marketing mix. Most consumers are only prepared to pay additional value if there is a perception of extra product value. This value may be improved by performance, function, design, visual appeal, or taste. Green marketing should take all these facts into consideration while charging a premium price. In our two case study countries, the prices of green products are identified to be very high and many people are not willing to pay for the premium price
- **Promotion:** There are three types of green advertising: adverts that address a relationship between a product/service and the biophysical environment; those that promote a green lifestyle by highlighting a product or service; and adverts that present a corporate image of environmental responsibility. Most promotion strategy by green marketers in our case study areas is the one that promote a green lifestyle by highlighting a product or service
- **Place:** The choice of where and when to make a product available will have significant impact on the customers. Very few customers are ready to go out of their way to buy green products in the study areas. This implies that green products have to be positioned in places where it can attract consumers' attention.

The Status of Green Marketing and Some Intervention Strategies in Nigeria and Kenya

Government of any nation wants to protect consumers and the environment. This protection has significant green marketing and sustainability implications. Government regulations relating to environmental marketing are designed to protect consumers in several ways which includes: reduction of production of harmful goods or products; modification of consumer or industry use; and ensure that all type of consumers has the ability to evaluate the environmental composition of goods (NeerajaRani *et al.,* 2014). Literature on the extent of adoption, drivers and influence of green marketing initiatives in Kenya and Nigeria, and case studies are few. The followings are some of our major findings on the two countries.

A Case of Nigeria

A recent study on green marketing by Karatu and Mat (2015) observed that in spite of global awareness towards the environment and green marketing, evidences in Nigeria revealed that only 5% of the population is engaged in green purchase behavior (Olamiyu, 2012; Karatu & Mat, 2015). Table 2 showed that about 42% of respondents in Nigeria still do not know what green products are compared to their counterparts in Kenya. The finding is in line with that of National Bureau of Statistics (NBS) which found that Nigerians have poor knowledge of green marketing and low purchasing power, with over 61.2% of the population living on less than a dollar (Abraham-Ajayi, 2013). It also corroborates the result of the findings of Jacob and Jolly (2012); Scott and Vigar-Ellis (2014) who observed that green marketing concept is not popular in developing countries. Consumer conceptions of what is green are

Table 2. Respondents understanding of 'green products'

Perception About Green Products	Nigeria		Kenya	
	Frequency*	Percentage	Frequency*	Percentage
Green colored products	40	80	21	42
Natural/organic products	48	98	49	98
Recycled/recyclable products such as shoes	21	42	42	84

generally inconsistent, and do not correspond with the prevailing views on sustainability. Findings from this study show that, inadequate green knowledge among the sampled respondents (Tables 2 and 3), lack of government control, high price of green product and distrust towards green products (Table 4) are some of the reasons while green marketing/products is not gaining popularity in Nigeria. This indicates that many respondents are yet to know what is green or not green. Therefore, their failure to adopt green behaviours can be ascribed to knowledge deficit which can be corrected by informational campaigns.

Rettie *et al.,* (2012) shows how consumer perceptions of the extent to which behaviours are normal or not normal can be identified and used in the design of sustainability marketing strategies. Products such as cans, tins, cellophane etc are disposed by consumers in Nigeria with little or no efforts at recycling them thereby contributing to environmental degradation (Gbadeyan & Omolekan, 2015). We found that even though green marketing builds customers loyalty and brand recognition, many manufacturers in Nigeria are still of the opinion that customer may not be willing to pay high price for environmental friendly products if they go into such business.

The most important factors affecting purchase decision of green products in Nigeria is concern for health and environment, followed by social awareness and value, and the absence of marketing as the third important factor (Table 4). Green products are always more expensive than the regular ones and Nigerians, being a mass-oriented market, always go for lowest prices. Despite these challenges of green marketing in Nigeria, Ahmad (2014) observed that if green marketing is properly exploited in Nigeria through provision of enabling environment and structure for eco-friendly products, it can serve as a solution to the vulnerable and volatile environmental situation.

Other findings also revealed that there is no well known record of consumerist movements or activists presently in Nigeria (Ogechukwu, 2013). But in the early 1970s due to industrialization and mass production of goods, coupled with increased education and sophistication of the buyers/consumers, there were

greater demand for quality products and the need to be informed in the country. Many of the consumers complained to the consumer protection unit, a section established in the Federal Ministry of Trade to take care of the problems of the consumers from the activities of most business organizations. There were journalistic exposures, especially in the print and electronic medium where newspaper and magazines have dedicated consumer rights page sections (Ogechukwu, 2013). The electronic media also dedicated airtime towards exposing the deficiencies in business practices and in the products. The Federal Radio Corporation of Nigeria, the Nigeria Television Authority, the African Independent Television and Ray Power were in the vanguard of the exposures. There were also new laws by the legislature and a growing numbers of pressure groups in most commercial cities such as: Aba in Abia State, Lagos, Onitsha in Anambra State, Ibadan in Oyo State, Kaduna and Kano. These pressure groups put more restraints on marketers and producers with conditions that marketers have to clear their plans with the company's legal, public-relations, public affairs, and the consumer affairs department before sales of green products.

The Case of Kenya

Kenya like other countries in the world has been implementing sustainable development and embracing eco-friendly technologies. In order to enhance efficiency in the use of natural resources and energy, the industrial sector has embraced cleaner production technologies through technical assistance by the Kenya National Cleaner Production Centre (National Environment Management Authority, 2012). As an evidence, this study revealed in Tables 2 and 3 show that respondents in Kenya have more understanding of green products than their Nigerian counterparts. This may not be unconnected with the influence of pressure groups, wider media coverage and more stringent legislation which are considered to be major factors that led to the increase in environmental behaviors (Aitken, 2006; Melillo, *et al.,* 2006). Table 4 shows that social awareness and value is the most important factor influencing green marketing in Kenya, followed concern for health and environment, and social responsibility respectively.

The Consumers Federation of Kenya (Cofek) is Kenya's independent, self-funded, multi-sectoral, non-political and apex non-profit Federation committed to consumer protection, education, research, consultancy, litigation, anti-counterfeits campaign and business rating on consumerism and customer-care issues. The green revolution in Europe, where Kenya sells most of her floricultural products, is putting immense pressure on the Kenyan firms to conform or lose out. Consumers are aware of the global pattern of labor rights, occupational safety and health and environmental abuses and have pressed on for sustainable cultivation of flowers (Meso & Wario, 2014).

Studies on green marketing from literature reviewed in Kenya include a study by Kiongera (2003) who surveyed green marketing practices in Bamburi cement in Kenya; Obuya (2003) who carried out a survey of the extent to which manufacturing firms in Nairobi practice green marketing; Kalama (2007) undertook a study on the green marketing practices by Kenya Petroleum refineries; Odhiambo (2008) surveyed the extent to which floricultural firms in Kenya practice green marketing; and Thiong'O (2009) undertook an investigation of green marketing practices among pharmaceutical firms in Kenya. Thiong'O (2009) observed that green marketing concept has not been fully embraced by the pharmaceutical industry due to lack of information although companies are trying to put in place several measures on green product, green pricing, green promotion and green distribution. The ongoing activities of the firm according to Thiong'O (2009) include: conserving energy, water and material resources in production to avoid wastages and improve efficiency, product production that meet the legal specifications, product production that do not harm animals and humans. Afande (2012) examined the relative influence of

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

drivers for adoption of green marketing in Kenya tea firms and a similar study in 2015 to analyze the extent of adoption of green marketing practices by Kenya tea firms and found that regulations, customer pressure, expected business benefits positively influence adoption and corporate social responsibility positively influences adoption of green marketing by the Kenya tea firms. Meso and Wario (2014) in their study on the determinants of the adoption of green marketing strategies in Kenya's floriculture industry established that both stakeholder pressure and regulatory pressure have a significant influence on the adoption of green marketing strategies.

Challenges of GM, and Factors Influencing Adoption of Green Products in Developing Countries

The need for sustainable marketing practices is a new challenge for marketing scholars (Kotler, 2011). There is still generally lack of standard or public consensus about what constitutes "green". As a result of this, consumers in most developing countries like Pakistan, Nigeria, Kenya no longer trust green products claims (Ali *et al.,* 2011). Establishment of credibility through a comprehensive plan is a major challenge of effective green marketing in developing countries. Companies are often reluctant to promote their attributes, and consumers are often skeptical about claims (Newton & Harte, 1997; Iweama, 2014). In a recent study on green marketing in Nigeria, lack of appropriate strategies for effective application of green marketing is observed as a major challenge (Gbadeyan & Omolekan, 2015). Green marketing strategies are expensive and difficult to implement in the short-run and the benefits to the environment are intangible, indirect or insignificant to consumers, difficult to measure and quantify (Kinoti, 2011). Other challenges facing green marketing in developing countries are however include: lack of government incentives, financial costs of altering processes, products and waste management (Thiong'O, 2009), lack of factual information about the green marketing concept to both the industry and to the consumers or the type of green marketing communications message to which consumers are exposed (Grimmer & Woolley, 2014). Cultural and institutional differences also affect green behaviour in Africa. An individual's consumption behaviour is a result of the individual culture value system developed over time as they socialize in a particular group which in turn is influenced by regional sub-cultures and familial values (Luna & Gupta 2001; Brosekhan & Velayutham, 2008). Cultural norms, and values relating to the environment and society lead to different patterns of green consumer behaviour (Peattie, 1995) while cconsumers attitudes on the government's role, and their personal norm towards environment have also been reported as having significant effect to their attitude toward green product (Tan & Lau, 2010).

In countries like India for example, the initial cost of green products is still considered as been high and consumers are price sensitive, many people are still less aware about "Eco-Mark" green washing or green sheen coupled with lack of standardization are still big challenges confronting green marketing (Govind, 2014).

Green purchase behavior in many developing countries is hampered by factors such factors like the consumer characteristics (gender, income, age, etc.), green product price, absence of environmental consciousness, situational factors and additional monetary incentives (Drozdenko *et al.,* 2011). Studies (Brecard *et al.,* 2009; Jansson *et al.,* 2009; Quah and Tan, 2010) revealed that high-income and well-educated individuals are willing to pay more for green products than the low-income and less educated. This shows that the levels of education and income have significant positive effect on the adoption of green products. Pricing the green product is also very important (Ewing, 2009). Eco-friendly products are more expensive than standard products because of the high manufacturing costs (Green & Peloza,

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

2011; Olson, 2013). In addition to these, the quantity of green messages, product type, and their source credibility influence the extent to which new green products change brand attitude (Olsen *et al.,* 2014).

CONCLUSION AND RECOMMENDATIONS

Green marketing is a part of corporate social responsibility, with focus on the environmental responsibility. Green marketing has the potential to contribute to the establishment of more sustainable form of society even though it is still at infancy stage in developing countries when compared with developed countries. In recent time, the concept is gaining ground in developing countries as one of the key business strategies of the future and a viable solution to address environmental problems (such as pollution, acid precipitation, threat to earth ozone layer, accumulation of greenhouse gasses, agricultural land consumed by deserts, vital habitual resources which are fastly depleted), improvement of organizational performance, better physical environment which will eventually lead to sustainable development. Using green marketing goes with some potential challenges that must be overcome. These include the issue of uprightness and straightforwardness.

Consumers are looking for green products as the companies want to turn into green, but there is a need for sincerity of the green products. In order to ensure the confidence of the consumers without breaching any laws or standards of products and business practices, the marketers of the green products have a moral and more socially responsibility of being transparent in describing what they are actually doing for green marketing. Companies should also realize that their products can only be certified green by a third party using the popular Green Certifications. The use of self-certification by some companies will not be credible, a third party needs to be able to review and approve the certification processes.

Enough information regarding promotion of green products and their features appears not to have been done in Nigeria and Kenya. Consumers need information about a business to evaluate its claims and reputation. Therefore, green product marketing companies should promote awareness of their products' histories, including origin and manufacturing. Green marketing tools, such as eco-label, eco-brand and environmental advertisement, will make perception easier and increase awareness of attributes and characteristics of green products. Government can boost green knowledge through educative campaign programs and by enforcing green agenda. Consequently, enhanced knowledge on green products will correct the biased impression on green products. Government can also mandate the firms to become more responsible by encouraging the firms/marketers to change their environmental marketing activities but while doing that, there must be a strong policy to protect the consumers.

Limitations and Suggestions for Future Research

The results of this research are only limited to sample of the exploratory study of two universities (one in Nigeria and the second in Kenya). Subsequent studies should include a cross-section of the Nigeria and Kenya population. Future research can even go as far as embarking on regional comparisons or analyze the gap on green marketing and consumerism in developing and developed countries. The study on the social norms is also suggested to be included in future research to compare its impact on green products. Attention should be devoted to examining the effects of perceived consumer effectiveness on environmental attitudes, green purchase intention and green buying commitment. Investigation of psychographics will also be very important in African green consumerism studies.

KEY TERMS AND DEFINITIONS

Brand: A name, term, sign, symbol, or design, or the combination of them, intended to identify the goods or services of one seller or group of sellers and to differentiate them from those of a competitor.

Consumer Attitudes: A composite of a consumer's beliefs, feelings, and behavioural intentions toward some object within the context of marketing (Ali and Wisniesk, 2010).

Consumer Purchasing Behavior: Final consumer behavior during the purchase. There are four types of purchase behavior: Complex purchase behavior, those purchasing behaviors that seek variety, purchasing behavior that seeks to reduce tensions after purchase and normal purchasing behavior (Kotler and Armstrong, 2010).

Consumer Social Responsibility (CSR): Decision making linked to environmental stewardship, ethical values, stringent compliance with legal requirements and respect for communities and the environment in totality (Seth and Khan, 2015).

Consumerism: A social movement seeking to augment the rights and powers of consumers in relation to sellers (Kotler, 1999).

Eco-Brand: A name, symbol or design of products that are harmless to the environment.

Eco-Efficiency: This is usually calculated as the economic value added by a firm in relation to its aggregated ecological impact.

Green Business: An enterprise that has minimal negative impact on the global or local environment, community, society, or economy.

Green Consumerism: The production, promotion, and preferential consumption of goods and services on the basis of their pro-environment claims (Akenji, 2014).

Green Consumers: Green consumer as one who avoids products that are likely to endanger the health of the consumer or others; cause significant damage to the environment during manufacture, use or disposal; consume a disproportionate amount of energy; cause unnecessary waste; use materials derived from threatened species or environments; involve unnecessary use of, or cruelty to animals; adversely affect other countries (Elkington, 1994; Boztepe, 2012).

Green Economy: This encompasses all activities or actions that help reduce carbon emissions into the atmosphere which is a major component of greenhouse gases that enhances global warming thus causing climate change (National Environment Management Authority, 2012).

Green Procurement: A process whereby organizations take into account environmental elements when procuring goods, services, works and utilities and achieve value for money on a whole life-cycle basis.

Green Product: A product that meets one of these criteria of possessing qualities that will protect the environment; replaced artificial ingredients with natural ingredients or products that are non toxic, energy and water-efficient, harmless to the environment, recyclable and biodegradable.

Socio-Efficiency: The relation between a firm's value added and its social impact.

Sustainable Consumption (SC): This shares a number of common features with and is closely linked to the terms sustainable production and sustainable development. SC is the use of goods and services that respond to basic needs and bring a better quality of life, while minimizing the use of natural resources, toxic materials and emissions of waste and pollutants over the life cycle, so as not to jeopardize the needs of future generations (UNEP, 2010).

Chapter 75
Multi-Criteria Decision Making Techniques for Green Supply Chain Management: A Literature Review

Samet Güner
Sakarya University, Turkey

Halil İbrahim Cebeci
Sakarya University, Turkey

ABSTRACT

Due to increasing importance of environmental issues, green practices became an important part of supply chain management. Today, various multi-criteria decision making techniques (MCDM) have been utilized for incorporation of green efforts in supply chain practices effectively. The purpose of this paper is examining the existing application areas of MCDM techniques in green supply chain management (GSCM) literature. Three questions will be investigated in relation to this issue: 1) Which MCDM techniques were prevalently applied in GSCM literature? 2) Which MCDM techniques have been overlooked in GSCM literature? 3) What are the major application areas of MCDM techniques in GSCM practices? To this aim, literature is reviewed between the period of 2008 and the first half of 2016. In total, ninety eight journal articles were examined. Consequently, this paper represents a detailed picture of application areas of MCDM techniques in GSCM practices and can definitely give a blueprint to researches in solving multiple objective problems effectively in the area of GSCM.

INTRODUCTION

The classical economic system assumes that the limited resources of nature should be used to their maximum potential in order to meet the infinite requests and needs of human. Free market economy prompts companies to be profit oriented regardless of any environmental damage that might be caused (Roarty, 1997). This system, which puts the profit maximization as the unique aim for companies, was support-

ing the traditional supply chains which based on profit, efficiency and effectiveness until the twentieth century (Güner & Coşkun, 2010). However, this view has led to ignore the natural environment while maximizing the profit and inevitably cause global environmental problems.

Global environmental problems, like holes in the ozone layer and global warming, puts the future of the human race at risk and have shifted people's attention towards these problems and their causes. These problems have weakened the assumption of *"there is one and only one social responsibility of business – to use its resources and engage in activities designed to increase its profits so long as it stays within the rules of the game"* which was proposed by Friedman (1962) and led to search for new management approaches that brings the environmental concerns into corporate decision making processes.

Today, some developments such as increasing number and activity of governmental and non-governmental environmental organizations, imposing several sanctions by governments in favor of environmental protection and increasing number of international symposiums and congresses on environment, books and other scientific publications that address the environment, environmentalism and environmental problems shows the increasing attention to environmental issues.

Not only external factors such as governmental and non-governmental environmental organizations and academics, but also supply chain members force companies to be more environmental. Environmental crises lead customers to consider environmental effects of what they consume (Güner & Coşkun, 2010). Today, many researches demonstrated that customers are much more sensitive to environmental issues when compared with past years and customers feel personal responsibility for purchasing environmental friendly products (Kotler, 2004; Grant, 2007; Zaltman & Zaltman, 2008). Beside consumers, other companies in supply chains (suppliers, buyers etc.) force companies to be green. Today, environmental requirements are influencing the supplier selection and the supplier evaluation processes (Larsen, 2000). Also, industry leaders support their suppliers to be more environmental friendly (Lee, 2008) and set requirements for all their suppliers to comply with stricter environmental regulations (Ho, Shalishali, Tseng & Ang, 2009).

As a result of these improvements, the traditional approach, which hallows the profit and ignores the environmental issues, gives way to a more proactive green approach in businesses (Azzone & Bertele, 1994). In today's market conditions, economic and financial results alone are not sufficient and they need to be accompanied by ecological achievements (Lee, 2009). This means firms need to leave their traditional way of pure profit and benefit orient and shift to a new understanding that advocates business ethics, social responsibility and green management (Molina-Azorin, Claver-Cortes, Lopez-Gamero & Tari, 2009). Furthermore, many researchers proposed the green management as a competitive weapon for companies (Taylor, 1992; Porter & Van der Linde, 1995).

Briefly, market factors force companies to be more social responsible (Baron, 1995) and these environmental pressures significantly influence the strategic decisions of both large and small enterprises (Sarkis, 1998). Thus, environmental issues merit a more noteworthy investigation in supply chain decision making processes.

On the other side, most researchers suggest that going green may increase the cost burden and reduce the competitiveness of companies (Palmer, Oates & Portney, 1995). There is thus a tradeoff between economy and environmentalism. However, along with the increasing environmental sensitivity of the market, basic principles of environmentalism became an important part of business life and they must be adopted by companies as a part of profit maximization. At this point, operations research provides useful multi-criteria decision making (MCDM) techniques to practitioners for balancing the profit and the environmental concerns.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

The purpose of this chapter is examining the existing application areas of MCDM techniques in GSCM literature. Furthermore, it aims to discover the potential application areas and potential benefits of MCDM techniques in GSCM strategies. Three questions will be investigated in relation to this issue:

1. Which MCDM techniques were prevalently applied in GSCM literature?,
2. Which MCDM techniques have been overlooked in GSCM literature?,
3. What are the major application areas of MCDM techniques in GSCM practices?

Thus, this chapter will provide a guidance for business practitioners and management scholars for effective use of MCDM methods in GSCM practices. In order to achieve this aim, the search was carried out using Google Scholar and Scopus search engines via ensuring a thorough check on journal articles that are accessible on the main databases. By this way, the majority of the GSCM related MCDM journals papers were reached. The following keywords were used during the search: "Green Supply Chain", "Green Supply Chain Management", "Reverse Logistics", "Multiple Criteria Decision Making" and "Multiple Objective Decision Making". Also, the well-known MCDM techniques and their acronyms were used in the research process. The research is limited between the periods of 2008 and the first half of 2016. Thus, in total, we reached 98 journal papers which are published in this timespan.

The remainder of this paper is organized as follows. In section 2, we give some basic principles of well-known MCDM techniques and their applications in GSCM strategies. Section 3 addressed the research findings. Summary and the conclusions are presented in the last section.

MCDM TECHNIQUES AND THEIR IMPLICATIONS TO GSCM

MCDM techniques include a wide range of methodology such as Analytical Hierarchy Process (AHP), Analytical Network Process (ANP), Technique for Order Preference by Similarity to Ideal Solution (TOPSIS), Decision Making Trial and Evaluation Laboratory (DEMATEL), Data Envelopment Analysis (DEA), The Compromise Ranking Method (VIKOR), Goal Programming (GP), Elimination and Choice Expressing Reality (ELECTRE), Preference Ranking Organization Method for Enrichment Evaluation (PROMETHEE), Simple Multi-Attribute Ranking Technique (SMART), Measuring Attractiveness by a categorical Based Evaluation Technique (MACBETH) etc. In total, over 40 MCDM techniques were developed and used. While some of them are more popular and widely used (such as AHP, ANP, TOPSIS and DEA), some others are relatively new and have a limited application area yet (such as VIKOR, SMART, MACBETH).

These techniques are useful tools for analyzing complex problems due to their ability to evaluate different alternatives on various criteria for possible selection of the best alternative and they help decision makers to choose the best option according to their individual or group preferences where multiple conflicting criteria exist. Through their practical methodologies, these techniques have been used from trivial decisions such as car choice to complex strategic decisions such as foreign policies.

MCDM techniques have already been used in supply chains successfully in order to manage the conflicting objectives such as profit maximization, increasing customer service level and minimizing the supply chain risks. With the increasing importance of environmental issues in supply chain strategies, green criteria have added as a new parameter beside other conflicting objectives. MCDM techniques assess relationships among a number of decision and environmental factors (Sarkis, 1998) and

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

aid companies for balancing the other objectives and the environmental concerns. As Mardani, Jusoh, Nor, Khalifah, Zakwan & Valipour (2015) demonstrated that energy, environment and sustainability are first areas that have applied MCDM techniques and approaches. Today, a wide range of GSCM related decision making problems have been addressed by MCDM techniques. These decisions include green supplier selection, GSCM benchmarking strategies, green performance management, evaluation of green supplier development programs, determination of GSCM success factors etc.

Although AHP, ANP, TOPSIS, DEMATEL, DEA, VIKOR, GP, ELECTRE and PROMETHEE have been applied to GSCM practices, some others, such as SMART and MACBETH, have not been applied yet. In this section, the MCDM techniques that applied to GSCM practices are examined in detail.

Analytical Hierarchy Process (AHP)

AHP method was introduced by Saaty in early 1970s and it is used for determining the relative importance of attributes and the priority of a set of alternatives where multiple criteria are exist (Saaty, 1980; Darmawan, Putra & Wiguna, 2014). The primary advantage of the AHP approach is the relative ease which it handles multiple criteria and performs qualitative and quantitative data (Meade & Sarkis, 1998). With applying the AHP, decision-makers simplify a complex issue that is not structured, strategic and dynamic to be parts and arranges in a hierarchy (Darmawan et al., 2014).

Due to ease of use and interpretable nature, AHP is widely used in GSCM related topics such as supplier selection and evaluation, barrier and pressures analysis, performance evaluation, risk analysis and benchmarking. In most of the cases, AHP is used in GSCM practices directly by giving the alternative solutions, but sometimes it is combined with other techniques, such as PROMETHEE (Tsui & Wen, 2012) and TOPSIS (Wang & Chan, 2013, Yazdani, 2014, White, Wang & Li, 2015), to complete the decision making process. Also in some cases, AHP is combined with Fuzzy number theory to cope with the uncertainty and vagueness nature of problem (Hsu & Hu, 2008, Che, 2010, Mangla, Kumar & Barua, 2015a, Mangla, Kumar & Barua, 2015b, White, Wang & Li, 2015, Kannan et al., 2013).

Table 1 presents the application areas of AHP method in GSCM practices. As it can be observed from Table 1, supplier selection and evaluation is the major application area of AHP in GSCM practices. AHP is also applied in GSCM practices for evaluation of green performance and risk analysis. Furthermore, in some cases it is utilized for barrier analysis, benchmarking and order allocation.

Analytical Network Process (ANP)

ANP is another MCDM technique that was introduced by Saaty. ANP is the general form of the AHP which has been used in MCDM problems to release restrictions associated with hierarchical structure (Hsu & Hu, 2009, Hsu, Kuo & Chiou, 2014) and to present a non-linear network structure with possible interdependences and feedback (Lin, Madu, Kuei, Tsai & Wang, 2015). Instead of AHP's unidirectional hierarchical structure, ANP enables interrelationships among the decision levels and attributes in a more general form (Büyüközkan & Çifçi, 2012b).

Similar to AHP, ANP is also widely applied in GSCM problem areas, such as supplier selection and evaluation, green supplier development program evaluation, strategy selection and market analysis. In most cases, ANP is combined with other MCDM techniques (Tuzkaya et al., 2009, Büyüközkan & Çifçi, 2012a, Hsu et al., 2013, Kuo et al., 2015, Uygun & Dede, 2016, Kuo et al., 2010). To cope with the inherent fuzziness or uncertainty in judgment during the pairwise comparison process, and also to deal

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Application of AHP in GSCM practices

Authors	Application Area	Description (Objectives) of Study
Nie, 2016	Performance Evaluation	Calculates an index with using AHP for evaluating the green performance of companies.
Yu & Hou, 2016	Supplier Selection and Evaluation	Uses modified multiplicative analytic hierarchy process (MMAHP) to determine the best alternative green supplier.
Boutkhoum, Hanine, Boukhriss, Agouti & Tikniouine, 2016	Implementation (Success Factors, Strategy Selection, Adoption or Benchmarking)	A combination of fuzzy AHP and fuzzy TOPSIS is presented for better understanding of sustainable strategies through the identification and evaluation of the most appropriate GSCM practices.
Mangla, Kumar & Barua, 2015a	Market Analysis (Risks, Barriers or Pressures)	Uses fuzzy AHP method to analyze the risks of implementation of GSCM practices.
Mangla, Kumar & Barua, 2015b	Market Analysis (Risks, Barriers or Pressures)	Combines the fuzzy AHP and interpretive ranking process (IRP) methods to create decision making model for evaluating risks associated with implementation of GSCM practices.
Sharma, Chandana & Bhardwaj, 2015	Performance Evaluation	Determines the key performance indicators for implementation of GSCM practices with factor analysis and AHP.
White, Wang & Li, 2015	Performance Evaluation	Uses a combination of fuzzy AHP (for determining weights) and fuzzy TOPSIS (for choosing the best alternative) for evaluating the green packaging performance.
Darmawan, Putra & Wiguna, 2014	Implementation (Success Factors, Strategy Selection, Adoption or Benchmarking)	AHP is used for analyzing the source of green wastes and calculating the green performance index to choose the best strategy for green productivity.
Govindan, Kaliyan, Kannan & Haq, 2014	Market Analysis (Risks, Barriers or Pressures)	Focuses on determining the GSCM implementation barriers based on procurement effectiveness. AHP is used for identifying the most important barriers.
Mathiyazhagan, Govindan & Noorul Haq, 2014	Market Analysis (Risks, Barriers or Pressures)	Determines the pressures on GSCM implementation and selects the most important ones with AHP.
Odeyale, 2014	Performance Evaluation	Evaluates the companies green performances with using AHP and weighing multiplication and additive model (WMAAM).
Yazdani, 2014	Supplier Selection and Evaluation	Presents a two-stage process (AHP + TOPSIS) to choose the right supplier with green criteria. Both stages include fuzzy numbers rather than crisp values.
Dey & Cheffi, 2013	Performance Evaluation	Uses an AHP based framework to evaluate and measure the environmental performance of manufacturing supply chains.
Hsueh & Yan, 2013	Supplier Selection and Evaluation	Combines four different methodologies, including AHP, to evaluate the green performances of public contractors.
Kannan, Khodaverdi, Olfat, Jafarian & Diabat, 2013	Supplier Selection and Evaluation	Presents an integrated approach of fuzzy AHP, Fuzzy TOPSIS and Multi-objective linear programming for selecting the best green supplier and calculate an appropriate order quantity.
Luthra, Grag & Haleem, 2013	Implementation (Success Factors, Strategy Selection, Adoption or Benchmarking)	Develops a mathematical model for choosing the appropriate greening strategy for supply chains with using AHP.
Shen, Muduli & Barve, 2013	Performance Evaluation	Determines the criteria that are related to effectiveness of GSC with using AHP and creates a guidance model for GSCM implementation.
Wang & Chan, 2013	Implementation (Success Factors, Strategy Selection, Adoption or Benchmarking)	Fuzzy TOPSIS is used for the evaluation of different green initiatives. AHP is used in first stage of the model for determining the criteria weights.
Peng, 2012	Supplier Selection and Evaluation	Combines the AHP and Grey Relational Analysis to choose the best green supplier combined with the green adjustment factor.

Table 1. Continued

Authors	Application Area	Description (Objectives) of Study
Shaw, Shankar, Yadav & Thakur, 2012	Supplier Selection and Evaluation	Present a two-stage model to determine the best supplier and order quantity. Model includes fuzzy AHP method and linear programming approach.
Tsui & Wen, 2012	Supplier Selection and Evaluation	Develops a two-stage model for green supplier selection procedure. AHP is used to determine each criterion weights in the first stage and PROMETHEE is used to choose the best alternative in the second stage.
Wang, Chan, Yee & Diaz-Rainey, 2012	Market Analysis (Risks, Barriers or Pressures)	A fuzzy AHP is used to incorporate uncertain variables into the model for risk assessment of implementing green initiatives.
Liu & Wang, 2011	Performance Evaluation	Constructs a performance evaluation index system for evaluating GSC. AHP is used to calculate the factor weights for indexing system.
Che, 2010	Supplier Selection and Evaluation	Fuzzy AHP method is used to determine the factor weights and particle swarm optimization to determine optimal values for order quantity and supplier selection problem in GSCM.
Sarimento & Thomas, 2010	Implementation (Success Factors, Strategy Selection, Adoption or Benchmarking)	AHP is used to determine the improvement areas for benchmarking processes with the adoption of green initiatives.
Lee, Kang, Hsu & Hung, 2009	Supplier Selection and Evaluation	Fuzzy AHP method is used to evaluate and choose the best green suppliers.
Hsu & Hu, 2008	Implementation (Success Factors, Strategy Selection, Adoption or Benchmarking)	Examines the GSCM implementation approaches by factor analysis in Taiwanese electronic industry. Fuzzy AHP is used to prioritize the relative importance of a number of dimensions and approaches.
Kannan, Haq, Sasikumar & Arunnachalam, 2008	Supplier Selection and Evaluation	The interaction of green supplier selection criteria in automobile industry is analyzed with using a combination of Interpretive Structural Modelling and AHP.

with the discrete scale of relative importance, ANP method is combined with Grey System Theory (Dou et al., 2014) and Fuzzy Numbers (Büyüközkan & Çifçi, 2011, Büyüközkan & Çifçi, 2012a, Büyüközkan & Çifçi, 2012b, Tuzkaya et al., 2009, Lin et al., 2014, Kuo et al., 2015, Uygun & Dede, 2016).

The application areas of ANP method in GSCM practices are presented in Table 2. Supplier selection and evaluation is the major application area of ANP in GSCM practices. In addition, it is utilized for the evaluation of green supplier development programs, implementation of green practices, strategy selection and market analysis.

Technique for Order Preference by Similarity to Ideal Solution (TOPSIS)

TOPSIS is initially proposed by Chen and Hwang (1992) and it is a multiple criteria method to identify solutions from a finite set of alternatives (Büyüközkan & Çifçi, 2012a). The basic idea of TOPSIS is that the optimal alternative should have the shortest distance from the positive ideal solution and the longest distance from the negative ideal solution (Kuo et al., 2015). Because of including an unlimited range of criteria and performance attributes and allowing explicit trade-offs between attributes (Kannan et al., 2013), TOPSIS approach is a widely accepted method for ranking problems. In some cases, TOPSIS is

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Application of ANP in GSCM practices

Authors	Application Area	Description (Objectives) of Study
Chung, Chao & Lou, 2016	Supplier Selection and Evaluation	Suggests a model that combines ANP and IPA (Importance–Performance Analysis) for selection of green suppliers in GSCs. ANP is used for selection process and IPA is used for performance evaluation.
Wu & Barnes, 2016	Supplier Selection and Evaluation	Presents a model for green supplier selection process by combining ANP and multi-objective programming (MOP) methodologies.
Uygun & Dede, 2016	Supplier Selection and Evaluation	Presents a three stage model to evaluate and choose the green suppliers. In this model, fuzzy DEMATEL is used to determine the cause-effect relations, fuzzy ANP is used for factor weighting and fuzzy TOPSIS is used for the selection process.
Lin, Madu, Kuei, Tsai & Wang, 2015	Supplier Selection and Evaluation	A combination of ANP and Triple Bottom Line (TBL) is used for green supplier selection decision for a Taiwanese Electronics Company.
Kuo, Hsu & Chen, 2015	Supplier Selection and Evaluation	Presents a mathematical model that includes fuzzy ANP and fuzzy TOPSIS methods for evaluating suppliers' carbon performances.
Dou, Zhu & Sarkis, 2014	Green Supplier Development Program Evaluation	Introduces a Grey ANP model to identify supplier development programs for improving suppliers' performance. Grey ANP is used for determining the involvement level of suppliers into green development programs.
Hsu, Kuo & Chiou, 2014	Supplier Selection and Evaluation	Presents a model for evaluating suppliers' carbon performances with using ANP and VIKOR. Initially criteria weights are determined by ANP and after that VIKOR is used for supplier selection process.
Lin, Tseng, Chiu & Wang, 2014	Implementation (Success Factors, Strategy Selection, Adoption or Benchmarking)	Proposes a hybrid approach, which includes applied interpretive structural modeling to build a hierarchical structure and uses the ANP to analyze the dependence relations. Researchers also applied the fuzzy set theory to determine linguistic preferences.
Theißen & Spinler, 2014	Supplier Selection and Evaluation	Introduces a decision support system that includes ANP model to identify the best suppliers based on their carbon management ability.
Felice, Petrillo & Cooper, 2013	Performance Evaluation	Suggests an integrated model for evaluating the greening performance of supply chains. Model does not only include some of the environmental indexes such as Environmental Performance Evaluation (EPA) and the Life Cycle Assessment (LCA) but also contains ANP method and Benefits, Opportunities, Costs and Risks (BOCR) analysis.
Büyüközkan & Çifçi, 2012a	Supplier Selection and Evaluation	Combines three different fuzzy MCDM methods (DEMATEL, ANP and TOPSIS) for green supplier selection process.
Büyüközkan & Çifçi, 2012b	Implementation (Success Factors, Strategy Selection, Adoption or Benchmarking)	Examines the components and elements of GSCM and suggests a GSCM evaluation framework. The identified components are integrated into a strategic assessment and evaluation using fuzzy ANP.
Cabral, Grilo & Cruz-Machado, 2012	Implementation (Success Factors, Strategy Selection, Adoption or Benchmarking)	Proposes an integrated model that includes Lean, Agile, Resilient and Green (LARG) paradigms with using ANP to support decision-making in choosing the most appropriate practices and KPIs to be implemented by companies.
Chen, Shih, Shyur & Wu, 2012	Implementation (Success Factors, Strategy Selection, Adoption or Benchmarking)	Proposes a model that associates the activities with greenness of design, purchasing, manufacturing, and marketing departments with using ANP.
Chen, Lin & Ting, 2012	Supplier Selection and Evaluation	Presents a mathematical model that includes ANP and liner programming (LP) for green purchasing process. ANP is used for green supplier selection and LP is used for order allocation.

Table 2. Continued

Authors	Application Area	Description (Objectives) of Study
Mehrabi, Gharakhani, Jalalifar & Rahmati, 2012	Market Analysis (Risks, Barriers or Pressures)	Uses ANP method to determine critical barriers in implementation of GSCM.
Zhou, Ma, Li & Li, 2012	Supplier Selection and Evaluation	Presents a green supplier selection model based on ANP and radial basis function (RBF) neural network.
Büyüközkan & Çifçi, 2011	Supplier Selection and Evaluation	Proposes a model that cope with unclear and lack of information situation for green supplier selection process by using fuzzy ANP.
Kuo, Wang & Tien, 2010	Supplier Selection and Evaluation	Introduces a novel four-stage model for supplier selection. Delphi method is used for gathering data and Artificial Neural Network is utilized for predicting performance measures. ANP is used for determining factor weights and DEA is used for selection process.
Hsu & Hu, 2009	Supplier Selection and Evaluation	ANP method is used to incorporate the issue of hazardous substance management into green supplier selection process.
Tuzkaya, Ozgen, Ozgen & Tuzkaya, 2009	Supplier Selection and Evaluation	Presents a two-stage model to evaluate the suppliers green performances. Fuzzy ANP is used to calculate factor weights and Fuzzy PROMETHEE is used to select the best alternative.

integrated with other MCDM methods such as AHP (Wang & Chan, 2013, Yazdani, 2014, White, Wang & Li, 2015) or ANP (Büyüközkan & Çifçi, 2012a, Kuo et al., 2015, Uygun & Dede, 2016).

As shown in Table 3, TOPSIS has also been applied to GSCM problems. Similar to AHP and ANP, supplier selection and evaluation is the major application area of TOPSIS in GSCM practices. Additionally, it is used for performance evaluation and implementation.

Decision Making Trial and Evaluation Laboratory (DEMATEL)

DEMATEL is firstly developed by Science and Human Affairs Program of the Battelle Memorial Institute of Geneva between 1972 and 1976 and it is a comprehensive tool for building and analyzing a structural model involving causal relationships between complex factors (Hsu, Kuo, Chen & Hu, 2013). It can elevate the understanding of the issues, groups of interacted factors and provide a feasible solution by building a hierarchical relevant network system (Muduli & Barve, 2013). All factors fall into two categories in DEMATEL: cause and effect. This categorization results in a superior understanding of the system's parts and consequently discovering solutions to obviate issues of convoluted systems (Govindan, Khodaverdi & Vafadarnikjoo, 2015).

In some cases, DEMATEL's cause effect structure requires integration of soft techniques such as fuzzy sets theory (Büyüközkan & Çifçi, 2012a; Govindan et al., 2015; Lin, 2013; Mavi et al., 2013; Pishdar et al., 2014; Uygun & Dede, 2016) and Grey System theory (Fu et al., 2012). Also, some researchers demonstrated that collaboration of pairwise comparison techniques like AHP and ANP is very useful for GSCM practices (Büyüközkan & Çifçi, 2012a; Uygun & Dede, 2016).

Application areas of DEMATEL in GSCM practices are presented in Table 4. Although supplier selection and evaluation is the major application area of DEMATEL, it is also used for performance evaluation, implementation and evaluation of the green supplier development programs.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 3. Application of TOPSIS in GSCM practices

Authors	Application Area	Description (Objectives) of Study
Uygun & Dede, 2016	Supplier Selection and Evaluation	Presents a three-stage model to evaluate and choose the green suppliers. The proposed model uses fuzzy DEMATEL for determining the cause-effect relations, fuzzy ANP for factor weighting and fuzzy TOPSIS for selection process.
Boutkhoum, Hanine, Boukhriss, Agouti & Tikniouine, 2016	Implementation (Success Factors, Strategy Selection, Adoption or Benchmarking)	A combination of fuzzy AHP and fuzzy TOPSIS is presented for better understanding of sustainable strategies through the identification and evaluation of the most appropriate GSCM practices.
Govindan, Khodaverdi & Jafarian, 2015	Supplier Selection and Evaluation	Examines GSC initiatives and identifies the best possible model for supplier selection problem by fuzzy TOPSIS.
Hu, Rao, Zheng & Huang, 2015	Supplier Selection and Evaluation	Presents an optimization model includes linguistic 2-tuple TOPSIS method for supplier selection process in green procurement under the mode of low carbon economy.
Kuo, Hsu & Chen, 2015	Supplier Selection and Evaluation	Presents a mathematical model that includes fuzzy ANP and fuzzy TOPSIS methods for evaluating suppliers' carbon performance.
Kusi-Sarpong, Bai, Sarkis & Wang, 2015	Implementation (Success Factors, Strategy Selection, Adoption or Benchmarking)	Evaluates six different categories of green factors in mining industry with using of Rough Set Theory and fuzzy TOPSIS methods.
Li & Wu, 2015	Supplier Selection and Evaluation	Proposes a new improved intuitionistic fuzzy TOPSIS based model to identify the best 3rd Party Logistic firm.
Wang, 2015	Performance Evaluation	Suggests a decision making model based on Fuzzy Delphi, Fuzzy extent analysis and Fuzzy TOPSIS to evaluate green performance of supply chains.
White, Wang & Li, 2015	Performance Evaluation	Utilizing fuzzy AHP (for determining the weights) and fuzzy TOPSIS (for choosing the best alternative) to evaluate the green packaging performance of supply chains.
Kannan, de Sousa Jabbour & Jabbour, 2014	Supplier Selection and Evaluation	Introduces a fuzzy TOPSIS model to identify the best green suppliers.
Yazdani, 2014	Supplier Selection and Evaluation	Uses a two-stage process (AHP + TOPSIS) to choose the right supplier with green criteria. Both stages include fuzzy numbers rather than crisp values.
Diabat, Khodaverdi & Olfat, 2013	Performance Evaluation	Introduces a fuzzy TOPSIS model to explore the relationship between green supply chain practices (initiatives) and performance outcomes.
Kannan, Khodaverdi, Olfat, Jafarian & Diabat, 2013	Supplier Selection and Evaluation	Presents an integrated approach of fuzzy AHP, Fuzzy TOPSIS and Multi-objective linear programming for selecting the best green supplier and calculating the appropriate order quantity.
Sahu, Datta & Mahapatra, 2013	Performance Evaluation	Presents an interval-valued fuzzy number used modified TOPSIS method to evaluate candidate companies that operate in similar GSC hierarchy.
Shen, Olfa, Govindan, Khodaverdi & Diabat, 2013	Supplier Selection and Evaluation	Proposal of a fuzzy TOPSIS based multi criteria model that incorporates subjective linguistic preferences to generate an overall performance score for each supplier.
Wang & Chan, 2013	Implementation (Success Factors, Strategy Selection, Adoption or Benchmarking)	Fuzzy TOPSIS method is used to evaluate different green initiatives. AHP is used in first stage of the model to determine the criteria weights.
Büyüközkan & Çifçi, 2012a	Supplier Selection and Evaluation	Combines three different fuzzy MCDM methods (DEMATEL, ANP and TOPSIS) for green supplier selection process.
Kannan & Muresan, 2009	Supplier Selection and Evaluation	Presents a fuzzy TOPSIS based MCDM model for selecting the best 3rd party reverse logistics provider.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 4. Application of DEMATEL in GSCM practices

Authors	Application Area	Description (Objectives) of Study
Govindan, Muduli, Devika & Barve, 2016	Implementation (Success Factors, Strategy Selection, Adoption or Benchmarking)	Examines the factors that affect the adoption of green practices with using DEMATEL.
Uygun & Dede, 2016	Supplier Selection and Evaluation	Presents a three-stage model to evaluate and choose the green suppliers. Fuzzy DEMATEL is used to determine cause-effect relations, fuzzy ANP is used for factor weighting and fuzzy TOPSIS is used for the selection process.
Govindan, Khodaverdi & Vafadarnikjoo, 2015	Performance Evaluation	Presents intuitionistic fuzzy sets based DEMATEL method to handle the causal relationships between GSCM practices and both environmental and economic performances.
Guo & Tsai, 2015	Supplier Selection and Evaluation	Presents DEMATEL based green supplier selection model.
Wu & Chang, 2015	Implementation (Success Factors, Strategy Selection, Adoption or Benchmarking)	Investigates the GSCM success factors gathered from literature and interprets the cause effect relationships with using DEMATEL.
Falatoonitoosi, Ahmed & Sorooshian, 2014	Supplier Selection and Evaluation	Presents an evaluation framework for selecting the most eligible green suppliers by examining the important criteria and cause-effect relationships between them with DEMATEL method.
Pishdar, Toloun, Zamani & Farzianpour, 2014	Implementation (Success Factors, Strategy Selection, Adoption or Benchmarking)	Determines GSCM success factors among a number of green factors by fuzzy DEMATEL method.
Hsu, Kuo, Chen & Hu, 2013	Supplier Selection and Evaluation	Presents a DEMATEL based model to evaluate overall performance of suppliers in terms of carbon management.
Lin, 2013	Implementation (Success Factors, Strategy Selection, Adoption or Benchmarking)	Fuzzy DEMATEL method is used to examine the influential factors of a number of GSCM practices and to find out the cause and effect relationships among criteria.
Mavi, Kazemi, Najafabadi & Mousaabadi, 2013	Supplier Selection and Evaluation	Presents a fuzzy DEMATEL model to evaluate green suppliers considering logistical criteria.
Muduli & Barve, 2013	Market Analysis (Risks, Barriers or Pressures)	Investigates the barriers against greening practices and examines the cause-effect relationship between barriers with using DEMATEL. Results of DEMATEL are used for green strategy development.
Büyüközkan & Çifçi, 2012a	Supplier Selection and Evaluation	Combines three different fuzzy MCDM methods (DEMATEL, ANP and TOPSIS) for green supplier selection process.
Fu, Zhu & Sarkis, 2012	Green Supplier Development Program Evaluation	Suggests systematic and structural Grey based DEMATEL model to evaluate green supplier development programs.

Data Envelopment Analysis (DEA)

Data envelopment analysis (DEA), which was first introduced by Charnes, Cooper and Rhodes (1978), is a non-parametric mathematical tool for assessing the relative efficiency of homogeneous decision making units (DMUs) which consume multiple inputs to produce multiple outputs. DEA is a powerful mathematical method that utilizes linear programming to determine the relative efficiencies of a set of functionally similar DMUs (Mirhedayatian, Azadi & Saen, 2014).

DEA has a wide range of application area including transportation, banking, education, supply chain management etc. Also, in recent years, it emerges as a novel technique for GSCM practices. Application areas of DEA in GSCM practices are presented in Table 5. Similar to other MCDM tools, DEA

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 5. Application of DEA in GSCM practices

Authors	Application Area	Description (Objectives) of Study
Fallahpour, Olugu, Musa, Khezrimotlagh & Wong, 2016	Supplier Selection and Evaluation	Presents an extended DEA model which includes fuzzy numbers and Genetic Algorithm to evaluate green suppliers.
Shabani & Saen, 2015	Implementation (Success Factors, Strategy Selection, Adoption or Benchmarking)	Develops a model based on DEA and program evaluation and review technique/ critical path method (PERT/CPM) for determining prospective benchmarks. The proposed model is utilized in benchmarking green supply chain management.
Shi, Yan, Shi & Ke, 2015	Supplier Selection and Evaluation	Green index system with DEA method is used to evaluate and choose the best alternative green supplier.
Azadi, Shabani, Khodakarami & Saen, 2014	Implementation (Success Factors, Strategy Selection, Adoption or Benchmarking)	Proposal of a two-stage DEA model to identify critical focus areas of GSC practices and offers green strategies for public transportation companies.
Kumar, Jain & Kumar, 2014	Supplier Selection and Evaluation	Presents a model called Green DEA with carbon footprint monitoring and compares empirical result with an AHP-TOPSIS based model.
Mirhedayatian, Azadi & Saen, 2014	Performance Evaluation	Suggests a novel DEA model which includes network structure to evaluate GSCM under dual-role factors, undesirable outputs, and fuzzy data conditions.
Sueyoshi & Wang, 2014	Implementation (Success Factors, Strategy Selection, Adoption or Benchmarking)	Presents a DEA based model to evaluate supply chain current condition with respect of sustainability point of view and provides critical information regarding about how to invest for technology innovation.
Kuo, Wang & Tien, 2010	Supplier Selection and Evaluation	Introduce a novel four-stage model to supplier selection. Delphi method is used for gathering data and Artificial Neural Network is utilized for predicting performance measures. After that ANP is used for determining factor weights and last, DEA is utilized for selection process.

has mostly used in GSCM literature for green supplier selection. Also, since DEA is a benchmarking method, it allows researchers to make further analysis like benchmarking the GSCM strategies (Shabani & Farzipoor Saen, 2015) and target setting for green companies (Azadi, Shabani, Khodakarami and Saen, 2014). It is important to note that in most cases DEA was combined with other techniques like Genetic Algorithm, PERT/CPM, TOPSIS, Artificial Neural Network and ANP.

The Compromise Ranking Method (VIKOR)

VIKOR, which was first presented by Opricovic (2004), focuses on ranking and selecting from a set of alternatives, and determines compromise solutions for a problem with conflicting criteria, and helps the decision makers to reach a final decision (Hsu et al., 2013). VIKOR is a relatively new technique when compared to other MCDM methods. Because of that, limited number of studies has been done in GSCM literature. These studies are listed in Table 6.

Similar to other MCDM techniques, VIKOR is mostly used for supplier selection and evaluation problems. Also, it is utilized for the evaluation of green supplier development programs and performance evaluation of the green supply chain.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 6. Application of VIKOR in GSCM practices

Authors	Application Area	Description (Objectives) of Study
Awasthi & Kannan, 2016	Green Supplier Development Program Evaluation	Presents a model that based on VIKOR and Fuzzy Nominal Group technique to choose the best Green Supplier Development Program alternative .
Akman, 2015	Supplier Selection and Evaluation	Offers a three-stage model to evaluate supplier with respect to greening degree. Evaluation factors determined by factor analysis and selection process performed by C-means and finally greening degree of suppliers are determined by VIKOR.
Rostamzadeh, Govindan, Esmaeili & Sabaghi, 2015	Performance Evaluation	Suggests a quantitative evaluation model to evaluate GSCM activities under uncertainty with using intuitionistic fuzzy numbers based VIKOR model.
Hsu, Kuo & Chiou, 2014	Supplier Selection and Evaluation	Presents a model for evaluating suppliers' carbon performances with using ANP and VIKOR, respectively. Criteria weights were determined by ANP in the first stage and after that VIKOR is used for supplier selection process.
Datta, Samantra, Mahapatra, Banerjee & Bandyopadhyay, 2012	Supplier Selection and Evaluation	Presents a model based on VIKOR, interval-valued fuzzy numbers and fuzzy expert system for green supplier evaluation.

Goal Programming (GP)

GP is an extension of traditional linear programming which includes several conflicting objectives. Due to methods ability to cope with several objectives, it is useful for design and configuration of GSCM practices. As can be observed from Table 7, GP has been used to solve different problems in GSCM practices. Different from other MCDM techniques, GP is only utilized for the network design, optimization and configuration of green supply chains.

Elimination and Choice Expressing Reality (ELECTRE)

Roots of ELECTRE methods are based on the work of Benayoun, Roy and Sussman in early 1960s. ELECTRE family of methods includes ELECTRE I, ELECTRE II, ELECTRE III. Method also usually classified as an "outranking method". ELECTRE is generally used for discarding the inappropriate al-

Table 7. Application of GP in GSCM practices

Author	Application Area	Description (Objectives) of Study
Boonsothonsatit, Kara, Ibbotson & Kayis, 2015	Network Design, Optimization and Configuration	Introduces a decision support model to optimize the supply chain network. Model also includes supplier selection and facility layout operations.
Brandenburg, 2015	Network Design, Optimization and Configuration	Proposal of a GP model for reconfiguration of the supply chain when new product occurs with respect of environmental variables.
Ghorbani, Arabzad & Tavakkoli-Moghaddam, 2014	Network Design, Optimization and Configuration	Proposal of a fuzzy GP model for designing reverse supply chain with the objective of minimize recycling cost, rate of waste generated by recyclers and material recovery time.

ternative and it is incorporated to the other MCDM methods for selecting the best alternative. Because of this elimination process, other MCDM methods become very productive with ELECTRE. In GSCM literature, ELECTRE method has a limited application area (see Table 8). ELECTRE III was used for two main problem areas; supplier selection and evaluation (Liu & Zhang, 2011; Tsui & Wen, 2014) and transportation path selection (Sawadogo & Anciaux, 2011).

Preference Ranking Organization Method for Enrichment Evaluation (PROMETHEE)

PROMETHEE methods family was firstly presented by Brans and Vincke (1985). Original PROMETHEE method (also known as PROMETHEE I) provides a partial ranking of alternatives, and the complete ranking can be derived from the PROMETHEE II method. PROMETHEE methods family is classified as "Outranking method" like ELECTRE and they require two types of information: the criteria weights and the performance values of alternatives for each criterion (Tsui, Tzeng & Wen, 2015). In most cases, criteria weights often calculated by other MCDM methods like ANP (Tuzkaya et al., 2009) or AHP (Tsui & Wen, 2012). In GSCM literature, PROMETHEE is only used for supplier selection problem as listed in Table 9.

Other MCDM Techniques

Over 40 MCDM techniques were applied to GSCM practices. However, in this chapter, we only examined well-known 9 MCDM techniques in detail. In addition to these techniques, other methods that

Table 8. Application of ELECTRE in GSCM practices

Authors	Application Area	Description (Objectives) of Study
Tsui & Wen, 2014	Supplier Selection and Evaluation	Presents a model that based on AHP and ELECTRE III to evaluate and select the best alternative suppliers with green variables.
Liu & Zhang, 2011	Supplier Selection and Evaluation	Uses entropy weight and ELECTRE III to select best alternative green supplier.
Sawadogo & Anciaux, 2011	Network Design, Optimization and Configuration	Introduced an ELECTRE based model to determine appropriate transportation path with green variables.

Table 9. Application of PROMETHEE in GSCM practices

Authors	Application Area	Description (Objectives) of Study
Tsui, Tzeng & Wen, 2015	Supplier Selection and Evaluation	Suggests a hybrid multiple criteria decision-making with extended PROMETHEE to evaluate and assist polarizer suppliers for improving the performance of green suppliers to achieve the aspiration level
Tsui & Wen, 2012	Supplier Selection and Evaluation	Created a two-stage model for green supplier selection procedure. AHP is used to determine each criterion weights and the best alternative is chosen with PROMETHEE.
Tuzkaya, Ozgen, Ozgen & Tuzkaya, 2009	Supplier Selection and Evaluation	Presents a two-stage model to evaluate the suppliers green performance. Fuzzy ANP is used to calculate factor weights and Fuzzy PROMETHEE used for selecting the best alternative.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

are applied in GSCM practices are listed in Table 10. Supplier selection and evaluation is the primary application area for these techniques. Also, performance evaluation and market analysis are the other application areas for these techniques.

RESEARCH FINDINGS

The evaluation of the literature review has shown that application areas of MCDM techniques in GSCM practices can be categorized in six groups (see Table 11). The major group is the "supplier selection and evaluation" which aims to evaluate the environmental performances of alternative suppliers and choose the best performer one. Indeed, 50 journal papers (51,02%) were addressed this issue. The second group is the "implementation" which aims to incorporating the green issues into traditional supply chains. Determining the success factors and key performance indicators in green supply chains, selection of the best green strategy, adoption of environmental criteria and benchmarking the environmental strategies are distinguished in this group. Literature review reveals that 18 journal papers (18,37%) were focused on

Table 10. Application of Other MCDM Techniques in GSCM practices

the implementation of green strategies. The third group is the "performance evaluation" which focuses on developing a framework to evaluate and measure the environmental performances of green supply chains. 14 articles (14,29%) are included in this group.

The fourth group is the "market analysis". Risk analysis, barrier analysis and pressure analysis are considered in this group. Risk analysis is the risk assessment of green practices. Barrier analysis is related with determining the implementation barriers of green initiatives into traditional supply chains. On the other hand, pressure analysis aims to determine the most important pressures from market factors that force companies to be green. Accordingly, researchers preferred to use MCDM techniques for market analysis in 8 papers (8,16%). Another group is "network design, optimization and configuration". Network design, optimization and configuration analysis are mainly carried out with using goal programming. These analyses include supply chain optimization and designing reverse supply chains. In total, 5 journal papers (5,10%) used MCDM techniques for these purposes. The sixth and the last group is the "green supplier development program evaluation" which aims to evaluate supplier development programs for improving suppliers' environmental performances and determining the involvement level of suppliers in these programs. In literature, only 3 articles (3,06%) used MCDM techniques for these purposes.

The literature review shows that AHP is the most widely used MCDM technique in GSCM practices (see Table 12). Twenty eight (25,00%) papers applied AHP in order to address a variety of problems in green supply chains. ANP, TOPSIS and DEMATEL are other widely used methods in GSCM practices. They were applied in 21, 18 and 13 papers, respectively. On the other hand, DEA, VIKOR, GP, ELECTRE and PROMETHEE were preferred in less frequency when compared to other techniques (8, 5, 4, 3 and 3, respectively).

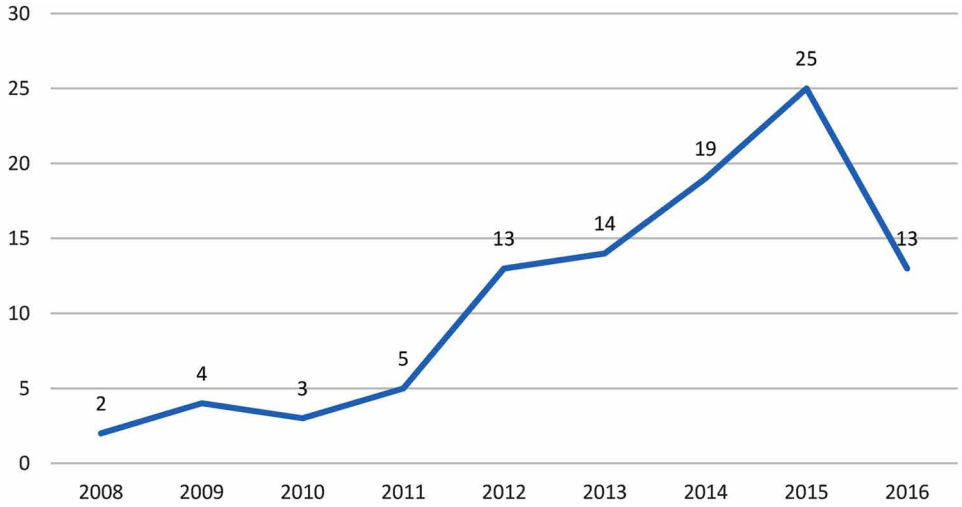
It is important to note that in twelve papers (12,12%), researchers preferred to combine two or more MCDM techniques in order to take advantage of each method. Ten papers (10,10%) integrated AHP or ANP methods with TOPSIS, PROMETHEE, DEA or VIKOR. Also, three MCDM techniques, ANP, TOPSIS and DEMATEL, were integrated in two papers (2,02%). In these studies, AHP and ANP were used for determining the criteria weights, DEMATEL was used for determining the cause-effect relations, and TOPSIS, PROMETHEE and VIKOR were used for selection of the best alternative.

Table 12. Frequencies of MCDM Techniques

No.	MCDM Techniques	In number	Percentage
1.	AHP	28	25,00%
2.	ANP	21	18,75%
3.	TOPSIS	18	16,07%
4.	DEMATEL	13	11,61%
5.	DEA	8	7,14%
6.	VIKOR	5	4,46%
7.	GP	4	3,57%
8.	ELECTRE	3	2,68%
9.	PROMETHEE	3	2,68%
10.	Others	9	8,04%
Total		**112**	**100%**

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Another important finding is that the combination of MCDM techniques with fuzzy number theory is quite common in GSCM practices. In thirty seven cases (33,03%), fuzzy number theory is combined with MCDM techniques. Also, two papers combined grey system theory with MCDM techniques (ANP and DEMATEL). Both fuzzy number theory and grey system theory were used for coping with the uncertainty and vagueness nature of problem and incorporating uncertain variables, such as linguistic preferences, into the model.



The last finding is about the distribution of examined articles over the research period. The distribution of the 98 journal articles between 2008 and the half of 2016 is presented in Figure 1. As it can be observed from Figure 1, there is an increasing trend towards the utilization of MCDM techniques in GSCM practices. While there are only 14 journal articles between 2008 and 2011, 84 papers were published between the period of 2012 and the first half of 2016. It is expected that the number of articles will increase by the end of 2016.

CONCLUSION

This paper is based on a literature review on the MCDM techniques for GSCM practices. It was found that 16 MCDM techniques were used for GSCM practices. However, only most frequent and well-known 9 techniques (ANP, AHP, TOPSIS, DEMATEL, DEA, VIKOR, GP, ELECTRE, PROMETHEE) were examined in detail.

Research results show that 50% of the examined papers focused on supplier selection and evaluation. Thus, it is clear that incorporation of environmental issues in supplier selection and evaluation process is the most popular issue for MCDM techniques. The most preferred MCDM techniques in GSCM practices are AHP and ANP. Indeed, almost half of the examined papers employed at least one of these techniques. Also, it was observed that the significant number of the MCDM problems in GSCM literature required the collaboration of grey system and fuzzy theories to cope with the vagueness, uncertainty, fuzziness, discrete interval use and linguistic nature of input variables.

Figure 1. Distribution of number of journal articles since 2008

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Another finding is that the integrated approaches are very common in GSCM practices. While some of the MCDM techniques provide the relative importance of various criteria (such as ANP and AHP), some others can be utilized for ranking the alternatives (such as TOPSIS, VIKOR ELECTRE, PROMETHEE). MCDM techniques can also be used for determining the cause-effect relationships (DEMATEL), benchmarking (such as DEA) and optimization (such as GP). Thus, integrating these techniques makes possible to take advantage of each method.

Despite the various advantages outlined in the paper, this study has its own limitations. First, only journal articles are examined and other publications (such as books, book chapters or proceedings) were excluded in this research. Also, only Scopus and Google Scholar search engines were used and specific keywords were scanned in this process. Furthermore, the research is limited between the periods of 2008 and the first half of 2016. Because of the abovementioned reasons, some of the literature could be missing from this paper. However, despite these limitations, we believed that this research has potential to provide some important insights for scholars and practitioners about the utilization of MCDM techniques for coping with GSCM problems.

For future researches, we suggest further exploring the usage of MCDM methods in GSCM literature with using data oriented systematic methods like web or text mining. Also, existing literature has a limited number of studies that integrates various MCDM techniques with heuristics, such as artificial intelligence techniques. GSCM practices will be much benefited by this integration since MCDM techniques can gain optimization and more complex problem solving capabilities. On the other hand, since DEA and GP are able to address different types of problems due to their benchmarking and optimization capabilities, they can be utilized for handling the different problems in GSCM practices. And last, although there are many MCDM techniques in literature, most of them haven't applied to GSCM practices yet. Some of these techniques can be listed as following: Aggregated Indices Randomization Method (AIRM), Characteristic Objects Method (COMET), Dominance-based rough set approach (DRSA), Generalized Regression with Intensities of Preference (GRIP), Measuring Attractiveness by a Categorical Based Evaluation Technique (MACBETH), Multi-attribute Value Theory (MVT), Multi-Objective Optimization by Ratio Analysis (MOORA), Simple Additive Weighting (SAW), Superiority and Inferiority Ranking Method (SIR), Stochastic Multi-criteria Acceptability Analysis (SMAA), Simple Multi-Attribute Ranking Technique (SMART), Step-Wise Weight Assessment Ratio Analysis (SWARA), Weighted Product Model (WPM), Weighted Sum Model (WSM). Consideration of the potential benefits of these MCDM techniques will provide alternative solutions for GSCM problems.

Chapter 76
Green Tourism and the Ambiguities of Sustainability Discourse: The Case of New Orleans's Lower Ninth Ward

Kevin Fox Gotham
Tulane University, USA

Joshua A. Lewis
Tulane University, USA

ABSTRACT

This paper uses a case study of the Lower Ninth Ward neighborhood in New Orleans to examine the relationships between green tourism and sustainability discourse in shaping the post-Katrina rebuilding process. Specially, we draw on long-term ethnographic field observations to highlight the tensions between abstract and idealized conceptions of sustainability and the complicated realities of uneven rebuilding and neighborhood disinvestment. We focus on changes in the tourism sector since Hurricane Katrina, the promotion of green tourism through actor Brad Pitt's Make It Right (MIR) Foundation, and the ambiguities and paradoxes of sustainability discourse. Overall, our goal is to develop a critical understanding of niche tourism in a disaster-devastated neighborhood and highlight the ways in which unspoken norms about sustainability create political-economic blind-spots to the ways in which socio-spatial inequalities, disinvestment, and entrenched social problems structure life in the city and the Lower Ninth Ward.

INTRODUCTION

Over the last decade or so, much research has focused on the increasing differentiation and specialization of tourism practices and activities into particular segments or niches. "Niche tourism" is a practice of splitting, fragmenting, and differentiating cultural forms, places, and groups into ever smaller slices in order to tap into and exploit consumer desires and preferences for profit and economic gain (for an

overview, see Novelli, 2012). What distinguishes "mass tourism" from "niche tourism" is that the profitability for the former rests on economies of scale and exploitation of mass, relatively homogeneous markets. Profitability and competitiveness in niche tourism in contrast depends on economies of scope and market segmentation (for overviews see Urry, 2002; Meethan, 2001). Examples of niche tourism include cultural tourism, heritage tourism, romance tourism, dark tourism, sports tourism, sex tourism, ethnic tourism, eco- or green tourism, and so on (Rojek, 1993; Stone & Sharpley, 2008; Stone, 2006; Miles, 2002; Wood, 1998; Sheller, 2003; Ryan & Hall, 2001; Picard, 1997; Gotham, 2007; Wearing & Neill, 2009; Murphy & Price, 2012). Overall, the growth of niche tourism represents conscious attempts by governments and elites to revitalize the local tax base, attract visitors to spend money, and enhance livability through the construction and promotion of urban or cultural niches where the tourism product relates to a particular symbol, topic, theme, or interest group (Hoffman, Fainstein, & Judd, 2008; Robinson & Novelli, 2005; Rath, 2007).

In this paper, we use a case study of the Lower Ninth Ward neighborhood in New Orleans to examine the relationships between green tourism and sustainability discourse in shaping the post-Katrina rebuilding process. Specifically, we focus on the ways in which the discourse of "green sustainability" has been appropriated by tourism boosters and used as a sophisticated niche marketing technique. Through various forms of advertising and promotion, tourism boosters seek to banish negative images of post-Katrina destruction from media and the public consciousness and encourage neighborhood repopulation and rebuilding. We argue that the term "sustainability" has a high level of interpretative flexibility (Jacob, 1997) and therefore symbolic value and utility for cities and neighborhoods struggling to rebuild in the aftermath of a major disaster. The term does not exclude any particular activity or group, exudes positive traits and inclusive activities, and does not seem to have any intrinsic negative features. More important, the term "sustainability" can allow a discursive space for vastly different interpretations and articulations, and can be aligned with a variety of touristic and entertaining activities. Thus, the term tends to be embraced by a variety of different communities, people, and groups for different goals. For tourism boosters and promoters, "sustainability" contains a multiplicity of meanings that provide social actors with a strategic vocabulary but one that leaves the specifics of content ambiguous. Overall, as we show, the growth of green tourism highlights the convergence between sustainability discourse and tourism in the sense that sustainability itself becomes a major tourist attraction and recovery tool for disaster-devastated places.

GREEN TOURISM AND URBAN SUSTAINABILITY

Ecotourism or green tourism is one of the fast growing areas of the tourism sector and has become a major economic revitalization tool for cities and rural towns. A number of scholars have developed typologies of green tourism, theories of green tourism experiences, and examined the role of climate change and sustainability in marketing green tourism, among other concerns (Butcher, 2007; Wu, Wang, & Ho, 2010; Béteille, 1996). One can find conceptualizations of green tourism as travel to places that are defined by their fragile natural environments, a form of natural resource management, a set of practices for generating environmental awareness and conserving biodiversity, and a force for environmental commodification (for overviews, see Holden, 2007; Honey, 2008; Weaver, 2012). Examples of green tour-

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

ism include tours that foster awareness for the environment and cultural practices in a local community, landscape museums, agritourism accommodation resorts, spa resorts, one-village-one-product programs, farmers' markets, and promotion of carbon reduction initiatives and carbon offsetting schemes (Kandari & Chandra, 2005; Font & Tribe, 2001). The notion of "green" tourism seeks to encourage people to pursue leisure activities in a manner that will benefit, rather than harm, the environment, a concern that is gaining popularity especially in the context of global climate change (Gibson, et al., 2003). Despite much research, only recently have scholars begun to examine the effect of green tourism on patterns of social inequality in cities, the social-ecological consequences of green tourism, and the impact of green tourism projects on local and indigenous cultures.

Around the world green tourism remains a source of much debate and controversy. On one hand, proponents claim that green tourism promotes sustainable development, enhances leisure facilities for residents, and empowers local people through the preservation and affirmation of local ecological knowledge (Bhattacharya & Dey, 2013; da Costa & da Costa, 2010; Zhang & Lai Lei, 2012). Critics, on the other hand, maintain that green tourism promotes the growth of low wage jobs with few benefits, diverts public monies from addressing crucial local problems, and damages the environment (for overviews, see Bramwell, 2012; Duffy, 2012; Higham, 2007). When planning for green tourism, for example, much of the academic literature rightfully addresses the potential for biophysical impacts resulting from hordes of tourists traveling to a particular place defined as "fragile." Research suggests that some variants of green tourism can promote inauthentic cultural representations and distort local ecological knowledge and history (for an overview, see Butcher, 2011). In contrast, other researchers argue that green tourism can be a mechanism to combat ethnocentrism and foster an appreciation of indigenous cultures (Singh & Mishra 2004). While planners have suggested that green tourism can contribute to problem amelioration and community revitalization, other scholars have argued that ecotourism can promote the external control of conservation spaces by international organizations that ultimately contribute to, rather than alleviate, poverty and dependency in local communities (Laudati, 2010).

In the study that follows, we use content analysis, ethnographic field research, and participant observation methods in the Lower Ninth Ward neighborhood of New Orleans to examine the tensions and contradictions of sustainability discourse in the context of the rise of green tourism in the city. Our analysis of green tourism focuses on the efforts of actor Brad Pitt and his Make It Right (MIR) Foundation to promote "environmental awareness," provide "financial benefits for conservation," and respect local culture (Make it Right Foundation (MIR), 2013a). Founded by Brad Pitt in 2007, the MIR Foundation seeks to leverage public and private resources to build environmentally conscious, "healthy homes" that enhance the natural environment and meet "the highest standards of green building" (MIR, 2013b). Green tourism extolls the virtues of sustainability, celebrates sustainability as a value in itself, and describes sustainability as vehicle of post-Katrina recovery and rebuilding. Yet, as we show, sustainability tourism and its related discourses can obscure the deeper socio-spatial inequalities in the city and mask the negative consequences of the post-disaster rebuilding process. What makes green tourism and sustainability discourse so potent and problematic is precisely the way they appear to engage contemporary social problems yet do not grasp the social inequalities and structural and historical roots that accompany them. Overall, our goal is to develop a critical understanding of niche tourism in a disaster-devastated neighborhood and highlight the ambiguities and paradoxes of sustainability discourse.

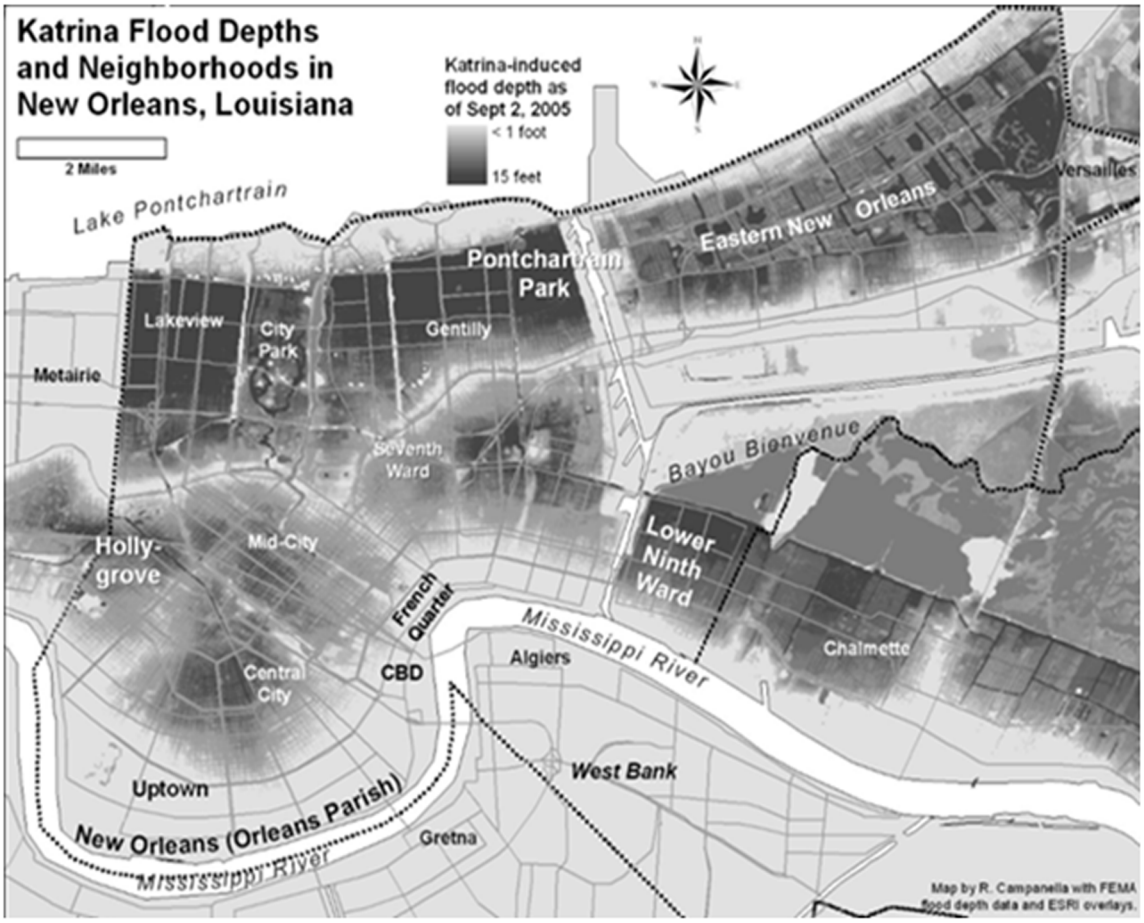
METHOD AND DATA SOURCES

Research Design

This study draws on content analysis of tourism publications, long-term ethnographic field research and participant observation since 2006 in New Orleans. Various promotional brochures, travel features, annual reports, websites, and policy and research documents published by New Orleans Tourism Marketing Corporation, the New Orleans Metropolitan Conventional and Visitors Bureau, and the New Orleans Multicultural Tourism Network were all analyzed for thematic and topical information on post-Katrina tourism rebuilding initiatives and strategies. Other promotional material advertisements from organizations such as Grey Line Bus Tours, Big Easy Tours, and Diamond Tours were analyzed to identify the major themes, symbols, and motifs used by tourism organizations to represent post-Katrina New Orleans. We also consulted the *New Orleans Times-Picayune* newspaper annual index and online search engines (e.g., Lexis-Nexis and Factivia) for references to newspaper articles on the Lower Ninth Ward, post-Katrina tourism rebuilding in New Orleans and other information on businesses and non-profit organizations involved in sustainability and redevelopment efforts.



The research for this project is part of a multi-year team ethnography composed of students and faculty working in several different New Orleans neighborhoods. The two authors of this ethnographic study are long-term residents who have lived in New Orleans since the 1990s. The second author took on the role of primary data gatherer and field researcher while the first author assumed the role of a detached observer, functioning as a sideline coach to the overall project. Since the field researcher had repeated interactions with residents, he had the opportunity to query them over time about their meanings and uses of "sustainability" and encourage them to expand on responses that were unclear. The purpose in being alert to the different meanings of sustainability was to dig below surface appearances, to appreciate more fully the cultural nuances we observed, and unravel the rich social and political texture of "everyday life" (Lefebvre, 1991) which ordinarily eludes surveys and statistical methods. Field observations and conversations with residents helped focus subsequent field encounters and move from an empirical analysis of sustainability and niche tourism to shed theoretical and empirical light on the ways in which tourism and sustainability intertwine with post-disaster recovery and rebuilding processes. Overall, this study is innovative because it uses a triangulation mixed-methods design to examine a phenomenon – niche tourism in a disaster-impacted city – that social scientists have not examined extensively and has the potential to advance theory on the relationships between tourism and post-disaster sustainability.

Research Site

The research site is the Lower Ninth Ward neighborhood in New Orleans, an area that was devastated by flood waters caused by the collapse of the United States Army Corps of Engineers levee walls, which line the Inner Harbor Navigation Canal (or Industrial Canal), a century-old waterway constructed in the 1920s to serve the Port of New Orleans (see Figure1). The levee breaches directed water swiftly through the area, pushing homes off their foundations, carrying a unmoored barge into the neighborhood, and creating the now infamous images of urban destruction that covered front pages and television screens throughout the world. Structural damage to homes in the neighborhood was widespread and hundreds of homes were demolished rather than rebuilt. The neighborhood was depopulated for months, as government engineers worked to drain the area, which was inundated again a few weeks later by Hurricane Rita.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Katrina flood depths and neighborhoods in New Orleans, Louisiana

As table 1 indicates, repopulation in the neighborhood has lagged far behind the city average. The Lower Ninth Ward registered a population decline of more than 71 percent after the deluge. According to the 2010 census, 5556 Lower Ninth Ward residents live in the neighborhood out of a pre-Katrina population of 19,515. Electricity and basic sewer services took up to a year or more to restore to many addresses. Business development has also been slow to return and, as of 2013, the neighborhood still did not have a grocery store, pharmacy, or many other anchor businesses.

The devastation of the Lower Ninth Ward can be explained with reference to longstanding patterns of socially produced marginality, flood risk, and vulnerability to storms. At various points in history, flood waters have entered the neighborhood across all four of its borders, though the primary flood risk for the area is the Industrial Canal, which flooded the neighborhood severely in 1965 during Hurricane Betsy as well as in 2005. Originally settled in the 1880s by primarily working class European immigrant families, development was initially constrained to the narrow strip of high ground along the Mississippi River (Campanella, 2008). The development of a municipal drainage system beginning in the early 1900s gradually opened up the contemporary footprint of the neighborhood to residential development. While

Asian	16 (<0.1%)	7 (<0.1%)	-9 (-43.7%)
Hispanic	147 (0.8%)	99 (1.8%)	-48 (-32.6%)

the older housing stock along the Mississippi River enjoys an elevation of up to ten feet above sea level, the rear portion of the neighborhood has subsided to up to four feet below sea level after drainage authorities cut and drained the freshwater swamps in the area during the early to mid twentieth century. City authorities have for a century made use of the fact that the neighborhood lies at the city's downstream perimeter, to site slaughterhouses, maritime industrial sites, drainage outfall canals, sewage treatment facilities, and landfills in the area (Landphair, 2007; 1999).

Three major developments during the twentieth century events contributed to the area's social and historic marginalization within the city while exacerbating the neighborhood's vulnerability to flood and storm damage. First, the Industrial Canal was modernized and expanded after the Second World War to create a direct ship canal between the city's inner harbor and the Gulf of Mexico. Second, a protracted battle over school desegregation in the early 1960s triggered a demographic transformation in the neighborhood, as the token integration of white schools in the Lower Ninth Ward led to a mass exodus of whites to neighboring St. Bernard Parish (Wieder, 1987; Spain, 1979). Third, levee breaks caused by Hurricane Betsy in 1965 flooded the neighborhood with 6-8 feet of water. Over 80 percent of the neighborhood flooded, leading to further out-migration by whites and wealthier African-Americans. By 2000, whites represented only 0.5% of the population of the lower-lying portion of the neighborhood, and only 10% along the high ground skirting the Mississippi, out of an estimated total population of approximately 20,000 people (Greater New Orleans Community Data Center, 2013). This classic pattern of "white flight" coincided with the increasing fiscal constraints in the public sector in the 1970s and later. By the 1980s and 1990s, researchers and neighborhood leaders recognized the neighborhood's increasing vulnerability to hurricane storm surges due to subsidence, coastal wetlands loss, substandard flood protection systems, and shipping canal construction between the city and the Gulf of Mexico (Campanella 2008; Landphair 1999; 2007).

With the emergence of the Environmental Justice (EJ) movement in the 1980s, some Lower Ninth Ward activists began to reframe the neighborhood's geographic dilemmas and flood hazards as an ex-

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

ample of environmental racism (Bullard, 2005; 2000; 1994; Cole & Foster, 2001; Harvey, 1996; Szasz, 1994). In particular, the neighborhood's relationship to the Port of New Orleans' Industrial Canal has been a major point of concern for residents, as the Port has worked for nearly eighty years to expand the canal, dig new connecting channels to the Gulf of Mexico, expand and enlarge the river lock system, and in general encourage public and private capital investment along the waterway. For residents, the canal acts as a physical and symbolic barrier between the neighborhood and the rest of the city that is a marker and source of inequality and injustice. Other resident concerns – e.g., the operation of the bridges which serve as the community's only evacuation route, the toxic sediments that line the canal bed, and the canal's involvement in the salinization and destruction of freshwater swamps - have been cited by neighborhood activists as examples of the rampant social and ecological injustices that plague the neighborhood. Most importantly, residents have targeted the canal's capacity as a conduit for floodwaters as a major focal point of mobilization and contestation and activists have initiated frequent protests and joined with civic associations to oppose the modernization and continued use of the canal.

Residents' emerging interest in the EJ framework in the 1980s and 1990s catalyzed the formation of new networks linking neighborhood activists with the broader environmental community and social justice movements around the world. One neighborhood association has repeatedly enrolled university-based attorneys to sue the Port and the US Army Corps of Engineers on their behalf to prevent the expansion of the Industrial Canal. By the late 1990s, the environmental community had largely come to embrace EJ as an important perspective in environmentalism, and more traditional environmental organizations, like the Sierra Club for example, began forming relationships with neighborhood activists. On the eve of Hurricane Katrina in 2005, Ninth Ward activists and residents had formed a plethora of cross-scale networks and connections with environmental groups, low-income housing advocates, anti-poverty groups, and civil rights organizations located in the United States and around the world. These diverse networks operated as communicatory infrastructure through which grassroots and global organizations could share information and resources to assist each other in their campaigns for social justice.

FROM ENVIRONMENTAL JUSTICE TO URBAN SUSTAINABILITY

Shortly after, Hurricane Katrina struck in August 2005, the neighborhood activists who had developed many close-knit and strategic partnerships over the preceding two decades activated their professional networks in an effort to bring public attention to the devastation of the Lower Ninth Ward. One of their first initiatives included the development of a grassroots post-disaster planning process to access state and philanthropic resources to rebuild the neighborhood. Prior to Katrina, neighborhood activists frequently articulated their grievances through a distribution-oriented EJ frame, but after Katrina, mirroring broader trends in environmentalism, neighborhood activists began using "sustainability" as a discursive strategy to articulate their agenda.

Specifically, neighborhood activists worked with residents, urban designers, and sustainability experts throughout late 2005 and early 2006 to draft the "Sustainable Restoration" plan for the neighborhood. This document, printed and posted online, is heavily infused with ideas about urban development rooted in sustainability and green urbanism. The circulation of this document within the sustainable urban design community attracted the attention of dozens of organizations and universities, including the staff of Global Green USA, an arm of the International Green Cross, who in 2006 began working on an initiative to build a cluster of green homes along the Mississippi River in the neighborhood. Actor Brad Pitt

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

was an early spokesman and fundraiser for the project, and through conversations with neighborhood activists and sustainability advocates, a North Carolina investment company agreed to provide financing for a more ambitious project, envisioned as the largest cluster of green homes in the United States. Over 2007 and early 2008, this project evolved into the Make it Right (MIR) Foundation, with Brad Pitt mobilizing his celebrity status and well-heeled networks to raise funds for the project. MIR organizers selected the tract of vacant lots along the Industrial Canal floodwall, where the most traumatic flooding had occurred in 2005.

In addition to the MIR Foundation, neighborhood activists hosted and facilitated projects by dozens of university-based groups and non-governmental organizations that, after hearing about the Sustainable Restoration Plan through professional networks or media, sought collaborative ties with community-based groups. Many of these organizations worked with community groups to identify individual families and homeowners to install various technologies of sustainability in their homes and yards. Common examples have included home weatherization and energy efficiency retrofitting technologies like radiant barrier, tree plantings, small-scale storm water management measures like rain gardens and bioswales, backyard gardening and urban agriculture, and so on. In some cases, these interventions have been only one component of a larger agenda of rehabilitating damaged homes and other more traditional disaster recovery projects.

Sustainability advocates from the world over have visited the neighborhood, and the narrative of the neighborhood's transformation from a devastated "wasteland" to a globally significant example of the power of sustainability in disaster recovery are frequently found in media and scholarly accounts concerning the neighborhood's redevelopment. Years after floodwaters overwhelmed the neighborhood, the Lower Ninth Ward now includes three urban farms, the highest per-capita use of solar arrays in New Orleans, and more "green" houses than any other neighborhood in the United States, as reported by the Sierra Club (Reckdahl, 2012). These transformations underscore a tension between the distribution-oriented discursive strategies of much of the neighborhood's civil society before Katrina, and the sustainability centered discourses that have emerged since the flood. The EJ movement emerged primarily out of the practical political experience of organizers, maintaining a focus on the uneven distribution of environmental hazards and amenities, and exploring the various legal and political strategies to contest particular industries, infrastructures, patterns of risk, and so on (Swyngedouw & Heynen, 2003). Post-Katrina sustainability discourse, on the other hand, has emerged from more elite policy concerns and abstract normative versions of how the Lower Ninth Ward should be rebuilt. As we point out below, these interrelated themes have been articulated with tourism modes of visualization, discourse, and staging.

GOING GREEN IN THE BIG EASY: SUSTAINABLE DEVELOPMENT AS POST-KATRINA REBUILDING STRATEGY

For decades, New Orleans has been one of the world's most popular tourist and convention destinations, drawing around nine million visitors per year in the years before Hurricane Katrina. With a variety of entertainment venues, celebrated festivals, niche tours, historical and cultural heritage sites, and other attractions, the city and region had acquired a reputation as a place of fun, enjoyment, and unquestioned authenticity. Before Hurricane Katrina, tourism was a $5.5 billion dollar industry that accounted for 40 percent of the city's tax revenues and employed 85,000 people. The levee breaches caused by Hur-

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

ricane Katrina flooded 80 percent of the city including hundreds of thousands of homes and businesses and contributed to more than 1300 deaths. While the main tourist areas - the French Quarter, Garden District and Uptown - escaped major flooding and suffered only minor wind damage, the tourism sector lost approximately 22,900 jobs.

Since the disaster, political and economic elites and local and regional tourism organizations have attempted to expel negative impressions, neutralize the stigma of disaster, and create a more favorable destination brand image using sophisticated marketing strategies. According to data gathered by the Morial Convention Center, the city hosted 111 events at the Morial Convention Center in 2008, an all-time high. Just over nine million tourists and business travelers spent a record $6 billion in New Orleans in 2012, the highest since Hurricane Katrina and the second-highest ever, according to a study commissioned by the New Orleans Metropolitan Convention and Visitors Bureau (CVB) and the New Orleans Tourism Marketing Corporation (McConnaughey, 2013).

One of the most significant changes in the tourism sector since Hurricane Katrina is the proliferation of a variety of niche marketing campaigns and advertising efforts to promote New Orleans as a place of environmental sustainability. Since the disaster, the Mayor's Office, the Chamber of Commerce, the Greater New Orleans (GNO), Inc. and other organizations have attempted to redefine New Orleans as place of entrepreneurship based on "green industry" and sustainability including art-based commerce, bio-technology, film and media production. In 2011, GNO Inc., a public-private organization promoting economic development in the region, unveiled its "Sustainable Industries Initiative" (SII), aimed at "developing sustainable services" that "will help companies not only manage environmental issues but even profit from them (e.g., waste-to-energy technology)" (GNO, 2011). Sustainability's potential as a catalyst for economic growth lies in cultivating what the GNO, Inc. calls a "sustainable entrepreneurial culture" premised on the use of "green incentives" to spur development and target businesses that specialize in water management/hydrology, sustainable building, renewable energy, coastal restoration and disaster mitigation. "Green incentives" include tax credits, tax exemptions, and enterprise zones to "make the region an ideal place to build sustainable technologies, products and services" (GNO, 2012). "There's no question the New Orleans area has an experience and a brand that is inextricably linked to the environment," according to Michael Hecht, President and CEO of GNO, Inc. "We have an opportunity to leverage that brand and that experience" (as quoted in Riegel, 2010).

Today, a variety of green tourism strategies and practices have been incorporated in the repertoire of urban place marketing to help rebuild New Orleans and influence social, economic, and environmental sustainability. The formation of the "Green Committee" of the New Orleans Chamber of Commerce in 2011 reflects an interest in developing sustainability strategies; raising the profile of green commerce in New Orleans; and assisting "New Orleans businesses to build local political support for green industries" (New Orleans Chamber of Commerce, 2012). In recent years, the CVB has created a meeting planner resources guide and assembled information on greening efforts and other eco-friendly attractions from the City of New Orleans and the local hospitality community (CVB, 2012). As part of their aforementioned projects in the Lower Ninth Ward, Global Green USA sponsored an international design competition for their housing development, voicing their "commitment to the sustainable rebuilding of New Orleans and demonstrating green building as a solution to global warming nationally" (Global Green USA, 2013). Global Green USA in particular has invoked the crisis of climate change as a central motivation for much of their programming in New Orleans, where notions of "carbon neutrality" and "carbon sequestration" were key themes in their public relations and programming discourse.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

In addition, Global Green USA and the New Orleans Tourism Marketing Corporation (NOTMC) have partnered to provide a list of eco-friendly "Green Hotels in New Orleans." The criteria for inclusion on the list of green hotels include "environmentally friendly practices in place to conserve water, electricity and reduce … overall carbon footprint." Green hotels are "making strides toward sustainability and offer the environmentally-conscious traveler to New Orleans some options" (New Orleans Tourism Marketing Corporation, 2013). Swamp tour companies now routinely advertise themselves as eco-tours that take travelers through the marshes and wetlands in the New Orleans region for the purpose of promoting conservation and appreciation of biodiversity as expedients to sustaining coastal ecosystems.

The previous points draw our attention to the significant cultural, political, and socio-economic importance and resources diverse actors and organized interests are placing on tourism to help rebuild post-Katrina New Orleans. From city government agencies, non-profit organizations, a variety of tourism industry players are attempting to brand New Orleans as a green tourism destination. In New Orleans, the development of green tourism has been an outgrowth of a variety of tourism and non-tourism practices that have been infused with sustainability discourses. By utilizing processes of strategic framing, cross-scale collaboration, and leveraging of public and private resources, various individuals and organizations within and outside the tourism industry have been able to develop and promote a tourism destination based on green sustainability.

GREEN TOURISM AND BRAD PITT'S MAKE IT RIGHT FOUNDATION

In the years since the Hurricane Katrina disaster, Brad Pitt's MIR Foundation has become a major institution for the promotion of eco-tourism and green sustainability by partnering with leaders in environmental design, sustainable redevelopment, and community organization. The mission of the MIR Foundation is to rebuild the Lower Ninth Ward by using high quality, affordable, and environmentally conscious building materials founded on the Cradle to Cradle design approach pioneered by architect William McDonough and chemist Dr. Michael Braungart. The Cradle to Cradle design approach stresses the use biologically safe materials and products designed for disassembly/recovery. The approach is premised on the idea that communities should be able to use renewable energy, maintain and enhance water quality, honor social fairness and human dignity, and improve in a continuous and aspirational fashion. MIR began by commissioning designs for an initial 150 low-cost homes from thirteen prominent architecture firms. Construction began on the first homes in early 2008. The houses have many flood-protection features including some with foundations that can float, roof patios for hurricane and flood relief, and innovative recycling and energy-generating installations to reduce costs. As of March 2013, the MIR Foundation had completed 87 homes in the Lower Ninth Ward (MIR, 2013b).

Brad Pitt's MIR homes not only function as physical dwellings for returning residents, but they operate as advertisements for a celebrity-inspired form of sustainability in which changes in architecture and physical form - e.g., construction of energy efficient homes, solar arrays, raised homes, and so on - become the *sine qua non* for sustainable post-disaster rebuilding. While Pitt and the MIR Foundation recognize the problems that have affected the Lower Ninth Ward, their narrative is crafted to persuade people to donate to the relief effort, and to help build 150 homes out of more than 220,000 that were flooded by Katrina. While praiseworthy and important to the individual homeowners who receive a

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

MIR home, the philanthropic approach is largely piecemeal and individualistic. That is, the goals of the MIR Foundation are not explicitly coordinated with federal or local low-income housing programs to sufficiently address and remedy the housing problems of the poor or the long-term displaced.

It is important to note that, in the Lower Ninth Ward, the newly erected beautiful homes cannot hide the swaths of neglect and ruin that plague the neighborhood and other parts of the metropolitan area. This chaotic arrangement of new homes amid blocks of destruction is accepted and celebrated as a result of a community wide and international concern with sustainable development, and celebrity advocacy on the part of Brad Pitt and his MIR Foundation. Because the new homes are advertised as exemplars of sustainable development, they focus and absorb the spectator's attention upstaging the devastated homes and neighborhoods spaces that exist in a perpetual state of disrepair and abandonment. For those who travel into the Lower Ninth Ward, the newly built homes become tourist spectacles that efface the distinctions between the real cityscape with its inequalities and injustices, and the entertaining spectacle.

We can view Brad Pitt's MIR Foundation as a conflictual and contradictory set of practices that interconnect philanthropic revitalization efforts with tourism modes of discourse, visualization, and staging. The MIR Foundation reflects and reinforces broader green tourism efforts to (re)present and showcase the Lower Ninth Ward as a site of tourist consumption. The MIR Foundation's "self-guided tour" advertises itself as a tour where "you will learn about our architects and their home designs, visit our sustainable playground and get more information on what makes this neighborhood 'the largest, greenest community of single family homes in the world,' according to the U.S. Green Building Council" (MIR, 2013c). The goal here is to enhance the tourism value of the Lower Ninth Ward in a way that will produce a ripple effect through the local community and economy and also sustain the unique cultural character of the neighborhood, especially its newfound status as an exemplar of sustainable development. On one hand, the representation of the neighborhood as a tourist site reflects conscious and strategic efforts to capitalize on the tourist's desire for the dramatic, spectacular, and the unusual. On the other hand, the MIR Foundation operates as a supplier of disaster tourism which depends on the commodification of leisure and the transformation of tragic events into as entertaining attractions that can deliver extraordinary experiences.

Through our ethnographic work and we find that the MIR Foundation is an institutional resource and set of relations that residents and non-local people can use to increase local capacity building and empower local communities to address a poorly managed formal recovery policies, and fight against social injustice. With an emphasis on enriching personal experiences and environmental awareness through interpretation, green tourism seeks to promote greater understanding and appreciation for nature, local society, and culture. The MIR Foundation appropriates this discourse of green tourism through practices such as hiring and training local workers in green building practices, creating volunteer opportunities for local residents to aid and assist rebuilding efforts, the establishment of an online "green library," and the promotion of critical dialogue and discussions in their "green building laboratory," a blog to encourage debate over sustainable development. While some groups have received funding for programming articulated in the language of sustainability, in many cases those programs represent only one facet of the scope of the organization's work in the community. Receiving resources through and participating in the "urban sustainability" work of the MIR Foundation and other neighborhood institutions has been a significant catalyst for the creation of new networks for community organizing and planning for a sustainable future.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

THE DARK SIDE OF SUSTAINABILITY DISCOURSE

What unites the sustainability discourse and practices of various tourism suppliers, government agencies, non-profit organizations, and the Make It Right Foundation is that all praise the merits of sustainability, proclaim sustainability as an end in itself, and describe sustainability as the new cornerstone, foundation, and hope for post-Katrina New Orleans. Yet there is a dark side to sustainability discourse. Particularly noteworthy are the ways in which unspoken norms about sustainability create political-economic blind-spots to the ways in which social inequalities, disinvestment, and long-standing and entrenched social problems structure life in the city and the Lower Ninth Ward. We point to three ambiguities.

One ambiguity concerns the tendency of niche tourism rhetoric to downplay and disavow past social problems and segregative actions that interconnect with current forms of poverty and uneven development. In much of the promotional rhetoric of niche tourism there is a tendency to downplay any negative features and undesirable characteristics of the past that may deter visitors from visiting a particular destination. In New Orleans, green tourism is rooted in future concerns with how post-Katrina New Orleans ought to look like, rather than acknowledging how past actions and decisions contributed to the flooding of New Orleans. Continuing poverty, for example, is explicitly ostracized from niche tourism promotional strategies and rhetoric.

More important, how current patterns of poverty may discourage the development of long-term sustainability is not mentioned in tourism promotional rhetoric or sustainability discourse, an omission that makes it difficult to construct a progressive politics of post-Katrina urban rebuilding. Table 2 shows poverty rates in the neighborhood and city. While the table shows declines in rates of poverty for individuals in New Orleans and the Lower Ninth Ward, the latter shows stubbornly high rates (34.4 percent in 2000 and 29.5 percent) compared to the overall city average of 27.9 percent in 2000 and 24.4 percent in 2010. The decline in the rate of poverty for New Orleans and the Lower Ninth Ward reflect the fact that the poor were the most vulnerable to flood damage and least likely to have the resources to return to the city after the deluge. The high poverty rate in the Lower Ninth Ward implicates the area as a very poor neighborhood plagued by disinvestment.

Second, sustainability discourse emanating from tourism organizations, city agencies, and the MIR Foundation obscures the negative socio-spatial consequences and inequality reinforcing features of current recovery programs and rebuilding policies. We see this very clearly in MIR efforts to link architectural design with sustainable development outcomes:

Design has the power to improve the quality of affordable housing and enhance occupants' living conditions; it also plays a key role in creating vibrant, sustainable communities. Innovation results in affordable building designs, methods and materials that drive new industry standards for green buildings. (MIR, 2013a)

Table 2. Poverty status of individuals, in 2000 and 2010 for New Orleans and the Lower Ninth Ward

	2000	2010	Change
New Orleans	135,224 (27.9%)	83,894 (24.4%)	-51,330 (-37.9%)
Lower Ninth Ward	6717 (34.4%)	1,639 (29.5%)	-5078 (-75.5%)

Aggregated data between Holy Cross and Lower Ninth Ward neighborhood data. Greater New Orleans Community Data Center Neighborhood (GNOCDC) Profiles. Based on US Census Bureau Data.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

The sustainability discourse of the MIR Foundation is infused with architecture and physical design principles, an orientation that views social problems such as continuing flood and storm risks as the problems of individual homes and households rather than as systemic problems that interconnect with the particular infrastructural and ecological systems that have produced those risks. These points resonate with McGregor's (2004) suggestion that the dominance of corporate-driven sustainable development discourse is troubling because of the extremely narrow urban policy repertoire based on capital subsidies, place promotion, supply-side intervention, and local boosterism. "It becomes extremely difficult to mobilize a population around issues that do not relate directly to sustainability" without the ideas, logic and language (e.g., critiquing inequalities, injustices, institutional discrimination, and the exploitative nature of global capitalism) that can be used as "rallying points" on other issues (p. 603).

In addition, the appropriation of sustainable development discourses by tourism organizations, the MIR Foundation, and other corporate proponents reduces the potency and applicability of sustainability ideas and makes the discourse much more amenable to relatively conservative environmental goals. More systemic theorizations and interconnected analyses can become marginalized and ostracized along with the discourses that support them. In doing so, the actions we can relate to sustainability are reduced to green design, recycling, energy conservation, and so on.

Third, what the MIR Foundation and other tourism promoters seek to promote is a simulated sustainability, a discourse that emphasizes anti-hierarchical relations and consensus, altruism, and cooperation while ignoring social divisions, conflicts, and struggles as essential features of the post-Katrina rebuilding process. This tendency, we argue, is most typical and problematic in local discussions about neighborhood identity and local control that are intended to address issues of inclusion, affordability, and grassroots input into public debates over the pace trajectory of the rebuilding effort. MIR's foundational principles are statements emanating from a vision that communities should have "energy efficient, well-designed homes" that are "affordable and available for everyone." Affordability is infused with sustainable development but the discourse of sustainability, as promoted by MIR and tourism organizations, does not offer a series of policy remedies for increasing housing affordability for low-income Katrina victims. Abstract statements such as "everyone has the right to live in a high-quality, healthy home that enhances the natural environment" avoid discussions of present inequalities that point to the centrality of race and class in structuring the life chances of Lower Ninth Ward residents. Moreover, statements such as "communities should be fully engaged in defining their own needs and have a leading role in designing appropriate ways to meet those needs" fail to address who gets to define the "community" and for what purpose.

Overall, rebuilding efforts in post-Katrina New Orleans reveal the dominance of a new sustainable development discourse that emphasizes physical design, green technology, niche tourism promotion, and celebrity activism as expedients of disaster recovery. This promotional rhetoric and orientation tends to valorize individually adopted technological solutions to the structurally produced and systemic problems of risk exposure particular to the Lower Ninth Ward. By presenting "green technologies" in the context of a flood devastated neighborhood, the designers and architects involved in the MIR project promote the fetishization of these technologies as individually adopted panaceas that are resilient to certain patterns of flood and storm risk. What is important is that patterns of risk and vulnerability to storms and flooding are not simple by-products of "natural" ecosystems but are outcomes of past land-use practices and the historically contested politics of urban development and policymaking (Gotham and Campanella 2011). Moreover, while the fusion of green sustainability discourse with niche tourism practices may offer new representations of cities and regions they also promulgate a series of obfuscations and blindspots that diminish chances for long-term sustainability.

CONCLUSION

The discourse of sustainability radiating through New Orleans institutions is not homogeneous but involves a diversity of multifaceted and contested themes and symbols that interconnect with tourism practices and discourses. For many advocates working in the Lower Ninth Ward, sustainability discourse depoliticizes complex political struggles over continuing quality of life concerns, equity and access to public services, and social problem melioration. But as David Harvey (1996) has noted, discourses are not monolithic, and are characterized by "all sorts of slippages, ambiguities, and incoherencies" (p. 89). As we have shown, this ambiguity enables sustainability programs to reframe, repackage, and (re)present urban disaster for spectators, and in doing so, tend to silence and shroud issues of uneven development and socio-spatial inequality. Yet our ethnographic work also suggests that for community activists in New Orleans, "urban sustainability" represents a toolkit of diverse themes, symbols, motifs that they can strategically appropriate and deploy in an eclectic fashion to challenge marginality and contest social injustice.

While our paper sheds light on the contradictory and paradoxical elements of green tourism, our findings also reveal positive features and suggest a series of recommendations for using tourism as a vehicle for post-disaster recovery and rebuilding. First, our ethnographic works suggests that greater inclusion of local residents in green tourism decision-making processes and in the design of green tourism sights and sites can facilitate local buy-in and help promote long-term sustainability of ecological and cultural resources. This was an admittedly difficult task in the Lower Ninth Ward, where many residents were displaced and the majority have yet to return, making them difficult to reach out to for neighborhood groups and activists. Still, community input can be important for strengthening environmental education and management of tourism sites and can also broaden the support base for attracting increased public and private sector funding for enforcement of environmental regulations protecting green spaces. Following past research, we agree that green tourism is concept that can promote environmental responsibility and post-disaster recovery provided that local residents are amenable and are meaningfully included in the planning and decision-making that will affect their lives and communities. Moreover, community input and grassroots participation in green tourism planning can mitigate the "dark" side of sustainability and can also be a means of both enhancing local economic vitality and strengthening community attachments to place.

In addition, our findings suggest that green tourism practices can be fruitful strategy of post-disaster rebuilding but active government participation at all levels is required. The establishment and regulation of green tourism in community and environmentally sensitive ways depends on the establishment and enforcement of public policies, municipal codes, and socio-legal regulations that integrate eco-businesses, green spaces, galleries and heritage sites, natural food stores, and sustainable transportation options among other features. Green tourism should not be viewed as an ancillary component of tourism or an add-on to already existing economic development tools. Rather, we believe that green tourism practices should be incorporated and integrated into the overall repertoire of economic development on a regional scale. These practices can include green tourism training and education programs, and information disseminated to tourists and residents on the need to understand the costs of destroying natural assets (Cheung & Fok, 2013), the potential impacts of global climate change on cities, continuing risks and vulnerabilities to hazards that many cities face. New training programs for tour guides and education promotion for tourists

and residents can curb tendencies toward sustainability discourses to be compartmentalized and used for exploitative economic activities. Active government participation including planning and monitoring toward the realization of sustainability goals must be central efforts to promote green tourism.

Chapter 77
Awareness of Sustainability, Green IT, and Cloud Computing in Indian Organisations

ABSTRACT

This chapter examines the level of awareness that organizations in India have of the concepts, strengths and benefits of sustainability, green IT and cloud computing. Very few research papers have examined the sustainability, green IT awareness and cloud computing issues in India, and it has become necessary to ascertain just where Indian organizations stand when it comes to these concerns. Before determining whether these organisations are progressing towards sustainability, green IT and cloud computing, it is first necessary to determine whether, and to what extent, they are aware of these concepts. This research is to obtain answers, which hopefully will be a first step in a shift towards sustainability and green IT, via an online survey. Seventy-five respondents from public and private Indian organizations participated in this survey and confirmed that cloud computing is efficient, flexible and easy to maintain, although security and privacy are major concerns for Indian organizations.

INTRODUCTION

Sustainability, green IT and cloud computing are currently hot topics in research studies as well as in organizations and businesses. Due to the increase of greenhouse gases and global warming, many organizations and businesses are shifting towards becoming green and sustainable. One of the first changes

that they implement is in their IT infrastructure because the ICT sector is a major contributor to the increase in greenhouse gases which leads to an increase in global warming. The topics of green IT and cloud computing are attracting much discussion and research. These changes in IT infrastructure and the IT sector are taking place all over the world, not just in a few countries. In some countries, governments are promoting green IT and cloud computing by providing policies and guidelines, and encouraging businesses to adopt environment-conscious practices by giving them special benefits. Much research has been conducted on the issues of sustainability, green IT and cloud computing with a common understanding that there is a need to initiate a shift towards sustainability and green IT because of increasing environmental problems and social pressure. Cloud computing is also emerging as a hot topic of research and discussion because it is considered to be the next wave of sustainability and green IT.

Sustainability means using resources wisely to save for the future generation without compromising the needs of the present generation. With technology moving towards sustainability, IT practices and products need to be made greener and safer. Green IT is considered to be the first wave of sustainability. Green IT means implementing green practices in terms of all IT processes and product life cycles. Green IT also includes the use of energy efficient IT products, use of power management software and reusing and recycling IT devices. Cloud computing, on the other hand, is considered as the second wave of sustainability and an extension of green IT which simply is the sharing of resources and applications by a number of people at a single cloud provided by a single vendor.

This conserves power that would otherwise be consumed by huge data centres, and requires less hardware at the user end which results in less wastage of resources. This chapter aims to examine the levels of awareness, regarding sustainability, green IT and cloud computing, of Indian organizations. India is the second largest country in terms of population so it contributes a lot to global warming so it becomes necessary to find out the initiatives and steps taken by the Indian government and organizations in making IT green.

Cloud computing is a relatively new concept in the business world and not many companies in India are thoroughly familiar with it. In actual fact, many Indian-based IT companies are outsourcing cloud computing services to companies in other countries, but have made little effort to introduce this concept in the Indian business world because of cost factors. The conclusion was that the awareness was there but the level of awareness was low or negligible. Some companies have adopted cloud computing in their operations but these are few and far between. The Indian government has done little to promote sustainability, green IT and cloud computing.

IT companies have shown the same lack of effort to promote these concepts in India. The time to take action is now – before it is too late and India is left behind by the more forward-thinking nations. India is also considered to be a technologically advanced country as there are numerous Indian-based IT companies who are actually providing IT services worldwide. In order to collect data for the research work, a survey questionnaire was prepared to determine whether or not Indian organizations are aware of the concepts of sustainability, green IT and cloud computing; and if they are, their level or degree of awareness. Non-probability sampling techniques were used to select the samples; in this case, the snowball technique was used. For the purposes of analysis, the Factor Analysis indicated that Indian organizations are aware of these concepts in their IT operations. They are also a little aware of the benefits of implementing these trends, and the potential harm to their organization by not adopting green IT and IT sustainability as security and privacy are major concerns from the Indian organizations' perspective.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Finally, this chapter aims to examine the level of awareness of Indian organizations' – public and private – about sustainability and cloud computing. This chapter is organized as follows: 1) Introduction; 2) Sustainability and IT; 3) Green IT 4) Cloud Computing; 5) Sustainability and Green IT awareness and Initiatives in India; 6) Chapter Significance; 7) Research Method Design and Research question; 8) Data Collection; 9) Participants; 10) Results; 11) Discussion; 12) Limitations; 13) Conclusion.

SUSTAINABILITY AND IT

Sustainability has emerged as an alarming issue much discussed by scholars and practitioners. This is because the last two decades have brought much economic growth accompanied by increasing concern about both wealth disparity and natural resource depletion (Dao, 2011). The concept of *triple bottom line* has been developed for defining sustainability that includes three components: the natural environment, society and economic performance (Dao, 2011). Sustainability as an issue has increased to the point where there is now a need to guide all businesses towards sustainable development. Consumers now are demanding much more energy-efficient and eco-friendly products, and businesses should recognize the needs of the new consumer that is emerging in the market. During the last two decades, there has been a rapid growth in the ICT sector which has resulted in an increase in the rate of greenhouse gas emissions (Prasad, Saha, P.Misra, B.Hooli, & M.Murakami, 2010).

In 2007, the ICT sector alone was responsible for 0.8 billion tonnes of carbon emission which was 2 per cent of overall emissions and estimation is that it is going to increase to 1.4 billion by 2020 (Prasad et al., 2010). The ICT sector, more than any other sector, needs to seriously consider a shift towards a green and sustainable future. Energy resources need to be used sensibly; irresponsible use will affect the environment and rapidly deplete these resources (Ketting, 1995). Many organizations are not moving towards sustainability as they think that it will increase the cost of production and will erode their competitiveness, but sustainability drives organization towards organizational and technological innovations that yield both top line and bottom line returns (Nidumolu, 2009).

Sustainability should not be confined to IT; it should be applied to the entire business process of an organization. Today, consumers are becoming more environmentally conscious than ever before, so there is a need to incorporate managerial concern with consumer concern about the natural and physical environment; this will contribute to superior business performance and enhance the corporate reputation (Sharma, 2010). Sustainability consists of seven key elements: *governance* which means top management should consist of people who support sustainability; *leadership* which means that the leader responsible for the sustainability agenda must pay attention to how the concept is to be framed and introduced; *business plan* should be made consisting of three diagnostics - situational, goal and implementation; *measure and report* which means activities need to be measured against identified progress and must be reported; *organizational learning* should be encouraged as this helps in speedy transition; *culture* is also necessary for sustainability; and lastly *information systems* - by developing models, information systems can help to achieve sustainability in an eco-efficient, eco-equity and eco-effective way (Smith & Sharicz, 2011). Basically, sustainable IT is also considered as green IT but now is the time to move on to the second wave of sustainable IT which would be more externally focussed and service oriented, allowing IT to exploit both enterprise and customer opportunities while addressing broader societal problems (Harmon & Demirkan, 2011).

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

GREEN IT

Green IT presents new concepts of manufacturing and recycling computers and devices with minimal impacts on the environment. Currently, data centre and servers are using green IT technology to reduce energy and cost, provide an effective performance, promote recyclability, and reduce the use of hazardous materials. Currently, several companies locally and globally are using green IT technology in their organizations to improve energy efficiency to protect our planet and saving the current resources for the seventh generation (Newton, 2000; Newton, 2003)

Green computing is intended to reduce hazardous material and maximize energy efficiency and it should be recyclable. Green IT refers to saving energy at various levels including hardware, software and services (Agarwal & Nath, 2011). Data centres should be set up in deserts where there is an abundance of available land and geo-tectonic stability, and non-conventional sources of energy - solar and wind - should be used, although the regulation of temperature and humidity must be considered (Vijaykumar, 2011). Virtualization is also important for green IT. There are three types of virtualization: storage virtualization which condenses several storage spaces to a single storage location; network virtualization divides bandwidth into independent channels and combines computing resources into one; and server virtualization hides the physical server resources (Yamini & Selvi, 2010). Data and programs are being swept away from the desktops and PCs, and software are used as services. The internet is the platform for cloud computing services (Hayes, 2008) and has the advantage of decreasing the amount of storage that individual computers require to store a software. Server and storage virtualization are the third generation of virtualization that brings together server and storage to form a whole entity combined into a dynamic, centrally managed resource pool, where any application or operating system can maintain continuous optimization and high availability status (Xianmin, 2011). Green cloud is also introduced as a new architecture for data centres. It will reduce power consumption and give guaranteed performance to the users by leveraging live virtual machine migration technology. This green cloud architecture uses virtual machines to meet the workload requirements (Liu et al., 2009)

CLOUD COMPUTING

Cloud computing refers to applications that are provided as services on the internet, and the hardware and system software in the data centres that provide those services (Armbrust, 2010). The data centre that provides these services including the hardware and the software is called a "cloud" (Armbrust, 2010). These services, when provided to the general public, are called "public cloud" and the services are called "utility computing" because the user can access services according to his/her requirements without having to know where these services are being hosted and how they are delivered (Buyya, 2009). When a company uses a data centre for its own purposes and this centre is not available to the public, this is called "private cloud" (Armbrust, 2010). It simply means that now the computing world is developing software not just for their own requirements, but for millions of others to consume as a service; this is what is done in cloud computing (Buyya, 2009; Singh & Malhotra, 2012; Zissis & Lekkas, 2012).

Buyya (2009) even compared cluster, grid and cloud computing: Cluster computing is a type of parallel and distributed system, which consists of a collection of inter-connected, stand-alone computers working together as a single, integrated computing resource. Grid computing is a type of parallel and distributed system that enables the sharing, selection, and aggregation of geographically distributed `autonomous'

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

resources dynamically at runtime depending on their availability, capability, performance, cost, and users' quality-of-service requirements. Cloud computing is a type of parallel and distributed system consisting of a collection of inter-connected and virtualized computers that are dynamically provisioned and presented as one or more unified computing resource(s) based on service-level agreements (SLA) established through negotiation between the service provider and consumers.

The hardware and infrastructure required for cloud computing are (Singh & Malhotra, 2012; Velte, Velte, & Elsenpeter, 2010; Weiss, 2007; Zhang & Chen, 2010): firstly, clients- the end user devices which are required to interact with the cloud. There are different types of client: 1) Mobile clients include devices like laptops, PDAs and smart phones. These devices generally are subject to security and speed issues as there are certain places where connections are slow (e.g. hotels, restaurants or WIFI- enabled public places) 2) Thin clients are those clients which lack hard drives and any kind of CD/DVD ROM and display just what is on the server. Thin clients are generally used when the applications or the information can be taken from the cloud and there is no additional requirement of storing on individual systems. These are less expensive and are used in small scale or medium scale businesses.

Security is good as no data is stored on the clients. 3) Thick clients are those which are normally used as desktops with all the required hardware. They are connected to the clouds for some particular applications. When cloud computing is introduced in the organization, if company has a low budget, they can use the desktops that are already present in the organisation instead of getting new thin clients. These are handy when one needs to store files on one's own systems instead of fetching it from clouds every time. Security is an issue as data is stored on the client machine itself.

Secondly, security is another aspect to consider when introducing cloud computing. There is always a concern about the security of data as the data is stored by a third party and not by the client itself. There are certain security benefits of storing data on cloud: for example, there is comparatively less data leakage as the storage is centralised and not spread among various clients; clients never need to worry about the security as this is the responsibility of the cloud provider; there are always new developments that address security issues related to the cloud; and lastly, if there is a security breach, the cloud provider can respond to the incident with less downtime than if this were done by the organisation itself (Marston, Li, Bandyopadhyay, Zhang, & Ghalsasi, 2011; Redmap, n.d)

Cloud computing can bring several benefits to an organisation including technical, user, architectural and organizational advantages as follows: (Aymerich, 2008): firstly, the technical advantages are that it does not require additional hardware to handle peak load situations because of which hardware infrastructure can be highly under-utilised; these resources can be virtualised and presented to customers as virtual servers which they can manage by themselves, but if this is done physically, it might require multiple computers or data centres. Finally, Nandgaonkar and Raut (2014) confirm that cloud computing services depend fully on availability, speed, quality and performance of the internet, which is provided by the service provider.

Secondly, the user is no longer stuck with traditional computing and there is no need to buy special devices such as PDAs or specially-configured phones in order to use a particular application. In future, any device that is internet-enabled will be able to use cloud-based applications. Moreover, when using those applications, the end user will not have to worry at all about capacity or compatibility or other issues apart from device maintenance. There are no concerns about upgrading a software version on the hard disk as the cloud provides the latest version.

Thirdly, cloud computing can be set up in places at lower costs of space and electricity. Furthermore, by using cloud computing, an organisation can achieve efficiency in their hardware and software infra-

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

structure as the related costs will be reduced and resource utilization will be increased, thereby increasing profitability. Furthermore, the resources can be pooled, thereby increasing utilization by delivering them only when they are required.

Fourthly, cloud computing is advantageous for low-capital, small and medium-scale businesses as they will not need to spend a great deal on buying in-house resources and technical equipment. Finally, even large-scale businesses and organizations are adopting cloud computing as it saves costs, can be remotely accessed, is easily available, and allows real-time collaboration.

Finally, cloud computing considers the new smart technology which needs to be adopted by organizations and users to reduce the impact of IT technology on environment from design, energy and e-waste (Brender & Markov, 2013; Johnson, 2013; Singh & Malhotra, 2012)

SUSTAINABILITY AND GREEN IT AWARENESS AND INITIATIVES IN INDIA

India is an emerging economy and IT products and services are used at a greater rate here because of the high population and therefore power consumption rate is equally high. The world is relying heavily on non-renewable sources of energy for its power supply. Eighty-five per cent of the world's power comes from fossil fuels, 9 per cent from hydro, 4 per cent from nuclear and 2 per cent from new renewable sources (Naidu, 1996). In India, there is a pressing need to adopt green IT because of the rapid growth of technology, expected shortages of power supply, huge maintenance of data centres and e-wastage of IT hardware and products (SaniaKhan, AbdulRazak, & KrishnaKumar, 2011). The adoption of green IT in India needs a mind-set wave in education, awareness programs and information, technology and commitment, as environmental issues related to carbon footprints, e-wastage and disposals of IT hardware, data centre maintenance are rarely discussed. However, some companies such as MNC IT and other international customers are trying to do business the green IT way, although it is still difficult to adopt green IT practices in India at every level due to the need for huge investment and a drastic change to the entire IT infrastructure (SaniaKhan et al., 2011). Implementing these approaches in India will increase green IT awareness, and this can lead to a reduction of e-waste and carbon footprints.

CHAPTER SIGNIFICANCE

In terms of its practical significance, this chapter will help organizations to acquire knowledge about sustainability, green IT and cloud computing from the base level. They will become aware of the progress made to date, in terms of adopting these concepts in organizational practice, in the world and in India. It will help them to gain a competitive edge because it will allow them to monitor the progress and they can adopt and implement appropriate practices before any other competitor in the market. The chapter draws its data from a wide range of industries in both the private and public sectors, thereby avoiding bias and providing a complete scenario of every organization. This chapter will enable both large organisations and small businesses to become more aware of these concepts. Also, the research data includes several companies which have already shifted to cloud computing, and this is useful for those who are still unsure of it, or are planning future implementation of cloud computing in their businesses. Vendors who provide cloud computing services will also benefit from this research as it also emphasizes the importance of the services provided by these organizations.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

At present, no company in India produces green IT products so this chapter will make companies aware of the potential market for such products that exists in India as it is one of the largest IT hubs in the world. The results of the surveys conducted will help organizations to identify the sectors that are already aware of these concepts and also the advantages and disadvantages of putting these into practice if they adopt them in their businesses. This will help new firms to gain a competitive edge by introducing these concepts in their businesses before entering into the market as they would be already familiar with the current scenario as a result of this research.

As for the theoretical significance, this chapter will help those students studying the issues of sustainability, green IT and cloud computing as it can be used as an article for analysis and evaluation. This will help them understand these concepts more broadly and thoroughly. The discussion presented in this chapter on the concepts of sustainability, green IT and cloud computing has been undertaken after analyzing many research works in the literatures, so students will be able to read one research work comprising various other research works. Researchers in the field of green IT, cloud computing and sustainability will benefit from this research as it takes into consideration these concepts in general and in relation to India in particular. This chapter will be of help to researchers who intend to carry out research on the concepts of sustainability, green IT and/or cloud computing based in India. The results of the research work will help them to analyze the current scenario in India and Indian organizations in regards to sustainability, green IT and cloud computing. The results of the surveys provide secondary data for research work and will familiarize students and researchers with the attitudes of Indian organizations towards sustainability, green IT and cloud computing.

RESEARCH METHOD DESIGN AND RESEARCH QUESTION

A mixed-method approach to data collection is used in this chapter. Quantitative data is gathered by means of an online survey. The online survey allows qualitative data to be collected as respondents are invited to provide personal opinions or comments in a separate text box in the survey itself (Issa, 2013; Sexton, Miller, & Dietsch, 2011). Based on the current literature review, the online survey was developed with the intention of examining Indian organizations' awareness of sustainability and cloud computing. The survey consists of two sections: the formal demographic information followed by a second section containing fourteen statements seeking participants' opinions regarding the risks and opportunities of cloud computing as well as sustainability via a five-point Likert scale with a range of 'Strongly Disagree, Disagree, Neutral, Agree, and Strongly Agree'.

This chapter aims to examine major and minor research questions. The Primary research aims to answer this question: To what extent are Indian organizations aware of sustainability, green IT and cloud computing technology? Furthermore, this chapter will address the following minor research questions: "What is the degree of sustainability and green IT awareness among India organizations? This question aims to identify the degree or level of awareness. Once we know whether or not Indian organizations are aware of sustainability, green IT and cloud computing, it will become easier to ascertain their level or degree of awareness, and whether organizations are just aware of these concepts (i.e. basic awareness) or whether they are planning to implement them (i.e. intermediate level of awareness) or whether they have already implemented them (advanced level of awareness). These levels of awareness will assist with the analysis of the results presented in this chapter.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Furthermore, the second minor research question is "What are the strengths and weaknesses of cloud computing in terms of its potential impact on the performance of Indian companies?" This question concentrates mainly on the level of cloud computing awareness. Responses to this question will indicate if Indian organizations actually have implemented cloud computing in their operations and to identify the advantages outweigh its shortcomings. Cloud computing is considered to be the second wave of sustainability and an extension of green IT, so if businesses and organizations have adopted cloud computing, this implies that they are aware of the concepts of sustainability, green IT and cloud computing and that they are shifting towards sustainability and green IT.

DATA COLLECTION

The data collection techniques include the techniques and procedures for data or sample collection which include the basis on which it was collected, how it was collected and from whom it was collected. Data is the main element of every research. It can be primary which means collected directly from sources such as surveys and samples, or it can be secondary collected from existing research work, magazines, articles, newspapers and theses. For collection of data, a sampling technique is used which includes probability sampling and non-probability sampling.

For the purposes of this study, a non-probability sampling technique was used because firstly, there was no way to select a sample population because our aim was to ascertain the awareness levels among Indian organisations from two sectors of industry, private and public, and from all across the country. Secondly, probability techniques would not have been feasible if a company chosen by the researcher as part of the sample, had not replied, thereby returning a negative result. Thirdly, the researcher did not want to predetermine a particular sample size, since it was desirable to collect as many surveys as possible. Non-probability technique provides flexibility in selecting sample size and the number of responses. It is the best technique to use when sample population is not to be selected on the basis of any factor and one has to take into consideration the entire population in that field. Non-probability techniques include: Quota sampling; Purposive sampling; Snowball sampling; Self-selection sampling; and Convenience sampling.

In this study, snowball sampling was used as a means of data collection. With this method, initial contact is made with a few potential respondents who are in turn invited to pass copies of the survey or the survey link to other individuals or companies who in turn forward these on and so on, creating a snowball effect, so to speak. To avoid sampling bias, the respondent sample included males and females, a range of professions, and a variety of industries from both the private and public sectors. Moreover, the researcher did not focus on only one particular region of the country, but made contact with people residing in different regions. This technique suited the purpose of this study which was to find out the degree of awareness of green IT, cloud computing and sustainable IT among Indian organizations.

PARTICIPANTS

This study was conducted in India to examine the *Awareness of Sustainability, Green IT and Cloud Computing in Indian Organisations*. The survey was distributed to organizations in India and the sur-

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

vey response rate was 83.3%. Table 1 provides a summary of the respondents' details including gender, industry sector type and qualifications.

Table 2 shows the number of survey respondents in public and private organizations in India. It was noted that the majority of respondents work in small, medium and large organizations. Furthermore, the majority of respondents worked in communication services and finance and insurance, 18% to 24% respectively (see Table 3).

Finally, Table 4 indicates confirmation that 61% of personnel in Indian organizations are still unaware of cloud computing applications although 16% are currently using various applications such as Amazon and National Green Database.

RESULTS

A total of 77 participants from India responded to the online survey. With two responses not accepted because of missing data, this resulted in 75 valid cases of responses for India for the following Factor Analysis. Based on the Mean and STD Deviation results, it was confirmed that the majority of the personnel in Indian organizations agreed that cloud computing services are efficient, flexible and sustainable (see Table 5).

To examine the online survey results further, the researchers adopted principal axis factoring for factor extraction, and oblique rotation was applied using the direct oblimin method to correlate the variables (Costello & Osborne, 2005; Hair, Black, Babin, & Anderson, 2009). To measure the sampling adequacy, researchers carried out specific testing from Cronbach's Alpha, Kaiser-Meyer-Olkin and Bartlett's test. Firstly, the Cronbach's Alpha for all 14 variables was .816, indicating an acceptable internal consistency of the items in the scale (Gliem & Gliem, 2003). Secondly, the Kaiser-Meyer-Olkin measure of sampling adequacy was .739 above the recommended value of .6, indicating that a sufficient sample size has been

Q8_14 Cloud computing contributes to organisations' sustainability	3.61	.857

obtained from the analysis (Hill, 2012). Thirdly, the Bartlett's test of sphericity is highly significant, $X^2 = 396.588$, $df = 91$, $p < .000$, indicating that the items of the scale are sufficiently correlated to factors to be found (Burns & Burns, 2008). Finally, the communalities were all over .05 (see Table 6) except for statements 11 and 14, as Indian organizations still have some concerns about security and sustainability.

Table 6. Cloud computing – Communalities

	Initial	Extraction
Q8_1 Cloud computing is more flexible than traditional computing	.651	.719
Q8_2 Cloud computing is more efficient than traditional computing	.606	.636
Q8_3 Cloud computing helps organisations become 'greener'	.585	.538
Q8_4 Cloud computing helps provide scalable services	.687	.657
Q8_5 Cloud computing helps provide reliable services	.440	.444
Q8_6 Cloud computing helps provide ease of maintenance	.662	.594
Q8_7 Cloud computing makes staffing easier	.624	.469

Q8_12 Cloud computing is more risky than traditional computing	.529	.704
Q8_13 Cloud computing reduces organisations' carbon footprint	.501	.467
Q8_14 Cloud computing contributes to organisations' sustainabiliy	.358	.321
Extraction Method: Principal Axis Factoring		

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Furthermore, the researchers used principle components analysis to estimate the factor loading matrix for the factor analysis model as well the standard correlation matrix. The Eigen values are assessed to determine the number of factors accounting for the correlations amongst the variables. As demonstrated in Table 7, this model of eight factors explains a total of 56.398% of the variation. The Eigen values and the amount of variances explained by each of these factors are presented in Table 7 (after rotation).

Furthermore, to measure the regression coefficients (i.e. slopes), the researchers carried out the factor loadings. The *factor loadings* are based on most of the items that have a high loading value and the one with the cleanest factor structure is considered as important. Hair et al (2010) suggested the

Table 7. Cloud computing - Total variance explained

Q8_11 Cloud computing increases operating expenses		.257	.832
Extraction Method: Principal Axis Factoring Rotation Method: Oblimin with Kaiser Normalization			
a. Rotating converged in 10 iterations			

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

lowest sample size is 50 cases. If the sample size ranges from 71 to 84, the sufficient factor loading is .60. Items Q8_8 and Q8_11 are shared with other factors (Costello & Osborne, 2005). The Q8_8 under Factor 1 and Q8_11 each has a factor loading below .6 (Hair et al, 2010). The statements 4, 8 and 11 were excluded and are highlighted in light blue.

The Pattern Matrix revealed three factors. However, factoring requires at least more than one variable or item grouped in the same factor, referred to share commonness or correlations (Hair et al, 2010). With this, only Factor 1 can be fit for labelling, as Factor 2 and Factor 3 each has only one variable which is Q8_12 and Q8_9 respectively. A score was calculated for this factor by averaging across each individual item. The mean and standard deviation of the factor average is presented below in Table 9.

Overall, it became evident that those who already know about 'cloud computing' even to a limited extent, think of such technology as efficient, flexible, scalable, reliable, easy to maintain. However, the survey outcomes confirmed that although cloud computing usage in India has brought various benefits, there is nevertheless some concern regarding the issue of risk and security of cloud computing as well as sustainability.

DISCUSSION

The chapter aims to assess the awareness of green IT, cloud computing and sustainability among Indian organizations. This research was intended to discover the extent to which Indian organizations are aware of green IT, cloud computing and sustainability in IT. The survey results indicated that organizations are aware of these concepts in their IT operations, but they have little awareness of the benefits of implementing these trends, and the potential harm that can be caused to their organization by not adopting green IT and IT sustainability. Cloud computing is a relatively new concept in the business world and not many companies in India are thoroughly familiar with it. In actual fact, many Indian-based IT companies (i.e. Wipro, Infosys, and Tata) are outsourcing cloud computing services to companies in other countries, but have made little effort to introduce this concept in the Indian business world because of cost factors.

According to the survey results, there is some degree of awareness of sustainability, green IT and cloud computing in Indian organisations, although this is very low. This is partly due to the fact that that both the government in India and Indian-based companies have made little or negligible efforts to promote green IT, sustainability or cloud computing in India. There appears to be no logical reason for this apparent indifference which seems to be the main reason for the low level of awareness and adoption of these concepts.

Finally, the results presented in this chapter indicate that the advantages of cloud computing outweighs its disadvantages: it helps organisation to become greener, increase operating profits, and provide more reliable services. Several studies ((Avram, 2014; Oliveira, Thomas, & Espadanal, 2014; Son, Lee, Lee, & Chang, 2014) indicate that cloud computing is more efficient and more flexible than traditional computing; it reduces the carbon footprint and promotes sustainability; it is easy to maintain and staffing

Table 9. Cloud computing – Descriptive statistics (N=75)

	Mean	Std. Deviation
Factor 1: Operational benefits	3.621	0.957

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

requirements are simplified. However, respondents also believed that it is more risky than traditional computing and increases the security threats to the organisation as the data is handled by some other entity that provides these services.

To conclude, it appears that Indian organizations are aware of these concepts of sustainability, green IT and cloud computing, but the level of awareness is very low or negligible. Hence, the government and IT companies need to put more effort into promoting cloud computing (i.e. training, workshops, conferences, newsletters via social networking and other facilities, education and others) as a better alternative to traditional computing in many ways. However, despite its many benefits and advantages, it may pose security risks to companies, of which they should be aware.

LIMITATIONS

The study presented in this chapter was limited to 75 participants from both public and private organizations in India. The rationale behind this study is to assess the Indian organizations' awareness of sustainability, green IT and cloud computing. The online survey responses strongly indicated that Indian organizations are aware of these concepts, although the level of awareness is low. Therefore, further research with larger and more diverse groups of organizations is required in the future to strengthen the research findings.

CONCLUSION

Sustainability, green IT and cloud computing are the current hot topics in the fields of IT research and IT business. This research was conducted with organizations located only in India and no other parts of the world. The results of the surveys were noteworthy, indicating that most of the personnel from organizations who participated in the surveys actually were aware of the terms 'sustainability', 'green IT' and 'cloud computing'. Most of them were even using cloud computing in their organizations. However, it emerged that although they knew about these concepts, none of them actually adopted the principles sustainability and green IT in their operations. The purpose of this research paper was to identify whether organizations in India are aware of the concepts of sustainability, green IT and cloud computing, and if so, what is their level of awareness, do they just know about it, or are they considering adopting it, or they are on their way to adopting it, or they are using it? The second important purpose was to identify whether or not those businesses that have adopted cloud computing actually know its strengths and weaknesses, and whether or not they find cloud computing beneficial for their organization.

The answers to the research questions led to the conclusion that, although businesses are familiar with the concepts of sustainability green IT and cloud computing, their levels of awareness of these concepts are very low or negligible. Although companies have responded to these questions, awareness alone is not enough to make a change. More effort should be made to increase companies' awareness of these concepts and move towards incorporating the notion of sustainability within their organisational and business practices. In order to increase both public and corporate awareness, the government and Indian-based IT companies need to collaborate more effectively to ensure that sustainability and green IT are being implemented in organizations and businesses in India. There is an urgent need to make a

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

transition towards sustainability and green IT because of the alarming rate of increase in carbon footprints and global warming. Cloud computing is a second wave towards sustainability and an extension of green IT. According to the survey results presented in this chapter, companies do know the strengths and weaknesses of green IT although few companies have attempted to adopt green IT practices in their businesses.

The security issues related to cloud computing are of concern to large organizations. There is a service level agreement between the vendor and buyer, but the data of the company stored with the vendor is always at risk because the employees working in the vendor's organization can pose a threat to the data. The conclusion of this research paper was that although companies are aware of the concept of sustainability, green IT and cloud computing, they are not actually planning or even considering implementing these concepts in their businesses or organizations. Government and IT companies need to put more effort into sustainability and encourage companies by giving them subsidies or rewards for implementing these concepts. In this way, companies can shift towards a more sustainable future because India needs to keep pace with other countries and global trends which are moving towards sustainability and green IT.

KEY TERMS AND DEFINITIONS

Cloud Computing: Is a smart technology used to save energy and reduce carbon emission.
Green IT: Using technology and computer resources in an efficient way.
Opportunities: Advantages and prospects occurred during practice of working with a technology.
Risks: Uncertain aspects occurred during usage or implementation a technology (new or Old).
Sustainability: Sustain and manage resources for the next generations.

Chapter 78
Green Marketing Mix:
A Review of Literature and Direction for Future Research

Prashant Kumar
National Institute of Industrial Engineering (NITIE), India

Bhimrao Ghodeswar
National Institute of Industrial Engineering (NITIE), India

ABSTRACT

The purpose of this paper is to report the findings of a systematic review of literature in green marketing domain and to propose directions for future research. Green marketing issues are delineated from literature extending marketing orientation and marketing mix frameworks. As society becomes more concerned with the natural environment, businesses modify their behaviour in an attempt to address society's concerns. Based on the literature review, the conceptual review and direction for future research have been delineated and discussed. The paper concludes with the evidences of integration between sustainability and marketing in forms of corporate environmental actions and green marketing practices in businesses. The paper deals with the concept of 4-Ps and the green marketing practice as business response to the increasing environmental consciousness of consumers in the market. The discussion highlights future research avenues and consequent implications for marketers of green products in designing their marketing strategies.

1. INTRODUCTION

Convergence of sustainability thoughts in marketing has given rise to addressing environmental issues in marketing (Hult, 2011). It believes that economic growth has greatly influenced by society and ecology, and emphasizes upon adopting a variety of management approaches (Crittenden *et al.*, 2011) that reflect business responsibility for the wider societal good (Matten and Moon, 2008). This gives an opportunity to elevate its focus from meeting the needs of consumers to managing a broader market-related issues related to economy, society and the natural environment. This has given rise to the debate to incorporate

social and environmental impact along with economic performance in business assessment. In result, rising worldwide public concern over degrading environmental quality resulting from harmful effects of certain industry practices and stricter environmental regulations posed by governments across the borders can be witnessed. This has altered established norms and rules of business across the world, and has raised the need to adopt environmentally friendly approaches in their sourcing, operating, and marketing activities for companies (Banerjee, 2002; Menon and Menon, 1997). So, companies embrace 'ecological consuming approach' perspective to ensure their survival in the market. They now address environmental issues in their management (Pujari *et al.*, 2003; Beamon, 1999) and marketing decision-making (Wong *et al.*, 1996). And, they choose to differentiate themselves by meeting the stricter national and international environmental regulations and demands of environmentally-conscious consumers (Banerjee *et al.*, 2003; Polonsky, 1995). They address environmental issues in several business activities such as designing and manufacturing products, their pricing, distribution and promotion, and develop green marketing practices and strategies (Papadopoulos *et al.*, 2010; Gurau and Ranchhod, 2005). This approach of green marketing is perceived as a profitable and sustainable management process to identify, anticipate and satisfy the requirements of consumers and society (Chan, 2013). Thus, once limited to the ideology of activists, environmental consciousness has become a matter of market competition (Follows and Jobber, 2000).

In contemporary business environment, marketing orientation is shifting to green marketing as firms' environmental actions and product offerings are now catering to eco-conscious consumers, and communicating their environmental actions to stakeholders and consumers (Jones *et al.*, 2008). The concept of sustainability is embraced by the marketing professionals that develop a long term vision for the growth and development of companies as well as for a sustainable future. The recent changes in marketing has raised the need to develop a holistic perspective of green marketing "that embraces all aspects of the company, the product, and the means of production, consumption, and disposal" so that opportunities to make substantive progress towards sustainability can lead to minimizing a transaction's negative impact on the natural environment and a change in corporate thinking towards environmental commitment (Peattie and Crane, 2005; Polonsky and Rosenberger III, 2001). Though environmental sustainability is gaining importance for business performance and competitive advantage, green marketing literature mainly elaborates upon its strategic development (Rivera-Camino, 2007; D'Souza, 2004; Peattie and Crane, 2005; Kilbourne, 1998; Polonsky, 1995). It lacks significant conceptual and empirical development (Polonsky, 1994) that can develop characteristics of green marketing to develop and exploit the benefits of the concept. There is a need to study green marketing to develop an understanding of interaction between firm and consumers in the marketplace that can act as a medium to develop an environmentally responsible marketplace and a sustainable society. Kotler (2011) has also raised several important issues to explore in green marketing, such as factors leading companies to compete on the basis of sustainability, changes required in marketing practices and opportunities offered by the concept of sustainability, etc. Further, Sharma *et al.* (2010) has recognized that research on inclusion of active role of environmental issues in marketing is still in infant stage and the related discussions are limited to the disciplines of environment management, production, and supply chain, and thus in context of entire value chain. Hence, developing green marketing mix to examine the interface of marketing with other functions of management and business with their impact on the environment is the objective of the paper.

1.1. Methodology for the Review

The objective of this paper is to understand the current state of research in green marketing and to conceptualize green marketing mix. Using a systematic review approach (Tranfield *et al.*, 2003) and methodologically guided by Greer and Lei (2012), it makes an effort to collect and synthesize the available literature (books, edited volumes and journal articles) in the domain from 1965 to 2013. A single research paper/book was considered as the unit of analysis. The literature in English language was accessed from popular electronic databases such as ABI Inform, ISI Web of Knowledge, Blackwell Synergy, Emerald, EBSCO and Elsevier Science Journals. A number of keywords were identified based on need for the review, and discussion of review proposal and objectives with academic experts. These keywords were constructed into search strings to access the literature. The list of keywords include green marketing, sustainability marketing, sustainability management, environmental marketing, environmental management, sustainability communication, communication tools for green products, eco-labels, green product design, green product development, green supply chain, green logistics, green distribution, green procurement, green consumers, and green consumer market segmentation. A preliminary search using these keywords was performed to identify further keywords for the main search. As suggested by Srivastava (2007), searching articles by cross-referencing was also adopted. This resulted in 196 research papers in total published in peer-reviewed journals which were filtered based on their relevance to the topic by analyzing the titles of the articles and then, analyzing the abstracts. The articles with highly technical work and highly ecological perspective, which were not in line with the outlined objective, were excluded. This resulted in total number of 105 papers for inclusion in the literature review out of which most (88%) of them were quantitative in nature. The several articles were categorized under several sub-categories of green marketing (as stated in Table 1): ethical standards, environmental responsibility, stakeholder engagement, social responsibility and marketing mix (product, price, place and promotion). Out of them, ethical standards were covered in 15% of the papers, environmental responsibility was covered in 68% of the papers, stakeholder engagement was covered in 55% of the papers and social responsibility was covered in 19% of the papers. Papers on green products included product design (in 18% of the papers), packaging design (in 12% of the papers) and stakeholder engagement (in 14% of the papers). 38% of the papers covered pricing-related aspects of green products and 26% of the papers covered retailing and distribution-related issues. And, 22% of the papers had sustainability focus in communication, 29% of them addressed eco-labeling aspects and 34% of them elaborated upon the use of internet and social media.

Out of the 105 papers, 4% of them were published in 1970s and 1980s, 16% in 1990s, 50% in 2000s, and 31% in 2010s. Out of 93 empirical papers, 38% of them were based in American cities, 32% in European cities, 18% in Australian cities and rest were in Asian cities. Also, 14% of the studies were comparative studies those captured the data from two or more cities across the globe.

2. MARKETING AND THE NATURAL ENVIRONMENT

Marketing is a broad term to represent the activities facilitating exchanges between companies and consumers. It is described in terms of distinct organisational culture, and a fundamental set of shared beliefs and values that lead to consumer-centered corporate strategy and operations (Deshpande and Webster,

Table 1. Examples of the topics included in the literature review

Sr. No.	Topics Included in Review	Sub-Topics
1.	Environmental ethics	Environmental protection
		Environmental code of conduct
		Ethical behaviour
2.	Environmental responsibility	Corporate behaviour
		Environmentally-responsible behaviour
		Firm actions
		Regulatory compliance
		Corporate policies and procedures
3.	Stakeholder engagement	Environmental stakeholders
		GRI indicators
		Community
		Strategic alliances
4.	Green products	Product design
		Packaging design
		Product ingredients
		Consumer perceptions
5.	Pricing	Higher pricing strategy
		Willingness-to-pay
		Value-for-money
6.	Green retailing	Retail atmospherics
		Sustainability-based programme
		Environmental goals and operations
7.	Green communication	Eco-labeling
		Information credibility
		Communication tools
		Consumer engagement
		Determinants of green purchase intentions

1989). Esteban *et al.* (2002) described marketing as "a set of attitude towards the market" that recommends distinct ways of thinking about the organisation, and its products and customers. Crane (1997) states that marketing comprises of content (what marketing decisions are made and which marketing activities are undertaken) as well as process (how the decisions are reached, and how the activities come to take place). Fundamental to marketing literature is a philosophy that "an organisation should try to satisfy customers' needs through the development of a coordinated set of activities that will allow the organisation to achieve its goals" (Deng and Dart, 1999). In the academic literature, marketing has evolved as a managerial function that focuses upon information accessibility and its processing. Originated from fundamental marketing concepts, marketing, at present, has dramatically advanced to address widely conscious and highly active consumers across the globe. In recent years, profound insistence of compa-

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

nies on marketing is observed. Marketing is based on the assumption that needs, which are originated at consumer end, should be identified by the companies and to be acted upon when these needs become consumer demand (Knights *et al,* 1994).

Since its introduction, the concept of marketing has undergone many changes with changing focus of the domain, changing orientation and changing consumer needs. With the time, issues faced by marketing have also changed. Recently, marketing domain witnessed how the competitive environment is changing. Now, consumers have become more assertive, have more understanding of marketing and related activities, look for high quality and high value products, and make and trust their own judgments. Recent developments have favoured relational marketing activities over transactional marketing. Developments in communication technologies, and changing national and cultural contexts have given rise to such market conditions that are demanding changes in objectives of marketing practices to customer retention (Webster, 1992). The importance of customer retention strategy and long-term customer relationship to achieve effective marketing performance is now recognized in marketing practices. This has motivated companies to develop unique marketing strategies to gain competitive advantage in the market. This has also raised the need of searching for new marketing approaches that is broad enough to provide unique and sustained competitive advantage. Incorporating sustainability issues in marketing is one of such approaches. This is rooted in the fundamentals of what impact marketing has on society and the environment. The present ideologies of consumption have brought concern over ecological impact of marketing under scrutiny. This has resulted in bringing environmental issues into public debate. Schot *et al.* (1997) describe sustainability with two different sets of imperatives for business – eco-efficiency and system change. Eco-efficiency describes company's acceptance of adverse impact on the environment as a result of its business activities and this has impact on competitive business environment (consumers, competitors and regulators). Survival of a company in the market is determined by the proven ability of companies to minimize resource input, to produce green products and to reduce environmental impact of their business processes. This has demanded company innovations to produce competitively priced goods and services satisfying human needs and improving quality of life. On the other hand, system change imperative reflects companies and the economic system a part of social and ecosystem. This view of sustainability focuses upon promoting compatibility of company practices with ecosystem and developing the new value system reflecting sustainable development. Both the imperatives in an integrated manner develop a better view on key issues and strategies in future, and to identify mechanisms and ways of transforming our society to a sustainable one (Schot *et al.*, 1997).

Many researchers have drawn conclusions suggesting that integrating environmental concerns and green strategies in corporate philosophy, and marketing policies and practices lead to sustainable growth (Shrivastava, 1995; Bernstam, 1991; Lecomber, 1975). The increasing trend of adopting eco-friendly business, eco-friendly technologies and services is creating new business opportunities presenting strong potential for making profit and satisfying stakeholders who have significant influence on the availability of financial, human and other resources of companies (Biloslavo and Trnavcevic, 2009). Thus, this trend is seen as growing relationship between marketing and sustainability (Jones *et al.*, 2008) and has led to emergence of the term 'Green Marketing'. Emerged in late 1980s, the concept of green marketing addresses environmental issues in several activities such as designing and manufacturing products, their pricing, distribution and promotion. It is perceived as a profitable and sustainable management process to identify, anticipate and satisfy the requirements of consumers and society (Chan, 2013). It involves greening of marketing by launching environmentally friendly products in the market for the ecologically conscious consumers (Kilbourne, 1998) and aims at developing competitive advantage, increasing mar-

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

ket share, improving customer loyalty, and promoting profitability (LeCren and Ozanne, 2011; Chang and Fong, 2010; Sharma *et al.*, 2010). Peattie and Crane (2005) view green marketing more as response to what consumers wanted, rather than a proactive initiative in companies. Though initially it lacked exhibiting patience and commitment to achieve full rewards from sustainability actions (Peattie and Crane, 2005), gradually it has been recognized that environmentally-conscious and ecologically-friendly strategies lead to superior financial performance as well as competitive advantages in the marketplace (Sharma *et al.*, 2010).

On the other hand, Wong *et al.* (1996) argue that green marketing is sensible only if consumers have taste and preferences for green products, and supply side decisions (availability, promotion, pricing etc.) meet consumers' need and requirements as well as government policies and regulations. Consumers have a key role as decision makers in moving towards sustainability (Jones *et al.*, 2008). Being educated through formal and informal environmental education channels, the environmental concerns have been altering consumers' basic habits and changing their consumption behaviour to preserve the environment (D'Souza, 2004) and the number is ever increasing (Gam, 2011; Mostafa, 2009). So, the relationship between consumer behaviour, marketing and the environment has emerged as a new trend in business which has led to increase in public awareness about environmental aspects as well as an increase in the evidences of environmental responsibility in the marketing activities (Gupta and Ogden, 2009; do Paco and Raposo, 2009). This has motivated marketers to focus on environmental dimension of their products, packaging and processes (Hur *et al.*, 2004) and incorporate green initiatives in their marketing strategies and advertising as well (Jansson *et al.*, 2010). Marketers now understand green marketing functionally so as to develop strategies aimed to meet the green consumers' needs (D'Souza, 2004). A number of companies have been implementing a number of green marketing strategies to meet the demand of environmentally conscious consumers. For instance, a number of companies are investing in research and development for developing green technologies and green products. For companies, energy saving and environmental protection policies are definitely a priority factor (Proto *et al.*, 2007). They are also engaged in establishing standards restricting the use of hazardous substances, environmental guidelines for their suppliers at all levels of the supply chain, and collaborating with their trading partners to develop environmentally conscious value chain (Hu and Hsu, 2010; Zhu and Sarkis, 2004). Recycling programs, cleaner production, environmental management systems and eco-efficiency, environmental certifications, water/waste reduction programs, packaging material and its design, environmentally-friendly purchasing, and lowering greenhouse gas emission have emerged as main environmentally friendly practices (Zhu *et al.*, 2010; Zhu *et al.*, 2005; Mandaraka and Kormentza, 2000). With such strategies, they also establish themselves in a niche for consumers with environmental concerns (Essoussi and Linton, 2010; Schubert *et al.*, 2010). Thus, the scope of environmental practices within their operations and supply chains with clear environmental objectives has become pronounced. Further, they regularly collect market-related information, implement their inferences across functional departments, and develop and improve of green marketing mix in response to the inferences. It represents their organisation-wide focus on creating superior value to the consumers and for the business, and behaving in the best interest of the consumers. As well, they identify special needs of consumers and develop environment-oriented business strategies to satisfy their changing needs. It aims at developing and offering superior products and value than the competitors catering to the present and future needs of the market. It is an indication of commitment to their relationship with the consumers. Thus, an increasing interest towards green marketing orientation is witnessed in the recent years.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Green marketing has attracted considerable research interest and green marketing orientation has gained significant importance in guiding companies' behaviour favourable to the environment. Green marketing orientation is described to place greater emphasis on collecting and using information related to consumer needs and developing strategies that respond to consumers' present and future needs, competitor actions and regulatory environments. The goal of green marketing orientation is to satisfy present and expressive consumer needs with their green product offering. It also aims at identifying hidden market needs as well future needs of the consumers, and accordingly altering existing product offerings and if required, develop and invest their resources, skills and capabilities to develop new products to cater to the rising needs in the market. Green marketing orientation has greater significance in development business practices and marketing strategies. It is determined important for companies to leverage their potential advantages of flexibility, market intelligence and adaptability into green product offering with superior value. Thus, green marketing orientation is perceived as a marketing philosophy that effectively and efficiently guides company behaviour to create learning from consumers and competitors, to create superior value to consumers of the company and continuously generate superior business performance.

The recent changes in marketing has raised the need to develop a holistic perspective of green marketing "that embraces all aspects of the company, the product, and the means of production, consumption, and disposal" so that opportunities to make substantive progress towards sustainability can lead to minimizing a transaction's negative impact on the natural environment and a change in corporate thinking towards environmental commitment (Peattie and Crane, 2005; Polonsky and Rosenberger III, 2001). Though environmental sustainability is gaining importance for business performance and competitive advantage, Sharma *et al.* (2010) has recognized that research on inclusion of active role of environmental issues in marketing is still in infant stage and the related discussions are limited to the discipline of management, production, and supply chain, and thus in context of entire value chain. This lays down the foundation for this study and explains the need to concentrate on this area of research.

3. GREEN MARKETING LITERATURE

Green marketing is deep rooted in earlier attempts of Lazer (1969) to address societal dimension of marketing in terms of finite environmental sources, societal and environmental impacts of conventional marketing, and greening of the different aspects of traditional marketing (Feldman, 1971). It is identified as one of the new forms of marketing which can play a very important role in the provision of the opportunities for well-being of the society (Prosenak *et al.*, 2008). It takes into consideration ecological sensitivity of natural environment, its constraints, and the laws of nature to ensure improved holistic quality of life, and to strengthen positive influence on natural and social environment (Prosenak *et al.*, 2008).

Since the evolution of the domain, a number of misconceptions associated with green marketing and a variety of terminologies and definitions have made it difficult to define the term (Kinoti, 2011). Polonsky (1994) identified that green marketing, sustainable marketing, environmental marketing and ecological marketing are synonymously used. Dam and Apeldoorn (1996) differentiated green marketing from its simultaneous terms. Green marketing "focuses on market pull and legislative push toward improved, environmentally friendly corporate performance". On the other hand, ecological marketing is related to ecological crisis and marketers' realization of their responsibilities towards the environment; sustainability marketing is related to marketing within sustainable economic development; and ecological, green and sustainable marketing altogether are labeled as environmental marketing.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

From the first definition of green marketing in 1976 to the most recent one in 2011, the term has evolved in its definitions and shifted its focus (Table 2 in the Appendix). It is witnessed that corporate responsibility for pollution prevention and resource conversation was the focus of green marketing definition initially, which shifted to satisfying marketing needs and to meeting organisational goals in later decades. Evolution of the term has improved relationship between sustainability and marketing, and advanced the research work in green marketing (Jones *et al.*, 2008). It has evolved as a philosophy that entails the recognition of effectively using limited available natural resources and taking more responsibility towards the environment. It has emerged as a set of environmentally favorable activities that follows a holistic management process compatible with eco-system (Peattie and Charter, 1994) to satisfy human needs with least impact on environment (Stanton and Futrell, 1987), and to fulfill consumer needs and organisational goals (Fuller, 1999). Having its significance for the 'future' over the 'present', it focuses on ecological sustainability rather than economic efficiency and recognizes intrinsic value of nature (Peattie, 1995). It also focuses on redefining products in the market, eliminating waste in production, usage and post-usage, adequate pricing and profitability (Pride and Ferrell, 2008). It intends to emphasize on environmental benefits from products usage, elaborates on cost over the lifecycle of the products rather than price, informs consumers about environmental aspects of the products rather than to generate sales, and focuses much beyond present consumer needs (Papadopoulos *et al.*, 2010). Thus, it can be seen as an amalgamation of environment management process, marketing activities and product/services for value creation to society, environment and sustainable future. Because this transformation entails a fundamentally different way of looking at the world and marketing's place in it, an expansion of the limits of marketing inquiry is required. This means that the discipline must become more macro in its focus and more multi-disciplinary in its methods.

Addressing demands of green consumers is another perspective of green marketing domain. Green consumers have been in the epicenter of the environmental marketing strategies (Papadopoulos *et al.*, 2010) and a large section of the literature in green marketing has focused on the determinants of their environmental behaviour, green purchase behaviour and post-purchase behaviour. A number of green consumer studies have shown that environmentally conscious consumers respond to environmentally responsible behaviour of the companies and it is exhibited in their purchase behaviour (Papadopoulos *et al.*, 2010; Paco and Raposo, 2009). Green consumer is defined by Strong (1996) as the one "who avoids products that are likely to endanger the health of the consumer or others; cause significant damage to the environment during manufacture, use or disposal; consume a disproportionate amount of energy; cause unnecessary waste; and use materials derived from threatened species or environments". Researchers have observed that green consumers are likely to prefer products manufactured by the companies that follow the practices of eco-friendly product design and processes (Pickett-Baker and Ozaki, 2008; D'Souza *et al.*, 2006). Studies show that behaviour in real life is not always governed by attitude, it is also intervened by the thoughts and feelings of an individual which ultimately influence her/his behaviour (Pickett-Baker and Ozaki, 2008). In marketing, market variables and branding with rational reasons have the power to influence the thoughts and feelings of an individual that result in developing his/her opinion towards green products and help in shifting consumer attitudes to more sustainable consumption (Pickett-Baker and Ozaki, 2008). For example, D'Souza (2004) studied intervening effect of eco-labels on consumer behaviour and argued that environmental information endorsed on labels and ecological attributes, and product efficacy characteristics may result in increase in sales of green products. Similarly, product attributes (health-related concerns, nutrition, taste, size, quality, ingredients,

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

flavor and appearance), reputation of the manufacturer, retail store and associated people, availability of environmental information and knowledge, consumers' past experience, and marketing communication targeted towards the consumers (interpersonal communication, influence of opinion leaders and word-of mouth, etc.) are other market-related variables. They are used to develop green marketing strategies to market their green products and practices so that consumers' attitude, decision making and behaviour can be influenced (Pickett-Baker and Ozaki, 2008).

Thus, green marketing is deeply rooted in understanding the changing consumer behaviour, and influencing their attitude and beliefs in decision making constraints imposed by price, brand and availability, and comprehensive reassessment of product design and development, pricing policies, distribution and marketing communications, and product and packaging disposal (Ko *et al.*, 2013; Jones *et al.*, 2008). It has emerged as a managerial concept to improve corporate reputation and image by displaying the environmentally-friendly manners companies operate which is governed by following ethical standards and undertaking environmental and social responsibilities, and engaging with societal and business stakeholders.

4. DISCUSSION

Green marketing can be described with three fundamental elements i.e. commitment, enrichment and differentiation that serve as guiding factors in developing green marketing mix for a company. First, commitment is facilitated by visionary management that is complementary to organisational values and culture to guide marketing decisions and to ensure coherence of marketing actions. Green marketing managers possess a set of values that develop green marketing practices around environmental vision and mission. They cultivate green marketing philosophy across strategic business functions in the company, to make a consistent commitment of resources for green product development, and to rationalize company processes to deliver a consistent consumer value. Second, differentiation is related to making a unique and robust set of product associations that markets wish to develop and maintain for differentiating their products from those of competitors. The green product associations originate from marketing innovations, incremental or radical, that aim at adding value to the total green product offering and establishing the product in the market. The differential element is communicated in the market to distinguish the product, the corporate culture and environmental commitment of the company, and the relationship of the distinguished product with customers. Further, green marketing managers utilize their skills and intelligence to understand how several features, benefits and attributes may create favourable perception of green products. Third, enrichment is rooted in core environmental values of a company which guide company's efforts on using greater creativity and developing strong unique product entities that create value (utility or added) for its consumers. This is facilitated by cross-functional team-based marketing operations in a holistic and integrative manner rooted in core environmental values. This motivates green marketing managers to use company's assets to create unique competitive products that fulfill consumers' present and future needs, develop a lasting eco-oriented personality, and possess a distinct combination of physical, functional and psychological benefits. This way, the emphasis is laid upon environmental impact and benefits of products, company's values and mission regarding impact on the environment, encouraging environmentally responsible behaviour among consumers, and developing engaging marketer-consumer relationships.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

4.1. Setting Future Research Agenda

Though green marketing is seen as an important sub-domain of marketing over the last five to six decades, only a handful number of studies are witnessed that focus upon developing green marketing strategies and motives of green marketing (i.e. perceived opportunities offered by green marketing to achieve organisational objectives, company's moral obligation, pressure from government bodies and competitors, cost saving, revenue generation and image building). Some of the studies evaluated green marketing strategies (Polonsky and Rosenberger III, 2001; Rivera-Camino, 2007) while others focused on relationship building with stakeholders and consumers (D'Souza *et al.*, 2006; Gurau and Ranchhod, 2005). Others examined relationship between green marketing and marketing professionals such as, Rivera-Camino (2007) developed an understanding of stakeholders' influence on green marketing strategies and stakeholders' prioritization. Further, Gurau and Ranchhod (2005) compared Romanian and British eco-firms for their international green marketing strategies. Thus, the literature addresses either theoretical development of green marketing or concentrated on stakeholders' perspective of green marketing.

Though the literature on green marketing witnessed several perspectives of the domain i.e. environmental, societal, and economical, yet the confusion persists for its appropriate conceptualization, how to measure it (specifically, green marketing orientation), and how it is developed (antecedents of green marketing orientation). Studies in the domain provide little information on what determines green marketing orientation of companies and how green marketing orientation results in developing effective green marketing practices. Further, it is imperative that together with companies putting their best to pursue green marketing efforts to contribute to sustainability, equally important is consumers' willingness to change their behaviour to become more sustainable so as to achieve green marketing objectives (Gordon *et al.*, 2011). So, it is important to understand consumers' perception of the green marketing practices and how they are addressed by innovative green marketing strategies. A need is realized to rethink marketing concept and subsequent marketing strategies so that the effect of green consumerism can be examined on the role of marketing mix (Prothero, 1990). Thus, academic contributions to developing marketing strategies incorporating environmental dimension, and green marketing practices catering to achieve environmental, social and economic goals and objectives in integrated manner are substantially needed.

4.2. Future Research Directions for Green Marketing Orientation

The literature review elaborates how green marketing has moved beyond simply promotion of products with environmental characteristics. So, future research should explore significant efforts for sustaining company's degree of adaptation to the market and a sequence of necessary actions guiding their behaviour. In other words, studies should be aim at developing an understanding on how green marketing-oriented companies move beyond internal marketing activities and include external activities that aims to associate consumers with the company. This will elaborate upon how market-related information is collected and disseminated across a company's functional areas so that a set of shared goals can be developed for guiding business functions for effective product development and marketing. This should further be replicated in developing and validating corporate behaviour and marketing practices that thoroughly incorporates environmental values into the decision-making process with extensive coordination across functional areas. This will develop an understanding of how the new ideas and concepts of green marketing lead to a paradigm shift in marketing theory and practice, and how green marketing orientation offers

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

marketers opportunities to achieve the overall objective of creating and providing value for companies as well as consumers. Exploring the domain as marketing response to the design, production, packaging, use and disposal of products will enrich the knowledge and establish ground for developing solutions to forthcoming challenges in green marketing. From the literature review, it is evident that green marketing now address moral concerns raised in environmental initiatives and handle them through genuine commitment to following tightened ethical standards. So, future work should explore tightening ethical standards, standards of societal and professional ethics beyond legal requirements and morally right marketing practices. This will further provide directions to revise traditional marketing practices, and design strategies and marketing mix for meeting needs of the market.

Studies on green marketing orientation should also explore how customer-oriented marketing decisions are driven by the philosophy and values pertaining to green marketing, and are influenced by the inferences drawn from company's understanding of its market and customers. The findings will be meaningful in developing organisation-wide innovations that help companies to identify chances of innovations required for catering to the present and future needs of the market as well as to make their organisational process and activities effective in the present competitive environment l. Establishing relationships between green marketing practices and consumer trust and satisfaction on effectiveness of company's products and business operations for reduced environmental impact will contribute towards developing managerial solutions to green marketing challenges. Measuring green marketing performance in financial terms (investment profitability, sales profitability, and financial profitability), operational terms (sale volume, sale increase rate, market share, customer retention rate, product quality) and in terms of organisational efficiency may prove other milestones in this direction. Further, measuring value creation (economic such as effectiveness of product and durability, and non-economic such as social image and self-appraisal) as outcomes of green marketing practices may offer meaningful managerial implications. Value creation for consumers can be studied from two perspectives. One perspective includes consumers who are satisfied with their current consumption pattern and lifestyles. For such consumers, they will be attracted towards green products, only if they recognize that the products demand modifications in line with improve their lifestyles. Another perspective includes consumers who are curious to change their current consumption pattern and lifestyles in an environmentally-friendly manner. For such consumers, they will be attracted towards green products if they recognize that the products demand modifications improve their lifestyles. This will enable green marketing managers to understand what green marketing practices can make real contribution to bringing a difference from environmental conservation perspective.

4.3. Future Research Directions for Green Marketing Mix

Though green marketing mix is recognized as fundamental of marketing, it needs to be carefully combined and utilised to produce the most viable mix. Based on the challenges involved in marketing of green products, retail mix and promotion mix are two important building blocks of green retailing. In other words, contributions towards informing consumers about green products and offering them green product exposure are utmost important in academic research. Exploring and developing green retail mix may produce interesting results to explain attempts creating awareness of green products, offering repeated green product exposure in retail stores to enable consumers to recognize and recall green products, and improving their familiarity with green products. Also, the role of retailers as leading actors in green marketing should be explored to understand how they proactively share the responsibilities of providing facilities to consumers to make trials of green products intended to provide personal product-

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

related experiences, to make consistent efforts to build long-term relationships with consumers, and to build up strong market position for green products.

From green advertising perspective, the content of the environmental information about their products, processes and practices has gained strategic position in green marketing. So, researchers may be interested to explore the linkage of environmental information with corporate activities, educating consumers about green products and enabling them to make more effective purchase decisions, and their meaningfulness from the aspects of understandability, clarity and convincing. Important managerial implications may be produced by exploring green communication practices and consumer engagement practices so that consumers' misconceptions, confusion, skepticism, and backlash surrounding green product claims and performance can be minimized or prevented, and the likelihood of information sharing, mutual understanding and informed decision-making can be maximized.

It is worth exploring how taking into account the new media and integrated marketing strategies caters to new and constantly changing consumer needs, and how adopting distinct approaches allow green marketing managers to improve communication with consumers in personalized and interactive manner. It may also be related with consumer empowerment and high degree of market transparency. Resulting co-creation marketing strategies that allow consumers to become a part of product development process and wide acceptance of the new product developed may produce important managerial implications. Consumer engagement practices for green products are also meaningful to relate products with personal values and value orientations of consumers, to answer to their curiosities, and to improve comprehension about products. Further, promotional practices enabling consumers to understand their needs and to compare their needs with products available in retail stores for making suitable choice of products are worth exploring. This may have important implications in developing relationships between the customers and green products, between the customers and the companies, between the customers and the green product in use, and among fellow customers. There will develop an understanding of interactions between company and consumers in the market that not only strengthens the relationship between consumers and green marketers but also substantially increases the role of consumers in contributing to product-related innovations. Further, integrating a locus-based perspective of green consumer behaviour (Kalamas *et al.*, 2014) with promotion mix elements may produce interesting implications.

The role of consumer engagement practices, credibility of environmental claims and effectively informing consumers about green products can be further examined to identify the constantly changing needs, to predict market trends early and accurately, to quickly respond to competitive movements, and thus, to understand effectiveness of green marketing practices on company performance. This way, the future research directions contribute towards understanding how green marketing it overcomes the shortcomings of traditional marketing mix, as described by Constantinides (2006), of lack of customer orientation and consumer interactivity by developing solution over products, sharing information over promotion and creating value over sales.

5. CONCLUDING REMARKS

The literature review witnessed the integration of sustainability and marketing. This results in prominence of corporate environmental actions and green marketing practices in businesses wherein importance is accorded to activities such as developing green products, and using innovative pricing and retailing

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

practices to promote them in the consumer market. Marketing managers develop a long term vision for the growth and development of companies as well as for a sustainable future. In result, they intend to develop specific marketing mix for green products and green segments of the market. This way, once limited to the ideology of activists, environmental consciousness has become a matter of market competition (Mostafa, 2009; Follows and Jobber, 2000). Thus, the literature review makes an attempt to propose conceptualisation of green marketing orientation and outlining green marketing mix by relating sustainability and marketing with each other. It further identifies research gaps and provides direction for future research to contribute in green marketing literature. These attempts differentiates this literature review from those of others such as Chamorro *et al.* (2009), Peattie and Crane (2005), Prakash (2002), and Polonsky and Rosenberger III (2001).

It is rational to state that strength of green marketing mix lies in its focus on long-term strategic and rational thinking that lays greater emphasis upon managing their marketing relationship and interactions with suppliers, distributors and retailers, and ensures long-term transactions between marketers and consumers. Thus, a considerable shift in marketing practices from internal orientation of traditional marketing mix to interactive and consumer-oriented is evident. It develops a perspective that supports an integrated approach towards marketing practices taking into account transactional, relational and organisational aspects of marketing activity. The study concludes with the possibility and relevance of developing the mix that serve as a basis of green marketing planning for the highly competitive, dynamic and technology-mediated market. The studies based on future research agenda proposed in the article intend to address issues related to total green product offerings and to adequately deal with new realities of marketing. For practical implications, it will enable companies to make superior contribution to continuously improving consumer value and to gain competitive advantage. Thus, the predominance of four Ps of marketing mix in green marketing perhaps relates to Kotler (2011) which explicitly incorporates each component of marketing involving from product and market intelligence to pricing, distribution, promotion, information credibility and ethics. It is worth theoretically significant to understand whether green marketing mix extends traditional marketing mix and overcomes its shortcomings, or is losing its relevance in green marketing domain.

Chapter 79
Green Investments and Food Security:
Opportunities and Future Directions in the Context of Sustainable Development

ABSTRACT

Green investments are the perfect tool to generate complex self-regenerating systems in order to achieve a sustainable development. Even if the burden of transition from high polluting economy to a green economy is high, the cost should be split among all that have interest in achieving this goal. The switch to green is an international current that will ultimately force the change if it is not made willingly. All parties have an interest to promote change before the change gets them on the wrong foot. In this regard, the chapter aims to emphasizing the potential benefits of the transition to a green economy in terms of reducing poverty, enhancing food security, nutrition and health on a sustainable basis while promoting ecosystem stability. Thus, increased green investments throughout the food system are imperatively needed so that changing the way food is obtained could become a powerful force for sustainable development.

GREEN INVESTMENTS IN THE CONTEXT OF SUSTAINABLE DEVELOPMENT

Green economy is a new concept related to sustainable development. At Seventh "Environment for Europe" Ministerial Conference held in Astana, 21–23 September 2011, the participants agreed that green economy is a "tool to help achieve sustainable development and eradicate poverty" (UNECE, 2011). Although United Nations member states have not established an agreement on the definition of the green

economy, UNEP defines it as "one that results in improved human well-being and social equity, while significantly reducing environmental and ecological scarcities" (UNEP, 2011). As an associated concept, green growth refers to growth that "emphasizes environmentally sustainable economic progress to foster low-carbon, socially inclusive development" (UN DESA 2012).

The greening of the economy is complex process and different from country to country because the particularities of each state must be taken in account. The differences are made by factors like: level of development, natural resource endowments, strength of institutions and laws, nature and size of market failures, public awareness on the green economy (stakeholders like consumers, businessmen, professors or students have their role in the transition to the green economy). The green economy ensures the growth, protects earth's ecosystems, contributes to the poverty alleviation and offers the right responses to the climate, food and economic crises. So, the green economy is compatible with the older concept of sustainable development (UN DESA, UNEP & UNCTAD, 2012).

Green investments have benefits on many fields: environmental protection, social inclusiveness and economic development. The main consequences of these investments are presented in the Table 1.

Taking into account the complexity of the phenomenon, the transition to green economy must be supported by public authorities, private sector and civil society. The first step is the identification of the main priorities in each country (Table 2). At the level of European Union, the main priorities have been detected and now, the major challenge is the establishment of the proper measures that must be taken.

The public authorities have the major role in this transition process because they must establish a robust framework available for public and private entities from real economy and civil society. For example, instruments like environmental taxes, charges and fees, carbon pricing and subsidies must be imposed in order to shape the behavior of the business. In addition, the companies must be encouraged

Table 1. The benefits of green investments

Environmental Protection	Social Inclusiveness	Economic Development
• decreased air pollution • decreased water pollution • decreased soil pollution • decreased ghg emissions • decreased biodiversity loss • decreased natural resources depletion • increased energy efficiency • increased water efficiency	• improved access to goods and services • improved affordability of goods and services • improved work safety • increased green jobs • strengthened effective public participation in environmental matters • improved health protection • improved equity	• increased innovation • increased technology transfer • improved infrastructure • removed barriers • improved competition

to have a social responsible attitude through different tools like voluntary guidelines and information-based instruments. In order to raise public awareness on the green economy, stakeholders like consumers, students and educators are important players. The consumers must to be encouraged to give up to unsustainable consumption patterns and to become more conscious about their role in the transition to green economy. The universities have the mission to offer education for sustainable development. According with Nelson Mandela, "Education is the most powerful weapon you can use to change the world." Taking in account this, a new concept has appeared: education for sustainable development. The promoters of this concept are international political and economic forums like United Nations, OECD, ministries like environment or health minister. Research and innovation are also important in order to create environmentally sustainable technologies that reduce waste and increase resource efficiency. In this context, the integrated collaboration between government, industry, academia and civil participants are essential if we consider the Quadruple Helix Model (Carayannis & Campbell, 2009). In order to make the progress, it is also important to established targets and to measure the results. So, the indicators are essential to evaluate the efforts made by different entities.

INTERNATIONAL INITIATIVES TO MEASURE AND ACHIEVE GREEN AND SUSTAINABLE DEVELOPMENT

Initiatives to measure the achievement of a sustainable development spawn different benchmarks composed by sets of indicators that indicate the completion of different goals of sustainable development. We will present some of the most important of them which had a great influence on sustainable development and sustainable food systems.

Millennium Development Goals and Its Follower: Sustainable Development Goals

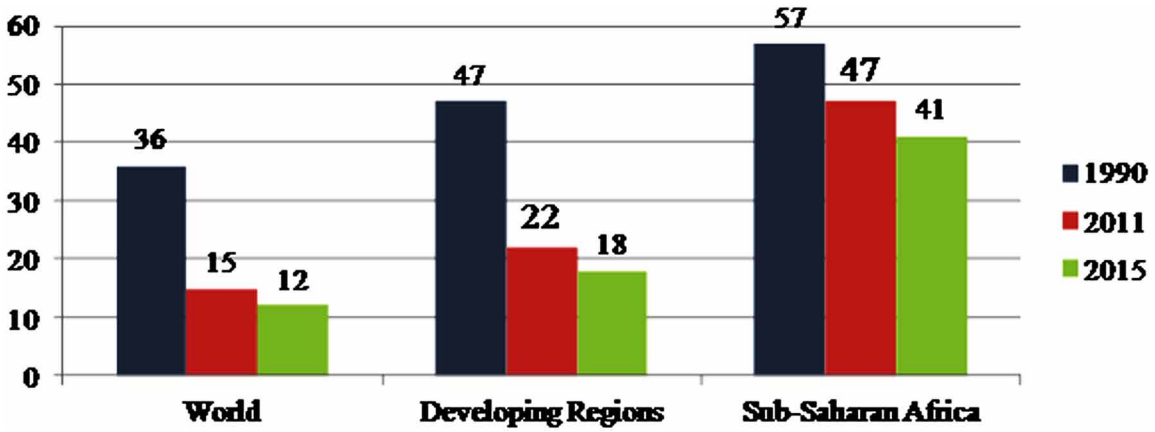
Millennium Development Goals is one of the most important initiatives to achieve a sustainable development by setting a set of eight goals in the year 2000 at the Millennium Summit which needs to be accomplished by the end of 2015. The base year for these goals is the year 1990. The United Nations Millennium Declaration was signed by the world leaders, committing their nations to reach the next goals (UN, 2000):

1. Eradicate extreme poverty and hunger
2. Achieve universal primary education
3. Promote gender equality and empower women
4. Reduce child mortality
5. Improve maternal health
6. Combat HIV/AIDS, malaria and other diseases
7. Ensure environmental sustainability
8. Develop a global partnership for development

In order to accomplish these goals, 12 targets had been put in place and 60 indicators have been used to follow the progress for each goal. The most relevant goals for our topic are goals 1 and 7.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

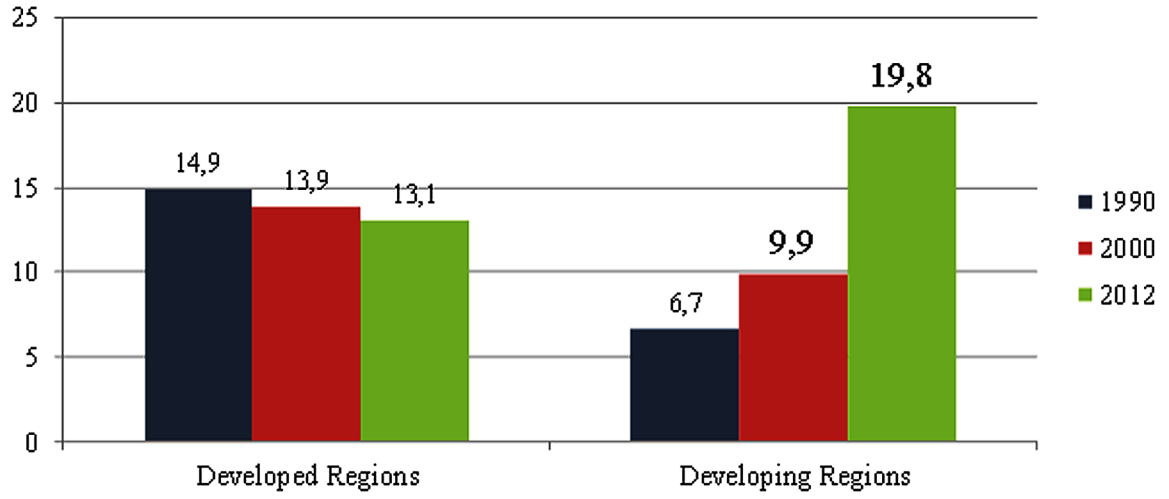
To eradicate extreme poverty and hunger many developments have to be made in the food production and supply systems to reduce the number of people that suffer from hunger and are undernourished.



As we can see from Figure 1, the share of people leaving on less than 1.25 USD/day registered an important decrease with 68% in the world and 69% in developing regions. In Sub-Saharan Africa the rate of decrease is slow with only 28% in the analyzed period. As a result of this evolution an excess of 1 billion people left the extreme poverty zone since 1990. Work still needs to continue as a number of 836 million live with less than 1.25 USD/day and the sad fact is that 80% of them live in Southern Asia and Sub-Saharan Africa. As a result, there are 795 million people that are undernourished around the world.

Ensure environmental sustainability is a general desiderate taking into account the influence of climate change on food producing systems. As a result of the acknowledgement of this danger to human kind, the world leaders decided to make the best effort to stop the global warming by reducing the green house gas emissions.

In Figure 2 we can observe that the developed regions registered a decrease of the level of CO_2 emissions, but the developing countries almost tripled their emissions in the analyzed period. As a result, the global emissions of CO_2 increased by 50% since 1990. This opposite trend is generated by the need of developing regions to reach a higher level of development and they argue that developed regions already contributed to the global warming problem before its manifestation through climate change. From this point of view the emission problem can only be resolved by the transition to a green economy of both groups of countries and developing countries should receive some kind of assistance because they lack the necessary funds for this transition. Green investments are the only way forward because if the emissions of green house gases continue the planet will get warmer and warmer with long-lasting changes of climate, endangering people lives and ecosystems with irreversible consequences. These consequences will be felt across the globe and will affect the agriculture which may lead to food shortages.



The Millennium Development Goals concentrated the international community towards the accomplishment of eight goals. As a result, the resources were concentrated on these goals and the results showed that fifteen year goals are feasible and eliminates the possibility of being concentrated on too many targets at the same time and miss them. The results were so good that the world leaders decided

"to free the human race from the tyranny of poverty" and "to heal and secure our planet" (UN, 2015) and in September, 2015 the General Assembly of United Nations approved the Agenda 2030 as the next level with 17 Sustainable Development Goals and 169 targets as it fallows:

1. End poverty in all its forms everywhere
2. End hunger, achieve food security and improved nutrition, and promote sustainable agriculture
3. Ensure healthy lives and promote well-being for all at all ages
4. Ensure inclusive and equitable quality education and promote life-long learning opportunities for all
5. Achieve gender equality and empower all women and girls
6. Ensure availability and sustainable management of water and sanitation for all
7. Ensure access to affordable, reliable, sustainable, and modern energy for all
8. Promote sustained, inclusive and sustainable economic growth, full and productive employment and decent work for all
9. Build resilient infrastructure, promote inclusive and sustainable industrialization and foster innovation
10. Reduce inequality within and among countries
11. Make cities and human settlements inclusive, safe, resilient and sustainable
12. Ensure sustainable consumption and production patterns
13. Take urgent action to combat climate change and its impacts
14. Conserve and sustainably use the oceans, seas and marine resources for sustainable development
15. Protect, restore and promote sustainable use of terrestrial ecosystems, sustainably manage forests, combat desertification, and halt and reverse land degradation and halt biodiversity loss
16. Promote peaceful and inclusive societies for sustainable development, provide access to justice for all and build effective, accountable and inclusive institutions at all levels
17. Strengthen the means of implementation and revitalize the global partnership for sustainable development

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

In order to accomplish the Sustainable Development Goals an immense financial effort must be made to develop specific mechanism that allow the efficient way towards the completion of these goals. New legal frameworks must be created in order to implement the Sustainable Development Goals. Also the Global Partnership for Sustainable Development must be strengthened by intensifying the cooperation between governments, private sector and civil society.

The EU Set of Sustainable Development Indicators (SDIs)

Sustainable development is an important objective of the European Union as it is stated in the Article 3 of the Treaty on European Union. The progress towards sustainable development of the EU is measured with the help of Eurostat through the set of sustainable development indicators (EU-SDIs). They are part of the EU Sustainable Development Strategy (EU-SDS) and every two years a report from Eurostat presents the evolution towards sustainable developments.

The first set of EU-SDIs was proposed in 2001 as a result of the EU-SDS adoption and revised in 2006. The EU-SDIs are revised by the Commission under the assistance of a working group formed by statisticians and policy representatives.

The EU-SDIs is composed by ten thematic areas from the economic, social, environmental, global and institutional dimensions (Sustainable development in the European Union — Key messages, 2015): socioeconomic development, sustainable consumption and production, social inclusion, demographic changes, public health, climate change and energy, sustainable transport, natural resources, global partnership, good governance.

Inside each theme there is a three level set of indicators. At the first level we have the headline indicators that are widely used indicators with high communicative power that monitors overall objectives. The second level is composed from indicators related to the operational objectives of the EU-SDS. The third level is composed from indicators that are perfect for progress analysis.

Next we will analyze some indicators with a high impact on the topic of green investments, food security and food systems.

The eco-innovation index is an indicator that wants to depict the eco-innovation performance between EU Member States. It is composed of 16 indicators grouped in five areas: eco-innovation inputs, eco-innovation activities, eco-innovation outputs, resource efficiency and socio-economic outcomes.

As we can see from Figure 3, the highest scores are obtain by the countries from northern Europe, which have a high level of development like Finland, Sweden, Germany, Denmark and United Kingdom with scores of over 120. At the opposite we find former communist countries like, Bulgaria, Poland, Slovakia, Latvia and Croatia with scores of under 60.

The organic farming is promoted and sustained by the European Action Plan for Organic Food and Faming. Between 2007 and 2012 there has been registered an increase of the area cultivated with organic cultures by 42.5%, with an average increase of 7.3% per year, reaching a total of 5.7% of all agricultural area in the EU, generating sales of 22 billion EUR.

In Figure 4 we can see the share of agricultural area used for organic farming in 2012. Austria leads, with a share of 18.5% of its total agricultural area and we cans see that latter members of the EU like Estonia, Latvia, Czech Republic, Slovenia and Slovakia find themselves above the EU average of 5.7%.

In 2014 the European Commission proposed a new regulation on organic farming, the labeling of organic products, and a plan of 18 actions for future of the organic sector up to 2020 (European Commis-

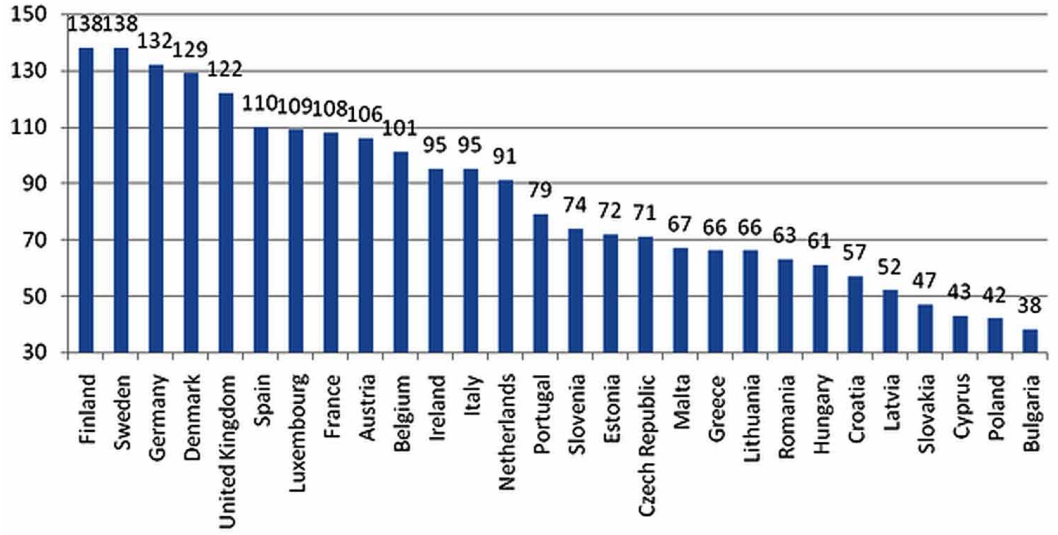
Figure 3. Eco-innovation index 2013 (EU=100)
Source: Based on the data available on Eurostat



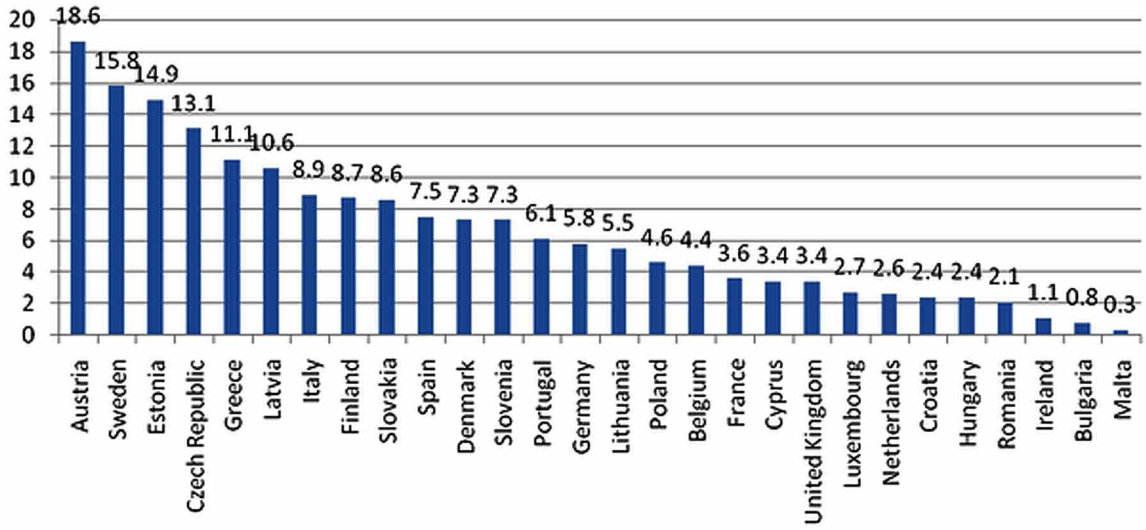


Figure 4. Areas under organic farming 2012 (%)
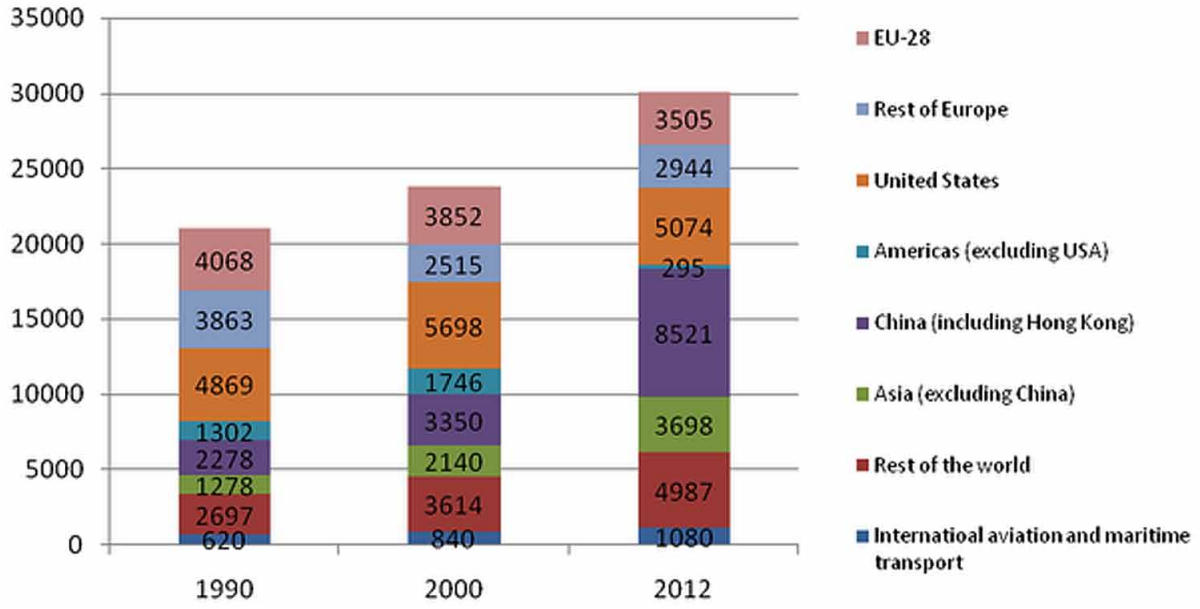
Source: Based on the data available on Eurostat

sion, 2014). This regulation focuses on two axes, one is to increase the EU organic farmers productivity and the second is to ensure consumer confidence.

The level of annual greenhouse gas emissions is an indicator that includes six gases: carbon dioxide, methane, nitrous oxide, hydrofluorocarbons, perfluorocarbons and sulphur hexafluoride. The emissions of these gases are transformed in CO_2-equivalent using weighting factors according with the global warming potential each gas has.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

In Figure 5, we observe that the total CO_2-equivalent emissions have increase over time. This increase is not generalized and we can observe that between 1990 and 2000 all the regions registered increases of greenhouse gas emissions except the EU-28. One aspect that needs to be mentioned here is that in the 1990 – 2000 period, many of the Central and Eastern Europe economies passed through the transition process from communism to capitalism system, which generated a painful restructuration of former industry companies, many of them disappearing and so they stop emitting greenhouse gas emissions. This also influenced the decrease registered by the rest of Europe along with the influence of the Yugoslavian Wars, which produce high economic damage, stopping the activity in former Yugoslavia's countries.



Between 2000 and 2012 we observe that the trend switch for United States, one of the highest generator of greenhouse gas emissions and Americas (excluding USA). EU-28 member states continued their emission reduction mainly due to the European Trading Scheme which is the mechanism used by the EU to implement the Kyoto Protocol stipulations, the success in implementing the national renewable energies promotion in the power sector, creating of building insulation standards, the changes of Common Agriculture Policy etc.

After the transition and the regional conflicts passed, the rest of the Europe group increased their greenhouse gas emissions after revitalizing their industrial and economic activity.

Asia (excluding China) had a steady increase of greenhouse gas emissions along with the rest of the World Group. The development of maritime and aviation sector contributes to the emissions with an important share.

China (including Hong Kong) became in 2012 the largest greenhouse gas emitter in the world surpassing the United States. China based its economic development by ignoring the pollution problem, which now generates important problem for the healthcare system, air and water quality for its citizens.

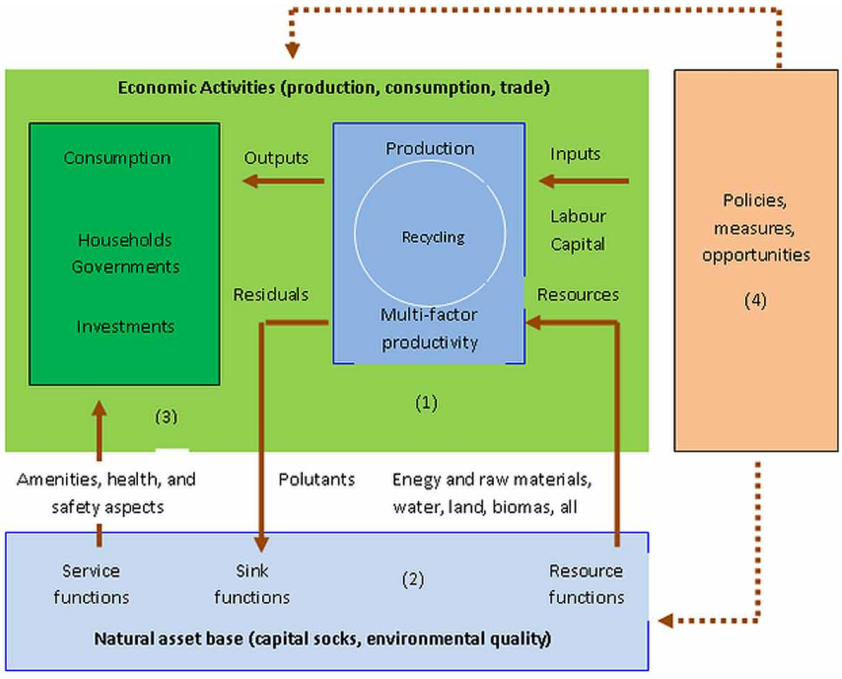
Green Growth Indicators



OECD Green Growth Indicators aims to measure the evolution towards a greener economy, to prevent climate change and to protect the natural resources and biodiversity. This set of indicators is in concordance with the international initiatives towards measuring the influence of human activities on the environment and the methods used to minimize it.

Green Growth Indicators are composed of four main areas (OECD, 2014):

1. **Environmental and Resource Productivity:** To capture the need for efficient use of natural capital and to capture aspects of production which are rarely quantified in economic models and accounting frameworks (1 in Figure 6).
2. **Economic and Environmental Asset:** Because sustained growth requires the asset base to be maintained and because a declining asset base presents risks to future growth. Attention is given to natural assets (2 in Figure 6).
3. **Environmental Quality of Life:** To capture how environment conditions and amenities interact with people's lives (3 in Figure 6).
4. **Economic Opportunities and Policy Responses:** To help discern the effectiveness of policy in delivering green growth (4 in Figure 6).

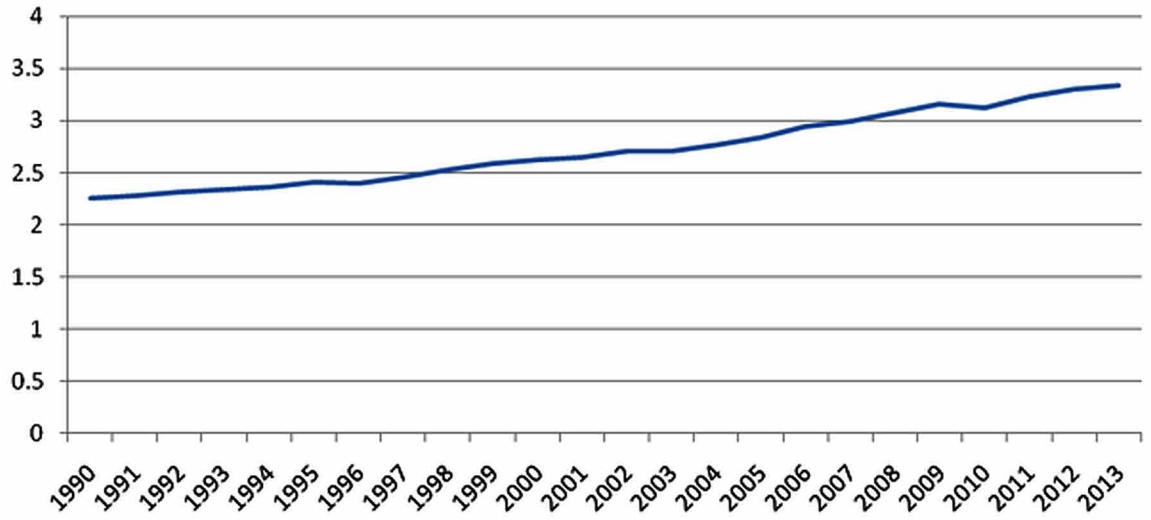
A fifth group of indicator is represented by the indicators that indicate the socio-economic context and the growth characteristics.

Figure 6. Conceptual measurement framework
Source: OECD (2011), Towards Green Growth Monitoring Progress OECD Indicators

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

The conceptual framework was presented in Towards Green Growth: Monitoring Progress Report from 2011 which focus on the connection of the principles of green growth, accounting principles and pressure-state-response model for environmental reporting.

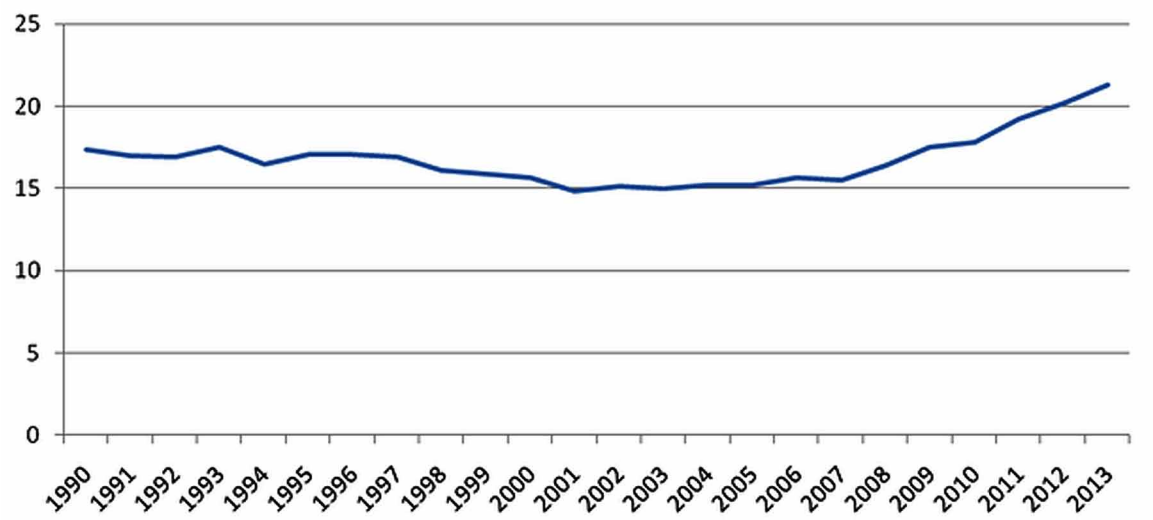
Next we will present some of the most relevant indicators to our study.



First indicator that we will explore is the productivity of CO_2 production based. As we can see from Figure 7 the productivity of OECD economies registered a steady growth throughout the entire period. At the same time the emissions of greenhouse gases has increased at a lower rate than the GDP, showing signs of decoupling. The financial crisis had an important effect on the reduction of greenhouse gas emissions due to the reduction of the economic activity. The increase of the production based CO_2 productivity may be the result of a switch towards non-fossil fuel energy, the results of environmental policies, the achievement of energy efficiency and the transition of industry away from energy intensive activities. This productivity is not achieved throughout all the sectors, as almost two thirds of emissions are from transport and electricity/heat generation.

Energy productivity increased in the last decade and this was achieved with the decoupling from environmental effects for some countries as a result of structural changes and the promotion of energy conservation policy. However, these results are not enough to achieve the goal of capping the global warming process.

In Figure 8, we can observe the evolution of the share of renewable electricity production from the total produced and we see that the share has increased in the later years. Now, renewable energy accounts for one fifth of the total electric energy generated.



Even though the energy mix changed a lot from 1990, when the oil and coal shares decline in favor of gas and other sources, the OECD countries still rely on fossil fuels in a proportion that exceed 80%. Only a few countries are above the 20% of electricity from renewable sources and the largest share come from biomass and hydropower followed by bioenergy, liquid biofuels, solar and wind.

Freshwater is one of the most important resource for environment and the economy, especially the agriculture. The main problem for this resource is represented by the overexploitation, degradation of environment quality. Its quality is influenced by water abstraction, pollution, climate and weather.

The main concern is to provide an adequate management of water sources so that it can be available and at a suitable quality for the use in human activities and to support aquatic and other ecosystems.

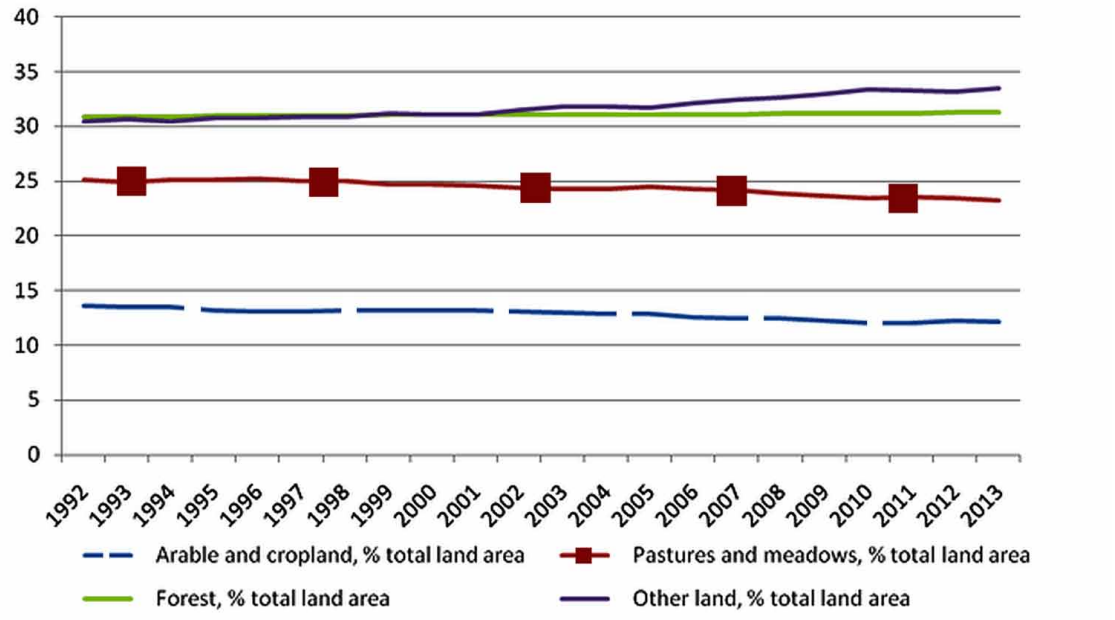
In Figure 9, we see that the level of freshwater abstraction registered a steady descending trend throughout the period. This means that there has been a decoupling effect from GDP growth. This trend

Figure 9. Total freshwater abstraction per capita (Cubic metres per capita)
Source: Based on the data available on OECD, Green Growth Indicators 2014

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

has been caused by the efficient use of freshwater in different sectors and the use of alternative water sources like water reuse and desalinization. The agriculture water use increased in many OECD countries, as the irrigated land increased, but the production showed a higher increase.

Another important natural asset base resource is represented by the land and soil. They are critical for the production of food and other biomass, the productivity of ecosystems and preservation of wildlife and plants. In order to ensure a sustainable management, we have to reconcile competing demands for land and soil resources, while keeping its essential ecosystem functions. In order to accomplish this we need territorial planning, appropriate governance and coherence with sectoral policies.



In Figure 10, we see the distribution of land use on the next domains: arable and cropland, forest, pastures and meadows and other land use. The arable and cropland registered a descending trend throughout the period from 13.55% in 1992 to 12.07% in 2013 as the pastures and meadows which decreased from 25.1% in 1992 to 23.22% in 2013.

Forest area registered an increase from 30.88% in 1992 to 31.24% in 2013. The highest increase was registered by the other land from 30.47% in 1992 to 33.47% in 2013. Because of these trends, the biodiversity has declined in OECD countries. The fragmentation, degradation of environment and conversions to other types of land is a phenomenon that needs to be closely watched. Pastures have declined as they have been converted to forests. As of 1990, the agricultural land area registered a decrease of around 0.5% per year as the farmland is converted to forestry and urban development.

Agri-Environmental Indicators

In order to promote sustainable development in agriculture, the Food and Agriculture Organization of the United Nations created a set of Agri-environmental indicators (AEI) with the role to describe and

Figure 10. Distribution of land resources (% of total land area)
Source: Based on the data available on OECD, Green Growth Indicators 2014

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

evaluate the evolution of agricultural environmental performance (Table 3). This has the role to supply scientists and policymakers with the suitable data regarding the environment and the effects and efficiency of policies on the environment. This set of indicators needs to be relevant to the targeted public and, that is why, they are organized to five categories in concordance with the Driving force-Pressure-Stat-Impact-Response (DPSIR) model proposed by the European Environment Agency (EEA, 1999) based on the PSR mode (OECD, 1993).

Next, we will analyze some of the representative of agri-environmental indicators. Ammonia emissions are generated by animal farms and they are responsible for acidification. The main sector with the highest ammonia emissions is the agriculture with shares of 80%-99%. Ammonia contributes to soil and water acidification, and the ammonia from atmosphere can combine with other industrial and transport contributing to secondary particle pollution.

Table 3. Agri-environmental indicators

Domain	Subdomain	Indicator
Air and Climate Change	*Ammonia emissions*	Ammonia (NH_3) emissions from agriculture as a % of total NH_3 emissions
Energy	*Energy use in Agriculture and Forestry*	Agriculture and forestry use as a % of total energy use
	Bioenergy Production	Bioenergy production as a % of total renewable energy production
Fertilizers Consumption	*Nitrogen consumption*	Nitrogen nutrient use on arable and permanent crop area (N tonnes/1000 ha)
	Phosphate consumption	Phosphate nutrient use on arable and permanent crop area (P205 tonnes/1000 ha)
	Nitrogen Phosphate	Nitrogen and Phosphate nutrient use on arable and permanent crop area (N+P205 tonnes/1000 ha)
Land	*Agricultural area*	Agricultural area as a % of land area
	Agricultural area use change	Changes in agricultural area (% per year)
	Area equipped for irrigation	Area equipped for irrigation as a % of agricultural area
	Conservation agriculture	Conservation agriculture area (>30% group cover) as a % of agricultural area
	Cropping patterns	Permanent crops area as a % of agricultural area
	Organic agricultural area	Permanent meadows and pastures area as a % of agricultural area
	Protected land area	Arable land area as a % of agricultural area
Livestock	*Livestock Density*	Livestock total per hectare of agricultural area (livestock total number/ha)
	Cattle and Buffalo	Cattle and Buffalo as a % of total livestock
	Pigs	Pigs as a % of total livestock
	Sheep and goats	Sheep and goats as a % of total livestock
	Poultry birds	Poultry birds as a % of total livestock
Pesticide	*Pesticides Use*	Pesticide use on arable and permanent crop area (tonnes/1000 ha)
Soils	*Soil Erosion - GLASOD*	Average soil erosion expressed in GLASOD erosion degree
	Land degradation - GLASOD	Average land degradation expressed in GLASOD erosion degree
	Carbon in topsoil	Average carbon content in the topsoil as a % in weight
Water	*Water use in agriculture*	Water withdrawal for agricultural use as a % of total water withdrawal

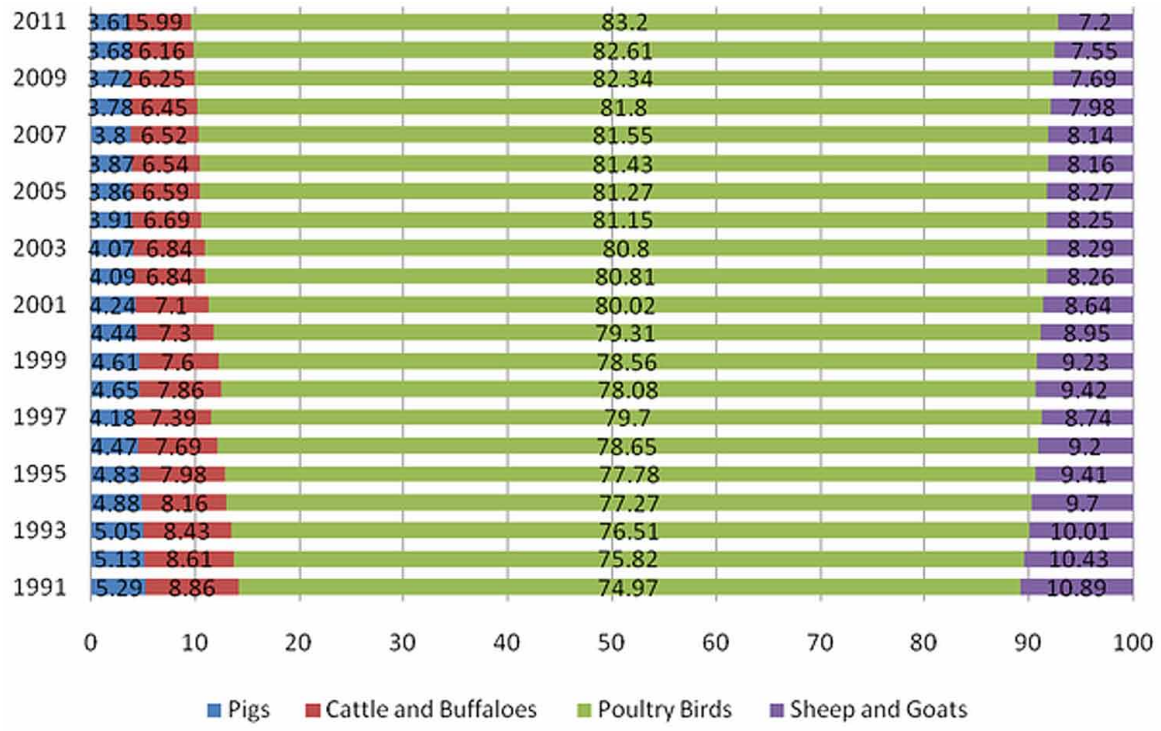
1000 Ha 2002 to 174.98 tonnes in 2010. The second ranking region is the Americas with 76.97 tonnes in 2010 followed by Africa with 62.79 tonnes, Europe with 58.72 tonnes and Oceania with 16.24 tonnes.



In Figure 13, we can observe the trend of cattle, buffaloes, pigs, sheep, goats, and poultry as a % of total livestock 1991-2011. We observe that the poultry birds increased their share in the analyzed period from 74.97% in 1991 to 83.2% in 2011 based on the reduction of sheep and goats share from 10.89% in 1991 to 7.2% in 2011, cattle and buffaloes from 8.86% in 1991 to 5.99 in 2011 and pigs from 5.29% in 1991 to 3.61 in 2011.

CURRENT DIMENSIONS AND CHALLENGES OF THE WORLD FOOD SECURITY

Humanity is today witnessing startling discrepancies: developed countries have accumulated significant food excess while low income and developing countries face the persistence of malnutrition which cause the death of millions annually, mostly children. In this situation, commendable efforts are made at internationa level, encouraging practical support and long-term involvement of a large number of states in terms of fairness and solidarity.

The concept of food security has dynamically evolved over time, expanding its meanings and connections, so that, at present, in the broadest sense, it encompasses all aspects that allow optimal access of population to food. Beyond any socio-economic, political or cultural differences, everyone has a

Figure 13. Trend of cattle, buffaloes, pigs, sheep, goats, poultry as a % of total livestock 1991-2011

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

fundamental right - the right to food - whose materialization is not accomplished everywhere in the best conditions.

The internationally dedicated definition – and the most popular - was established at the World Food Summit (WFS) in 1996 and reaffirmed in 2002, affirming that food security exists "when all people at all times have access to sufficient, safe, nutritious food to maintain a healthy and active life"(World Food Summit, 1996).

The concept of food security, as defined above, was approached and developed on multiple levels during many international meetings on food security worldwide, expressing an essential goal of economic and social development. It is built on three pillars which form its foundation and practical reflections (United States Agency for International Development, 1992; World Health Organization, 2015):

- **Food Availability:** Sufficient quantities of food available on a consistent basis;
- **Food Access:** Sufficient resources to procure adequate foods for a nutritious diet;
- **Food Use:** Appropriate use based on knowledge of basic nutrition and care, as well as adequate water and sanitation.

Food security obviously depends on food availability and food access (Gavrilescu & Giurcă, 2001), but it certainly means addressing extended issues simultaneously, including aspects such as food innocuousness and nutritional balance. Individual food consumption behavior also plays a major role within the food use aspect, due to its complex linkages with personal preferences, dietary habits and traditions (Stancu, 2015) and nutrition education level.

These sides can be covered by right correlation between food and nutrition policies. Food policy aims to ensure the necessary quantity and quality of foods for the entire population at affordable prices, while nutrition policy should effectively approach food and nutrition education (Jukes, McGuire, Method, & Sternberg, 2002).

All these meanings and correlations involve, firstly, ensuring adequate foods obtained either from domestic production, imports or food aid. As a specific type of measure, the motivation of international agricultural interventions assumes that generating income at family level is an effective means to reduce poverty and ensure food security (Bonnard, 1999). Thus, achieving food security is synonymous with dealing with many facets of the food problem - globally, regionally and nationally (Gavrilescu & Giurcă, 2001).

At the moment, the world food situation is not reassuring, since widening disparities between rich and poor countries continuously add new dimensions to the food problem. Inequality and inequity in foods distribution lead to absurd situations that are hardly conceivable for the contemporary civilization.

In this context, international cooperation is becoming more geared towards tackling the food issue and its related aspects - of systemic nature - that humanity is facing today.

Being an essential starting point at global level, the WFS in 1996 set the target of halving the number of undernourished people by 2015 compared to the period 1990-1992. Four years later, the same objective was reaffirmed by the Millennium Development Goals (MDG) proposing two related goals: halving both the proportion of people suffering from hunger and the proportion of those living on less than $ 1.25/day (United Nations, 2000; United Nations Development Programme, 2002). On this theme, the Food and Agriculture Organization of the United Nations (FAO) report entitled "The State of Food Insecurity in the World" (SOFI) is drafted each year as a result of the continuous efforts of FAO and other international partners to monitor nutritional status and to analyze the vulnerability of worldwide

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

population facing the food problem. All editions of SOFI report provide the latest estimates of the number of chronically undernourished people at global level as well as reports on global and national efforts made to achieve the WFS and MDG goals.

A common element of SOFI reports of recent years until 2010 was the indication that, globally, the pace of reduction in population suffering from hunger was so slow that, if it persisted, it would not allow the accomplishments of WFS and MDG commitments. Yet, each successive report starting 2011 pointed out that in several countries and regions significant progress have been made in reducing the number of undernourished people. In this regard, the SOFI 2014 report outlines essential estimates and accomplishments, as follows(Food and Agriculture Organization of the United Nations [FAO], International Fund for Agricultural Development [IFAD] & United Nations World Food Programme [WFP], 2014):

- Even if global hunger reduction continued, in the period 2012–2014 about 805 million people were still chronically undernourished, while the prevalence of undernourishment has fallen from 18.7% to 11.3% globally and from 23.4% to 13.5% for developing countries;
- Regarding the comparison with WFS and MDG goals, since 1990-1992, 63 countries have reached the hunger target of MDG and 25 countries have achieved the WFS target, while undernourishment level fell below 5% for 11 of the 63 developing countries, proving that the hunger target of the MDG still was within reach;
- Even though overall progress in increasing food security was obvious, significant differences persist across regions: while Latin America and the Caribbean have made the most visible overall progress – by strengthening political commitment to food security and nutrition, modest progress were reported for sub-Saharan Africa and Western Asia - afflicted by conflict and natural disasters;
- Hunger eradication should rely on sustained political commitment at the highest level, considering food security and nutrition as top priorities, as it requires an integrated approach including: investments for enhancing agricultural productivity; access to inputs and markets; measures for rural development; social protection; specific nutrition programmes.

Marking the moment of final balance from the perspective of the MDG monitoring period, the SOFI 2015 report highlights a series of facts revealing global and regional dates and facts (FAO, IFAD & WFP 2015):

- Over the last ten years, global hunger has continued to gradually decline, with a reduction of 167 million hungry people, to an estimated 795 million undernourished people (especially in developing countries);
- The MDG hunger target was missed by a small margin, considering the developing regions, while some regions (Latin America, the eastern and south-eastern regions of Asia, the Caucasus and Central Asia, and the northern and western regions of Africa) have reached the target due to their fast progress in reducing undernourishment;
- Out of 129 developing countries, 72 have reached the MDG hunger target due to economic growth, stable political conditions and adequate social protection policies;
- Inclusive economic growth is a key factor of success in reducing undernourishment, providing real opportunities for the poor to improve their livelihoods: raising the productivity of family farmers, strengthening social protection mechanisms, well-functioning markets and equitable governance;

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

- Protracted crises caused by conflict, political instability or natural disasters had a heavy impact on vulnerability and food insecurity, imposing the need for strong political commitment, and the integration of humanitarian and development.

Yet, despite the progress made by some countries and regions, the food global problem is far from being resolved in a definitive and durable manner.

Every edition of SOFI report reveals several factors hindering the growth of food production in some parts of the world, the most common being:

- Reducing the areas of agricultural land due to desertification, erosion, floods, waste deposit, use for various construction;
- Lack of irrigation water during the crops growing season;
- Application of primitive technologies;
- Poor availability of permanent pastures for the whole livestock;
- Low level of agricultural yields;
- Insufficient financial resources allocated for agricultural production and food industry compared to other branches of the economy;
- Population growing faster than agricultural production.

Also, most SOFI reports insist that a healthy agricultural sector could be the way out of the crisis, especially in low-income countries, and a possible decline in investment in the sector should be avoided (FAO, 2009), so that agriculture plays its role as an engine of resuming growth, poverty reduction – being a long-term pillar in the fight against hunger.

COULD GREEN AGRICULTURAL PRACTICES BECOME THE KEY TO FOOD SECURITY?

In order to analyze the food issue as a global problem of humanity and to identify possible eradication ways it is necessary to start with a systematic approach to economic phenomena and processes. Currently, this complex array includes a number of trends, contradictions and paradoxes, of particular concern being the danger of environmental degradation, with serious implications for the future of humanity.

The Key Role of Agriculture in Ensuring Food Security

As a primary field of activity, agriculture has known over time stages that have strengthened its economic and strategic importance, its results being closely linked with the very existence and development of mankind. Agriculture has always been and remains the main source of food for a growing population, especially considering the demographic explosion in low-income countries.

For these reasons, it is clear that agriculture plays a decisive role for the rapid economic progress, the industry development and raising living standards depend on it; for that matter, agriculture ultimately enables access to food security.

World's experience shows that before reaching their actual level, industrialized countries went through an agriculture-based development, and that, at present, a modern economy is inconceivable without an

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

advanced agriculture. Everywhere in the civilized world, food production is considered of high priority, agriculture representing a main branch of economy, while food security is considered to be a key element in any project for agricultural development.

This approach involves prioritizing and according facilities to increase the capacity of agriculture to feed the population, based on the rational use of natural resources and on specific opportunities that support the development of numerous upstream and downstream activities, revitalizing and improving the attractiveness of rural areas (Zahiu, 1999), using a complex set of instruments (Figure 14).

Specifically, a number of national and sectoral policies and measures could support the role of agriculture in solving the food problem (Bulgaru, 1996; Chivu, 2002; Gavrilescu &Giurcă, 2001):

- **Fiscal Policy:** It aims to create fiscal incentives for farmers to enhance their ability to be profitable and to obtain loans for investment. This policy accompanies and guides the transformation dynamics of farmers from households scale farms (created for subsistence) to investment-oriented commercial farms, implying a gradual adjustment of fiscal policies;
- **Agriculture Support Policies:** These aim to create the necessary support structures so that farming becomes a profitable branch: investments in rural infrastructure (electrification, road maintenance, irrigation); support for agricultural research and development – focusing on family farms; support for the development of agriculture extension and advisory services;
- **Food Production Development Support Policies:** Measures to facilitate investment in research etc.
- **Support Measures for the Development and Operation of Agriculture:** Input/output market, market transparency, exports support
- **Support Policies for Quality:** Their objective is to ensure that foodstuffs (local or imported) comply with accepted international standards. This involves defining standards for quality and safety, establishment and operation of control bodies which operate according to internationally accepted standards.

Another aspect of food security lies in the adequacy of food intake, which implies a permanent balance between body's physiological needs and the amount of nutrients consumed. An important fact is that not all agricultural projects that have a potential nutritional impact aim to explicit nutritional purposes. Often, the nutritional impact appears as an unplanned, indirect effect. In this case, it is not monitored within the projects, even if it exists (Bonnard, 1999).

At present, there is a strong orientation trend towards sustainable agriculture based on organic fertilizers and pest control measures derived from nature, which could constitute the key to environmental protection and to solving food problem in the same time.

Figure 14. Instruments for agri-food policies

The Need for Green Agriculture: Present and Perspectives

In many countries, global economic and environmental developments lie in the core of growing concerns, intensified by prolonged global crises (including energy, financial and food crises) and underscored by scientists warning about the effects of exceeding environmental limits.

In these conditions, green economy (in its various forms) has been proposed as a means of supporting sustainable development by catalyzing national policy development and international cooperation (United Nations Department of Economic and Social Affairs [UN DESA], 2012).

During the last years, these preoccupations continuously amplified, but a series of setbacks have slowed the development in this field: confusion or lack of consensus on terminology; a lack of clarity regarding specific policy measures and their integration within national priorities and objectives, a lack of experience in designing, implementing and reviewing the costs and benefits of green economy policies (UN DESA, 2012).

A series of recent publications regarding green economy or green growth show the growing interest in this approach which is regarded as a possible solution, a necessary way to go and as an integrated manner of addressing current and future local and global stringent issues. the most important contributions in the field belong to the following organizations: UNEP, UN DESA, the United Nations Conference on Trade and Development (UNCTAD), the International Labour Organisation (ILO), the World Bank, the Organisation for Economic Cooperation and Development (OECD), the Global Green Growth Institute (GGGI), the Green Economy Coalition, Stakeholder Forum, the Green Growth Leaders etc. (UN DESA, 2012).

A decisive set of discussions on the green economy held place within the United Nations Conference on Sustainable Development at Rio de Janeiro in June 2012 (also referred to as Rio+20), which covered two themes: (a) a green economy in the context of sustainable development and poverty eradication; and (b) the institutional framework for sustainable development. FAO's contribution to the Rio+20 agenda included an initiative aiming to shaping the definition and implementation of the green economy, named The Greening the Economy with Agriculture (GEA), with a particular emphasis on food security (FAO, 2012).

The "Green Economy" approach of UNEP to sustainable development is based on the need to catalyze sustained economic development through the regeneration of life-sustaining natural resources by re-focusing the global economy towards investments and expenditures in specific economic sectors, including agriculture.

Food security and nutrition as a global issue is also a major preoccupation of the Group of Twenty (G20) agenda, which turns to an integrated and sustainable "food systems" approach. In this direction, G20 actual Food Security and Nutrition Framework drafted in 2014 sets out three integrated priority objectives, as follows (G20, 2014):

1. Increase responsible investment in food systems
2. Increase incomes and quality employment in food systems
3. Increase productivity sustainably to expand the food supply

Unfortunately, agriculture itself is a part of the range of human activities that generate pollution effects of air, water and soil (Iacovoiu, 2009) due both to massive deforestation and to the use of pesticides, fertilizers and genetically modified organisms. Because of unsuitable management practices, agriculture

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

is a significant contributor to climate change; crop and livestock production is responsible for 13.5% of global greenhouse gas emissions. Its considerable ecological impact stimulates increasing global concern.

The perspective of increasing environment degradation gradually acquired new dimensions since, in the context of increased globalization, the setting of permissive environment countries in developing countries facilitated the transfer of highly polluting activities through foreign direct investment made by developed countries (Iacovoiu, 2009).

While the Green Revolution was the right solution for the food crisis fifty years ago, FAO appreciates that today the world needs an innovative way forward that responds to actual needs, as challenges are different (FAO, 2014).

In the context of global concern for food security of recent years, the concept of sustainable agri-food development was formulated - inextricably linked to the global development process. Within this frame, food availability is derived from domestic agricultural output resulting from the use of sustainable natural resources (Webb & Rogers, 2003).

In the same line, The Committee on World Food Security (CFS) which acts as an intergovernmental body for review food security policies approved in October 2014, during its Committee on World Food Security 41st Session, the Principles for Responsible Investment in Agriculture and Food Systems, applicable to all types and sizes of agricultural investments. These principles promote sustainable and inclusive economic development, supporting the conservation and sustainable management of natural resources, diversity, innovation for safe and healthy agriculture and food systems (CFS, 2014).

The global problem of future food security rises from the challenge of feeding a population of 9 billion by 2050 (FAO, 2009; UN DESA 2011), which decisively depends on higher agricultural output.

UNEP's 2011 report, Towards a Green Economy, drafted by Green Economy Initiative in collaboration with economists and experts worldwide contains essential clarifications about greening the global economy, and consistently assist policy makers on reforms needed in order to fructify the full potential of a green economy.

The report contains relevant key messages regarding the role of sustainable agriculture in this context (UNEP, 2011), showing that actual concerns regarding the growing population, poverty, undernourishment, climate change, depletion of natural capital (deforestation, loss of biodiversity, excessive quantities of pollutants), waste and losses could be addressed by investments and policy reforms aimed at greening agriculture, which could ensure food security on a sustainable basis by providing better employment and higher nutritional levels.

In this context, in 2011, FAO also recognized that agriculture based on the intensive use of inputs for the past fifty years led to increased global food production and average per capita food consumption but also created the premises of jeopardizing future productivity by depleting natural resources of agro-ecosystems, and adding to many factors responsible for climate change. As a result, FAO proposed a new paradigm – named "Save and grow" (FAO, 2014) based on sustainable food management for obtaining of intensive crop production that is both highly productive and environmentally sustainable.

This ecosystem-based approach, suitable for small-scale producers is assimilated to a "greening of the Green Revolution" and combines traditional knowledge with modern technologies. It encourages the use of conservation agriculture, soil organic matter, water flow regulation, pollination, biocontrol of insect pests and diseases, judicious use of mineral fertilizer etc (FAO, 2014). Though, its success depends on

tangible advantages for farmers – who should be compensated for generating environmental benefits – such as higher incomes, reduced costs and sustainable livelihoods.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

The need for innovation in family farming is highlighted in SOFA 2014 report, which shows that over 500 million family farms manage the majority of the world's agricultural land and produce most of the world's food – thus playing a key role in ensuring global food security. The need to feed a growing global population requires solutions adapted to local conditions, providing productivity growth only through sustainable intensification (FAO, 2014), by protecting and enhancing natural resources and ecosystems.

Despite difficulties and crisis, significant achievements were made in the agricultural sector regarding the increased global crop production, opportunities for employment and livelihoods and the shift to organic farming, which proved to be economically profitable (UNEP, 2009). Research show that this new approach in the agricultural sector brought various benefits (UNEP 2009, UNEP 2011) in terms of:

- **Environmental Protection:** Sustainable farm management results in: higher soil fertility, equivalent or higher yields than conventional farming, energy efficiency, lower greenhouse gas emissions than conventional farms, higher carbon sequestration efficiency, higher levels of biodiversity as, as a long-term soil fertility and therefore healthy ecosystems;
- **Food Security:** Increased yields and productivity, sustainable jobs creation – thus supporting community development.

In order to benefit from the economic, social and environmental advantages associated to greener and sustainable agriculture, governments and businesses should follow existing investment opportunities in this field, including: storage and transport infrastructure, green processing, production, marketing and trade of green inputs (e.g. organic fertilizers, biological/ integrated pest control methods), irrigation infrastructure; loans programmes for farmers (UNEP, 2009).

This commitment towards greening agriculture requires national and international policy reforms, innovation and technology transfer (G20, 2014), backed by investment, research and capacity building (UNEP, 2011).

On the same note, in order to minimize adverse impacts of biofuels production on global food security, there is a need to intensify efforts for the development of technologies for second-generation biofuels produced from non-food biomass feedstock (UNEP, 2011).

The transition to green and more sustainable farming practices is expected to enhance agricultural production and improve the quality and quantity of food supplies (Herren, Bassi, Tan, & Binns, 2012). In terms of job creation, transitioning to a green economy is expected to create more employment – over 200 million fulltime jobs by 2050 (FAO 2012; Herren at el., 2012) – and many more over the long term across the entire food production and related systems. (Herren et al., 2012; Fan, Ringler, Nkonya, & Stein, 2012).

This shift towards more sustainable practices will require substantial changes in policy interventions:

- Fiscal measures (such as subsidies, taxes, public R&D);
- Regulatory actions (such as standards, mandates and certification procedures);
- Public and international funding, especially for interventions in developing countries, due to their limited access to financial capital and foreign exchange;
- Public information and awareness campaigns.

This shift towards green agriculture should be sustained by governments and stakeholders focus efforts in creating and maintaining the appropriate framework involving subsidies, fiscal and monetary

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

instruments, trade measures, agricultural research, personnel training, building partnership, waste reduction, sustainable choices, health and environment requirements, institutions and entrepreneurial skills (UNEP, 2009).

Large corporations in the field will play a major role in supporting the transition to greener agriculture (UNEP, 2011), as they have the capacity to develop specific strategies and support sustainably oriented investments.

Investments in Agriculture: Under the Sign of Sustainability

The agricultural sector has an important role in the transition process to the green economy. This transition must have an ecosystem approach because the agriculture has the role:

- To ensure the right to adequate food, food and nutrition security (food availability, access, stability and utilization)
- To meliorate the quality of rural livelihoods
- To manage efficiently natural resources
- To improve resilience and equity throughout the food supply chain

At international level, there are many initiatives that focused on o sustainable agriculture and are interesting for many stakeholders implicated in this field (like states, inter-governmental and regional organizations, financing institutions, donors, foundations, research organizations, universities, smallholders, business enterprises, including farmers, civil society organizations, workers and their organizations, communities, consumer organizations):

- UNCTAD, FAO, IFAD and World Bank promote the Principles for Responsible Agricultural Investment
- The Committee on World Food Security (CFS) endorsed the Principles for Responsible Investment in Agriculture and Food Systems

In addition, FAO launched The Greening the Economy with Agriculture (GEA) Initiative. The main objective of this initiative is to increase the stability and resilience of food systems. Factors like extreme weather events, energy scarcity, economic and social disruption, malfunctioning of global markets are threats to the stability of food systems. (FAO, 2012).

The process of transition to green agriculture must take in account:

- The importance of agriculture in the national economies and the numerous stakeholders implicated
- The negative impact of agriculture on environment (loss of biodiversity and degradation of ecosystem services, depletion and erosion of top soil nutrients, an increasing scarcity of freshwater, aggravated water pollution)
- The existence of two types of agriculture:
    - Conventional/industrial agriculture that are energy-intensive, highly mechanized, has high productivity relies on the extensive use of chemical fertilizers, herbicides, pesticides, fuel, water, determined the shrinking the agricultural labor force and request continuous new investments in different types equipment and seeds

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

- Traditional (subsistence) smallholder agriculture based on older farming practices and characterized by low productivity

In fact, the specialists proposed a mix of the farming practices and technologies used for the greening of agriculture inspired by these types of agriculture. The purposes of the green investments in agriculture are the increase of farm productivity, the assurance of provision of food, the generation of positive externalities, the reconstruction of ecological resources, the more efficient use of natural resources and reduction of pollution.

The transition to green agriculture (Table 4) is a complex process that implicates public and private efforts. The activity of international organizations is essential in this process because they have the role to support the national authorities and to endorse guidelines or principles that are voluntary used by private actors.

FUTURE RESEARCH DIRECTIONS

In order to ensure good nutrition, in addition to the policy of ensuring the food availability (through production, distribution, international trade) to cover the consumption needs of the whole population, there is a strong need for a policy regarding the responsible resources utilization. The more so as, in the food chain of industrialized countries, the amount of energy consumed for processing, preparation, packaging, transport, distribution and storage of food is much higher than for agricultural production itself, further research is needed in order to design and promote both new concepts on the cost and value of food consumption and calculations for determining its effectiveness.

As a result, the objective of food security - to ensure for all, at any time, effective access to the food they need at a reasonable cost - must be doubled by optimizing the energy and nutritious cost of food up to the final consumption stage.

Other possible direction for research aims to establish a set of indicators of food security regulation, which include eco-investment in agriculture as an administrative tool to harmonize supply and demand of agricultural products, to increase employment level and to fulfill the requirements of sustainable development at the same time.

Table 4. Potential indicators for measuring progress towards green agriculture (UNEP 2011)

Action Indicators	Outcome Indicators
number of enacted and implemented policy measures and officially approved plans that promote sustainable agriculture	percentage and amount of land under different forms of green agriculture
level of governmental support to encourage farmers to invest in conversion to green agriculture and get the farm and the product certified	decline in use of agro-chemicals as a result of conversion to green agriculture; and the number and percentage of farmers converting to green agriculture
percentage of agricultural budget that is earmarked for environmental objectives	increasing proportion of payments for environmental services as a percentage of total farm income
proportion of available producer support used for environmental objectives as a percentage of total agricultural producer support	number of agriculture extension officers trained in green agriculture practices
approved measures that reduce or eliminate barriers to trade in technologies and services needed for a transition to a green agriculture	number of enterprises set up in rural areas, especially those that produce local natural agricultural inputs, to offer off-farm employment opportunities.

CONCLUSION

During the last decade, several concurrent crises – including food crisis – have unfolded, putting the livelihoods of billions at risk, affecting food security and consequently human health. Current economic approach based on sustainable development requirements are closely related to the recent orientation towards green economy, which could be a new engine of growth and a strategy for the elimination of persistent poverty and food insecurity. The efforts to achieve the goals of sustainable development are huge and suppose private initiative and public actions. The stakeholders like the private companies and individuals, governments, foundations, civil society organizations, development banks, governments, research and academic institutions response individually to the challenges of greening, but collective efforts are better and synergetic.

Sustainability is a desiderate that must be achieved in agriculture field too. Taking in account the importance of this sector in some national economies, the process of greening the economy is lead by agriculture. Even in the developed countries, the promotion of green agriculture is essential because the agriculture has many negative impacts on environment like land conversion and habitat loss, wasteful water consumption, soil erosion and degradation, pollution.

Agricultural sector is the focus of national and international efforts to ensure food security, remaining the engine of development of most low-income countries. Food security is an inalienable human right, an essential component of life safety, national security, and a supreme obligation of governments. The categories facing difficulties in terms of food security can fit in a wide variety of situations or typologies:

- Countries having significant agricultural potential in terms of natural and human resources (e.g. Asia, Latin America)
- Countries with low natural potential in terms of soil quality, climate, infrastructure, institutions (e.g. Africa)
- Countries with imbalances between forms of habitat, improper nutritional status of the population in rural areas, seasonal malnutrition, harvest instability due to climate and weather conditions (e.g. drought, floods)
- Conflict and political instability as major obstacles to development;
- Outdated agrarian structures
- Inadequate agricultural policies

Solving the food security issue should be addressed in a systematic and differentiated manner, both globally and nationally by:

- Reducing malnutrition
- Demographic growth regulation
- Ensuring food availability by developing agricultural production as a matter of priority, in accordance with the natural resources available in each country, avoiding depletion of nonrenewable natural resources
- Redesigning and improving food production in developing countries by industrialization, changing agricultural structures and introduction of green technologies and techniques that would simultaneously solve the problem of unemployment, increasing population incomes and purchasing power

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

- Obtaining clean and safe food, reducing food overconsumption and excess and malnutrition in industrialized countries, as it calls forth severe health implications of some categories of population
- Saving food resources, reducing costs and wastage, better utilization of resources in the food chain from the farm to the final consumer, in order to get affordable products with high nutritional value

Food access and use directly depends on the purchasing power of the population – which can be increased by creating jobs through investment policies that help reducing unemployment, increase income, thus enabling effective acquiring of necessary livelihood.

Emergency aid or imports do not provide a reliable basis for reducing the frequency and scale of food crises, so this doesn't provide a solution for sustainable agricultural development in poor countries to improve food consumption for the starving population.

Thus, the goal to ensure food security requires the reconsideration of the importance of agriculture by promoting its strategic role of utmost importance to the overall success of food policies. In this respect, it is necessary to establish several strategies to foster green investments directed towards specific areas like:

- Small farms production or farms that use extensive workforce
- Raising agricultural productivity
- Encouraging local processing of raw materials
- Enriching food resources by reconsidering certain plant and animal species

Addressing the food-population equation cannot occur by chance but by economic and social restructuring measures of agriculture in developing countries and by the systematic support of the international community, particularly through the facilities of green investment and technology transfer.

To ensure food security in the decades ahead, the focus will be on developing specific food security programs in each country, which will include orientation towards green agriculture and attracting the necessary investments in this area.

At present, agriculture stands as a key sector for greening economies, having a high potential to generate trade opportunities while contributing to the transition to a green economy. Food security and sustainable agriculture are placed at the center of the green economy and represent top priorities for many international meetings (e.g. Rio 20+).

In agriculture field, a new challenge is the production of the biofuels. The problem is that the land, the water and other resources are not used to produce foods. So, the food security could be affected. Because of that, the public authorities must have correlate the food security policy and biofuel policy and the main priority should be food security and the right to food. Taking in account the efforts made at international level to promote social responsibility in agriculture sector, the Principles for Responsible Investment in Agriculture and Food Systems should be implemented and monitored in the case of investments for biofuel production. The implications of foreign investors in the land acquisitions in developing countries raise an additional problem. The purchases of lands, often characterized as "land grabs", have implications on the local agricultural production and on the availability of foods for the local population.

KEY TERMS AND DEFINITIONS

Carbon Sequestration: Capturing anthropogenic or atmosphere carbon dioxide (CO2) before it is released to the atmosphere.

Food Insecurity: Lack of secure access to sufficient amounts of safe and nutritious food for a normal and healthy life.

Food Intake: An amount of food taken into the body as nourishment.

Greenhouse Gas: Gases whose absorption of solar radiation is responsible for the greenhouse effect.

Undernourishment: A state of inability to acquire enough food resulting in insufficient food intake to meet dietary energy requirements.

Chapter 80
Green Performance Strategies in Romanian Economy in the View of EU 2020 Strategy

Violeta Sima
Petroleum-Gas University of Ploiesti, Romania

Ileana Georgiana Gheorghe
Petroleum-Gas University of Ploiesti, Romania

ABSTRACT

This chapter aimed to investigate green performance strategies in the Romanian economy. In the first part, authors exposed specific definitions and concepts related to the green economy, as they appear in the literature in the field. The European context and the main ways of implementation of the green economy are presented as they result from the objectives of The Agenda 2020 UE and The Agenda 2030 UNO. Green Performance in Romania during 2010-2014 is assessed by analyzing the environmental protection expenditures, environmental taxes, greenhouse gasses emissions, green jobs roles, and Environmental Performance Index. The sustainable economic growth effects are materializing in a major growth of the ecological productivity, an increased amount of energy derived from renewable sources, emissions reduction, improved air and water quality, widened access to the benefits of civilization - education, water sanitation. Thus, this green growth "can fight" against climate change. Also, green growth provides opportunities for creating new jobs requiring new skills.

INTRODUCTION

Ecological concern began to become apparent in the early 70s. It has gained consistency after summits in Rio (1992) and Johannesburg (2002) and especially after the signing of the Kyoto Protocol, becoming an important element in defining organizational culture. Thus, "Green Revolution, environmental protection, turning in "green", sustainable lifestyles, sustainable development, planet protection and many such manifestations have become a phenomenon increasingly evident in our current life" (Sima & Gheorghe, 2014). Businesses have started to be reshaped on the one hand to meet the legislative pressures on the environment, and on the other hand to take advantage of new trends.

The transition to the green economy involves implementing social investment policies and addressing concepts like economic development, green marketing, biodiversity, ecosystems preservation, climate change, health and welfare for the medium and long term. Green buildings, green products, eco-friendly companies - all these words have become increasingly used in recent years. People around the world are striving to keep the Earth healthy by driving hybrid cars or electric cars, using solar and wind energy, recycling.

The green economy is a model of economic development or an economy based on sustainable development and knowledge of the green economy. Karl Burkart (2012) defines green economy as being based on six main areas:

1. Renewable energy (solar, wind etc.);
2. Green Buildings (ex. Construction LEED - Leadership in Energy and Environmental Design);
3. Alternative fuels (hybrid electric vehicles etc.);
4. Water management (water treatment systems, rainwater collection, etc.);
5. Waste management (recycling, etc.);
6. Land management.

A 7th category can be identified. This is represented by "green markets", including green banking and financial investment services; carbon trading etc.

BACKGROUND

Specific Definitions and Concepts Related to Green Economy

The concept of "green economy" began to become increasingly more present in the topics for debate of researchers across the world on sustainable development.

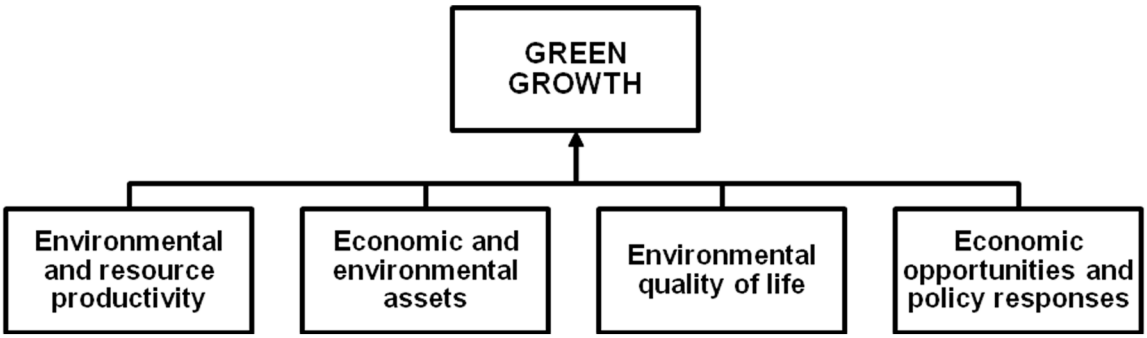
Reducing the level of non-renewable resources, climate change and, not least, the recent economic recession constitute challenges for academics, but especially for practitioners in economics. Thus, the tone was given by the UN Conference on the Human Environment (Stockholm, 1972), when The Environmental Programme of the United Nations (UNEP) was created. As a global player, the EU is in the forefront in international efforts to promote sustainable development, the EU applying some of the most advanced environmental standards in the world. Thus a UNEP Report in February 2011 released the following definition: "The green economy is defined as an economy that results in reducing environmental risks and ecological scarcities, and that aims for sustainable development without degrading the environment. It is closely related with ecological economics, but has a more politically applied focus."

The green economy can be a means to achieve sustainable development, representing an adaptation of the socio-economic system to the multiple challenges of the current period.

The transition to a green economy cannot be done instantly, but gradually through the elaboration and implementation of development policies and investments having as main goal to disconnect economic growth from increased consumption of raw materials and energy. Also, performances following the implementation of this model have proved that green economy was a good response to the global crisis of recent years, especially in managing social and environmental issues.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

According to Andersen and Massa (2000) the economic growth and a sustainable use of resources do not exclude each other. Green economy implies the adoption of specific environmental policies. This should lead to structural changes of the production and consumption patterns for the long term.



Specific concepts have been defined in the literature. According to Loiseau et al. (2015), seven main concepts are associated with green economy. They are: Bioeconomy or Biobased economy, Cleaner Production, Waste hierarchy approach, Nature-based solutions, Industrial ecology, Circular economy, and Servicising, functional economy.

1. Bioeconomy or biobased economy was defined as the economy involving the development and use of biological products and processes. In Europe, this concept takes into account in especially the use of renewable resources, innovation, sustainable growth and creation of added value (OECD, 2009; Brunori, 2013; EC 2012).
2. Cleaner production is a concept introduced by The United Nations Environment Programme in 1990, as "the continuous application of an integrated preventative environmental strategy to processes, products and services to increase efficiency and reduce risks to humans and the environment."
3. Waste hierarchy approach. The Directive 2008/98/EC set out a priority order five stages in waste prevention and management legislation and policy, as follows: prevention, preparing for re-use, recycling, recovery and finally disposal.
4. Nature-based solutions (NBS) refer to the sustainable management of the natural environment to address current challenges in order to ensure public health and risk management in case of disaster (EC, 2015, p. 5).
5. Industrial ecology has been defined by Brad (2006) as a "systems-based, multidisciplinary discourse that seeks to understand emergent behaviour of complex integrated human/natural systems". This concept assumes that sustainable industrial systems design should be based on the analogy with natural systems (Frosch & Gallopoulos, 1989).
6. Circular economy represents a restorative or regenerative system by intention and design, aiming to design out waste. It replaces the end-of-life concept with restoration, shifts towards the use of renewable energy, eliminates the use of toxic chemicals, which impair reuse and return to the biosphere, and aims for the elimination of waste through the superior design of materials, products, systems and business models.
7. Servicising, functional economy was defined as one that optimizes the use of goods and services, aiming to create the highest possible use value for the longest possible time while consuming as few material resources and energy as possible (to create the highest possible use value for the longest possible time while consuming as few material resources and energy as possible (to create the highest possible use value for the longest possible time while consuming as few material Stahel, 1986).

In 2011 OECD has formulated a comprehensive definition for Green Growth, stating that: "Green growth is about fostering economic growth and development while ensuring that the natural assets continue to provide the resources and environmental services on which our well-being relies. To do this it must catalyse investment and innovation which will underpin sustained growth and give rise to new economic opportunities." According this definition, four main areas have been identified as representing landmarks in achieving green growth (Figure 1). These areas can be assessed by specific indicators.

European Context

All human activities may cause in some way environmental degradation. Ecosystems provide resources and services for human socio-economic system. Their use must be made within the limits of the supporting and self-regulating capacity of the ecosystems, their overcoming generating environmental degradation.

The Europe 2020 Strategy emphasizes increased competitiveness generated by a development model characterized by low emissions of greenhouse gases, effectively used resources and new technologies for environmentally friendly production and biodiversity.

The Europe 2020 emphasizes the opportunities and the role which SMEs can play in shaping a sustainable European economy.

Those companies that will be able to have an innovative and proactive management are those that will gain the winning positions at the 2020 horizon. The challenges are related to globalization, demographic change, natural resource depletion, climate change and acceleration of the use of new technologies. To maximize business contribution to the Europe 2020 targets and to strengthen its competitive advantages, the most important European network of social responsibility (CSR Europe) launched the Enterprise Strategy 2020 dedicated to business environment.

Green Economy is about using of natural resources, energy and new technologies together with new cleaner production methods, in order to promote economic growth and create new jobs. In this respect we need to communicate about sustainability of the enterprises, in order to respond to consumer demands for greener products and for more information about these products.

According classical economic approach, the entrepreneurship' role in society is to create new jobs and to pay more taxes, which leads to the emergence of new incomes, determining economic and social development and finally, increasing the welfare of the human society.

At the next level the entrepreneurs should have in sight social aspects by including of the social responsibility practices into their businesses.

The issue of Green Performance Strategies have become a topic of general concern for researchers worldwide. In implementing the performance management process the social and the environmental components hold important roles. Sustainable development and the fulfilment of the sustainable development indicators are dependent on how the refurbishment is designed, this substantiating the eco-performance. Thus, the eco-performance can be considered a multifaceted concept.

Ways of Implementation of Green Economy

Green economy, as it was cited above, is resulting in an increased level of "well-being and social equity, while significantly reducing environmental risks and ecological scarcity" (UNEP, Green Economy Reports: A Preview, 2010, p. 4-5). In order to achieve the specific objectives of the green economy specific policies and investments are required, able to decouple economic growth from increasing of current intensive consumption of raw materials and energy. In short, a green economy can be characterized by some main features as the Figure 2 shows.

The role of government occurs in both the public and in the private sector. Thus, in both cases, specific legislative regulations can constitute very effective tools, aiming to stimulate commercialization organic products with low environmental impact. Specifically, this can be achieved, as Gheorghe and Sima stated (2014), by "eliminating outdated subsidies, reforming policies and providing new incentives, strengthening market infrastructure and market-based mechanisms, redirecting public investment, and greening public procurement".

As shown in Table 1, the Agenda 2020 and The Agenda 2030 aim at common goals, so that certain correlations can be highlighted between specific objectives undertaken in the two documents (Figure 3). Raising the employment rate leads obviously to an increase of human welfare. All countries must cooperate to ensure labor mobility, which should contribute to a decrease of the disparities between countries in terms of employment. Investment in research and development is an important element.

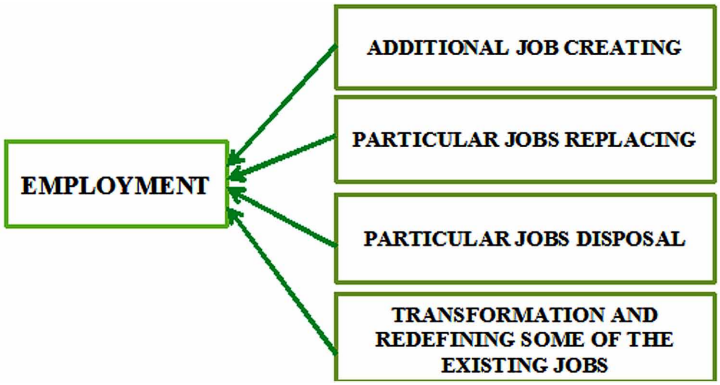
Figure 3. Correlations between objectives of the agenda 2020 UE and objectives of the 2030 UNO
Source: Proposed by the Authors

This area was affected in the period of economic crisis. Allocate a significant percentage of GDP is needed for this purpose. This is smart growth through the development of an economy based on knowledge and innovation which is able to ensure the protection of the planet, ensuring the prosperity of its people, which can be achieved only in peace. Achieving the objective of "20/20/20" in terms of energy and climate change is also important. This leads to sustainable growth by promoting globally, a green economy that is efficient and competitive. Education plays an important role in decreasing early school leaving among young people, helping to increase social welfare. Globally consistent policies are needed. These can lead to the implementation of social programs in this regard. Promoting an economy with high employment of labor is necessary in order to reduce social exclusion.

According to the latest documents adopted by the EU (Agenda 2020) and UN (Agenda 2030), the green economy aims to increase social welfare and the role of human capital by reducing environmental risks and ecological issues in order to achieve sustainable development. A highly ambitious UN goal is the eradication of poverty. The green economy, according to United Nations experts, providing an environment with fewer adverse environmental effects and substantial benefits on society and each person can contribute to achieving this objective. A new opportunity is represented by redesigning through greening of the national strategies, in terms of creating new green jobs, as a result of the expansion of green industries, which demand specific skills and competencies (Figure 4).



EU 2020 STRATEGY IMPLEMENTATION IN ROMANIA

Context

An extreme dynamics represents the essential feature of the current socio-economic environment. In this context, in 2010 the "Europe 2020" was launched, which represents the EU's growth strategy for the period 2010-2020. This strategy emerged in the context of a deep economic crisis and intensifica-

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. Effects on employment of the orientation towards sustainable economic
Source: Sima and Gheorghe, 2014, p.117

tion of long-term challenges such as globalization, pressures on resources use and an aging population. The strategy "Europe 2020" has taken into account the peculiarities of each Member State, at the same time aiming a consistent reform program which had as a general goal to increase the competitiveness of Europe, based on the strengths of the EU - single market, common currency, and common policies. Through this strategy, the EU aimed to become a smart, sustainable and inclusive economy. These three stated priorities are converging, supporting each other and being able to "help the EU and the Member States deliver high levels of employment, productivity and social cohesion" (José Manuel Durão Barroso, former Chairman European Commission). These priorities are:

- **Smart Growth:** Developing an economy based on knowledge and innovation.
- **Sustainable Growth:** Promoting a more resource efficient, greener and more competitive economy.
- **Inclusive Growth:** Fostering a high-employment economy delivering social and territorial cohesion (COMMUNICATION FROM THE COMMISSION EUROPE 2020, A strategy for smart, sustainable and inclusive growth, p.5).

The Headline Targets of "Europe 2020"

This strategy has targeted five areas considered as the biggest challenges for the contemporary world:

1. **Employment:** Ensuring an employment rate of 75% for people aged 20 to 64 years;
2. **The Role of Research and Development:** An increase of the investment in R&D to 3% of the EU GDP;
3. **Climate Change:**
   a. Limiting the emissions of greenhouse gas by at least 20% compared to 1990;
   b. Providing of 20% of the demanded energy by using renewable resources;
   c. Improving the energy efficiency by 20%;
4. **Education:**
   a. Reducing early school leaving to below 10%;

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

   b. An increased share of population with higher education, for people with ages between 30 and 34 years;
5. **Fight Against Poverty and Social Exclusion:** Reducing the number of Europeans suffering or being at risk to suffer from poverty and social exclusion with 25% (reducing the number of people at risk of poverty by 20 million).

In developing the Europe 2020 objectives, the EU Commission took into account the heterogeneity of its members so that objectives were relevant to all 27 states, as were in 2010 and 28 today. For this purpose a flexible approach has been chosen, the European objectives being translated into national targets, reflecting the peculiarities of each country.

In March 2010, Romania established the National 2020 targets, under the coordination of the Department for European Affairs of the Romanian Government, based on the conclusions of the European Council. The main fields of action targeted by Romania are:

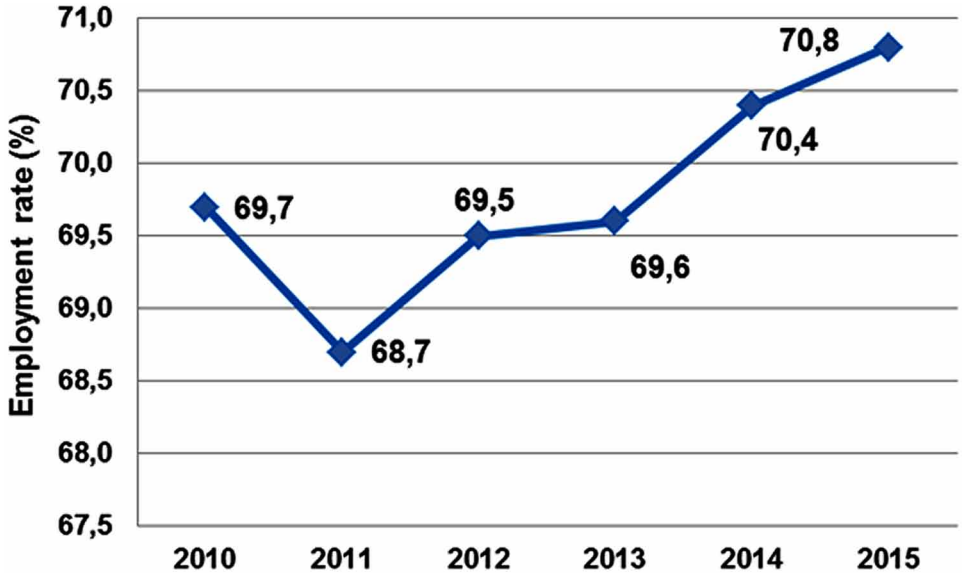
1. **An Increase in the Employment:** In order to achieve this, a reform of the legal framework is required to encourage employment and continuous training of the labor force considered being relevant instruments in this field. Romania has assumed only an increase of up to 70%, given that, in 2008, the employment rate was 64.4%.
2. **The Allocation of 2% of GDP for Research and Development:** This is a target difficult to attain in Romania because the current structures of research and development in our country show a very low intensity of the field. The share of expenditures for research and development in Romania's GDP in 2008 was 0.45%, but the economic crisis has reduced it to 0.30% in 2009 and 2010, which has caused significant damage to ongoing research projects.
3. **A Reducing of the Greenhouse Gasses (GHG) Emissions:** In this field, Romania has assumed, realistically, only a decrease of 19% compared to 2005, due to the current possibilities compared with the value stipulated by the European standards (30%).
4. **An Increase by 24% in the Share of Renewable Energy in Final Consumption**: For Romania, the target means 6.2% more than in 2005 (when the share of this category in final energy consumption was 17.8%).
5. **An Increase of the Energy Efficiency by 10%:** Romania's objective in this area aimed at reducing the primary energy consumption, this sector having a great potential for saving.
6. **A Reducing of the Early School Leaving**: In this field, Romania has assumed a decrease of 11.3%. Some progress has been made, in part due to the implementation of social programs (reducing the school leaving rate from 22.9% in 2000 to 15.9% in 2008, but the indicator rose again in 2009 to 16.6%, due to the economic crisis).
7. **An Increase in the Share of Population under 30 Years Old Having Completed Tertiary Education to 26.7%:** For this purpose, reforms are needed, not only in education but also in the economy designed to support education expenditure.
8. **Increasing the Social Inclusion**: This objective envisages primarily the ensuring of the social and territorial cohesion. Romania has assumed to reduce the number of people at risk of poverty by 580 000 persons. For this purpose, Romania is expected to increase funds for social assistance and to continue the healthcare reform.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Stage of Implementation of the Europe 2020 Strategy in Romania

Regarding the employment rate, as it has been shown above, for people aged 20-64 years, the proposed EU target is 70%. In 2015 Romania reached 70.8%, higher than in 2014 when the employment rate was 70.4% (Figure 5). This trend confirms that Romania has made progress in this area, the assumed goal being practically achieved. This was due to the fact that the National Plan on Stimulating Youth Employment was implemented. An ongoing project is important to mention, namely, related to the Development of Local Economies and New Jobs Creation.

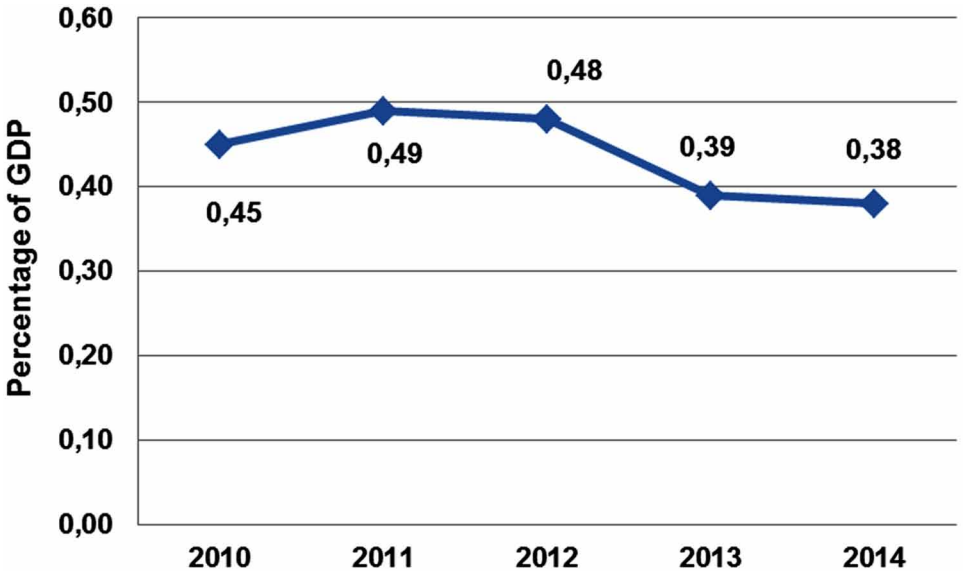
This project has the following objectives:



- To decrease undeclared work (undeclared);
- To decrease youth unemployment and increasing employment.

To achieve these objectives, three directions are envisaged:

- A continuous training of young people, especially those in rural areas;
- The development of micro-enterprises, both in the non-agricultural sector, but especially in agriculture;
- The integration of people who left school early by recognizing their skills.



Regarding Total intramural R & D Expenditure - the target assumed by Romania was to reach 2% of GDP. In this area, Romania registered a growth of 0.39% in 2013 and 0.38% in 2014. There is a downward trend in values (Figure 6), even if over 750 projects were with Romanian and international participation were supported in this domain. The public sector was the one where cuts in expenditure were higher

Figure 5. Employment rate, 2010-2015

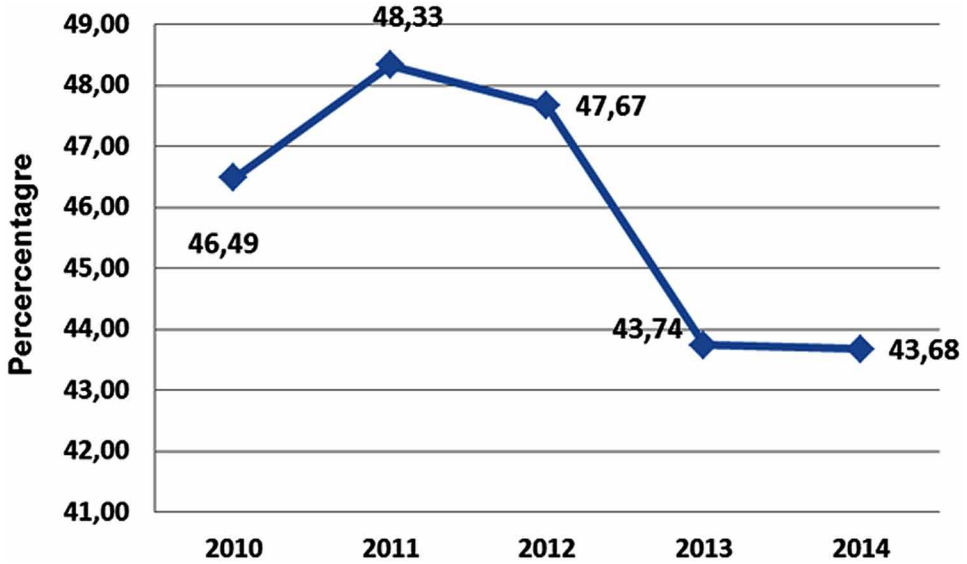
EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 6. Total intramural R&D expenditure, 2010-2014
Source: Data provided by EUROSTAT (rd_e_gerdtot)

Thus, to achieve the objective, Romania will have to increase R & D Expenditure on average by 31.7% per year between 2015 and 2020.

To increase on average by 31.7% per year between 2015 and 2020 in the future two main issues are taken into account:



- To develop the relationship between theory (research) and practice (businesses) by promoting R & D activities in economic sectors with growth potential and public importance;
- To upgrade the national R & D investments to increase efficiency in administration.

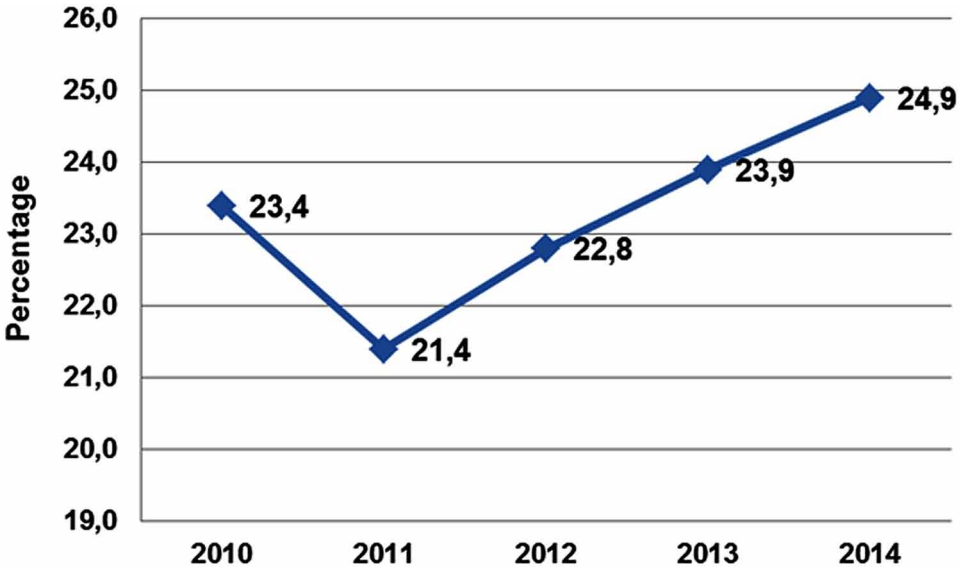
Regarding Greenhouse gas emissions reduction the target assumed by Romania is 19%. Figure 7 shows the evolution of Greenhouse Gas Emissions. Thus, after 2005, the highest value of Greenhouse Gas Emissions was recorded in 2011 (48.33%), followed by a continuous decrease. The lowest value was being recorded in 2014 (43.68%). The contraction of the national economy has essentially contributed to this decline, due to the economic crisis. On fields, the causes of this trend are:

- **In the Energy Sector:** The following issues are to be mentioned: increasing the share of energy from alternative sources, upgrading of major combustion plants and stimulate energy production from clean sources - Program for increasing energy production from renewable sources, Program "Green House."
- **In the Transport Sector:** A determinant factor was the stimulation of the national car park renewal and monitoring of the road transport vehicles clean and efficient energy - Program Rabla.
- **The Increase of the Afforested Areas:** Program for improvement of the environment quality through afforestation of degraded lands, ecological restoration and sustainable management of forests.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 7. Greenhouse gas emissions, base year 1990, 2010-2014
Source: Data provided by EUROSTAT (t2020_30)

- **Expansion of Green Areas in Towns:** National Programme for improvement of the environment quality by creating green spaces in cities.



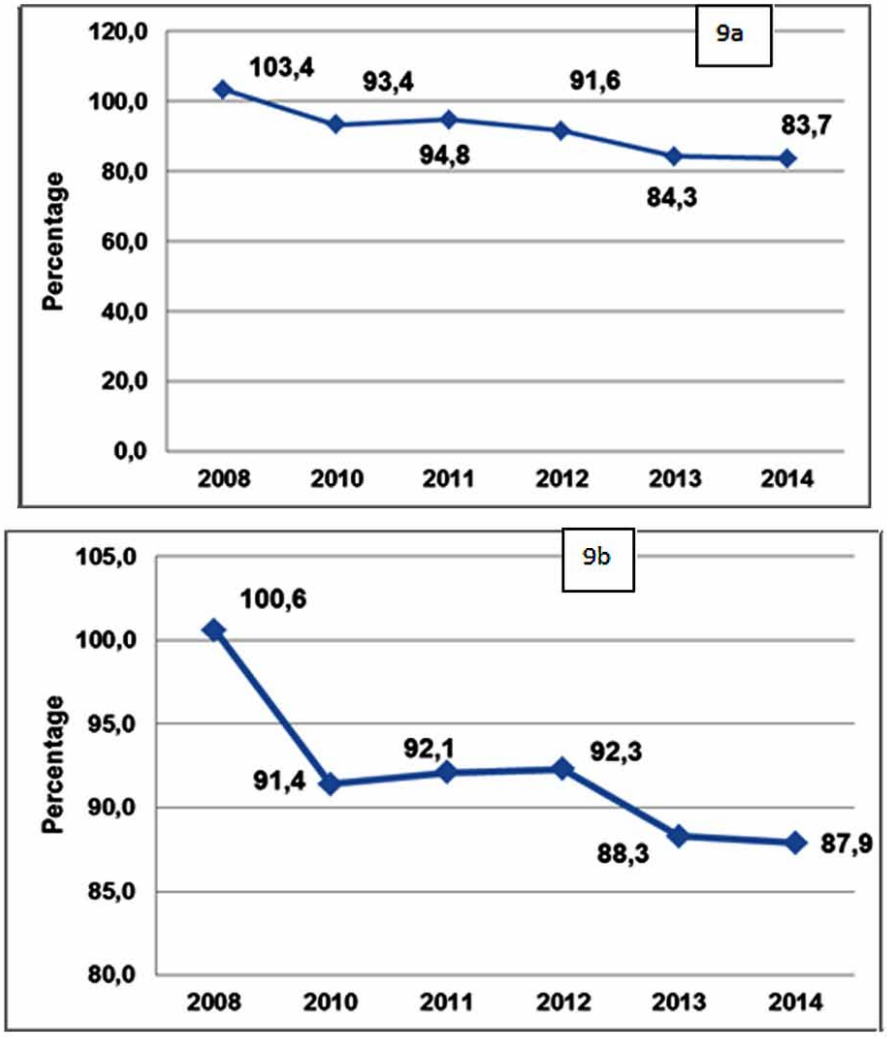
Some national programs are to be mentioned here, namely: Green House, Rabla, accreditation of The International Airport Henri Coanda Bucharest according to the standard of certification of the CO2 emissions management.

Regarding Share of renewable energy in gross final energy consumption (Figure 8), the target assumed by Romania is to cover 24% from the necessary of energy using renewable resources. A share of 23.9% was reached in 2013 and in 2014 one of 24.9%. Thus, we can affirm that Romania has already exceeded the target for 2020, although, from a legislative point of view, there still may be emphasized certain vulnerabilities. The economic crisis had a major contribution also in this domain but the implementation of some energy efficiency measures is also to be mentioned. The most important are:

- SRE promotion by means of green certificates;
- Modernization and achievement of new capacities of producing electric and thermic energy;
- SRE promotion by means of Medium Fund, the program regarding the installing of the heating systems which use renewable energy, inclusively the replacement and the completion of standard heating systems (Green House);
- Elaboration of some equivalent certification systems or qualification systems for the electricians working in the SRE domain, introducing 4 new qualifications in the Romanian Professions' Classification (fitter for heating pumps, geothermal systems, PV solar systems and for thermic solar systems) and the elaboration of 2 new occupational standards (fitter for systems of thermic use of SRE and fitter for PV systems);

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 8. Share of renewable energy in gross final energy consumption, 2010-2014
Source: Data provided by EUROSTAT (t2020_31)



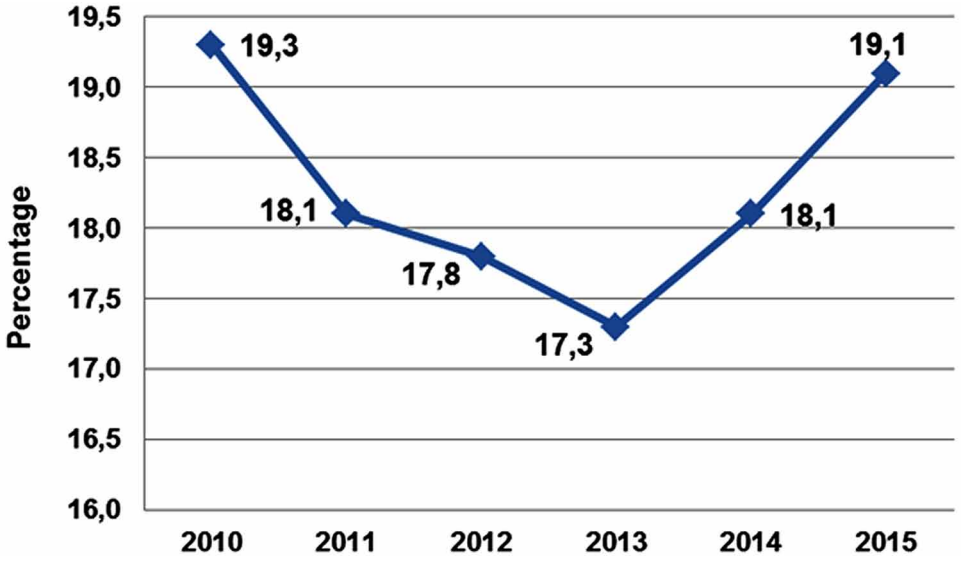
- Modification of the support scheme regarding the promotion of the energy resulting from renewable energy in order to avoid overcompensation;
- Supporting the measures aiming at the modernization and rehabilitation of the transport and distribution network in order to obtain a better take over in the network of the energy produced from renewable energy sources.

Regarding Primary energy consumption, Romania target for energy effectiveness in 2020 is of 43 Mtep, expressed in primary energy consumption (30.3 Mtep expressed in the final energy consumption). In Romania, after 2008, there may be noticed a constant lowering of the primary energy consumption (Figure 9a). This lowering was the result of some measures:

- The implementation of the state support scheme for the promotion of the high efficiency cogeneration;
- Popularizing campaign to inform the population and business medium regarding the importance of the increasing of the energy efficiency; there were organized eight seminaries in six towns, with a total of above 370 participants;
- The Program "Heating, Heat and Comfort";
- The modernization and realizing of some units and new equipment in the industry plants;
- Thermic of the buildings;
- The improvement of the energy efficiency in the communities with low income from Romania;
- Promotion of some projects regarding the intelligent counting at the level of the electric energy distribution systems.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 9. (a) Primary energy consumption, base year 2005, 2010-2014; (b) Final energy consumption, base year 2005, 2010-2014
Source: Data provided by EUROSTAT (t2020_33)



As concerns Final energy consumption there is to be noticed approximately the same evolution (Figure 9b). The highest level was registered in 2008 (100.6%), and the lowest in 2014 (87.9%).

As concerns Early leavers from education and training status, after a relatively linear decrease during the period 2010-2013, starting with 2014, an increase tendency may be ascertained (Figure 10). Therefore early leaving school rate, increased at a level of 18.1% in 2014 and, respectively, at 19.1% in 2015, in spite of the measures approved by the government (the implementing of the social programmes in order to support the pupils from the disadvantaged regions – School Supplies, Money for High School, Euro 200, and Roll and Milk, Honey and fruits, Refunding of the Transport Money and School Buses, implementing of some programmes, stipulated in the National Education Law for the support of the coming back to school and the increasing of the liquidation of illiteracy level for population.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 10. Early leavers from education and training status, 2010-2015
Source: Data provided by EUROSTAT [edat_lfse_14]

The second chance, School after school, the liquidation of illiteracy programmes, assurance of the educational process quality within the secondary school education, the development of the vocational education, high school education (technological type) and college education. This evolution situates Romania among the countries with the highest rates of early school leaving in EU, Romania being moved away from its target. It also has to be mentioned the fact that there are gender and residence discrepancies (a higher rate among boys and in the rural area compared to girls and urban area).

Regarding Population by tertiary education (levels 5-8) attainment, Romania registered progress and an increasing tendency of this index may be noticed (Figure 11), the value of this index substantially improved, reaching the quota of 25.6% in 2015. Therefore, Romania is on its way to reach the assumed target.

The measures which contributed to this evolution:

- Adapting the academic education to the labour market demands by means of elaborating an analysis of the indexes reported by the universities and the implementing of specific projects;
- The Management of the correlation of the educational system with the labour market and public policies inserted in the academic education: a necessary premise for Romania development;
- Implementing of the social programmes for the students;
- The development of the national systems of qualifications for the academic education in Romania by means of the operationalization of the National Academic Education Qualifications Register (RNCIS) and adopting The National Qualifications Framework.

Concerning Reduction of the number of people at risk of poverty or social exclusion, in Figure 12, it may be noticed that the target has already been surpassed. This important progress was possible due to:

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 11. Population by tertiary education (levels 5-8) attainment, 2010-2015

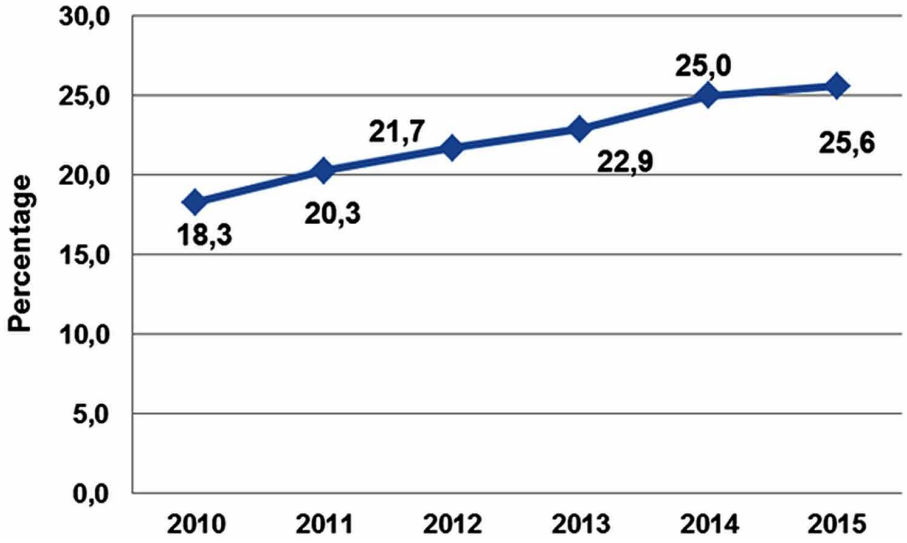

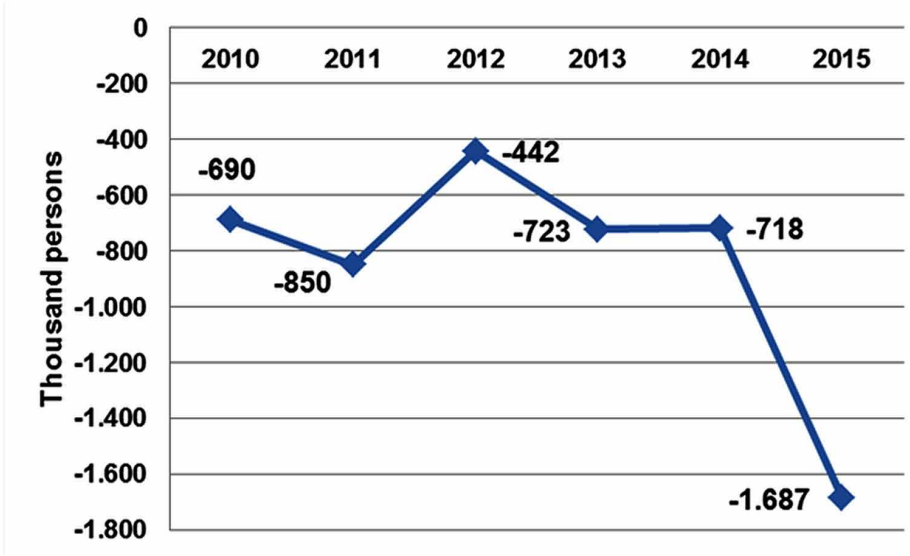

Figure 12. Reduction of the number of people at risk of poverty or social exclusion, 2010-2015
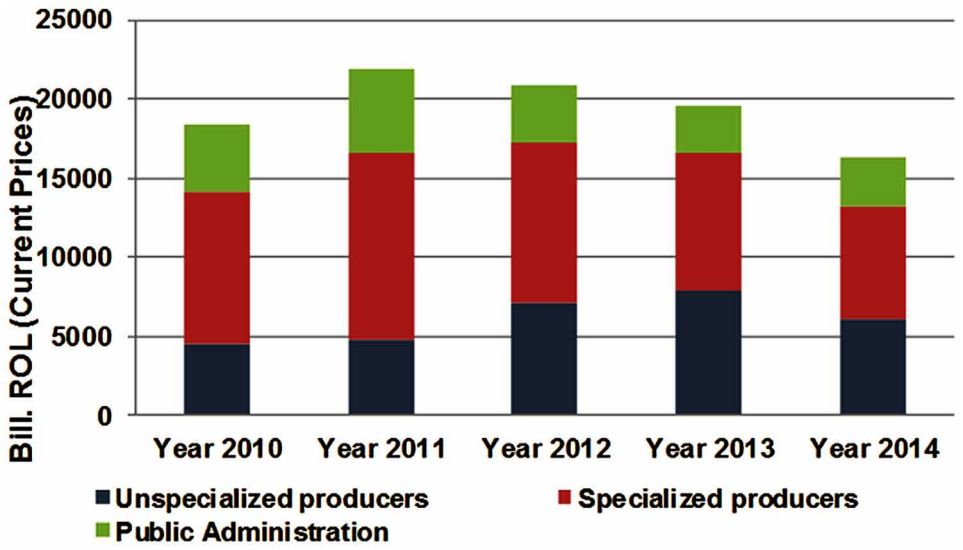
Source: Data provided by EUROSTAT [ilc_peps01]

- The support of the poorest families with children;
- **The Assurance of the Social Protection and of the Most Vulnerable Population Categories:** Granting of an allowance for the support of the family, insurance of a minimum guaranteed income;
- **Social Protection Measures for the Vulnerable Consumers and for the Diminishing of the Energy Poverty Risks**: Support for the heating with natural gases and for the heating with electric energy;

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

- **Increasing of the Children Social Services Quality**: Improvement of the care services, closing of the old institutions and founding recovery centers and houses of family type;
- **Facilitating the Access and Participation of the Individuals Taking Part in Vulnerable Groups on the Labour Market**: Implementing some qualification/re-qualification;
- The development of the social substructure and education substructure;
- **The Improvement of the Access for the Vulnerable Persons to Health Services**: Implementing health national programmes (Screening Programme for the early active identification of the col cancer), the assurance of the access to the medicaments ambulatory provided to the pensioners with low income;
- **Economic Efficiency of the Health System**: Computerization of the health system by implementing the National Health Framework and of the programme the Electronic Card of the patient.

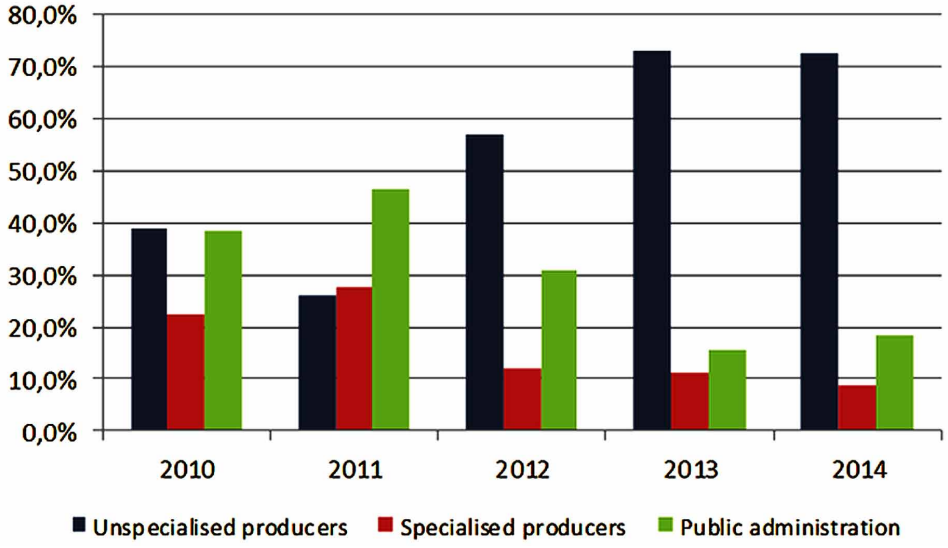
GREEN PERFORMANCE IN ROMANIA



Environmental Protection Expenditures Evolution During 2010-2014

As concerns the expenses for the medium protection in Romania, it may be noticed that, taking into account the activity sectors, the specialized producers own the highest quota which records, generally, over 50% of the total environmental expenditures (Figure 13).

This category is followed by the category of the specialized producers in public administration. It has to be mentioned that, starting from 2012, the percentage represented by the public sector was drastically reduced.



From the total of these expenses, the amounts assigned to the investments have a different evolution (Figure 14). In this respect, the nonspecialized producers are the one who assign the highest percent-

Figure 14. Environmental protection expenditures for investment, by activity sector, 2010-2014
Source: Data provided by National Institute of Statistics

age for investments in medium protection, excepting 2011. Starting with 2012 the figures have become increasingly higher, showing an increased concern for the environment. As for manufacturing, in the 2010-2013, it represented about a half of environment protection expenditure of unspecialized producers.

After 2013 their share decreased, to 25.3% in 2014. Specialized producers assigned for the investments the highest quota in 2011 (25.9%). Starting with 2012 their assignments for the investments continually decreased reaching 8.8%, in 2014. The public sector manifested similar trends.

By environment field, the highest share of expenditure was recorded for waste management, more than 50%. It was followed by water protection expenditure (Figure 15).

Environmental Taxes Evolution in Romania and Efficiency of Revenue Generated by Them During 2010-2014

Romania has an inefficient economy from the energy point of view. Energy has among the lowest cashing obtained from environmental taxes as PIB percentage both at general and activity sectors levels (energy taxes, transport taxes and environmental and pollution taxes). The Table 2 shows the evolution of the energy taxes in Romania compared to EU. A first observation is that the level is under 2.5% from PIB, being under the European media. In 2011 (the year when in Romania manifested the strongest economic crisis in all activity domains) registered the lowest value for the analyzed period, namely 1.69% from PIB, and in 2014, the highest value, namely 2.16% from PIB. In the case of the transport taxes and environmental and pollution taxes the value is under 1% from PIB.

This situation may be explained by the intention of the state to maintain the taxes and excise duties at minimum duties. Moreover, in the case of the pollution and use of the resources taxes, the collecting capacity for the majority of taxes is diminished in comparison to the charging potential basis. This thing is even more serious as the pollution and use of the resources taxes are, in fact collected in order to finance projects meant to diminish the negative effects of the human activities against the environment.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Source: Processed by authors using data provided by EUROSTAT [env_ac_tax]

The competitive advantage offered by a low level of the charging is not exploited in Romania at all. As a matter of fact European Union recommends a change of the accent from the work charging (where Romania emphasizes a high fiscality level) to the charging of the consumption and pollution.

Within this context it may be noticed that the evolution of the taxes and contributions in Romania has an increasing tendencies and the registered values are over the European mean of 6%. It may be also emphasized the year 2011 with minimum values. As concerns the Energy taxes, it registered an increasing tendency during the studied period, reaching in 2014, at the level of 7.79%, which surpasses the European mean (Table 3).

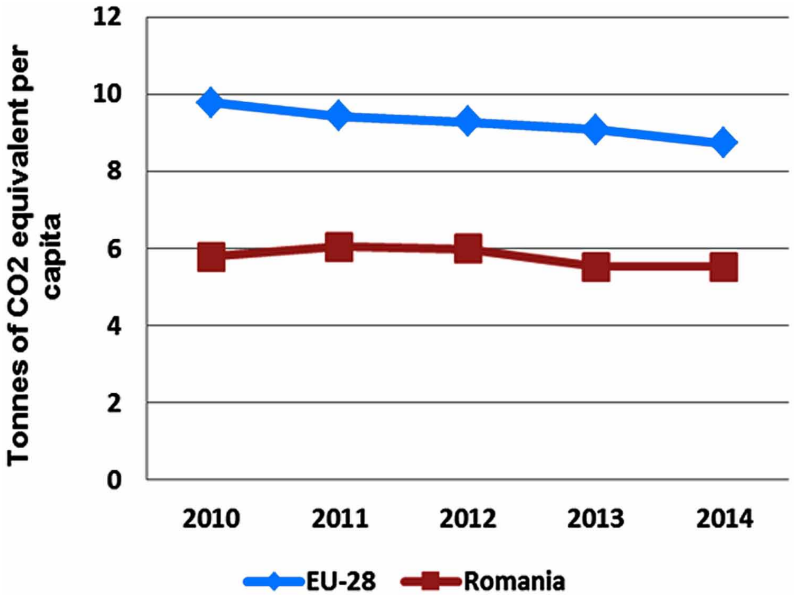
Evolutions of Greenhouse Gas Emissions

According to The European Environment Agency (EEA), the five main emission source sectors of greenhouse gasses include:



- Energy (fuel combustion and fugitive emissions from fuels), which also includes transport;
- Industrial processes and product use;
- Agriculture;
- Land use, land use change and forestry (LULUCF);
- Waste management.

According to European Environment Agency (EEA), emissions of greenhouse gas in Europe declined by 19% from 1990 to the present, despite a 45% increase in economic output. European Environment Agency (EEA) published a report in 2014 that evaluated the greenhouse gas emissions in the European Union from 1990 to 2012. It showed that the commitments of the EU countries to reduce the amount of greenhouse gas emissions in 2020 was close to being met (Figure 18). It is expected that, by the deadline, they can be overcome. Romania has reduced its emissions of greenhouse gasses, especially after 2012.

The main reasons that led to these changes are:

- Decrease of CO2 emissions in road transport;
- The economic crisis and the economy contraction. Emissions have decreased primarily in countries most affected by the economic recession: Italy, Spain, and Greece;

Figure 18. Greenhouse gas emissions per capita, 2010-2014
Source: Data provided by EUROSTAT (t2020_rd300)

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

- The drop in CO2 in manufacturing and cement production. The drop was 11 million tons, representing 3% compared to 1990. The countries with the biggest reductions were Italy, Germany, Britain, Spain, and Portugal;
- The reduction in the production of solid fuel.

But there were sectors where the amount of GHG emission increased. The most important are related to electricity consumption in public space and heating plants, which led to an increase of 3%. The highest increases were in Germany, Great Britain, and Spain. Another significant increase was recorded in consumption in households and services, bringing a plus 4%. Experts claim that winters are becoming colder so that the increasing demand for heating could represent an explanation of these changes.

"In Europe, supply and use of energy is the most important source of GHGs emissions (80%). Agriculture has a sectorial share around 9%. So, impact of agriculture on climate change is modest" (Matei, Stancu & Vuković, 2009).

In Romania, more than 13% of the greenhouse gas emissions come from the transport sector, and 96% of them are caused by road transport. According to Greenpeace (2014), 18% of greenhouse gas emissions in Romania come effect of coal power plants.

As a result of the economic downturn after 1989, in Romania, a significant reduction in GHG emissions was recorded. Total emissions of CO2 equivalent (without LULUCF) for Romania accounted for 2.61% of total EU emissions. Table 4 shows the sectoral contributions to GHG emissions in 2014. Table 3 shows the sectoral contributions to GHG emissions in 2014. Thus, in 2014, the energy sector contributed about 83% of GHG emissions representing a priority for reduction. The transport sector has grown rapidly - by over 35% compared to 1990. This trend is likely to continue, indicating that this sector, especially road transport, deserves attention in terms of limiting the increase in GHG emissions.

In urban areas, 56% of the population lives and most of the economic activities are conducted. This is a diverse and complex sector, with a wide range of opportunities to reduce the GHG emissions by

improving energy efficiency in buildings, a more efficient urban transport, and implementation of waste management. Agriculture is responsible for over 18% of total GHG emissions. It is worth mentioning that net absorption of CO2 from the atmosphere by forestry offsets about 20% of emissions in other sectors at the national level. It offers a wide range of mitigation measures - conservation and enhancement of existing C deposits, improvement of the absorption rate of atmospheric CO2 and land use change.

Green Jobs in Romania

Millions of green jobs could occur if the green economy were more emphasized.

In Europe, there are over 20 million jobs linked to the green sector.

In our country, the number of "green" jobs is becoming increasingly higher in the following areas:

- Renewable Energies;
- Ecological Agriculture;
- Food Industry;
- Transport.

In this context, a revolution takes place in the labor market, "green" jobs representing a lifebelt. People trained in fields concerned with the environment are beneficiaries of some extra employment opportunities. Romania has a potential for growth, particularly in the non-renewable energy sources - the wind and solar energy: environmental consultant, environment manager, energy buyer, technical operator, responsible for maintaining and wind turbines and solar panels. Also, in 2014, in Romania, there were over 2,000 companies in the recycling and waste management field, and their number is growing.

EU 2020 strategy includes the increasing employment rate among its objectives. Green sector has a clear upward trend, which requires new training programs and an adaptation of sustainable business practices. Green products are increasingly requested. These changes contribute to an increase in the number of green jobs. In specialty literature, the concept of "green collar" has appeared. In this context, green jobs can be a way to support the economy. They can contribute to economic growth.

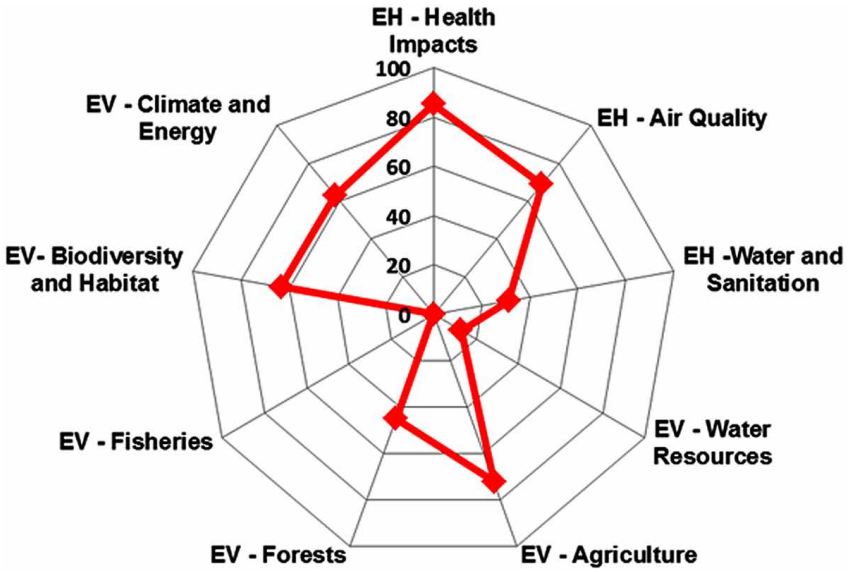
Environmental Performance Index (EPI) in Romania

Environmental Performance Index (EPI) measures the performance of countries in terms of human health protection from harm and protection of the environmental ecosystems, using 25 indicators grouped into ten categories as follows:

- Health Impacts;
- Air Quality;
- Water and Sanitation;
- Water Resources;
- Agriculture;
- Forests;
- Fisheries;
- Biodiversity and Habitat;
- Climate and Energy.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

In 2014 Romania was ranked 86. Figure 19 shows that the best result for Romania had been registered in the field of Health Impacts, with a score of approx. 85 and the weakest one, in the field of Water Resources, with a score of approx. 13, despite the government's efforts, demonstrated by the increasing expenditures in this area. According to Sima and Gheorghe (2014), the value of the correlation coefficient (0.74) confirms a moderate direct link between the environmental performance index and the GDP /capita, a better air quality, etc.



CONCLUSION

Specific indicators are designed to measure sustainable economic growth. Its effects are materializing in a major growth of the ecological productivity, an increased amount of energy derived from renewable sources, emissions reduction, improved air and water quality, widened access to the benefits of civilization - education, water sanitation. Thus, this green growth "can fight" against climate change. Also, green growth provides opportunities for creating new jobs requiring new skills. Romania has the chance to be among the EU countries that will practice this social model based on these new skills that could lead to an improved quality of life.

In the latest statistics, there are some fields in which Romania holds honorable positions, as follows:

- According to the European Wind Energy Association, in 2014 Romania ranked 9 in the EU depending on the capacity of wind farms with an installed capacity of 2,952.9 MW. Germany ranked first with 39,127.9 MW.

Figure 19. Environmental Performance Index in Romania, 2014
Source: http://www.epi.yale.edu/epi/country-profile

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

- According Eurostat data, in 2014 Romania ranked 10 in the EU depending on the amount of carbon dioxide emissions in the energy sector. Germany, the leader, emitted 12 times more pollutants than Romania.

There are also fields in which Romania is at the end of the list, as follows:

- After the amount of municipal waste generated by population, Romania ranks 22 in the EU, with 389 kg per capita, in a ranking led by Denmark with 668 kg per person.
- In terms of recycling, Romania ranks last in the EU. Romania recycles only 1% of its waste, while Germany recycles 65%.

There is a close relationship between environmental taxes and efforts to protect the environment. Romania has low energy taxes. However, paradoxically, Romania is a country with low CO2 emissions. Despite the fact that the environmental taxes have lower levels than the EU average, and the capacity to collect these fees is quite limited, Romania is in a very good situation in terms of the overall level of CO2 emissions. Deindustrialization, the economy contraction, a decrease of the synthetic fertilizer use, the drop in growing areas could explain this.

KEY TERMS AND DEFINITIONS

Environmental Performance Index: It measures the performance of countries in terms of human health protection from harm and protection of environmental ecosystems, using 25 performance indicators grouped into ten categories including: Health Impacts, Air Quality, Water and Sanitation, Water Resources, Agriculture, Forests, Fisheries, Biodiversity and Habitat, and Climate and Energy.

Environmental Protection Expenditures: "Statistics on environmental protection expenditure present data on the economic resources devoted by resident units to environmental protection" (Eurostat).

Environmental Quality: A state of environmental conditions, expressed in terms of indicators or indices, which measures environmental health, referring to air and water purity or pollution, noise, resources, flora and fauna.

Environmental Tax: A tax whose base is a physical unit (or a proxy of a physical unit) of something that has a proven, specific negative impact on the environment. Environmental tax statistics present data on taxes in the following areas: Energy, Transport, Pollution, and Resource (Eurostat).

Green Economy: A means to achieve sustainable development, representing an adaptation of the socio-economic system to the multiple challenges of the current period.

Green Growth: "Green growth is about fostering economic growth and development while ensuring that the natural assets continue to provide the resources and environmental services on which our well-being relies. To do this it must catalyse investment and innovation which will underpin sustained growth and give rise to new economic opportunities." (OECD, 2011).

Greenhouse Gasses Emissions: A group of compounds which are able of absorbing infrared radiation to trap heat, keeping the Earth's surface warmer than it would be if they were not present.

Green Jobs: A "work in agricultural, manufacturing, research and development (R&D), administrative, and service activities that contribute(s) substantially to preserving or restoring environmental quality. Specifically, but not exclusively, this includes jobs that help to protect ecosystems and biodiversity; reduce energy, materials, and water consumption through high efficiency strategies; de-carbonize the economy; and minimize or altogether avoid generation of all forms of waste and pollution" (2008).
