Table of Contents

Preface xix

Volume I

Section 1
Fundamental Concepts and Theories

Chapter 1
Ecological Responsibility and Sustainable Development as Preconditions for Development of the Concept of Circular Economy 1
Olja Munitlak Ivanovic, Institute of Economic Sciences, Serbia

Chapter 2
Consumer Cooperation in Sustainability: The Green Gap in an Emerging Market 17
Njabulo Mkhize, University of kwaZulu-Natal, South Africa
Debbie Ellis, University of KwaZulu-Natal, South Africa

Chapter 3
Application of Circular Economy for Sustainable Resource Management in Kuwait 35
Osman Gulseven, American University of the Middle East, Kuwait
Jacques Mostert, American University of the Middle East, Kuwait

Chapter 4
Exploring Client Perceptions and Intentions in Emerging Economies: The Case of Green Banking Technology 49
Mehree Iqbal, North South University, Bangladesh
Nabila Nisha, North South University, Bangladesh
Afrin Rifat, North South University, Bangladesh
Pradiptarathi Panda, National Institute of Securities Markets, India

Chapter 5
The Green School: A Superintendent's Perspective 71
Maggie Shook, Thomaston-Upson Schools, USA
Michael D. Richardson, Columbus State University, USA

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 6
Green IT Adoption: Lessons From the Philippines Business Process Outsourcing Industry 88
Alexander A. Hernandez, De La Salle University, Philippines & Technological Institute of the Philippines, Philippines
Sherwin E. Ona, De La Salle University, Philippines

Chapter 7
Green Supply Chain Management Model for Sustainable Manufacturing Practices 125
Surajit Bag, Tega Industries South Africa Pty Ltd, South Africa
Neeraj Anand, University of Petroleum and Energy Studies, India
Krishan Kumar Pandey, O.P. Jindal Global University, India

Chapter 8
Green Customer Satisfaction 153
Violeta Sima, Petroleum-Gas University of Ploiesti, Romania
Ileana Georgiana Gheorghe, Petroleum-Gas University of Ploiesti, Romania

Chapter 9
Green Marketing in India: A Theoretical Perspective 181
Ajit Kumar Shukla, Mahatma Gandhi Kashi Vidyapith, India

Chapter 10
Eco-Friendly Culpabilities of Modern Corporates on Ecological Marketing: An Overview 192
Thangasamy Esakki, Poompuhar College (Autonomous), India

Section 2
Development and Design Methodologies

Chapter 11
Consumer Values and Green Products Consumption in Malaysia: A Structural Equation Modelling Approach 206
Brahim Chekima, Universiti Malaysia Sabah, Malaysia

Chapter 12
Constructing Green IT Alignment Framework: Car Manufacturer Case 232
Leelien Ken Huang, Feng Chia University, Taiwan

Chapter 13
Understanding Attitude Towards Green IT Among Professionals in IT Service SMEs in Bangladesh 255
P. L. Gan, Universiti Sains Malaysia, Malaysia
Imran Mahmud, Daffodil International University, Bangladesh
T. Ramayah, Universiti Sains Malaysia, Malaysia
Fatema Tuz Zuhora, Daffodil International University, Bangladesh

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 14
Implementation of Green Supply Chain Management in a Globalized Economy 274
Harish C. Chandan, Argosy University, USA

Chapter 15
The Role of a Strategic and Sustainable Orientation in Green Supply Chain Management 291
Kuo Ming Chu, Cheng Shiu University, Taiwan

Chapter 16
CSR in Cultural Organizations: A Valorization Model 310
Lucia Aiello, Sapienza University of Rome, Italy
María del Pilar Muñoz Dueñas, University of Vigo, Spain

Chapter 17
Green Growth Intervention on Employment Generation in India: Dynamic CGE Model Approach 328
Anandajit Goswami, The Energy and Resources Institute (TERI), India
Saswata Chaudhury, The Energy and Resources Institute (TERI), India

Chapter 18
Contextual Relationship Among 3 C's and Innovative Green Procurement Practices Using ISM and Its Validation Using MICMAC Analysis 346
Surajit Bag, Tega Industries South Africy Pty. Ltd., South Africa

Chapter 19
Development of a Research Framework for Green IT Enablers Using Interpretive Structural Modelling 365
Sania Khan, GITAM University, India
Abdul Razak Honnutagi, Indian Institute of Technology Bombay, India
Mohammed Shahid Ahamed Khan, CSH Co. LTD., Saudi Arabia

Chapter 20
Eco-Innovation Enablers and Typology in Green Furniture Manufacturing 379
Yudi Fernando, Universiti Sains Malaysia, Malaysia
Muhammad Shabir Shaharudin, Universiti Sains Malaysia, Malaysia
Wah Wen Xin, Universiti Sains Malaysia, Malaysia

Chapter 21
Cloud Computing Technologies for Green Enterprises: Fundamentals of Cloud Computing for Green Enterprises 395
Parkavi Ravi, Thiagarajar College of Engineering, India
Priyanka Chinnaiah, Thiagarajar College of Engineering, India
Sheik Adullah Abbas, Thiagarajar College of Engineering, India

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 22
Collective Green Creativity and Eco-Innovation as Key Drivers of Sustainable Business Solutions in Organizations 415
Ziska Fields, University of KwaZulu-Natal, South Africa
Sulaiman Olusegun Atiku, University of KwaZulu-Natal, South Africa

Chapter 23
A Business Model Framework for Crowd-Driven IoT Ecosystems 440
Xenia Ziouvelou, University of Southampton, UK
Frank McGroarty, University of Southampton, UK

Section 3
Tools and Technologies

Chapter 24
Green Attitudes and Thinking in The New Green Market: Using Mathematical Modeling to Satisfy Green Customers' Needs 463
Nicoleta Valentina Florea, Valahia University of Targoviste, Romania

Chapter 25
Green Marketing as a Tool for Reducing Environmental Footprint of the Construction Industry 490
Begum Sertyesilisik, Istanbul Technical University, Turkey

Chapter 26
Green Marketing Initiatives and Sustainable Issues in Hotel Industry 512
Neeti Kasliwal, Banasthali University, India
Srishti Agarwal, IIS University, India

Chapter 27
Building Theory of Green Procurement Using Fuzzy TISM and Fuzzy DEMATEL Methods 530
Surajit Bag, Tega Industries South Africa Pty. Ltd., South Africa

Volume II

Chapter 28
Green Information Systems for Sustainability 565
Mahesh S. Raisinghani, TWU School of Management, USA
Efosa Carroll Idemudia, Arkansas Tech University, USA

Chapter 29
Value Engineering-Based Method for Implementing the ISO14001 System in the Green Supply Chains 580
Jun-Der Leu, National Central University, Taiwan & Munich University of Applied Sciences, Germany
Larry Jung-Hsing Lee, National Central University, Taiwan
André Krischke, Munich University of Applied Sciences, Germany

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 30
Intelligent IoT-Enabled System in Green Supply Chain Using Integrated FCM Method 602
Rui-Yang Chen, Aletheia University, Taiwan

Chapter 31
Green Information System for a Sustainable Enterprise..... 624
Laura-Diana Radu, Alexandru Ioan Cuza University of Iasi, Romania

Chapter 32
Concurrent Design of Green Composites 643
Muhd Ridzuan Mansor, Universiti Teknikal Malaysia Melaka, Malaysia
S. M. Sapuan, University Putra Malaysia, Malaysia
Mohd Azli Salim, Universiti Teknikal Malaysia Melaka, Malaysia
Mohd Zaid Akop, Universiti Teknikal Malaysia Melaka, Malaysia
M. T. Musthafah, Universiti Teknikal Malaysia Melaka, Malaysia
M. A. Shaharuzaman, Universiti Teknikal Malaysia Melaka, Malaysia

Chapter 33
Cloud Computing Technology for Green Enterprises 664
Prachi Chaturvedi, Madhav Institute of Technology and Science, India

Chapter 34
Green Specifications: A Concrete Example..... 683
Thomas Schulze, University of Mannheim, Germany
Colin Atkinson, University of Mannheim, Germany

Chapter 35
Introducing Eco Friendly Urban Traffic Control Room: A Green Approach 707
Somasree Bhadra, University of Calcutta, India
Anirban Kundu, Netaji Subhash Engineering College, India
Sunirmal Khatua, University of Calcutta, India

Section 4
Utilization and Applications

Chapter 36
Green Practices Implementation as Prerequisite to Sustain Firm Competitive Advantages: The Empirical Study from Indonesia Large Scale Enterprises (LSEs)..... 731
Kardison Lumbanbatu, University of Diponegoro, Indonesia
Vincent Didiek Wiet Aryanto, Dian Nuswantoro University, Indonesia

Chapter 37
The Drivers, Practices and Outcomes of Green Supply Chain Management: Insights From ISO14001 Manufacturing Firms in Malaysia 752
K.S. Savita, Universiti Teknologi PETRONAS, Malaysia
P.D.D. Dominic, Universiti Teknologi PETRONAS, Malaysia
T. Ramayah, Universiti Sains Malaysia, Malaysia & Universiti Teknologi Malaysia, Malaysia

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 38
Green Investments and Returns: A Developing Country Perspective 781
Nabila Nisha, North South University, Bangladesh

Chapter 39
Why Do Companies Engage in Green Marketing? Alternative Green Marketing Strategies and the Motivations for the Green Marketing Approach 797
Özge Kirezli, Istanbul Bilgi University, Turkey
Melis Kaytaz Yiğit, University of Marmara, Turkey

Chapter 40
Educated Young Consumer Purchase Behavior Towards Green Products: An Empirical Study in India 821
Gyaneshwar Singh Kushwaha, Maulana Azad National Institute of Technology, India
Nagendra Kumar Sharma, Maulana Azad National Institute of Technology, India

Chapter 41
Tourists Becoming Increasingly Aware of Green Tourism: Tourist Intention to Choose Green Hotels in Bangalore, India 838
Nichola A. Ramchurjee, University of Mysore, India
Esther P. Ramchurjee, Independent Researcher, India

Chapter 42
Improving the Supply Chain (SC) Stream With Green Product Design (GPD) Strategy: Green Supply Chain Management (GSCM) 859
Rodrigo Villanueva, Universidad Autonoma de Ciudad Juarez, Mexico
Emilio Jimenez-Macias, Universidad de la Rioja, Spain
Julio Blanco-Fernandez, Universidad de la Rioja, Spain

Chapter 43
Ethical Practices, Buyer-Supplier Relationship, and Innovative Green Procurement Performance: Some Exploratory Results 884
Surajit Bag, Tega Industries South Africa Pty Ltd., South Africa
V. G. Venkatesh, University of Waikato, New Zealand
Sunil Luthra, Government Engineering College, India
Neeraj Anand, University of Petroleum and Energy Studies, India

Chapter 44
Increased Value Through Sharing in Multi-Sided Markets: Sustainability With Ridesharing 907
Nina Tura, Lappeenranta University of Technology, Finland
Aino Kuitunen, Lappeenranta University of Technology, Finland
Lauri Lättilä, SimAnalytics, Finland
Samuli Kortelainen, Lappeenranta University of Technology, Finland

Chapter 45
The Italian Doctrine *Economia Aziendale* and the Primary Interest of the Organizations 925
Emiliano Di Carlo, University of Rome "Tor Vergata", Italy

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 46
Green Brand Personality: Its Relevance to the Green Marketing Practices 950
Anitha Acharya, ICFAI Foundation for Higher Education (IFHE), India
Manish Gupta, ICFAI Foundation for Higher Education (IFHE), India

Chapter 47
A Temporal Case Study of Green Business Initiatives of a Leading Firm in the Indian Hydrocarbon Industry 964
Kamalika Chakraborty, Indian Institute of Management Calcutta, India
Nishant K. Verma, Indian Institute of Management Bangalore, India

Chapter 48
Environmental Sustainability Practices for SMEs 989
Gurudas Nulkar, HRD, India

Chapter 49
Institutional Perspective on the Drivers of Green Innovations in Firms 1009
Wiboon Kittilaksanawong, Saitama University, Japan

Chapter 50
The Leading Practices of Green Mobile Telecommunication Base Station Design 1020
Yazan Migdadi, Yarmouk University, Jordan

Section 5
Organizational and Social Implications

Chapter 51
Green Innovation and Ethical Responsibility: Do They Improve Customer's Green Purchase Intentions? 1032
Harsh Tullani, SRM University-Delhi NCR, India
Raiswa Saha, SRM University-Delhi NCR, India
Richa Dahiya, SRM University-Delhi NCR, India

Chapter 52
Driving Green Marketing in a Developing Country: Reducing the Attitude-Behaviour Gap 1048
Shweta Pandey, International Management Institute, India
Deepak Chawla, International Management Institute, India

Chapter 53
Customers' Perceptions of Green Banking: Examining Service Quality Dimensions in Bangladesh 1071
Mehree Iqbal, North South University, Bangladesh
Nabila Nisha, North South University, Bangladesh
Syed Ali Raza, IQRA University, Pakistan

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 54
Evaluating Factors Affect Green IT Readiness (Part 1) 1091
Yas A. Alsultanny, Arabian Gulf University, Bahrain
Fatma M. Alnassar, Arabian Gulf University, Bahrain

Chapter 55
Created Shared Value and Sustainable, Inclusive Development of Developing Countries 1105
James Odia, University of Benin, Nigeria

Volume III

Chapter 56
Green Entrepreneurship in Transitional Economies: Breaking Through the Constraints of Legitimacy 1136
Yang Gao, Dalian University of Technology, China
Sang-Bing Tsai, Foshan University, China & Dalian University of Technology, China
Shuo Zhang, Dalian University of Technology, China
Guodong Li, Civil Aviation University of China, China

Chapter 57
Customer Satisfaction in the Consumption of Green Products 1161
Violeta Sima, Petroleum-Gas University of Ploieşti, Romania
Ileana Georgiana Gheorghe, Petroleum-Gas University of Ploieşti, Romania

Chapter 58
Perception of Romanian Consumers on Ecological Products 1195

Preface

The constantly changing landscape of Green Business makes it challenging for experts and practitioners to stay informed of the field's most up-to-date research. That is why Business Science Reference is pleased to offer this three-volume reference collection that will empower students, researchers, and academicians with a strong understanding of critical issues within Green Business by providing both broad and detailed perspectives on cutting-edge theories and developments. This reference is designed to act as a single reference source on conceptual, methodological, technical, and managerial issues, as well as to provide insight into emerging trends and future opportunities within the discipline.

Green Business: Concepts, Methodologies, Tools, and Applications is organized into eight distinct sections that provide comprehensive coverage of important topics. The sections are:

1. Fundamental Concepts and Theories;
2. Development and Design Methodologies;
3. Tools and Technologies;
4. Utilization and Applications;
5. Organizational and Social Implications;
6. Managerial Impact;
7. Critical Issues and Challenges; and
8. Emerging Trends.

The following paragraphs provide a summary of what to expect from this invaluable reference tool.

Section 1, "Fundamental Concepts and Theories," serves as a foundation for this extensive reference tool by addressing crucial theories essential to the understanding of Green Business. Introducing the book is "Ecological Responsibility and Sustainable Development as Preconditions for Development of the Concept of Circular Economy" by Olja Munitlak Ivanovic: a great foundation laying the groundwork for the basic concepts and theories that will be discussed throughout the rest of the book. Section 1 concludes and leads into the following portion of the book with a nice segue chapter, "Eco-Friendly Culpabilities of Modern Corporates on Ecological Marketing: An Overview" by Thangasamy Esakki.

Section 2, "Development and Design Methodologies," presents in-depth coverage of the conceptual design and architecture of Green Business. Opening the section is "Consumer Values and Green Products Consumption in Malaysia: A Structural Equation Modelling Approach" by Brahim Chekima. Through case studies, this section lays excellent groundwork for later sections that will get into present and future applications for Green Business. The section concludes with an excellent work by Xenia Ziouvelou and Frank McGroarty, "A Business Model Framework for Crowd-Driven IoT Ecosystems."

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Section 3, "Tools and Technologies," presents extensive coverage of the various tools and technologies used in the implementation of Green Business. The first chapter, "Green Attitudes and Thinking in the New Green Market: Using Mathematical Modeling to Satisfy Green Customers' Needs" by Nicoleta Valentina Florea, lays a framework for the types of works that can be found in this section. The section concludes with "Introducing Eco Friendly Urban Traffic Control Room: A Green Approach" by Somasree Bhadra, Anirban Kundu, and Sunirmal Khatua. Where Section 3 described specific tools and technologies at the disposal of practitioners, Section 4 describes the use and applications of the tools and frameworks discussed in previous sections.

Section 4, "Utilization and Applications," describes how the broad range of Green Business efforts has been utilized and offers insight on and important lessons for their applications and impact. The first chapter in the section is "Green Practices Implementation as Prerequisite to Sustain Firm Competitive Advantages: The Empirical Study from Indonesia Large Scale Enterprises (LSEs)" written by Kardison Lumbanbatu and Vincent Didiek Wiet Aryanto. This section includes the widest range of topics because it describes case studies, research, methodologies, frameworks, architectures, theory, analysis, and guides for implementation. The breadth of topics covered in the section is also reflected in the diversity of its authors, from countries all over the globe. The section concludes with "The Leading Practices of Green Mobile Telecommunication Base Station Design" by Yazan Migdadi, a great transition chapter into the next section.

Section 5, "Organizational and Social Implications," includes chapters discussing the organizational and social impact of Green Business. The section opens with "Green Innovation and Ethical Responsibility" by Harsh Tullani, Raiswa Saha, and Richa Dahiya. This section focuses exclusively on how these technologies affect human lives, either through the way they interact with each other or through how they affect behavioral/workplace situations. The section concludes with "Looking Good and Thinking Green: Can Green Personal Care Products Be Promoted?" by Gauri Joshi and Gurudas Nulkar.

Section 6, "Managerial Impact," presents focused coverage of Green Business in a managerial perspective. The section begins with "Psychological Factors Influencing the Managers' Intention to Adopt Green IS: A Review-Based Comprehensive Framework and Ranking the Factors" by Mohammad Dalvi Esfahani, Mehrbakhsh Nilashi, Azizah Abdul Rahman, Amir Hossein Ghapanchi, and Nor Hidayati Zakaria. This section serves as a vital resource for developers who want to utilize the latest research to bolster the capabilities and functionalities of their processes. The chapters in this section offer unmistakable value to managers looking to implement new strategies that work at larger bureaucratic levels. The section concludes with "Green Retailing: A New Paradigm in Supply Chain Management" by Arnab Adhikari, Indranil Biswas, and Balram Avittathur.

Section 7, "Critical Issues and Challenges," presents coverage of academic and research perspectives on Green Business tools and applications. The section begins with "A Review on Green Trust and Environmental Quality Awareness Affect Towards Environmental Attitude" by Trianna Rosli and Fauziah Sh. Ahmad. Chapters in this section will look into theoretical approaches and offer alternatives to crucial questions on the subject of Green Business. The section concludes with "Awareness of Sustainability, Green IT, and Cloud Computing in Indian Organisations" by Tomayess Issa, Girish Tolani, Vanessa Chang, and Theodora Issa.

Section 8, "Emerging Trends," highlights areas for future research within the field of Green Business, opening with "Green Investments and Food Security: Opportunities and Future Directions in the Context of Sustainable Development" by Corina Ene, Marian Cătălin Voica, and Mirela Panait. This

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

section contains chapters that look at what might happen in the coming years that can extend the already staggering amount of applications for Green Business. The final chapter of the book looks at an emerging field within Green Business, in the excellent contribution "Green Performance Strategies in Romanian Economy in the View of EU 2020 Strategy" by Violeta Sima and Ileana Georgiana Gheorghe.

Although the primary organization of the contents in this multivolume work is based on its eight sections, offering a progression of coverage of the important concepts, methodologies, technologies, applications, social issues, and emerging trends, the reader can also identify specific contents by utilizing the extensive indexing system listed at the end of each volume. As a comprehensive collection of research on the latest findings related to using technology to providing various services, *Green Business: Concepts, Methodologies, Tools, and Applications* provides researchers, administrators, and all audiences with a complete understanding of the development of applications and concepts in Green Business. Given the vast number of issues concerning usage, failure, success, policies, strategies, and applications of Green Business in countries around the world, *Green Business: Concepts, Methodologies, Tools, and Applications* addresses the demand for a resource that encompasses the most pertinent research in technologies being employed to globally bolster the knowledge and applications of Green Business.

Chapter 1
Ecological Responsibility and Sustainable Development as Preconditions for Development of the Concept of Circular Economy

Olja Munitlak Ivanovic
Institute of Economic Sciences, Serbia

ABSTRACT

Ethical and ecological responsibility represent the root of sustainable development taking into account intergenerational justice. Mass production and consumption have left negative effects on the environment. Disregarding ecological responsibility, production processes were mainly based on uncontrollable use of raw materials and non-renewable energy sources. Taking into account limitation of raw materials, economic and ecological disasters, a concept of resilience has been developed to make all elements of society flexible in terms of unwanted shocks. This chapter describes two conceptual economic models: linear and circular. The linear model is based on the principle "take, produce, consume, and throw," meaning that usability of waste is reduced and that waste is simply thrown out after consumption. Circular economic model takes into account environmental responsibility, but it also makes companies more competitive. Waste is treated and processed adequately and used as raw material in production, thus increasing competitiveness. Waste that cannot be processed is disposed permanently.

INTRODUCTION

Sustainable development, in the essence of numerous definitions, has a common denominator – intra-generational and intergenerational justice. The most popular definition of sustainable development from report Our Common Future points out that development should satisfy the needs of present generation without questioning the possibility of future generations to satisfy their needs (World Commission on Environment and Development, 1987). Such perception of the concept of sustainable development im-

poses ethics review, especially ecological ethics review (Cifric, 2000). Cifric defines ecological ethics as needs for different pragmatical approach to development and environment. Ecological ethics became a part of the concept of sustainable development as a result of long-term inadequate treatment of the environment in the post-industrial society.

The issue of ecological ethics or ethical responsibility on micro and macro level refers to facing dilemmas on socially responsible behaviour and therefore, ecological responsibility (Krivokapic, Vujovic & Jovanovic, 2014). The issue of social responsibility and socially responsible behaviour shifted over time from the domain of voluntary philanthropic activities to conscious ethical behaviour and ethical responsibility or ecological legal frame that affect ecological behavior.

Disrupted relationship between people and natural resources resulting from mass production and consumption affects a modern man's behavior. Not only does he exploit nature, but he also destroys it. Nobel laureate Bertrand Russel thought that raising human consciousness about the necessity of changing the relationship towards nature is important for their existence (Russel, 2009). Mass production and consumption logics resulted in ecological crises, energetic crises, unsustainable treatment of natural resources and the value of the product itself. Modern issues of environmental protection are the consequence of the so-called linear economic model. The essence of such economy is exploitation of resources for production of products/services that is followed by consumption and throwing of unused parts representing the waste in this model.

Intensification of production and consumption in consumer society resulted in economic, ecological and social crisis. The response to these challenges was development of a new, essentially different economic model – circular economic model. Simply speaking, circular economy follows circular movement of production and brings it to a higher level. The essence of this model is reuse of waste and remaining byproducts in production. In this way, greater energetic efficiency is achieved, and consumption remains are brought back in the reproduction process. Therefore, unwanted waste coming from production and consumption becomes raw material and production is continued with less externalities (Lacy & Rutqvist, 2015) directly increasing GDP, especially in transition economies (Mitic, Munitlak Ivanovic & Zdravkovic, 2017).

BACKGROUND ON ECOLOGICAL RESPONSIBILITY

Ethical or ecological responsibility is not a new discipline, but the approach to interpreting of producer and consumer's behavior towards nature and environment has changed. A new ethical approach emphasizes the significance of components making the concept of ecological ethics itself. Many of these components are the result of high industrialization of society: economic and social justice, value pluralism, modern moral standards with regard to the environment, new forms of multiculturalism etc. (Cifric, 2000).

The question up to what level it is ecologically justified to use natural resources is an ethical question relating to intragenerational and intergenerational justice of sustainable development (Munitlak Ivanovic, 2017). This question is a basis for formulating of an adequate economic model (circular economy) that respects the concept of resilience as well (with a special emphasis to ecological and economic resilience) (Munitlak Ivanovic, & Zubovic, 2017). Speaking of ethical and ecological considerations, two conceptual bases are predominant in literature (Jost, 1996), namely (1) Perception of the concept of sustainable development based on science and (2) Perception of the concept of sustainable development based on human will.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

The concept of sustainability that is based on science starts from scientific researches and thus obtained results relating to natural capacities of the Earth. This concept formulates political and technical conditions and indicators needed for implementation of thus understood concept of sustainable development. There are two models of sustainability that are based on this concept and they are related to the possibility of substitution of the natural and physical capital. Two extreme attitudes are determined within this model: "pessimistic" (neoclassical) approach to sustainability and "optimistic" approach to perspective of sustainability (Jost, 1996). Natural capital implies stocks of natural renewable and non-renewable resources and usability stocks result from work and represent physical capital.

The essence of pessimistic theory of sustainability refers to possibilities of substitution of the most important resources and ecological capacities. In this way, the attitude that selective and restrictive approach to exploitation of natural resources is needed for implementation of the concept of sustainable development is emphasized. This enables "natural" survival of resources over a longer period of time (Munitlak Ivanovic, 2007). The arguments the theoreticians of pessimistic variant of sustainable development refer to are reflected in the fact that there is no optimal way for solving of majority of ecological problems caused by accelerated economic development. Pollution problem is solved mainly by transferring of pollution from one medium to another (Munitlak Ivanovic, 2009). The activity of paper industry can be taken as an example. In order to solve the problem of water pollution, factories use water filters. However, large amounts of toxic sludge are produced during filtration. This residual has to be burnt in special furnaces or disposed in specially protected areas. In this way, the problem of water pollution as the first medium is transformed in the problem of air pollution or soil pollution as the second, i.e. third medium (Golusin et al., 2011). The need for abandoning of linear economic model and accepting circular economic model is perceived already in this perception of the concept of sustainable development.

Theoreticians of an optimistic approach start from an undefined time horizon for realization of economic activities. The essence of optimistic theory is that majority of natural functions that are important for performing of economic activities (receiver of externality and supplier of natural resources) can be replaced (substituted) with physical capital. Theoreticians who advocate this approach refer to previous historical experience. Namely, optimists advocate the attitude that each developed society always finds an adequate substitute in case of a lack of resources (Munitlak Ivanovic, Mitic, & Popovic, 2015). A lack of wood as raw material in England in the 18th century, which resulted in substitution of the insufficient forest resource with available coal, is usually taken as an example. Such activities caused positive subsequent reactions resulting in new discoveries and innovations. In the first place, this refers to construction of the steam engine that marked first revolution, i.e, had an effect on many other discoveries and innovations and led to general technical progress (Landes, 1999).

Both theories are of extreme character, but it is still possible to find elements which can be implemented adequately in practice. What is common for both theories is that sustainable development, among other things, can also be defined as a responsibility for (Sachs, 2015):

1. Nature and environment.
2. Future generations (intergenerational justice).
3. Intensity of satisfaction of needs.

Pessimistic theory of sustainable development advocates proper perception with regard to ecological capacities for absorption of waste and waste materials, in cases when substitution is not possible at

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

all. Optimistic theory of sustainable development advocates proper perception with regard to renewable natural resources.

Ethical responsibility and all forms of ethical considerations are the essence of different perception of the concept of sustainable development. Market mechanism cannot implement the concept of sustainability without the help of the state and its institutions and this developed a real need for identification of ethical responsibility and new ethical basis for perception of sustainable development. Perception of the market as an automatic instrument for timely adjustment to pollution and exploitation of natural resources has failed. This raised the issue of organization of economy in a new – sustainable way. Therefore, the analysis of ethical and ecological responsibility for realization of the concept of sustainable development stems from the theory and practice at the same time (Stiglitz, 2004). In order to realize the concept of sustainability that is understood in this way, it is necessary to change human standards and activities thus enabling undisturbed long-term life functioning. However, a basic condition for such changes is a clear and conscious will to change behaviour and this will have to be articulated (Viscuci, 1983).

Basic ethical question is whether selfish attitude should be used to raise the present generation's standard of living if this reduces any form of richness of the future generations. This is the essence of intergenerational justice which is integrated in the definition of sustainable development from Brundtland Report. In addition to intergenerational justice, the report "Our Common Future" also insists on intergenerational justice, i.e. on as fair distribution of natural wealth during one, present generation as possible. The question that arises from this is if the present generation should have and if it has rights to satisfy all its needs, even luxurious ones, or only some of them. The issue "our present needs - needs of future generations" distinguishes two basic ethical approaches: anthropocentric and biocentric ethical approach (Max-Neef, Elizalde, & Hopenhayn, 1989).

The possibility of future generations to satisfy all their needs or the level of satisfying of the needs of present generations is an ethical issue that has become the issue of ecological responsibility over time. This results in various relationships and perception of the purpose of the nature. Is the nature only an "inexhaustible" resource or a condition of the survival of mankind (Jost, 1996)?

According to Human Development Theory, basic human needs have to be satisfied. These needs include:

- Need for socialization.
- Need for education.
- Need for culture, expression, information and other social needs that are not of existential nature. As a role of economic science is to help people live better and easier, human development theoreticians advocate an intensive economic development that is sustainable. Such development is a human development at the same time.

Traditional perception of needs depending on the culture, environment, historical period, economic and technical and technological development denies the existence of difference between the needs that have to be satisfied and those that don't have to be satisfied. In effect, the main question is: does the existence of a need expresses the right to satisfy that need? This issue was not essential before the period of mass production and consumption. There were enough raw materials and fuels and waste disposal was not problematic as it is today. In the post-industrial society, this is not only ethical and ecological issue, but also the issue of survival and quality life both of this generation and of future ones.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

The subject of the following chapters is representation and comparison of two concepts of economy: linear and circular model. Transition from linear to circular model in the European Union is growing faster as a result of development of new business models and new technologies. Ellen MacArthur Foundation was established in 2010 with the aim of making the transition to circular economy faster by its reports (Ellen MacArthur Foundation, 2012; Ellen MacArthur Foundation, 2013; Ellen MacArthur Foundation, 2014; Ellen MacArthur Foundation, 2015; Ellen MacArthur Foundation, 2016; Ellen MacArthur Foundation, 2017). The report from 2015 indicates that the value chain changes and that households in the European Union spend 60% of the average budget for rents and food, as well as that 80% of the total resources is exhausted in this way. This opens the space for more intensive application of circular economic model, which would result in the improvement of economic performance of the European Union.

THE CONCEPT OF LINEAR ECONOMY

So far, economy developed based on the simple principle: "take, produce, consume and throw". This is a basis of the so-called "linear" model implying unlimited and easy access to resources. This way of functioning of economy is characteristic from previous accumulation of capital to the present form of neoliberalism.

The perception that natural resources, especially ores and petroleum, are inexhaustible have been abandoned recently. At the end of the eighteenth century, in his "Essay on the principle of population", Thomas Robert Malthus questions an uncontrollable population growth rate from the point of view of survival funds (Malthus, 1798). Malthus states that population grows by geometric progression and funds needed for life, especially food, grow by arithmetic progression. Furthermore, the capacity of the Earth as a planet is limited, not only with regard to resources, but also to acceptance of industrial waste. Uncontrollable growth of world population and industrial growth are not possible as such processes require even bigger consumption of material resources.

Some other authors also pointed out to unsustainability of such growth. The Report of the Club of Rome from 1972, named "The limits of growth" was not accepted well by economists and therefore it did not have an influence on economic and ecological policy (Donella, Meadows, Randers, & Behrens III, 1974). According to critics of this report, an emphasis was on the significance of redistribution.

The Three Limitations Representing Real Limits of Growth

1. Soil as a source of non-renewable natural resources and food.
2. Ability of the environment to accept waste and other negative externalities of production and consumption processes.
3. Life in cities that incites consumption as a way of life and one of its values.

It is interesting that Brundtland's commission started from the similar postulates in the report as in "The limits of growth". While the report of the Club of Rome was sharply criticized, the report "Our Common Nature" was accepted well and understood as a desirable continuation of economic growth and a condition for sustainable growth and development.

The principle of linear economy "take, produce, consume and throw" treats waste as a residual of production that finishes its life cycle as a trash in the environment. Waste is a material or an object which

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

is not usable and which its owner plans to dispose permanently. According to Stevanovic (2003) waste is divided into solid and hazardous waste. According to the same source, solid waste is further classified into:

- **Municipal Waste:** It occurs in populated, mainly urban areas and it consists of residential and commercial waste.
- **Industrial Waste:** It occurs during production. Speaking of impacts on the environment, it can be hazardous and non-hazardous.
- **Internal Industrial Waste:** It occurs during production, but it is not dangerous for people's health and the environment according to its characteristics.
- **Medical Waste:** It occurs in health institutions. It can be hazardous and non-hazardous.

In linear economy, all waste will be permanently disposed after consumption, regardless which group of waste it belongs to, whether it is hazardous or not, whether it can be recycled or not. Such attitude towards the nature and production is unsustainable and it has to be abandoned. Figure 1 shows a linear economic model indicating that waste is the end of the life cycle of that production process.

Current period is characterized by the concept of linear economy, as ecological crises are not understood seriously enough. Due to advanced technology, raw materials are more available and cheaper and therefore, the concept of linear economy is accepted as an optimal model of growth as it is reflected in the growth of production and employment, profit and standard of living, but also in the growth of cities and demand for all kinds of products and services. Hyper production and consumerism are the bases of such perception of production.

However, the question is when linear economic model is not adequate, i.e. when it can and should be replaced by a new, circular model. Linear model of production was acceptable in the twentieth century. The advent of the next century has brought different demographic motions, from densely populated industrial centers to new growing markets and economies, and therefore the existing methods of production have to adjust to these changes. Growing consumerism requires bigger and bigger quantity of raw materials in order to satisfy growing demand and puts pressure on the prices of raw materials and energy products. Therefore, the model of reuse of waste could be a solution in terms of a new input. The future shifts to a new economic model – circular economy. This is confirmed by the numerical datum published by the Sustainable Europe Research Institute (SERI, n.d.), that 21 billion tons of materials, which were used in production, were not installed in the end products (losses incurred in production as unsuitable, inefficiency, storage problems, unnecessary loss of energy etc.). Although the transition in a wider sense implies processes through which states and people try to achieve economic growth and

Figure 1. Production process in linear economic model
Source: Authors own design.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

development as well as social welfare of developed countries, namely North America and Western Europe (Jovanovic, & Eskinja, 2008), this concept can be perceived differently. Transition can be perceived as a process of overall improvement of economy, i.e. abandoning the previous concept of linear economy and accepting another concept that has more modern perception of social responsibility, especially with regard to concretization of the concept of sustainable development.

Exploitation of natural resources in production during which a new usability is created and the remaining resources (waste) are not processed, i.e. are thrown out, is unsustainable in the long run due to limitation of resources. The economic crisis in 2008 and a sequence of frequent ecological crises caused by climate changes intensified the need for application of the existing concept of circular economy. In circular economy, products have longer expiration date and they are upgraded, repaired or recycled at the end of their life cycle, i.e. they are used again. In this way, less waste is disposed in large water areas, less food is thrown, and biodegradable waste is used more intensely, for example, for compost or energy production. All this has positive effects on opening of new jobs locally (Drljaca, 2015).

MODERN ECONOMIC MODEL: CIRCULAR ECONOMY

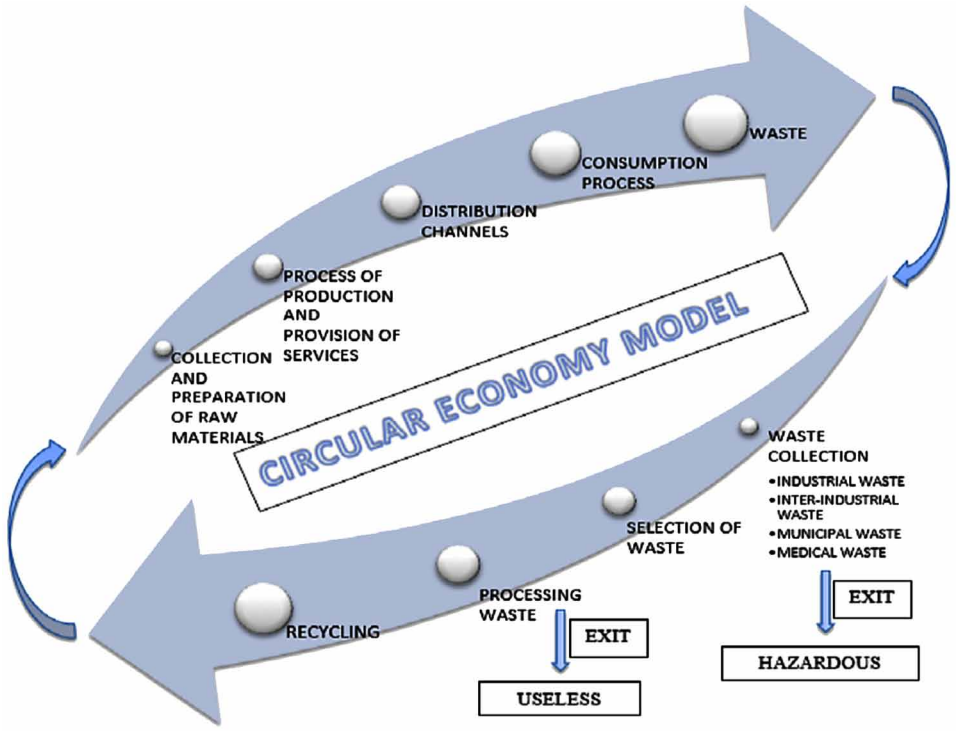
Based on all above mentioned, it could be said that the concept of circular economy follows circular motion of substance in the nature. The approach to relationship between production and consumption is different, as byproducts of production and consumption are used again in the new production process. The use of non-hazardous waste as an output of one production cycle and as an input for another production cycle results in distinguishing trash and waste. Waste no longer has the role of trash that pollutes the environment, but it becomes a raw material and material resource that reduces the price of the end product (Milanovic, Radovic, & Vucic, 2002). Therefore, circular economy can have an effect on competitiveness on the market. In circular economy, value-added product is used longer before it becomes waste meaning that material resources are used longer and more rationally.

Circular economic model is needed not only for environmental protection, but also for cost savings. The benefits of circular economy can be felt both on micro and macro level. Reduction of needs for new raw materials can save millions or billions of dollars depending on the size and intensity of economy. According to the assessments of the Ellen MacArthur Foundation, the European Union could save 400-600 billion dollars per year, primarily in automated and machine industry (Sariatli, 2017). Apart from the limitations listed below, this model should be used wherever production and technical requirements enable it (e.g. when the waste is toxic or dangerous, this model cannot be applied). However, likewise in all fields of business, managers and policy makers must have (in addition to developed ecological conscience), excellent knowledge on production processes in order to know when and how linear model can be replaced by a circular model. This is especially important if we take into account the lack of standardization in this field of business and that the decisions of this type depend on good knowledge of technology and processes. These exact data indicate the need of transition from one economic model to another only when and if it is possible.

As a new concept, circular economy is one of the reactions to economic crisis from 2008, as it represents a new concept of waste management. Waste is collected and processed, it does not have a negative impact on the environment and it is used again as a raw material in the production process. Each process enabling recycling, regeneration, using of valuable properties of waste as an input or energy source, direct reuse, reduction of quantity and volume of waste before permanent disposal is considered

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

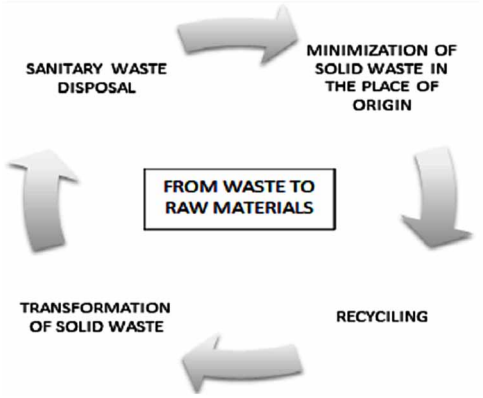
as waste processing. This means that recycling and processing are not the same terms, i.e. that recycling is a method of processing of waste (Stevanovic, 2003). The part of waste that cannot be processed is disposed permanently and safely. This process is shown in the scheme below.



Circular economy keeps some elements of the concept of linear economy. The path of the raw material from a resource through production, distribution, consumption and occurrence of waste is identical in both concepts. If the expiry date of a product is not only considered through the lifetime but also through the further life cycle (following motion of waste occurring from the product), the concept of circular economy is perceived completely. Phases of circular economic model are shown in Figure 2. Basic premise of circular economy is that there is a feedback bringing collected, processed and recycled waste back in production as a raw material.

In order for this system to function it is necessary to establish an integrated system of waste management. The idea of creating of such system is minimizing of unusable waste. In this respect, we can arrange phases in the following order (Figure 3):

1. Minimizing of solid waste at the place of its occurrence (end of production or consumption).
2. Recycling.
3. Transformation of solid waste.
4. Sanitary disposal.



Recycling is considered only when all possibilities of minimizing waste at the place of its occurrence are exhausted. Transformation is applied after achieving a maximum recycling level. Recycling is most

Figure 3. Phases of minimizing unusable waste
Source: Authors own design.

important in the process of waste processing, as these activities reduce consumption of new raw materials and quantity of waste that has to be disposed permanently. The same waste material or some its parts can be used once or more than once as a substitute for a new raw material or commercial products. In effect, the process of recycling is done in two ways: 1. Separating useful and usable parts from the integral solid waste and processing them or 2. Removing components that pollute the environment from waste and enabling their reuse. All above mentioned phases and processes being a part of water management system are necessary as they are a condition for transition to circular economic model.

On a global scale, transition to circular model should be intensified. Some highly developed countries, such as Japan, achieved great results in this area. Until 2020, Japan plans to organize such production in the city of Kamikatsu that will leave no waste, i.e. Kamikatsu will become the first zero waste city (Medlock, 2017). In its report from 2013, Ellen MacArthur Foundation (Ellen MacArthur Foundation, 2013) points out that only 35% of waste, 75% of which is municipal waste, is used as material inputs in the economy.

Likewise, any other concept, there are certain disadvantages and challenges with which circular economy faces. These disadvantages indicate that there are production processes, technology and/or situations that should function according to linear economic model. Essentially, all disadvantages can be classified in three groups (Circular Academy, 2017): (1) Achievability and desirability; (2) Social dimension and (3) Lack of standardization and strategic guidelines.

Achievability and desirability refer to certain production processes (such as paper recycling), materials and technological processes in which there are limits to which waste can be processed into raw material. As it is shown in Scheme 2, there are materials, such as dangerous waste, that cannot be processed further and therefore they cannot be covered by circular economic model. If dangerous waste remains after a production process, circular economic model cannot be applied, but only linear economic model. Insisting on recycling of waste in terms of production of new raw material at the level of 100% does not make sense if costs of waste recycling are higher than the value of the raw material obtained. Also in this case, economic logic suggests that in such cases linear economy is a better choice than circular economy.

Being focused on recycling the remains from production, circular economy pays less attention to social dimension. Work of employees is harder to standardize and recycling and re-processing require more work. This can have negative impacts on the employees' creativity, as well as on the loss of local

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

jobs if recycling is not done locally, but it is centralized and shifted to areas where labour is cheaper. (Ellen MacArthur Foundation, 2013). This jeopardizes human rights in the developed countries and indirectly supports poor economies.

Lack of standardization and strategic guidelines indicates the disadvantage of circular economy in terms of non-existence of accurately identified criteria, activities or guidelines for implementation of this concept in all situations (such as ISO). The application of circular economic model varies greatly depending on the market and products and therefore any generalization and standardization is imprecise. Although there are no guidelines covering these issues (Ellen MacArthur Foundation, 2014), it still cannot be said that there is an internationally recognized standardization referring to recycling and circular economy for all products and processes.

As researchers from the Republic of Serbia deal with this issue as well, although on a limited scale, we will mention the results of present application of circular economic model, which is still in the initial phase in Serbia. It mainly refers to industrial production. The examples of good practice mainly refer to recycling of: Tetra Pak, water proof eco boards, plastics, multy-layer packaging for beverages and liquid food, waste tires, used antifreeze, then ash processing and heating by means of briquettes made of coffee beans. Development of circular economy strategy in the Republic of Serbia, together with the action plan for tools for full application is planned for 2017.

Over 70 companies with more than 40.000 employees in total participated in cleaner production and chemical leasing projects in Serbia in the last nine years. Average savings amount to cca. 100.000 € per year together with (Circular economy as a chance for development of Serbia, 2016):

- **Average Reduction of Water Consumption:** 50.000 m3/year.
- **Average Reduction of Electricity Consumption:** 500 MWh/year.
- **Average Reduction of CO2 Emissions:** 500t/year.

It is estimated that 30.000 new jobs can be opened and competitiveness of the economy increased by introduction of the circular economy in Serbia. The Republic of Serbia follows the processes of adoption and introduction of the circular economy in the European Union and it reacted promptly by accepting the recommendations of the European Union on the circular economy. The Ministry of Agriculture and environmental protection has recognized the needs for amendment of the law and suggested amendments to the law on environmental protection in cooperation with the Chamber of Commerce and Industry of Serbia and other relevant institutions. The amendments from February 2016 created legal basis for introduction of circular economy.

CONCLUSION

Development of consciousness, ethical and ecological responsibility resulted in creation of various concepts: sustainable development, resilience, linear and circular economy. Ethical issues and issues relating to ecological responsibility and sustainable development are observed from various aspects in this paper: Human development theory, perception of the concept of sustainable development based on science (“pessimistic attitude”) and perception of the concept of sustainable development based on human will (“optimistic attitude”).

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Sustainable development is based on three pillars: economic, ecological and social. The essence of this concept is in the attempt to distribute natural wealth to all generations, minimize pollution, minimize global warming and solve other issues that are important for environmental protection.

Resilience is a step further to creation of an optimal model of functioning of global society in unstable and unpredictable conditions. It is based on the idea of as much flexibility of four pillars – economic, social, environmental and institutional – as possible. Speaking of this concept, flexibility implies readiness of each pillar to adjust to unwanted situation (shock) and returning of all pillars in the state before shock as soon as possible. In this respect, various strategies (scenario models) are developed in advance within strategic management.

Linear economy, being based on the principle "take, produce, consume and throw", does not treat waste adequately. Due to application of modern technologies, the price of raw materials falls resulting in the attitude that linear economy is an optimal model of growth which is characterized by: employment growth, production growth, profit growth and growth of a standard of living, i.e. hyperproduction and mass consumerism. However, such attitude towards the environment is not sustainable in the long run due to limitation of resources.

In addition to the above-mentioned disadvantages: achievability and desirability, social dimension and lack of standardization and strategic guidelines, circular economic model is the economic model of the future. In order to make a transition from linear to circular economy, it is necessary to define guidelines for each production sector on how to implement a circular economic model and establish an internationally recognized institution for standardization of the circular economic model that would define regulations, standards and necessary activities for each field of business. Unlike linear economic model, audience and consumers are still not familiar enough with the circular economic model. In this respect, social marketing campaigns should be intensified in order to familiarize general public with the advantages of circular economic model. All above mentioned points to the need for larger investments in order to make circular economic model a dominant production model. Manager and policy makers need to know production processes, i.e. characteristics of production sectors very well, so that they could standardize the steps for implementation of circular economy first, and then raise it to the national and international level by forming an official organization for standards related to this model. This means that general theoretical knowledge in economics is not enough and that continuous specialization and collection of new information and knowledge is needed. Lifelong learning and continuous education on higher levels of top management is a precondition for application of circular economy.

Circular economy is a new global response to ecological crisis and climate changes on one hand and economic crisis on the other hand. This new concept of economy of the twenty-first century has a different approach to all economic processes, not only from the aspect of sustainable development, but also from the aspect of social responsibility and therefore ethical and ecological responsibility. In this economic model, waste that occurs after consumption is used again after processing. There is a feedback bringing selected and processed waste back in the new production cycle as a raw material. Speaking of the described characteristics of different concepts, i.e. economic models, it can be perceived that circular economic model is sustainable in the long run. This model is economically justified as it has a positive effect on competitiveness and takes care that economic development is humane at the same time. It is economically justified as it reduces the use of raw materials and quantity of waste. Circular economic model, i.e. its elaboration on micro and macro level, is close to the concept of sustainable development. This model is also a response to ethical and ecological responsibility which each generation and society should implement in practice as intensely as possible.

KEY TERMS AND DEFINITIONS

Circular Economy: A desirable concept of the economic model, as non-hazardous waste is processed in various ways and returned in production. Raw materials are used less which increases competitiveness of the company over competition as usability of waste is prolonged.

Ecological Responsibility: A concept which implies socially responsible behavior towards nature. It is an ethical attitude to natural resources during their exploitation and during waste disposal.

Environment: A precondition for the existence of all (economic and other) processes and creatures. It is divided into non-living nature (water, air, soil, minerals, and similar) and living nature (plants, animals, bacteria in ecosystems). Briefly, no system could survive without the environment.

Intergenerational Justice: One of the principles on which the concept of sustainable development is based. The essence of this justice is in intra-generational and intergenerational justice. This means that, within the same generation (i.e., among generations), the principle of equal right to similar quantities of natural resources is respected.

Linear Economy: Still, a predominant form of production that treats waste after product consumption as the end of the life cycle of production and consumption, disposing of it permanently.

Raw Materials: Various natural resources that are used as an input in production. Production of goods or services would be impossible without raw materials.

Resilience: A concept representing the "upgraded" concept of sustainable development. It is based on four pillars, three of which are the same as in the concept of sustainable development and the fourth pillar being institutions. The concept of resilience insists on flexibility of all four pillars in case of an unwanted situation (shock), fast adjustment of pillars to new situation (i.e., returning the whole system in the state before shock).

Sustainable Development: A concept that is based on three pillars: economic, ecological, and social. The main idea of this concept is that economic processes take place on an optimal level, satisfying social needs without prejudice to environmental protection.

Waste: A residual of production (i.e., consumption). It is a material or an object that is not suitable for further use and therefore, it is permanently disposed or thrown. Depending on the category or determined class which it belongs to, waste is treated in the process of waste processing (in circular economy) or rejected immediately as unusable without previous processing (in linear economy).

Chapter 2
Consumer Cooperation in Sustainability:
The Green Gap in an Emerging Market

Njabulo Mkhize
University of kwaZulu-Natal, South Africa

Debbie Ellis
University of KwaZulu-Natal, South Africa

ABSTRACT

The planet is under threat. Unless all stakeholders, that is governments, businesses, and consumers, become more environmentally friendly, some predict dire consequences for the earth and all those who inhabit it. While governments and businesses have a role to play, green consumer behavior is vital to the sustainability of the environment. Consumers have been shown to express increasing concern for the environment, but in many studies this concern has been found not to be matched by actions, a phenomenon labelled the green gap. This chapter describes a study that investigated the existence and extent of the green gap amongst a sample of South African adult consumers and sought to determine possible reasons for a lack of green behavior. Recommendations are made to marketers and policy makers to encourage consumer cooperation in environmental sustainability.

INTRODUCTION

António Guterres, the United Nations Secretary General, warns that climate change and competition for scarce natural resources threaten peace and sustainable development globally and that protecting the environment and having an emphasis on environment prevention methods is imperative (United Nations, 2016). There are two main drivers of the human impact on the environment, namely population and consumption (de Sherbinin, Carr, Cassels, & Jiang, 2007). The last century has seen an increase in the global population, which has resulted in an increase in the food consumption and a deterioration of the environment caused by over consumption and an increase in the use of natural resources (Chen & Chai,

DOI: 10.4018/978-1-5225-7915-1.ch002

Copyright © 2019, IGI Global. Copying or distributing in print or electronic forms without written permission of IGI Global is prohibited.

2010). The global population has more than tripled in the last century from an estimated 1.5 living on earth in 2003 to 6.3 billion people and there is a prediction that the population will reach 9.7 billion by 2050 (United Nations, 2015). Most of this growth will come from emerging markets.

From a marketing perceptive an increase in the number of people and their consumption levels may be seen as advantageous since products are being consumed. However thirty to forty percent of the environmental issues are caused by the consumption patterns of human beings (Chan, 2001) thus the decisions and behaviours of consumers have a significant impact on the environment (Tobler, Visschers, & Siegrist, 2012). Climate change, global warming, deforestation, pollution and depletion of the ozone layer are just some of the global environmental crises facing the world (Juwaheer, 2005). These environmental issues give rise to environmental concern amongst governments, activist groups, some businesses and some consumers, which has led to the emergence of the green economy consisting of green or pro-environment governments, companies, marketers and consumers. Global consumers' cooperation in achieving global sustainability is arguably more important than government or business actions as consumers have the greatest impact on sustainability or the lack thereof.

In most studies on environmental concern, it has been found that people are concerned with their impact on the environment and the deterioration thereof (Takács-Sánta, 2007) and these levels of concern have been increasing especially in the last three decades (Kim & Choi, 2005; Synodinos & Bevan-Dye, 2014). This increase in environment concern should translate into green consumer behaviour, i.e. the purchase and use of products and services which are environmental friendly. While some prior research studies indicate a significant positive relationship between environmental concern and green consumer behaviours (Davari & Strutton, 2014; Kim & Choi, 2005) with some even finding environmental concern to be a predictor of green consumer behaviours (Sinnappan & Rahman, 2011), this is not always the case. Other researchers have found that more consumers in the modern society are concerned about the environment than has translated into environmentally friendly behaviours and the purchase of green products (Fisher, Bachman, & Bashyal, 2012; Flynn, Bellaby, & Ricci, 2009; Young, Hwang, McDonald, & Oates, 2010). This gap between green concern and green behaviour is known as the 'green gap' (Kennedy, Beckley, McFarlane, & Nadeau, 2009; Nielsen, 2011).

The efforts made by green consumers to purchase green products and support green initiatives have been hindered by several constraints to adopting green lifestyles. Addressing these constraints will assist in decreasing the green gap globally. This research investigates the extent of the green gap in an emerging market and surfaces some of the perceptions respondents have regarding green behaviour which might indicate reasons these consumers give for not adopting green lifestyles. de Barcellos, Krystallis, de Melo Saab, Kügler, and Grunert (2011) indicate that research on the green gap has been scarce in developing countries, such as South Africa. Without the cooperation of emerging market consumers in achieving sustainability, the efforts of developed nations' governments, business and consumers is unlikely to be enough to save the planet. It will ultimately be vital to garner the support and cooperation of the emerging market consumers as they represent 80% of the world's population (European Central Bank, 2017).

The mission of this chapter is to expose the reader to research conducted on emerging market consumers to determine the existence of, and reasons given for, the green gap among these consumers. After reading this chapter, the reader will understand a key sustainability concern which is understanding of the challenges to getting emerging market consumer cooperation in achieving global sustainability goals. The reader will also be exposed to recommended solutions to enhance green behaviour among these consumers so as to ultimately better achieve global sustainability.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

THEORETICAL FRAMEWORK

Various social-psychological theories have been used by researchers of green behaviour to understand this behaviour (Stern, 2000). However, the Knowledge Attitude-Behaviour model has been used widely to describe behaviour change (Derzon & Lipsey, 2002). In the context of green behaviour it represents a linear model which explains that environmental awareness (knowledge) influences environmental concern (attitude) which in turn influences pro-environmental behaviour (Kamate et al., 2009). This study focuses specifically on the concern-behaviour link in the model by investigating the existence of a gap between concern and behaviour and possible reasons for this gap.

Green Consumer Behaviour

There are several terms which have been used in past studies to describe green consumer behaviour such as 'ecological conscious consumer behaviour (ECCB)' (Straughan & Roberts, 1999), 'pro-environmental consumer behaviour' (Kaufmann, Panni, & Orphanidou, 2012), 'environmentally conscious consumer behaviour' (Gan, Wee, Ozanne, & Kao, 2008), 'environmentally friendly consumer behaviour' (Thøgersen & Ölander, 2003) and 'green consumer behaviour' (Jansson, Marell, & Nordlund, 2010). This section uses these names interchangeably.

Green consumers are understood to be people who have a particular interest in, and awareness of 'green' issues and make an ongoing attempt to change their behaviours to protect the environment (Chen & Chai, 2010). Moisander (2007) states that green consumers are characterised by the willingness to use their purchasing power to cause a social change. With the purpose of reducing the negative effect on the environment they engage in behaviours of recycling materials, buying green products, being aware of and supporting companies which are green, checking labels and packaging to see if they are environmentally friendly and adopting behaviours which lessen or reduce green issues (Albayrak, Caber, Moutinho, & Herstein, 2011; Laroche, Bergeron, & Barbaro-Forleo, 2001) such as conserving energy and water and supporting conservation campaigns such as 'Save the Rhino'.

Environmental Concern

Environmental concern or concern for the natural environment (Hartmann & Apaolaza-Ibáñez, 2012) can be defined "as a global attitude with indirect effects on behaviour through behavioural intention" (Kaufmann et al., 2012, p. 53). Environmental concern is an important attitude in the struggle for the sustainability of the environment. According to Pagiaslis and Krontalis (2014), ecological or environmental concern is a concept of general belief that is an antecedent of more specific concepts such as green knowledge and environmental beliefs associated with green products. The levels of environmental concern across the globe have been increasing steadily. In America for example, studies show that there was an increase in environmental concern from 62% to 77% between 2004 and 2006 (Ryan, 2006) and in a recent study by van Riper and Kyle (2014) high levels of environmental concern amongst US respondents were found. Environmental concern has also become important for the international community too. In a study in Hong Kong, 80% of respondents expressed dissatisfaction with the city's environmental quality (Lee, 2008) indicating concern for the environment. In the United Kingdom, approximately 47% of consumers have favourable attitudes towards organic foods (Albayrak et al., 2011). Studies of various aspects of environmental concern in several populations in South Africa have found environmental

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

concern for pollution, waste (Rousseau & Venter, 2001), air and water (Berndt & Petzer, 2011; Davari & Strutton, 2014; Kim & Choi, 2005; Straughan & Roberts, 1999) however levels of environmental concern have generally been found to be lower in developing nations than in developed nations (Paul, Modi & Patel, 2016).

In some cases a positive correlation has been found between the environmental concern and environmentally friendly behavior, and environmental concern has been found to predict green behavior (Kaufmann et al., 2012; Lee, 2008; Sinnappan & Rahman, 2011). However this concern does not always match behaviour and a green gap has been found between concern and behaviour.

The Green Gap

Generally individuals consider themselves as eco-friendly or sensitive to the environment but their behaviour often contradicts their confessed sensitiveness (Albayrak et al., 2011; Fisher et al., 2012). This gap has been called the value-action gap (Honabarger, 2011), the environmental values-behaviour (EVB) gap (Kennedy et al., 2009), and the 'green gap' (Honabarger, 2011).The 'green gap' can also be defined as "the observed disparity between people's reported concerns about key environmental, social, economic or ethical concerns and the lifestyle or purchasing decisions that they make in practice" (Flynn et al., 2009, p. 158).

Evidence of the green gap: There is compelling evidence supporting the existence of the green gap at least in developed nations. For example, in a Canadian study done in 2004, it was shown that 72.3% of the respondents stated they were concerned about the environment but their actions did not support their concern as only 10.8% stated their lifestyles were supportive of the environment (Kennedy et al., 2009, p. 156). Similarly, a global survey done by McKinsey & Company indicated that 87% of the participants were concerned about the environmental and social impact caused by their purchase behaviour but only 33% admitted to have bought products that assist in sustaining the environment (Bonini & Oppenheim, 2008). More recently in a study by Nielsen, it was shown that 83% of consumers in the world are aware of the need to implement programmes to assist with environmental recovery yet less than 20% are willing to pay more for their green products (Nielsen, 2011).

The above studies mostly reflect research done in developed countries. Few studies have been conducted in developing nations. A study conducted in Turkey which looked at consumer skepticism towards green products found a disparity between green consumer behaviour and environmental concern (Albayrak et al., 2011). Another study conducted in India explored the green concern and behaviour in the lodging industry and found that respondents were conscious of environmental issues but they still did not adopt green lifestyles, because they were not willing to pay a premium price (Manaktola & Jauhari, 2007). Pantelic, Sakal, and Zehetner (2016) found that their Serbian sample also exhibited positive attitudes towards sustainability but lacked the corresponding actions. In South Africa, some studies have been done on environmental perceptions, awareness and behaviour (e.g. Anderson, Romani, Phillips, Wentzel, & Tlabela, 2007). A study conducted in the Durban Municipality researched making laws at local government level to adapt to climate change (Roberts, 2008). However, no studies could be found that specifically investigate the green gap in South Africa. This study aims to fill this research gap.

Reasons for the Gap: Understanding green behaviour is far more complicated than previously thought (Gifford & Nilsson, 2014) and determining the reasons or the barriers for consumers to adopt green lifestyles has been said to be a complex issue (Kaufmann et al., 2012). While individuals can state that

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

they value the environment, in some instances other issues take precedence over their concern for the environment e.g. financial security and safety (Kennedy et al., 2009). Han, Hsu, and Lee (2009) state that monetary and non-monetary costs are reasons for the small numbers of eco-friendly consumers who are in the market. Several reasons have been proposed for why consumers do not adopt ecologically conscious consumer behaviour:

- **Green Products Are Perceived to be Expensive:** Green products are, and are perceived to be, more expensive yet provide the same functions (Bennet & Williams, 2011). Although long-term cost savings may come from using energy efficient products like hybrid cars and light bulbs, initial costs are usually higher (Stephenson & Rodriquez, 2014). Majláth (2010) states that price is the biggest reason that consumers do not buy green products. A study conducted in India found high prices as a major barrier to organic food consumption as Indian customers are price sensitive compared to developed nations (Yadav & Pathak, 2016, p. 123).
- **Green Product Availability:** Takács-Sánta (2007) argues that it is not the weakness of environmental concern but the lack of alternatives, which jeopardises adoption of ecologically conscious behavior. Tilikidou (2007) found that some green products, such as organic wine, toiletries, pasta and clothing, are difficult to find. GrailResearch (2011) reports that 34% of their US respondents indicated low availability of green products as a reason for not buying these products. In India, also a developing market, green choices were perceived to be low (Paul et al., 2016).
- **Perception of Inferiority of Green Products in Terms of Quality and Efficiency:** Sharma (2011) states that one of the biggest obstacles to consumers' adopting a green lifestyle or purchasing eco-friendly products is the lack of trust in green products. Consumers' scepticism, or distrust of green products, reduces their ability to make a pro-environmental decision (Albayrak et al., 2011).
- **Perceived Consumer Effectiveness:** Perceived Consumer Effectiveness (PCE) is defined as the extent to which consumers believe that their individual efforts can have a positive impact on the environment (Chang, 2011; Kim & Choi, 2005). PCE is seen to be a significant predictor of a variety of ecologically conscious and pro-environmental consumer behaviours (Chang, 2011; Majláth, 2010; Rex & Baumann, 2007; Straughan & Roberts, 1999; Vicente-Molina, Fernández-Sáinz, & Izagirre-Olaizola, 2013). Roberts (1996) argues that PCE is the single strongest predictor of green consumer behaviour, surpassing both psychological and demographic factors.
- **Lack of Information About the Availability of Green Products:** Lack of information is one factor affecting the practicality of adopting a green lifestyle (Kollmuss & Agyeman, 2002).

These reasons are investigated in this study of South African consumers. Soyez (2012) states that in terms of environmental research, researchers ought to concentrate more on examining emerging economies that have an effect on the environment such as South Africa in order to understand the actions of consumers better.

A STUDY OF EMERGING MARKET CONSUMERS

Research Methods

A descriptive research design using quantitative data was used to describe participants concern for the environment and green behaviour so as to determine the existence and extent of the green gap, as well as the reasons for a lack of green behaviour. The questionnaire was developed to measure the constructs of this study. Ethical clearance was obtained from the university's Research Office before the commencement of the study. All respondents were assured of their anonymity and confidentiality.

Measures

The questionnaire included the environmental behaviour questions from the ECCB scale developed by Roberts (1996) and used by Straughan and Roberts (1999) and more recently by several authors (e.g. Datta, 2011; McEachern & Carrigan, 2012). To measure environmental concern the Environmental Concern scale, also called the New Ecological Paradigm (NEP) scale developed by Dunlap, Kent, Angela, and Robert (2000) was used. This scale has also been used in many other studies (e.g. Amburgey & Thoman, 2012; Vikan, Camino, Biaggio, & Nordvik, 2007). The Perceived Consumer Effectiveness scale items were taken from the Straughan and Roberts (1999) questionnaire. The other questions on reasons for the lack of ECCB, were developed from the literature review. Previous use of the main measures indicated that these scales exhibit internal consistency and can thus be deemed reliable. For example, the Cronbach's alpha for the ECCB scale was 0.96, Environmental Concern scale 0.84 and the Perceived Consumer Effectiveness had an alpha scale of 0.72 (Roberts, 1996, p.223-224). Hair, Bush, and Ortinau (2009) state that a co-efficient alpha of less than 0.6 indicates a low to marginal (unsatisfactory) internal consistency. Therefore, looking at the Table 1, the constructs exhibited acceptable internal consistency reliability in this study.

Pilot studies are used to identify weaknesses or limitations of the questionnaire (Hair et al., 2009; Muijs, 2010). The pilot study sample was chosen to represent the research sample. A sample of 30 was selected to represent all the demographic variables relevant to the study in relation to race, gender and age. The sample was conveniently selected and this was seen as reasonable since the study was also using convenience sampling. The pilot study ensured that different types of respondents would be able to understand the research instrument. The pilot study was conducted at the same study location as the main survey. The length of the questionnaire was particularly taken into consideration while conducting the pilot test as it was seen as a critical factor to receiving unbiased data. The longest time it took a respondent to complete the questionnaire was 10 minutes but some respondents were able to complete it in 5 minutes. It was decided that this was an acceptable time for respondents to complete the questionnaire

Table 1. Cronbach alpha scores for the current research instrument

Scale	Cronbach Alpha
Ecologically conscious consumer behavior (ECCB)	0.88
Perceived Consumer Effectiveness (PCE)	0.67
Environmental Concern (EC)	0.76

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

without negatively affecting response rate. Therefore, there were no changes in terms of the length of the questionnaire. Pilot study respondents were also asked to give feedback on the questionnaire. They experienced no difficulty in answering the questions therefore no changes were made to the research instrument. The original Likert scale format was used where 1=*strongly agree* and 5= strongly *disagree.*

The Sample

Since the research investigated the 'green gap', which is the difference between the levels of concern and the purchasing behaviour of consumers, an adult population was seen as an appropriate population since they possess purchasing power. In the South African constitution any person older than 18 is considered to be an adult, and thus has the capacity to make their own decisions (Strode, Slack, & Essack, 2010). The study took place in a municipality in South Africa with approximately 423 000 people who are over the age of 15 with 53% female and 47% male. The race distribution of residents is approximately 81% African, 10% Indians, 6% White and 3% Coloured (StatisticsSA, 2011).

Since the questionnaire included a large number of constructs each with multiple measures, it was fairly lengthy, thus, needed to be distributed to respondents where it would be convenient for them to complete. The study site chosen was the Mkondeni Test Driving Centre (MTDC) Licensing Department. This study site was chosen because it is the place where all residents have to go to book their learners and driving tests, to be tested for their learner and driving licenses, and to renew their licenses every 5 years, and thus, it provided access to a large number of relevant members of the target population. There are also usually fairly long queues thus providing people who may be more likely to have time to answer the questionnaire, thereby improving the response rate. The MTDC is ideal for data collection as it is the only testing centre in the city and the people who go there are over the age of 18 years, due to legal age restriction for driving. It is acknowledged that any study site is likely to have some limitations. In this case the site may exclude certain elements of the population, for example, those who do not drive. Overall it was believed that the benefits of the site outweighed the limitations, as the site provided a good cross-section of respondents from all race groups, genders and ages above 18. Other study sites such as shopping malls were considered to be inferior as they have been over-used in consumer behaviour studies in the past and are also unsuitable for lengthy questionnaires. Data was collected over a period of a month, 3 days per week, chosen to ensure all days were eventually covered during the month.

At the confidence level of 95% and with a 5% confidence interval, a sample of 378 was desired. Using non-probability, convenience sampling 378 questionnaires were distributed and 330 questionnaires returned of which 317 were usable. This gave an effective response rate of 84%. The demographic profile of the sample is presented in Table 2.

As illustrated in Table 2, the gender and race profile is not too dissimilar to that of the municipality's population, although the sample is somewhat skewed in terms of age with the majority of respondents being in the age groups 18 to 30. In terms of the level of education of this sample, it indicated a highly literate group as the majority (98.4%) of respondents hold a National Senior Certificate (NSC) qualification and above. The NSC qualification is the national school leaving certificate after 12 years of schooling. This is in contrast to the municipality statistic indicating that only approximately 24% of the municipality's population hold a NSC or higher (StatisticsSA, 2011). It should be kept in mind however that the study was restricted to adults while the city statistics reflect all ages. Thus, overall it is felt that this sample bears close resemblance on demographics, to the city's adult population.

Results

After reversing negatively worded item scores, composite scores were created for each construct representing the mean score for the construct i.e. for Environmental Concern (EC), Ecologically conscious consumer behaviour (ECCB) and Perceived Consumer Effectiveness (PCE).

The Green Gap

As with other studies on the green gap (e.g. Nielsen, 2011), the difference between ecologically conscious consumer behaviour (ECCB) and environmental concern (EC), was calculated. In terms of an equation, the Green Gap = ECCB - EC (Nielsen, 2011). If the mean of the ECCB construct is greater (i.e. showing more green behaviour) than the mean for the EC construct, then a positive gap exists (there is no 'green gap') and there is more action towards a sustainable environment than there is concern. The green gap occurs when the ECCB mean is less than the EC mean. The results of this study indicate a green gap of -.661. Thus concern is greater than behaviour. This difference in composite scores is significant $t(58) = -6.671$, $p < .000$(2-tailed) and the eta squared statistic (.43) indicates a large effect size. This suggests that the respondents of this study have higher levels of concern than behaviour. This is consistent with a global study conducted by Nielsen which found that 87% of the participants were found to be concerned about the environment but only 33% converted their concern into action when they bought products. In the current study 73% of respondents were concerned but only 22% converted their environmental concern into green consumer behaviour. Possible reasons for the lower levels of behaviour were then explored.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Reasons for the Green Gap

This section is divided into two parts, firstly a discussion of Perceived Consumer Effectiveness as a possible reason for lack of ECCB, and secondly other reasons for the lack of ECCB.

Perceived Consumer Effectiveness (PCE) is defined as the extent to which consumers believe that their individual efforts can make a positive impact on the environment (Chang, 2011; Kim & Choi, 2005). Thus consumers may not behave in an environmentally-friendly manner because they do not believe their actions will make a difference (Straughan & Roberts, 1999). In this study the composite mean score for PCE was 2.17 (STD = .691) where 1 represents a highest PCE and 5 the lowest PCE. Fifty eight percent of the respondents, as well as the relatively low mean (2.17) indicates that respondents believe that their individual actions can make a difference towards the sustaining of the environment. Thus it seems that a lack of perceived effectiveness should not be the reason for the low levels of ECCB. Other reasons are investigated below.

Table 3 indicates that the reasons for the lack of green consumer behaviour in this sample were predominantly the perceptions of a lack of promotion of green products (M=2.34), the lack of availability of green products (M=2.66), that green products are not clearly labelled (M=3.14) and the lack of mechanisms to support a green lifestyle (2.77) where 1 = strongly agree and 5 = strongly disagree.

BUSINESS AND POLICY IMPLCATIONS AND RECOMMENDATIONS

Lee (2008) argues that environmental concern is the second top predictor of green purchasing behaviour. In an application to the eco-hospitality industry, Han et al. (2009) found that there is a significant relationship between level of environmental concern and the number of people who intend to stay at an Eco-hotel. Similarly Laroche et al. (2001) state that there is positive relationship between the willingness of consumers to pay a premium price and the extent of environmental concern. Thus it seems environmental concern may be a necessary prerequisite to environmental behaviour. Similar to other studies

Table 3. Other reasons for the green gap

Reasons for the 'Green Gap'	Frequency (Percentage)					
Statement	**ATSE**	**N**	**DTSE**	**Missing**	**Mean**	**Std dev.**
Product quality of green products is inferior	84 (26.5)	98 (30.9)	125 (39.5)	10 (3.1)	3.22	1.21
Promotion of eco-friendly products is lacking	197 (62.1)	56 (17.7)	58 (18.3)	6 (1.9)	2.34	1.09
Unable to distinguish between green and conventional products	104 (32.8)	94 (29.7)	109 (34.4)	10 (3.1)	3.03	1.14
Green products are not easily available	152 (38)	81 (25.6)	78 (24.8)	6 (1.9)	2.66	1.09
I am not aware of any green products	64 (20.2)	60 (18.9)	188 (59.3)	4 (1.3)	3.55	1.14
I don't trust green branded products	45 (14.2)	77 (24.3)	191 (60.2)	4 (1.3)	3.65	1.01
Green products are clearly labelled	102 (32.1)	88 (27.8)	121 (58.2)	6 (1.9)	3.14	1.11
There are no or limited mechanisms available to practice a green lifestyle	130 (41)	99 (31.2)	82 (25.9)	6 (1.9)	2.77	1.11

ATSE= Agree to some extent; N= neutral; DTSE= Disagree to some extent

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

(e.g. Lee, 2008; Nielsen, 2011) the current study found that respondents showed high levels of concern about the environment. However it is behaving in an environmentally friendly way that is the required consumer cooperation essential in the fight against the depletion of the environment. Concern may be necessary but studies have found that it is not always sufficient to ensure behaviour and a green gap has often been found between concern and behaviour (Laroche et al., 2001; Nielsen, 2011). In this study, ECCB item scores indicate that respondents have participated in some actions that are pro-environmental e.g. reducing electricity consumption but on the whole, green behaviour lags behind concern. Only 13% of respondents can be said to frequently act in a green manner. Although very low, this figure is not totally dissimilar to a similar global study where the percentage was 22% (Nielsen, 2011). Thus like many other countries, this study of South African consumers also indicates a significant gap between environmental concern and behaviour.

The second objective of this research was to try to understand why green behaviour may be lacking in developing nations such as South Africa. Barriers to adopting of the green lifestyle are evident in prior studies (e.g. Kollmuss & Agyeman, 2002; Nielsen, 2011). The participants of this study also indicated that these barriers impede their green behaviour. The main reason for not behaving in a green manner appears to be a perception of a lack of promotion of green products. If consumers are not made aware of the existence of green products or of the benefits of these products to consumers and the environment, then consumers cannot be expected to cooperate in achieving global sustainability by purchasing green products. Promotion is a fundamental aspect of the marketing mix and necessary for the adoption of these products. Better information by organisations that are promoting the adoption of green products and services is vital to gaining the trust of consumers in the market (Ozaki, 2011). Producers of green products need to address this problem by actively promoting their products so that consumers recognise green products as strong alternatives to traditional products which are more harmful to the environment. Money is needed to aggressively promote green products in all forms of media. An integrated marketing communication plan needs to be designed and implemented.

Eco-labels are also a good way to notify consumers that products are environmentally friendly. According to Rashid (2009, p.134) eco-labels are eye-catching tools that notify consumers. The Global Ecolabelling Network states that an eco-label is a label which "identifies overall environmental preference of a product or service within a specific product/service category based on life cycle considerations" (Global Ecolabelling Network, 2011, para4). To be of use in steering consumers towards green products, these labels have to be credible, meaningful and recognisable to consumers (D'Souza, Lamb & Taghian, 2006). Third party environmental labelling has superior reliability as they involve a 3rd party evaluation of a company's environmental principles (D'Souza et al., 2006). Once a manufacturer passes the certification process the product is awarded a seal or symbol which is a sign that the producer's product has been deemed environmentally safe (Engels, Hansmann & Scholza, 2010). As independent verification is used to determine if a manufacturer meets the criteria, the consumers trust these labels more in comparison to the manufacturers' self-installed labels (Grankvist, Dahlstrand & Biel, 2004). Consumers' assessment of environmental performance of brands is usually affected completely by environmental symbols (Roe, Teisl & Rong, 2001). Unfortunately there is no independent third party to officially certify environmentally friendly products in South Africa (Scott & Vigar-Ellis, 2014) however these authors recommend organisations apply to use international symbols or alternatively use terms such as non-harmful, biodegradable or recyclable on packaging as these were found in their South African study, to be associated with environmentally friendly packaging.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

The government also has a role to play here. Firstly, the development of a national environmental certification process and symbol would ensure that environmental claims made by companies are legitimate. Secondly, having one symbol that consumers can look out for and trust will assist them in identifying truly green products. This is important as Brennan and Binney (2008) state that green washing (the false claims made by companies about the greenness of their products) has resulted in consumer skepticism. Scott and Vigar-Ellis (2014) also state that where there is no national symbol and certification is industry specific, consumers are likely to become confused by what constitutes environmentally friendly products. Thus to alleviate green washing, consumer skepticism and consumer confusion, and national certification system and symbol is required.

A similar potential reason for the lack of green behaviour is the perceived lack of availability of green products in the marketplace. While the above discussion assumes green products exist but are not effectively promoted, here the respondents indicate a perception that there are not many green products available. While the number of green alternatives is likely to be less than in developed countries, green products certainly do exist and the challenge to the producers of these products is to increase consumer awareness of these and to make them more readily available to consumers. This may include more aggressive advertising of these products as mentioned above but distribution of green products also plays an important role in giving a competitive advantage (Smith & Perks, 2010). Improved availability of green products means that consumers need to find green products whenever they need them. Green products have to be in close proximity to consumers. This can be done by each store having a green product shelf easily visible in the supermarket. Green product manufacturers can also investigate joint awareness-building campaigns undertaken with leading retailers or distributers of these products and more intensive distribution. Certain retailers, such as Woolworths have positioned themselves as supporting the green initiative and thus green products assisting them to achieve this position while maintaining product quality standards may be well received. Of course organisations that have not produced green alternatives can look at greening their processes and products to make more green products available.

A major aspect of green behaviour is green activities as opposed to the purchasing of green products which only represents one aspect of green behaviour. Green activities are part of a broader green lifestyle and include reducing the use of non-renewable or scarce resources e.g. electricity, fuel and water; recycling and reusing; and supporting animal and plant conservation campaigns. The second most likely reason for a lack of green behaviour amongst this sample of South African consumers was the perceived lack of mechanisms to practice a green lifestyle. A lack of the necessary infrastructure or a civic movement promoting and supporting green behaviour may well cause the green gap (Pantelic et al., 2016). While businesses may support these initiatives, these mechanisms often need to be supplied, or initiated by government or non-profit organisations. Thus all parties in society need to share the responsibility of conserving the planet. However, specifically in terms of mechanisms to support a green lifestyle, a basic example of such mechanisms is the provision of recycling stations. In comparison to most developed countries, these are sorely lacking in South Africa. Social marketing campaigns can also be a critical marketing activity required here. Eskom, South Africa's only supplier of electricity, ran a media campaign aimed at convincing the general public to reduce their electricity consumption during the peak demand hours of 18h00 to 21h00. The Power Alert campaign was successful in reducing peak time load between 100 and 900 megawatts, depending on the level of criticality (Etzinger, 2011). Eskom's provision of energy efficient light bulbs to replace traditional bulbs was also successful. This initiative has seen the rollout of 54 million compact fluorescent lamps saved more than 1000 megawatts (Eskom, 2015). Thus more needs to be done by government at national and local level to make it an easy option for consumers to adopt the green lifestyle.

LIMITATIONS AND DIRECTIONS FOR FUTURE RESEARCH

As with most study sites, the chosen site had some limitations in that the sample appeared to be skewed towards a slightly younger and more educated sample than perhaps other sites would have. Older and less educated respondents may have had different concerns, behaviours and perceptions. The highly literate sample however did have the advantage of minimising language problems with using an English questionnaire with a predominantly African sample for whom English would have been a second language. The NCS qualification which the majority of respondents had attained includes English so translation problems were not believed to hinder the quality of the data. As the combined effort of all consumers is required to achieve global sustainability, future studies should investigate the perceptions, concerns and behaviours of the less literate emerging market consumers. Although this is acknowledged to be a more difficult task, qualitative studies conducted in mother tongues could provide valuable insights into this important, and relatively large, component of emerging markets. The study was focused in one city, in one, relatively small, emerging market and it is possible that other regions may have yielded different results. With the number of studies beginning to be done in emerging markets such as China and India, a comparative study would be useful. Finally, neutral or indecisive scores were recorded for a few of the concern statements. This may need more in-depth investigation. Why were respondents indecisive? Was it because they didn't understand the statement or because there were mediating factors? Environmental concern and behaviours are complex constructs which may be productively investigated using more in-depth qualitative methods. Could for example, relatively higher concerns for poverty, health and safety make green behaviour impractical for emerging market consumers?

CONCLUSION

As in many other countries a green gap exists between the environmental concern and behaviours of this sample of South Africa consumers. Consumer cooperation is arguably more important in sustaining the global environment than the actions of businesses and governments, thus understanding the reasons for this lack of green behaviour is vital in achieving consumer cooperation. In this chapter, a study of emerging market consumers green gap and possible reasons therefore was undertaken. Barriers or inhibitors of environmental behaviour in this emerging market were found to be the perceived lack of green products and promotion of those that do exist, as well as a lack of mechanisms to assist in the adoption of green activities such as recycling, reuse and support of conservation initiatives. These emerging market consumers are concerned about the environment but these barriers prevent the behaviours required to sustain the planet. To assist consumers to do their bit for global sustainability, businesses and governments must play their respective parts as indicated in the recommendations of this chapter. Ultimately a great deal of cooperation between the major stakeholders: governments, businesses and consumers is necessary to have a positive impact on the sustainability of the environment.

This research received no specific grant from any funding agency in the public, commercial, or not-for-profit sectors. Permission for the study was granted by the KZN Road Traffic Inspectorate.

KEY TERMS AND DEFINITIONS

Eco-Labels: Symbols indicating that a product is environmentally friendly.

Environmental Concern: Consumer concern for the environment and the sustainability thereof.

Green Consumer Behavior/Ecological Conscious Consumer Behavior (ECCB)/Pro-Environmental Consumer Behavior/Environmentally Friendly Consumer Behavior: The consumer behavior of supporting green initiatives such as energy conservation as well as buying green products which do not harm the environment.

Green Consumers: People who have a particular interest in and awareness of environmental problems and make an ongoing attempt to change their behaviors to protect the environment.

Green Gap: The gap between consumers expressed environmental concern and their actual behavior.

Green Products: Environmentally friendly products that do not negatively affect the environment.

Perceived Consumer Effectiveness (PCE): The extent to which consumers believe that their individual efforts can have a positive impact on the environment.

Chapter 3
Application of Circular Economy for Sustainable Resource Management in Kuwait

Osman Gulseven
American University of the Middle East, Kuwait

Jacques Mostert
American University of the Middle East, Kuwait

ABSTRACT

Circular economy is an alternative to traditional industrial system based on producing and consuming as much as possible. Contrary to produce and dispose model, circular economy emphasizes resource efficiency in both consumption and production cycle. This research aims to reveal potential role of circular economy with specific applications to small and medium sized enterprises in Kuwait. It is proposed that by applying circular economy concepts, Gulf Cooperation Council countries, particularly Kuwait, can achieve a competitive edge in global economy while minimizing the impact of industrial activities to the environment. Is it also proposed that small and medium sized enterprises tend to be the least efficient enterprises. Therefore, they have the highest potential for circular economy applications that lead to innovation, sustainability and resource efficiency.

INTRODUCTION

As early as the onset of the 1990s, "the public's demand for policies that encourage environmental protection [had become] more evident with each passing year" (Granzin & Olsen, 1991). The current zeitgeist in environmental policy and practice is experiencing significant challenges with the advent of the new regime in the United States of America. At this point, with a stronger presence in the global media, the topic of climate and environmental science has the opportunity to increase proposing sustainable solutions to avert climate and environmental disaster. One solution proposed in this article is the Circular Economy and its applications.

Circular economy is a challenge to the traditional "take, make, and dispose model" which relies on large quantities of resources and energy. Whereas, displacement economy is the long-term economic growth generated by the creation of the new, and the displacement of the old, in a capitalist society, a circular economy proposes that a sustainable growth generated model of use and re-use is implemented as the base of economic behaviours (Lin & Lin, 2014). This concept refers to a revolutionary economic system based on usage of renewable energy, eliminations of toxic chemicals and recycling of waste. All of this is done voluntarily through motivationally designed mechanisms which maintain a competitive edge.

Achieving a circular, resource-efficient, and resilient economy requires innovation and investment in resource-efficient technologies, and creating better market conditions for sustainable products and services. This research aims to enhance the creative and innovative potential of Gulf Council Countries, (particularly Kuwait) by introducing multidisciplinary field of circular economy in small and medium enterprises (SMEs). Circular economy is an increasingly important field as the world's resources started showing signs of depletion. SMEs are integrated into the circular economy policy framework through research and development of a variety of solutions.

There is an academic and social consensus for the need to provide an extended taxonomy of strategic sustainability behaviours in SMEs. Following the examples of some large enterprises, SMEs need to remove the barriers that impede the exploitation of circular economy benefits. For example, in energy efficiency, a sector of circular economy, Trianni and Cagno (2012) analysed the barriers to its adoption by SMEs. Following their work, the three pillars of the circular economy are addressed within the context of SMEs: Innovation, Sustainability, and Efficiency. Thus, three tier taxonomy is suggested in order to aid SMEs to develop sustainable growth and economic diversification: innovation, sustainability and efficiency. The first tier forms the foundation of the triadic structure. Enveloped in the first tier three supporting factors exist: public-private partnerships, policy development and incentive creation. The second tier proposes that sustainability through circular economies is central to strategic development initiatives and finally, the third tier depends on efficiency in execution of policy, strategy and implementation of sustainable resource management.

There have been sector wide initiatives, especially in large enterprises, to implement circular economic concepts such as automotive industry or chemical industry. However, limited research has been done on the potential to integrate SMEs into a circular economy. Specifically, none has been discussed within the context of Kuwaiti applications. This research aims to close this gap by promoting ideas for Kuwaiti SMEs to apply. Literature review discusses the past research regarding the circular economy with a focus on small and medium enterprises. Next section discusses the role of innovation in enterprise management followed by discussions regarding the roles of sustainability and resource efficiency, respectively. Challenges and opportunities for SMEs operating within the State of Kuwait are presented with concrete examples. Finally, the last section summarizes the research findings.

LITERATURE REVIEW

In some articles, circular economy is also referred to as green economy, efficient resource management, or even reutilization of resources. Therefore, in the literature review a comprehensive analysis has been performed to include all different aspects of circular economy. In the literature there exists a wide range of studies ranging from geographical location based policy taxonomies to product specific applications

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

of circular economy. Here, both the research on the theoretical economic framework as well as critics of circular economy is included.

Among the geographically identified applications, China is one of the most researched countries. As mentioned by Xinan and Yanfu (2011) there is an increasing government involvement in the process of China's economic transformation and this involvement also plays a decisive role in implementation of circular economy. In a recent article, Wu et al. (2014) discuss the effectiveness of the policy of circular economy in China. The authors find that the efficiency of the Chinese state policy on implementation of circular economy varies within each region. Therefore, the authors suggest that promoting the adaptability of the regional policies within the comprehensive state plan is a key concern for realizing sustainable development. This research is in line with Qing et al. (2011) who analyzed the circular economic efficiency in Western China. In another related article, Qiping (2011) suggests an action plan for small and medium-sized resource based cities in Zibo City of Shandong Province in China. Kun and Jian (2011) suggest that low extraction, high use and low emissions could be successfully implemented in China's oil and gas industry.

Europe is among the leading regions when it comes to utilizing circular economy concepts by means of institutional supervision and policy setting. As mentioned by Despeisse et al. (2015) the recent European Directive on end-of-life vehicle treatment will affect the policies of major car manufacturing countries such as UK and Japan where automakers will need to reconsider their initial production stage to ease the end-of-life disposal. The redesigned manufacturing systems shall consider the recycling process to recover energy and reduce material waste. A similar act is imposed by the State of Germany where the new legislation was legalized, namely the German Closed Cycle Management Act. As mentioned by Nelles et al. (2016), this act aims to turn the waste management into an integrated resource management system. This act is in line with the global emission reduction agreed in Kyoto protocol. The German State aims to increase the recycled input material use to 20% to achieve the target set by the German Kyoto agreement.

Besides China and Europe, several regional case studies are present in literature. Soo et al. (2016) perform a comparative life cycle component analysis for the car door materials for differentiated automobiles regarding their age and model. The authors claim that the vehicle designs have been improved to reduce environmental impact but more needs to be done for achieving a sustainable circular economy within the Australian auto industry. Abu-Ghunmi et al. (2016) discuss the water industry in Jordan where there is a big potential gain from the application of circular economy. The authors calculate that there is a strong economic case for transforming the Jordanian water industry into circular economic framework. Ilic and Nikolic (2016) perform a case study on the waste resource management for Serbia. The authors suggest that there is a big potential for improvement in the Serbian waste management system. However, this potential is deeply underutilized due to bottlenecks such as low levels of reuse, recycling and recovery of waste and weak economic incentives.

Industry specific applications are also widely present in the literature. Circular economy is specifically applied in the waste management systems. Applications of circular economy are mostly discussed within the sector of the waste input and output analysis. As discussed by Li (2012), sustainable development can be achieved by thoroughly implementing a circular economy principles in an enterprise setting. This can eliminate or at least minimize the waste resulted due to production. George et al. (2015) presents a theoretical model which is based on a polluting input and recyclable input. Their model suggests that environmental quality can be improved as the recycling ratio for production increases. Bhaskar et al.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

(2016) advocate circular economy in the waste biorefinery system. Mohan et al. (2016) suggest that biorefinery transforms waste into a renewable material that recovers biobased energy through sustainable mechanisms. Liguori and Faraco (2016) state that biorefineries where the lignocellulosic wastes are utilized to generate fuels, chemicals and energy are eco-friendly mechanisms that support the adaptation of circular economy.

Of course, there are also other applications in different sectors. In a case study Li and Ma (2015) discuss how energy and material efficiency can be achieved in China's paper mill industry. The authors introduce Guangdong Silver Island Lake (GSIL) Papermaking Park as an example of Circular Economy development by means the region achieved cleaner production and sustainable development. This is a very good example as the industrial region formed a unique integration of papermaking and power industries which reduced the pollutant emission of the park. Another application based research is suggested by Reuter and Schaik (2016). The authors propose that recycling of the gold, silver, and platinum in waste electric and electronic equipment is a well-known example of circular economy. However, this is better achieved by including other non-precious metals such as copper, cobalt, lead, nickel, tin, and zinc to be recycled from these equipment. Johnson et al. (2016) use the example of precious metal recycling from old cell phone handsets as an example of economic incentive for circular economy. The authors suggest that production managers should encourage longer lifetime use and increase the product return levels for initial use in order to achieve higher recycling levels.

The theoretical, economic and political framework is also explained in several articles. Martins (2016) argue that circular economy can find its theoretical framework within the classical political economic theory. As the classical theory emphasizes the sustainability and aggregate capital it best supports the circular economy as its contribution to the society is better explained compared to the neoclassical economics. Singh and Ordonez (2016) point to an interesting distinction between economic circulation and circular economy. The authors suggest that contrary to common belief, recirculating resources to make different types of products is not circular economy. Instead a circular economy requires the manufacturer to recycle their own product and use it as an input in the production system. Witjes and Lozano (2016) propose circular economy as a concept that addresses both environmental and socio-economic issues. In their article, the authors reveal a comprehensive framework that considers not only the socio-cultural specifications, but also the physical and social proximity between the involved stakeholders. Therefore the authors suggest that the procurement process between the suppliers and producers could be enhance by means of common ground to achieve sustainable resource efficiency.

Circular economy has also been criticized as well. One critic is the over recycling to the extent that products that shall not be recycled are recycled. Leslie et al. (2016) suggest that there is a delicate balance between consumer safety/cleaner production and resource efficiency. While society wants to achieve higher recycling ratio, one need to be careful not to include any harmful toxic chemicals recycled from the obsolete materials. Therefore, hazardous materials should be kept out of the recycling chain and disposed properly instead of recycling. Another critic is the notion that recycling does nothing to reduce the post-capitalist consumption-based economic models. Hobson and Lynch (2016) claim that the radical sudden transformation imposed by European Union and global business leaders may not be the best solution to the challenges of consumption society and sustainable consumption lifestyle. The authors suggest that sharing economy where resources are commonly utilized by the society might be a better alternative for world's growing resource scarcity problems.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

INNOVATION

Since the industrial revolution, the world has experienced standardized manufacturing in large enterprises. Growing as much as possible to become pre-eminent in the field was the trend of 20th century businesses. However, the fall of century old companies showed that being big may not always be the best solution. Innovation does not just come from large enterprises, SMEs started to become a prominent field in the innovation field. Incremental innovation explains the day-to-day activities that enable companies to gain small continuous advantages on their competitors. Conversely, breakthrough innovation comes from entrepreneurs developing novel ideas and large-scale research and development (Morris, 2013). As nations achieve higher levels of gross domestic product per person, the main source of this change becomes innovation. However natural resource depletion may direct the displacement economy that has served as the driving force of economic growth towards a circular economy where reconstitution of materials become the central focus of innovation and sustainable growth and development.

According to Sheth and Ram (1987) the need for innovation is driven by four features of development: technological advancement, changing customer needs, intensified competition and a changing business environment. To develop an environment within which innovation, as a key aspect of sustainable resource development, can flourish. There are three main facets that contribute to creating such an environment: public-private partnerships, policy development and risk tolerance.

Public-Private Partnership

Public-private partnerships drive innovation through both policy and financial support. In cases where large-scale research and development have succeeded the Public-Private Partnerships have been driven by clear government policies that incentivise and encourage innovation process. For example, the national governments of both Taiwan and Singapore have fast-tracked policy development aimed at underpinning their national innovation structures (Lin & Lin, 2014). In addition, the national innovation strategy for Luxembourg encourages public investment into research and development in order to enhance the government's goals to diversify the economy (OECD, 2016). Thanks to this public-private partnership strategy, the region has shown an increase of 238% increase in research and development. These examples of economic growth, in economies of parity with Kuwait, supports the notion of a strong public-private partnership in the establishment of research and development of a circular economy.

It also makes sense to support the development of circular economy from an economic point of view. As mentioned by Ferreira, Ratten, and Dana (2016) there is an underestimated spillover effect that is highly connected with the strategic management approach. Thus, an unintentional outcome of circular economy is to create additional knowledge flows which can be utilized by entities other than the original creator of this knowledge. As a result, there might be a highly beneficial multiplier effect where the initial positive outcome gets magnified through knowledge spillovers in the network. Therefore, the total benefit of supporting circular economy might get much higher than the cost of government support.

Policy Development

Government policy is often charged to provide an umbrella approach to manage the various initiatives and stakeholders in the economic playing field through a series of strategic tasks, guiding principles and recommendations. To encourage active participation of the private sector in innovation, four areas of

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

policy development are suggested to support increasing innovation in Kuwait: Establish National Areas Sustainable Innovation, Incentivizing University Research, Research Innovation Networks and Initiation of Challenge-Driven Innovation programs.

Government policy that is focused on clear areas for innovation is at the heart of developing innovation on a national level. It is important that the government looks at possibilities at hand when establishing National Areas of Sustainable Innovation (NASI). An example may be the large number or discarded rubber, plastic and metal that resulted from a growing automotive market. As mentioned by Jones (2015), the engagement of private sector is easy when it involves a large upfront investment. Therefore, policy framework is needed to promote private sector's involvement.

Government policy that incentivizes institutions of higher education to enhance research into the NASI that have been identified can become the driver of successful and continued national innovation. In addition to fiscal incentives, support through hosting national and international conferences on innovation, providing support for international research cooperation and encouraging cooperation between higher institutions within Kuwait may enhance the drive for innovation. In addition, providing scholarships for post graduate research, both at home and abroad is essential to driving innovation. It is also of interest to promote project-oriented learning as an essential learning mechanism as it supports the implementation of sustainability concepts at earlier ages. (Filho et al., 2016)

Government policy may provide an increased awareness of science and innovation by enhancing the role of research collaboration across institutions through Research Innovation Networks. Collaboration between institutions may relieve the fiscal and human resource pressure of driving innovation within a single institution. Government policy should encourage a strategy where each of the NASI are presented as a challenge to be solved in the form of a national competition. The outcomes of the competition may be supported by a financial prize as well as the opportunity to develop the winning proposal into a sustainable business.

Financial support has an equally significant role to play in encouraging innovation. A recent OECD (2015) report on research and development incentives indicates that where government support is equal to the input of the private sector, growth indicators are significantly higher. Albeit, such incentives were mostly provided in tax relief, government support, both through policy and financial backing contributes a significantly to research and development growth. However, several corporations consider developing such partnerships as a strategy beyond governmental regulations to augment their market shares. (Buysse & Verbeke, 2003)

Risk Tolerance

One of the most significant challenges of developing and implementing a sustainable circle economy is the uncertainty that goes hand-in-hand with new scientific developments. Central to any business model is the core concept of reducing or avoiding risk. However, where new frontiers in science driven manufacturing becomes the genesis of the business model, risk tolerance becomes a strengthening attribute of the SME.

Insofar as, understanding the impact of risk in the sustainability of renewable resources and the role SMEs play in developing these resources, one needs to consider that decisions in SMEs are made by individuals, each with their personal subjective estimation of risk and personal level of tolerance of risk. Therefore, it is important to consider human behaviour as a factor of risk aversion.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Environmental risk reflects what happens in the physical world within which the economic behaviours occur. The environmental risk element functions as a link between resources, ideology and geo-political initiatives. The simplest way to explain environmental risk elements is by looking at the controversial debate regarding human influence on climate change. Scientific consensus that climate change is a result of human economic activity in indisputable. Moreover, significant measures to reduce the growing impact of climate change are imperative to ensure sustainable development on the planet, yet within the context of energy affordability, the ideology of social equality (the belief that all people should have reasonably priced access to goods and services) requires that governments and corporations provide goods and services at reasonable cost. A balancing act between developing new sustainable industries and the loss of revenue is a weighty driver of corporate policy making within the boardrooms of corporations as well as SMEs.

Sources of social influence clarifies how geo-political and national corporate voices guide social opinions. A significant amount of money, airtime and lately social media time is devoted to directing social opinion on sustainable development. These sources of influence have a significant influence on a regional and local level insofar as social representation reflect systems of widespread or shared beliefs and values (Breakwell, 2014), and these representatives often hold the purse strings of the general consumer. Thus decision-makers, especially within SMEs where access to larger political players is slight, pay a significant amount of attention to the prevailing unanimity created by social influence. Consequently, the attitudes towards sustainable development and circular economy initiatives are largely driven by those who have access to the greatest sources of social influence.

Institutional standards are the parameters and guidelines instituted through policies and laws of on regional and national level. As indicated earlier, public policies that favour innovation and the expansion of sustainable resource are essential to developing risk tolerance of SMEs. Where policies are ambivalent to the impact of social influence and normative pressure, SMEs find that the pressure to continue with current methods contribute to the perceived risk of developing sustainable economic methods and behaviours.

Normative pressures illuminate the active, day-to-day communication and interactions within the environment where the economic behaviour is implemented. Initiating innovations that go against the custom model of economic behaviour may introduce a sense of alienation. Consumers tend to be habit driven, steering towards what is trusted and dependable. Thus, in a time, where geo-political trends are aimed inwards towards self-protecting localism, introduction of novel technologies that enhance a circular economy, but have no track record of efficiency or sustainability, may increase the aversion to risk of decision-makers in SMEs.

Past action reflects the former activities of the SME that are perceived to be low risk. This is particularly the case for chemical and related industries as they operate at a high environmental cost. (Sharratt and Choong, 2002). These approaches to innovation and development of sustainable economic models have a direct impact on how the SME tolerates risk. In addition to the SME itself, proximal attitudes towards innovation and sustainable resource development have an indirect impact on decision-makers in the SME. The risk tolerance of the direct competition of an SME may prove to have an impact on their economic behaviours. For instance, if a competitor that is more risk tolerant than the SME has success in implementing a new economic model or innovation, this may be encouraging to other SMEs to also engage in innovative developments.

Finally, an individual's cognitive and conative processes relate to the internal mental life that drives the individual's striving, desire and motivation. Thus the decision-makers' personal ideological approaches

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

to sustainable resource development as well as their education level have a direct impact on the risk tolerance that can be seen in the SME. If the decision-makers are educated in a tradition of innovation supported by pro-sustainable development public policy, it may be easier for such decision-makers to be open to innovation. This, in turn will benefit the entire organization.

SUSTAINABILITY

As mentioned by Geissdoerfer et al. (2017), the Circular Economy is increasingly becoming a new sustainability paradigm globally. This is also becoming a more popular term in the Arabian Gulf region. In the aftermath of the global financial crises and later depressed oil prices, it became obvious that the GCC economies need sustainable development policies to be more innovative and competitive. This can be done while reducing resource usage and lowering the environmental impact. Establishing a circular economy initiative can help GCC companies to become more resource efficient and competitive. There are some positive movements in this field, but these initiatives usually target well-established large enterprises ignoring the SMEs. In the first place, this research aims to tap the potential of SMEs by analysing their supply chains and identifying the sectors where the waste of one company can be a raw material for another. Secondly, the use by one company or sector of by-products, including energy, water, logistics and materials, from another is an example of industrial symbiosis within a circular economy. Finally, this new model is slowly transforming the way industrial production is resourced and is a challenge for individual companies to create this interactive synergy. However, by providing a knowledge base for SMEs, such challenges can be turned into opportunities.

The supply chain procurement techniques need to be readjusted in order to comply with circular economy. In some cases, this is done naturally by the laws of supply and demand. For example, in many developed and developing countries, there are specific production zones that specialize in a diversified but similar products. This is commonly observed in the automobile industry. There are many different branded automobiles but they all have some of the parts in common. That is because they are utilizing the same supplier. One hurdle in this type of efficiency is the need to geographical closeness between different producers and (usually) the only supplier. By producing in significant quantities, the supplier is able to offer cheaper prices to the final product producers.

In some cases, there needs to be an institutional involvement to redesign the supply chain. Consider the example of cell phone chargers. As soon as cell phones became widespread, all households ended up holding several different types of chargers in order to use them for each different brand of phone. But then institutions such as European Union decided to get involved and imposed that all cell phones to be sold in the EU shall be compatible with simple USB type of adaptor. This type of successful involvement of the state proves that institutional settings play a crucial rule in even supply chain management systems.

The by-product of one enterprise can sometimes be an essential input for the production of another product by the same or another company. In Kuwait there is a very good example for the useable by-product utilization. Kuwait is known for its harsh weather that is incredibly hostile for growing food. Yet, there is an entire region called Wafra which is known for its greenery scene and vast lands of vegetation. While there are underground water sources in this area, this all became possible thanks to the recycling of waste water. Water is a rare commodity in Kuwait, as such the recycling of water to be reused for vegetation was a brilliant idea. Thanks to the farms in Wafra, now one can consume locally grown fruits

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

and vegetables in Kuwait. Kuwait needs to create more examples like this in order to sustain its economic activities within the circular framework.

A synergy is created if two or more companies apply joint production systems where their productivity is increased thanks to joint operations. The synergy created between those joint operations can help to utilize the resources more efficiently. Consider the example of an auto mechanic and vehicle removal company. The vehicle removal company often witnesses automobiles that were so badly damaged and have almost no potential to be back on the road. Those companies can form a union and consequently deliver all those cars in non-useable state into a common parking ground. In turn, the auto mechanics need the spare parts for fixing the cars of their customers. It will be much more efficient for them to obtain those parts from the local car parts instead of waiting for those imported parts to arrive from the ports. It will also be a lot cheaper and the cost to the consumer will be lower. This network type of agreement can create new revenues as well as provide cost savings to those involved. The junk cars will be valued as treasures by the mechanics. It will also reduce the amount of waste and the unsightly appearance of accident-seen cars near the roads.

RESOURCE EFFICIENCY

Resource-efficiency, eco-intensification and sustainability are major issues in the energy sector and are at the heart of Circular Economy thinking. Resource efficiency is a critical component to ensure access to sufficient and nutritious food. It is a key priority that impacts all world citizens. Given the structure of this sector, SMEs play a critical role. However, general procurement problems exist in in the supply chain management. Such problems can be solved by the use of Circular Economy and symbiotic paradigms. These suggestions are based more or less on the best practices applied around the globe.

There is an increasing global trend, particularly in Europe, from energy efficiency to resource efficiency where nothing is wasted (Bundgaard, 2017). The idea of zero waste means that the resource efficiency is reached to a level that nothing goes for waste. While this is a very ideal approach which currently seems implausible, in future it may be possible. The resource efficiency can be significantly improved by imposing zero waste rule. This implies a full recycling of all waste produced by both producers as well as consumers. The EU commission emphasizes a particular role for the municipal waste. It is aimed to minimize the landfill amount by maximum 10% by 2030. That also implies recycling and repacking up to 90% of all the municipal waste by the same deadline. This is an unlikely scenario for the GCC countries where there is a natural waste due to carbon-based economy. However, still GCC countries, particularly Kuwait can benefit from imposing similar targets with solid deadlines. At least one possible action to be taken is to separately collect waste so that they can be recycled in the later stages. The separation can be based on recyclable plastic, glass, and paper. This way the recycling process will be much easier and also more profitable for the companies involved in recycling.

Another action plan is to create economic incentives to discourage landfilling and encourage greener product usage. This of course requires state involvement, but it is a necessity to save the environment for future generations. A similar incentive plan could be provided for putting greener products with high recycling rate throughout the region. Plastic bags are an increasingly common problem for the region and their usage could be discouraged by putting a price on them instead of offering them for free. Another product category that needs to be separately dealt is the electronic equipment in the region. Currently

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

there is no incentive to reutilize the old computers, cell phones, batteries, etc. There should be some sort of mechanism to promote the proper disposal of those items as they are highly dangerous as a trash and needs to be properly disposed. It is also important to emphasize that those old electronics contain valuable materials which can be reused as an inputs in the production stage.

CHALLENGES AND OPPORTUNITIES IN KUWAIT

Similar to other GCC states, Kuwait's economy is heavily dependent on oil production and revenues. In fact it would not be a mistake to consider Kuwait as a carbon-based economy. The rise in the oil prices since the last century has provided a great amount of wealth to the region. Citizens as well as expatriates living in the country has greatly benefited from the oil wealth. However, the recent decline in oil prices prompted the relevant parties that a pure oil-based economy is not the best development option. The idea of selling oil and importing almost everything else do not seem to be a feasible solution to the growing fiscal problems in the region. Therefore, one needs identify the diversification options and apply them for sustainable development in the region. Applications of circular economy can greatly benefit everyone regarding this concept. SMEs can play a significant role in the implementation of circular economy within Kuwait and the GCC region.

As a starting point one can consider the recycling of carbon-based products in Kuwait. There is no doubt that oil is cheap in Kuwait. As a result, plastic bags are also a cheap commodity available not only in the markets but also almost everywhere around. One of the reasons is that there is no recycling culture in the society. There is also no fiscal motivation for recycling plastic bags. In fact contrary to Western European stores, bags are free and offered abundantly in the supermarkets. In a scenario where plastic bags are free, it is considered as a trash after being utilized only once. However, in countries where plastic bags are sold as a commodity there is a motivation to reuse them or at least minimize the number of bags used in shopping. Of course it may not be the most profitable solution to offer bags for sale, but a small shop can recollect those bags for a small fee. This way they will not show up on the streets and the unsightly abundance of plastic waste will disappear. The proper disposition of tires is another issue. The tire graveyard in Sulaibiya, Kuwait is one of the biggest in the world. This enormous tire dump has been growing both in depth and also in size and it is very visible in Google Maps. Proper recycling of the tires can be utilized in making a diversified variety of products ranging from children's playgrounds to artificial sports pitches.

A similar case could be made for recycling card boards. While paper is not that much used compared to plastic in Kuwait, it is a rare commodity that is imported abroad. Nevertheless a significant amount of non-recycled cardboard trash appears after the purchase of material equipment, household appliances, and even furniture by consumers. Normally, in advanced countries it is the responsibility of the retailer to recollect this waste to recycle as an input. However, this is rarely the case in Kuwait and the purchaser ends up disposing the cardboards in the trash. This is another opportunity for SMEs to get involved by collecting this cardboard waste and turning it into valuable inputs for the production processes.

Recycling plastic and paper trash is not the only way SMEs can get involved in circular economy. In the automotive industry, the obsolete materials need to be disposed properly. In the best case scenario these obsolete materials are recomposed into the production of new cars. In the worst case scenario the obsolete materials keep decaying within the car while the car is unsightly standing somewhere in public. In Kuwait, where accidents are common, this unsightly sight can frequently appear almost anywhere.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Recycling this valuable material can save significant income and is also beneficial for the entire society. Another recycling opportunity exists for electronic equipment. Almost every electronic equipment carries a tiny bit of precious metal inside. The extraction of these precious materials can be a profitable business who specialize in this field. It can also help to diversify the carbon-based Kuwaiti economy.

Of course, all of those opportunities need to be incentivized by the state. This is perhaps the biggest challenge faced by those proponents of recycling and circular economy. There is an environmental legislation that aims to protect the environment. However, this falls short of imposing recycling rules similar to that of Western world. Therefore, the lack of proper legislation is the primary challenge against potential recycling companies. A new law similar to that of EU and Japan initiatives can close the gap and promote companies to engage in circular economy. Another challenge is the lack of recycling culture which is partly due to wealth brought by the oil. That hurdle can also be eliminated by means of proper environmental education starting from very early ages of education. Considering all of these facts, an active role is proposed for the state involvement in order to achieve a better circular economy within the State of Kuwait.

SUMMARY

SMEs are faced with numerous complex challenges that require a strong collaboration between industry, academia, government and private business. This collaboration can create a new ecosystem, which can promote an open innovation mechanism and lead to sustainable product systems. This open innovation offers SMEs a special avenue to better compete in the global economic marketplace.

In this article, the concept of circular economy is discussed with potential specific applications that are feasible within the Kuwaiti enterprise system. The applications are based on circular economic framework and emphasizes recycling and resource efficiency. That is a significant challenge for a welfare-supported oil-based economy where everything is imported, abundantly available and relatively affordable for the wealthy society. However, given the lower oil prices, diversification of carbon-based economic system has gained more supported within the GCC countries. As such, applications of circular economic framework has gained more momentum within the region.

There are of course several barriers particularly for small and medium sized enterprises to get involved in circular economy. It is proposed that innovation, sustainability, and efficiency are key drivers behind achieving circular economy. State shall get actively involved by means of creating the necessary institutional setting and legislations. Thus, there needs to be public-private partnership promoting policy development and supported by financial incentives. In the literature, several studies are mentioned from European Union, individual European States, as well as Japan, Australia, and China. While each region has its specific dynamics those examples can work as a benchmark for the GCC region.

In case of small and medium enterprises, the human role, particularly that of the manager or the owner is essential for application of new production techniques that reduces waste. Therefore, the role of risk tolerance in circular economy also needs to be emphasized. Thus, for SMEs, the factors such as environmental context, sources of social influence, institutional standards, normative pressures, past actions, and cognitive and conative pressures are highly valuable. This in turn implies that education is a key factor in waste reduction and resource management. Therefore, the role of state should also include public training for resource efficiency.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

This research can be extended in several directions. One line of research is to compare and contrast the legislative frameworks in the regional countries with that of globally leading economies in the Circular Economy field. The legislative frameworks in the Arabian Gulf countries are substantially different than that of Western countries. Therefore, issues such as recycling and environmental protection are not among the state priorities. By identifying the key environmental initiatives in the Western legislations, one can help establishing similar initiatives in the region. Another line of research is to determine how the social capital in the GCC countries can be enhanced in order to raise awareness regarding the resource waste. Currently, the economies of GCC countries are almost entirely dependent on carbon-based oil and gas industries. Thanks to the accumulated and flowing income from these industries, the recycling culture is almost nonexistent among households. It is of interest for researchers, industry players and policymakers to figure out how to establish an environmentally sound practices to minimize the waste at both the production and consumption stages.

Chapter 4
Exploring Client Perceptions and Intentions in Emerging Economies:
The Case of Green Banking Technology

ABSTRACT

This article describes how in response to the global initiative to save the environment, many emerging economies today promote environmental-friendly practices by implementing various forms of green banking services. Beyond its usefulness for the environment, green banking also benefits the clients by offering new channels of financial services delivery. As such, there may be various factors which can shape the behavioral intentions of clients for adopting green banking, including their environmental concerns, perceived financial cost and timeliness factor attached to these services. Using UTAUT model and Structural Equation Modeling (SEM), this paper thus proposes a model to identify such adoption factors in the context of an emerging economy. The article finds that timeliness, facilitating conditions, environmental concerns, effort expectancy and performance expectancy, plays an important role in capturing clients' overall perceptions of green banking. Results therefore indicate clients may be fairly pragmatic in developing general attitudes towards the use of green banking.

INTRODUCTION

In recent years, the eminent problem of global warming has finally shifted the attention of business practices of all functional areas to climate change, resource efficiency and environmentally conscious issues. As such, initiatives related to green safety and sustainable ecological balance is growing in support. Environmental degradation has become such a pressing issue today that even the financial sectors need to address this universal concern (Goyal and Joshi, 2011). This is because financial institutions, particularly banks, play a vital role in the economic system of a country and generally affects all types of business practices through their financing activities (Bahl, 2012). Thus, banks should contribute to the saving of the environment by considering environmental aspects as part of their lending and investing principles, which would then divert industries to invest in environmental management and the use of appropriate green technologies (Masukujjaman and Aktar, 2013).

As a response to this global development and environmental degradation, financial sectors of many developed and developing countries have adopted green technologies to address the issue of sustainable business practices. As such, various eco-friendly practices and in-house operations, broadly known as green banking, are now part of most banking activities (The Daily Observer, May 26, 2015). Green banking mainly involves the environmental and social responsibility of banks in terms of the contribution they make towards ensuring sustainability of the environment and ecological system, through their in-house operations and the wide range of financial products and services that they offer (Nisha, 2016).

Green banking focuses on two aspects: green revolution of internal operations through the consumption of renewable energy, digitalization and other measures that can reduce the emission of carbon mark from the banking activities and the use of environment-friendly financing like sustainable banking, ethical banking, green mortgages, green loans, green credit cards, mobile banking, online banking, etc. (Inderst et al., 2012). Additionally, banks worldwide use energy-wise Green Machines, which source power from clean, emission-free methods such as wind power and invests hugely for local environment and wildlife projects in their community (Hossain et al., 2015).

Since the objectives of green banking provide incentives for environmental sustainability, its adoption is increasingly growing in emerging economies to promote the concept of social responsibility towards the environment (Masum, 2015). This is because most of the emerging economies tend to be prone to natural calamities which often cause huge losses to the environment, adversely affecting biodiversity, agriculture, forestry, water resources and human health (Biswas, 2011). For emerging economies like Bangladesh, this issue is all the more pressing because people in this country have very little awareness about environmental hazards, air and water pollution, industrial, medical and household wastes community, etc. (Hossain and Ahmed, 2015). Thus, the growth of green banking initiatives can be rightly justified in Bangladesh.

The Central Bank of Bangladesh has already shown keen interest in promoting environmentally-friendly and socially responsible approaches to banking, following which leading commercial banks of the country now follow various forms of green banking policies within their banking operations (Rahaman et al., 2015). However, the application of green banking chiefly requires the involvement of the bank clients as well, since they are the ones who are at the forefront of using such initiatives to conduct their banking transactions. This is where it becomes imperative to examine the thought process of the clients towards the concept and implementation of green banking in Bangladesh. In particular, since environmental concern is the focal point of green banking, clients' views related to environmental

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

sustainability, along with the relative advantages like timeliness and the financial cost attached to such initiatives needs to be examined.

To pursue this purpose, a conceptual research model has been developed on the basis of the original Unified Theory of Acceptance and Use of Technology (UTAUT) model and the method of Structural Equation Modeling (SEM) applied to investigate the underlying relationships related to the perceptions of bank clients towards green banking practices in the country. Findings of this research provide further insights into identifying the factors that can influence clients' perceptions into adopting and using green banking in Bangladesh. This study can also assist banks to understand and assess the level of social responsiveness of bank clients in context of emerging economies.

The remainder of the study is organized in the following manner. Section two presents review of literature, section three describes the research model and hypotheses, section four discusses research methods, section five presents data analysis and results, section six concludes the findings of the study and provides implications and section seven discusses limitations and further research directions for this study.

LITERATURE REVIEW

To further this study, the need for green banking and the current practice of green banking services in Bangladesh has been highlighted, followed by the research platform and finally, the theoretical background of the proposed determinants of timeliness, environmental concerns and perceived financial cost, has been discussed to determine the gaps of this study.

Necessity of Green Banking

Bangladesh achieved a reasonably high rate of economic growth over the last decade, the average growth rate exceeding 6% per annum that nearly doubled the per capita income of the economy (Masum, 2015). There has been considerable improvement in human development as well with Bangladesh moving from low to medium Human Development Index (HDI) country group (The Financial Express, 15 July, 2015). This high economic growth rate is the result of significant progresses in the rice production, shrimp farming, readymade garments and textiles, leather and leather goods, ship building & ship breaking industries of Bangladesh (Faroque et al., 2013). In turn, these developments are rapidly increasing the urbanization of the overall economy too.

However, an unfortunate consequence of these economic developments is severe environmental degradation. For instance, any developments in the farming sector requires intensive farming which results in decreasing soil fertility due to overexploitation of soil nutrients, imbalance and loss of organic matters using chemical fertilizers, pesticides, etc. (Alam and Islam, 2013). Farmers also try to bring in forest and wetland under cultivation by increasing their cropping intensity facilitated by irrigation. Although this compensates the loss of river erosion, intensive farming is pursued all over again (Hossain, 2014). Moreover, arable land has been shrinking by 0.6% every year due to demands from housing and several industries and to meet the infrastructure needs of Bangladesh (Masum, 2015). Even the readymade garments and leather industries adversely effects the available water due to more than 1700 washing/dyeing/finishing (WDF) units consuming 1500 billion liters of ground water annually and discharging waste

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

water in the country (Rahaman et al., 2015). Lack of proper solid waste management solutions further leads to water pollution and cause health hazards for the residents of Bangladesh. As such, the emerging economy of Bangladesh can be cited as one of the most severely affected countries as a consequence of global environment pollution (The Financial Express, 1 August, 2015).

A more adverse aspect of the highlighted environmental problems is the fact that it is expected to accentuate, since Bangladesh may lose one sixth of its land due to a rise in sea-level with global warming and farming risks may also increase due to climate changes like current erratic monsoon rains and increased frequency of floods and storms (Hossain, 2014). Additionally, there has been significant movement of environmental refugees, victims of river erosion in particular to urban areas leading to increased rural landlessness in the country.

The financial sector is nowadays aware of and concerned about all these environmental problems of Bangladesh and considers the sustainability of the environment as part of their corporate social responsibilities (Kaeufer, 2010). As a result, the central bank of Bangladesh – Bangladesh Bank, formulated a guideline related to environmental risk management. The guideline, named as the Green Banking Policy, aims to ensure environment-friendly business practices by banks and financial institutions by incorporating environmental risks into Core Risk Management (CRM), thereby promoting sustainable financial and economic growth across the entire country (Nisha, 2016). Green banking has been made mandatory for all commercial banks of Bangladesh, since these financial institutions indirectly contribute to environmental pollution through investing in different pollutant industries (Hossain and Ahmed, 2015). Hence, the banks should be more active, responsible and enthusiastic for bringing about a positive change in the environment and this can only be achieved by being socially responsive and embracing the concept of green banking in Bangladesh.

Scope of Green Banking in Bangladesh

Global awareness about greenhouse effects and climate change gave rise to the notion of green banking in many developed countries and alongside, few developing countries also adopted the concept of "GO GREEN" (Singhal, 2014). Following the footsteps, Bangladesh joined the bandwagon around 2011. Green banking entered its first phase of drafting the policy framework and setting up of an institutional arrangement in Bangladesh under the leadership of Bangladesh Bank (Masum, 2015). The contribution of Bangladesh Bank to make green banking a reality in Bangladesh is a commendable move, as it is the only central bank in the South-Asian continent which has issued such an analytical guideline for the adoption of green banking.

Under the Policy Guidelines for Green Banking, all scheduled banks are required to adopt a comprehensive Green Banking policy in a formal and structured manner in order to reduce environmental degradation and to ensure sustainable banking practices (Ahmad et al., 2013). Bangladesh Bank initially selected ten commercial banks in the country, based on their CAMELS (capital adequacy, assets, management capability, earnings, liquidity and sensitivity) rating and Risk Based Capital Adequacy (RBCA) measurement for executing green banking practices under this Policy (The Daily Observer, May 26, 2015). The central bank instructed these banks to consider the following major activities under green banking: Green Banking Unit, Green Banking Policy, Green Banking Budget, Online banking, Mobile and Internet banking, Allotment of funds in green financing and Environment risk rating. Eventually, all the scheduled banks of Bangladesh initiated their own Green Banking Policy Guidelines approved by their respective Board of Directors as well as have Green Banking Unit (GBU) for pursuing Green

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Banking activities (Nisha, 2016). In fact, many of them have their own Green Office Guide for conducting various in-house green activities today. This includes the extensive use of online communications like video/audio conferencing, voice mail and e-mail instead of paper memos; using more daylight instead of electric lights or using energy saving bulbs; ensuring double-side printing to save papers; common use of table stationeries; efficient use of printer cartridges, photocopy toner and office stationary; installation of energy-efficient electronic equipment and their automatic shutdown after office hours; the use of solar energy to save electricity, etc. (Shakil et al., 2014; Hossain and Ahmed, 2015).

However, the most important aspect of this Green Banking Policy is actually directed towards the bank clients. Bangladesh Bank has mandated the commercial banks to introduce rigorous programs in order to educate clients and influence them to comply with the environmental regulations as well as to undertake activities which are going to benefit the environment (Islam and Kamruzzaman, 2015). For instance, leading commercial banks of the country have started communicating virtually with the clients through the use of e-statements instead of printed statements or e-mails instead of paper documents. Additionally, banks have radically transformed the distribution of services from the brick-and-mortar model to the branchless mode of banking (Saleem and Rashid, 2011; Nisha et al., 2015). This includes the use of technological services like internet baking, SMS banking, mobile banking, the use of Automated Teller Machines (ATM), Bangladesh Automated Cheque Processing System (BACPS), Bangladesh Electronic Fund Transfer Network (BEFTN) or other mobile financial services in the form of e-currency like bKash, mCash, EasyCash, etc. (Masukijjaman and Aktar, 2013). All these innovative mediums of financial services delivery promote green banking since it reduces the use of paper and works towards the achievement of environmental sustainability.

Although the commercial banks have introduced various forms of green banking services for the clients, these initiatives will only be successful if the clients are ready to adopt such environmental-friendly banking services. Hence, not only the environmental concerns of the clients, but relative advantages like timeliness and the cost attached to such services can be crucial factors here. As such, this study focuses on the examination of all factors that may influence the perceptions of bank clients towards green banking services in Bangladesh.

Research Gap

Recently, banks have started to design their financial products and services in such a way that they contribute to the saving of the environment by considering environmental aspects as part of their lending and investing principles (Masukujjaman and Aktar, 2013). In the process, banks have adopted eco-friendly banking practices through the extensive use of green technologies, broadly known as green banking.

Since green technology forms the basis of green banking, it is necessary to understand individual acceptance and use of this kind of information technology under the information systems research. Several theoretical models primarily developed from theories in psychology and sociology has been employed to explain technology acceptance and use. For instance, Davis (1989) and Davis et al. (1989) examines the determinants of computer technology acceptance and its utilization via the Technology Acceptance Model (TAM). On the basis of these prior researches, Venkatesh et al. (2003) developed the unified theory of acceptance and use of technology (UTAUT) model. Venkatesh et al. (2003) empirically compared eight competing models - namely the TRA, TAM and TAM2, Theory of Planned Behavior (TPB) and Decomposed Theory of Planned Behavior (DTPB), combined TAM and TPB (C-TAM- TPB), Innovation Diffusion Theory (IDT), Motivational Model (MM), Model of PC Utilization (MPCU) and

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Social Cognitive Theory (SCT) by surveying 215 respondents from four organizations. Based on their longitudinal studies, the authors further integrated and ultimately refined the new model of UTAUT. Four factors (performance expectancy, effort expectancy, social influence and facilitating conditions) were included in the model, primarily directed to predict the behavioral intention to use a technology and technology use in organizational contexts, moderated by individual difference variables like age, gender, experience and voluntariness (Venkatesh et al., 2012).

UTAUT served as a baseline model to study a variety of technologies in both organizational and non-organizational settings. However, given the number of technology devices, applications, and services that are targeted at consumers in recent times, it became necessary to identify the factors that can influence consumer adoption and use of technologies (Stofega and Llamas, 2009). This led to the introduction of the UTAUT2 model by Venkatesh et al. (2012). Venkatesh et al. (2012) adapted the four key constructs (i.e. performance expectancy, effort expectancy, social influence and facilitating conditions) that influence behavioral intention to use a technology and/or technology use from the original UTAUT model and tailored it to fit the consumer context. Thus, performance expectancy is defined as the degree to which using a technology will provide benefits to consumers in performing certain activities; effort expectancy is the degree of ease associated with consumers' use of technology; social influence is the extent to which consumers perceive that important others (e.g. family and friends) believe they should use a particular technology; and facilitating conditions refers to consumers' perceptions of the resources and support available to perform a behavior (Venkatesh et al., 2012).

Past studies like Venkatesh et al. (2003) claimed that the constructs of performance expectancy, effort expectancy and social influence determines the behavioral intention to use a technology, while behavioral intention and facilitating conditions influence the technology use in a particular context. In addition, Venkatesh et al. (2012) added three new constructs to the UTAUT2 model - hedonic motivation, price value and habit and included only three moderating variables of age, gender and experience to make the model applicable to the consumer use context. Venkatesh et al. (2012) further claimed that the addition of new constructs in a consumer context can contribute to the expansion of the theoretical horizons of UTAUT. Against this backdrop, this study has selected the original UTAUT and UTAUT2 model as a theoretical foundation to develop a proposed research model for this study. The goal of this study is not to replicate the UTAUT or the UTAUT2 model, but to ascertain the factors that can considerably influence clients' intention to use green banking in the context of an emerging economy.

Proposed Constructs: Environmental Concerns, Cost and Timeliness

Green banking mainly involves the use of online or mobile banking instead of branch banking in order to reduce the overall use of paper. The need for green banking is rightly justified in emerging economies like Bangladesh, since natural calamities are a common phenomenon here and Bangladesh is particularly more vulnerable to climate changes and environmental degradation (The Financial Express, 29 July, 2013). Perceptions, in view of environmental care, financial cost and relative advantages like timeliness among other factors, can therefore play an important role in influencing the behavior of the bank clients regarding the use of green banking in Bangladesh.

Nowadays, people have become fairly conscious about the environment - as a result of which, they often expect visible attempts from various sectors in terms of social responsibility and environmental sustainability (Rifat et al., 2016; Iqbal et al., 2017). These expectations are far greater from the banking sector owing to their involvement with the economic development of the country. In fact, past studies

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

like Bahl (2012) and Ahmad et al. (2013) stated that failure to fulfill the social responsibility towards environmental protection tends to tarnish the image of the banks in the eyes of their potential clients. This can be pretty costly to repair and the banks may end up losing clients. Hence, environmental concerns of the clients can play an influencing role in capturing the clients' overall perceptions and may even prompt them to adopt green banking. Few studies like Kranz and Picot (2011), Hossain et al. (2015) and Gomez and Scholtz (2016) have also identified environmental concerns as a major construct that can determine the behavioral intentions of clients in adopting green banking services. Following the lead, this study attempted to examine the extent of significance that environmental concerns of bank clients can have upon the adoption of green banking technologies.

Another issue that has been proposed as a construct in this study is the perceived financial costs related to the use of green banking services. Even though researchers generally investigate consumers' adoption of a technology from psychological and sociological theories, it has been proved by several empirical evidences that technology acceptance is highly influenced by financial factors as well (Luarn and Lin, 2005). Financial cost is therefore a significant predictor of the acceptance behavior of technological services as it refers to the cost associated with the learning and using of that technology (Nisha et al., 2015). If a user needs to spend a considerable amount of money to learn or use the technology-based service, he/she will not be willing to adopt it. This means a negative relationship can be established between financial cost and the behavioral intention of consumers. Several prior studies like Yu (2012), Nisha et al. (2015) and Sanakulov and Karjaluoto (2015) argue that increasing costs always has a negative impact on the willingness to adopt green banking services. Thus, in order to explore this relationship between perceived financial cost and acceptance of green banking technology from the clients' perspective, this study has chosen cost as a significant construct.

On the other hand, timeliness has also been observed to have a direct and positive impact upon the usage intentions of consumers in a number of technology acceptance studies. Empirical findings from past researches claimed that the time-saving feature under the relative advantages of technology-based services is one of the key reasons why users adopt such services. There are few studies like Lin (2011), Khraim et al. (2011) and Ketkar et al. (2012) which further measured the influence of timeliness on the usage of green banking technologies like internet banking or mobile banking. Findings of these studies reported timeliness to be a predominant factor of technology acceptance in the domain of green banking from the client perspective. This is because green banking services often reduces the need of clients to physically visit the bank, thereby saving time for the clients (Bihari, 2010). As a result, the association between timeliness and the adoption of green banking technology seems prominent and has been investigated in this study.

RESEARCH MODEL AND HYPOTHESES

The conceptual research model used in this study to address the influencing factors for clients' perceptions of green banking has been presented in Figure 1. Along with four key constructs of the original model, three additional constructs (e.g. environmental concerns, perceived financial cost and timeliness) drawn from previous literature of green banking services, has been incorporated in the proposed model to make a significant theoretical contribution to the client context of the UTAUT model. Thus, all variables hypothesized in this study and their likely relationships towards client acceptance and use of green banking services in Bangladesh has been discussed next.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Performance Expectancy

According to Venkatesh et al. (2003), performance expectancy reflects a users' view of the usefulness of adopting a technology. Mobile and internet based technologies generally frees users from temporal and spatial limitations, and thereby enables them to acquire information or services at any point of time from anywhere. Past evidences like Park et al. (2007), Lu et al. (2009) and Alwahaishi and Snasel (2013) reveals the impact of performance expectancy is the most relevant factor for the adoption of internet-based technologies like green banking. Nisha et al. (2015), Afshan and Sharif (2016), Chaouali et al. (2016) and Malaquias and Hwang (2016) further claimed that the usefulness in the context of green banking technologies can only be captured by the extent to which it can meet the expectations of the clients. If clients believe that using green banking services can satisfy their expectations, they are more likely to adopt this technology. Hence, the hypothesis is:

H1: Performance expectancy significantly affects individual intention to use green banking technologies.

Effort Expectancy

Effort expectancy depicts the perceived difficulty of using technologies. If the technology requires the users to invest great effort on learning to use, they cannot feel satisfied. In this regard, effort expectancy has a direct relationship with user satisfaction. In fact, users may discontinue their usage of a technology-based service if the providers cannot present an easy-to-use interface to them (Alwahaishi and Snasel, 2013). Prior empirical researches upon the adoption of technology-based services such as Sreenivansan and Noor (2010), Afshan and Sharif (2016), Alwahaishi and Snasel (2013), Chaouali et al. (2016) and Malaquias and Hwang (2016) have revealed effort expectancy as one of the salient determinants that can influence people to use internet banking or other internet related technologies like green banking. Therefore, this study hypothesizes that:

H2: Effort expectancy significantly affects individual intention to use green banking technologies.

Social Influence

Social influence can be defined as the extent to which an individual perceives that others who are important to them believe he or she should adopt a technology (Venkatesh et al., 2003). It basically reflects the impact of referees' opinion on individual user behaviour (Zhou, 2011). The idea behind social influence is that even though an individual may not be in favour of adopting a new technology like green banking, they intend to use it because of the belief that it will boost his/her image among his/her family and peers (Venkatesh and Davis, 2000). Researchers like Yu (2012), Slade et al. (2015), Afshan and Sharif (2016) and Malaquias and Hwang (2016) empirically find there is a significant positive relationship between social influence and adoption of green banking technology. Thus, the proposed hypothesis is:

H3: Social influence significantly affects individual intention to use green banking technologies.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Facilitating Conditions

Users generally need to be equipped with necessary resources and knowledge to operate any technology-based services. According to Venkatesh et al. (2003), facilitating conditions can be defined as the resources and technical infrastructure that a user believes should exist to support the adoption of a particular technology. Lack of these resources and knowledge may impede the adoption of technology related services (Zhou, 2011). On the other hand, availability of facilitating conditions like the access of clients to computer or Internet often results in a higher adoption rate for technological advancements like green banking. Many prior researchers like Yu (2012), Alwahaishi and Snasel (2013), Shaikh and Karjaluoto (2015), Afshan and Sharif (2016) and Chaouali et al. (2016) also claim a positive significant relationship between facilitating conditions and green banking technologies. Taking this concept into account, the next hypothesis is:

H4: Facilitating conditions significantly affects individual intention to use green banking technologies.

Environmental Concerns

According to Kranz and Picot (2011), environmental concerns arise from the basics of environmental psychology. They are typically used as the predictor of the adoption of environmental friendly behavior by most people. Few prior studies like Kranz and Picot (2011) and Gomez and Scholtz (2016) found positive correlation between environmental concern and adoption of behavior favoring the preservation of natural resources and sustainability of the environment. In this regard, many people today support the use of sustainable practices in business and expect social responsibility from all levels of functional activities (Nisha, 2016). As such, it is quite possible that people with greater environmental concern will have a higher likelihood to use green banking technologies (Hossain et al., 2015). Considering this aspect, the next hypothesis is:

H5: Environmental concern significantly affects individual intention to use green banking technologies.

Perceived Financial Cost

It has been proved by several empirical evidences that technology acceptance is influenced by economic factors to a large extent and hence, an important driving factor for the adoption of green banking technology is the financial cost or cost burden related to the use of such services. Past studies by Cruz et al. (2010) and Huili and Zhong (2011) empirically find economic factors like transaction fees of banking and service fees required to connect to green banking technologies play an essential role in green banking adoption. Researchers like Sripalawat et al. (2011), Yu (2012) and Sanakulov and Karjaluoto (2015) also found this construct to have a negative impact upon the behavioral intention of clients to use green banking services. In order to focus on this relationship further, this study hypothesizes that:

H6: Perceived financial cost significantly affects individual intention to use green banking technologies.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Timeliness

According to Taylor and Todd (1995), the extent to which a person views an innovation as offering an advantage over previous ways of performing the same task is known as relative advantage. One of the relative advantages in the context of green banking innovation is timeliness. Due to the busy lifestyle of people, anything that saves time is generally appreciated by the users. Thus, more people are using green banking technologies like internet banking, mobile banking, etc. today than ever before because of its convenience and time saving feature. Green technology can actually help clients to save time and do daily banking transactions in a branchless mode. Even prior studies like Lin (2011), Khraim et al. (2011) and Ketkar et al. (2012) found positive correlation between timeliness and individual intention to use green banking. Hence, the next hypothesis is:

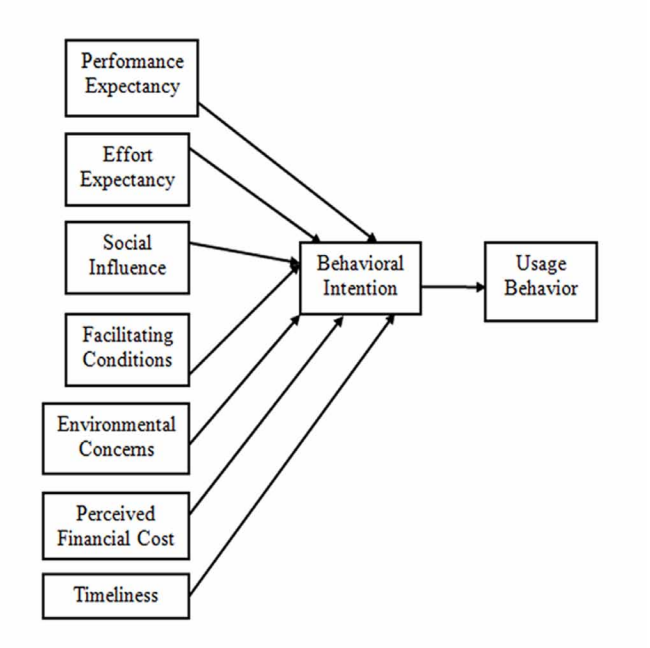
H7: Timeliness significantly affects individual intention to use green banking technologies.

Behavioral Intention

Many empirical studies reveal that the behavior of using any technology is often influenced by the intention to use that technology. Particularly, the studies by Venkatesh and Zhang (2010), Yu (2012) and Nisha et al. (2015) argue that individual behavior is predictable and can be influenced by individual intention that, in turn, can have a significant influence on technology usage. Now, in the context of green banking, the ultimate goal of banks is to ensure that consumers adopt their services rather than just having an intention to adopt it. As such, Alwahaishi and Snasel (2013), Shaikh et al. (2015) and Afshan and Sharif (2016) took this relationship between behavioral intention and actual use into consideration against the backdrop of green banking technologies. Following the lead, this study next hypothesizes that:

H8: Behavioral intention significantly affects individual behavior of using green banking technologies.

RESEARCH METHOD



Data Collection

To investigate the proposed research model, methods and techniques employed for data collection involved a primary research. The primary research involved gathering of data by conducting survey of a representative convenience sample of 1000 bank clients from selected commercial banks operating in the capital city of Bangladesh - Dhaka. The use of this particular sampling method allows us to avoid biasness in data and provide equal opportunity for all city dwellers who are the present or potential users of green banking in Bangladesh.

The survey requires developing and circulating questionnaires for the clients by presenting the information in quantifiable terms, in order to determine the factors that can influence their perception towards green banking services. Since most of the respondents were educated and had English proficiency, they were asked to self-administer the English version of the questionnaire. In other cases, the participants self-administered the Bengali version of the questionnaire or the research assistants themselves filled in the questionnaire based on the respondents' verbal responses. After a three-week survey, 908 completed and usable responses were finally obtained from the survey.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. The Proposed Research Structure

Measurement

All the items used to measure the research variables of the survey were adapted from previous studies, with minor changes in wording to tailor them to the different green banking context in Bangladesh. This ensured the content validity of the questionnaire used to assess each constructs depicted in Figure 1.

The quantitative survey contained 31 statements in order to evaluate the five constructs of the UTAUT model and the three new constructs proposed for the model, as listed in Table 1. The scales for the UTAUT constructs (performance expectancy, effort expectancy, social influence, facilitating conditions and behavioral intention) were adapted from Venkatesh and Zhang (2010), Lin (2011), Yu (2012), Nisha (2016) and Rifat et al. (2017). The scale for environmental concerns was drawn from Ahmad et al. (2013) and Hossain et al. (2015), while the items used to assess perceived financial cost and timeliness were based on Luarn and Lin (2005), Khraim et al. (2011), Ketkar et al. (2012) and Nisha et al. (2015). All these items were measured using a five-point Likert scale, ranging from "strongly disagree" to "strongly agree".

DATA ANALYSIS AND RESULTS

The research model of this study is tested using the structural equation modeling (SEM) facilitates of SmartPLS (version 3.0). For this purpose, an exploratory factor analysis is run on the survey dataset to determine the underlying factor structures, i.e. to explore which observed variables are associated with each latent variable. Using the results of the exploratory factor analysis, a confirmatory factor analysis is run to examine the reliability and validity of the measurement model without identifying the directional relationship among the factors.

Table 1. Constructs and Corresponding Items

Constructs	Corresponding Items
Performance Expectancy	[PE1] Using green banking can make my banking transactions more efficient [PE2] Using green banking can save me time in conducting banking transactions [PE3] Using green banking can make my banking transactions more convenient [PE4] Using green banking can be useful in managing my finances
Effort Expectancy	[EE1] Learning to use green banking is easy for me [EE2] Becoming skillful at using green banking is easy for me [EE3] Interaction with green banking is easy for me [EE4] Overall, I think green banking is easy to use
Social Influence	[SI1] People who are important to me think that I should use green banking [SI2] People who are familiar with me think that I should use green banking [SI3] People who influence my behavior think that I should use green banking [SI4] Most people surrounding me use green banking
Facilitating Conditions	[FC1] Using green banking suits my living environment [FC2] Using green banking fits into my working style [FC3] Using green banking is compatible with my life [FC4] Help is available if I have problems in using green banking
Environmental Concerns	[EC1] I believe green banking will lead to better care for the environment [EC2] I believe green banking is a sustainable environmental practice by banks [EC3] I believe green banking will help to deal with environmental vulnerabilities [EC4] I believe green banking to be a socially responsible activity of the banks
Perceived Financial Cost	[PFC1] The cost of using green banking is higher than other banking channels [PFC2] The internet charges required to use green banking are expensive [PFC3] The mobile devices required to use green banking are expensive [PFC4] Using green banking services can be a cost burden to me
Timeliness	[T1] Using green banking provides me access to bank anytime-anywhere [T2] Using green banking reduces the waiting time for my banking transactions [T3] Using green banking provides me banking information in a timely fashion [T4] Using green banking makes transactions faster by reducing human interventions
Behavioral Intention	[BI1] I prefer to use green banking [BI2] I intend to use green banking [BI3] I believe it is worthwhile for me to use green banking

The method of partial least squares (PLS) is chosen to conduct this analysis since a number of interaction terms have been included in the research model and PLS is capable of testing these effects (Chin et al., 2003). The PLS path modeling approach is also known to be more accurate in explaining the complex relationship than any other approaches (Pavlou and Gefen, 2005). Through partial least squares (PLS) method, first the measurement model is examined to assess the reliability and validity of all variables and then, the structural model is analyzed to examine the relationships hypothesized in the research model. To do this, a detailed assessment of the measurement models at the item level and higher-order level are done and later an analysis of the posited structural relationships is conducted. Extensive tests for convergent validity and discriminant validity to assess the measurement model are done as well; while, the direction of path coefficients, the value of t-statistics, and the explanatory power of the independent variables is further tested for the structural model.

To test the validity of the measurement model, a conformity analysis test is conducted which includes both convergent validity and discriminant validity (Campbell and Fiske, 1959). Convergent validity measures whether the items effectively reflect their respective constructs, whereas discriminant validity shows whether the constructs are statistically different from each other. The convergent validity has

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

been checked through the standardized item loadings, average variance extracted (AVE) and composite reliability (CR) of the items and constructs. In order to test the discriminant validity, it is suggested that that square root of AVE of each construct should be greater than its highest latent variable correlation (Fornell and Larcker, 1981). If the result of the Fornell-Larcker criterion is satisfactory, the model is known to pose good discriminant validity. The bootstrapping method from PLS path modeling approach has been next used in this study to examine the structural paths of the proposed research model. Results of the study are subsequently reported in the following sections.

Measurement Model

Results from the measurement model are presented in Table 2 and Table 3 and it includes information about the reliability, validity, correlations and factor loadings. The composite reliabilities of the constructs ranged between 0.842 and 0.895, which exceeds the 0.7 recommended cut-off values (Nunnally and Bernstein, 1994). The average variance extracted (AVE) is greater than 0.5 in all cases and greater

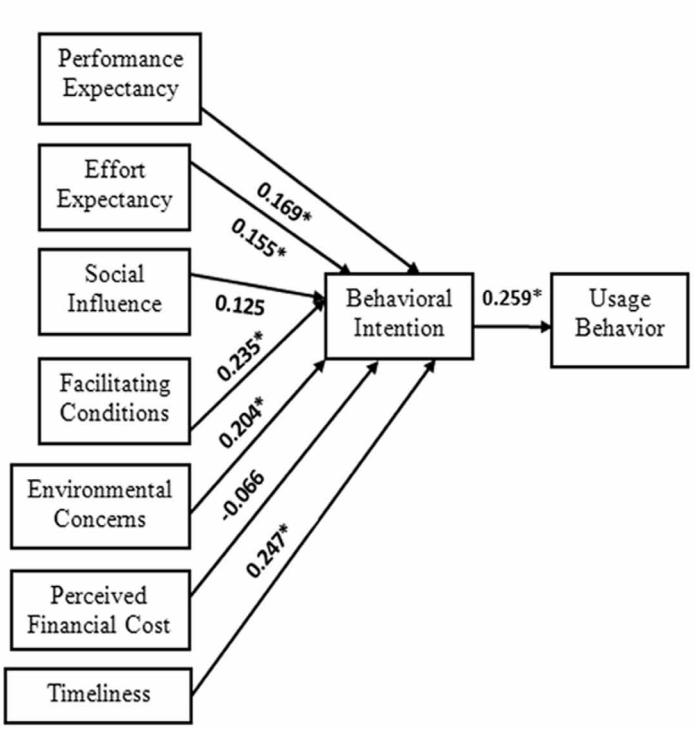
T	0.866	0.407	0.430	0.355	0.334	0.159	0.376	0.324	**0.955**

Notes:

1. BI (Behavioral Intention); EC (Environmental Concerns); EE (Effort Expectancy); FC (Facilitating Conditions); PE (Performance Expectancy); PFC (Perceived Financial Cost); SI (Social Influence); T (Timeliness).
2. Diagonal elements represent the AVEs, while off-diagonal elements represent the square correlations.

than each square correlations, which indicates that all the three models have both convergent validity and discriminant validity (Fornell and Larcker, 1981). Moreover, the internal consistency reliabilities (ICRs) of multi-item scales modeled with reflective indicators was 0.75 or greater, suggesting adequate reliability. The pattern of loadings and cross-loadings also supported internal consistency and discriminant validity, with some exceptions: two items from the construct of environmental concerns and timeliness; and, one item from each construct of social influence, facilitating conditions and perceived financial cost were deleted, due to their low loadings and high cross-loadings.

Structural Model



The path coefficients and significance levels in the structural model are presented in Figure 2. Furthermore, the t-statistics - calculated using the path coefficients of the constructs and their bootstrapped standard errors - are presented in Table 4. Results reveal that the constructs of timeliness (0.247, $p<0.05$), facilitating conditions (0.235, $p<0.05$), environmental concerns (0.204, $p<0.05$), performance expec-

Table 4. Path Coefficients, t-statistics and Hypotheses Results

Hypothesis	Path Coefficients (P)	Standard Error (STERR)	t-Statistics (P/STERR)	Results
H1: Performance Expectancy to Behavioral Intention	0.169	0.1153	1.4657	Supported
H2: Effort Expectancy to Behavioral Intention	0.155	0.1028	1.5078	Supported
H3: Social Influence to Behavioral Intention	0.125	0.1965	0.6361	Not Supported
H4: Facilitating Conditions to Behavioral Intention	0.235	0.1187	1.9798	Supported
H5: Environmental Concern to Behavioral Intention	0.204	0.1033	1.9748	Supported
H6: Perceived Financial Cost to Behavioral Intention	-0.066	0.1516	0.4354	Not Supported
H7: Timeliness to Behavioral Intention	0.247	0.1004	2.4602	Supported
H8: Usability to Behavioral Intention	0.259	0.1259	2.0572	Supported

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Results of Structural Equation Modeling

tancy (0.169, $p<0.05$) and effort expectancy (0.155, $p<0.05$) show significant and positive paths to the behavioral intention of using green banking services, in their order of influencing strength.

However, the constructs of both social influence (0.125, $p>0.05$) and perceived financial cost (-0.066, $p>0.05$) report an insignificant path towards the individual behavior of using green banking services. Therefore, all hypotheses (except H3 and H6) dealing with behavioral intention to use green banking are supported. Subsequently, the hypothesized relationship between behavioral intention and usage (0.259, $p<0.05$) is statistically significant, thereby supporting hypothesis H8.

FINDINGS AND IMPLICATIONS

The objective of this study is to determine the constructs which stimulates the intention to adopt green banking in Bangladesh. The current study finds that timeliness, facilitating conditions, environmental concerns, performance expectancy and effort expectancy plays an important role in capturing clients' overall perceptions of green banking. Results therefore indicate that clients may be fairly pragmatic in developing general attitudes towards the use of green banking. On the other hand, constructs of social influence and perceived financial cost are identified as insignificant factors of client's behavioral intention in Bangladesh. The inclined reasons behind such findings are quite obvious and most of it is shaped by the local culture and infrastructure. Findings are presented below and are separately inclined with each hypothesis of the current study.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

- The first hypothesis of the study claims that performance expectancy significantly affects individual intention to use green banking technologies. Performance expectancy is an important construct according to the research findings of this study. Sustainable qualities of green banking such as efficiency, saving time, convenient transaction and useful in managing finances, etc play an important role in shaping client behavior in terms of adopting green banking. Nisha et al. (2015), Chaouali et al. (2016) and Malaquias and Hwang (2016) have also found such similar results in their studies. The underlying cause behind such result is the novelty of such service in the culture of Bangladesh, where most of the errands are preferred to be served in a traditional manner from physical locations. Clinching benefits such as the efficiency, high responsiveness with empathy, ease of using services and the relative conveniences that are attached with such usages should be used as the major promoting ideas of their CSR to build a strong positive comprehension in the response process of the target clients. The banks must also ensure a lot of empathy and a high level of responsiveness while providing the accurate information through the website email and call center personnel to the clients.
- The second hypothesis states that effort expectancy significantly affects individual intention to use green banking technologies. Results of this study drills that most of the current and potential clients of green banking tend to judge the importance of the adoption based on the required effort expectancy for it. Respondents who expect less effort input in the service consuming process, especially at the adoption stage like that of green banking services in Bangladesh, are more likely to show positive attitude in embracing this service. This finding of the current study claiming that effort expectancy plays a deterministic role in influencing the adoption of green banking has also been supported by Sreenivansan and Noor (2010), Alwahaishi and Snasel (2013) and Malaquias and Hwang (2016). Hence, communications of the banks should focus more on the actual handiness of such services. By making sure that the target clients perceives the efforts needed to avail these services at an ease, banks can net a positive attitude towards these services. To do this, the software platform of the green banking service applications should be made more compatible and user-friendly for the ease of use of the clients.
- According to the third hypothesis, social influence significantly affects individual intention to use green banking technologies. However, the construct of social influence had no effect upon the clients' intentions of adopting green banking as per this study. This finding is certainly not in line with the results revealed by Yu (2012), Slade et al. (2015) and Malaquias and Hwang (2016). Even though the cultural stance of Bangladesh is mainly based on collectivism, the adoption decision of the target clients in case of green banking is not influenced by the family, friends, colleagues or acquaintances. As such, the banks need to focus on direct marketing while attracting the clients in adopting green banking since no word of mouth or social influences will work effectively and affect their intentions. Hence, the clients should be informed about new services and benefits related to green banking by the bank officials in order to enhance the chance of usage for such services.
- The fourth hypothesis of the study claims that facilitating conditions significantly affects individual intention to use green banking technologies. Facilitating conditions is found to be the second strongest direct determinant in influencing client's behavioral intention of adopting green banking in this study. This finding is consistent to Shaikh and Karjaluoto (2015), Afshan and Sharif (2016) and Chaouali et al. (2016). The penetration of green banking is a comparatively new concept in Bangladesh and particularly, when such services are being used as a platform of commuting other errands such as receiving conducting instant banking transactions, ensuring facilitating conditions

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

has a strong role to play. Facilitating conditions generally tend to be the wide availability of computers, strong mobile networks and fast internet services in the context of Bangladesh. Therefore, banks need to emphasize upon the compatibility between the offered services and the working/living styles of their target customers. That is, banks should put efforts in designing suitable services and infrastructures to meet specific needs of different customer segments. Only the availability of strong facilitating conditions can ensure to build the right perception in the mind of target clients by repeatedly focusing upon the benefits of green banking.

- The fifth hypothesis states that environmental concern significantly affects individual intention to use green banking technologies. This construct is found to positively affect the adoption of green banking for clients as per this study. Since Bangladesh is generally prone to natural calamities, it often causes huge losses to the environment. As a result, many people today are concerned about the protection and sustainability of the environment. Moreover, as per the Human Development Report by UNDP (United Nations Development Programme), the HDI (Human Development Index) of Bangladesh is currently 0.558 with a positive growth. This indicates that the healthcare, education and living expense of the country is positively increasing, which in turn increases the social and environmental awareness and understanding of people. This finding is similar to the results revealed by Kranz and Picot (2011), Hossain et al. (2015) and Gomez and Scholtz (2016). Bank clients thus particularly believe that green banking can lead to a better care for the environment, dealing with environmental vulnerabilities and degradation. This thought of the target clients of the banks has led to an increased adoption of green banking in Bangladesh.
- According to the sixth hypothesis, perceived financial cost significantly affects individual intention to use green banking technologies. An insignificant and negative impact of perceived financial cost is observed upon the behavioral intention of adopting green banking in Bangladesh in this study. It supports previous findings like Sripalawat et al. (2011), Yu (2012) and Sanakulov and Karjaluoto (2015). In the context of Bangladesh, this insignificance may have resulted due to the low call and internet subscription rates charged by the mobile network operators as well as for the credibility and trust that has been long-established by the local telecom providers. Additionally, most of the country's well-known banks have already managed to ensure a strong credibility among their target clients' through their banking services and low transaction rates. In fact, the cost of using green banking is much lower than the traditional banking services in Bangladesh due to the increased use of internet and mobile devices at the cheapest possible price. Hence, general people mostly have no complaints related to the cost of green banking services in the country – thereby, making it an insignificant factor in this study.
- The seventh hypothesis of the study claims that timeliness significantly affects individual intention to use green banking technologies. Adoption of green banking can help the clients in terms of saving their time and avoid travelling to bank branches and queuing up for simple banking transactions. Green banking allows banks to offer more services on electronic medium such as internet banking and mobile banking which benefits the clients by available information and service in real time. It requires less time for transaction or getting information for services such as bank statement, online payment, card instructions, etc. Also, green banking technologies provide banking anytime-anywhere, reducing waiting time, fastest transfer facility and such others. Hence, it is not surprising that the relative advantage of timeliness came out as the strongest positive factor that can influence the perception and intention of clients towards green banking adoption. In fact, past studies like Lin (2011), Khraim et al. (2011) and Ketkar et al. (2012) also supported this finding.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

- The eighth and last hypothesis states that behavioral intention significantly affects individual behavior of using green banking technologies. This has been found positive and significant according to the results of this study. Therefore, the argument by previous studies like Rifat et al. (2016), Iqbal et al. (2017) and Rifat et al. (2017) that individual behavior is predictable and can be influenced by individual intention can be supported. Moreover, these past studies further claim that behavioral intention can, in turn, have a significant influence on green banking technology usage. Therefore, the government and the central bank should be more forthcoming in this regard by making budgetary allocations and by providing more financing facility for extensively implementing green banking in the financial sector of Bangladesh.

In conclusion, the development of behavioral intention and then usage of green banking might be a long-term project in emerging economies; but, the fairly positive perception of clients for the environment and an equally positive attitude towards the relative advantage of timeliness clearly paves the way of a higher rate of adoption of green banking in Bangladesh.

LIMITATIONS AND FUTURE RESEARCH DIRECTIONS

Like most empirical research, this study has several limitations. First, the conclusions drawn from this study are based solely upon the urban population. Future research can explore the behavioral intention of the rural people, since access to green banking services still remains restricted to a certain extent in the rural areas of Bangladesh. Second, the moderating impact of voluntariness needs to be explored for a thorough understanding of the influencing factors from the client perspective towards green banking. Finally, other than the proposed dimensions of this study, there can be other factors that can influence the acceptance and use of green banking. Further research considering different factors can thus enhance the understanding of precise determinants for green banking services in Bangladesh.

Chapter 5
The Green School:
A Superintendent's Perspective

Maggie Shook
Thomaston-Upson Schools, USA

Michael D. Richardson
Columbus State University, USA

ABSTRACT

Green schools are supportive and efficient spaces, the places that the authors speculate should inspire others to value students, sustain the environment, and promote learning. They illustrate that the benefits of a green school go far beyond the environment to include student health and student academic performance. Seen from a superintendent's perspective, the authors conclude that green schools also help lower operational costs and reduce waste, while also encouraging the active involvement of occupants in these conservation efforts, teaching them to be responsible stewards of the environment and learning.

INTRODUCTION

More than 53 million children and 6 million adults spend their days in one of the 120,000 public and private school buildings in the United States (United States Environmental Protection Agency, 2008). Over half of these school buildings have polluted indoor air, lead, asbestos, chemical fumes, pesticides, and other harmful toxins (Healthy Schools Campaign, 2010). "It's estimated that at least 22 million school days are lost every year because of colds caught by students and faculty, according to the Centers for Disease Control and Prevention" (Alderson, 2009, p. 1).

Not surprisingly, there is a growing realization that K-12 schools can play a pivotal role in preventing environmental degradation (Edwards, 2010; Edwards & Naboni, 2013)). By influencing human minds at an impressionable age, K-12 institutions can instill a more long-term mindset among future policy makers, business leaders, politicians, and decision makers about the benefits of preserving the environment (Gordon, 2010; Gough, 2005). K-12 institutions that follow practices that prevent environmental damage are typically referred to as "Green Schools" (Freeman & Klein, 2011; U. S. Department of Education, 2009). Some issues that green schools have focused on are benefits of recycling, biological

pest control, energy conservation, and sustainability (Association for Enterprise Opportunity, 2013; Gleed, 2009; Sneirson, 2009).

The term "Green Schools" has its origin in the literature on "Green Ergonomics" (Thatcher, 2013), and represents a fusion of the interrelated concepts of (a) environmental education and (b) sustainable utilization of natural resources (Gutter & Knupp, 2011; Iffrig, 2009). While several conceptualizations of green schools are available, from an operational standpoint, a school is considered as "Green" if it adheres to leadership in energy and environmental design or an internationally recognized certification system that focuses on (a) energy savings, (b) water efficiency, (c) sustainable land use, (d) air quality, and (e) stewardship of natural resources (Leadership in Energy and Environmental Design, 2013). What is a "green school?" No generally accepted definition exists either from professional organizations or from researchers and educators (DuBose, Bosch, & Pearce, 2007; Gisason, 2009; Hornman, Lapinski, Korkmaz, Pulaski, Magent, Luo, Hardig, Dahl, 2006; Mardaljevic, Heschong, & Lee, 2009). For some, green school buildings are the definition of green schools, while for others it means a healthy school environment, and for others it might indicate an environmentally literate student body (Kensler, 2012; Inside Binghamton University, 2011; Kats, Braman, & James, 2010). The U.S. Department of Education (2008) defined a green school as a school that produces environmentally literate graduates, minimizes its environmental footprint, and has a positive impact on student and staff health (Kats, 2003; Matich, 2012).

While conventional schools incur costs to create physical infrastructure and other tangible assets, they are often lacking sufficiency for their human occupants (Matsuoka, 2008; Olson & Kellum, 2003). In contrast, green schools provide an atmosphere through energy efficient lighting, solar panels, green roofs, water efficiency, day-lighting, sound control, and recycling (Murphy, 2010; Orsato, 2006; Roe & Mell, 2013).

The "Greening" of America's schools has resulted in several tangible performance outcomes such as increased school attendance, teacher retention rates and better student grades (Kats, 2006; Hoffman 2009). Green schools have also contributed better outcomes for student health and staff welfare (Bell & Dyment, 2008) as well as impressive operational savings (Issa, Attalla, Rankin, & Christian, 2010). Despite the undeniable benefits of green schools to society, selling the concept to K-12 administrators remains a huge challenge given significant up-front investment costs (Psacharopoulos & Patrinos, 2004). For example, optimally designed green schools are estimated to cost almost 70% more than conventional school buildings (Kats, 2006). For green schools to be adopted and used effectively, administrators and other stakeholders must be convinced of their benefits (Lavy & Bilbo, 2009; Lawton, 2007; Oreopoulos & Salvanes, 2011). According to the U.S. Energy Information Administration (2009), buildings are significant contributors to energy consumption and global warming (EIA, 2009; Ornstein, Moreira, Ono, Franca, & Nogueira, 2009). Famous politicians, celebrities, and journalists have continuously stressed the effects of buildings on environmental isses such as global warming and resource depletion (American Federation of Teachers, 2006).

The basic goals of green school are to:

- Cut energy costs through creative use of daylighting, solar heating, and shade and building placement.
- Improve air quality by minimizing or eliminating sources of indoor and outdoor pollution.
- Reduce noise to aid teaching and learning.
- Use recycled and recyclable building materials
- Conserve natural resources

GREEN SCHOOL POLITICS

The need for the interwoven dimensions of political, economic, legal, social and environmental has been agreed upon for achieving sustainability and green school efficiency (Bentzin & Lombardo, 2012). In order to accomplish efficiency with green schools, a critical understanding of its complementary parts is needed, such as how environmental, socio-political and economic factors influence people, as well as impacting choices and actions regarding the development and commitment to green schools (Benedict & McMahon, 2006; Bentzin & Lombardo, 2012; Christiansen, Joensen, & Nielsen, 2007; Davies & Quirke, 2007; Duran-Narucki, 2008; Edwards, 2006; Elliott, Fourali, & Issler, 2010; Humblet, Owens, & Roy, 2010; Murphy, 2010).

Economists, politicians and policymakers are interested in education in part because of their interest in securing a return on school investments (Olson & Kellum, 2003; Schimmel, 2011; Schneider, 2002). The American educational system is funded out of public resources meaning, that governments have an ethical obligation to optimize rates of return on the educational investment (Ahuja, 1996; U.S. Green Building Council, 2009; U. S. Energy Information Administration, 2013). Politicians often have broader objectives that inform their push for adequate return on investments (Ackley, 2009; Ackley & Begley, 2010; Barr, Leigh, & Dunbar, 2011; Blackwell, Cobb, & Weinberg, 2002; Crosss, Byrne, & Lueck, 2010). Some politicians and leaders often have particular preferences; some see equity as better than efficiency, to some productivity means more effective use of funds than equality, etc (Bertels, Papanin & Papania, 2011; Houston, 2009; McDonough, Braungart, Anastas & Zimmerman, 2003; Peponis, Bafna, Bajaj, Bromberg, Congdon & Rashid, 2007).

As the saying goes, 'information is power' and this is especially so in today's school (Evans & Lindsay, 2005). The world is experiencing an information revolution making the industrial revolution obsolete (Christensen, Horn, & Johnson, 2008). With this change comes an explosion of data, which educators are left to assimilate into useful information (Christiasen, Joensen, & Nielsen, 2007). However, the ability to interpret this avalanche of data, to extract meaning from artificial fields of data, has expanded much more slowly, if at all (Dunbar & Plaut, 2008). Education is experiencing a social and economic change that is evolving from an industrial focus at a national level, to an information focus at a global level (Christensen, Horn, & Johnson, 2008). There is so much data, that some describe districts as drowning in it (Celio & Harvey, 2005). With this flood of available data in education, when is too much data detrimental and no longer powerful (Corcoran, Fuhrman & Belcher, 2001)? What is the optimal level of data that educators can manage before rendering themselves powerless and unable to manage or process that data?

The positive effects of investments in education on the level and evolution of earnings, employment, and other aspects of well-being is one of the most robust and important empirical findings in labor economics (see e.g. Blundell, Dearden, Meghir & Sianesi, 1999; Oreopoulos & Salvanes, 2011; Psacharopoulos & Patrinos, 2004). In developed countries, education is an important resource for the economy and assumed to be one of the key determinants in development, production and, thus, economic growth. Therefore, as politicians seek to increase the population's educational level they often focus on the individual's (economic) benefits of education, mainly the increase in earnings due to investments into more education (Buckley, Schneider & Shang, 2005). Such politicians are now beginning to see the importance of investment in green as a demonstrated method for increasing economic and development productivity (Lockwood, 2006).

Green building is not a matter of choice or luxury but a necessity for the environmentally conscious industry professionals, owners, developers, government officials and the rest of the stakeholders (Crampton & Thompson, 2008). Growing awareness of environmental aspects and demand on green building worldwide shows that, the status quo as it exists in the construction industry simply cannot go on. The industry must, and is, changing. In the United States, buildings are responsible for 72% of electricity consumption, 39% of energy use, 35% of carbon dioxide emissions, 40% of raw material usage, 30% waste output and 14% potable water consumption. (USGBC, 2009) It is estimated that 73% of these buildings will stand for decades to satisfy demand with their negative environmental impact. As more and more research has been done over the years, the results confirm the positive impact from building with sustainability and green building standards in mind (Williams & Brown, 2013).

BENEFITS OF GREEN SCHOOLS

As the demand for 'sustainable' or 'green' buildings continues to increase, the need for a better understanding of how these buildings are designed has also increased (USGBC, 2009; Yudelson, 2008). Despite the many aspects of going green, most research focuses on cost, performance aspects, and the benefits of green buildings (Christopherson & Clark, 2006). A recent GSA study of green buildings indicated that, they had 33% less carbon emissions, 27% higher occupant satisfaction, used up to 45% less energy, experienced 13% lower aggregate maintenance costs and used up to 54% less water when compared to national averages (Healthy Schools Network, 2013; Olson & Carney, 2006). Even though the benefits are categorized as environmental, health and community, financial, market, and industry, most of the categories have secondary financial benefits as well (Edwards, 2010). Employees in buildings with interiors that are compliant with green building standards experience less absenteeism and fewer turnovers.

Fortunately, green buildings can be designed and in unique places are being designed explicitly with environmental education in mind (Rainwater & Hartke, 2011). The phenomenon is best seen today in school buildings. School building research has focused on air quality, daylighting, and energy performance (Mardaljevic, Heschong, & Lee, 2009; National Research Council, 2007; United States Green Building Council, 2009). The school building is arguably the largest and most visible physical artifact of school sustainability, and one that changes less often relative to other aspects of the school environment such as curriculum or the sourcing of green office supplies. The notion of sustainability has evolved significantly from the conventional view of being "green" to the linking of social and economic dimensions with ecological protection goals (Kohler, 2002).

BENEFITS OF GREEN SCHOOLS

- Enhance and protect eco-system and biodiversity,
- Improve water and air quality,
- Reduce solid waste,
- Conserve natural resources,
- Improve air, thermal, daylight and acoustic environments,
- Enhance occupant comfort and health,
- Minimize strain on local infrastructure,

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

- Contribute to the overall quality of life,
- Reduce operating costs,
- Reduce life cycle energy costs,
- Improve employee productivity and satisfaction,
- Lower absenteeism / increased productivity,
- Lower health related costs such as insurance premiums,
- Lower employee turnover,
- Promote longer economic life of the facility,
- Obtain federal grants used as enticements to promote green buildings, and
- Improve student performance.

Researchers investigating effects of green building design on occupants have indicated green building occupants experienced fewer rates of absenteeism, lower turnover, and higher productivity (Kats, 2006; Steinberg, Patchan, Sehunn, & Landis, 2009). Kats (2006) validated that green buildings do not come at high premiums as originally assumed. According to Kats, premium for green is typically 2% of total cost of the project. Green school buildings on average are 25-30% more efficient compared to conventional buildings, use less water, produce less waste, are cheaper to maintain, and enhance occupant productivity (Kats, 2006). When a small increase in total project cost is compared to savings of lifetime energy costs, there is potential financial savings equal to ten times the initial investment to construct a green building (Kats, 2003).

Schools have the unique freedom to develop new ideas, comment on society, and engage in bold experimentation, as well as to contribute to the creation of new knowledge (Cortese, 1999). Schools contribute to the health and well-being of society through the creation and dissemination of knowledge and values (Cortese, 1992). As Vierderman (2006) concluded,

Higher education will play a role in shaping the vision and practice for a sustainable society for better or worse. It has a responsibility and an obligation for the better. Its graduates will be leaders of countries, corporations, religious institutions, art thought, science, engineering, and people of power. They will be citizens, great and small, asked to participate in decision making for the commonwealth. Its faculty will have access to the halls of power and will be called upon by society for assistance. (p.2)

Educational institutions should be responsive to the social, economic and cultural needs of the communities in which they are located and foster a more active engagement with communities (Chatterton & Goddard, 2000).

GREEN IMPACT ON STUDENT PERFORMANCE

The "greening" of schools—a growing national movement that now includes thousands of K-12 private, public, and charter schools across the country—can provide solutions to many economic and community challenges (Metzger, 2011). Tanner (2008), in a recent survey by the University of Colorado-Denver of 100 "green" schools in 28 states, found a positive correlation between student achievement in science and green school practices (Tanner, 2008, 2009). These green practices included a curriculum that advances environmental literacy and sustainability, opportunities for stewardship and service learning,

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

sustainable facilities design and management, and an emphasis on student health and well-being (Taylor, 2009). Student achievement can also increase with building improvements alone (Clark, 2006; Frantz, 2010; Gough, 2005; Heerwagen, 2000).

The link between quality school facilities and student achievement is well-documented in research. The continued state investment in school facilities should improve schools, communities, and the lives of students (Waughray & Kerr, 2012). Schools should be learner--centered, safe, and sustainable centers of their communities (Humblet, Owens & Roy, 2010).

Roughly one quarter of the US population spends the majority of their day in K-12 school buildings—students, the youngest citizens (Hatrick, 2010). Although schools have been studied and analyzed, recent scholarship on building performance has focused primarily on commercial buildings. But school buildings are very different from offices; they have different occupants, different daily routines, different management systems, different budgets, and different decision making structures (Olson & Carney, 2006). Additionally, as more schools move towards "green" design, there is an increased need to verify that they are meeting expected energy-related goals (Weston & Brooks, 2008). Green schools are not achieved through green building alone; all aspects of the school must support and embrace the green philosophy (Ramesh, Prakask & Shukla, 2010). Incorporating green (an environmentally-conscious perspective) into the curriculum has become an important part of green schools. Improved productivity, performance, and happiness are simply by-products of overall improvement in health. Conversely, the main contributors to improved health are better day lighting and indoor air quality, making it difficult to analyze whether increased student performance is due to overall building design or these variables alone (Anastas & Simmerman, 2003).

HEALTH BENEFITS

Researchers have found that the benefits of building green appear quickly in the form of energy savings and decreased human resource costs related to staff turnover and employee absenteeism (Clark, 2006; Edwards, 2006; Frantz, 2010). Proof that green schools can positively impact academics, student health, and a school's financial health continue to mount among green-minded administrators, teachers, and students (Coffey, 2001). Whether the topic is a curriculum that advances environmental literacy and sustainability, recycling programs and organic foods on the cafeteria line, or improving indoor air quality, the "greening" of the nation's schools points the way toward saving money, improving student health and achievement—and saving the planet in the process (Corcoran, Fuhrman & Belcher, 2001).

This movement began as individual educators advocating the "greening" of schools, but the green school movement now has broad appeal for school boards that want initiatives to save energy costs, and for teachers who want curricula changes. Green efforts significantly impact school culture and school planning and progress. The question of how the form and functioning of schools can be changed to create the least possible adverse impact on their local environment through the way they are planned, designed, laid out, and managed is only just being asked (Fast, 2013). It is important for green building initiatives to identify: the organizations that accelerate the adoption of green building guidelines in a society, the incentives and barriers associated with the green building guidelines, and the necessary motivations for the adopter organizations (Elliott, Fourali & Issler, 2010; Santone, 2010).

Another common health risk in today's buildings is poor indoor air quality. Individuals spend 80-90% of their time indoors (USGBC, 2009). Poor air quality is often unnoticed by occupants but clearly

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

reflected in the number of sick days and in employee complaints. In schools, poor air quality can have pronounced effects on asthma and allergies, increasing sick days taken by students and teachers (Kats, 2006). Because nearly 25% of our nation's schools are considered below standard, designed with minimum required performance for lowest cost, with air quality and ventilation rarely regulated by the state, these poor air quality conditions will most likely continue in years to come (Kats, 2006).

FINANCIAL CONCERNS

Why are there not more green schools? Most observers would indicate that the supposed financial concerns about green schools have limited both the discussion and building. But what about the financial impacts of a green school building? As school leaders strive to make schools more environmentally inclusive and "green," fiscal constraints are making schools more "lean" (Rothenberg, Pil, & Maxwell, 2001). The twentieth century reminded the world's population that the earth is finite in both its ability to produce raw material and safely process waste (Janda, 2009). The past century also showed how industrialization gone unchecked can pollute water and airways making the very elements of life toxic (Christopher, 2009). Although technology has greatly decreased the environmental impact of industry, the rate of consumption and production outpaces these innovations (Richardson, Chan, & Lane, 2000; Schelly, Cross, Franzen, Hall, & Reeve, 2011). One of the essential components of a sustainable society is "green development and productivity." Yet, given all of the importance of green productivity to the global environmental problem, many are still skeptical about the business benefits of green productivity especially in schools (Rudd, Reed, & Smith, 2008). However, if all new school construction and school renovations went green starting today, energy savings alone would total $20 billion over the next 10 years (Ryland, 2003; Sackett, 2007). Green schools typically cost less than $3 per square foot more to build, an investment that is paid back within a few years of operation (Waughray & Kerr, 2012).

ONE SCHOOL DISTRICT'S JOURNEY TO GREEN

The Thomaston-Upson School System (Georgia) Leadership and Board of Education recognizes that it is the responsibility of the school system to ensure that every effort is made to conserve energy and natural resources while exercising sound financial management. According to Chapman (2013), "the nation's schools spend more than $8 billion a year on energy, and as much as 30 percent of that energy is used inefficiently or unnecessarily" (p. 41). Chapman went on to generalize that when schools recognize that they have the potential to significantly cut their electricity use, they will save money and reduce their burden on the environment (Fast, 2013). Schimmel (March/April2011) emphasized "America can no longer use energy today and pay for it tomorrow. Schools have the opportunity to be leaders in modeling energy use" (p. 8).

The Thomaston-Upson School System started looking at ways to save money through energy management as early as 2006 (Frantz, 2010). Gutter and Knupp (2011) support this savings initiative by saying "a series of incremental improvements can lead a school district to reduced utility costs" (p. 26). In order to produce energy savings throughout the school system, the Thomaston-Upson County Board of Education entered into a five-year partnership contract with Energy Education, Inc. in March of 2006. The cost of this partnership was $310,000. Schimmel advised school districts to not try and go

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

it alone, but to seek help for research and changes (2011). He went on to say how important it was to do a cost analysis and to decide whether to outsource or manage alone. That is exactly the process the Thomaston-Upson School district went through in a partnership with Energy Education. The purpose of the partnership was to provide training and assistance with an Energy Education program. This approach started with an in-depth, on-site assessment of every facility in our district. The school buildings' use and needs of energy at all hours of the day and night were analyzed. Logs of temperatures, humidity, and other conditions important to equipment and facility use were obtained.

Gutter and Knupp (2010) speculated that a district has not made energy savings a concrete initiative unless it is someone's job to oversee the implementation. The school system demonstrated an agreement to this thought by hiring an Energy Manager to oversee the implementation of the energy savings program. The Energy manager was responsible for implementing a cost avoidance program through gathering data through the energy caps computer program, monitoring the school system's HVAC system, and implementing an energy education program for all of the Thomaston-Upson County School system employees.

Gutter and Knupp (2010) said that committing to an energy management program and adopting a policy or resolution will make the initiative official. The Thomaston-Upson County School System adopted an Energy Management Conservation Policy in October of 2006. The school system also implemented guidelines for energy conservation and building management. Gutter and Knupp said "show me the money" (p. 19). After implementing the energy management program, the estimated energy savings for the school system after 6 months was $57,643 or 12%, and after 11 months of reviewing plans and implementations of suggested cost effective measures, the estimated energy savings for the school system was $136,354 or 15%. Beyond initial energy savings benefits, this school district remove we realized we made a positive environmental impact by demonstrating stewardship of our natural resources. Leaders have continued to make energy conservation a priority to further shift dollars for energy costs to educating our students. Throughout the remainder of the partnership though 2010 the district realized a consistent savings in energy of approximately $100,000 per year. This was a necessary help not only in energy conservation costs but also with other budget restraints (Hatrick, 2010).

In 2010, the district continued to experience budget shortfalls and could no longer keep the position of energy manager in our budget. The responsibility of monitoring energy fell to an assigned individual at each school who also had additional responsibilities. While our savings have not continued to be as significant through the 2013 school year, our budgeted amount for energy has remained consistent even though costs for energy have increased. The school system continues to make energy conservation a priority. During school shut-down periods, we keep the ball rolling (Gutter & Knupp, 2010). We continue to tackle low- and no-cost improvements and follow the "un-plug" concept for all energy consuming devices during long breaks. If a benefit is described as "something that aids or promotes well-being" (wordnet.princeton.edu/), green building is all about promoting wellbeing, usually as it relates to environmental health and community wellbeing. There are also direct economic benefits through the reduction of energy and water use. Green buildings also produce many less obvious benefits, such as market and industry benefits. The biggest obstacle to green buildings is misconception regarding the perceived overwhelming costs of environmentally efficient products. In summary, the Superintendent and Board of Education knew how important it was to "Green" our schools. We did this by following a plan like Chapman recommends today: by developing policy, empowering leadership, organizing the effort in a partnership, developing a plan by completing an audit, and following a consistent process (2012, p. 44).

WHAT OF THE FUTURE OF GREEN?

Green buildings are receiving increased attention in the public sector in the United States (Weston & Brooks, 2008). Over the past ten years, public sector organizations have gone from "testing the waters" with green building pilot projects to developing wide-reaching policies that incorporate green building practices and standards as a formal part of capital project decision processes (Sims, 2012). Like other green buildings, green schools decrease our reliance on fossil fuels, thus decreasing carbon dioxide emissions and other forms of harmful pollution (Schmitz, 2008). Green schools can help turn back the clock on global warming, improving the environmental outlook for the children who will one day be faced with the challenge of finding resolutions to this problem (Bardacke, 2009; Bell & Dyment, 2008).

According to researchers, green design increases productivity, performance, health and well-being, and satisfaction (Buckley, Schneider, & Shang, 2005; Center for Green Schools, 2010). School culture consists of elements such as core norms, traditions, mission, rituals, organization, leadership, roles, curricula and programs (Chapman, 2013). Leadership plays a large role in how each of these elements manifest (Bottery, 2008). The operation of the facility, and the ability for students to interact with its operation, enhance the school's ability to be an educational tool (Brager & Baker, 2009). Kats (2006) showed that green schools average a 3% increase in cost, but have a financial return of 20 times that amount. Benefits accumulate through lower water and energy use, increased teacher retention and lower health costs (Kats, 2006). An additional benefit, not measurable in dollars, is the increased competitiveness of the school. As parents are provided greater choice and freedom about where to send their children to school, the benefit of green building will become even more valuable. Research on the healthy indoor environment present in green buildings demonstrates benefits beyond cost effectiveness into the realm of societal responsibility (USGBC, 2009; Kats, 2006).

KEY TERMS AND DEFINITIONS

Environment: The world in which life exists and shared by all whose actions affect the environment.

Environmental Education: A learning process that increases knowledge and awareness about the environment, including challenges and opportunities for the environment.

Green Design: Green design provides the opportunity to achieve exceptional performance above requirements including innovative performance not typically addressed in schools.

Green School Cost: The financial commitment and resources to obtain, operate, repair, and decommission (or salvage) a building over a defined period of time.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Green Schools: Green schools "are education buildings that operate in harmony with the natural environment. They are built to reduce energy costs and conserve natural resources, make use of recycled and recyclable materials, and operate in a sustainable manner" (AFT 2009).

School Environment: Total space within which children learn inclusive of equipment, furniture, and the context within which the school is situated.

Sustainability: It is the continuous regrowth promoted as an alternative process to examine the role of humans in the environment. It is the ability to meet the needs of the present without compromising the future.

Chapter 6
Green IT Adoption:
Lessons from the Philippines Business Process Outsourcing Industry

Alexander A. Hernandez
De La Salle University, Philippines & Technological Institute of the Philippines, Philippines

Sherwin E. Ona
De La Salle University, Philippines

ABSTRACT

Green Information Technology (GIT) refers to using information technology in ways that help to reduce environmental impacts including the use of energy more efficiently and reducing waste. To date, however, few studies attempt to provide a holistic understanding of GIT adoption in developing countries, which GIT plays a significant role in achieving a sustainable environment and economic performance. This paper explores the practices, processes and enablers in GIT adoption within the Philippines Business Process Outsourcing Industry (BPO). The authors used the revelatory multiple-case study as a research approach in understanding GIT adoption in BPO organizations. They found five areas of GIT adoption covering IT procurement, IT applications as low carbon enabler, working environment, data center and IT end of life management. Essentially, strategy and governance, processes, structure, people, technology support, and measurement and improvement enabled GIT adoption in BPO organizations. The authors further found that BPO organizations have the strong long-term commitment to environmental sustainability.

1. INTRODUCTION

Green IT refers to the using of Information Technology (IT) resources in an energy-efficient and cost-effective manner (Bose & Luo, 2011), and it is foreseen as the most important strategic technology in the imminent future. According to Mines (2009), the GIT service market was expected to reach nearly $5 billion by 2013. Organizations are now actively pursuing GIT solutions for a multitude of reasons and benefits, including lower power consumption, lower costs, lower carbon emissions, less environmental impact, improved system performance and use, increased collaboration and interaction amid constituents,

space savings, and an agile workforce (Bose & Luo, 2011). According to a 2009 GIT report surveying 426 companies in North America including a total of 1052 companies worldwide, 86% stated that it is significantly important that their IT organization implement GIT initiatives. This report also states that 97% of these firms are at least considering a GIT strategy (Symantec, 2009).

GIT is attributed to the initiatives and programs that directly or indirectly address environmental sustainability. According to Siegler and Gaughan (2008), GIT is about information technology and system initiatives, including programs that address environmental sustainability. It also addresses energy consumption as well as waste associated with the use of hardware and software which tends to have a direct and positive impact (Jenkin, McShane, & Webster, 2011a). Hilty et al. (2006) also support this view by stating that the production, use, and disposal of IT have a direct effect on the natural environment and eco-sustainability (Hilty et al., 2006). Estimates indicate that the IT industry accounts for 2% of global CO2 emissions, which is equivalent to the amount generated by the aviation industry (Goasduff & Forsling, 2007). Jenkin et al. (2011b) outlined the objective of GIT to be reducing the overall environmental impact of Information Communication Technology (ICT) by adopting a number of measures ranging from (1) taking environment-friendly approaches to the production; and (2) use of IT equipment and facilities to optimize the use of ICT equipment along with network infrastructure in order to reduce energy consumption at every stage.

A study by the Australian Computer Society (2010) noted that in 2009, Australia's ICT users consumed 13.248 million KWh of electricity which generated an equivalent of 14,248 million tonnes of CO2 emission, which is nearly 2.5% of Australia's total emissions (539 million tonnes). In 2010, Google's overall consumption of electricity was reported to be 2.26 million MW h (Albanesius, 2011). As Google has operations and major servers in many countries with different types of energy sources and different Green House Gases (GHG) emission rates, it is difficult to translate accurately this energy consumption figure to its GHG emission equivalent. Corbett, Sayili, Zelenika, and Pearce's (2010) analysis of articles published in the CIO magazine shows that economic benefit is the most commonly cited driver for Green IT. In Australia, the ANZ Bank's initiative to eliminate screensavers has resulted in approximately 4% reduction in the annual electricity bill with an estimated value of AU$500,000 per year (Molla & Cooper, 2010). A global survey of 1260 IT professionals indicated that 50% are concerned about climate change (Info-Tech, 2008). Governments, in particular, can encourage the adoption of Green IT by legislations that create the framework for a low-carbon economy (Chen, Boudreau, & Watson, 2008).

Prior studies deal with introducing Green IT as a research focus in information systems research. Also, research gaps have been identified. First, most of these studies explore only general Green IT and practices (including virtualization, IT end of life management and general data center practices). Only a handful of studies assesses a broad aspect of green IT such as IT procurement, IT working environment, data center operations, IT as low carbon enablers and IT end of life management. Furthermore, green IT is relatively new research topic, several studies developed a research model that predicts the adoption of a broad range of green IT initiatives. Also, many of these studies aggregate green IT adoption experience across multiple industries within a country using quantitative methods. Second, in the perspective developing countries, there are limited researches on Green IT adoption from small to large organizations. In addition, there are limited empirical studies in understanding green IT adoption by developing countries, in spite of a number of growing number technology diffusions that have taken place in those nations in the recent years (Kartiwi & MacGregor, 2007; Chowdhury, 2003). For a detailed summary, refer to Table 2 in Appendix A. An understanding of the adoption of GIT by developing countries is thus significant for both practitioners and academics. Moreover, the contextual situations of countries are

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

arguably different in nature. For example, the maturity of the ICT infrastructure, e-commerce readiness, the degree of government support, and extent of business competitiveness vary considerably, not only between the developed and developing countries but also among developing countries. Furthermore, it would be inappropriate to assume that various dimensions of national culture remain somewhat similar across all developing countries. In fact, distinct cultural differences are noted among developing countries. Hence, it could be argued that qualitative studies focusing on GIT adoption in some developing countries not be necessarily reflective of the GIT trends and adoption dynamics of all developing countries across the globe. Thus, a detailed understanding of organizations' adoption experience is lacking.

Therefore, in summary, we argue that there is currently a lack of rich understanding of the GIT adoption phenomenon in developing countries due to the dominance of quantitative studies and the limited application of adoption theories (Oliveira & Martins, 2011). In fact, the adoption process involves dynamic interactions among social, legal, economic, political and technological factors that call for more studies involving several theoretical perspectives to understand better the adoption phenomenon in different contexts of developing countries. Each developing country may have specific GIT experience involving different dynamics and interplays, which may have differing effects on the adoption phenomenon. In-depth studies of how GIT is adopted in a context that has not yet been thoroughly investigated, thus, contribute to the present knowledge in the GIT area.

The key goal of the present work is to build a holistic understanding of GIT through a qualitative study to address the identified knowledge gap. In this study, we investigate the enablers, practices and processes in GIT adoption. As GIT adoption is complex and heavily negotiated by contexts within which organizations operate (Seyal & Rahim, 2006), we have employed multiple case study approach to help us better understand the underlying enablers, processes and practices in GIT adoption. The specific research questions we address are as follow:

1. What are the practices and processes in Green IT adoption?
2. What are enablers that contribute to Green IT adoption?

To address these questions, we conducted a revelatory multiple case study involving three organizations with different business nature, position, and experience within the Philippine BPO industry. These participating organizations represent typical IT-BPO, Business Process Management, and IT-Supply Chain within that industry. The BPO industry was chosen because it is characterized by a higher volume of use in IT, contributions in economic performance and, therefore, often pioneers technology adoption. The study focuses on single industry rather than multiple industries to allow for thorough and detailed investigations into the interplays of GIT adoption by organizations within the industry. The Philippines was selected as a reference of a developing nation since it represents typical features of developing countries, particularly in the ASEAN region (Lertwongsatien & Wongpinunwatana, 2003; Seyal et al., 2007). The Philippines, despite the benefits from the stable economic development at an average of 5.2% between the period of 2010 and 2014, the E-Readiness Index (ERI) and Network Readiness Index (NRI) is still very low. Also, it has only dedicated a small amount of its Gross Domestic Product (GDP) to Information and Communications Technology (ICT) adoption (Indjikian and Siegel, 2005). Hence, this research is expected to be significant for other growing nations, leading countries with comparable technological, socio-economic, civic, cultural, and legal environment as the Philippines. At present, there has been no comprehensive study on the enablers, practices and processes in GIT adoption in the Philippines.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

2. LITERATURE REVIEW

This section presents the background of GIT, practices and initiations by organizations. Furthermore, we also present the GIT adoption phases, approaches and strategies and relevance of the BPO industry.

2.1. Background of Green IT

In this section, we describe GIT, initiation, and adoption phases in organizations.

2.1.1. Green IT Definition

There are considerable varying definitions of GIT in the literature. According to Hedwig et al. (2009), GIT comprises activities, programs and efforts that embeds ecologically friendly innovative processes and technologies in the information technology lifecycle; the data center's sustainable operation plays an essential role in this area by emphasizing on conservation and reduction of energy used during its function. On the other hand, Srivastava et al. (2001) defined "environmental technologies" as "production equipment, method and procedures, product designs, and product delivery mechanisms that conserve energy and natural resources, minimize the environmental load of human activities, and protect the natural environment." It includes both operational approaches (e.g. resource conservation-oriented work environment and waste management practices) and hardware (cleaner design and production technologies, pollution control equipment etc.) More importantly, GIT challenges include emissions of greenhouse gases and CO2, climate change, resource and energy use, and end of life or electronic waste. Koo et al. (2014b) suggests that GIT deals with the IT purpose/industry, which acts an important role in decreasing the ecological impacts caused by IT and using IT as solutions for environmental problems.

For end-users standpoint, GIT has been linked mainly with innovative technologies and initiatives devised to reduce the cooling, power and operational costs related with IT functions (Molla et al., 2009). Also, it affects the environment throughout the full lifecycle starting from the design, development, production, utilization, and eventual disposal (Murusegan, 2008). More importantly, it is aimed to establish a win-win solution for both environment and end users.

2.2. Green Practices and Initiatives

2.2.1. Benefits

Given the newness of GIT, prior empirical findings present direct and indirect benefits of reducing energy consumption in the data center (Kurp, 2008, Nanath & Pillai 2012) and lesser carbon emissions (Overby, 2007). Also, some studies explain commitment to reducing energy resource used in business and data center operations (Beach, 2008), savings earned from the total cost of ownership (Swanborg, 2009) and increased profitability (Ricknas, 2009). There are studies tried to present technologies aligned to GIT practices. For instance, Perenson (2009) presented an energy-saving green storage device. In another study, GIT via virtualization and cloud computing are identified useful technologies to consolidate data centers highlighting the benefits on resource conversation (Oliveira et al., 2014). Lastly, several studies have dealt with GIT in office environment through the Leading in Energy and Environmental Design

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

(LEED) to achieve higher performance in energy-efficiency (Sartori & Hestnes, 2007; Hwang & Tan, 2012; Dwaikat & Ali, 2015; Huang et al., 2015).

The significance of GIT is now slowly becoming more familiar with organizations. Kuo and Dick (2010) emphasized the important role of GIT as a solution to environmental challenges. In another study, Murusegan (2008) found that lowering costs and reducing power consumption were the main motivations for adopting GIT. It is consistent with the study of Hopper and Rice (2008) suggesting cost reduction as a primary advantage of GIT practices overarching operating and maintenance costs in IT systems within organizations. Vykoukal et al. (2009) suggests that GIT practices had both economic and environmental benefits through several adoption strategies. Also, Bose and Pal (2012) explore on green supply chain management adoption complementing stock price needs of the organization.

In general, we argue that benefits of GIT should not be limited only to the reduction of environmental footprint, however, can be used to design strategic business embedding GIT in a wider range of activities. Therefore, the benefits established from GIT practices and initiatives in the literature. However, we argue that their several eco-goals for GIT practices result in different economic and environmental benefits. Lastly, GIT can bring other benefits not only cost reduction, but it can also result to enhanced business processes, systems efficiency, quality of outcomes and corporate competitive advantage and image.

2.2.2. Initiation

The GIT literature has started discussing the factors, challenges, and enablers in GIT adoption. Based the existing literature, Lei and Ngai (2012) categorized the antecedents of GIT adoption in organizations. However, few studies have been empirically validated to better understanding the factors in GIT adoption. Prior empirical studies investigated individual and contextual factors affecting GIT. Technological characteristics were found significant in GIT adoption including compatibility, complexity, and observability consistent with the practices, attitude and values of the organization and level of difficulty of GIT and observability of the outcomes of adoption (Moore & Benbasat, 1991; Kuo & Dick, 2010; Corbett, 2012). For organizational contexts, the literature continuous to prove that organizational resources (Lei & Ngai, 2012; Bose & Luo, 2011; Sayeed and Gill, 2008), strategic orientations (Seidel et al., 2010; Molla, 2009; Seidel et al., 2010; Sayeed & Gill, 2008) and altruistic objectives (Molla, 2009), and support plays a significant role in GIT adoption (Seidel et al., 2010). Also, external environmental context affects decisions such as external pressures (Lei & Ngai, 2012) and external supports (Bose & Luo, 2011; Tarafdar et al., 2010). Furthermore, individual factors such as attitude and resistance to change are more likely to affect decisions to adopt GIT (Sarkar & Young, 2009; Carlet, 2015; Oliveira et al., 2014). Prior studies in technology adoption are consistent with new empirical findings in GIT emphasizing the effects of individual factors in any technology adoption (Harison et al., 1997; Riemenschneider & McKinney, 2001; Olson and Boyer, 2003). Thus, we argue that individual and contextual factors are affecting decisions to adopt GIT in organizations.

2.2.3. Green IT Adoption Phases

There are also limited studies on phases for adopting GIT. However, these studies present salient phases such as (1) assessment, (2) planning and (3) implementation (Mines, 2009). In the assessment phase, organizations understand their present situation and construct a baseline for possible GIT activities; specifically it involves creating an overall GIT strategy and plan while assessing the return on investments

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

(Elliot, 2011, Erek et al., 2011). Subsequently, planning covers developing the roadmap and direction for certain GIT initiatives and identifying a preferred GIT initiatives that are more significant based on the strategy and plan initially formulated in the earlier phase (Mann et al., 2009). In the implementation phase, organizations procure and establish appropriate IT assets and related systems to implement a specific GIT initiative (Park et al., 2012). More importantly, organizations implement a new IT infrastructure; introduce a new set of business processes and procedures, related policies and guidelines. Therefore, GIT adoption requires careful planning a selection of GIT initiatives complemented by appropriate IT investments and management activities.

2.2.4. Green IT Approaches and Strategies

With GIT approaches and strategies, the literature suggests how to achieve the benefits from GIT activities. For instance, Murusegan (2008) explains a comprehensive approach to GIT focused on four complementary directions including green design, green use, green manufacturing and green disposal. These categories cover area of importance and actions such as energy-efficient computing through virtualization, power management, and conservation; designs and approaches for environmental sustainability by energy-efficient data center design and location; disposal and recycling practices such as supplier-take back, 3R program and remarketing activities that are more sustainable, compliant and ecologically responsible to relevant regulatory requirements with gradual reduction of waste and pollution prevention. Prior studies also present design of GIT metrics, review, assessment and evaluation tools for effective adoption and practice. Also, Murusegan (2008) proposes Enterprise GIT strategies that organizations could follow including three-level approach: strategic, deep green, and incremental tactical approaches. The literature emphasizes that GIT can spread in several forms not only reduction of energy consumption, cost savings and efficiency. Furthermore, these studies are more directed towards eco-efficiency provided that benefits mostly come from energy efficiency and savings. Prior studies relate eco-effectiveness with green design and manufacturing highlighting lesser natural resource use and enhanced longer product lifespan. Also, eco-collaboration efforts are mainly focused on improved IT asset disposal practices, new green design outcomes and procedures and integration of green manufacturing standards. In general, GIT literature highlights eco-goals to determine better possibilities, advantages, and benefits derived from GIT.

2.3. Overview of the Philippine BPO Industry

The Philippines is an archipelago consisting of 7107 islands, and its location is in the Southeast Asia. Its population is estimated to be over 100 million, and it is the twelfth most populous country in the world (UNFPA, 2014). The Philippines has 82 provinces, and the capital is Quezon City-NCR. Regarding national culture, Philippines has a relatively high power distance index (94) low individualism index (32) and moderate masculinity index (64) and uncertainty avoidance index (44) (Hofstede, 1983). Therefore, Filipinos generally accept power inequality within the society, value collective actions, traditions, and norms; tend to avoid actions such as confrontations that lead to ambiguous consequences; and strive for harmony, the establishment of a caring society, and quality of life.

The Philippines has many natural resources, and its economic position has developed rapidly. The Philippines economy is ranked 13th in Asia-Pacific region based on GDP, and its BPO industry ranks 1st among top destinations in developing countries (IBPAP, 2015). Philippines has been an important BPO

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

destination in the world in many developing countries. In particular, foreign companies quietly seek to develop BPO presence in any country with large population base capable of speaking in English. Also, given years of continuous impressive and sustained economic growth in the Philippines during 2000, the BPO industry presented the tremendous potential for future growth in the eyes of foreign investors (Alexander and Myers, 1999).

Strong growth in the Philippine economy comes from robust information technology and business outsourcing sector. It has proven to be largest and fastest growing industry in the country. It plays an important role in providing quality jobs, encouraging economic activity and investments in various locations outside the country's capital city. In 2015, the BPO industry generated a revenue of 15.5 billion US dollars that comprised of 5.4 percent of the country's total GDP and it employed 900, 000 Filipinos in full-time (IBPAP, 2015).

The division of the current BPO industry into the information technology and business process innovation includes software development, digital technologies, financial and banking, tourism, health and medical, game development, and sustainability services. In the National Capital Region, there is more than competing for market share and in tight competition with new entrants in the BPO business. The first foreign BPO companies, however, continuous to dominate the NCR BPO market, which competition is much more intense (Usui, 2011; Magtibay-Ramos, 2008).

In the last five years, the BPO industry has been the fastest growing sector in the Philippines. During 2009-2013, the BPO market grew by as much as 19.8% per year, the highest among other industry (Gereffi, 2010). The BPO industry continued to have the largest share of other industries up until 2014, with up to 42.5% of the total market share. However, since 2010, the BPO industry has been a dominator in developing countries, which is the most profitable in the Philippine economy. The BPO industry is expected to grow continuously, projected to generate 1.3 million jobs by 2016, with 17 percent annual growth. The influence of the growing BPO business has driven technology adoption within the industry (IBPAP, 2015).

3. METHODOLOGY

This study utilizes a revelatory multi-case study approach (Dubé & Paré 2003, Yin, 2008) to explore GIT adoption by organizations within the Philippine BPO industry. Case study research enables researchers to conduct in-depth investigations of a phenomenon of interest over a period, which is currently lacking in the literature on GIT adoption by developing countries. This study is at the theory-building stage, contributing to the growth of knowledge associated with GIT adoption, mainly in the context of developing countries. The case study approach is considered an appropriate method for research building theory (Shanks & Arnott, 1993). In comparison to the single case study approach, the multiple case study approach is often considered more compelling and more robust, although it typically requires extensive resources and time beyond the means of a single researcher. Multiple case studies are preferred over single case studies, as analytical conclusions independently arising from multiple cases tend to be more powerful than those from single case studies alone (Yin, 2003). This argument serves as the main motivation behind the selection of a multiple case study as our research method. The use of multiple case study involving different types of organizations within the industry that have different BPO business activities is particularly valuable for the purpose of this study. There should be a development of

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

a more comprehensive understanding of the adoption experience, particularly concerning the enablers, practices, and processes.

Several foreign-owned companies, including information technology, business process management, and supply chain within the Philippine BPO industry, were selected for the multiple case study. Presented in Table 1 is a brief descriptor of the interviewees from the three cases. There were also several interviews conducted with primary participants concerned in GIT-related roles within the three cases. We employed semi-structures open-ended questions during the interviews and documented upon full consent and agreement of the participants. There were follow-up interviews performed after the initial interviews. Besides this, we collected additional organization's relevant digital documents.

Furthermore, we transcribed the interviews for multi-level approaches qualitative analysis such as open coding, axial coding, and selective coding techniques (Neuman, 2006). As defined, a unit of analysis is an individual, a group or unit, an organization, part of social life and a case under consideration (Neuman, 2006). It is essential to data collection and analysis, observation, empirical measurement, and concept development. This research utilizes three companies within the BPO sector as the unit of analysis that sufficiently provides breadth and depth of GIT adoption background which serves as the basis for answering the research questions adequately.

Addressing Rigor in this study follows the guidelines of Yin (2003) and Neuman (2006). Four techniques are used to ensure construct validity. It includes triangulation through the use of multiple sources of evidence, a thorough literature review on relevant areas related to the research topic, interviewee reviews of the case study reports. All these techniques ensure the accuracy of the transcription and translation and establish a chain of evidence through the use of case study repository, and the use of a case study protocol. Addressing external validity is through the utilization of the replication logic technique. The design of the multiple case study approach helps increase the generalizability of the overall study findings. Addressing internal validity is by a careful selection of cases and interviewees, sound data collection procedures, correct selection of theory and literature review that can explain the GIT adoption phenomenon. Internal validity is tested to ensure that the causal relationship identified in the study reflects the theoretical ground.

To address Reliability in this study is through the use of a case study protocol for all interviews, the use of case study repository to store all research data, and a pilot study to ensure interview questions are appropriate. The use of a pilot study is advised by Neuman (2006) as a method that can increase the reliability of measures. Two preliminary studies with BPO companies were conducted to assess the feasibility of investigating the research topic among some organizations within the Philippines BPO industry. The pilot study serves as a solid foundation for further follow-up interviews in the study and helps identify subsequent case study participants.

Table 1. Participants of multiple case study

Company	BPO Type	Annual Revenue	Designation(s)	Interview Period*
A	Information Technology	USD $30 Billion	IT Manager, IS Manager, Purchasing Manager, Facility Head	1,2,3
B	Business Process Management	USD $140 Million	IT Director, Assistant IT Manager, Purchasing Head, Facility Officer,	1, 3
C	IT Supply Chain	USD $34 Billion	IT Manager, IS Manager, Assistant Purchasing Head, Facility and Engineering Head	1, 2, 3

*Interview Period: 1(March 2014-July 2014), 2(August 2014-December 2014), 3(November 2014 – February 2015)

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

4. CASE STUDY BACKGROUND

Table 1 lists the participating companies and the interviewees involved in each case study. A short profile of each company is provided in Appendix C. In general; we involved large information technology – BPO, one business process management – BPO and one supply-chain - BPO. All of the companies are foreign owned from the very start of their operation in the Philippines. The three companies have distinct business activities within the BPO industry. Company A is focused on software development while Company B's business is mainly on business process management and Company C is the only IT supply chain that distributes products and services to its retail partners. All interviews were conducted between March 2014 and February 2015. Both Company A and C participants were interviewed in three periods to ensure that all necessary GIT information were covered. However, Company B participants were interviewed in two periods given that the first interview period already provided significant volume information of GIT adoption experience, thus, the second interview period was only dedicated to some follow up interviews and clarifications. In the end, all interviews conducted sufficiently helped in fully understanding GIT adoption experience of the three BPO companies.

In terms of GIT adoption, all organizations apply five areas of GIT including asset procurement, IT as low carbon enabler, working environment, asset disposal, and data center operations. Furthermore, one company has matured GIT in supply chain within the BPO business. However, only one organization has sufficiently matured to adopt in all GIT areas practice.

5. RESULTS

In this section, we describe the enablers, practices and processes in GIT adoption within BPO organizations. We also summarize the practices and processes from Table 3 of Appendix B. Discussed below are the enablers, practice, and the process.

5.1. Green IT Practices and Processes

All three cases are committed to environment protection and accountability. Through their corporate mission and business strategy, they were able to develop guidelines incorporating sustainability objectives and target, which GIT is an important implementation approach. Analysis of findings revealed that all three cases are pursuing innovations in environmental technology, product development and promoting business activities supporting the lead for a sustainable environment and economy to reduce environmental risks and continuously improve environmental performance in their respective areas of businesses. The focus areas are on reducing environmental impact in every phase of business or product life-cycle, environmental management by enhancing environmental management systems furthering strategic management and fostering environmental education and awareness of their employees, and proactive environmental conservation and by strong coordination and collaboration with social enterprise and community.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

5.1.1. IT Procurement and Management (ITPM)

The empirical findings revealed two important approaches to IT procurement including supplier and product approach. In supplier approach, a major consideration is verifying the supplier's compliances to environmental management standards and performance such as the EMS and commitment and actions towards reducing environmental footprint in the supply chain lifecycle. In product approach, it takes priority in the procurement of GIT products and services with strong adherence to the elimination of hazardous materials, energy-resource saving, and end-of-life management through 3R (reduce, reuse, recycle), which all these are conforming to environmental conservation. These approaches are introduced by all three cases as their basic framework in green procurement. Enforcement of these activities is significantly observed and monitored by a central purchasing unit, which plays a significant role in achieving the entire green purchasing objectives. More importantly, any green purchasing decisions are primarily targeted to satisfy increasing business needs and customers' expectations.

All of these are bind with strong top management commitment from all three cases to escalate continuous education, skills and knowledge relevant to the success or failure of the initiatives. Also, the findings of the study revealed that top management support is essential to progress in raising awareness and education among all stakeholders involved in the program. Collaboration and coordination with suppliers complements these activities, which well-defined roles have considerable effects in ensuring that they proactively engage themselves to voluntary measures that reduces resource use and save energy, banning of toxicity and hazardous materials, and decrease waste generation in the supply chain.

The findings revealed that communication of these activities to the public improves the corporate image in all three cases as well as recognizing them as good stewards of environment protection and preservation by the customers, business partners, regulatory agencies, and competitors. Its attribution is through the commitment of the three cases in environment management systems (EMS) implementation along with other internal practices and processes in IT purchasing.

The empirical findings revealed significant challenges experienced by the three cases in IT procurement such as supplier relationship management, a limited number of local suppliers adhering to environmental standards and lack of rewards and incentives systems to facilitate greater reduction of environmental impact from supply-chain. First, the suppliers are covered by supplier relationship management to observe levels of strategic performance while reducing total cost of ownership. However, risks exposures in the supply chain are not yet fully developed as a major success factor concerning GIT adoption. Second, limited suppliers in the country have full compliances to EMS because of the insufficient regulatory framework to govern the transition of vendors to a greener approach in supply-chain activities. Although the government recently signed an agreement to commit the country to the green supply chain, there was no publicly available guideline on how "green" criteria should be operational, monitored, assessed and evaluated in supply-chain activities. Lastly, rewards and incentives program to increase value creation further than conventional cost reduction objectives driven by sustainability and innovation through co-creation that encourages understanding and commitment in the entire GIT procurement.

5.1.2. Working Environment

In this study, another major theme that emerged from the analysis of empirical data is working environment. All three cases from this study have considerable efforts to increase energy efficiency by promoting energy-conscious working environment among all employees. The majority of the three cases have

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

introduced energy-efficient computing devices as practice in saving energy and conservation. Also, energy-management solutions are available to monitor consumption and compliance to resource saving practices by all employees. As observed, there is a considerable reduction of consumables through the 3R program, which builds a culture of maximizing the use of technology support tools such as software to minimize resource-intensive activities. There are also efforts to enhance office design by sectoral arrangement to reduce practically energy consumption and usage of LED lighting systems. Moreover, provisions to monitor working environment temperature through building management systems are made available for some BPOs.

However, there are challenges in improving the office design and setup to incorporate green office design standards such as natural lighting due to constraints in leasing the working environment with property and building owners. Leasing agreements were found to be unsupportive in improving office designs by all three cases that could be fully utilized to take advantage of reducing power consumption through the use of automatic sensor-based intelligent lighting systems. Additionally, there is the growing number of employees working in the BPOs that requires additional office space and IT equipment to be reconfigured to improve mobility among the three cases.

Another major challenge is in the area of measurement and improvement in work environment practices and processes. Although there are efforts to reduce considerably energy consumption through IT investments, raise awareness and education among all employees in these activities, no further analysis is conducted by a majority of the three cases to measure the effectiveness of the programs regarding environmental benefits, which could be attained by this continuous management strategy. While the energy efficiency of IT equipment is a major consideration, concrete monitoring processes and related rules are lacking.

More importantly, there was no objective evidence discussing and identifying areas of growth in increasing collaboration and involvement of property managers in effectively planning improvements in working environment by developing joint scorecards that include performance indicators in both parties that measure the quality of outcomes produced from these endeavours.

All of these practices and processes are part of the long-term investments of three cases in GIT adoption to enhance working environment, signifying major responsibility to top management to exercise their decision-making capabilities and authority to introduce the changes needed continuously. Furthermore, the IT investments made along with financial budget are helpful, therefore, increased the level of GIT adoption maturity in the area such as the working environment. More importantly, these considerable efforts are directly linked to GIT maturity expected to result in major cost reduction among them.

5.1.3. IT Applications as Low Carbon Enabler

Another major theme that emerged from the empirical findings is IT enabled work practices. All of the three cases significantly employs IT applications for work practices as low carbon enabler. Digitization of most business activities is highly observed together with optimized and designed web-based systems for an efficient transaction with stakeholders such as business partners, customers, and suppliers. Paperless transactions are the highly considerable effort to lessen the use of consumables and other expense in maintaining information and using them in succeeding business needs. More importantly, the empirical findings revealed strong top management support in investing in communication systems that improved collaboration and creation of shared value among stakeholders. A major finding is the high level of travel reduction by practicing web-conferencing and virtual meetings regularly, which minimize physical

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

travelling, costs, and environmental footprint. It complemented with home-based work programs that encourage employees with relatively good web-based technology support making them more productive and efficient in performing tasks at home with preferential and flexible schedules activated.

Additionally, the majority of the three cases raise awareness and education on resource-intensive business transactions, which contributes to their understanding and commitment to involving themselves in practices and processes that reduce environmental footprint. First, in-house training is made available supported by learning management systems, which allows employees to update constantly themselves on practical ways to apply GIT at their level of functional business tasks. Also, the formation of focus groups is observed to provide a venue to share, interact and solicit inputs on enhancing GIT adoption practices, evaluated later on in its winning ideas for possible implementation in the organizations. A major challenge raised by one of the cases is decentralization of their office locations to reduce travel expense along with its contribution to the environmental footprint. By establishing decentralized offices, employees will likely accept nearby job offers based on their proximity to the office locations. Although the three cases have become aware of risks involved in their business cases that could contribute to environmental footprint, few can implement adequate measures to allow their processes to further analysis of environmental impacts concerning all instances of activity with the main indicators of performance on reduced costs and increased environmental benefits.

Also, there is a lack of measurement in the individual contribution of employees to achieving GIT practices about IT aided work practices. It could be a good source of input to identify areas of development to strengthen related mechanisms and programs and establish a policy or guideline to advance IT aided work practices as low carbon enabler together sound management system and established policies. Furthermore, review of job roles within business processes could be explored to align them with GIT adoption targets and objectives.

5.1.4. IT End of Life Management (ITELM)

This work also discovered a major theme in GIT adoption by all three cases is IT asset disposal and management. It is an important area of practice by all three cases, which significantly contributed to reducing the environmental footprint of their business activities. A major finding is the available ITELM disposal guidelines that promote environmentally-friendly 3R program, disposal practice and remarketing initiatives. First, the 3R program implemented contributes to a close-loop end of life management approach, which ensures that no IT equipment is sent to landfill for disposal. It is supported by the strong observance of planning end of life management options at the beginning of the IT equipment purchasing process along with constant monitoring and maintaining optimum stock levels based on efficient asset replacement and inventory management practices. Moreover, take-back scheme enhances the effectiveness of the 3R program by committing suppliers to take full ownership and responsibility of end of life management in all IT equipment used within organizations. Second, reassignment and redeployment of computers to less critical business functions and roles are highly implemented to maximize return on investments including licensing, warranties and preventive maintenances services provided by suppliers. Next, the adoption of remarketing activities is in partnership with vendors and Treatment, Storage and Disposal (TSD) facilities to recover precious components through remanufacturing and recycling by third-party companies to gain additional business value. Lastly, few of the three cases encourage the donation of used IT equipment to social enterprises; however, the passing of ITELM management's responsibility to the recipients may not have formal experience in end of life management. It will result in

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

environmental risks once the IT equipment donations made have reached the end of life, a possibility of non-conformities in the responsible end of life management will happen at the recipient's liability. These efforts have considerable direct impacts to reducing the environmental footprint of the three cases. It is a result of a strong collaboration with suppliers, TSD facilities and social enterprises who committed to environmental protection and accountability related to ITELM management.

In measurement and improvements, the majority of three cases have conducted Life-Cycle Assessment to further analysis of costs and benefits of IT end of life management activities and its contribution to reducing environmental footprint. However, the three cases need to optimize the use of consumables to reduce wastes by introducing new processes and rules to govern acquisition and reuse of consumables. Despite the continuous awareness and education program conducted by the three cases in ITELM, full engagement of all employees on these activities are lacking as well as rewards and incentives system, which could encourage further participation in ITELM activities and boost their morale of the potential efforts related to reducing environmental footprint recommended.

Another challenge of the three cases is few e-waste or TSD facilities are supporting 3R programs in the country, which could potentially provide full-scale end of life management backed by environmental management systems and compliances to regulatory requirements found in prior studies critical in minimizing environmental footprint in end-of-life management. Moreover, few participants from the three cases conducted further review end of life management processes by suppliers and determine potential risks and challenges experienced by the TSD facilities. More importantly, the majority of the three cases mentioned the need for concrete training plans for ITELM. The cascading of these plans should not only be to the facilities unit but all employees, whose in-charge of the ITELM and end of life management. Although there are considerable efforts made by the three cases on ITELM, there is no regulatory framework available in the country to support their practices and processes, which could have stringent policies and guidelines on ITELM, offer disposal alternatives and remarketing programs and measurement of outcomes.

5.1.5. Data Center, Cloud Computing and Virtualization

The last theme that emerged from the empirical findings is the group of the data center, cloud, and virtualization. Analysis of empirical findings revealed that majority of the three cases are focused on continuous development in data center operations mainly on embedding energy-efficiency measures on server assets, support infrastructure, and physical equipment. Consolidation and rationalization of data center become two major approaches to reducing the number of data center along with virtualized servers in offering new IT services. In addition, procurement of energy-efficient data center equipment is highly observed; however, few participants mentioned that they have used real-time power and energy monitoring systems, and continuous effort should be made to evaluate constantly and optimize energy efficiency.

Although there are efforts in enhancing the design of data center energy-efficiency, there are challenges in improvement power supply equipment to minimize power losses in conversion to energy. More importantly, few BPOs have implemented real-time PUE and DCiE monitoring constantly the energy consumption used by the data center as well as carbon emissions produced. There also need to enhance intelligent refreshing and orchestration tools to manage effectively manage service control.

Additionally, participants revealed that they also experience issues and challenges in multi-vendor performance management to maintain with them various services level agreements based on the design of the data center improvements as well as the ensure the quality and reliability of services provided.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Furthermore, data security and privacy issues are brought by growing multi-platform IT services provided by the organizations to their client organizations. However, considerable efforts have implemented to manage accordingly critical assets, which have to be secured and protected by increasing risks involved in network and connective and the internet.

5.2. Enablers in Green IT Adoption

Based on the results and cross-case synthesis, it is not enough to explore on the practices and processes in GIT adoption. The cross-case analysis also suggests to present the enablers in GIT adoption of the three cases. The enablers include strategy and governance, process, structure, people, technology support and measurement and improvement. It centered on collaboration, partnership, and relationship and their corresponding discussions.

The first enabler of GIT adoption in BPOs is strategy and governance. It is setting of major direction, what to achieve in GIT adoption aligned to the organization's business strategy and long-term goals and objectives. More importantly, it is fully centered on shared value creation of GIT strategy in concert with business strategy. It is found a significant enabler for direction setting in the organizations that resulted in an increase performance and competitive advantage. The organizations clearly described shared value creation in GIT through the structured approach to value mapping to progress from strategy and governance. Significantly, value mapping encouraged the organizations to think beyond decreasing costs and facilitating means to embed value enablers and key drivers contributing to growth revenue, deployment of assets and risk reduction. By mapping shared value in GIT, it provided better communication among stakeholders and defining the corporate business goals as input to the GIT program. The aims and objectives in GIT were documented and signed off explicitly and shared within the organization, therefore, internally aligning always lead external alignment with stakeholders such as vendors and suppliers. Lastly, the business case was developed with finance and accounting to build confidence and credibility to defining the impact of GIT and regularly carry out benefits tracking. According to the Purchasing Manager of BPO (Company A):

We want to add value to the GIT ecosystem. We set GIT as corporate strategy for sustainable products and services with lesser environmental footprint and to assist them to maintain our client business needs.

IT Manager of BPO (Company C):

We came up with a clear GIT strategy and embedded it in the overall corporate strategy. I believe that is a biggest positive factor, the driver that we have achieved.

Second, the establishment of the process that the organizations played and how GIT's sustenance through a standard documented process. The GIT process' full integration, collaboration and partnership strategy jointly developed and managed by the organizations. The study confirmed from the analysis of data that majority of the organizations developed their processes tailored to GIT. It is supported by the strategy and governance direction to fully accelerate GIT adoption in organizations. Formalization of processes encouraged GIT language across partnerships and stakeholders that indicated the need to harmonize and formalize GIT adoption process including the use of appropriate tools and templates. As a result, GIT become more cost-efficient and effective as well as encouraged time collaborating, and

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

knowledge development and sharing. Also, organizations incorporated GIT into the working framework while facilitating integration with other processes is guaranteed. Thus, important processes and IT support systems are not missed. According to the IT Director of BPO (Company B):

In our early transitions to GIT, we have mapped our GIT targets to existing business activities; we defined core processes, standardized way in a process-oriented way to have a holistic view and then integrating them into line of business.

IS Manager of BPO (Company A):

We have streamlined our business processes in adherence to emerging global and standardized sustainable practices to achieve our key strategic goals.

Thirdly, structure refers as to how the organization structures GIT, its establishment, and centralization of roles and responsibilities of every unit to manage it. GIT leadership was significant in driving full support, participation and actions towards the attainment of GIT adoption goals and objectives. The organizations established a well-defined cross-functional team to facilitate better collaboration and partnership to encourage full participation and serve the interest of all relevant stakeholders, which also means that organizations owned the relationship and foster collaboration with external stakeholders to achieve GIT objectives. More importantly, top management promoted the significance of partnerships with the organizations while ensuring that support ensures GIT objectives are aligned, establish key priorities and lead informed decisions and actions. Lastly, the organizations developed a devoted governance structure for the GIT adoption program and partnerships similarly with existing functional units of the organization. It means there is a need to design fully the organizational chart to highlight the functional unit charter with its description of roles and responsibilities, the definition of goals and objectives, required competencies, communication plans and measurement, and improvement tasks of an organization. According to the IT Director of BPO (Company B):

It is important that you know the skills of your people. Our objective is a better implementation of GIT through our in-house initiative to build success through partnering with highly competent technology champions.

IT Manager of BPO (Company A):

If you observed at our GIT, the decisions primarily came from the central office. The head office is stressing overseas office of the value of GIT in their respective areas.

Fourthly, people refer to the unique competencies does the organizations needed to establish and manage to adopt GIT. The empirical findings revealed that people skills and competencies should be upgraded to provide deep GIT competencies through tailored GIT training. The organizations invested in people capability building, which required the design of GIT skills and competency model covering technical, relational and developmental competencies need to accelerate GIT adoption. Moreover, they also established a GIT training program covering diverse areas completely aligned with GIT competency model. Lastly, the organization observed excellent actions and pursued a co-creation approach, which

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

promoted better understanding and commitment to GIT supported by a directed GIT training program that built a culture of continuous innovation and change among employees. According to the IT Manager of BPO (Company A):

Green IT procurement was lead from the start by our sustainability manager, who has 25 years strong supply chain and logistics experience.

IT Director of BPO (Company B):

We have thought of people who can work on the requirements. We have talent resource that can execute project plans and measure areas of growth more often in certain areas such as requisition, data center, and cloud services.

Fifthly, technology support is an important enabler of GIT adoption in organizations. It refers to a set of support systems that the organizations deployed. The analysis of empirical evidence revealed that real-time communication of strategic, operational and tactical information was important in GIT adoption. The findings revealed that IT aided work processes as low carbon enabler improved transparency, efficiency and effectiveness in achieving GIT adoption target enhancing knowledge management, which highlights constraints and benefits of its continued utilization. More importantly, the organizations emphasized improving real-time monitoring of expense in GIT, compliance to contract and timely performance reporting, which guides informed decision-making activities to benefit from an IT support system. Lastly, organizations assessed accuracy, reliability and timeliness of data and information requirements critical to decision-making in conjunction with implementing open systems promoting collaboration with internal and external stakeholders. According to the IT Manager of BPO (Company C):

We continuously adopt the latest technologies suggested by our suppliers. We have upgraded our IT infrastructure and information systems to allow us to implement emerging GIT solutions.

IS Manager of BPO (Company C)L:

So I think without systems support, IT would be challenged to the management sustainability.

Lastly, measurement and improvement enabler is focused on how does organizations measure and improve partnership performance and identify and mitigate risks at key actions with suppliers. The organizations jointly developed with vendors the measurement of performance covering wide-range areas of GIT adoption. Also, the study suggests well-defined risks mitigation plan and relevant approach with all stakeholders. The organizations focused on using the value mapped to develop performance management scheme and indicators that measure the quality of outcomes from GIT and partnerships established. Scorecards using KPIs and KRAs jointly developed with stakeholders clearly build an understanding of the expected performance of all groups involved. Lastly, co-develop and initiate risk analysis approach in GIT with stakeholders embedding complete risk management approach fully integrated with strategic planning, control, and CQIs. According to the IT Manager of BPO (Company A):

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

The reason it worked well is because they really sustain the continuous improvement and make everyone accountable for that. We also apply our IT maturity models to assess and evaluate improvement opportunities as we continue GIT. It was part of our targets, was part of the company targets.

6. ANALYSIS AND DISCUSSION

This study revealed the GIT experience of the Philippines BPO industry through the empirical findings of the study. We have identified five major areas of GIT adoption including IT asset procurement, IT applications as low carbon enabler, working environment, data center, and IT end of life management. These major areas contribute to the goal of sustainability, specifically, reducing energy consumption, carbon footprint and resource conservation that leads to protecting the natural environment. First, IT procurement has seen important in ensuring that all products or services procured by the organizations from suppliers and vendors are environmentally compliant. These ensure that suppliers take full responsibility in verifying acceptable standards mandated by regulatory agencies and private organizations. It resulted in major compliance with the most number of IT equipment sourced out by the BPO organizations. More importantly, continuous monitoring of IT procurement activities is essential in achieving lower total cost of ownership, thus, translating it into savings and extended product lifespan and other related benefits. In the area of IT applications, the BPO organizations have migrated to digital business processes signifying productivity, efficiency and accuracy and reliability of outcomes. Also, telecommuting and work at home programs have helped in reducing the impacts of physically traveling. It resulted in a lower resource used and conservation, awareness in energy-savings, and low carbon enabled business activities. These outcomes contribute to increasing the potential benefits of GIT in both operational and maintenance activities. Next, the working environment of the organizations has been responsive to the need of GIT adoption. Although there are some challenges in leasing agreements of these organizations, they are still able to reconfigure office environments embedding some green office environment standards such as the use LED, smart and intelligent lighting systems and automation of temperature control. These practices contribute to resource conservation as well as reducing carbon footprint. More importantly, the case study participants have initiated a good number of practices and processes in improving data center through adopting to green data center design as well considering energy-efficient data center equipment and support systems to monitor efficiently energy consumptions and carbon emissions. Likewise, monitoring tools assisted the organizations to set a higher level of targets in term of energy consumption reduction and carbon emissions. Lastly, the IT end of life management has seen critical in ensuring that no IT waste are sent to landfills, which resulted in major success in 3R program along with remarketing activities. These activities are valuable in lessening IT waste disposal given its potential occupational, health and environmental risks within the organizations. It also allowed the organizations to promote awareness and education among end users to become more responsible for IT waste disposal processes and initiatives. Generally, the GIT practices and processes within the Philippines BPO organizations have been situated to continuously achieved long-term sustainable business and environmental protection, thus, contributing to the reduction of carbon footprint, resource conservation, and other related benefits.

We discovered salient enablers in any GIT adoption including structure, strategy, and governance, process, people, technology, measurement, and improvement. In this study, strategy and governance played a significant role as an enabler in formally establishing GIT within BPO organizations. It was

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

helpful in setting a direction to understand fully the benefits and needs of the adoption of GIT, thus, allowing for stakeholders participation complementing with top-down decisions aligned to objectives of making GIT as corporate strategy. Second, the established processes as an enabler in GIT-assisted in realizing the strategy and governance at an operational and management level. Through formalization of processes, the organizations have device appropriate measures and tools to monitor all process implementations quickly. Next, the structure as enabler assisted the organizations to identify the roles and responsibilities and also allowed them to create a central unit to manage GIT adoption activities, therefore, providing support for other functional business units on how to proceed with GIT. It has resulted in improved cross-functional activities aiming at involving all stakeholders as key implementers of GIT in various units. Also, the structure as an enabler situated the organization to take advantage of the available human resource to develop their skills and competencies in several GIT areas. Hence, it helps the BPO organizations to raise awareness and education on several implications of GIT as they continue to grow their competencies within the GIT ecosystem adopted within organizations. More importantly, people as an enabler played an important role in co-development of GIT programs, training, and other work initiatives. Likewise, technology support significantly assisted the organization in promoting GIT at various levels of operations and management. It provides the architecture to adopt efficiently the strategy and governance approach as well as execute the well-defined GIT processes to ensure that these goals and objectives are continuously achieved by the organizations. Lastly, measurement and improvement as an enabler for GIT adoption promotes continuous quality improvement resulting in cost efficient IT infrastructure, increasing business outcomes and long-term commitment to GIT implementations. Therefore, these enablers played an important role in the case study participants' organizations to facilitate better roles and responsibility in developing an appropriate GIT ecosystem within the Philippines BPO industry.

The practices, processes and enablers in GIT adoption address the need to develop organizational capabilities to become economically, ecologically, and socially sustainable. More importantly, the BPO organizations strive to provide GIT solutions for sustainability to their clients. Thus, ecological and social sustainability should be observed from responsibility and also from an economic viewpoint. Likewise, these initiatives and efforts are urged by internal needs and guided by ethical motivations; there is also need to become internally sustainable to be recognized as credible contributors of sustainable solutions.

7. RECOMMENDATIONS FOR GREEN IT PRACTICE

This section details the recommendations for three cases to enhance GIT adoption based on the empirical evidence including IT asset procurement, working environment, IT applications as low carbon enabler, data center operations and IT end of life management. It guides the organization to further areas needing improvement by implementing a strategy and key tasks.

7.1. IT Procurement and Management

In this study, IT asset procurement is a major practice in the three cases. Essentially, ITPM required supplier relationship management to enable business performance and leadership with consistent value orientation driven by proactive innovation and sustainability metrics. The organizations should critically

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

assess suppliers and vendors capability to deliver more environmentally friendly options in products and services, requiring them to be evaluated on their environmental management systems commitment and compliances to relevant government regulations. Also, they should highlight responsible resource management at an optimum level by fully integrating asset and inventory management, serving the needs of both customers and internal stakeholders of the organizations. Also, companies may introduce enhancements in purchasing logistics to the suppliers via route optimization and tracking tools. Lastly, strong collaboration should take place between suppliers and the organizations to carefully assess and measure environmental impacts, benefits, and risks involved in IT procurement and management.

7.2. Working Environment

Although the three cases have considerable efforts in improving the working environment, the study recommends enhancing collaboration with building and property owners to allow provisions in energy-centered office design. Establish a formal structure to improve participation in virtualization or home-based work program with decentralized office locations or environment to newly developed green buildings and offices extending better office design, setup and collaborative working to increase efficiency and productivity. Significantly decrease consumables by purchasing and using more environmentally friendly products that can be reused or recycled after usage. Moreover, improve wireless connectivity by reducing networks and switches used in different locations. Lastly, foster better GIT education programs to develop awareness and understanding of GIT benefits to increase commitment and participation among the employees building higher positive attitude, communication, and atmosphere fully.

7.3. IT Applications as Low Carbon Enabler

The three cases should continuously increase value in using digitization and paperless business processes as main support to business process management centered on their green management strategy. Also, review of GIT governance structure to reflect major roles and responsibilities of each employee in the organization, setting up targets and performance indicators aligned with GIT strategy and business objectives. More importantly, provide means to enhance collaborative remote support using web-conferencing tools and work support systems to increase cost-efficiency and productivity. It is also important to establish optimization plans at the beginning of every new IT services to be launched to lessen resource use such as power and consumables. Finally, the organizations should develop processes for environmental impact and benefits recording and reporting aligned with value driven GIT strategy.

7.4. Data Center

The organizations should focus on enhancing server and storage virtualization to optimized its infrastructure increasing energy-efficiency while real-time infrastructure monitoring and reporting. Also, they should completely deploy backup integration tools in servers and storage installed. It also recommended to constantly conducting measurement and management systems in a decentralized approach to monitor environmental footprint and impacts of data center operation. Also, renewable or alternate source energy to balance power consumption jointly with optimized building energy management systems and transition to LEED certified green data center and buildings, which considered more environmentally

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

friendly and allowed various reconfigurations of building space to take place. Furthermore, automate heating and cooling management systems to improve the efficiency of the data center equipment. Lastly, consider benchmarking from international standards developed by independent and government agencies that promote best practices in data center operations.

7.5. IT End of Life Management

Lastly, ITELM is part of the growing e-waste globally proved by prior empirical evidence. It is considered as an important GIT practice within the three cases which contribute to the environmental footprint. However, measures should be in place to maximize the value of IT equipment and lessen waste disposal. Organizations should focus on enhancing 3R guidelines and policies incorporating clear procedures on resource reuse and recycling at an individual level for employees. It will contribute to developing awareness and education on risks involved in ITELM. Analysis of the findings also suggests the establishment of suitable rewards and incentive to encourage of winning mindset ideas reducing negative environmental impact. Cross-functionally integrates IT asset procurement with IT asset disposal to facilitate better reporting and decision-making concerning performance in ITELM and diagnosing risks of any unsolicited actions, thereby, contributing to the achievement of 3R program. Finally, the continuous building of network suppliers with environmentally compliant 3R program jointly with accredited local TSD facilities by the government, needing careful evaluation.

8. CONCLUSION, CONTRIBUTION, AND FUTURE WORK

This study is based on a revelatory case of GIT experience within the Philippines BPO industry. We describe the GIT adoption enablers, practices and processes within the organizations providing implications for both academe and professional practice. First, we describe major areas in GIT adoption from the empirical findings including IT asset procurement, IT applications as low carbon enabler, working environment, IT end of life management and data center operations. The GIT adoption practices and processes clearly indicate the commitment of case study participants towards sustainability through GIT. Second, we also explain some challenges of the organizations in adopting GIT including technical, operational, awareness and education, and management. Based on the empirical findings, structure, strategy and governance, people, technology, and measurement and improvement are significant enablers in GIT adoption in organizations. These enablers contribute to speedily accepting GIT in organizations, thus, allowing them to design appropriate measures to initiate GIT technologies that are more appropriate to the needs of the BPO industry. However, GIT adoption in the Philippines BPO industry is still at an early stage; it signifies the necessity of policy framework as regulatory support and guide in implementing GIT within organizations.

The result of our work presents essential insights about the state of adoption of GIT in the Philippines BPO industry. It is valuable to identify which GIT areas are appropriate and presently in use and how the GIT vision of being implemented realized differently by organizations in the Philippines, as a good case of a developing country. This new understanding is also useful for locally owned Philippine BPO companies within the sector should they aspire to remain updated with most recent GIT technologies, initiatives, and practices to keep competitiveness with foreign-owned organizations considering the growing BPO industry in the country.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Despite the contribution of our study, it is not free from limitations. First, we only consider organizations within the Philippines BPO industry. Other industries with different characteristics (e.g., power distribution in the semiconductor) may have different experiences with GIT adoption. Second, we do not explore the role of industry associations and standard bodies in assisting organizations in adopting various GIT and resultant benefits. By including such third parties, a more comprehensive understanding of GIT adoption could be developed. Furthermore, from the interviews with the participating organizations, we discover that the industry associations and standard bodies are currently playing an active role. It would be useful for future studies to investigate how the roles of such bodies change over time and the impacts of this change on the GIT adoption process within the industry. Finally, as our study is based on a multiple case study involving three organizations within the Philippines BPO industry, the findings should be interpreted carefully within the relevant contexts. This study compromises statistical generalization to obtain a more detailed understanding of the adoption experience of the participating organizations. Significantly, the case study participants have successfully implemented programs to sustain skills and knowledge of human resources associated with the adoption of GIT.

APPENDIX A

Table 2. A detailed summary of Green IT adoption studies undertaken in developed and developing countries

Country	Literature Sources	Green IT Type/Area	Industry Type	Research Approach	Data Analysis	Theoretical Frameworks	Significant Factors
Australia	Molla, 2009	Sourcing, operations, end of life management	Across industries including IT companies, health, wholesale sector, utility, transport, construction, manufacturing, finance and insurance	Survey(n=109)	Principal component and cluster analysis	Institutional theory	Cost reduction consideration, cost of Green IT, strategic target definition, social responsibility, mimetic pressures, normative pressures, regulatory support
Australia	Molla & Abareshi, 2011	Energy-efficiency of IT infrastructure and pollution	Across industries and government organization	Survery(n=176)	Exploratory factory analysis, confirmatory factor analysis	Organizational motivation theory	Cost reduction consideration, eco-effectiveness motive, coercive pressures
Australia	Karanasios et al., 2010	Green data center	University, data center provider	Qualitative case study	Qualitative data analysis	Institutional theory, motivational theory, performance-expectancy theory	Performance and effort expectancy, organizational capability, motivation, normative pressures, coercive pressures
Australia	Nedbal et al., 2011	Sustainable is-outsourcing, B2B	Small-medium enterprise	Qualitative case study	Qualitative data analysis	Technology-organization-environment, diffusion of innovation, transaction cost theory	Compatibility, complexity, top management commitment and support, firm size, transaction costs, coercive pressures, regulatory support
Australia	Sarkar & Young, 2009	Carbon emissions, green IT Infrastructure and governance	University, information technology services and telecommunications	Qualitative case study	Qualitative data analysis	Theory of reasoned action	Managerial attitudes, normative pressures
Australia	Cooper & Molla, 2012	Green IT capability (G-readiness) including, Green IT policy and governance, green IT practice and technology	Green IT vendors (consulting, technology provider, educator), legal firm, small-medium enterprises, university	Qualitative case study	Qualitative data analysis	Theory of absorptive capacity	Organizational learning
Australia	Ijab et al., 2012	Eco-sustainability practices, green IS	Telecommunications	Qualitative case study	Qualitative data analysis	Institutional theory	Mimetic pressures, normative pressures
Australia, Thailand	Aoun et al., 2011	Collaborative technologies for eco-mobilisation	Environmental non-governmental organisations	Qualitative case study	Qualitative data analysis	Actor network theory	No specific factors
China	Tan et al., 2011	Green Leadership, IP-based network, Intelligent ventilation and heat transfer systems, green packaging	Telecommunications provider	Qualitative case study	Qualitative data analysis	Organizational theory	Commitment trust, dependence, transaction cost economics, relational norms
China	Cai, Chen & Bose, 2013	IT for energy and environmental sustainability	Across industries including IT and non IT firms	Survey(n=70)	Smart partial least square analysis	Porter's concept of competitive advantage; diffusion of innovation theory	Public concerns, regulatory forces, cost reduction, differentiation, perceived complexity
Cross-Country (Europe)	Thomas et al., 2015	IT-enabled process virtualization capabilities	Across industries	Survey(251)	Partial list squares, correlation	Technology-organization-environment framework, process virtualization theory, and diffusion of innovation theory	Competition intensity and regulatory support, sensory readiness, relationship readiness, synchronism readiness, and identification and control readiness
Germany	Schmidt & Kolbe, 2011	Green IT governance	Transportation, computer software, financial services, newspaper media, pharmaceuticals and chemicals	Qualitative case study	Qualitative data analysis	Contingency theory	Competitive strategy, firm size, organization structure, performance strategy, environmental impact of industry, environmental strategy, IT infusion, observed green IT governance

Table 2. Continued

Country	Literature Sources	Green IT Type/Area	Industry Type	Research Approach	Data Analysis	Theoretical Frameworks	Significant Factors
Germany	Loock et al., 2013	Energy-efficiency and conservation	Private households – electricity consumers	Survey(1791)	Anova	Extended model of goal-directed behavior	Goal setting
Germany	Schmidt et al., 2010	Enterprise green IT, corporate social responsibility	Across industries under german stocks indexes	Survey (116)	Regression analysis	no specific theory	Technological uncertainty, perceived importance of green IT
Hong Kong	Zhang, 2012	IT enabled environmentally friendly consumption	Fishing	Qualitative case study	Qualitative data analysis	Theory of planned behavior	Attitude, subjective norm, perceived behavioral control
Hong Kong	Chow & Chen, 2009	Green IT	University	Survey(n=267)	Regression analysis	Theory of reasoned action and theory of planned behavior	Attitude toward green computing, subjective norm, perceived behavioral control, intention to green computing, actual behavior
India	Datta et al., 2010	Sustainable IT services value chain	IT service providers	Qualitative case study	Qualitative data analysis	Inter-organizational knowledge transfer view, resource dependency theory	Supplier education
India	Mithas et al.,2010	IT equipment energy consumption, energy-efficiency, profits in green IT	Across industries in india	Survey (293)	Descriptive analysis	Belief-action-outcome theory	Perceived importance of green IT, top management commitment and support
Malaysia	Gholami et al. (2013)	Green IS	Manufacturing, services	Survey(n=405)	Partial least square based structural equation modelling	Belief action outcome framework, institutional l theory	Coercive pressure, mimetic pressure, attitude, consideration of future consequences
North America	Corbett, 2012	Utilities smart grid	Utilities, system operator, industry association, software vendor and consulting	Qualitative field study	Qualitative data analysis	Institutional theory	Technological uncertainty, mimetic pressures
Spain	Benitez-Amado & Walczuch, 2012	IT enabled capabilities	Across industries including banking and insurance, electronics, IT, telecommunications, food and beverages, chemicals and pharmaceuticals, consulting and outsourcing, aerospace, apparel, construction and hotels	Survey (n=63)	Structural equation modelling, path analysis	No specific theory	IT capability, corporate environment strategy, firm performance
South Korea	Jung et al., 2011	Green IT management performance, use of IS and IT resources	Small-medium enterprises	Survey (n=178)	Confirmatory factor analysis	Resource based theory	Information technology resource, top management commitment and support, coercive pressures
South Korea	Ryoo et al., 2011	Green manufacturing, marketing, green IT/IS, green supply Chain	Manufacturing	Survey (n=47)	Partial least square analysis	Ecological theory, complementarity theory	Coordination
South Korea	Wati & Koo, 2010	IT environmental concerns, environmental management systems, energy-efficiency, emission and reduction actions, green disposal, alternative energy	Telecommunications, information technology	Content Analysis	Chi-square analysis	No specific theory	Awareness of environmental problems, coercive pressures
South Korea	Koo et al., 2013a	Green IT energy-efficiency	Manufacturers	Survey(n=104)	Partial list squares, regression analysis	Reference group theory	Social influence, media influence, perceived enjoyment, environmental problem, saving money, legislative pressure, perceived usefulness, sustainable use

Table 2. Continued

Country	Literature Sources	Green IT Type/Area	Industry Type	Research Approach	Data Analysis	Theoretical Frameworks	Significant Factors
Sweden	Bengtsson & Agerfalk, 2011	Sustainable logistics, ordering and work practices	Municipal agency	Canonical action research – Survey	Qualitative data analysis	Actor network theory	Innovation system, market place, regulatory regime
United States	Seidel et al., 2010	Sustainability program (data center, working environment, IT procurement, IT waste disposal, IT applications as low carbon enabler)	IT software solution	Qualitative case study	Qualitative data analysis	No specific theory	Strategy definition, organizational support, motivation, traceability
United Kingdom	Kuo & Dick, 2010	Virtualization, data center consolidation, electronic waste, collaboration technologies, telecommuting, use of reduction of paper use through electronic systems and printer configurations	Across industries	Survey (n=43)	Regression analysis	No specific theory	Technological constraints, cost reduction consideration, organizational capabilities, social responsibility, top management commitment and support, normative pressures, coercive pressures
United States of America	Sayeed & Gill, 2008	Data center consolidation, virtualization, energy-efficiency, IT waste disposal, green procurement, IT application as low carbon enabler	Software and equipment manufacturers, utility company, co-location/ hosting company	Qualitative case study	Inductive analysis	No specific theory	Cost reduction consideration, IT governance, social responsibility, top management commitment and support
United States of America	Sayeed & Gill, 2009	Data center consolidation, virtualization, energy-efficiency, IT waste disposal, green procurement, IT application as low carbon enabler	Software and equipment manufacturers, utility company, co-location/ hosting company	Qualitative case study	Inductive analysis	No specific theory	Strategic target definition, coercive pressures
United Kingdom	Butler & Hackney, 2012	Energy-efficiency, greenhouse gas	Government organization	Qualitative case study	Qualitative data analysis	Institutional theory	Mimetic pressures, coercive pressures, normative pressures
United States of America	Chen et al., 2009	Green IT/IS, product stewardship	Across industries including manufacturing and service industries	Survey (n=75)	Partial least squares, confirmatory factor analysis	Natural-resource-based view, institutional theory	Mimetic pressures, coercive pressures
United States of America	Butler, 2011	Compliance to Product (C2P)	IT manufacturers	Qualitative case study	Qualitative data analysis	Institutional theory	Coercive pressures, mimetic pressures
United States of America	Deng & Ji, 2015	Sustainability	Information technology company	Qualitative	Content analysis	Diffusion of innovation theory, institutional theory, organizational culture theory, resource-based view, natural-resource-based view	Relative advantage, technological complexity, compatibility, top management support, greening organizational culture, strategic intent, mimetic pressures, coercive pressures, normative pressures

APPENDIX B

Table 3. Summary of Green IT adoption practices and processes in BPO organizations

Area	Practices and Processes	BPO A	BPO B	BPO C
IT Procurement	Guidelines and Objectives	Sustainable purchasing program	Green purchasing program	Smart sustainability program
	Assessing Supplier Capacity, Costs and Benefits	Supplier and product approaches to sustainable purchasing.	Leasing Model with major consideration in reducing total cost of ownership	Supplier and product approaches to sustainable purchasing.
	Introducing Environmental Standards in Procurement	Products or service compliant to environmental standards	Eco-labelling and certifications with lower carbon emissions, Suppliers commitment environmental management systems	Highest environmental benefits and lowest supply chain footprint
	Skills and Competencies	Supply chain expertise is available	Experienced SP staff and decentralized training and special roles	Centralized purchasing with skilled staff and improvements by focus-group.
	Awareness and Education	Collaborative learning with suppliers and internal stakeholders	Continues education of supply chain staff is majority priority.	Capitalize son experienced supply chain staff and in-house capacity trainings.
	Challenges and Opportunities	Compliances to contract and procurement standards and risks exposure to supply chain processes	Limited local suppliers conforming to environmental standards	Rewards and incentive programs
	Technology Support	Availability of end to end procurement and logistics systems	Availability end-to-end web based purchasing system	Availability end-to-end web based purchasing system
	Assessment, Monitoring and Evaluation	Quantitative process improvement goal and CQIs using LCA approach.	Electronic Product Assessment Tool (EPEAT), Supplier-Driven performance evaluation,	Supply performance management systems.
Working Environment	Guidelines and Objectives	Energy-conscious workplace, Occupational Health Safety Administration (OHSA)	Good housekeeping in workplace environment with energy-consciousness.	Limited guidelines on greening work environment, uses traditional office acceptable use policy
	Energy-Efficient Computing Devices	80% energy-efficient desktops, 20% laptops, Thin-client solutions, Central power management system	80% energy-efficient laptops for FBU, Use of intelligent energy and power management software, Hardware based power saving features, Consistent preventive maintenance, Restrictions in PC setup configurations, PC monitoring systems to monitor compliance of users	Use of power management features with energy-efficient desktop and laptop computers, Use of screen mirroring systems to monitor compliance, Considerable use of energy-efficient UPS to manage electrical faults and losses
	Consumables, Printers and Support Software	Use of multifunction devices, Remanufactured and recycle consumables, toner saving solutions, print management software to control printing of unnecessary documents	85% multifunction printing devices 15 single function, Use of service printers through leasing model, Use of print management service to control printing	Limited printing devices, highly discourage printing “think before you print”, No print management used, Minimize use of consumables
	Office Design, Setup and Lighting Systems	Use of LED lighting systems for energy-efficiency and savings.	Sectoral arrangement for small group lighting zones, Use of efficient lighting systems	Energy-efficient lighting systems provided by building owners but no adaptive sensor based lighting, Provisions to monitor temperature using building management systems, Provisions for natural light in some areas

Table 3. Continued

Area	Practices and Processes	BPO A	BPO B	BPO C
Working Environment	Awareness and Education	Power shut off during non-working hours and weekends, Communication of utility expense, consumptions and savings, Eco-Warriors to act as champions in energy-efficiency program, Partners education program	Communication of environmental benefits and practices in working environment, Trainings on EMS, Facilitate idea generation through suggestion scheme	Lack of communication plan to better understand green working environment
	Challenges and Opportunities	Full implementation of intelligent lighting systems, Constraints in physical space set due to leasing agreements, Incorporation of green office and building standards in office design and setup, Use of alternative source of energy	Constraints in physical space set due to leasing agreements, Continuous environmental education for new hires not familiar with energy-saving practices, No communication plan on IT asset power consumption reports, No rewards and incentive systems in place, Incorporation of green job roles and responsibilities in HR	Increasing number of employees in functional areas became a challenge in monitoring compliances, Use of automation tools for real-time monitoring of EES, Updating of network equipment and inventory, Fully engage new hires provided with training plans, Attitude and resistance to green work practices, Full participation of all employees in EMS education, Limited control over temperature and heating systems due to leasing agreements
	Technology Support	Use of HVAC with real-time monitoring systems.	Use of HVAC systems to heat and cool only when necessary	Use of responsibility matrix to ensure full ownership and responsibility in IT asset use and other work environment goals
	Assessment, Monitoring and Evaluation	45% reduction of carbon footprint in work place environment, Use of separate utility for IT power usage, Use of green workplace score card, Strong collaboration with implementing agencies and stakeholders	No-energy audits and limited energy-saving outcomes tracking; No evidence of historical compliance, No further analysis conducted of practices; Challenge to develop an inventory model for EEC plans. Property managers were not fully engaged in planning EEC activities.	Use of automation tools for real time monitoring of EECS, Monitoring reports were underutilized-no further analysis to measure effectiveness of the programs, Lacks work environment and energy audits and reporting plans
IT Applications as Low Carbon Enabler	Guidelines and Objectives	Digitization of all work and business practices	Digitization is major priority in all business activities.	Digitization with employee-focused office at home program.
	IT Applications/Software as Low Carbon Enabler	Majority of business activities are supported by IT applications and other digital technologies to minimize resource use	Paper-less business activities supported by IT applications and related tools, Use of collaboration tools to easily manage business docs and increase interaction among stakeholders, dedicated software for special business functions, Paper-less transaction processing	Resource conservation through IT applications
	Communication Support, Travel Reduction and Telecommuting	Unified communication systems to provide efficiency and reduce travel requirements, Implementation of virtual meetings and web-conferences, Provisions for telecommuting – home based work programs	Compressed work week (10 hrs a day instead of 8 hours, alternate Friday vacation), Work at home through in-house developed CloudSource platform	Provisions for telework to reduce travel need and expenses, Use of self-service kiosks in HR processing
	Leadership, Awareness and Education	Consistent delivery of green IT education among employees and new entrants/hires, Regular communication of updates on practical tips on green IT through LMS and email, Online forum on green IT to allow sharing and collaboration, Formation of small groups to act as "eco-warriors" to handle environmental activities, Presentation of winning green IT ideas in learning forums and meetings.	Regular communication of organization's environmental compliances, Use of LMS to discuss resource intensive business activities	Use of knowledge management system (KMS) to cascade updates on green IT and related services. Strategic alignment of employees training towards full understanding of green IT at various levels.

Table 3. Continued

Area	Practices and Processes	BPO A	BPO B	BPO C
IT Applications as Low Carbon Enabler	Challenges and Opportunities	Lack of detailed discussion on individual contributions to green IT work practices; Lack of quantitative analysis on the extent of engagement of employees in green IT work practices.	Started individual training plans for employees to cover various green IT skills and competencies, however, Lack of explicit discussion on how employees' initiatives must be supported; New hires need further green IT education to reduce negative attitude towards green IT; No rewards and incentives program to increase individual energy-saving initiative; Improving security and IT governance.	Decentralization of office locations to improves proximity and accessibility of resource for employees.
	Technology Support	Ready and updated IT infrastructure and life-cycle to support business activities, Technological expertise is available in all technology support and integration programs.	Partial dependence to suppliers/ vendors tools, established IT unit for in-house custom applications.	Strong dependence of the organization suppliers/vendors technologies, Optimization of IT services
	Assessment, Monitoring and Evaluation	Regular conduct of environmental impact analysis to monitor costs and benefits of business activities, recognition of employees as "value-creators" for outstanding contribution aligned to green IT	Lesser work flows performed manually and standardized business practices.	Continues quantitative business process improvements, Review of job roles to align IT in green IT goals and objectives.
IT End of Life Management	Guidelines and Objectives	3R (Reduce, Reuse, Recycle)	IT asset replacement program with suppliers by means of leasing model	3R (Reduce, Reuse, Recycle), Supplier take-back program
	Disposal Practice	3R program is major priority to reduce IT asset disposal with supplier take-back program.	Supplier take-back program and disposal through TSD facility are major priority.	3R program is a major priority to reduce IT asset disposal
	Reduce, Reuse, Recycle (3R Program), Donation, Remarketing, Trade-Ins	Optimal stock levels are maintained, Reassignment or redeployment of existing computers to other business units, Donation of computers to social enterprise, Reuse of consumables is 95%.	Remarketing of used component parts through TSD facility, Reassignment or redeployment of existing computers to other business units	Reassignment or redeployment of existing computers to less critical job roles, Donation of computers to social enterprises
	Raising Awareness and Education	Encourage employees to attend to environmental programs, 5S checklist - Japanese culture of housekeeping, 3R education program	Safety guidelines in 3R program, No formal training in ITELM activities, Small groups called as Employees Conserving Our Earth (ECOE) Squad – to encourage participation in environmental programs	EMS awareness trainings, Continuous in-house training and education in 3R program.
	Challenges and Opportunities	No rewards and incentive program, Logistics of disposal to lessen risks, which will emit carbon and other gasses, Few certified fully integrated e-waste management company, No regulatory framework is dedicated for e-waste management in the country	Increase financial value from ITELM, Insufficient training plans for 3R program.	No clear direction from the managers as to how other stakeholders should be fully involved in the 3R program including property owners and building managers.
	Technology Support	Use of asset replacement and inventory management software for monitoring of IT asset	Readily available inventory management software for IT asset monitoring and movement	Recycling manager application provided by Cloud Blue
	Assessment, Monitoring and Evaluation	Life-Cycle Assessment (LCA) – Waste Reduction Model (WARM), ROI, Audit activities conducted by PEZA	No further analysis conducted to verify reduction of carbon foot print as a result of ITELM activities, TSD is subjected to accreditation and regulatory compliances and no performance management scheme	Life-Cycle Assessment (LCA) to assess full product life-cycle

continued on following page

Table 3. Continued

Area	Practices and Processes	BPO A	BPO B	BPO C
Data Centers Consolidation, Virtualization and Cloud Computing	Guidelines and Objectives	Energy-efficiency in data center equipment and operations	Energy-efficiency in data center equipment and operations	Greening data center guidelines
	Consolidation and Rationalization, Virtualization and Cloud Technologies	Intelligent refreshing, Single-storage network for efficiency in data collection, real-time monitoring of data center equipment power usage, temperature and moist control automation	Virtualized servers and cloud based systems for new IT services	Consolidation and rationalization programs to reduce data centers, equipment and carbon footprint
	Skills, Competencies, and Education	Availability of data center operation expertise, Supplier–driven trainings and special IT certifications are available for employees	Data center expertise are sourced out from IT vendors, Industry-Driven trainings and certifications provided	Availability of financial funding for continuous development of data center experts, Supplier-driven skills and knowledge are passed to in house IT data center experts, Strong pool of expertise in virtualization and cloud based technologies
	Challenges and Opportunities	Multi-vendor management in maintaining different Service Level Agreements (SLA) resulting in poor reliability, performance and scalability	Infrastructure complexity driven by SLAs in connectivity, storage and software, Quality of services by IT vendors and technology integration	Data security and privacy, Systems monitoring and performance
	Technology Support	Energy-efficiency in design and operation is a major priority in power and data center equipment	Efficient temperature and humidity, and power equipment, enhancement of air flow management, Use UPS and HVAC systems	Full dependence with supplier and vendor technologies in data center, Energy-efficiency in IT data center equipment, Cost and savings are major priority in updating data center facility
	Assessment, Monitoring and Evaluation	Real-time PUE and DCiE are used to monitor energy savings and carbon footprint, Life-Cycle Assessment for full product-life cycle management	Monitoring of data center energy use and consumptions, Business continuity is a major priority, Provisions for ISMS for security management, No further analysis on environmental impacts of data center operations	Life-Cycle Assessment, Leadership in Energy and Environmental Design to monitor energy-consumption and reduce carbon footprint.

APPENDIX C

C.1. Company A

Company A is well-known information technology and business processing outsourcing firm. It is a multi-national company that has established its presence in the Philippines since 1992. It has approximately 40,000 employees and five delivery centers in the National Capital Region with annual sales of USD 30 billion. It has more than 25, 000 people in its IT services department who are primarily responsible for software development, project support and maintenance activities. It serves two types of customers, local and foreign customers. Foreign customers are typically Fortune Global 100 that are mainly served to provide information technology, consulting, digital, and sustainability, while local customers are typically large companies across sectors and government agencies.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

C.2. Company B

Company B is one of the largest business processing outsourcing companies in the Philippines. It has been providing more than 20, 000 BPO jobs since 2003. Overall, 90% of its business comes from the foreign market, serving Fortune 50 clients. It has two major business activities such as business process management and technology catering to banking and financial, mortgage, government, healthcare, insurance, retail, technology, communications, travel and transportation. The revenues were USD 140 million in 2014. Of the 20,000 people, there are approximately 150 people in the IT department.

C.3. Company C

Company C is large IT supply chain expert of the leading global technology brands in the world. Since its establishment in 2009, it has approximately employed 18, 000 people proving supply chain services, retail, and support services. It represents approximately 1400 suppliers providing support from approximately 21, 000 associates worldwide. It has a significant presence in the Asia-Pacific region. It has been serving approximately 45, 000 customers and a total of 200, 000 in 170 countries. The IT department has around 75 people working on various software developments, sustainability and shared services.

APPENDIX D

Interviews Areas and Questions

In this work, we covered three areas for interviews from each case study. The interview areas (see Table 4) establish understanding and allow more systematical data collection and generate information constituting the enablers, practices and processes views.

To keep the focus on the right direction for data gathering, a set of five levels of questions were developed. These questions are exclusively for the goal of guiding the researchers and giving organization to the interview sessions and not to be given to the participants. In essence, the main goal of the protocol questions is to facilitate the interviewers in gathering data concerning Green IT adoption in the BPO area by presenting five levels of questions in each case study. Using these key questions as a rough structure, we allowed in the interviews for further follow-up inquiries in order to gain a deeper understanding of the subject matter or to clarify an individual response. These have been summarised in Table 5.

Table 4. Interview areas

Interview Areas	Description
General Background	General information on each organization, taking into account the size of the organization, hierarchy, nature of organization etc.
Technical Information	To gather information on Green IT and relating issues, to identify Green IT adoption solutions, to explore the enablers for Green IT adoption
Business Information	To identify practices and process, phases concerned and examine how Green IT adoption can be useful for the BPO organizations.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 5. Questions

Question No.	Questions
1	What are the enablers applied by case organization that influences decision-making regarding Green IT adoption?
2	What are the enablers associated with Green IT adoption?
3	What are the practices and processes associated with Green IT adoption?
4	What are the benefits, requirements, and barriers associated with Green IT adoption?
5	What are the evaluation criteria used by the case organization for evaluating integration technologies and Green IT solutions?

Chapter 7
Green Supply Chain Management Model for Sustainable Manufacturing Practices

Surajit Bag
Tega Industries South Africa Pty Ltd, South Africa

Neeraj Anand
University of Petroleum and Energy Studies, India

Krishan Kumar Pandey
O.P. Jindal Global University, India

ABSTRACT

The purpose of this chapter is to identify the dimensions of green supply chain and their impact on manufacturing practices. In this study, the authors used two extended strategies. First thorough review of literature was done considering articles from reputed journals. Second the factors identified from literature review was further refined through experts by forming a problem solving group consisting of seven experts from the manufacturing sector. These factors were used to develop the green supply chain management model using Interpretive structural modeling. Further MICMAC analysis was used to identify the driving and dependence power of the factors. The results of the analysis are very encouraging. Finally, the authors have presented the relationship management strategy for sustainable manufacturing practices.

INTRODUCTION

The paradigm shift of policies towards green economy is forcing manufacturers worldwide to consider the green initiatives seriously. There is need for the companies especially manufacturing companies to take a proactive approach rather than reactive approach. According to UNEP (2011) report, global manufacturing sector accounts for 35% of the total electricity consumed worldwide and responsible

for 20% of the world's carbon dioxide emissions, which is detrimental to lives on the earth. While the above arguments indicate, that this is the high time for research on green supply chain management and implementation of GSCM practices, especially for developing countries like India which is becoming one of the global manufacturing hubs next to China.

The term "green" is now widely used interchangeably on the more established "sustainability" concept, which points to a more holistic view of environmental, social and economic dimensions. World leading firms including IBM, Dell, HP, Sony, Toyota, Nokia have adopted GSCM as a strategic initiative. A framework is developed which portray the various complex relationships involved in a green supply chain with the aid of interpretive structural modeling (ISM). Before we funnel down to the framework, let us understand the basics of sustainability and green supply chain management, how firms exploit it for gaining competitive advantage, and how to build a contextual framework using ISM methodology.

LITERATURE REVIEW

We have adopted "*Systematic Literature Review (SLR)*" in our paper as suggested by Tranfield et al. (2003). The present section is divided into two stages and its phases.

Stage 1: Planning the Review

Phase 0: Identification for the Need for a Review

The field of Manufacturing and Operations has seen radical changes through the years. It started with the "*The Industrial Revolution*" in the late 1700s, has been through several phases but real challenge emerged in front of manufacturing was its sustainability. The issues that have forced developed economies to shift their manufacturing base to India were cost and other was to put check on greenhouse gas emissions. However the approach of these developed economies was questionable. Shifting the location of manufacturing hubs is never going to solve problems but there is need for more sustainable solution which can optimize between cost and environment. The search of amicable solution has led to the growth of green supply chain management. In our present work we will discuss theoretical concept used for building a green supply chain management model. We will review latest research works related to evolution of green supply chain dimensions, green supply chain as a source of competitive advantage.

Phase 1: Preparation of a Proposal for a Review

In this section we will identify reputable journals which publishes potential works related to green supply chain and its related areas.

To begin with green supply chain management it's very important to understand "Green Manufacturing" and its dimensions. Though there are lot of definitions and arguments, but from various literatures it can be derived that during manufacturing or production, lot of wastes are generated in the form of solid, liquid and gas, which are harmful to earth and to lives supported by the earth. In order to minimize the harmful effect of these wastes, innovative manufacturing practices to be deployed which is blend of technology, culture, leadership and policies, at economical cost so that firm should not be overburdened with excessive cost of production which force them to outsource which is the present scenario in the western part of the world.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Phase 2: Development of Review Protocol

We decided initially to review all published work. In order to eliminate our biasness towards any work we reviewed all possible articles published in past fifteen years in reputed journals related to green supply chain management, sustainable manufacturing & related concepts so that we do not end up with sketchy literature or irrelevant literature.

Stage 2: Conducting a Review

Phase 3: Identification of Research

We reviewed over 100 articles related to SSCM, green manufacturing, strategy & methodologies.

Based on review, we have derived two important questions which will further drive our investigation.

Green Supply Chain Management

In the present section we have highlighted some of the respected studies carried out by past researchers in the area of green supply chain management.

We must understand the concept of supply chain management before piercing down into green supply chain management (GSCM). Within each organization, the supply chain includes all functions involved in receiving and filling a customer request. These functions include, but are not limited to new product development, marketing, operations, finance, distribution and customer service. A supply chain is dynamic and involves the constant flow of information, product and funds between different stages.

If we look back into the history, we see that before 1780 during the Agrarian era supply chain type was ‘standard’ and firm characteristics used to be small, organic, horizontal hierarchy and depended on quality of product to sell. Between 1780 and 1960 it was the era of Industrial revolution where a major change took place and the standard supply chain type shifted towards lean with expansion in size, variety, complexity and diversity. After 1960, the post industrial revolution phase witnessed another sea change globally and the trend shifted from lean to agile, hybrid and presently green, (Nelson et al, 2009).Thus the journey of SCM theory development has started long back and is still evolving.

Sarkis et al., (2011) has documented about various organizational theories applied to GSCM related study such as Complexity theory, Ecological modernization theory, Information theory, Institutional theory, Resource based view, Resource dependence theory, Social network theory, Stakeholder theory, and Transaction cost economics. Some of the selected studies have been presented in Table 1.

Some examples to show the impact of green practices on supply chains are evident in Table 2.

It is clear that green supply chain has attracted attention of top global companies. Green practices are being used presently by these companies in some form or other. Companies are focusing mostly in reduction of natural resources, reuse of material and energy recovery program. This is really working like wonder and can potentially stop tons of green house gases in entering the atmosphere. Moreover, these companies are significantly saving costs across the supply chain. Ongoing, company-wide sustainability program has generated significant environmental and financial benefits. Commitment to reduce fuel and electricity use is a good approach to protect scarce natural resources. Converting to eco friendly operations has resulted in increase in production tenfold while reducing manufacturing costs. This has also attracted more customers due to enhanced customer satisfaction.

Table 1. Literature review on green supply chain management (GSCM)

Author(s), Year	Objective of Study	Key Findings	Variables Identified
Brandenburg et al. (2014)	To understand and review mathematical models focusing on environmental/social factors in the forward supply chains.	Major publications and models were found in a limited set of six journals (JCLP, IJPR, IJPE, TRE, EJOR & DSS). AHP, ANP and LCA were commonly used tool for developing the models.	Environmental; Social and Economic dimensions
Mirhedayatian et al. (2014)	To propose a novel network DEA model for evaluating the GSCM in the presence of dual role factors, undesirable outputs and fuzzy data.	The proposed model can be easily computerized so as to serve as a decision making tool in decision making.	Cost of quality; Supplier flexibility; Carbon dioxide emission; Satisfaction; Facility technology level
Suering (2013)	To review research on quantitative models for green or sustainable supply chains.	Different kinds of models are applied in this area but the social dimension is not taken into consideration. On the modeling side there are three popular methods: Equilibrium models, MCDM & AHP.	Environmental; Social and Economic dimensions
Zhu and Lai (2013)	To develop and empirically test a theoretical model.	The research contributes to the literature on institutional theory in corporate environmental practices.	Institution pressure: Coercive, Normative, Competitive
Reefke and Trocchi (2013)	To develop a framework to facilitate a balanced approach to performance measurement for SSCM.	A scorecard design customized for sustainable supply chain is proposed along with the development and implementation process.	Cost savings; Profit; customer satisfaction; quality management
Liu et al. (2012)	To integrate green marketing and SSCM.	Development of a new hub and spoke integration model. Drivers: Improve company's sustainable supply chain capabilities; reach green customers before competitors; government regulations; green customers demand; community expectation.	Products; Promotion; Planning; Process; People and Project
Hoejmose et al. (2012)	To understand the general engagement with GSCM in both B2B & B2C supply chains.	Firms in B2B market is generally less engaged with green practices compared to firms in B2C markets. Developing Trust with supply chain partners and top management commitment is a crucial GSCM driver among firms in B2B markets.	Trust; Top management commitment
Ageron et al. (2012)	To develop a Sustainable Supply Management framework.	External pressures have positive impact on the development of SSM; Waste reduction programmes have greater impact on greening supply chains; MNC & SMEs' have differential impact on SSM; Financial barriers have more impact on SSM; Top management support is a critical success factor in SSM; Key benefits such as customer satisfaction, supplier innovation, quality & capacity have greater positive impact on SSM.	Top Management Commitment; Govt. regulatory requirements; Quality; Flexibility; Waste Reduction; Clean Programs; Reducing carbon footprint; Financial costs; ROI; Green Investments; Customer Satisfaction; Innovativeness
Bose and Pal (2012)	To investigate the influence of GSCM initiatives on stock prices of firms.	Firms observe greater positive change in stock price by undertaking green initiatives. Firms with high R&D expenses show strong positive impact. Early adopters of GSCM show greater positive impact.	R&D; Size of firm; Stock prices
Dekker et al. (2012)	To review research on green logistics.	The review highlighted the contribution of operations research to green logistics	Mode choice; Intermodal transport; Equipment choice and efficiency; fuel choice and carbon intensity
Chaabane et al. (2012)	To present a generic mathematical model to assist decision makers in designing sustainable supply chains over their entire life cycle.	The model can serve as a tool that facilitates the understanding of optimal SC strategies under different environmental policies.	Economic: Cost; revenue; taxes; transfer Environmental variables: Carbon footprint; Raw material use; Energy use; Social variables: Noise; pollution
Dubey and Bag (2013)	To explore sustainable manufacturing practices that improves environmental and business performance.	Green Purchasing, SRM, Green logistics and regulatory norms are positive determinants of firm business performance and Environmental performance.	Green Purchasing; SRM; Green logistics and Regulatory norms
Gunasekaran and Spalanzani (2012)	To bring important issues related to sustainable business development in both manufacturing and services sector.	Developed a framework for sustainable development along with strategies, techniques and tools.	Sustainable Product and process design; sustainability in supply operations; sustainability in production operations; sustainability in distribution operations; sustainability through reverse logistics
Gimenez et al. (2012)	To analyse the impact of environmental programmes on each dimension of the triple line.	Internal environmental programmes have a positive impact on the three components of the triple bottom line. Social initiatives have a positive impact only on two components: social and environmental performance.	Environmental; Social and Economic performance; Internal and external action programs
Hassisni et al. (2012)	To review literature on sustainable supply chains from 2000-2010.	Based on the findings authors have developed a framework for sustainable supply chain metrics.	Market Forces; Policy& Regulations; Science& Technology; Product Development; Process Capability; Sourcing& Operations; Logistics; Marketing &PR; Social issues
Barari et al. (2012)	To provide integrated and holistic conceptual framework that combines the practical aspects of green supply chain with the objective of profit maximization.	A strategy set have been designed based on the game theory approach that promises maximum economic benefit.	Green tax; green burden

Table 1. Continued

Author(s), Year	Objective of Study	Key Findings	Variables Identified
Kang et al. (2012)	To establish the framework for strategy development to construct the sustainable supply chain.	Identified the factors leading to SSCM.	Leadership for knowledge sharing; Innovation of product and process
Wang et al. (2011)	To provide a multi objective mixed integer formulation for the supply chain network design with environmental concerns.	The model can be effectively used in the strategic planning for green supply chain.	Demand and Supply of Product; Carbon dioxide emission; capacity of facility; environmental investment cost; environmental protection; Transportation cost; Handling cost for products
Wu and Pagell (2011)	To understand how organizations balance short term profitability and long term environmental sustainability when making supply chain decisions under uncertainty.	Factors contributing to the uncertain decision environment are: Uncertainty about environmental outcomes & future regulation, the saliency of each environmental issue to multiple stakeholders, lack of visibility and influence in one's supply chain.	Operating principles; Technical standard
Gupta and Desai (2011)	To review the current state of academic research in sustainable supply chain management.	Authors developed an integrative framework summarizing the existing literature under four broad categories: strategic considerations, decisions at functional interfaces, regulation and government policies, integrative models and decision support tools.	Product design and product life cycle; Regulation and government policies
Azevedo et al. (2011)	To investigate the relationships between green practices and supply chain performance.	A conceptual model of the relationships between green practices and SC performance was developed.	Environmental friendly practices in purchasing; Environmental collaboration with suppliers; Minimizing waste; Environmental collaboration with customers; Reverse logistics
Pereira (2009)	To understand how Information Technology can foster information management and help sort out supply chain problems.	IT must be used to develop strategies to make supply chains more robust and resilient.	Information Technology
Longo and Mirabelli (2008)	To present an advance modeling approach and a simulation model and provide a decision making tool for supply chains.	An advance model is proposed based on programming code, tables and event generators and provides the user with a simulator capable of high efficiency for executing simulation runs.	Inventory Control; Lead Time; Demand Intensity; Demand variability
Linton et al. (2007)	To prepare a background to better understand current trends in the area of sustainable supply chains.	Research on Sustainable supply chain is still at an infant stage. It has strong links with government policy.	Product life extension; Product design; Recovery process at end of life.
Zhu and Sarkis (2004)	To determine the economic and environmental relationships of GSCM practices among Chinese firms.	Significant win-win opportunities exist for Chinese firms practicing GSCM. Strong relationship exists between GSCM practice and positive economic performance.	Commitment of GSCM from senior managers; Total quality environmental management; Environmental compliance and auditing programs; Supplier relationship; green design
Croom et al. (2000)	To conduct literature review.	Lack of theoretical work in the field as compared to empirical based studies	Sourcing strategy; attitude and commitment to collaborative improvement program

Table 2. GSCM practices

Companies	Green Supply Chain Practices
Wal-Mart	Focused on green packaging; Reduction in packaging costs and reduction in carbon dioxide emissions
Nestle	Eco friendly product packaging and focus on source reduction, re-use, recycling, and energy recovery
Heinken	Conservation of Natural resources and energy savings
Environmental Lubricants Mfg. Inc.	Technological up gradation to improve productivity and eco friendly manufacturing process
Bank of America	Eco-friendly operations and recycling program
General Electric's	Development of green products
Dupont	Green operations and lowering emissions of airborne carcinogens and greenhouse gases
Starbucks	Green operations, use of recycling paper cups and protecting environment
Coca-Cola	Focus on three environmental goals: water stewardship, sustainable packaging, and climate & energy protection
Toyota	Development of hybrid vehicle. Saving natural resources
Honda	Developed fuel efficient cars
Dell	Recycling program
Hewlett Packard	Owning and operating "e-waste" recycling plants

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Use of alternate source of energy such as solar panels, CNG is widely used by manufacturers. The step toward more sustainable operations has drastically lowered emissions of airborne carcinogens and greenhouse gases. Another company has also gone a step ahead by appointing an ex-Greenpeace head as an advisor to the board. And this company successfully reduced greenhouse gas emissions. Top companies has also partnered up with many environmental organizations, such as Conservation International and the Earthwatch Institute, in efforts to do right for the communities it operates in. Waste-elimination is now in the corporate philosophy to make the operations more eco-friendly than ever.

Lanxess and China Petroleum and Chemical Industry Federation (CPCIF) joined hands to present the Green Rubber Day on December 2nd, 2013 at the China World Summit in Beijing. Among other topics, Green Rubber Day dealt with the subject of high-performance tires, also known as "green tyres". The use of these tyres can help significantly to reduce rolling resistance, which is the friction that tires encounter when rolling. A tire's rolling resistance is a major factor in a vehicle's fuel economy. Using a high-performance tire that has been produced with state-of-the-art rubber can decrease the fuel consumption of a car by as much as half a liter per 100 kilometers – and consequently reduce the emission of carbon dioxide by 1.2 kilograms.

Few Definitions on Green Supply Chain Management (GSCM)

- Schrettle et al. (2014) defined GSCM as a "tool which helps to position a company from strategic viewpoint".
- Gunasekaran and Spalanzani (2012) defined GSCM as "an organizational philosophy which provides competitive edge to an organization".
- Ali and Govindan (2011) defined GSCM as "an organizational philosophy to reduce environmental risks".
- Zhu et al. (2008) defined GSCM as "adoption of eco friendly practices considering internal environmental management, green purchasing, cooperation with customers, and eco design for developing corporate and operational strategies for the firm's environmental sustainability".
- Seuring and Muller (2008) defined GSCM as "the management of material, information, and capital flows as well as cooperation among companies along the supply chain while taking goals from all three dimensions of sustainable development" which are derived from customer and stakeholder requirements".
- Carter and Rogers (2008) defined GSCM as an "integration of environmental dimensions with traditional supply chain network".
- Srivastava (2007) defined GSCM as "integrating environmental thinking into supply chain management, including product design, material sourcing and selection, manufacturing processes, delivery of the final products to the consumers, and end-of-life management of the product after its useful life".
- Vachon and Klassen (2006) defined GSCM as a "strategy, which assists to reduce wastages in supply chain network".
- Kogg (2003) defined GSCM "the set of supply chain management policies held, actions taken and relationships formed in response to concerns related to the natural environment with regard to the design, acquisition, production, distribution, use, re-use and disposal of the firm's goods and services".

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

- Sarkis (2003) defined GSCM as a "combination of the activities of an environmental dimension and reverse logistics".
- Gilbert (2000) defined GSCM as an "integration of environmental criteria with traditional supply chain network by redesigning purchasing policies and involving suppliers in the entire procurement process".
- Beamon (1999) defined GSCM as "utilizing the supply chain between a central company and a cooperating company, to support the company with knowhow of eco management practices and development of clean manufacturing techniques".
- Narshiman and Carter (1998) defined GSCM as "involving the procurement strategies that reduced the use of materials in addition to recycling and reuse."
- Godfrey (1998) defined GSCM as "organizational practices that continuously monitor the environmental impact of a supply chain and improve the performance."

Based on the above definitions the authors propose GSCM definition as "integrating the green dimensions into the traditional supply chain management so that the product will impose reduced environmental impact during its entire life cycle. It is the set of clean and hygienic practices which starts right from the product design stage and flows through all activities of the supply chain such as procurement, manufacturing, packaging, transportation and end of life management. Firm's internal resources mediate the relationship to external forces and its adoption. It improves the organizational performance and is the source of competitive advantage to sustain in the turbulent business environment."

Green Supply Chain Management (GSCM) Dimensions

- **Internal Environmental Management (IEM):** IEM includes Top management commitment, Cross functional cooperation for environmental improvements, Total quality environmental management, Environmental compliance and auditing programs, ISO 14001 certification, Environmental management system.
- **External Environmental Management (EEM):** EEM includes Green Purchasing, cooperation with customers for cleaner production, green packaging and eco-design.
- **Investment Recovery (IR):** IR includes sale of excess inventories, sale of excess capital equipment.
- **Eco-Design:** Eco design includes design green products for reuse, recycle and recovery of material and energy. Design eco friendly products to reduce health hazards of human beings.

Green Supply Chain Management (GSCM) as a Source of Competitive Advantage

A respected work has proved that environmental management is partially an extension of advanced manufacturing practices, continuous improvement and supplier management (Yang et al., 2010). Therefore GSCM can be regarded as a mechanism through which sustainability can be achieved leading to manufacturing competitiveness.

GSCM improves firm performance by improving Agility, Adaptability and promotes Alignment:

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

- **Improves Agility:** Firms adopting GSCM practices can react fast to any changes in customer demand than competitors and hence better positioned in the market.
- **Improves Adaptability:** Firms can achieve better flexibility and can lead to innovative processes and continuous improvement.
- **Promotes Alignment:** Better alignment of business process is achieved by those firms practicing GSCM.

Theoretical Discussion on Antecedents of Green Supply Chain Management (GSCM)

The key drivers of GSCM are regulatory pressures and market pressures. In developed countries government has framed environmental policy and guidelines to provide environmental solution to the manufacturers. With globalization and the increased number of countries entering the W.T.O. has led to increased GSCM practices. Several studies have mentioned how foreign firms such as Toyota and Ford have encouraged and motivated their Chinese suppliers in adopting green practices. In European Union they have a policy (WEE) for disposing waste electrical and electronic equipment after the end of their life so as to reduce the harmful effects.

Cap and trade legislation for GHG emission is applicable for manufacturers across European Union, U.S and Australia. Aberdeen group survey (2013) reports that 50% of the companies are planning to redesign their entire supply chain in order to be more sustainable and 80% of them have to comply with new environmental policies. As a result companies face new challenges and adopt best technologies to meet their legal obligations.

Companies can earn carbon credits through one of the mechanism such as Emission trading system and carbon trading or contribution to climate change technology fund.

In an effort to reduce the GHG emissions globally the carbon trading markets were first introduced under the Kyoto Protocol, known as the United Nations framework convention on climate change (UNFCCC).

Market pressures play a vital role in driving firms to adapt GSCM. Foreign customers demand environment friendly product and services from their suppliers globally including India. Foreign customers conduct strict environmental audit of their Indian suppliers before placing the orders as they demand environmental friendly goods, (Mitra, 2004). GSCM can be used as an environmental tool to improve the environmental image with in the business arena and enhancing export sales. Suppliers and community stake holders also influence GSCM adoption.

Supporting the GSCM project requires tremendous support from the top management to highlight that the project is really important and will receive proper attention from the members of the organization. Lack of resources and financial support will lead to failure of the GSCM project. It is interesting to note that top management commitment leads to success of GSCM project. Firms having proper environmental policy are always ahead and the success rate of GSCM adoption are high. Top management must motivate junior managers and ensure that every employee within the organization is aware of the environmental policy, (Zhu et al., 2005).

Several studies on GSCM were conducted in Chinese context. Without environmental awareness it is difficult to implement green practices. Regulatory, competitive, and marketing pressures led to increased environmental awareness and are the drivers of GSCM, (Zhu et al., 2005). Chinese manufacturers have taken proactive measures in closing the supply chain loop by adopting GSCM practices. GSCM can be used as an environmental tool to improve the environmental image and gain competitiveness within

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

the international business arena, (Zhu et al., 2008). Greening any supply chain involves imbibing environmental principles in the design and operations of supply chain. A background of environmental principles for achieving eco efficiency and building of environmentally friendly organization system have been presented and emphasis is put on application of such principle in life cycle of product (Tsoulfas & Pappis., 2006).

It is very important for any practicing manager to understand the links between GCSM practices, environmental and economic performance for successful GSCM implementation. Environmental pressure act as a driver for successful GSCM practices. Market and regulatory pressures help organization to improve environmental pressures which are believed to influence eco design and green purchasing. Manufacturers facing higher regulatory pressure tend to implement green purchasing and investment recovery. Competitive pressure significantly improves the economic benefits from adoption of different GSCM practices (Zhu et al., 2007).

Computer parts' manufacturers in Thailand have adopted Environmental Management Systems (EMS) due to strict environmental regulations and export Pressure (Seksan et al., 2010).

Environmentally and socially responsive supply chains are in the early adoption stages in Indian automobile industry and actual implementation lacks a holistic approach (Shukla et al., 2009). Major Indian manufacturing firms feel that there is lack of awareness of environmental issues which is a challenge and biggest perceived barrier to adopting GSCM is that it is not cost effective (Bhateja et al., 2011).

Important factors to implement GSCM in Indian manufacturing industry are innovative green practices, awareness level of customers; supplier motivation; technology advancement and organization adoption, organization encouragement, quality of human resources, IT enablement, top management commitment, Government support policies, International Environmental agreements (Luthra et al., 2012). External factors affecting GSCM are Environmental regulations, suppliers, consumers and community stakeholders. GSCM practices can enhance the environmental, operational and financial performance of firms.

Research Questions

- What are the key GSCM factors and the nature of relationship between them in context to Indian manufacturing sector?
- Can a GSCM model be developed for the Indian manufacturing sector?

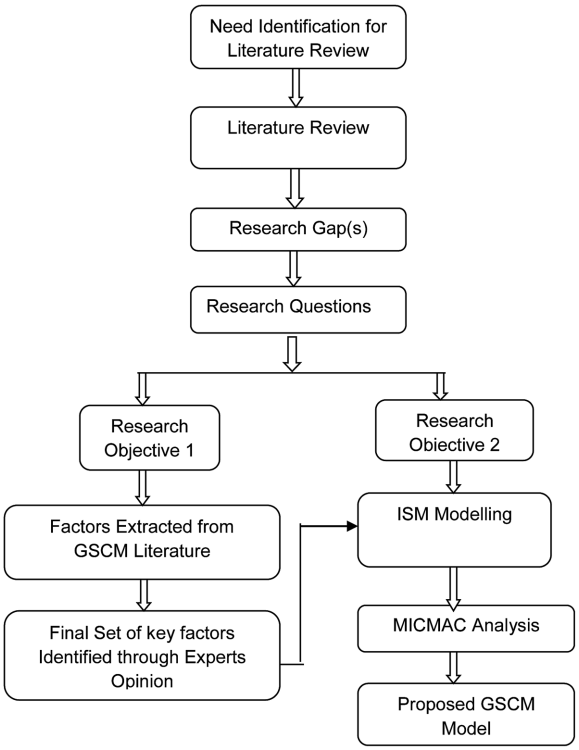
Research Objectives

Literature review has given a direction to identify the research gaps and to develop the below two specific research objectives for the present study are as follows:

- To identify the key factors influencing GSCM practices and the underlying relationships in context of Indian manufacturing sector.
- To develop a GSCM model for the Indian manufacturing sector.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

METHODOLOGY



This section discusses on theoretical model development. The purpose of research methodology is to present the research design that will be used to conduct the research for this study. Based on the synthesis of literature review and experts' opinion from industry; the key factors influencing GSCM practices have been identified. GSCM model has been developed by using ISM technique which was further refined using MICMAC analysis (See Figure 1).

Interpretive Structural Model (ISM)-Based Methodology

ISM is a proven and popular methodology for understanding relationships among specific items that define a problem. ISM is useful to achieve the objective in presence of large number of directly and indirectly related elements and complex interactions among them which may or may not be expressed in a proper manner. ISM plays a vital role in this kind of situation and helps in understanding a structure within a system. The ISM model depicts the structure of a complex problem in a carefully designed pattern.

ISM has been used in the past by several researchers due to multiple benefits which have been mentioned in Table 3. It guides and records the results of group response on complex issues in an efficient and systematic manner, (Source: Attri et al., 2013; Warfield 1994; Warfield 1974). ISM has been applied in different areas of the supply chain starting from purchasing to production and logistics management. Sushil (2012) have contributed in the ISM literature by providing directions to interpret the links in ISM using the tool of interpretive matrix.

Figure 1. Research process flow chart

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

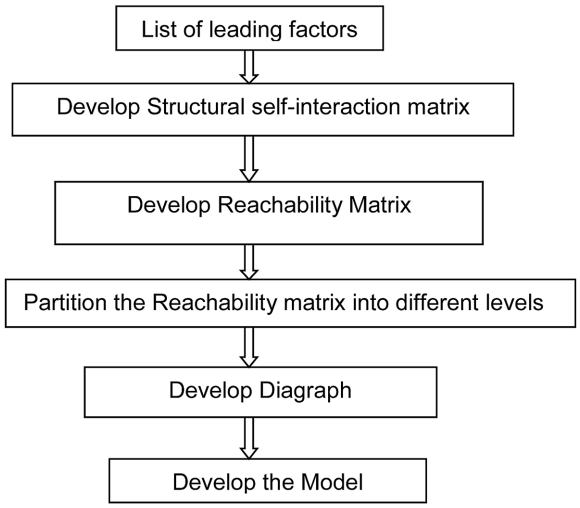
Table 3. Review on ISM application

Author and Year	ISM Application
Hawthrone and Sage (1975)	Higher education program planning
Sage (1977)	Modeling complex situations
Jedlica and Meyer (1980)	Exploring factors involved in a cross cultural context
Saxena et al (1992)	Determining the hierarchy and class of elements in cement industry
Mandal and Desmukh (1993)	Vendor selection
Kanungo et al (1999)	Developing an IS effectiveness framework
Ravi and Shankar (2004)	Explore reverse logistics barriers
Jharkaria and Shankar (2005)	Enablers of IT implementation in SC
Ravi et al. (2005)	Indentify key reverse logistics variables
Faisal et al. (2006)	Modeling the enablers for supply chain risk mitigation
Thakkar et al. (2006)	Integrated approach with ISM and ANP to develop a balanced scorecard
Singh and Kant (2008)	Knowledge Management
Subramanian et al. (2010)	Buyer Supplier relationship
Diabat et al. (2012)	Modelling various supply chain risks
Gorane and Kant (2012)	Modelling supply chain management enablers
Khan and Haleem (2013)	Technology Management enablers
Dubey et al. (2014)	Flexible Manufacturing Systems
Dubey et al. (2014)	Modelling Antecedents of Innovation

The Steps Interpretative Structural Modeling

There are six basic steps under ISM and these have been presented in Figure 2.

DATA ANALYSIS AND FINDINGS



In this step the contextual relationship between elements with respect to the pairs of elements is examined. To investigate the relations between ten elements, a questionnaire was developed. The questionnaire was sent to ten referees, who are working in the position of senior management in manufacturing sector. The questionnaire was tested for content validity. Content validity primarily depends on an appeal to the propriety of content and the way it is presented (Nunally, 1978). The instrument developed in this study demonstrates the content validity as the selection of measurement items was based on both, an exhaustive review of the literature and detailed evaluations by senior managers during pre-testing.

List of Leading Factors

The green supply chain management literature was thoroughly reviewed. As a result of the review, 20 factors were found to be influencing green supply chain management processes. A problem-solving group was formed comprising seven experts from industry who are also members of CII. The group was asked

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Flowchart for the ISM Methodology

to analyze the listed factors, take out the repeated ones and rearrange the list including the ones thought to be valid in relation with Indian context. The first tour resulted with reducing each of the factors to 17. Through the second tour 12 and the third tour total 10 factors were determined.

The ten key factors shown in Table 4.

Developing the Structural Self-Interaction Matrix (SSIM)

For developing SSIM, the below symbols have been used to denote the direction of relationships between variables (i and j) (Table 5):

V: i lead to j but j does not lead to i
A: i do not lead to j but j lead to i
X: i lead to j and j lead to i
O: i and j are unrelated to each other

Develop Reachability Matrix

The SSIM has been converted into a binary matrix i.e., the rechability matrix (Table 6) by substituting V, A X and O by 1 and 0. The substitutions of '1' and '0' have been done as below:

1. If the (i, j) entry in the SSIM is V, then the (i.j) entry in the rechability matrix becomes '1' and (j,i) entry becomes '0'
2. If the (i, j) entry in the SSIM is A, then the (i.j) entry in the rechability matrix becomes '0' and (j,i) entry becomes '1'
3. If the (i, j) entry in the SSIM is X, then the (i.j) entry in the rechability matrix becomes '1' and (j,i) entry also becomes '1'

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 4. Final set of key factors with items are listed

SL No	Factors	Items
1	Top Management Commitment	Well defined environmental policy of Company
		Employee awareness about the firm's environmental policy
		Top management support to environmental programs
		Top management approval to special funds for investment in cleaner technologies
		Positive attitude of senior managers towards green practices
		Senior managers motivate and support new ideas received from junior executives
		Employees recognition for innovative ideas
2	Regulatory Pressures	Regional pollution control board pressures to adopt green practices
		Government regulations to control pollution level
		Strict monitoring by Pollution control board
		Green practices decrease incidence of penalty fee charged by pollution control board
3	Market Pressures	Company focus on Export sales
		Foreign customers sensitivity towards green practices
4	Supplier Relationship Management	Environmental criteria for supplier selection
		Environment collaboration with suppliers
		Technological integration with suppliers
		Training and educating suppliers in implementing ISO 14001
		Environmental audit for suppliers
5	Total Quality Environmental Management	Total Quality Environmental Management implementation
		Green practices promote product quality
6	Green Technology Adoption	Company focus on green design of products
		Wastage reduction from green design
		Real time information available any point of time by using Information technology infrastructure SAP/ERP
		Usage of alternate source of energy
		Process optimization to reduce wastage
		Eco friendly packaging
		Reduction of emission of Green House Gases by use of clean technology
7	Profit	Green practices improve firm's profit
8	Market Share	Green practices improve firm's market share
9	Reduction in Carbon emission	Green practices Reduce solid waste generation
		Effluent meets CPCB norms by converting into green operations
		Green practices reduce environmental accidents & hazards
		Green practices decrease of cost of raw materials
		Green practices reduce the inventory levels
		Green practices reduce cost for energy consumption
10	Customer Relationship Management	Green practices improve customer satisfaction
		Firm recover end of life products from customers
		Customers appreciate eco friendly products

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 5. Structural self-interaction matrix (SSIM)

	X	IX	VIII	VII	VI	V	IV	III	II	I
I	V	V	V	A	V	V	A	A	O	
II	V	V	V	A	V	V	O	A		
III	V	V	V	A	V	V	A			
IV	O	O	V	X	O	V				
V	O	V	V	A	A					
VI	V	V	V	A						
VII	O	O	V							
VIII	O	V								
IX	O									
X										

Table 6. Reachability matrix

	I	II	III	IV	V	VI	VII	VIII	IX	X	Driving Power (Y)
I	1	0	0	0	1	1	0	1	1	1	6
II	0	1	0	0	1	1	0	1	1	1	6
III	1	1	1	0	1	1	0	1	1	1	8
IV	1	0	1	1	1	0	1	1	0	0	6
V	0	0	0	0	1	0	0	1	1	0	3
VI	0	0	0	0	1	1	0	1	1	1	5
VII	1	1	1	1	1	1	1	1	0	0	8
VIII	0	0	0	0	0	0	0	1	1	0	2
IX	0	0	0	0	0	0	0	0	1	0	1
X	0	0	0	0	0	0	0	0	0	1	1
Dependence Power (X)	4	3	3	2	7	5	2	8	7	5	

4. If the (i, j) entry in the SSIM is O, then the (i.j) entry in the rechability matrix becomes ‘0’ and (j,i) entry also becomes ‘0’

Level Partitioning

The final reachability matrix obtained in Table 6 is now partitioned into different levels. After the first iteration, the variable classified to level 1 are discarded and the partitioning procedure is repeated on the remaining variable to determine the level 2. These iterations are continued until the level of each variable has been determined. The results for iterations 1 to 7 are shown in Tables 7-13.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 7. Level partitioning (iteration 1)

Variables	Reachability Set	Antecedent Set	Intersection Set	Level
1	1,5,6,8,9,10	1,3,4,7	1	
2	2,5,6,8,9,10	2,3,7	2	
3	1,2,3,5,6,8,9,10	3,4,7	3	
4	1,3,4,5,7,8	4,7	4,7

Diagraph

From the final Reachability Matrix and level partitions, the structural model is generated by means of nodes and lines of edges. If there is a relationship between the factors j and i, this is shown by an arrow which points from i to j. This graph is called digraph (see Figure 3).

The analysis yields an ISM hierarchy in which Market share and Profitability is at (level 1); reduction in carbon emission (second level); Green technology adoption (third level); Total quality environmental management (fourth level); SRM & CRM (fifth level), Top management commitment (sixth level), Regulatory and market pressures (bottom level).

Figure 3. Diagraph

ISM Model

The resulting ISM model is presented in Figure 4.

MICMAC Analysis

MICMAC analysis Matrice d' Impacts croises multiplication appliqué an classment (cross-impact matrix multiplication applied to classification) is abbreviated as MICMAC. The objective of MICMAC analysis is to analyze the drive power and dependence power of factors. Based on the drive power and dependence power the factors have been classified into four factors: autonomous factors, linkage factors, dependent and independent factors (see Figure 5 and Table 14).

The MICMAC graphical representation is shown in Figure 5.

Interpretation of MICMAC Analysis

Cluster 1: Autonomous Factors

These factors have a weak drive power and weak dependence power. In this cluster we do not have any factors.

Cluster 2: Dependence Factors

These factors have a weak drive power but strong dependence power. In this cluster we have three factors, i.e., 5 (Market Pressures), 8 (Carbon Emissions Reduction), 9 (Market Share) and 10 (Profit).

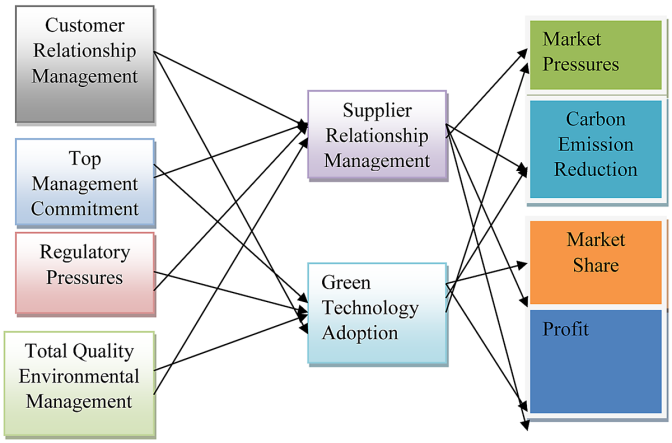
Figure 5. MICMAC graphical representation

Cluster 3: Linkage Factors

These factors have a strong drive power as well as strong dependence power. In this cluster we have two factors, i.e., 1(Supplier Relationship Management) and 6 (Green Technology Adoption).

Cluster 4: Driving Factors



These factors have a strong drive power but weak dependence power. In this cluster we have four factors, i.e., 2 (Customer Relationship Management), 3 (Top Management Commitment), 4 (Regulatory Pressures) and 7 (Total Quality Environmental Management).

We have developed appropriate research methodology to develop contextual relationship among identified factors using expert's opinion. We developed ISM model and have further refined the ISM model using MICMAC analysis in order to understand the characteristics of identified factors.

Based on ISM and MICMAC analysis we propose the below model as shown in Figure 6.

The proposed GSCM model depicts the Driving factors (Customer Relationship Management), (Top Management Commitment), (Regulatory Pressures), (Total Quality Environmental Management); Linkage factors (Supplier Relationship Management) and (Green Technology Adoption) and Dependence factors (Market Pressures), (Reduction in Carbon Emissions), (Market Share) and (Profit).

Figure 6. Conclusive GSCM model

CONCLUSION

- Present study provides a systematic approach in developing a structural GSCM model for manufacturing sector. The ISM model has identified a hierarchy of factors for better decision making and building a clean system with minimum environmental impact.
- The ISM Model yields a hierarchy in which Market Share and Profitability is at level 1 (the top level) followed by Reduction in carbon emission (level 2), Green technology adoption (level 3), Total quality environmental management (level 4), Supplier relationship management and Customer relationship management (level 5), Top management commitment (level 6), Regulatory pressures and market pressures is at bottom level (level 7).
- Four factors are identified as driving factors and four factors as dependent factors using MICMAC analysis. Also there are two linkage factors but no autonomous factors emerged from the analysis.
- Customer relationship management, Top management commitment, Regulatory pressures and Total quality environmental management have been analyzed as driving factors. The driving factors play a vital role in successful GSCM practices. They condition the rest of the system and are called independent variables or drivers.
- The dependent factors characterize desired objectives for achieving success and identified from the analysis are Market pressures, Reduction in carbon emission, Market Share and Profit. These attributes are weak drivers but strongly dependent.
- Linkage factors are very sensitive and unstable. Any action on these factors will trigger an effect on other factors and also a feedback on themselves. Supplier relationship management and Green Technology adoption have emerged as the linkage factors.
- Based on the data analysis authors propose Relationship strategy for developing sustainable supply chain management in a manufacturing firm. Relationship strategy is based upon cooperation and collaboration with suppliers and customers.
- Buyer firms which practice supplier collaboration approach integrates procurement with other functions and achieve higher level of discipline and successful implementation of environmental certifications. Collaborative planning and information sharing helps to identify the strengths and weakness of suppliers. In this process it will be easy to educate suppliers and also pressurize for environmental certification. Collaboration and partnership develops innovation and enhances green practices.
- Cooperation leads to better understanding, Joint decision making, sourcing alternate/recyclable packaging material at economic costs, cost reduction. This creates more confidence and builds green culture within the organizational system.
- Relationship building improves company's image, gain competitive advantage, more value addition and ultimately happy customers.
- Relationship strategy leads to waste reduction, Lowers environmental costs and more profitability.
- The model presented in this study may enable management and decisions-makers involved in manufacturing companies to identify and classify the enablers that have either strong dependence or strong driving power or both strong dependence and driving power that enhances the process of GSCM practices.

SOLUTIONS AND RECOMMENDATIONS

Focus in Customer Relationship Management

There are no shortcuts to improving customer experience and driving GSCM practices. The need of the hour is to embrace GSCM practices in order to suit business goals and objectives in manufacturing sector.

CRM solutions and services that can demonstrate how the evolution of marketing, sales, customer service, customer analytics and data management processes can drive successful interaction and collaboration across customer and partner channels.

Customers are always curious about interesting organizational practices which benefit society and environment. If there is a new creative solution to a problem, that creates net positive value for customers, then certainly it will be attractive to customers. Customers will expect low risks involved in the organizational offerings.

Strong Leadership and Commitment of Top Management

Greening success is driven by dynamic leaders. In large sized manufacturing organizations greening is driven by these leaders in a more professional manner than smaller sized manufacturing organizations. Top management should prepare GSCM policy and create awareness among all employees.

Focus on Total Quality Environmental Management

Firms today are experiencing increased demands for enhanced social responsibility from investors, activists, regulators and consumers. These demands go beyond product quality, which was the focus of the total quality movement of the 1980s, and now encompass other areas, such as, responsible environmental management. Indian manufacturing firms are progressively making organizational changes to integrate the environment into their production decisions and are shifting from a regulatory driven, reactive approach to a proactive and beyond-compliance strategy towards environmental management

External market and regulatory considerations, such as the desire to improve a firm's image with customers and regulators, earning good-will with regulators and the anticipation of future regulations is associated with the adoption of TQEM.

Organizational change in the form of Total Quality Environmental Management leads firms to adopt pollution prevention practices, after controlling for the effects of various regulatory pressures and firm-specific characteristics.

There Is No Single Formula for Reducing Carbon Emissions

Every organization must chart its own greening course. Green practices, the subject of green supply chain management, and even the central objective can vary a lot from organization to organization. Organizations have different opportunities for greening, vary in resources, institutional pressures and different leaders available, each with their own innovative ideas, who do green practices distinctively. The greening strategies are unique in details across organizations. It is seen that organizations progress with green practices through standardized measurement and data capturing protocols. Reducing carbon

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

emissions requires a sustained and focused effort. Organizations must form a cross functional team and proceed with the action plan for implementing GSCM in a holistic way. It takes long to adopt GSCM practices and therefore organizations must monitor progress on a periodic basis to understand the progress. In summary the differences in structure, size, availability of resources and market opportunities exists across organizations, which means the details of green practices are diverse.

Green organizations drive greening among their supply chain partners in the entire network. Greening organizations alter product design with emphasis on green design and waste disposal protocol to facilitate reuse and recycle in order to close the supply chain loop; this is simply to reduce environmental impact during the stages of product life cycle., i.e. from birth to the end of its useful life.

A set of ISO standards, ISO 14040 and ISO 14044, has been established and manufacturers should therefore make sure that the work in question is performed in accordance with these ISO standards.

Green Organizations Help to Increase Profitability

Green practices improve quality and lower wastages which results in significant savings and improved profitability. Green firms switch to low carbon energy sources to reduce carbon emissions. This reduces the market pressures and government pressures. The enhanced brand image of the organization helps to increase in sales volume with lower input costs. Hence GSCM is the path to achieve sustainability for those aspiring to become world class organizations in the future.

Systematically Green Necessitates an Organization to Be Competent at SRM

With fierce competition, changes in market dynamics such as emergence of GSCM practices and raw material price volatility, procurement professionals in the manufacturing firms are looking for better visibility across supply chain to control costs. Supplier innovation has also become key, with procurement looking towards suppliers for new raw materials that aid in product development. Organizations that aspire to be green must emphasis on supplier relationship management. Suppliers should be provided training and education so as to implement EMS and ISO 14001. Care should be taken to ensure suppliers follow the policy strictly. Organizations that are high on SRM have a strong sense of discipline, and focus on value creation.

Greening Can Become Fully Embedded in an Organization's DNA Sequence

The promotion of Green technologies has been included in the draft strategy for the manufacturing sector prepared by the Department of Industrial Policy & Promotion (DIPP), Ministry of Commerce and Industry. Greening must be embedded within the organization system so that it flows normally through the arteries and produce desired results. Organizations with strong Information Technology (SAP/ERP) setup help to develop it more systematically. Proper MIS is generated which gives 360 degree view of the organization in terms of producing the correct production related wastage report, energy savings, and activity based costing report etc. Managers and decision makers must understand the links of the GSCM model clearly before adopting implementing the system. This leads to the development of green culture and set of behaviors, until ultimately, holistic approach is expected as a part of each activity.

Green Is Not Free: It Requires Investment in Training and Development

Organizations aspire to be green must be prepared to take risks, and a tolerance for efforts that fetches failure. Since at the initial stage it involves financial risks therefore proper training of human resources is required so as to develop a culture that undertake risks. Further investment in clean technologies and best practices is necessary which will fetch long term benefits. Focus on maximizing energy efficiency potential by replacing obsolete, inefficient equipments and adopting best available technologies is vital for organizations who aspire to develop competitive edge in the market.

Greening Helps Organizations to Attract and Retain Talents

Talented human resources at all levels are attracted to progressive organizations since these organizations do world class practices. Hence green practices support reputational advantages and help in enhancing the brand image. Greening is associated with high employee motivation, low employee turnover and ultimately, labour market success.

FURTHER RESEARCH DIRECTIONS

Like every methodology ISM also suffers from certain limitations since it is purely based on the opinion of experts and qualitative in nature. To eradicate the limitations of present research we propose to validate the model empirically in other sectors using Exploratory factor analysis and further test using regression analysis using SEM packages such as AMOS/LISREL.

KEY TERMS AND DEFINITIONS

GSCM: GSCM can be defined as integrating environmental thinking into supply chain management, including product design, material sourcing and selection, manufacturing processes, delivery of the final products to the consumers, and end-of-life management of the product after its useful life.

ISM: Interpretive Structural Modelling is a proven and popular methodology for understanding relationships among specific items that define a problem.

Sustainability: SSCM is defined as an efficiency of utilizing the finite resources and achieve flexibility to changeable business environment.

Chapter 8
Green Customer Satisfaction

Violeta Sima
Petroleum-Gas University of Ploiesti, Romania

Ileana Georgiana Gheorghe
Petroleum-Gas University of Ploiesti, Romania

ABSTRACT

This chapter aims to identify those factors that determine green consumer satisfaction, having as the emerging point the definition of consumer behavior and the concept of sustainable development. The authors propose a new approach of the dimensions of the evaluation model for customer satisfaction including a new one, called The Green Dimension. An important goal is identifying the drivers of the consumer purchasing. The authors identify three main specific levels of the green dimension of customer satisfaction. They are related to: Company, Product/Service, and Price. Then some considerations regarding an integrated approach of strategic mix from a 'green' perspective are presented. According to the U.S. consultancy Boston Consulting Group, in order to obtain a Green Advantage, companies should enhance their strategic mix, taking into consideration green planning, green processes, green product and green promotion. The authors add two more elements, namely people and eco-efficiency, resulting "The Green Strategy Mix".

INTRODUCTION

Green Economy involves the use of natural resources, energy and new technologies together with cleaner production methods in order to promote economic growth and create new jobs. To implement this concept, we need to create new models of sustainable consumption and production, which does not force the ecosystem.

In order to operationalize the Green Economy concept, the three aspects of sustainable development (environmental, economic and social) should be incorporated. Obtaining a multi-dimensional outcome changing consumption patterns will require a multi-prong strategy focusing on demand, meeting the basic needs of the poor people, and reducing wastage and the use of finite resources in the production process.

In order to implement the green economy at the national level it is required close involvement of consumers and producers, along with the implementation of the main measures proposed and adopted by the national and international governing bodies.

Green economy requires changing consumer habits.

In order to assess consumer satisfaction it is important to know the degree to which they are willing to pay extra for green products and services. This chapter is a theoretical approach to this problem.

The authors identified three main specific levels of the green dimension of customer satisfaction. They are related to: Company, Product/Service, and Price.

The objective of this study is to highlight the links between green satisfaction and the three mentioned elements but also the transformations they bring in consumption patterns.

BACKGROUND

The concept of satisfaction has been subject of study for many researchers. However, satisfaction is still difficult to be defined, as Oliver asserted in 1997 in his book, "Satisfaction: A Behavioural Perspective on the Consumer" (p. 13). Thus, although satisfaction seems to be a widely known concept, when a definition is required it is difficult to obtain.

The subject of this thesis is to reveal multiple senses of customer satisfaction emphasizing the Green Dimension (Sima & Gheorghe, 2009).

Customer satisfaction is subject of study not only for scholars, but also for companies. The purpose of this analysis is very pragmatic, namely to determine its maximizing in order to increase customer loyalty. To achieve this, it is essential to identify key factors which determine customer behaviour.

Although in the literature of specialty there is widely accepted opinion that satisfaction represents a response to consumption related experiences (Yi, 1990; Anderson, Fornell & Lehmann, 1994; Oliver, 1997; Giese, & Cote, 2000), it has a wide range of definitions and assessment ways (Peterson & Wilson1992; Giese, & Cote, 2000).

A customer who has achieved a high level of satisfaction will be tempted to repeat the purchase, thus becoming loyal. The final effect will be the customer retention (Zairi, 2000). Moreover, he will be prompted to provide positive recommendations to other potential customers. On the contrary, a dissatisfied customer will give up in the future buying the product or service or even he will return it. Another possibility to reduce dissonance is also searching for information that confirms the high value of the product or service (Kotler, 2000).

In research studies for satisfaction more operationalizations of satisfaction were used (Westbrook, & Oliver, 1981; Hausknecht, 1990; Peterson, & Wilson, 1992; Wirtz, & Lee, 2003). Thus, Hausknecht (1990) listed 34 measures, including measures of behaviour (namely, behaviour registrations, such as number of complaints about the main product) and self-report measures (namely, survey items, such as rating scales).

Also, the marketing studies showed that customer satisfaction depends on the specific psychological construction such as reliability, quality, customer loyalty, commitment, word-of-mouth and image, and customer profitability. It has been shown that quality and reliability are required by satisfaction, which in turn is necessary for customer loyalty and customer profitability (Yi, 1990; Anderson et al., 1994; Oliver 1997; Verhoef, 2001; Hennig-Thurau, Gwinner & Gremler, 2002).

The meaning of the concept is context-specific satisfaction (Giese & Cote, 2000).

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

As a result of a learning process which can be developed only in the presence of a permanent client, who asks repeatedly for a particular product, brand or company, in order to meet a specific need, as a form of attachment to the benefits provided by the company, static vision of the satisfaction resulted from the client-producer relationship, has been replaced gradually and improved by cumulative satisfaction paradigm.

Satisfaction refers to the fact that a particular feature of a product or the product itself offered a "pleasurable level of consumption-related fulfilment, including levels of under or over fulfilment" (Oliver, 2006, p.13).

According to Rust and Oliver "consumer satisfaction can be seen as the consumer's fulfilment response." (1994)

In 2001 Parker and Matthew referred to the existence of two complementary approaches of the concept of consumer satisfaction, namely satisfaction as a process and respectively satisfaction as a result of consumption experiences.

In 1977 and two years later, in 1979, Olson and Oliver asserted that in terms of process, customer satisfaction can be defined as an assessment of the significance of what was received and what was expected. Vavra, in 1997, emphasized that perceptual, psychological and assessment processes determine consumer satisfaction.

The approach as a result of consumer satisfaction is defined as a final state resulting from the consumption experience. This condition may be the result obtained without comparing expectations (Oliver, 2006) or a cognitive state obtained as a result of comparing the expected and actual performance or cost comparison of rewards and anticipated consequences (1997, p.4).

In marketing literature two main groups of models evaluation of consumer satisfaction can be identified:

- Models that put in relation the concept of customer satisfaction with concepts such as quality, value, and loyalty behaviour complaints. These models have an essential role at the level of organizational policy. Thus, they provide strategic context for designing a marketing research on consumer satisfaction.
- Models based on the constructs of the customer satisfaction concept such as the discrepancy between expectations and actual results, attribution, equity, affect, and regret. These models allow proper operationalization of measurements of customer satisfaction providing appropriate constructs.

In order to measure consumer satisfaction in a broad range of organizations indexes have been developed. Thus, at national level, customer satisfaction index (CSI) is used in order to measure how companies and organizations are able to satisfy customer needs. The CSI Model is also used for comparing the services and products within a sector. Most countries have developed their own customer satisfaction indexes. The first such model was the national Swedish customer satisfaction barometer (SCSB), developed in 1989, which was to include 31 major industries the Sweden. This model used perceived value and single measure of customer expectations (Fornell, 1992). In 1992, in Germany, was introduced Deutsche Kundenbarometer (DK), who in 1994 also includes 31 industries.

In USA American Customer Satisfaction Index (ACSI) is being used since 1994. This model takes into account both the field of production as well as the field of public area. Thus, seven economic sectors, nearly 40 industries, 200 private sector companies and two local public services are taken into account.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Customer satisfaction index is calculated by taking into account proportional role of three categories of variables, namely: overall satisfaction, satisfaction expectations and satisfaction with the organization "ideal".

A model used in EU to assess customer satisfaction is European Customer Satisfaction Index (ECSI) Model. This is an econometric model that links customer satisfaction index with a set of causal latent variables (such as customer expectations and customer perceptions about quality and value), being based on verified theory of consumer behaviour modelling. It aims to determine the perceived quality and the company image to customers and customer loyalty.

Kristensen et al. (2000) described it as "a structural equation model with unobservable latent variables ... that link customer satisfaction to its determinants and, in turn, to its consequence, namely 'trust' and 'repurchase intention".

Customer satisfaction study aims at four main aspects, namely:

1. Identifying the means of measuring customer satisfaction.
2. Finding the ratio of the number of satisfied clients and the total number of customers.
3. Identifying key indicators for the satisfaction assessing.
4. Finding the evolution of the level of customer satisfaction.

In order to answer those questions, the relationship between actual performance and desired performance must be considered. The Bender Model (1991) and The Rapp Model (1995), cited by Schneider emphasize five dimensions to be considered when assessing customer satisfaction:

1. Technical quality of the product,
2. Reputation quality,
3. Service quality,
4. Quality of personal relationships,
5. Price perception.

According to Meyer-Waarden (2004), satisfaction is an essential element for modelling customer purchasing behaviour, based on three categories of variables:

1. Cognitive variable;
2. Affective variables;
3. Co-native variables.

In the beginning, pro-environmental models started from the premise that between environmental knowledge and concern about this there is a direct linear relationship, leading to pro-environmental actions as a consequence (Kollmuss & Agyeman, 2002).

Ottman (1993) defined "environmental consumerism" as a reaction of the consumers, who, noting environmental problems, increasingly buy more eco-friendly products, gradually abandoning classic products. The stated purpose is to protect "themselves and the planet".

Thus, marketers should address this category of products similarly to the target market (Ottman, 2006), because consumers look for them, especially (Pickett, 2008).

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Consumers claim to be well informed about the benefits of the products they intend to purchase. In doing so, marketers must consider this aspect in establishing the communication strategy and use instruments which best matching with the beliefs and behaviour of consumers, determining thus interest for the product (Kilbourne, 1995).

Ottman (1993) defines green consumers as "those who actively seek and support those products satisfy their needs that are having less impact on the environment". Besides that, Macdonald, S. et al. (2006) say that all consumers are potential green consumers, because when a consumer has the opportunity to choose between two products that satisfy the same need, he will prefer to buy green products.

If gender is taken into account, it was found that there is no a "significant relationship between women and men and green behaviour" (Kreidler and Joseph, 2009). However there are studies which showed that women are generally more concerned about the environment being more willing to buy green products (Mainieri et al., 1997).

If the geographic region is taken in consideration, it is demonstrated on the basis of consumer surveys that across Europe consumers express concern for the environment. Thus, they look for eco - friendly products and services, being at the same time willing to pay more for environmental features. This obvious serious concern of the European consumers for green products has led over 90% of European multinationals to adopt programs of environmental sustainability (Peattie & Crane, 2005).

People can be induced to adopt green consumption model if additional benefits, cost effective or environmentally friendly solutions are offered (Ottman, 1993).

In marketing literature is shown by research (Pickett, B. J., 2008) that product perception is influenced by situational variables and social reference groups. Also, there are studies which show that many of the consumers perceive organic products having high price and low quality (Mendleson, 1994; Ginsberg, and Bloom, 2004).

Gupta, S.et. al. (2009) referred to the „green buying behaviour". Thus, he showed that the concern for the environment and about pollution, willingness to recycle, and to pay more for environmentally friendly products form this behaviour. Many studies on this topic have been performed starting from the analysis of the willingness of the consumer to pay more for green energy (Wiser, 1998; Hansla et. al., 2007).

Marketers may contribute to change consumer behaviour by emphasizing benefits and desired features of the products in the messages communicated by the producing companies to their potential customers. In relational marketing "long term benefits" of the product are submitted, leading to attract and retain consumers for long periods (Antonies & Raaij, 1998).

Thus, consumer behaviour can be shaped by emphasizing relative advantages of eco-friendly products in comparison with those products which create environmental damages (Peattie, 2001).

Related to this, Ottman (1993) stated that consumers can be the emotionally motivated to get involved because they want to differentiate themselves from other members of society or in their groups.

Another issue taken into consideration by the American scientist J. Ottman is the period of life when certain purchasing and consumption behaviours are induced. Thus she stated that „habits are decided early in life" (1993). The conclusion is that consumers will take more favorable to environment decisions if environmental education will start early.

Instead, Peattie (2001) believes that to form such habits, companies should be those that should get involved. Thus in the early stages of forming purchasing habits, they should use some systems to reward customers.

Mass media is another factor that can contribute decisively to the the formation of buying habits. This, as a stakeholder (Ottman, 1993) and opinion promoter, can effectively convey environmental information.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

However, practice has shown that consumers tend to become suspicious in some cases when companies put too emphasis on the environment in their communication systems.

The label is another factor to be taken into account in substantiation of the decision to purchase (Chase & Smith, 1992). The label may highlight specific environmental information that can contribute to an attitude of buying a eco - friendly product.

In other words, we can say that a system of environmentally friendly communicating system can lead to a favorable attitude to green products (Baldwin, 1993).

It follows from the above that the companies need to pay great importance to developing long-term strategies (Darling et. al., 2009).

There are a number of studies that have shown that environmental issues have become important issues for the population. This, also, led to changes in purchasing and consumption behaviour. Thus, consumers become more aware of environmental issues, giving more time for the prospection stage, seeking, primarily those energy efficient products. These behavioural patterns suggest the intention of engaging in a green consumer behaviour (Roberts, 1996; Kalafatis et. al., 1999). However, the explanation may come from increased energy prices.

Factors which consumers take into account in substantiation the purchasing decision, ultimately support marketers when they design the marketing mix. Thus, if environmental factors are considered, sustainability goals can be more easily pursued. In order to achieve these objectives criteria of compatibility of the ecosystems with production systems should be considered. In this respect, Fuller stated that „Customers need to learn to base purchasing decisions not only on how well the products meet the individual needs but also on how these products affect the natural environment" (1999).

Regarding the evaluation of the substantiation of the decision to purchase, Ottman, J. (1993) stated that the products or services are evaluated not only in terms of "performance and price", but also on the "social responsibility of manufacturers".

Consumers tend to repeat purchase in those cases where post-purchasing evaluation gives them satisfaction (Wood & Neal, 2009).

Thus, the concept of customer loyalty is related to environmental concerns and decisions having an impact on them.

IMPLICATIONS OF THE SUSTAINABLE DEVELOPMENT IN CONSUMER BEHAVIOUR

Sustainable Development: Frame for Sustainable Consumption

Sustainable development offers a frame for communities for an efficient use of the resources, in order to create new commercial activities, to protect and improve the life quality, to create new commercial activities which consolidate their economy. It can help to create a healthy community, which can sustain even the actual generation, and the next one. The concept of the environmental degradation unplumbed from the economic growth by eco-efficiency promotion and by interpretation of the high standards of environmental protection as a challenge to innovation, new markets and new business development, if we take into consideration the fact that a healthy environment is essential to ensure welfare and quality of life.

Sustainability principle designates the gear of three dimensions – ecology, economy and social sphere. Mixing up the consumer behavior with the ecological dimension of sustainability is very important.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Economic development and social welfare are possible on long term, only in a well-established frame which involves nature as a vital element. The economic and social aspects are important in order to make ecology becoming feasible: ecological manufacturing and consumption are elements that can be realized only if consumer is able to afford them and if both are realized under acceptable social guidance. 30-40% of the environmental problems are based directly or indirectly on some prevailing consumption models (Using UBA, 1997, p. 1).

In this context, new strategies must propose a way for the sustainable development:

- Taking into account the quality and preservation of the environment and natural resources as essential elements of the sustainable development;
- Management of the manufacturing flow, so that, taking into consideration the finite character of resources, to facilitate and encourage reutilization and recycle at an optimum level, in order to avoid loses and depletion of natural resources;
- Modification of the plain society concordant to confined character of the natural resources, so that their consumption or use to be not made in another's detriment, so that exploitation by a generation of the natural resources to not confine consumption possibilities of the future generations.

Environmental policies components must endorse regulatory sphere, but also of the consumers and producers.

Components of the environmental policies must endorse regulatory sphere, but, also, changes in producers and consumers behavior and of the whole civil society, by financial measures and resorts. Problems of Know How transfer and communication in the environmental area must be added to those above mentioned.

The regulatory policy tools must be chosen so that they outcrop a matched mix of their, adapting them for specific application situations. They include:

- Persuasion policy, which assumes promotion of the ecological technologies and research, awareness and education and use of market mechanisms;
- Information transfer policy encompasses tools for social communication - education, mass-media and public relation – meaning informational systems affordable for public.

Traditional policies pursuing minimization of the environment harmfulness, policies having as main goals demand satisfaction with a minimum input are added in manufacturing area, production policies with a minimum output of wasted resources and, also changes in the demand profile.

Nowadays, urban environment became more and more crowded especially by increasing the frequency of the transportation activities. Urbanities specialists are highly concerned with problems of the territorial use. Planning of the territory use needs to be closely correlated with regulatory for activities of the transportation services, which must accurately reflect costs of the needs of environment rehabilitation and social costs of maintaining or development of the transportation infrastructure.

A more deepened knowledge of the premises of consumption structuring for other goods and services, is, also, necessary, as a response of the multitude of needs expresses by different consumers' categories. For instance, option for replace an old product with a new one can be underlined by many motivations – that the old one can't be mended, that the new one has superior properties, that there is a use for periodic

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

shopping. Emergency of the consumerism era, in occidental countries, was possible just as a complexity of the consumption behavior of modern people and his leaning to newness (Stanciu, M., 2006).

Paper is a consumer good, which manufacturing depends, essentially of the exploitation of wooded lands. Paper consumption, clearly reflects level of civilization and economic development for a country. But the industry of cellulose and paper is not only the biggest wood consumer in the world, but, also the third industry in the world in respect of the financial results, being, in the same time among the first ten most polluting industries. Therefore, in the next 50 years there is expected a hundred percent increasing of demand for cellulose and paper, according to The National Institute of Statistics of Romania, 2004. But, by the other hand, there are still over a billion of illiterate people and over 100 millions of children who don't yet benefit of primary school education.

Generally, encouraging of goods and services demand, mass-media and advertising industries play a decisive role. Mainly, advertising industries affect consumers' motivations, having a decisive role for consumption structuring and modelling of the concepts regarding goods and services. Some recent studies of the consumption habits sustain that manufacturing response for some consumption needs can become more sustainable, by encouraging the tacking up some services destined to contribute to the raising of sustainability of the goods already purchased, instead to encourage purchasing of new goods. These kinds of practices lead to diminishing pressure of the extractive industries to the environment that can lead to a new conceptualization of the life quality increasing. Also, some recent analyses of companies affirmed that consumers' loyalty for a brand seems to be more encouraged by a bid for services destined to extend the life of the goods in use and less by encouraging of the purchasing new products.

Sustainable consumption and manufacturing models represents an important determinant for the environmental problems at every level, from the local level to the global level. For this reason, a main object in Agenda 21 (The World Conference in Rio de Janeiro, 1992) was Changing Consumption Patterns. Sustainable consumption represents a very wise area, requesting an interdisciplinary approach. The change of the consumer behavior is a process involving many social groups: ménages, which represent the biggest group of consumers, authorities, economy, educational institutions, NGOs and many others.

A change of the consumers' behavior means primarily a fundamental transformation of the values and life style. The change of the thinking and acting kind of the consumers can't be imposed by the authorities. The emergence of new and durable traditions in consumers' behavior requests a wise informing and consulting campaign. As regards of the consumer, goods and transportation ways must become more transparent, price of the ecological true need to be clearly expressed and those alternatives for the environment protection must be as soon as possible shown.

AREAS OF ACTIVITY OF THE SUSTAINABLE CONSUMPTION

Question about the concrete measures for the implementation of the sustainable behaviour regarding consumption appears only in a second stage. A very important role was allotted for areas as:

- Avoiding of the waste products accumulation;
- Energy and water consumption;
- Mobility;
- Feed;
- Reuse of the objects.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

In order to attain a sustainable growth, material consumption of the industrialized countries must be diminish. This is possible because in the last period goods having a low content of raw material was introduced in market, for the automobile industry, for the equipment industry and for that of the wrapper. There are motives for which a decrease of the material and energy consumption doesn't necessarily lead to a diminution of the total consumption. Thus, increasing total quantity of the used merchandise cancel savings obtained in technology of their realization. Secondly, motivation for producers to realize ecologic goods is related mainly with economic interest, which operationalizes the new sustainable technologies. The classic case is represented by the fridge with low energy consumption, but more expensive than the conventional one. Another solution for the sustainable consumption consists of realization of goods having long term of working. This is only a part of the new approach, which imposes a new vision to merchandise, according consumers' needs.

There are many problems: it is not clearly how the consumers are prepared to accept prises of the ecologic goods. A strict legislation in this area imposes serious pressures to the economic agents.

They began to understand that not only attention paid to different goods separately seen. This imposes a new approach, named metabolic, which approach the whole anthropic system.

Also, they began to understand that the attention paid to different goods separately seen is not sufficient.

Some specific studies showed the ecologic impact of the services, building concept of services efficiency meaning to offer a maximum result for consumers by use a minimum quantity of raw materials and energy. The most important feature of this concept consists of the fact that in our days, satisfaction is generated not only by the products, but even by services which they provided. In other words, products offered represent only tools for services obtaining.

Implications to the Elementary Processes Which Define Consumer Behaviour

All the same, consumer behaviour is influenced by numerous variables acting tightly. Consumers' behaviour is influenced by many factors:

1. **Direct Observable Influences:**
    a. Demographic factors.
    b. Economic factors.
    c. Factors specific for the marketing mix.
2. **Endogenous Influences:**
    a. Perception.
    b. Information/learning personality.
    c. Motivation.
    d. Attitude.
    e. Exogenous influences.
    f. Family.
    g. Membership group.
    h. Reference group.
    i. Social class.
    j. Culture.
    k. Sub-culture.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

In the last two decades, social analyses, focused on goods and services consumption of the occidental people changed significantly, as regards ideatics and general sense of the message, leaving pro-consumerist messages for those anti-consumerist.

Some papers published after 2000, underlined a new criticism current in the area of consumption patterns in occidental area, highlighting more clear tendencies of some social categories, to engage in activities less oriented to consumption. Some authors, as Zavestoski (2002), Schor and Holt (2000) or Hamilton and Mail (2003) was concerned even to initiate market studies for anti-consumeristic attitude or for return to some extremely simple consumption practices, protective with maintaining the environmental ecologic equilibrium. There are analysts of the consumption patterns like Lunt & Livingstone (1992) or Humphery (1998), who study a new orientation of the consumers – to limit satisfaction of the consumption needs by different good and services markets, as a consequence of the highly critic attitudes.

Perception

The most important feature of perception is the fact that is selectivity, as being complementary for needs, because of the consumers' features.

A useful concept is just a difference indistinguishable, for instance, in cases of price increasing motivated by different factors, such as green tax. If the increasing of price doesn't exceed the difference just indistinguishable, it is possible that demand for a specific good to be not affected.

The Need of Comprehensive Regulations

The ecological manufacturing and sustainability can gain a certain influence against consumers' decisions, but the price still represents the key variable. All researchers agree this. Nobody will pay, for instance, fourfold for a fridge just for its low energy consumption. Central administrations need to establish specific regulations, to recommend minimal prices for the unfriendly goods for the environment, in order to make certain the fact that they are not cheaper than those being friendly for the environment. These could increase consumers trust.

Feelings and Emotions Consideration

There is a real potential in this area, for instance that demonstrated by the success of some brands in cosmetic industry. Companies should recognize opportunities and gains generated by the sustainable goods and shouldn't only pertain to risks and costs.

Another example in this area is represented by the fact that some studies demonstrated that those advertisings which highlight the fact that the good had in sight doesn't encompass children' work, are irritating for consumers, because they assume a priori that manufacturing is correctly from the point of view of the policies. Furthermore, terms like children exploitation have negative connotations and can cause damages to the positive experience of goods or its purchasing, irrespective of context.

In marketing terms, it is vital, the fact that green goods meet their goals, this making consumer fell that do the right things.

Selection of the consumers' perceptions is much influenced by their attitudes in the moment of their reception.

Consumers' expectations are closely linked to the process of perceptual selection, implying them percept goods and their performances from the point of view of the benefits they expect to obtain. Market

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

researches show that consumers consider first personal benefits and not these for the environment. For instance, in a supermarket consumers don't wonder first: Do I the right thing buying this? But: If I will buy this, it will be good for me? Thus, they are ready to pay more for this kind of goods. And only after that, they consider that the good must be manufactured in ecological conditions.

Reasons can play an essential role, too, in perceptual selection, being known the fact that people perceive good related their needs and desires. An intense need determines a person to ignore some perceptions and select only those are related to these satisfaction.

Information

Perception is firstly, related to the awareness/learning process, which represents an ensemble through people know goods.

In awareness process, specialists pay attention to information sources.

Researches upon consumers' behaviour and attitudes in last decades showed a real interest of them for problems of environmental harmfulness. But there is still a long distance from attitude to their transformation in practices. In real life, consumers almost don't possess information about present and future effects of consumption decisions to environment or to other people.

In the same time, consumers manifest their decisions in a world where merchandise already are in last processing stage a major change being hard to obtain. The observed changes in consumer behaviour can be seen only in tight areas; they must be supported by strong awareness campaigns in order to become dominant market behaviour being significant for producers. But there is another dike: market is already saturated by advertising messages that increase chances that these campaigns be fast forgotten.

Generating important changes will occur only after a radical change of consumers' attitude. This requests a redesigning of prices policies in order that non-harmful for the environment goods to be chosen and opposite policies to be punished. These request other policies for consumers' information. A study performed in 1990 by Winkler and Voller identified a correlation between consumers' attitude and environmental impact of goods. This correlation was revealed related domestic energy consumption which decreased in those countries where ecological attitude increased, Holland, Germany, Denmark, and Sweden.

Attitude

Attitude was accepted more and more as a multidimensional concept, as a syndrome of constant reactions against social objects (WBCSD, 1996).

An interesting fact is that, in fact, consumers are not concerned directly in reducing energy consumption, but in a specific choice about buying daily goods. Consumers take decisions when use or discard concrete goods. This means that concrete manifestations of these mental attitudes need to be analysed.

Globally, specific studies identified phenomena of take-over consumption models from developed countries by the developing countries; there is a problem regarding this because first habits related goods having most important impact against environment (cars, steel, and electricity), whilst consumption models for less harmful goods are less convincing. Though, solution consists of modelling consumption attitudes.

Care for environment protection is confronted with interest for personal satisfaction obtaining.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Investments for Sustainability

Transparency and accessibility of goods and producers are essential both for consumers and stakeholders. Many companies accomplish increasingly sustainability criteria. A specific degree of this criteria knowledge can determine consumers of the goods they offer to identify themselves with these companies' values.

Motivation

Motives have a broad multidimensional character, being built between biologic and social, between internal manifestations and knowledge, between subjective necessity and values as reference system, between objects and their linkages with people. Because of these they can't be reduced only at a determinant factor. In order to design an efficient marketing policy, it is important to concern that motives are learnt and they have stability in time, being hardly changeable.

Effective Behaviour

Effective behaviour is not an autonomous process, though it can be studied relatively independent; it is a specific resultant of a system constituted of the above-mentioned elementary processes.

Avant-Gardist Demand

There are practically demonstrations of the fact that avant-gardist demand establishes trends which involve most of the consumers. In this respect, female consumers play a decisive role as follows they manifest much more responsibility and involvement in buying acts. They stand on utility, longevity and social or ethical standard.

THE GREEN DIMENSION OF THE MODEL OF CUSTOMER SATISFACTION

Drivers of the Green Dimension of the Model of the Assessment of Consumer Satisfaction

Reality has shown that proactive, long term, visionary strategies, companies bring more benefits for companies than those based on classical management based on traditional resources. The companies concern for the environment represents, from this perspective, an opportunity. Thus an organization will gain a competitive ecological advantage over the competition ecological if it is "better" than this, in terms of environmental issues, at least in a specific area.

The companies' interest for environment first appeared in campaigns for social responsibility inspired by the multinationals model. The adoption of "green" strategies has been boosted, too, by environmental regulations in certain areas.

In the current context, economic organizations are evaluated not only in terms of economic performance, but also in relation to their contributions to economic and social development of the community. Thus, the concept of social responsibility (SR) emerged. WBCSD World Business Council Sustainable Development) defined corporate social responsibility as "the Continuing Commitment by business to

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

contribute to economic development while improving the quality of life of the workforce and Their Families as well as of the community and society at large" (WBCSD Business Solutions for a sustainable world). Thus, SR aims to help companies to become actively involved in local community life, enabling them to assume roles as global citizens and local neighbours in a fast-changing world. Such programs have become, genuine marketing tools designed to bring image benefits for their proposers. Corporations acquire "human face" is more than just products and services (Sima & Gheorghe, 2007).

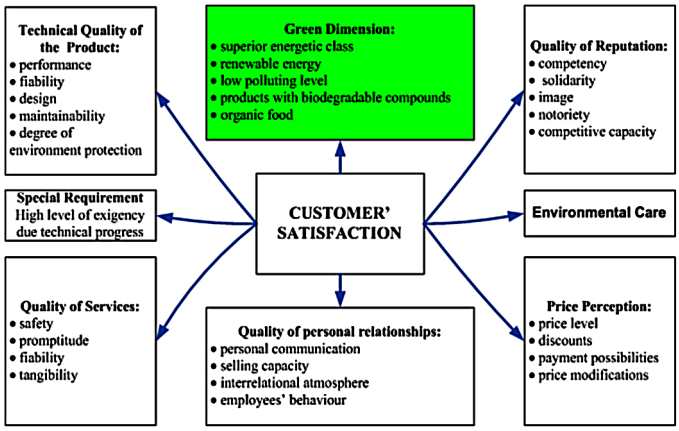
"More green means cheaper." Investment in "green products" is manifested as an eco-trend in business. Some players have already intuited this trend and began to pay attention to this segment.

Companies that make the step to launch organic products want to achieve consumer awareness by associating their image with clean products, but they also look for new customers.

People want an ecological approach to everyday life, but they seek, primarily, personal gain, which can be transposed into incentives and facilities.

On the one hand, green customers and the public generally are more aware to the ecological behaviour of organizations and to their social involvement.

On the other hand, organic products and environmental activities are not easily accepted by a large part of the audience, especially by the one who does not have a strong and clear ecological awareness.



The degree of concern for the environment has increased significantly, so that environmental problems have come to represent now an essential factor in making consumer decisions.

The items presented above have led us to take into account a new category, in modeling and evaluation of customer satisfaction, which the authors have called Green Dimension. (Figure 1).

ECSI model was the starting point. In relation to the determinants of ECSI model, green dimension can be justified at least by a few elements namely:

- In terms of *image*, green dimension can be expressed in the concept of Corporate Social Responsibility. CSR activities of a company provide benefits at two levels: the social level and the company level. The social benefits are related to the welfare and the public interest. In terms of benefits of the company, at least four issues are to be mentioned, namely:

Figure 1. A new model of the assessment of customers' satisfaction
Source: Sima, 2010.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

- Possibility of differentiation over the competition and achieving brand loyalty. There are studies which have shown that when consumers have to choose between similar products, their preferences are turning to those brands perceived as being "responsible". Thus:
  - 70% of European consumers believe that the responsibility of a company is important in the decision to buy a product or service (MORI 2000)
  - 86% of Americans were inclined to change a brand in favour of another similar, but involved in a social cause (2004 Cone Corporate Citizenship Study).
- Improving the company reputation. Currently, companies' success depends directly on the trust given them by the authorities, media, partners and the community in which it operates. On the other hand, if a company demonstrates its responsibility to the community, the related to reputation benefits have immediate consequences. Thus:
  - 61% of opinion leaders around the world are willing to recommend the products of a responsible company (The Insightpoll.com Opinion Elite Panel 2004),
  - 84% of Americans believe that social responsibility is important when they think about the companies they agree to see operating in their community (2004 Cone Corporate Citizenship Study.
- Increased sales and market share of the company
- Attracting and retaining valuable employees.

- In terms of *perceived value*, The Green Dimension may be considered in many respects. Thus, in Romania, Daedalus Consulting and Green Report conducted the first quantitative Romanian research on environmental issues. The result of the survey was published in February 2008 and showed a high willingness of Romanian people to pay more for green products. Compared to values at international level, almost 90% of Romanian citizens have expressed willingness to pay more for environmentally friendly products. After Romania, according to the TGI survey the highest availability was recorded in Brazil, India and Mexico. Countries that were not subjected to the rigors of environmental discipline are top ranking. This result can be explained by the fact that those countries, not having the costs experience of these measures, have a higher receptivity to them. Thus a few results are noticeable:
  - Over 73% of respondents are willing to pay more for organic food.
  - Over 49% of respondents are willing to pay more for renewable energy.
  - Over 36% of respondents are willing to pay for products with biodegradable compounds. (Daedalus Consulting, Green Thinking, prepared for Green Report, 2008)
- In terms of customer expectations, The Green Dimension can be primarily expressed by their expectations about the energy efficiency of products, meaning that they seek products operation of which does not require high energy consumption. Also, customers have expectations regarding low emission of pollutants. A good example is the case of passenger cars, for which the level of the paid taxes is inversely proportional to the emissions level. It appears, therefore, that customer expectations related to green product features are primarily determined by the pragmatic attitude of the new consumer.
- Regarding perceived quality of the green products, the green dimension can be recognized in the low polluting level of the eco-friendly products, due to the use of new production technologies.

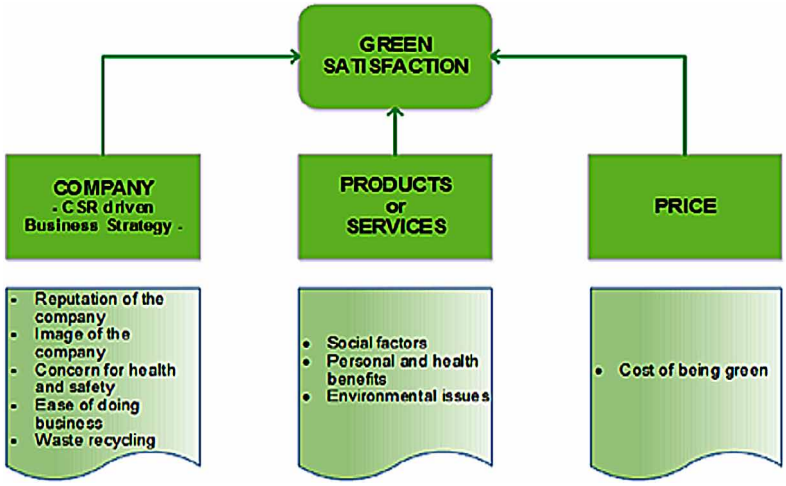
EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Specific Issues of the Green Dimension for Customers Satisfaction

People seek personal benefit rather than an ecological approach of the everyday life. Beyond awareness, the ecological approach should be assumed by consumers (Sima, V., Gheorghe, I.G., 2009).

The question arises is: How strong is consumer interest in environmental issues?

Based on the results recorded in The 2009 BBMG Conscious Consumer Report: Redefining Value in a New Economy, Raphael Bemporad, co-founder of BBMG, said that brands would be able "to close the green trust gap" if they would take into account new customer expectations, which evaluates acquisitions "based on both value and value" (BBMG Conscious Consumer Report: Redefining value in a new Economy, June 2009, p.34). Thus, they have to provide performance products that match consumers' goals; with acceptable prices that for them.



Taking into account the above, we can identify three specific levels of customer satisfaction green dimension, namely (Figure 2):

- Company;
- Product/Service;
- Price.

The Company Level: Consumers Reward Those Brands Which Are Based on the Best Practices of the Company

In addition to the classical requirements such as economic performance, quality management and communication policies, a modern assessment of a company is also considering specific issues such as the organization's involvement in the social life of the community. Modern organization as a legal entity - has primarily, duties to society.

Figure 2. Tree of customer satisfaction for the green dimension
Source: Adapted after Sima and Gheorghe, 2009.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Customer satisfaction is considered by Scott M. Smith as "a reflection of the expectations and experiences that the customer has with a product or service".

Evaluation of products and services is actually made following customer expectations. They are found in the rules of performance that reflects accepted environmental standards set by the business environment, other companies, industries, and even organizational and national culture. The most effective strategic approach seems to belong to those companies that have adopted social responsibility and sustainable development as a business philosophy. Integrating social and sustainability principles in their operation provides long-term value for the shareholders through practices that are, in fact, satisfactory to all stakeholders. Social Responsibility was developed by taking into account environmental and social opportunities as business opportunities. In this respect, the strategic capacity of organizations is adapted in order to efficiently exploit such opportunities.

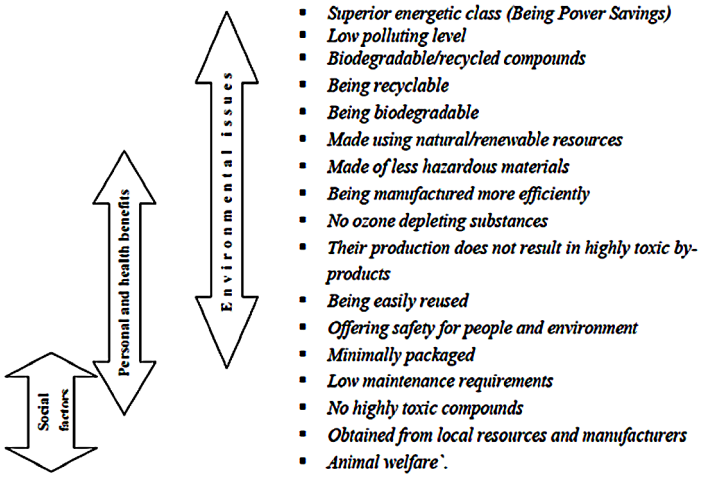
The new consumer is increasingly more concerned about his image that reflects the image of his suppliers. Therefore, their reputation becomes, in turn, increasingly more important to the consumer. Thus elements which are subject of social responsibility activities such as concern for health and safety as well as customer requests, ensuring environmental conservation, supporting philanthropy, come to be positioned in the core of companies concern. The result of such strategic approach is to eliminate barriers of communication with the customer, such as mistrust, negative perceptions, lack of information, low availability, leading, ultimately, to increase sales of environmentally sensitive products. The importance of each factor varies by product, industry and geographic area.

The 2009 BBMG Conscious Consumer Report: Redefining Value in a New Economy has found that 77% of American consumers agree that "can make a positive difference by purchasing products from socially or environmentally responsible companies".

The Product/Service Level: Consumers Are Looking for "Green" Features of the Products and Services

Climate changes seem to be those that have drawn attention to environmental issues in the greatest extent. At the same time rising energy prices is another factor that appears to significantly influence the buying decision. Thus, the consumers are getting more and more interested, firstly, in products of high energy efficiency classes. At the same time the low level of environmental damage may represent an important factor in decision of purchasing. The conclusion is that, firstly, the personal benefits are tracked and only after that the ones affecting the environment.

The most popular and demanded "green products" are:



- Organic food.
- Renewable energy.

But in addition, other important ecological features of the products / services may be considered to represent important factors in purchasing decisions: "superior energetic class, low maintenance requirements, low polluting level, biodegradable/recycled compounds, no highly toxic compounds, being easily reused, recyclable or biodegradable etc." (Sima & Gheorghe, 2009).

Thus, in terms of involvement in purchasing decisions, environmental issues can be classified in three categories, namely: environmental issues, personal benefits and social factors (Figure 3).

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Green satisfaction sources
Source: Sima and Gheorghe, 2009.

The Price Level: Consumers' Willingness to Pay More for "Green Products/Services"

There are numerous studies conducted all over the world that show the green procurement volume is increasing, but the question that arises is: Are the consumers willing to pay more for green?

A McKinsey survey of 1,000 consumers in Europe and the United States performed in 2012, showed that many people would pay more, but only up to a point (Miremadi et. al., 2012). The study took into account acquisitions in the automotive, building, electronics, furniture, and packaging categories. Between 70 and 80 percent of the respondents said they would pay an additional 5 percent for a green product if it is at the same level of performance as a non-green alternative. But as the premium increase first, willingness to pay decreases.

The "historical" reluctance to pay a bonus for ecological products is reduced as consumers associate the responsibility for protecting the environment to their health and other direct benefits.

The core of this internal belief system is ecological value.

Ecological value can be explained by implicit or explicit philosophy of desired value and it may be placed as a behavioral variable within the system of values.

THE GREEN STRATEGY MIX: A NEW HOLISTIC APPROACH

Two international studies, conducted in 2009 (Sustainability in the 2009 Recession and Green Brands Survey 2009) showed that the recession has not lowered the interest in 'green' products or services, quite the contrary. Worldwide consumers associate ecologic products with the idea of reducing consumption and saving, despite the fact that the main barrier for purchasing of these products is the perception that their price would be higher than that of the classic ones.

In January 2009, the Boston Consulting Group presented the results of a study entitled "Capturing the Green Advantage for Consumer Companies". The aim of this study was to discover if and how

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

consumer attitudes towards green products and services has been affected by the economic crisis. The conclusion was that during the crisis, consumers remained interested in organic products. Determinants of this behavior were represented by the benefits that eco-friendly products have, on the one hand, upon the environment and, on the other hand, at the personal level. As a conclusion, BCG advised companies on how to respond to consumer expectations regarding environmental protection being, in the same time, able to reach, their business targets.

It should be noted that the study was conducted in a gray period, characterized globally by uncertainties, among others, regarding the appropriateness of investing in new environmental strategy.

As a concrete result of the study a best practice guide for the company was drawn up.

In this guide advices for companies were offered, divided into four categories, based on which companies can meet consumer requirements on environmental protection and their business objectives. The four categories are:

1. Planning,
2. Process,
3. Product, and
4. Promotion.

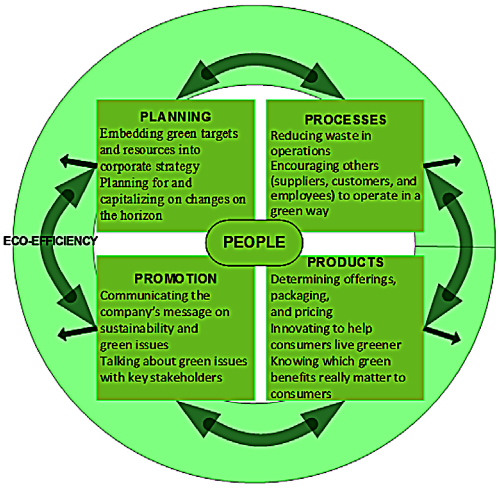
From our point of view, "the green products and services are designed, manufactured, priced and promoted by people for people" (Sima & Gheorghe, 2009). This approach has led us toward a holistic approach of green satisfaction, according to which people and their double the role of producers and consumers should be in the same time considered.

Some analysts say that for companies, there is only one thing which is more important than environmental initiatives, namely the ability to communicate it to consumers.

Thus, in terms of green strategy, we consider that a fifth element can be added, namely the People.

Another observation we had regard was that the eco-efficiency represent a production principle requested by the green products. It refers to less polluting production systems used to produce goods and services which have a lower environmental impact, which better corresponding with customer needs, being, thus, more competitive.

Starting from this, the authors, also, integrated Eco - Efficiency into a mix strategy that they named "The Green Strategy Mix" (5P+EE) (Figure 4).



- Planning Strategy;
- Processes Strategy;
- Product Strategy;
- Promotion Strategy;
- People Strategy;
- Eco-Efficiency Strategy (Sima & Gheorghe, 2009).

The first four was highlighted by the Boston Consulting Group into a recent study, aiming to assess green attitudes and shopping behaviors. They call them *The Four Ps of Green Advantage.*

Being "green" has become a business plan itself. Producers attempt to differentiate the competition and gain a large share of the market. There is a "green" competition, in which each company tries to

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. The 'Green Strategy Mix'
Source: Sima and Gheorghe, 2009.

move forward, aiming to move forward having regarded the continuous growth of the customer preferences for 'green' products.

Nowadays, producers, not just consumers, seem to show a wave of interest in the environmental aspects of the business, because they realized that eco-environmental production methods and can be profitable. So we can say that in a comprehensive approach, the strategic mix can be improved.

Given the continued growth of customer preferences for 'green' products, the existence of a product having a less impact on the environment, in the company's portfolio, it is often better in terms of quality and marketing.

Being "green" has become a business plan itself.

SOLUTIONS AND RECOMMENDATIONS

Four main determinants of population's attitude towards the green dimension can be identified:

1. Phenomena with negative environmental effects;
2. Activities to protect environment;
3. Willingness to save and motivation for it;
4. Willingness to pay extra for green products and justification for it.

Phenomena With Environmental Impact

According to the above mentioned study conducted by Daedalus Consulting in Romania in 2008, atmospheric pollution and deforestation are considered to have the highest environmental impact (Over 84% of respondents placed this issues on the first and second place). Respondents considered that pollution can be greatly influenced by each of us.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

These two results seem to be in a relationship of interdependence that can be verified in future research through correlation analysis.

Genetically modified foods are ranked third, nearly of the above mentioned two categories.

Regarding how respondents considered that they might influence each of these phenomena, it can be observed that in all cases the population is considered largely unable to act.

Activities for Environment Protection

As regards activities for the environmental protection, there is a clear correlation between the activities about which respondents say they have performed over the past 12 months and those who declare that they intend to undertake in the next 12 months.

There is also an increase of approximately 10% of those who declare that they intend to be involved in such activities in future, which may suggest a tendency to declare rather to act or to reflect the behavioural changes induced by economic recession.

Willingness to Save and Justification for It

Regarding products that respondents say they save, the most name energy (over 70%). On the second place they considered water (60%).

Regarding the reasons for showing this kind of attitude, most respondents stated that they try to reduce costs (85%) and only 13% say they care about environment.

This shows serious problems in society and requires a deep study in order to identify determinants of this behaviour to improve.

"Green Products" and Willingness to Pay More for Them

The products were grouped into three categories: organic food, renewable energy and products with biodegradable compounds.

Organic foods are outlined of these, almost three quarters of the respondents (73.1%) saying they were willing to pay higher amounts. About a half (49.1%) were willing to pay more for renewable energy and almost a third (36.3%) for products with biodegradable components.

And this result match to the behavioural pattern mentioned above, showing that for Romanian people care for the environment not prevail, but rather care for them.

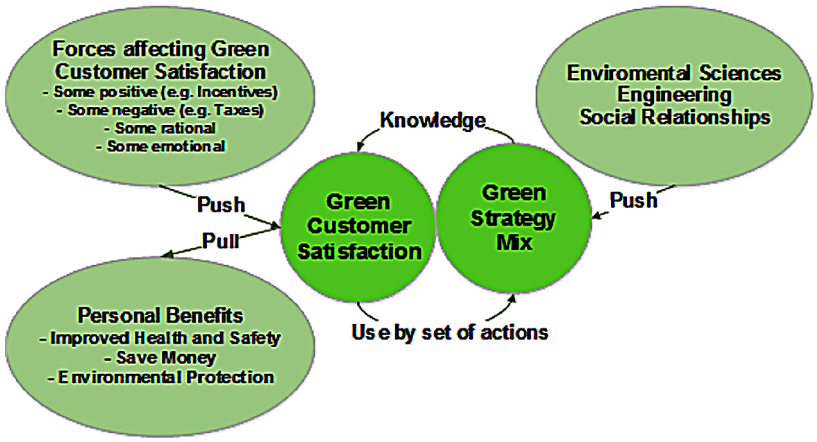
A mismatch occurs when respondents are asked to respond if they are willing to pay more for "green products". On this question, nearly two-thirds affirmative answer, and if we add them those who are in partial agreement, we achieve a percentage of over 84%. This response comes, however, contradict the results mentioned above. Thus, this it seems to support, too, the conclusion that the people of Romania are well in words, but less than in facts.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

FUTURE RESEARCH DIRECTIONS

All of these above mentioned elements determine a model of an ecological community, including:

- **Resource Ecology:** Identifying local resources that can be ecologically exploited;
- **Activity Ecology:** Directing investment towards non-polluting activities (ecological agriculture, "clean" technologies, ecological services, ecological tourism etc.) and writing and implementation of local development projects that take into account ecological constraints;
- **Ecological Behavior:** Building awareness within the local community regarding the serious long-term consequences of non-ecological behavior (development of ecological citizenship);
- **Ecological Culture:** Introduction of ecology information in school curricula, as a support for the formation of ecological culture.



Given the above, we believe that an investigation should be conducted in order to helps us to shape and measure the consumer green behavior. The ultimate goal is to develop a system of indicators which may be used to measure the green satisfaction of the consumers, namely, Green Dimension Index.

The starting point of this research will be the model shown in Figure 5.

CONCLUSION

Operationalizing studying of the needs, values, behaviours, psychology or aspirations of goods and services consumers is a laborious and complex process because every chapter of people consumption as well as market dynamic of every good or service follow specific laws and there are necessary separate investigations for every good or consumption chapter, in order to explain or forecast general or sequential behaviour of the consumers.

Figure 5. Model for Green Dimension index evaluation
Source: Proposed by the Authors.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Nowadays, there is no exhaustive understood of consumption components or of real motivations for adopting specific consumption practices, even in this area there already are accumulated many studies, observations and methodical researches.

But it was never possible an investigation totally satisfying in respect of the rationality of the consumers, so much the less in respect of the unconsciousness impulses lying the effective consumption behaviour. Anyway, the social and economic theory of consumption mad important steps in respect of the delimitation between rational and emotional motivations of goods and services purchasing.

Changes dynamic in goods and services markets was very high in the last two decades. In those countries having market economies, where profile if demand rapidly changed, these lead to a rapidly change of the offer parameters and default changes of some elements of the research methods and techniques of the consumption patterns.

Adoption of some sustainable practices of consumption involves use of correlated goods and services which answer to satisfaction of basic needs, under conditions of minimization of the natural resources exploitation, avoiding resources waste and polluting emissions, along an entire life-cycle, so that these don't affect life chances of future generations.

Desirable changes of some features of the consumption patterns as follow as new exigency imposed to manufacturing processes involve:

- Promotion of the examination of those consumption patterns which block sustainable development, as well as of the modalities of changing this behaviour, at global level, endorsing especially those people having a consumerist life style.
- Identification of the most efficient policies and tools for break-up the unsustainable consumption/manufacturing patterns, including by information dissemination and ecological alert.
- Performing a more equitable distribution of developing resources inside and between countries.

KEY TERMS AND DEFINITIONS

Green Behavior: A pro-environmental behaviour, people being good administrator of natural resources.

Green Customer Satisfaction: A state which results from the green consumption experience, including: green product satisfaction, companies reputation and image satisfaction, and less harmfulness satisfaction.

Green Dimension: A new category proposed in order to model the customers' satisfaction. The main elements need to be had in sight are: superior energetic class, renewable energy, low polluting level, products with biodegradable compounds, organic food.

Green Product: An ecological product. It's manufacturing process and its use does not generate negative environmental effects.

Green Strategy Mix: A strategic system which integrates Planning Strategy, Processes Strategy, Product Strategy, Promotion Strategy, People Strategy, and Eco-Efficiency Strategy.

Sustainable Consumption: A consumption model which seeks to preserve resources for future generations to be able to satisfy their needs.

Sustainable Development: A concept "that meets the needs of the present without compromising the ability of future generations to meet their own needs" (Brundtland Commission, 1987, Report of the World Commission on Environment and Development, United Nations). It includes economic development, social development and environmental protection.

Chapter 9
Green Marketing in India:
A Theoretical Perspective

Ajit Kumar Shukla
Mahatma Gandhi Kashi Vidyapith, India

ABSTRACT

Green marketing is the study of all efforts to consumer, produce, distribute, promote, package and reclaim products in a manner that is sensitive or responsive to ecological concerns. As consumers, we simply don't think about it on a day-to-day basis because the message does not surround us. Most of us did not grow up in a resource starved environment and so the implications of wastefulness have had no direct repercussions on our daily lives. We acknowledge the issue is out there and demonstrate concern for what is being done to improve our collective condition but beyond recycling or an interest in non-toxic HH cleaning products, we simply don't have access to green products or services, let alone do we have an understanding for how to evaluate their functionality or benefit- to us or the environment. In the present study narrows down on one specific area and that is to measure the awareness level of the customers with reference to the green marketing.

INTRODUCTION

The term green marketing generally sends shivers down to our spine. Still very much in its nascent years, the term has developed enough baggage to seemingly constrain it to a niche audience. However, all macro trends start in a micro-fashion and green marketing has both a global scientific grounding and non-debatable symbolic characteristics finding it. That is to say that green marketing has a clear and substantive role in driving forward the dialogue and demand for sustainable products and services, which ultimately will influence real change in the marketplace with long term implications for our resource consumption and environmental preservation. Green Marketing refers to holistic marketing concept. It comprises the planning, development and promotion of products or services that satisfy the needs of consumers for quality, output, accessible prices and service, without however a negative effect on the environment, with regard to the use of raw material, the consumption of energy etc.

Prothero & Fitchett (2000) argue that greater ecological enlightenment can be secured through capitalism by using the characteristics of commodity culture to further progress environmental goal. Marketing not only has the potential to contribute to the establishment of more sustainable forms of society but, as a principle agent in the operation and proliferation of commodity discourse, also has a considerable responsibility to do so.

Karna, Hansen, & Juslin (2003) interpret that proactive marketers are the most genuine group in implementing environmental marketing voluntarily and seeking competitive advantage through environmental friendliness. The results also give evidence that green values, environmental marketing strategies, structures and functions are logically connected to each other as hypothesised according to the model of environmental marketing used to guide this study.

Sanjay K. Jain & Gurmeet Kaur (2004) in their study environmentalism have fast emerged as a worldwide phenomenon. Business firms too have risen to the occasion and have started responding to environmental challenges by practicing green marketing strategies. Green consumerism has played a catalytic role in ushering corporate environmentalism and making business firms green marketing oriented. Based on the data collected through a field survey, the paper makes an assessment of the extent of environmental awareness, attitudes and behavior prevalent among consumers in India.

Donaldson (2005) in his study realized in the Great Britain initially concluded that in general the ecological attitude of consumers changed positively. This study reported the strong faith of consumers in the known commercial brands and in the feeble behaviour referring to the "green" claims, which was the main cause behind the consuming failure to interpret their concerns beyond the environment in their behavior.

According to the American Marketing Association, green marketing is the marketing of products that are presumed to be environmentally safe. Thus green marketing incorporates a broad range of activities, including product modification, changes to the production process, packaging changes, as well as modifying advertising. Yet defining green marketing is not a simple task where several meanings intersect and contradict each other; an example of this will be the existence of varying social, environmental and retail definitions attached to this term.

William J. Stanton (1986) manifests, 'Green Marketing is any marketing activity of an institution that is intended to create a positive impact or to lessen the negative impact of a product on the environment in order to capitalize on consumer's concerns about environmental issues. It encompasses everything from using recycled material in making a product to claim on advertising or on package labels.'

Thus, Green Marketing is the movement by companies to develop and market environmentally responsible products. Other similar terms used are Environmental Marketing, Ecological (Eco) Marketing, Eco-centric Marketing, Environmentally Responsible Marketing, and Responsible Marketing.

OBJECTIVE OF THE STUDY

The main objectives of the study are as following:

1. To throw light on the awareness levels of the customer in the various age groups regarding their understanding about green marketing in India particularly in Uttar Pradesh.
2. To elaborate the awareness levels of the customer in the various geographical areas regarding their understanding about green marketing in India particularly in Uttar Pradesh.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

RESEARCH HYPOTHESIS

The following Null hypothesis has been tested as a part of research:

HO1: There is significant difference in the awareness levels of the customers in the various age groups regarding the green marketing.

HO2: There is significant difference in the awareness levels of the customers in the various geographical areas regarding the green marketing.

RESEARCH METHODOLOGY

The study has been exploratory in nature and a sample survey method has been employed for data collection. Primary data is used for the purpose of the study. Research design for this research is planned structure and strategy of investigation conceived so as to obtain answers to research question or objectives and also to control variances. The said study is conducted to understand the behaviour of the customers in Uttar Pradesh while purchasing an environment friendly car and also to understand their willingness to pay more in case the environment friendly car cost more. The scope of the research is limited to environment friendly car in Uttar Pradesh.

Sampling Design

In the present study, all the cars owners or prospective car buyer in Uttar Pradesh is considered as the population. The prospective car owners could be all those people who intend to buy a car in near future or are visiting the car showroom for a test drive or for collecting the information of the cars.

The Sample

The sampling plan used has been consistent with the methodological guidelines provided for conducting survey research in marketing. The stratified random sampling technique was used for the present work. A sample of 500 respondents was selected with the help of stratified random sampling method. The sample has been chosen at selected dealers of cars in big cities e.g. Varanasi, Lucknow, Kanpur, Ghaziabad, Aligarh, Meeruit, Allahabad, Jhansi, Gorakhpur etc. and few small cities i.e. Mirzapur, Gazipur, Ballia, Muradabad, Bareily, Sultanpur, Etawah, Saharnpur, Rampur, Faizabad, Jaunpur etc. in Uttar Pradesh. These included prospective car buyers and people who came to buy their next car. The sample consisted on the basis of demographical variables such as, qualification, and place of stay.

Data Collection Tools

A non-disguised structured questionnaire has been used as the tools for collection of data from the field. It has been designed with utmost care so that accuracy of the work could be high. The five point Likert scale has been used for the research purposes. A pilot study was undertaken first in order to determine whether the questionnaire and the scale is easily understood and responded to by the respondents.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Data Collection Process

A pilot study was also undertaken to pretest the questions in order to determine whether they are easily understood and responded to by the respondents. The automobile dealers were selected in both metros and non-metros as the ideal place for identifying the respondent who would be interested in buying a car. The people who had already owned cars or who are thinking of buying a car and have approached the showroom of a car dealer for buying a car have been considered as potential respondents. Data was collected with the help of the structured questionnaire has been tabulated, analyzed and interpreted using suitable statistical tools including the t test, and simple percentages. Tables have facilitated the representation of the data. The data was analyzed using the SPSS (Statistical Package for Social Sciences) While constructing the questionnaire researcher has made every effort to take the view of the prospective buyers towards the manufacturer. The flow of the questions is from the most general topic about the basic awareness on pollution by automobiles, carpooling, use of public transport etc. to set the flow of the respondent. Customer's expectation from the government is also being measured as a part of the study. Role of the regulator and legislation which can prompt customers to buy EFC is also explored in the questionnaire. The various factors which are important in buying a car have been carefully considered after discussing with the buyers and the sellers in the market place. Customers were expected to rank these factors in the order of their preference. Environment friendly design has also been considered as a factor to understand where this factor stands in the order of the preference while buying the EFC. The reliability of the scale was checked with the sample size as 100, which is 20 percent of the total sample size. All the filled up questionnaires have been screened for completeness and the ones in which responses of all the statements have been complete, were selected for analyses. The questionnaires incomplete in any respect were rejected.

GREEN PRODUCTS AND ITS CHARACTERISTICS

The products those are manufactured through green technology and that caused no environmental hazards are called green products. Promotion of green technology and green products is necessary for conservation of natural resources and sustainable development. We can define green products by following measures:

- Products those are originally grown,
- Products those are recyclable, reusable and biodegradable,
- Products with natural ingredients,
- Products containing recycled contents, non-toxic chemical,
- Products contents under approved chemical,
- Products that do not harm or pollute the environment,
- Products that will not be tested on animals,
- Products that have eco-friendly packaging i.e. reusable, refillable containers etc.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

MARKETING MIX OF GREEN MARKETING

When companies come up with new innovations like eco friendly products, they can access new markets, enhance their market shares, and increase profits. Just as we have 4Ps- Product, Price, Promotion and Place in marketing, we have 4ps in green marketing too, but they are a bit different. They are buttressed by additional Ps, namely People, Physical Evidence, Process, Probe, Politics, Penetration, Plan, Positive Implementation, Priority, Partition, Public Relations, Packaging, Performance, Power, Precedent, Perception, Participation, Profit, Position, Peerless, Productivity and Planet.

1. **Product:** The term is applied to systems and products that save energy directly or indirectly. It describes a product that meets on of these criteria: (1) It has qualities that will protect the environment. (2) It has replaced artificial ingredients with natural ingredients e.g. Organic products, Paperless transactions. The marketer's role in product management includes providing product designers with market-driven trends and customer requests for green product attributes such as energy saving, organic, green chemicals, local sourcing, etc., For example, Nike is the first among the shoe companies to market itself as green
2. **Price:** Green pricing refers to an optional utility service that enables customers of traditional utilities to support a greater level of utility investment in renewable energy by paying a premium on their products via electronics medium. Green pricing takes into consideration the people, planet and profit in a way that takes care of the health of employees and communities and ensures efficient productivity.
3. **Promotion:** A specific type of promotion that is centered around the factors having to do with the environment. Often times the companies that use green promotion also use very environmentally friendly operations and product packaging as well. Green promotion involves configuring the tools of promotion, such as advertising, marketing materials, signage, white papers, web sites, videos and presentations by keeping people, planet and profits in mind.
4. **Place:** Green Place practices and strategies that reduce the environmental and energy footprint of freight distribution. It focuses on material handling, waste management, packaging and transport Green place is about managing logistics to cut down on transportation emissions, thereby in effect aiming at reducing the carbon footprint.

SIGNIFICANCE OF GREEN MARKETING

Green marketing offers business bottom line incentives and top line growth possibilities. While modification of business or production processes may involve start-up costs, it will save money in the long term. For example the cost of installing solar energy is an investment in future energy cost savings. Companies that develop new and improved products and services with environmental impacts in mind give themselves access to new markets, substantially increase profits and enjoy competitive advantages over those marketing non environmental responsible alternatives. Issues like Global Warming and depletion of ozone umbrella are the main for the healthy survival. Every person rich or poor would be interested in quality life with full of health and vigor and so would the corporate class. Financial gain and economic profit is the main aim of any corporate business. But harm to environment cost by sustain business across the

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

globe is realized now though off late. This sense is building corporate citizenship in the business class. So green marketing by the business class is still in the selfish anthological perspective of long term sustainable business and to please the consumer and obtain the license by the governing body. Industries in Asian countries are catching the need of green marketing from the developed countries but still there is a wide gap between their understanding and implementation.

CHALLENGES IN GREEN MARKETING

Need for Standardization

It is found that only 5% of the marketing messages from "Green" campaigns are entirely true and there is a lack of standardization to authenticate these claims. There is no standardization currently in place to certify a product as organic. Unless some regulatory bodies are involved in providing the certifications there will not be any verifiable means. A standard quality control board needs to be in place for such labeling and licensing.

New Concept

Indian literate and urban consumer is getting more aware about the merits of Green products. But it is still a new concept for the masses. The consumer needs to be educated and made aware of the environmental threats. The new green movements need to reach the masses and that will take a lot of time and effort. By India's Ayurveda heritage, Indian consumers do appreciate the importance of using natural and herbal beauty products. Indian consumer is exposed to healthy living lifestyles such as yoga and natural food consumption. In those aspects the consumer is already aware and will be inclined to accept the green products.

Patience and Perseverance

The investors and corporate need to view the environment as a major long-term investment opportunity, the marketers need to look at the long-term benefits from this new green movement. It will require a lot of patience and no immediate results. Since it is a new concept and idea, it will have its own acceptance period.

Avoiding Green Myopia

The first rule of green marketing is focusing on customer benefits i.e. the primary reason why consumers buy certain products in the first place. Do this right, and motivate consumers to switch brands or even pay a premium for the greener alternative. It is not going to help if a product is developed which is absolutely green in various aspects but does not pass the customer satisfaction criteria. This will lead to green myopia. Also if the green products are priced very high then again it will lose its market acceptability.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

STRATEGY FOR GREEN MARKETING

Marketing Strategy decision plays a vital role in designing the low waste product systems that serve as pollution abatement mechanisms.

The marketing strategies for green marketing include:

- Marketing Audit (including internal and external situation analysis)
- Implement marketing strategies
- Develop a marketing plan outlining strategies with regard to 4Ps
- Plan results evaluation
- Challenges ahead
- Green products require renewable and recyclable material, which is costly
- Requires a technology, which requires huge investment in R&D
- Water treatment technology, which is too costly
- Majority of the people are not aware of green products and their uses
- Majority of the consumers are not willing to pay a premium for green products.

PRESENT TRENDS IN GREEN MARKETING IN INDIA

Organizations believe they have a moral obligation to be more socially responsible. This is in keeping with the philosophy of CSR which has been successfully adopted by many business houses to improve their corporate image. Firms in this situation can take two approaches:

- Use the fact that they are environmentally responsible as a marketing tool.
- Become responsible without prompting this fact. Governmental Bodies are forcing Firms to become more responsible. In most cases the government forces the firm to adopt policy which protects the interests of the consumers. It does in following ways:
- Reduce production of harmful goods or by products
- Modify consumer and industry's use and /or consumption of harmful goods; or
- Ensure that all types of consumers have the ability to evaluate the environmental composition of goods.
- A Firm develops a technology for reducing waste and sells it to other firms.

There are many institutions/organizations which are busy to protect environment by various means. Some of them are following:

- **State Bank of India:** SBI is entered into green service known as "Green Channel Counter". SBI is providing many services like; paperless banking, no deposit slip, no withdrawal form, no checks, no money transactions form, All these transaction are done through SBI shopping & ATM cards.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

- **Patanjali Ayurved Ltd.:** Patanjali Ayurved Ltd. uses maximum green vegetables and herbs in its medicines and also uses green colour in its packaging to make awareness among the people about environment.
- **McDonald's:** McDonald's restaurants use paper tray, paper glass, paper cup, paper bag during their services.
- **Indian Oil's Green Agenda Green Initiatives:** Indian Oil is fully geared to meet the target of reaching EURO-III compliant fuels to all parts of the country. Major cities will upgrade to Euro-IV compliant fuels by that time.
- **Wipro's Green Machines:** Wipro Infotech was India's first company to launch environment friendly computer peripherals. For the Indian market, Wipro has launched a new range of desktops and laptops called Wipro Greenware.
- **Going Green: Tata's New Mantra:** Tata Motors is setting up an eco-friendly showroom using natural building material for its flooring and energy efficient lights. Tata Motors said the project is at a preliminary stage. The Indian Hotels Company, which runs the Taj chain, is in the process of creating eco rooms which will have energy efficient mini bars, organic bed linen and napkins made from recycled paper.
- **BSNL:** Bharat Sanchar Nigam Limited provides rebate to the customers who make payments via electronic mediums. Thus, BSNL encourages paperless activities.
- **Nike:** Nike is the first among the shoe companies to market itself as green. It is marketing its Air Jordan shoes as environment-friendly, as it has significantly reduced the usage of harmful glue adhesives.
- **CNG in Delhi:** Introduction of Compressed Natural Gas (CNG) in Delhi, was being polluted at a very fast pace until Supreme Court of India forced a change to alternative fuels. In 2002, a directive was issued to completely adopt CNG in all public transport systems to curb pollution.

THE FUTURE OF GREEN MARKETING

There are many lessons to be learned to be learned to avoid green marketing myopia, the short version of all this is that effective green marketing requires applying good marketing principles to make green products desirable for consumers. The question that remains, however, is, what is green marketing's future? Business scholars have viewed it as a "fringe" topic, given that environmentalism's acceptance of limits and conservation does not mesh well with marketing's traditional axioms of "give customer what they want" and "sell as much as you can" .Evidence indicates that successful green products have avoided green marketing myopia by following three important principles:

Consumer Value Positioning

- Design environmental products to perform as well as (or better than) alternatives.
- Promote and deliver the consumer desired value of environmental products and target relevant consumer market segments.
- Broaden mainstream appeal by bundling consumer desired value into environmental products.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Calibration of Consumer Knowledge

- Educate consumers with marketing messages that connect environmental attributes with desired consumer value.
- Frame environmental product attributes as "solutions" for consumer needs.
- Create engaging and educational internet sites about environmental products desired consumer value.

Credibility of Product Claim

- Employ environmental product and consumer benefit claims that are specific and meaningful.
- Procure product endorsements or eco-certifications from trustworthy third parties and educate consumers about the meaning behind those endorsements and eco certifications.
- Encourage consumer evangelism via consumers social and internet communication network with compelling, interesting and entertaining information about environmental products.

DO THIS

We have to use the following activities in our daily routine of life.

- less use of polythene
- crush plastic bottle after use
- use disposable items
- love nature
- save water
- save fuel
- avoid smoking
- many more

CONCLUSION

Green Marketing is a lifestyle change that will help in your business contribution . The study investigates the awareness levels of the customer in the various age groups regarding their understanding about eco-friendly car. The results of study indicate that there is no significant difference in the awareness of the respondents for environment friendly car with reference to the two age groups which was considered in the research. Study also examines the awareness levels of the customer in the various geographical areas regarding their understanding about eco-friendly activities. The results of the study show that customer who responded were either from the big cities or small cities in Uttar Pradesh. There is a significant difference in the awareness level of the customer in big cities and small cities. The results indicate that

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

awareness level of the respondents is higher in big cities as compared to the small cities in Uttar Pradesh for environment friendly activities.

There is a need to increase the awareness levels in small cities metros of Uttar Pradesh by the marketers, media houses, and government. Population wise there exists a big potential in rural districts of the state and if one has to really make the impact of the pollution less than focus should be rural parts. Currently the scene is not very bad from the rural front but before it gets the same level of pollution in the rural Uttar Pradesh, it is suggested that preventive steps to be taken right from now to create the right level of awareness amongst the rural population about the protection of the environment. Marketers concerned with environmental impact may benefit from a better understanding of green marketing strategies and tactics to enable the firm to appeal to a greater extent to consumers with similar concerns.

Chapter 10
Eco-Friendly Culpabilities of Modern Corporates on Ecological Marketing: An Overview

Thangasamy Esakki
Poompuhar College (Autonomous), India

ABSTRACT

Modern marketing is consumer-oriented. However, very often, for immediate gains, many corporates surpass the ecological value. Gradually, the importance of ecology is grasped among the corporates in the modern marketing environment. This gave a birth to green marketing which is safe to the consumers and highly profitable to the corporates simultaneously. Thus, a systematic investigation into the emerging phenomena of ecological marketing and the modern corporates' responsibility becomes the need of the hour universally. In this context, the objectives of this study are to present a detailed conceptual framework of Green marketing and its impact on environment, to highlight the Green Marketing initiatives undertaken by the selected modern corporates, encompassing some prominent banking companies, to analyze the benefits accruing out of the eco-friendly responsibilities shouldered by the corporates, and to suggest measures to the corporates to perform better in the context of sustainable marketing.

INTRODUCTION

Before we pronounce about Green Marketing, it is appropriate to understand the term 'Green' in the context of Green Marketing. Green is the indication of purity. It means pure in quality and fair or just in dealing. For instance, if we talk about green advertising, it refers to advertising without an adverse impact on society.

Thus, Green Products are naturally durable, non-toxic, made from recycled materials or minimally packaged. Of course, there are no absolutely green products, for they all utilize energy and resources and create by products and emissions during their manufacture, transport to warehouses and stores, usage and eventual disposal. Hence, the term, 'Green', is relative describing those products with less impact on the environment than their alternatives.

Green Marketing refers to the marketing of products which are environmentally preferable to the consumers presumably. In other words, it is the process of selling products and/or services based on their environmental benefits. Such products may be environmentally friendly in itself or produced/and/or packaged in an environmentally friendly way. Green marketing, thus, incorporates a broad range of activities, including product modification, changes to the product process, packaging changes, as well as modifying the advertising strategy. It concerns with three aspects, viz:

1. Promotion of production and consummation of pure or quality products,
2. Fair and Just dealing with customers, and
3. Protection of ecological environment.

However, it is not very easy define 'Green Marketing' multiple meanings intersect and contradict each other. Green Marketing is also known as 'Environmental Marketing and Ecological Marketing.

GREEN MARKETING AND ITS ORIGIN: CONCEPTUAL FRAMEWORK

The term 'Green Marketing' emerged as an important phenomena during the period 1980-1990. In the year, 1975, the American Marketing Association (AMA) conducted its first workshop on 'Ecological Marketing'. The proceedings of the workshop gave the birth of a book for the first time on Green Marketing entitled 'Ecological Marketing'. The CSR (Corporate Social Responsibility Report) initiated with an ice cream seller Ben & Jerry, supplemented by a greater view on the company's environmental impact.

Subsequently, in the year 1987, the World Commission on Environment and Development defined the sustainable development as meeting ' the needs of the present without compromising the ability of future generations to meet their own need'. Later, it was known as the Brundtland Report which stimulated thinking further on sustainability in every day's activity.

During the past decade, it was witnessed that harnessing consumer power to effective positive environmental change is far easier said than done. The 'Green Consumer' movements in the United States of America (USA) and other country have struggled to reach critical mass and the minds of the forefront shoppers. When public- opinion-polls conducted since 1990 revealed a consistency that a substantial percentage of consumers in the United States confessed a strong willingness to favour environmentally conscious products and companies, consumers' efforts to do so in real life have remained sketchy at best.

Definitions on Green Marketing

- **American Marketing Association:** 'Green Marketing is the marketing of products that are presumed to be environmentally safe'.
- **Polonsky B. (1994):** Defines Green marketing as all activities designed to generate and facilitate any exchanges intended to satisfy human needs or wants, such that the satisfaction of these needs and wants occurs, with minimum detrimental impact on the natural environment'.
- **Pride & Perel (1993): '**Green marketing, also alternatively known as environmental marketing and sustainable marketing, refers to an organization's efforts at designing, promoting, pricing, and distributing products that will not harm the environment'.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

- According to *Joel Makower*, a writer on Green Marketing, one of the prominent challenges of green marketing is lack of standards or public consensus about what constitutes 'Green'. Often, companies are highly reluctant to promote their green attributes whereas consumers of cynical about their claims, as being observed in reality.

Attributes of Sustainable Marketing

Green products are those products which are produced through green technology. Such products cause no environmental hazards. In order to conserve natural resources to ensure sustainable development, promotion of green technology and green products is the need of the hour. We may define the green products if they have any of the following characteristics:

- They are originally grown.
- They are recyclable, reusable and biodegradable.
- They are not to be tested on animals
- They contain natural ingredients.
- They have eco-friendly packaging i.e. reusable, refillable containers etc.
- They contain recycled contents, non-toxic chemical.
- They do not harm or pollute the environment.
- They contain only approved chemical and limits.

Green Marketing: Golden Rules and Ethical Issues

The following are the golden rules of Green Marketing:

- **Knowing the Customers:** It is to be ensured that the customer is aware of the issues that the company's products attempt to address.
- **Educating the Customers:** It should be an obligation of a company that it should educate its customers about what a company is striving for to protect the environment and how does it influence it. Or else, the green marketing campaign of a company will go in vain.
- **Ensuring Transparency:** There should a transparency in implementing the company's policies on green marketing. A gap between what a company claims for and what it does should be not too wide. The company should also make environmental-friendly policies consistently without which any green marketing programme will fail in the target market.
- **Assurance to Buyers:** The customers are to be assured that the company will not dilute the quality of the products while attempting to make eco-friendly products.
- **Appropriate Pricing:** If any premium is charged for the eco-friendly products, appropriate pricing strategy should be adopted in such a way that the consumers can afford the price of the product.
- **Customers' Participation:** The company must extend adequate opportunity to its customers in its eco-friendly initiatives by their participation.
- **Meeting Customers' Expectations:** The company must position its products according to the changing tastes and preferences or expectations of its customers while offering green products.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Ethics is about what is right and wrong and who we arrive at such judgement. It deals with questions of absolute values, and their application in the real world. Ethical issues are an important consideration in controlling marketing strategies.

Green Pressure on Business

The Green pressure on a business is outlined as under:

- Pressure for better environmental performance is coming from many quarters.
- Consumers are demanding a better environmental performance from companies – in recent surveys, it has been demonstrated that around three-quarters of the population are applying environmental criteria in many purchase decisions.
- Green pressure groups have increased their influence dramatically.

Challenges of Green Marketing

The following may be considered as some of the key challenges of sustainable marketing:

- Currently, there is no standardization to certify a product as organic. Hence, a regulatory body has to be established to certify as green products. Besides, a Standard Quality Control Board should be vested with the task of granting labeling and licensing.
- Consumers must be educated about the benefits of green marketing and environmental threats. However, it will consume considerable time to reach the masses.
- The companies should not anticipate immediate profits through green marketing which may yield its results in the long run. Therefore, it needs a lot of perseverance and patience for such corporates.
- Normally, the green products are priced high which may create green marketing myopia among the consumers.

It is, therefore, apparent that it is not very easy to adopt green marketing strategy which necessitates constant monitoring to succeed for a firm in its marketing endeavor.

Impact of Green Marketing

As should be clear, there are strong reasons for bringing the environment into the business equation, but the strongest reasons is the consumer. The ‘green consumer’ must be the driving force behind changes in marketing and business practice.

- Green consumption can be defined as the decisions related to consumer choice which involves environmentally-related beliefs.
- There is increasing evidence of the importance of this market.
- Surveys which indicate increased levels of environmental awareness and concern.
- Increasing demand for, and availability of, information on environmental issues, Green product concepts and green substitute products.
- Value is shifting from consumption to conservation.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

- Effective PR and marketing campaigns by environmental charities and causes.

The impact of Green Marketing can be realized in the following ways;

- People started demanding green products such as fruits, vegetables, edible items etc.
- Reduction in use of plastics and plastic-based products.
- There is an increase in consumption of herbal products, rather than the use of processed products.
- Increase in use of leaves instead of plastic, jute and cloth bags.
- There is an increase in use of bio-fertilizers.
- Recycling of wastes of consumer and industrial products.
- People prefer to use herbal medicines, natural therapy, and Yoga.
- Strict legislations for protecting forests, flora and fauna, wildlife, etc. from pollution.
- Restrictions on production and use of harmful weapons, atomic tests, etc.
- Increasing emphasis on social and environmental accountability of manufacturers/marketers.
- Strict norms for pollution control.
- 05th June has been declared as the World Environment Day.
- Prevalent legal provisions for restricting duplication or adulteration.
- Setting up of multifarious national and international agencies for constant monitoring of business firms with regard to pollution control and production of eco-friendly commodities.

Green Marketing is needed due to various reasons which include Social Responsibility, Governmental Pressure, Competitive Pressure, Cost Issue, and Opportunity.

Green Marketing Contexts

- Manufacturers of consumer goods may be seen as ‘enemies’.
- Damaging the environment or social institutions to meet consumer demand.
- Producing ‘dirty’ products is increasingly becoming unacceptable.
- Using up scarce and/or environmentally significant raw materials is also an issue.
- Some manufacturers are already making products which contribute to environmental improvements (biodegradable packing, for instance) while large manufacturers are under pressures to act in a socially responsible manner because of their size and social prominence.

Marketing Environment

In general, society is concerned with ecology and the need for preserving the environment from further human pollution. Business and Industry are the leading contributors to the environmental pollution. However, marketers are not accountable and answerable. Packaging is the pollutant feature of marketing. The marketers use packaging to differentiate the brands and buyers’ preferences for butter, cream, cheese etc. They use disposable products also. Since paper napkins replace cloth napkins, this requires disposal. It can be noticed that the disposable drinking cups, beverages etc. add considerably to environmental pollution due to marketing operations.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Marketing and Society

Marketing is no longer an activity confined to the exchange of products and services in the conventional sense. It has become highly versatile with the passage of time. The modern marketing concept may therefore be viewed as a philosophy of service and mutual gain. All marketers may not follow the marketing concept. Business is marketing and in turn marketing is business. A business firm can be considered as an economic institution of society and the businessmen and marketers are the members of society. Their actions and performance are focused on the consumers who are also members of the society. Business is therefore something which has social implication. Society-oriented marketing is a basic necessity rather than the marketing-oriented society. The objectives of the business and the marketing policies of business should be framed in such a way that would contribute liberally to the social well-being. In nut shell, Marketing and Society go hand in hand which are highly inter-reliant.

Influence of Society on Marketing

Political pressures and public opinion are the outcome of pleasure and displeasure of the society. According to Cundiff, "marketers have not often bothered to investigate society's reaction to their marketing practices. Society has often taken the initiative in communicating its displeasure through various forms of social pressure against offenders. The mildest form of social pressure is public opinion aimed at causing the offending marketers to change their ways. When public opinion does not accomplish the desired result, stronger action takes the form of political pressure, with an implied threat of ultimate legal action to force the offender to abide by society's wishes. And the strongest form of social pressure is restrictive legislation outlawing the unpopular product or marketing activities."

Social Responsibility and Sustainability

Green Marketing is founded on two main ideas; one is a response to and responsibility for the community; the other is sustainability. Sustainability involves developing strategies so that the company uses resources at a rate which allows them to be replenished. At the same time, emissions of waste are confined to levels which don not exceed the capacity of the environment to absorb them. In relation to the development of the world's resources, some policies are based on sustainability.

The following benchmarks must unfailingly be maintained in focus:

- Pursue equity in the distribution of resources.
- Maintain the integrity of the world's ecosystems.
- Increase the capacity of human populations for self-reliance.

Social Responsibility of Business

Social Responsibility means an intelligent and objective concern for the welfare of society that limits or prevents corporate behavior from destructive activities-unfair practices. Such destructive activities may be immediately profitable to business but they cannot be tolerated by the society.

These days, modern business is very large and complex, catering to the emerging needs of the national and international markets. It exercises a definite and extensive influence on our economic and social

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

life styles. As a social unit, marketing is responsible to deliver a standard of living and a standard of life-style consumers. Modern business should have the approval of society to function successfully. In the current world, the expectation of a society is much more from business as compared with the past. In fact, society demands quality of life management, integrated business plans and controls are expected to act as instruments of social transformation and such plans are to be implemented for enhancing the social public welfare. Modern business must also demonstrate social awareness or sensitivity and social performance.

Social Criticism of Marketing

In fact, business firms base their marketing decisions largely on immediate profit earning. Philip Kotler states that a firm should earn a satisfactory level of profit, no doubt, but it must also assume its social responsibility as a member of society. Further he says that a firm's profit must be harmonized with society's interest and wellbeing. Most of the companies did not group or embrace the social marketing concept until driven to it by circumstance. If we consider the sale of cigarettes, companies are customarily free to sell cigarettes and smokers are free to buy them.

Regulatory Bodies and Environmental Safety

The following are some of the prevalent regulatory bodies to ensure environmental safety and protection:

- Occupational Safety and Health Act (OSHA).
- Comprehensive Environmental Respond Compensation Liability Act (CERCLA).
- Toxic Substance Control Act (TSCA).
- The Hazardous Materials Transportation Act (HMTA).
- Federal Insecticide, Fungicide and Rodenticide Act (FIFRA).
- Federal Food, Drug and Cosmetic Act, Clean Air Act, Clean Water Act (FFDCA).
- Globally Harmonized System of Classification and Labeling of Chemicals (GHS).

SIGNIFICANCE OF THE STUDY

A study on Green Marketing becomes very important and inevitable due to the following reasons:

- Increasing Production and Business activities are polluting the natural environment. It damages the people, wildlife, crops heavily.
- Optimal and efficient utilization of natural resources becomes inevitable due every growing human needs and wants. It entails the adoption of green marketing.
- Growing interest and concern among the people all over the world on the protection of environment stimulates thinking on green marketing. The consumers started changing their behavior patterns and the corporates also started producing eco-friendly products.
- To capitalize the opportunities and seize competitive advantage.
- To shoulder Corporate Social Responsibilities (CSRs).
- To adopt Green Marketing due to Governmental pressure.
- To emerge out of cost or profit issues.

LITERATURE REVIEW

Many research studies have been undertaken on green marketing worldwide. Few of them have been presented below;

- Banerji J. & Amit Kumar D. (2014) have undertaken a study on Green Marketing: Necessity as well as Opportunity for Industries in current era'. Their study found that green marketing requires a lot of researches which should focus more on green corporate image rather than on mere environmental benefits.
- Kandavel D. (2013) has conducted a study on Green Banking Initiatives of the Commercial Banks in India which revealed that the green banks expand their operations rapidly. Hence, prudent and efficient management of such banks for growth become necessary .
- Sahitya U., & Lalwani V. (2014) investigated into 'Sustainability in Indian Banking Industry' whose study concluded that the adoption of green marketing enhances the image of the banks and also protects the environment to ensure overall growth.
- Sara., & Madhumita G., (2014) surveyed on Green Marketing: Companies Urging Towards Green Revolution whose study resulted that many companies have undertaken green marketing initiatives for creating brand image and gaining customers' attention.
- Yadwinder S., (2015) has researched on Environmental Management Through Green Banking': A Study of Commercial Banks in India' and found that the banks should use the information on environment extensively in its operations, credit extension and investment decisions to improve their environmental performance and create long term values.

RESEARCH METHODOLOGY

The present study is based purely on secondary data. It is descriptive in nature. There are 11 modern corporates, including 7 banking companies, 1 Paint Manufacturing Company, 2 IT companies, and Indian Railways taken as a sample for the study. In India, since the Government makes legislations for regulating the green marketing initiatives carried out by the corporates, the Ministry of Forests and Environment has also been taken into consideration for analysis.

The data was collected from the secondary sources which include Government Published documents, internet, books, magazines, journals etc. Then, the collected data was tabulated, edited, and analyzed for interpretations and also for drawing meaningful conclusions therefrom. Based on the interpretations, the responsibilities of the modern corporates have been presented as suggestive measures and recommendations for those corporates to strike a balance between the sustainable marketing and their ecological responsibilities by integrating their goals. Besides, based on their initiatives on green marketing, the anticipated accruing social benefits have also been presented to promote better understanding of the problem in question under this study.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

OBJECTIVES OF THE STUDY

The primary objectives of the study are as under:

- To present the conceptual framework of Green Marketing and its impact on Environment.
- To highlight the Green Marketing initiatives undertaken by the modern corporates, encompassing some prominent banking companies.
- To analyze the benefits accruing out of the eco-friendly responsibilities shouldered by the corporates.
- To suggest measures to the corporates to perform better in the context of sustainable marketing.

ECO-FRIENDLY INITIATIVES OF MODERN CORPORATES: AT A GLANCE

In general, corporates are of different types in nature which are innumerous throughout the world. Their production and marketing objectives do also vary from one to another, be it national or international/ global companies. They may exist and function in any part of the world like human beings, having different organizational structures. However, the purpose of their survival and existence remains the same, irrespective of their products or services what they produce or render in a society. Needless to say that it is not any other objective other than maximization of profit and wealth in the long run. All the business activities are, therefore, triggered upon by all the business corporates towards the objective of achieving their short term and long term goals universally. Many a times, it has been constantly witnessed that many corporates fail to protect the environment while they produce their products or render their services. Ultimately, those products benefit the society on one hand and cause environmental degradation on the other hand which, very often, result in irrecoverable damages to the environment. This indirectly affects adversely the social wellbeing.

Keeping the welfare of the society, the environmental degradation must be prevented and for this reason, all the consumers are being educated worldwide. In every nook and corner of the globe, including India, Governments have been enforcing laws through several regulatory bodies to monitor the green marketing endeavours undertaken by the corporates engaged in production of products or services. Accordingly, the corporates are accountable to change their marketing or service mix in accordance with the dynamic needs and wants of the consumers with green products, without polluting the environment.

As explained above, several modern corporates are undertaking green marketing projects. Here are the few instances of such projects undertaken by the modern corporates, as shown in Table 1.

Table 1 shows that the initiatives undertaken by the different Corporates/Ministry and the benefits accrue to the society in columns 3 and 4 respectively. The column 5 of the above table also reveals their responsibilities of the modern corporates, based on an analysis, so that both the producers and consumers will benefit without environmental degradations. There will be attractive returns to the corporates while ensuring green products to their consumers at affordable rates.

The present study finds from the overall analysis that most of the banking companies are more active in green marketing endeavours as compared with IT or Government companies.

Table 1. Eco-friendly initiatives of modern corporates

Sl. No.	Name of the Corporate/ Ministry/Department	Nature of Initiative	#Benefits to Society	#Suggestions/Solutions/ Recommendations
[1]	[2]	[3]	[4]	[5]
1.	Forest and Environmental Ministry of India	Ordered to the retail outlets not to provide polythene carry bags unless they are ready to pay for it.	Reduces the use of polythene bags and thereby environment protection is ensured.	Alternative bio-gradable products instead of polythene bags must be put at use. Strict legislations must be enforced.
2.	Indian Railways	• Permitted its customers to travel without printed versions of tickets. • Carrying their PNR numbers on their mobiles or Laptops is sufficient.	• Reduces the cost of printing and wastage of papers. • Eliminates the pollution arising out of dumping the waste printed tickets after use.	More innovative customers' eco-friendly products are to be launched to augment the benefits of green product.
3.	State Bank of India(SBI)	• Introduced Green Channel Counter, paperless banking through ATM cards and SBI shopping. • Launched green banking program in the form of wind project.	• The customers need not use withdrawal forms or cheque books for withdrawal of their deposits in the bank. • It reduces its carbon footprints. • Reduces the dependence on the polluting thermal power.	Product differentiations in the target market, keeping the importance of green marketing in tact, will be of greater use.
4.	IndusInd Bank	Introduced Solar-powered ATMs in Mumbai as a part of its 'Green Office Project'.	• Banks could save 1980 kw of energy annually. • Saved power bills for about Rs.20000/- per annum. • Replaced Diesel Generators with Solar Panels which reduced environmental pollution.	More Green Marketing projects will entail better eco-friendly environment.
5.	ICICI Bank	• Introduced numerous innovative concepts such as deep beneficiation of coal, coal bed methane etc. • Assisted companies to replace the conventional air conditioners with eco-friendly air-conditioners. • Organized sensitization programmes for the institutions, banks, government agencies etc. involved in project planning on issue like bio-diversity, wildlife habitats etc. • Introduced various eco-friendly schemes which include House Financing Schemes, Loan schemes for conveyances etc.	• It ensures conservation of wildlife and natural environment. • It prevents pollution of environment.	More sensitization programmes may be organizer, keeping the environmental responsibilities in view.
6.	Industrial Development Bank of India (IDBI)	• It has an exclusive team working on clean development Mechanism advisory services. • Launched refinance schemes for energy savings projects for small and medium scale sectors.	It ensures clean development and environment protection.	Constant monitoring of green marketing projects will promote the welfare of the community.
7.	Yes Bank	Taken community development initiatives such as clean and green drives, energy efficiency practices, workplace health and safety and development of local disaster management.	• Ensures good health and safety of the people at work place. • Reduces damages of lives and properties during the natural disasters.	Social security measures may be effectively integrated with its business venture profitably for sustainability.
8.	HDFC Bank	• Launched Green Banking by constituting an Environment Management Committee. • Worked on areas like alternate energy sources, watershed management, planting trees, formation of green clubs etc.	• Green Banking initiatives are environment-friendly in nature. • Conserves energy and provides a health environment to the society.	Product and service mix strategy will be more helpful to succeed in its green marketing endeavours.
9.	Bank of Baroda	Adopted environment-friendly systems in the design of the new data centre.	• Provides energy efficient and chiller-based HVAC design. • Ensures temperature monitoring.	Inter and Intra green initiatives promote the wellbeing of the bank and the environment as well.
10.	Kansai Narolac	Worked on removing hazard metals like chromium, mercury, lead etc. from their paints.	Prevents from adverse effects on humans by causing heavy damages to the central nervous system, kidneys, and reproductive systems.	Appropriate Marketing Mix may be designed.
11.	WiproInfotech	• Launched environmentally friendly computer peripherals for the first time in India. • Introduced a new range of laptops and desktops known as 'Greenware'.	It reduces e-waste in the environment.	Continuous market researches will help immensely to strike a balance between profit earning and environmental protection.
12.	*Toyota*	*Launched Prius Hybrid Vehicles*	*Unique style reflects the owner's passion for sustainability.*	*Product Differentiation will attract the consumers in the target market.*

Source: Secondary Data # Inference drawn from Analysis

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

LIMITATIONS AND FUTURE DIRECTIONS OF THE STUDY

The present study has used only secondary data. Overall extensive analysis on the green marketing initiatives undertaken by the modern corporates and their responsibilities, based on the availability of data, is made for drawing conclusion therefrom. Intensive case studies, on each company, will throw more light on their respective green marketing issues. Primary data will add more of its validity and reliability. Amongst innumerous corporates, only few IT companies and banking companies have been taken for the present study. Since the number in the universe containing the prospective corporates is indefinite, the researcher has selected only 11 companies and a single Ministry in India conveniently, based on the availability of data for analysis. This drawback can be overcome by a more detailed investigation by adopting case studies or survey method by using both the primary and secondary data. Under this study, analysis of the phenomenon of green marketing initiatives undertaken by the corporates is made on universal basis. The study touches only the key actions extensively. It does not therefore focus deeper into those initiatives and also on the initiatives of Indian companies in depth as well. All other companies producing consumer goods or rendering services are kept outside the purview of the study. Besides, the production of industrial goods does also adversely affect the environment, and therefore, they are not taken into account, as it is irrelevant to this current study. Further, there is a research gap in the present study in terms of information on green marketing norms, specific government legislations on green products, consumers' consumption patterns, satisfaction etc., along with the detailed analysis on the regulatory bodies of green marketing etc. It would be better a detailed study by analyzing all the aspects of the objectives set in the present study, by integrating the primary and secondary data will yield better results. Thus, the current study will provide more insight into the phenomenon of green marketing and pave a way for future direction for more researches. Further, it will not also fail to add some literature to the existing body of literature on environmental or green marketing.

CONCLUSION

Any business aims at maximization of profit. Modern marketing provides a key to the marketers to tap the profits by producing the products what the consumers want in the target market. Consumer satisfaction will entail good returns to a firm for its survival and growth in the long run. In the process of accomplishing its objective of satisfying the consumers profitably, environmental aspects cannot be ignored by the corporates. Simultaneously, the corporates must act responsibly in protecting the environment in general and the wellbeing of the consumers in particular. In this context, green marketing is the only solution in the contemporary society which will not pollute the environment. Thus, the ecological marketing ensures the charming of the people without harming the environment.

More innovative efforts should be called for achieving the broader goals of green marketing. Such efforts on sustainable marketing should be initiated by the corporates. Their implementation should be followed by strict monitoring by the regulatory bodies, to be established by the Government. Consumers should also be educated accordingly to extend cooperation with the corporates or Government, through suitable sensitization programmes periodically, to reap the benefits of ecological marketing together. Last but not the least, it is concluded that the sustainable marketing will succeed only with the joint responsibilities of corporates, consumers and the government in the days to come.

KEY TERMS AND DEFINITIONS

Corporation: It is a business that is legally independent from its members. It may incur or pay debt, negotiate contracts, sue and be sued. It ranges in size from local retails stores to Ford Motor Company or the General Electric, the nation's largest corporation.

Environmental Pollution: It is the undesired spread of toxic chemicals into the aquatic and terrestrial habitats of the world. There are different types of pollution, usually named for the location that has become polluted.

Environmental Responsibility: It refers to the social responsibility or duty that a company has to operate in a way that it protects the environment.

Green Marketing: It refers to all the activities designed to generate and facilitate any exchanges intended to satisfy human needs or wants, such that the satisfaction of these needs and wants occurs, with minimum detrimental impact on the natural environment. It is also called as 'Ecological Marketing.

Marketing: It is the study and management of exchange relationships.

Marketing Environment: It refers to the factors and forces that affect a firm's ability to build and maintain successful relationships with customers.

Marketing Mix: It is a set of tools or actions or tactics that a company uses to promote its brand or product in the market. 4Ps make up the typical marketing mix – Price, Product, Promotion and Place.

Service Marketing Mix: It is also known as an 'Extended Marketing Mix' which is an integral part of service blue print design. Three additional marketing mix components needed are people, process and physical evidence. It is also called as '7Ps of Marketing Mix'.

Sustainable Marketing: It is the idea that the goods should be marketed in such a way that ensures that the future generations are not impacted.

Chapter 11
Consumer Values and Green Products Consumption in Malaysia:
A Structural Equation Modelling Approach

Brahim Chekima
Universiti Malaysia Sabah, Malaysia

ABSTRACT

To impede environmental deterioration and promote a more sustainable economy, one solution is to shift consumption from conventional to green products. However, inadequate information on how to promote consumers' green behavioral intention is slowing the growth of green markets and has become a barrier for when developing segments and communicating strategies for effective promotion of green products, in countries like Malaysia where the trend is new. This study attempts to examine consumers' green purchase intention motivational drivers and determine the moderating effect of education levels, gender and income. Structural Equation Modeling (SEM) technique was used to evaluate the causal model. The results suggest that cultural values and environmental advertising are the main influence in building green purchase intention while environmental knowledge is not significantly related. It also indicates that gender and education level have a significant positive moderation effect while income is not. The discussions and implications of these findings are further elaborated.

INTRODUCTION

Rapid economic development, unsustainable consumption and the increasing global population have direct negative impacts on the environment. This has led to alarming environmental degradation and natural disasters (Selles, 2013). Hoornweg et al., (2013) revealed that municipal solid waste (MSW) alone, one of the most important by-products of the urban lifestyle, is growing faster than the rate of urbanization. In the earlier global report of over 100, 000 cities surveyed in 2012, they warned that the generated global solid waste is expected to double by 2025, from over 3.5 million tons per day in 2010 to more than 6 million tons per day by 2025, with the amount expected to exceed 11 million tons per

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

day by the year 2100. Inevitably, it resultes in n increase for the overall estimated cost of dealing with the waste from $ 205 billion per year in 2010 to $ 375 billion by the year 2025. The mentioned alarming facts clearly suggest that a transformational change in consumer consumption toward more environmentally friendly consumption is essentially necessary. The adaptation of sustainable consumption does not only save the environment, it also saves and reduces the costs associated with the usage of conventional products (Chekima et al., 2016).

Godelnik (2012) in his study explained that despite the fact that consumers' spending witnessed an increase, including spending for green products, the market share remained to be very small. Even though millions of people have adopted sustainable consumption in 2012; the shift has a very minor reflection in within the overall economic activity. In the following year the estimated market share for green products was less than 4% (Gleim et al., 2013). For the past few years, environmental issues along with green consumption became the focus of the public and the media and more importantly it is the focus of green marketing research field. Researchers, producers, and marketers have been focusing their energy in searching for factors that encourage and motivate consumers to buy green products. While this gives an opportunity for marketers to venture into a new category of green products to increase and maximize profits via the expansion of their market share, they struggle to develop and communicate effective strategies to stir the consumers' purchase intention towards the buying of green products.

In attempt to tackle the issue facing green products and their market share, a number of studies have been conducted out over the last 20 years to identify the factors that promote pro-environment behavior among consumers (Wu et al., 2015; Chekima et al, 2015), however the focus was mainly on marketing strategies rather than consumer behavior. Without an in-depth understanding of consumer behavior in the green product category it becomes almost impossible to develop effective marketing plans and strategies (Tseng & Hung, 2013). Based on previous studies and the mentioned alarming condition of the environment, along with the position and market share of green products, the main objective of this study is to investigate and identify some of the factors that influence and motivate consumers' intention to purchase green products based on the theory of planned behavior (TPB) by Ajzen (1985). Additionally, based on the authors' best knowledge, very few existing studies focused on the influence of cultural values, environmental advertising and particular demographic characteristics on green products purchase intention. The Theory of Planned Behavior which has been advanced by Ajzen is widely accepted and adapted as a robust model for predicting green intention and actions. The study in hand focuses on purchase intention, for intention has broader implications and often does have a positive impact on individuals' actions (Schlosser et al., 2006; Ajzen & Driver, 1992).

For the last two decades cultural components have been acknowledged to have an impact on individual's behavior in the market ((Vicente-Molina et al., 2013; Chekima et al., 2016; Kim et al., 2002; Yaveroglu & Donthu 2002). Culture has a strong influence on consumer behavior and is a fundamental determinant of a person's desire (Kotler, 2003). Similarly, Strizhakova and Coulter (2013) further suggest that culture can encourage pro-environment behavioral and ultimately encourage green purchasing intention. It is explainable that culture is dynamic and plays an important role in shaping attitude and behavior. Soyez (2013) concluded that the main drivers of eco-friendly behavior are attitude and norms, with the latter inclusion of individuals' cultural values. However, little research focused on investigating its effectiveness to form a positive attitude and encourage consumers' intentions to buy green products. Thus, by integrating and investigating the role of cultural values (man-nature orientation and long-term orientation), this study will bring new insights and grasp the existing gap relates to the effects of cultural influence on consumers' intention to purchase green products. Additionally, understanding these

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

cultural values/orientations will help us understand the motivation of individual behaviors along with their decision-making and social atmosphere within and across cultures.

This research contributes to the understanding of the examined motivational factors of consumer purchasing intention. The findings of this research are also anticipated to provide a useful reference for the producers and marketers of green products to further develop appropriate marketing strategies and plans to communicate and promote green products effectively. This research may also pave the way for future studies to replicate such a model with an additional variables or share certain findings with care by the countries in the region (Southeast Asia countries) with which Malaysia shares several aspects of culture, economics, politics and geography.

The chapter proceeds with a literature review presenting a summary of research findings surrounding the variables examined in this study such as green purchasing intention, environmental knowledge, man-nature orientation, long-term orientation, environmental advertising and demographic characteristics. Following an overview of the methodology, the findings and discussions are presented. Finally, the chapter closes with implications and limitations/directions for future research.

LITERATURE REVIEW

Green Purchase Intention and Underpinning Theory

Purchase intention is one of the pillars that make the process of buying a whole. Newberry et al. (2003) observed that purchase intention is a frequent tool engaged to anticipate consumers' purchase behavior. O'Keefe (2002) affirms that behavioral intention is the most suitable aspect for predicting the actions of individuals under many conditions including the green market. In the same line of definition, Spears and Singh (2004) and later Peter and Olson (2008) elucidated the purchase intention as a conscious decision to make an effort to purchase a particular product. Aligned with the general purchase intention definition, Nik Abdul Rashid (2009) defines green purchase intention as the probability and willingness of individuals in their purchase consideration to give preference to green products compared to conventional products. The green purchase intention is described as a distinct kind of environmentally friendly behavior that individuals perform to express their concern to environment. Furthermore, green purchasing intention was confirmed as a proxy for the actual green purchasing behavior (Ramayah et al., 2010) and an accurate measure of future sales (Armstrong et al., 2000).

Correspondingly, Theory of Planned Behavior (TPB) is a comprehensive, accurate and widely used theory to assist in explaining green purchasing intention (Steg & Vlek, 2009; Ajzen 1985; 1991). TPB is a very successfully applied model in predicting and explaining variance in volitional behavior (Watson et al., 2014; Kaiser, 2006; Ajzen, 1991) in addition to the examining of the causal link between values, beliefs, attitudes, intention and action, (Beedell and Rehmanm, 2000; Webb and Sheeran, 2006). TPB suggests that when exposed to a behavioral option, consumers will start to consider alternatives and evaluate the effects involved grounded by their beliefs related to the actions and its effects. Eventually, such beliefs will determine an individual's attitude regarding potential actions, ultimately affecting the intention to act. The impact of cultural values measured in this study utilizing the TPB is based on Luna and Gupta (2001) and McCort and Malhotra (1993) which suggest that culture influences individual through the affective and cognitive functioning resulting in behavior. This is in line with the statement of Ajzen (1991) and Lee and Green (1991), in which it is explained that the TPB model is based on cog-

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

nitive and affective processing and the level of behavioral change. The utilization of TPB in predicting green consumer behavior, and robustness of the theory has been confirmed several studies (Wu, 2015; Yazdanpanah & Forouzani, 2015; Chekima et al., 2016; Kim & Chung, 2013).

Environmental Knowledge

Studies show that consumer behaviors and intention are affected by many factors, including environmental knowledge. Vining and Ebreo (1990) claimed that consumer knowledge about environment been acknowledged as an important motivator for environmental friendly behavior. Along with Chan (2001) Haron et al., (2005) refer to environmental knowledge as an individual ability to understand and evaluate the impact of ecosystem on the society as well as the amount of information they have regarding environmental issues. Werner and Alvensleben (2011) suggested that knowledge creates a positive influence on a consumers' viewing habits of buying and using eco-friendly products. According to Mostafa (2006) environmental knowledge consists of relationships leading to environmental features or effects, joint responsibilities required for sustainable development, what people know about the environment, and appreciation of 'whole systems'. By employing TPB, researchers found that the more knowledgeable the consumers are about the environment, the more they know about the effects of the human actions towards the environment, and the more they can be expected to purchase green products (Rahbar & Abdul Wahid, 2011; Nik Abdul Rashid, 2009; Mostafa, 2006; Laroche et al., 1996).

Bradley et al., (1999) found that environmental attitudes will improve in parallel with increased environmental knowledge. Amyx et al., (1994) also concluded that consumers with sufficient knowledge on environmental issues are more willing to pay a higher price to purchase environmental friendly products. In the same line, Loroche et al., (2001) confirmed that environmental knowledge is significantly correlated with attitudes and environmental behavior. In Malaysia, in their study of the environmental volunteers in Penang, Rahbar and Abdul Wahid (2011) found that individuals with more environmental knowledge tend to positively influence their green purchase intention and behavior. In fact, a lack of knowledge or information has been identified as an important barrier to environmental behavior (Kennedy et al., 2009). As environmental knowledge appears to be a necessary motivator for environmental behavior, a close examination on the impact of environmental knowledge on green purchase intention is worthwhile. Thus, it is hypothesized:

Hypothesis 1: Green purchase intention is positively influenced by environmental knowledge.

Man-Nature Orientation

Over the past few decades, different cultural value orientations were discussed by some social theorists (Schwartz, 1994; Hofstede, 1980, 2001; Rokeach, 1979; Kluckhohn & Strodbeck, 1961; Kluckhohn, 1956). Values are considered as principles that guide the formation of attitudes to act (Rokeach, 1973). This is because by understanding cultural values, this could help us explain many elements of individual behavior and the social atmosphere across and even within cultures (Schwartz and Sagiv, 1995; Schwartz, 1994). In the study, the researchers examine man-nature orientation dimension which was developed in the 1940s and 1950s by Florence Kluckhohn and Fred Strodtbeck (Kluckhohn and Strodtbeck, 1961) and is found in the Value Orientation Theory. Man-nature orientation (MNO) is defined as the friendly conducts of humans toward nature, because of the love of nature and the vigor of protecting nature

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

behavior (Churchill, 1979). In addition, Chan (2001) referred to man-nature orientation "as the relationship between human beings and the natural environment". According to Samovar et al., (1981) MNO is concerned with the relationship rooted between man and nature. Man-nature orientation considers how human dominates, lives harmoniously with nature or is subjugated to nature. Chan (2001) argues that the orientation of human nature operates at the level of which can stimulate affective norms, where all consumer behavior rests. Previous studies have found that the norms sometimes change and lead to a certain ambivalence in the attitudes; however, the impact is greater in guiding the practice of everyday life through intentions and behavior (Chekima et al., 2016; Chung et al., 2012; O'Neal, 2007; Ajzen, 1991).

Since to date, the relationship and influence in respect of man-nature orientation regarding green product purchase intention has been inadequately researched despite the mentioned theories that proposed cultural values as an influence on individual intention and behavior. Man-nature orientation has been examined in clothing fashions and impulsive buying, confirming its positive role in facilitating buying behavior (Rajagopal, 2011; Kacen & Lee, 2002). Likewise, man-nature orientation associated positively with consumer pro-environmental attitude on environmentally friendly buying behavior (Sabrina, 2007). This is desirable in terms of psychology, in which usually attitudes influence the reasoning function and emotional function that ultimately leads to affecting consumer behavior and buying intention (Hoyer & MacInnis, 2004). Hoyer and MacInnis (2004) recommend cultural orientation values to be included in future research when examining the factors influencing purchase intention. Based on the reviewed literature, this study aims to contribute to the very few studies to measure man-nature orientation values towards green purchase intention. Following on from this discussion, the second hypothesis is postulated:

Hypothesis 2: Green purchase intention is positively influenced by man-nature orientation.

Long-Term Orientation

Based on the review of literature, this study is among the earliest ones of its kind that attempt to incorporate and investigate the influence of long-term orientation values on purchase intention of green products. Long-term orientation is among the dimensions of cultural orientation that deals with time - past, present and future. Long-term orientation "stands for the fostering of virtues oriented towards future rewards, in particular perseverance and thrift" (Hofstede, 2001). This is an additional dimension to Hofstedes' initial four national cultural dimensions, uncovered by Bond (1987) and later proposed by Hofstede (1991) as the long- versus short-term orientation as it has been proven to be an important, independent dimension, particularly in Asian cultures. According to Bearden et al., (2006), long-term orientation is a prominent facet of national cultural values and of its influences on consumer's decision-making process; however research on its impact is lacking.

Despite the fact that Hofstede proposed that his cultural dimensions should not be measured at neither organizational nor individual level (Minkov & Hofstede, 2011), this study adopted the Cultural Values Scale (CVSCALE) proposed by Yoo et al., (2011) to capture Hofstede's long-term orientation at the individual level. It was developed as an extension of Hofstede (1991) cultural scale values. Bearden et al., (2006) further explained that long-term orientation will influence the individuals' level of ethical values. Thus, it would be expected that those who plan for future success would be less likely to engage in unethical behavior such as conventional purchasing behavior which holds harmful long term consequences affecting the environment. Hence, long-term oriented consumer is more likely to plan ahead before making purchases and are less tempted by immediate desires and purchasing temptations. This is

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

supported by Gul (2013) who found that long-term orientation was the best predictor for environmental attitude formation in Turkey. Consequently, it is expected that long-term oriented consumer will have a positive green purchase intention and thus the next hypothesis is hypothesized as:

Hypothesis 3: Green purchase intention is positively influenced by long-term orientation.

Environmental Advertising

According to Goodrum and Dalrymple, (1990) advertising is considered a business strategy intended to attract consumers to a new or existing product by generating positive emotional attachment. Baldwin (1993) is quoted stating that "environmental advertisements are designed to help form a consumer's values and translate these values into the purchase of green products". Haykto and Matulich (2008) mentioned several consumers' responses in manifesting the effectiveness of green advertisements in terms of willing to pay premium price; such as trusting the safety of the advertised product and believing it to be less harmful as demonstrated. By applying the Theory of Planned Behaviour (TPB), Litvine and Wüstenhagen (2011) established that increasing environmental messages allow consumers to recognize the advantage to purchase green power and it would significantly enhance green power market.

In his research, Xue, (2014) indicated that the green visuals in an advertisement lead to more advertising response and a more favorable perception of the brand's environmental effort. Besides, Kao et al., (2013) and Zhu, (2013) conducted empirical studies in Taiwan and China respectively, while the latter suggested that environmental advertising impact significantly influence consumer purchase intention of green products, the former found that appeals in environmental advertising lead to form a positive attitude towards advertising. In addition, Bator and Cialdini (2000) suggested that message involvement is a critical factor in broad behaviors and proper indication of messages is one of the main strategies to enhance environmental behavior through information share. In short, it is established based on the theory of planned behavior that people's behavioral intention (green purchase intention) are a function of their positive attitudes toward a specific behavior or subject (environmental advertising). Thus, it is hypothesized that:

Hypothesis 4: Green purchasing intention is positively influenced by environmental advertising.

Demographics

Previous studies indicate that socio-demographic are associated with green product consumption behavior. Berkowitz and Lutterman (1968) were pioneers in studying the green consumer profile and even reported demographics as one of the most influential factors to predict pro-environmental behavior. Gender, age, occupation, education level, income level and family size are among the demographics that have been found to have a significant relationship with environmental behavior (Sang and Bekhet, 2015; Kaufman et al., 2012; Yau, 2012). Additionally, Yin et al. (2010) noted that many studies have investigated the effect of demographics regarding purchasing intention; however, some studies reported contradictory results. Therefore, it is necessary to verify the moderating role of the income, education level and also gender between the independent factors investigated in this study and green purchase intention. This study employs a bi-dimensional approach to income (high income and low income), gender (i.e., male and female) and education (higher education and low education), to identify if there are differences in

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

the strength of their moderating impact. Compared with previous studies, they examine the direct effects of income, education and gender as uni-dimensional and found a significant influence on the intention to purchase, which is inaccurate and rather misleading. Thereby, it is difficult to identify if there is a difference between the strength's effect of income levels, education levels and gender on consumers' motivational factors and green purchase intention. With this, it will help contribute to a better understanding of the role of demography in enhancing green purchase intention motivational drivers. In addition, it can help to guide managers of green products to segment their target market appropriately (i.e., high income or low income, male or female and highly educated individual or low educated individual or considering both categories of each investigated demography); thus focusing on this segment when developing products and strategies for communicating more effectively in promoting green products.

Income

Based on the model of purchasing decision process Engel, Blackwell and Miniard, (1995) suggested that purchasing intention is strongly influenced by consumers' income. Hockett et al., (2004) reported that individuals with higher incomes are more likely to be pro-environmentally. Meantime, Roitner-Schobesberger et al., (2008) study concluded that in Thailand high earners are more likely to have purchased organic food. Moreover, Csutora and Mozner (2014), Abdul Wahid et al., (2011), Mahmoud et al. (2011), Fotopoulos (2002), Laroche and Bergeron (2001) have considered income as a significant factor influencing consumers toward green product purchasing intention. Mahmoud et al. (2011) argues that green purchase behavior depends on the economic conditions of the consumer. This can be explained in which people will be most interested and intend to spend money on green products when they have a sufficient level of income and welfare are maintained, allowing excess of money. This leads to the next hypotheses:

Hypothesis 5: Income will moderate the influence of environmental knowledge on green purchase intention.
Hypothesis 6: Income will moderate the influence of man-nature orientation on green purchase intention.
Hypothesis 7: Income will moderate the influence of long-term orientation on green purchasing intention.
Hypothesis 8: Income will moderate the influence of environmental advertising on green purchase intention.

Education

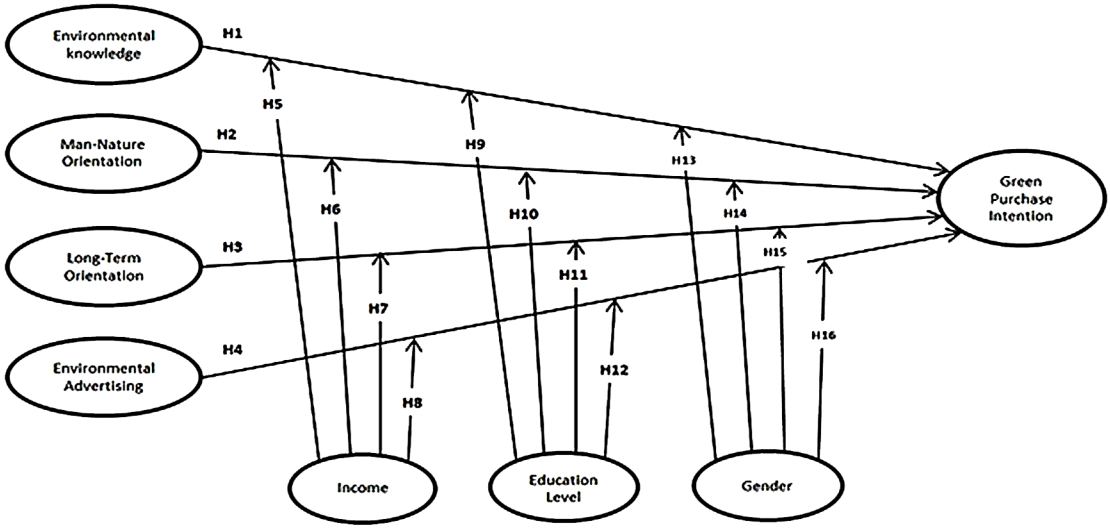
The majority of studies that examined and tested the level of formal education/literacy, found a positive relationship between education and the green consumer behavior (Schwartz and Miller, 1991; Zimmer et al., 1994). Zsoka and colleagues (2013), in Hungary, found that most of their respondents who were university students acquired more knowledge about the environment in the university possess a satisfactory level of environmental knowledge and are highly aware of the need for change in consumer behavior compared with high school students. In Pakistan, consumers who are highly educated show a positive attitude towards green products, and are more willing to buy the products. This is confirmed by the fact that well educated people often are better informed, and thus, have a strong desire to protect the environment (Torgler & Garcia-Valinas, 2007). Another study, in California, revealed that college-educated respondents prefer electric/hybrid vehicles (Brownstone et al., 2000). This is also feasible because they

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

are sensitive to the cause and are aware of the effect and tend to act in accordance. On the other hand, Straughan and Roberts (1999) suggested that education level does not have a significant relationship with the individual's pro-environmental behavior. In this study, education is divided into two categories: highly educated in reference to tertiary education qualifications and low educated covers high school and below. Thus, we predict the following hypotheses:

Hypothesis 9: Education will moderate the influence of environmental knowledge on green purchase intention.
Hypothesis 10: Education will moderate the influence of man-nature orientation on green purchase intention.
Hypothesis 11: Education will moderate the influence of long-term orientation on green purchase intention.
Hypothesis 12: Education will moderate the influence of environmental advertising on green purchase intention.

Gender



The empirical results of the role and effect of gender on environmental behavior are indeed contradictory. Several studies found that compared to males, females are more likely to participate in pro-environmental behavior as well as having higher intention to purchase green products, especially organic food (Rezai et al., 2011; Zelezny et al., 2000; Davidson and Freudenburg, 1996). Zelezny et al., (2000) conducted a survey in 14 countries, focusing on gender differences in pro-environmental attitudes, their findings show a significant difference between the genders in behavior patterns and environmental attitudes, the results showed that women are more consistently pro-environment than men are. Although many researchers suggested that women are more likely to act in a way that is more environmentally friendly than men, final results are not conclusive. Furthermore, Davidson and Freudenburg (1996) claim that gender differences in environmentalism are not to be generalized. This is very much supported by Diamantopoulos et al., (2003) who concluded that numerous researchers found that men have more knowledge about environmental issues than women and that the latter act accordingly. Contrary to the previous claims, Tan and Lau (2010) found no significant difference between male and female 'attitude' of green products for undergraduate students in main private universities in Malaysia. Guided by the past literature and findings, this study will explore the impact of gender interaction between the significant motivational factors toward green purchasing and identify of which gender is significant and contributes to pro-environmental. Accordingly, it is hypothesized that:

Hypothesis 13: Gender will moderate the influence of environmental knowledge on green purchase intention.
Hypothesis 14: Gender will moderate the influence of man-nature orientation on green purchase intention.
Hypothesis 15: Gender will moderate the influence of long-term orientation on green purchase intention.
Hypothesis 16: Gender will moderate the influence of environmental advertising on green purchase intention.

Our research model included pro-environmental motivational factors and its impact on green purchasing intention. The hypotheses are formulated based on aforementioned research studies to define the research framework shown in Figure 1. The research framework was developed using structural equation modeling.

Figure 1. Research framework

METHODOLOGY

Sample and Data Collection

This study conducted a self-administered questionnaire surveys to collect the research data. Since green products are a relatively new product category in Malaysia, they are primarily available at large supermarkets and malls in the major and more populous states such as Kuala Lumpur, Selangor and Sabah. This study thus targeted both male and female customers at the age between 18 and 65 who have purchasing power and active in shopping (Salzman, 2012), at major supermarkets and malls in the cities of the three states mentioned above as the research sample. The sample was selected by convenience, as there was no available access to sampling frames, databases or records to select individuals randomly. Additionally, to ensure participants were qualified to answer the survey questions and meaningful data collected, a screening question that asked participants if they aware of or and had previously purchased green products was asked. In total, 600 questionnaires were distributed and 405 valid questionnaires were obtained, making the response rate of 67.5 per cent, which is above the 60 percent response rate recommended by Babbie (1990).

Measurement Instruments

Previous studies have been reviewed to ensure a comprehensive list of measures and consequently have been included. The initial instrument consists of 34 items that were pre-tested on a sample of 30 subjects. The pretest was developed and administered in a series of meetings and interviews with post-graduate students and senior academics to review and evaluate that constructs are comprehensible. Based on their feedback, two items were dropped and some minor wording changes were made to the final version.

The questionnaire comprised of two sections. Section A gathers demographic information of respondents and determine green consumer profile of respondents based on Suplico's (2009) categorization.,

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

while section B comprises of 32 items examining the factors affecting consumers' green purchase intention. Measurement of items was assessed using a five-point Likert scale ranging from 1 strongly disagree or highly unlikely to 5 strongly agree or highly likely. Items adapted from the following sources: green purchase intention (Mostafa, 2006; Chan, 2001), environmental knowledge (Haron et al., 2005; Tanner and Kast, 2003), man-nature orientation (Chan, 2001), long-term orientation (Yoo et al., 2011), and environmental advertising (Rahbar and Abdul Wahid, 2011).

FINDINGS

Respondents' Green Consumer Profile

In matter of practice 'green living', figures in Table 1 shows the majority of respondents (48.0 percent) claimed to be Sprouts in which they are fairly aware of environmental issues, believe in environmental causes in theory and buy green products from time to time. They should be encouraged with appeals to get involved in environmental activities (Ottman, 1998).

Respondents Profile

The demographic profile of respondents includes, gender, age, educational level, employment and yearly income level is presented in Table 2.

Just over half the sample (51%) was female with a majority having tertiary education. Most respondents are between 20 and 29 and 30 and 39 years old, with two most common annual income categories between RM36001 and RM60000 (26.7%) and RM60001 to RM96000 (22.2%) and the mean is RM74726.60. According to Economic Planning Unit of Malaysia, households with annual incomes between RM36001 and RM96000 are belong to middle income group.

This study used structural equation modeling (SEM) to examine the proposed model. SmartPLS 2.0 software was used to evaluate the relationships among the constructs of the research model by conduct-

Table 1. Respondents' green consumer profile

What Best Describes You as a Consumer?	Frequency	Percent
True Blue Green: I buy only green products. I spend time and effort in environmental activities such as recycling. I believe that an individual can do much to promote the environment.	46	11.4
Greenback Green: I am able to buy green products but I don't have the time and energy for environment activities. I do not want to change my lifestyle to promote the environment.	107	26.4
Sprout: I can buy green products from time to time but I am not involved in any environmental activities.	194	48.0
Grouser: I do not buy green products. I believe that business and government should be fixing environment problem.	28	7.0
Basic Browns: I am the least involved in environmentalism ad I believe that there is not much that an individual can do in solving environmental problems but the government and business should promote the environment.	29	7.2
Total	405	100

ing partial least squares (PLS) analysis. As widely accepted rule of thumb, structural equation modeling (SEM) should be conducted on samples of no less than 200 (Kline, 2005). Partial Least Squares (PLS) assesses the psychometric properties of the measurement model, and estimates the parameters of the structural model. PLS analysis was preferred as the methodological choice as it allows us to simultaneously evaluate both the measurement and structural model (Chin, 1998), maximize the variance explained of the dependent variables and allows the simultaneous analysis of a large number of constructs, allowing extensive examination of interactions between latent predictor variable and moderator (Hair et al., 2012). As suggested by Anderson and Gerbing (1988), the data analysis began with confirmatory factor analysis (CFA) to determine whether all indicator variables appropriately reflect their underlying constructs, and whether the measurement model has acceptable fit to the data.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Assessment of the Measurement Model

As suggested by Hair et al. (2010), reflective measurement model assessment in the PLS analysis includes composite reliability (CR) to evaluate internal consistency among items for each construct, item loading, and average extracted variance (AVE) to assess convergent validity.

As shown in Table 3, the item loadings are greater than 0.70 (Agan et al., 2013), varies from 0.733 to 0.919. The results of composite reliability (CR) for constructs were confirmed satisfactory with values above cut-off value 0.70 (Hair et al., 2010). The average variance extracted (AVE) which reflects the overall amount of variance in the indicators accounted for by the latent construct, were between 0.673 and 0.899, given the benchmark is 0.50 (Chen, 2014; Hair et al., 2012). Therefore, convergent validity was established.

Discriminant Validity of Constructs

Discriminant validity is the extent to which items measure distinct concepts and is indicated by the low correlations between the measure of interest and the measures of other constructs (Cheung & Lee, 2010). Discriminant validity can be examined by comparing the ratio between the square root of AVE and correlations (Fornell & Larcker, 1981). As shown in Table 4, the diagonal elements of the matrix, which represents the square root of the AVEs, are higher than the corresponding interconstruct correlations indicating adequate discriminant validity (Agan et al., 2013). The correlation between latent constructs' composite and all other constructs are also less than 0.7, indicating that constructs differ sufficiently from one another (Urbach & Ahlemann, 2010).

The Structural Model and Path Analysis

After the constructs were confirmed to be reliable and valid, we proceeded with the path analysis to test hypotheses. Figure 2 and Table 5 show the structural model parameter estimates. The overal model explained a significant variance of ($R^2 = 0.53.4$) 53.4% in green purchasing intention via latent variables and the moderating variable; considered significant and meaningful for the purposes of interpretation (Hair et al., 2012). In social science research, R^2 of 0.75 is substantial, 0.50 is moderate, and 0.25 is weak (Wong, 2013).

A close look shows that man-nature orientation is positively significant ($\beta = 0.359$, $p < 0.01$) to green purchase intention and so do long-term orientation ($\beta = 0.\ 298$, $p < 0.01$) and environmental advertising ($\beta = 0.252$, $p < 0.01$), whereas environmental knowledge is not a significant predictor of green purchase intention. Thus, H2, H3 and H4 are supported, whereas H1 is not. In this study, it was found that the cultural value of man-nature orientation is the strongest predictor of green purchase intention follows by cultural value of long-term orientation and environmental advertising.

For the moderating (interacting) variables, statistically significant beta path coefficients were indicated in both Figure 2 and Table 5. Bootstrapping procedure was used to test the moderating effect. The results show that income level is insignificant; thus, H5 through H8 are not supported. Results indicate that education is significantly influenced the effects between long-term orientation and green purchase intention ($\beta = 0.212$, $p < 0.01$) and environmental advertising on intention to purchase green products ($\beta = 0.256$, $p < 0.01$), however did not moderate man-nature orientation.Therefore H11 and H12 are sup-

DISCUSSIONS

Sustainable consumption has attracted the attention of both academic researchers as well as the practitioners. Identifying and understanding how various factors affect the intention of green purchasing is a critical topic of green consumer behavior discipline. Accordingly, the study in hand was to explain consumers' green purchase intention motivational drivers. Of the examined 16 hypotheses, eight hypotheses demonstrated a significant relationship towards green purchase intention.

The results of the study show that environmental knowledge did not have a significant influence on green purchase intention. Therefore, the finding brings to question the assertion that in the theory of planned behavior, the more knowledgeable the consumers are about a subject, the more they know about the effects of the human actions towards it, the more they may be expected to adapt the right action. The possible explanation for the result of the study is supported by Tanner and Kast (2003) and Schahn and Holzer (1990) who concluded that action-related knowledge is positively related to green food purchases and environmental action, whereas the factual knowledge was not a significant predictor of the latter. The questions in this study were adopted from surveys administered based on factual knowledge. Moreover, Smith-Sebasto and Fortner (1994) quoted claiming that "when the relationship between environmental knowledge and behaviors/intention appears to be stronger, it is knowledge about environmental behaviors rather than factual knowledge about the environment that is related to ecological behavior.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

As for cultural influence, the statistical result supported the hypothesis confirming that man-nature orientation was found to be positively related to green purchase intention. This is consistent with previous studies (Rehman & Dost, 2013; Chan, 2001). The finding of the study indicates that man-nature orientation is a constant part of individuals' life, which shapes people's eco-friendly behavior ultimately leading to positive green products purchase intention. In other words, man-nature orientation values, as a way of expressing their wish to protect the environment, allow and increases consumers' interest in and desire for green products. Man-nature orientation is recognized as an important factor influencing consumer's intention and behavior. Schiffman and Kanuk (2010), Kotler (2003) and Schiffman and Kanuk (1994) stated that culture has a strong influence on consumers' behaviors that occur so "natural" and "automatic" and is a crucially fundamental determinant of a person's desires and behavior. It can be reasoned that man-nature orientation values will evoke consumers' desire and intention to buy green products as a mean to preserve the environment and maintain living harmoniously with nature as demonstrated by respondents in this study. This may be due to the fact that Asians in general perceive themselves as living in harmony with nature (de Mooij, 2004), causing them to adhere to the values of man-nature orientation that have consequently influenced their purchase intention of green product.

The cultural dimension of long-term orientation was also hypothesized to be positively related to green purchase intention. This study found that the hypothesis was supported and is in support of previous studies (Gul, 2013; Beardon et al., 2006) the findings conclude that long-term orientation is a prominent cultural facet and influencer on consumers' purchase decision making as well as a good predictor for the formation of environmental attitude. The respondents in this study exhibited a positive relation between long-term orientation and green purchase intention since green consumption is believed to save money and conserve the environment in the long run guaranteeing a better living. The results support the works of Sarigollu (2009) which theorize that long-term oriented people are more likely to develop values and attitudes pertaining to the protection of the natural environment.

Among the supported hypotheses is the hypothesis that environmental advertising significantly influence green purchase intention. This is in line with findings from from the studies by Xue (2014), Zhu (2013), Litvine and Wüstenhagen (2011) and Kao et al., (2013). The finding is reasoned by the fact that as environmental advertising would enhance consumers' knowledge and attitude towards green products while recognizing the advantages of the purchasing of such products. This could very much be due to the suggestion that the messages in environmental advertising are perceived to be credible, making them more socially responsible to the environment and keys in distinguishing green products from ordinary products and in avoiding confusion in identifying green products in the market and acknowledging its availability in the country. It is in line as proposed by Ruiz and Sicilia (2004), who suggested that through environmental advertisement there will be greater advertising effectiveness, which will arouse positive behavioral intention within the consumers.

The findings of the study suggest that gender and education level moderate the relationship between man-nature orientation, long-term orientation and environmental advertising. However, income had no moderating effect on the relationships between the independent variables and green purchase intention. This concludes that education level as well as gender can explain green purchase intention and show that its interaction with cultural values and environmental advertising represent more effective antecedent variable of green purchase intention. In terms of education level, the study finding indicates that individuals with higher education level (university and college degrees) show stronger relations between environmental advertising and green purchasing intention and long-term orientation and green purchasing intention compared to individuals with lower educational level (high school and lower).

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

The result suggests the potential impact of tertiary education/knowledge on the recognition and trust of environmental advertising and nature of being long-term oriented that may lead to the strengthening of the impact of the both on the green purchase intention. This finding supports the earlier study by Rezai et al., (2011) which testified highly educated individuals have a positive attitude on green products and a stronger intention to buy them. As for gender, the relationship between man-nature orientation and purchasing intention, long-term orientation and purchasing intention as well as environmental advertising and purchasing intention is stronger among females compared to that among males. This confirms the previous findings suggesting that women are more likely to be pro-environmentalists (Rezai et al., 2011; Lee, 2010; Laroche et al., 2001; Zelezny et al., 2000). Being the gatekeepers who are more likely to be pro-environmentalists with higher green purchasing intention, it is essential to recognize the influence of female gender on the relationship between pro-environmental motivational factors and the purchasing intention of green products.

IMPLICATIONS

From theoretical perspectives, this study is the first to develop a model that explain influencing factors and drivers of consumers' green purchasing behavior by integrating and examined various major aspects; namely individuals' possessed knowledge on environment, man-nature orientation and long-term orientation, marketing/organizational effort (environmental advertising) and the moderating effects of income, education level and gender in a single framework. The findings of this study bring new insights and interesting findings where it has identified and confirmed that cultural values, man-nature orientation and long-term orientation, play significant role in influencing green consumer purchase intention while the premium price factor is found to have no effect on green purchase intention. Thus, this study provides a building ground and paves the way for future researchers to explore in depth other cultural values along with other predictors that could promote pro-environmental activities and buying intention in Malaysia and other countries.

In terms of research, clearly, the study provides further evidence of the usefulness and validation of using CVSCALE developed by Yoo and colleagues to measure the influence of culture at the individual level. Due to the globalization of markets with products crossing national and geographical borders; making cultural context important in understanding the consumer behavior (Patterson et al., 2006). However, the existing literatures of cross-cultural business are rather inconsistent and chaotic due to the cultural valuation methods in using conflicting scale and the absence of a universally accepted scale. It is understood that by measuring the cultural values and not equate it with the national culture, researchers can avoid the ecological fallacy, which occurs when the ecological or country-level relationships are construed as if they apply to individuals (see Hofstede 1980). Thus, adoption of CVSCALE is recommended and can benefit multi-cultural business practitioners and cross-cultural researchers.

Based on the results of the partial least square (PLS) technique in testing the hypotheses in the study, man-nature orientation values exerted the most significant influence on green purchase intention, followed by long-term orientation and environmental advertising. Cultural values of both man-nature orientation and long-term orientation provide a stronger effect and therefore more useful profile of green behavior and product consumption. In term of managerial implications for green marketers, the results offer consumer segments (based on cultural values and personal/demographic traits) and execution of environmental advertising for green products in green marketing. Understanding how different

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

consumer orientations and value responses vary enables green marketers develop customized strategies aligned with specific consumer segments, ultimately increasing the effectiveness and efficiency of green marketing and sales activities.

Based on the finding of the study concluding that the influence of culture is dynamic, it is recommended for marketers to direct individuals toward green products through advertising based on cultural reasoning inducing their intention to purchase green products.This can be carried out by applying or instilling certain elements of the man-nature orientation and long-term orientation in advertising, such approach may include the demonstration of how green product can maintain and protect the environment, save money that benefits in the long run and reminders of the responsibility to act accordingly through environmentally friendly behaviour. Marketers can engage and reflect certain cultural values effectively through environmental advertising while providing environmental advertising a competitive advantage over normal advertising by affecting consumers' cognitive emotional functioning and exert strong intention to obtain green products. Additionally, through systematic educational program and proper societal and social marketing approach, marketers along with governments can utilize these cultural values to increase individual's' environmental awareness and stimulate intention to buy green products.

Although green advertising is widely recognized and accepted in this study, benefits, validity and credibility, associating with it rather controversial (Pfanner, 2008) due to the use of false green claims, ambiguous information, lurid and exaggerate language (Polonsky et al, 1997). The researchers suggest that managers need to constantly monitor the credibility of green claims in green advertising accordingly because it plays an important role in influencing consumers' green purchase intention. Therefore, a specific and well-planned strategy is required to execute a green advertising campaign, which consists of concise and clear information about the products' features as well as trustworthy environmental claim and benefits of using green products. This will eliminate consumers' doubt of the products advertised and establish a green corporate image for the firm, such image will stimulate stronger intention leading to an increase in sales of green products.

As the results suggest that women with higher education expressed higher purchase intention of green products than in men and individuals with lower education level it is recommended that green product managers should pay special attention to this segment of consumers by customizing green products that meet their personality preferences (e.g. design, size, and color options) to arouse stronger purchase intention which will encourage them to buy more green products and be active in green brand loyalty.

As confirmed in this study, interestingly environmental knowledge has been found to have insignificant relationship towards green purchase intention. Coddington (1990) quoted that "the seeds that are sown under the right approach to environmental marketing are the seeds of environmental education". Hence it is strongly suggested for the government to introduce an environmental subject in the formal curriculum in schools and higher institutions to enhance citizens' specific knowledge concerning the environment to foster green buying behavior.

LIMITATIONS AND FUTURE DIRECTIONS

Just like any other research, the study has certain limitations highlight the need for further research. Firstly, although the result of this study has further proven the usefulness of the CVSCALE in measuring Hofstede's cultural dimension, the cultural assessment method for individual-level is rather chaotic and needs future researchers to keep validating these measures on pro-environmental behavior using a larger

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

sample, demographically diverse samples and respondents from other countries, as well as employing other dimensions based on CVSCALE (etc. Collectivism, individualism, feminism and masculinity). A convenient start will be to replicate existing studies to see whether similar findings may be made when culture is measured at the individual level. Such similarities or differences between individual-level and national-level of Hofstede's' cultural dimensions will provide insights into psychological, sociological and business managerial differences of the same construct.

Secondly and clearly, more variables could be examined as an extension to this study. Other variables reflecting factors such as product attributes, social factors, psychological factors, premium price, and organizational and government roles and initiatives could be included.

Thirdly and finally, it would be interesting to extend this research by examining specific green products or industry. It can be implemented with a special focus on electrical and electronic appliance, automobiles, environmentally friendly cleaning products, food and agriculture.

Despite the mentioned limitations, the study evidently makes several contributions to the field of consumer buying behavior and green marketing.

KEY TERMS AND DEFINITIONS

Environmental Advertising: Environmental advertising is defined as a specific type of communication designed towards promoting social, economic and environmental benefits of products to form a responsible values and behavior of consumers.

Environmental Knowledge: Environmental knowledge is the amount of information individuals have concerning environmental issues and their ability to understand and evaluate its impact on society and the environment.

Green Purchasing Intention: Green purchase intention stands for a willingness and distinct kind of environmentally friendly behavior by individuals to give preference to green products compared to conventional products to express their concern to the environment.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Long-Term Orientation: Long-term orientation is a cultural orientation that deals with time - past, present and future to foster virtues oriented towards future rewards, in particular perseverance and thrift.

Man-Nature Orientation: Man-nature orientation is referred as the friendly behavior or relationship between human beings and the natural environment because of the love of nature and the passion to protect it.

Structural Equation Modeling: Structural equation modeling (SEM) as a second-generation technique, is a statistical technique for building and testing simultaneous modeling of relationships among multiple variables.

Chapter 12
Constructing Green IT Alignment Framework: Car Manufacturer Case

Leelien Ken Huang
Feng Chia University, Taiwan

ABSTRACT

Using contingency theory (CT) of fit as a foundation for this research, we report the development of the notion of 'green IT alignment framework' and its determinants. This is followed by an analysis of the relationship between capability areas (i.e., contextual factors) and green IT alignment while the company pursues GREEN. Data were collected from a case study where a car manufacturer is our research setting—considered as suitable for this type of research. The author found that a total of 18 capability areas over three domains of technical, organizational, and environmental are a premise for green IT alignment. Such capability areas are considered as new and interdependent of traditional strategic alignment capabilities. The results of this research demonstrate an appropriate green IT alignment framework that is trust worthy to construct for understanding the factors of IT-business fit while pursing GREEN. Implications are discussed.

1. INTRODUCTION

With intensive public discussions and widespread coverage in the media, the impact of global warming on the environment has been the foremost issue to governments, non-government organizations, and consumers (Enkvist, Naucler, & Oppenheim, 2008; Friedman, 2007; Kuo & Dick 2009). Stronger national (or international) commitment to reduce greenhouse gas (GHG) emissions and achieve other environmental goals creates pressure for finding ways to achieve greater efficient use of energy and other resources while sustaining economic growth (Dedrick, 2010). This environmental issue has shifted from being solely the concern of scientists and/or environmentalists to being recognized by business executives now concerned with impact on shareholder value (Bonini, Hintz, & Mendonca, 2007). The notion of "GREEN" (i.e., environmental considerations [e.g., environment friendly products/services, etc.])

has therefore become important to sustainability (i.e., company success) in terms of business strategy (Elkington, 1998; Enkvist & Vanthournout, 2008; Price Water House Coopers & SAM, 2008) and social responsibility (Kuo & Dick, 2009).

To achieve sustainability, the notion of 'green information technology (IT)' has emerged and is considered as reducing the direct environmental impact of designing, manufacturing, using, and disposing of computer, servers, and associated sub-systems (Murugesan, 2008). For example, recycling electronic wastes can be a priority for many companies (Herat & Bahadir, 2007). Energy efficiency in hardware and data centres also receives great attention, given the potential to reduce carbon emissions and lower energy costs (Forrest, Kaplan, & Kindler, 2008). However, researchers argue that the scope of green IT mentioned above is too narrow (Dedrick, 2010). A broader scope includes the use of IT to improve sustainability across the economy (Watson, 2008). For example, improving efficiency in industries such as transportation, manufacturing, and energy sectors, where they or their products are the major sources of GHG emissions. A broad view of green IT to drive business innovation, productivity, and thus company growth in terms of environmental considerations, can also be a potential source of solutions to improve a company's overall performance (Ghose, Hasan, & Spedding, 2008).

In the literature, green IT toward sustainability has become a significant issue in the narrow sense, whereas less attention has been paid in the broad view (Dedrick, 2010). That is, conceptual and anecdotal evidence indicates that green IT is linked to energy and cost efficiency; it is mainly discussed in terms of equipment utilization (e.g., hardware, networking, applications, etc.) rather than organizational (strategic) impact of IT while pursuing GREEN. This is supported by a recent survey by Forrester (2009), which indicates that the top motivation for adopting green IT practices is still reducing costs. Because broad-viewed green IT involves business innovative practices that enhance the recognition of organizational situations (Ghose, Hasan, & Spedding, 2008; Swnson & Ramiller, 2004), and it is a company's adaptation to the external dynamics with the use of IT (Huang, 2009), a strategic nature is embedded. In particular, broad-viewed green IT considers IT organizational impact, which is a typical alignment issue where IT must support business and vice versa while the company pursues GREEN toward sustainability (Dedrick, 2010; Loeser, Erek, Limbach, & Zarnekow, 2013; Molla, 2009). This means 'green IT alignment'.

Our research focuses on broad-viewed green IT and conceptualizes 'green IT alignment' as equivalent to the traditional strategic alignment that has appeared as the top concern for IT practitioners and business executives (Luftman et al., 2005). The impact of strategic alignment between IT function, IT infrastructure, organizational infrastructure, and business planning processes on company performance has been widely studied (Sabherwal & Chan, 2001; Sabherwal, Hirschheim, & Goles, 2003; Tallon, Kraemer, & Gurbaxani, 2000). With the concept of GREEN, strategic alignment practices should consider how a company responds (or adapts) to the business market with the use of IT underlying increased public environmental concern (Molla, 2009).

Although green IT alignment can be referred to as traditional strategic alignment, it requires new organizational capabilities (Molla & Cooper, 2009). Therefore, a traditional step-by-step strategic alignment framework may not be a reliable guide for practitioners. Green IT alignment needs to start with a clear assessment of those capabilities (or factors) that can help identify the company's position, intended state, and IT progress in supporting the business in its pursuit for GREEN. This requires a framework that not only accounts for factors that allow (or inhibit) the diffusion (spread and usage) of IT that supports the business, but also explicitly considers the role played by different key stakeholders (e.g., IT, business, etc.). Unfortunately, the current green IT alignment framework is unclear (Molla & Cooper, 2009). As a result, there is a lack of understanding and guidance to help assess the extent to which how

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

IT supports the business while company pursues GREEN. An immediate field of research is necessary, and therefore conducted in order to examine how companies assess their green IT alignment.

Grounded on contingency of fit, this research uses the concept of 'strategic alignment' to examine whether fostering and/or development of a certain capability area is more effective toward green IT alignment. Use of the contingency theory (CT) is considered 'suitable' because its key concept of 'fit' indicates a feasible set of equally effective and internally consistent patterns of factors (Khazanchi, 2005), which fulfils our research objective of constructing a green IT alignment framework that demonstrates an optimal (or fit) model of organisational effectiveness that consider appropriate antecedents (or moderators). Thus, the contribution is the identification of a configuration that demonstrates key emphases specific to achieve green IT alignment.

In the sense of broad-viewed green IT, car manufacturing sector is suitable for this type of research to understand how IT supports the business while the company purses "GREEN" (e.g., electric vehicles--EVs). This research believes that both the government and car manufacturers are interested in knowing how green IT alignment can be achieved by considering the company's environmental performance, and therefore, improving overall competitiveness. To fulfil the research objective, we conceptualize green IT and contingency of fit first, then strategic alignment. Next, a notion of green IT alignment is presented. This is followed by a methodology. Findings and implications are also presented.

2. LITERATURE REVIEW

2.1. Green IT

Green IT has been conceptualised in several ways, with wider or narrow scope and a variety of terminologies and concepts. As noted, Murugesan (2008) defined 'green IT' as the study and practice of designing, manufacturing, using, and disposing computer, servers, and associated sub-systems efficiently and effectively with minimal or no impact to the environment. This definition emphasizes energy improvement and equipment utilization in terms of designing energy efficient chips, virtualization, reducing data centre energy consumption, using renewable energy to power data centres, and reducing electronic waste (Watson, 2008). In this sense, green IT is usually associated with technologies and techniques for improving the efficiency of data centres to reduce the environmental impact of IT operations (Nunn, 2007). Table 1 lists the traditional conceptualization of green IT.

Table 1. Exemplars of Green IT

Conceptualization of Green IT	Contributors
Reduction of energy consumption and subsequent CO2 emissions form ICT equipment	ACS (2007)
Equipment recycling, sever consolidation and virtualization, optimizing data centre energy efficiency, print optimisation, data centre airflow management, rightsizing IT equipment, green considerations in souring and RFPS, budget allocation for green IT projects, liquid cooling for IT equipment, DC powered IT equipment, airside/waterside economizer, carbon offsetting.	Info Tech (2007)
Managing IT assets and services in a more energy-efficient way to limit and reduce the company's overall carbon foot print	Nunn (2007)
Energy efficiency through solving challenges of cooling, power and space	Mitchell (2008)

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Nevertheless, IT use should allow organisational-wide green initiatives (Gartner, 2008). Green IT should encompass not only technological solutions, but also business practices and managerial actions that respond to the public environmental concern in terms of business sustainability (Mines & Davis, 2007). In other words, a broad scope of green IT should include the use of IT to enhance business sustainability. As noted, this includes improving efficiency in industries where they or their products create significant GHG emissions, and also considers business innovation that drives company growth. In particular, a broad scope of green IT should consider both the environmental and organizational impact created by the use of IT while pursuing GREEN.

The literature started to seriously consider the role IT can play in both creating and reducing global warming when IT was viewed as part of both the problem and solution (Fuchs, 2008). Thus far, much of the discussion and activity in green IT focus on the direct environmental impacts caused by making data centres and personal computing equipment more efficient. Such efforts can directly reduce IT costs, and therefore, there has been a strong incentive for companies to adopt them (Dedrick, 2010; Forrester, 2009). Cost reduction confirms the profit perspective of most businesses for greener IT practices (Dedrick, 2010). However, an unclear business value for green IT may discourage companies to adopt green IT practices (Molla, 2009). In other words, companies generally adopt green IT practices only when it makes economic sense. (Dedrick, 2010). In particular, nowadays, green IT is part of a fundamental change in business: it is a subset of the larger sustainable trend that reconciles sustainable business practices with profitable business operations (Mines & Davis, 2007).

2.2. Contingency of Fit

CT provides internal/external business and technology factors for identifying alternative courses of action in order to obtain an optimal model of organisational effectiveness (Khazanchi, 2005). CT contributes to the quality and productivity of IT and the company at large by providing feedback (i.e., business adjustments) to manage and improve IT to better meet business needs (Benlian & Hess, 2007). This process of seeking fit is often part of the strategic planning process that reflects a company's appropriate response to its business dynamics (Anderson & Paine, 1975).

Several contextual factors or situational characteristics (e.g., environmental, technical, or organisational factors) have been included in the analysis of a fit relationship (Benlian & Hess, 2007; Ducan, 1995; Earl, 1993; Jiang, 2003; Kearns, 2000; Kearns, 2005; Kearns & Lederer, 2004; Wang, 2001). With these contextual variables, IT contingency research on fit examines the problems, benefits, methodologies, and management issues of the IT strategic planning process that adapts IT to the dynamic business environment (i.e., strategic alignment) (Doherty, Marples & Suhaimi, 1999; Lederer & Sethi, 1996; Ragu-Nathan et al., 2004; Tang & Tang, 1996; Teo & Ang, 2001).

According to Van De Ven and Drazin (1985), a satisfied organisational outcome depends upon a 'fit' or match between two or more contextual factors. There are three ways for defining and testing the concept of fit: selection, interaction, and systems approach (Van de Ven & Drazin, 1984). Because of its relevance to this research, we focus on the systems approach. Underlying this approach, such a fit can be treated as a feasible set of equally effective and internally consistent patterns of contextual factors, structural alternatives, and organizational performance (Khazanchi, 2005; Van de Ven & Drazin, 1984). In a sense, the concept of fit has broad utility to various areas of theory development where organizational performance is a function of match, congruence, intersection, or union of two or more factors (Van de Ven & Drazin, 1984).

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

2.3. Strategic Alignment

Over the past decades, many empirical and conceptual works have examined IT/business alignment (Chan & Reich, 2007a). Some studies adopt a strategic perspective in which alignment is the fit between IT and business strategies (e.g., Benbya & McKelvey, 2006; Chan & Huff, 1992; Huang, 2009), whereas others argue from the operational perspective that IT/business plans and structures (e.g., company/IT department) should be matched simultaneously (e.g., Ein-Dor & Segev, 1982; Fiedler, Grover & Teng, 1996; Fonstad & Subramani, 2009), and that business needs should fit information system priorities (Chan & Reich, 2007b).

We focus on the strategic perspective and define 'strategic alignment' as the degree to which IT and business missions, goals, and plans are matched internally and are externally valid, as well as the extent of the shared vision and commitment between business executives and IT managers on the congruence of the mission, goals, and plans (Chan & Huff, 1992; Henderson & Venkatraman, 1999; Luftman, 2000; Reich & Benbasat, 2000).

With this definition, strategic alignment can generally be viewed as the social and intellectual process of strategy formulation that seeks a fit among environmental, organisational, and technical factors (or situations as noted) and depends on those factors (Doty, Glick, & Huber, 1993; Kim, 2003; Reich & Benbasat, 2000). This process involves continuous adaptations that ensure successful alignment implementation results (Chen, Sun, Helms, & Jih, 2008). Simply speaking, when formulating IT strategy and actually implementing IT plans that support business (or vice versa), managers must consider (or adapt) relevant situations over time to ensure cohesive goals across market and technological domains (Pfeffer & Salancik, 2003).

The literature has argued that the inability to realise better organisational performance is due in part to strategic misalignment (e.g., Benco & McFarlan, 2003; Croteau & Bergeron, 2001; Fonstad & Subramani, 2009; Henderson & Venkatraman, 1999; Kearns & Lederer, 2003; Preston & Karahanna, 2009; Tallon, 2003). This indicates that an effective and efficient IT organisational impact requires strategic alignment. To respond effectively to a dynamic environment, appropriately exploiting IT (based on situations) has been viewed as an important strategic alignment resource (Chung, Rainer, & Lewis, 2003; Khazanchi, 2005; Kohli & Devaraj, 2004; Porter & Millar, 1985). However, the literature agrees that strategic perspective alignment is an on-going issue, and in the long term, a difficult task because of the need for a high-quality set of inter-related IT and business plans (Chen et al., 2008; Henderson & Venkatraman, 1999; Luftman et al., 2006; Reich & Benbasat, 2000).

2.4. Green IT Alignment

As noted, a narrow scope of green IT is the direct environmental impact from IT hardware during a product lifecycle, including production, use, and disposal of computer equipment, whereas broad-viewed green IT is longer term and more dynamic, as are the effects of IT on processes such as transportation and industrial production (e.g., products/services provided), influencing their environmental impacts. The environmental impact of broad-view green IT occurs when widespread use of IT leads to changes in lifestyle and economic structure, for example, widespread use of IT that supports manufacturing automobiles, which in turn leads to suburbanization, motels, fast food chains, and other changes in lifestyles and economic systems; however, the changes and environmental impact generated from these changes are not evident until decades later (Dedrick, 2010).

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Because environmental considerations can be significant for the long-term environmental impact of IT-based products/services that change lifestyles, they form important dimensions in company sustainability (Pricewater House & SAM, 2008). Social responsibility becomes a concern in business strategy, and the triple profit measure of company success that includes economic, social, and ecological sustainability should be considered (Elkington, 1998). Therefore, green IT practices should take a longer term and more dynamic view to examine both IT organizational and environmental impacts. This often requires broader organization operations, for example, the IT department is not the only one directly involved in the company's efforts to pursue GREEN. Comparable efforts are also required by personnel and/or other business units when making decisions about telecommuting; operations and logistics managers that are concerned with transportation, production, and supply chain issue; and product development that is responsible for reducing the environmental footprint of products or services (Dedrick, 2010). This sense of strategic alliance between IT and all other relevant units within an organization for GREEN ensures both the business value of IT (i.e., IT organizational impact) and environmental performance, which is a green IT alignment issue.

However, even encountering pressure from legitimation, social responsibility, and rival competition, unclear business values (i.e., strategic misalignment) can be a disincentive to adopting green IT practices (Molla, 2009). Therefore, green IT alignment should be viewed as the company's adaptive process of the strategy formulation that is a function of the fit among environmental, organisational, and technical factors, and depend on those factors.

3. METHODOLOGY

Because of the idiosyncratic nature of those conditions or contextual factors that we explore in this paper, and there should be no generalized IT contingency model according to CT, a single case study is used. We employ the approach of Wintershield (1994) to identify the conditions for achieving green IT alignment through interviews with managers. This allows us to capture and understand the social and organizational context where the phenomenon 'technology adoption' (e.g., green IT practices) occurs (Bunduchi, 2005). Following Bunduchi's (2005) rationale, we search for happenings and not occurrences. That is, we attempt to understand the phenomenon of green IT alignment issues or difficulties in relation to the strategic alignment of IT and business perception without necessarily looking for the statistical significance of findings (Bunduchi, 2005).

3.1. The Case

Taiwan is an ideal location for examining the green IT alignment issue. Global warming has drawn the government's attention, and clean energy and the reduction of GHG emissions have been the primary focus of Taiwan green policy (Lee, 2009). In support of this, Executive Yuan launched the Dawning Green Energy Industry Program. In this program, one of the major green goals is to be a major Asian production base for EVs. This provides local car manufacturers with an incentive for developing EVs (Li, 2013).

For example, Luxgen EV, a new electric car prototype model recently released by local major automobile manufacturer Yulon Motor (noted as Y Motor), is the outcome of using IT to support auto technology

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

that considers both environmental impact (i.e., reduction of GHG emissions) and fuel efficiency. EVs have become an essential product to meet public environmental concerns.

We limit our case to Y Motor because it is suitable for this type of green IT alignment research given that it has relied heavily on IT to support engineering techniques and green business innovation in the development of EVs that are both fuel efficient and produce zero carbon dioxide (CO2) emissions. With the readiness of IT resources, auto manufacturing, and ET, Y Motor has been aggressively pursuing EV for years, partnering with Nissan Japan and Geely China.

GREEN towards sustainability has been the vision of Y Motor. Green products inevitably become the primary business strategy. To fulfil the research objective, it is worthwhile for us to examine how Y Motor uses IT strategically, generating business value while pursuing GREEN. We identify critical contextual factors, and accordingly, develop a general green IT alignment framework.

Participants for interview were selected if they had worked on the IT department that supports GREEN practices, and were typically located at headquarters, where there is a significant IT presence. Single source bias is well recognized. We also selected business executives familiar with the company's strategic position, and participants from other business units with GREEN experience in production, supply chain issue, and product development. These participants are believed to be knowledgeable about the entire company's strategic position with regard to green IT alignment. Six participants were selected (i.e., two from the IT side and four from the general business side), which is consistent with Sanders' (1982) argument that three to six individuals can provide sufficient information. Table 2 lists their profile and the characteristics of Y Motor.

Table 2. Characteristics of Case: Y Motor

General Information							
Company Size	1350	Annual Sales (US$)	>= 9.3 Bn	IT Dept. Size	>=40	IT Dept. History	>=20

3.2. Case Research Concept

As noted, **g**reen IT alignment requires new organizational capabilities (e.g., new technical and business skills) (Molla & Cooper, 2009); the traditional strategic alignment mechanism may not be applicable to explain how companies assess the relationship between IT organizational impact while considering their environmental performance. This is supported by the information systems (IS) community, which claims that in most cases of strategic alignment studies, conclusions cannot be generalized easily (Chan, 2007). Therefore, the use of CT with a nature of 'it depends' is encouraged for examining strategic alignment issues (Chan, 2007).

Given CT, we describe the notion of green IT alignment as consisting of the conditions under which Y Motor should consider itself a likely successful candidate for adopting broad-viewed green IT practices (i.e., satisfied IT organizational impacts and environmental performance). Thus, we construct an exploratory study to identify the contextual factors considered by Y Motor to evaluate how IT supports business (and vice versa) while pursuing GREEN (e.g., EV products) in terms of potential fit (i.e., adaptive) and its ability to influence benefits accrued to the company. In view of contingency of fit, we address two research questions in terms of the content (knowing) and the process (know-how), as indicated in Table 3. This is used for a subsequent interview guide for the data collection and analysis of constructing a green IT alignment framework.

3.3. Data Collection

As indicated in Table 4, the interviews were semi-structured based on the interview guide, which attempts to answer the preceding two major research questions (demographic questions not included). The interview questions were cited and justified according to extant literature in green IT practices and traditional strategic alignment (e.g., Dedrick, 2010; Huang, 2009; Huang, 2010; Kuo & Dick, 2009; Gupta, Karimi, & Sommers, 1997, Mollar & Cooper, 2009, etc.).

To ensure content validity and question reliability, we requested IS professors to review the preliminary English version of the interview questions, as well as the Chinese translation to ensure that the meaning was not altered, the terminologies and technical terms were translated accurately, and the participants understood the questions. The Chinese version of the questions was tested to examine whether there were major modifications to the questions. The pilot test result was satisfactory and provided valuable comments for the interview guide revisions.

Table 3. Research questions: the content and the process

What	Why
The Content: Under what conditions (contextual factors) should the company consider itself a likely candidate for IT planning and implementation that support business and vice versa while the company pursues GREEN? (RQ1)	This provides a better understanding of the structure and characteristics of appropriate green IT alignment framework.
The Process: What and how is the relationship of those factors on the company performance during the planning process in terms of green IT alignment? (RQ2)	This addresses the notion expressed earlier from the contingency of fit that suggests that there needs to be a match between organizational, environmental and technical factors on the company performance that pursues GREEN with the use of IT.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Data were collected over an eight-month period. Each participant was interviewed for at least 90 minutes. While interviewing the participants, we attempted to ensure that they express their opinion on the contextual factors they considered important, and answer our questions related to strategic alignment and green IT alignment concerns. Although the pilot test was satisfactory, the questions were still modified to incorporate the findings of the previous interviews after each interview in order to help strengthen and develop a green IT alignment framework.

Field notes were captured in order to record a detailed account of the participants' thoughts, feelings, experiences, and perceptions throughout the research process. Follow-up interviews were conducted to ensure that all necessary data were collected. With the prior consent of participants, tape recording was also used. We also examined internal documents (e.g., presentations, internal newsletters, etc.), public records and news articles, and press releases related to the GREEN practices used by Y Motor's IT department.

4. RESULTS AND DISCUSSION

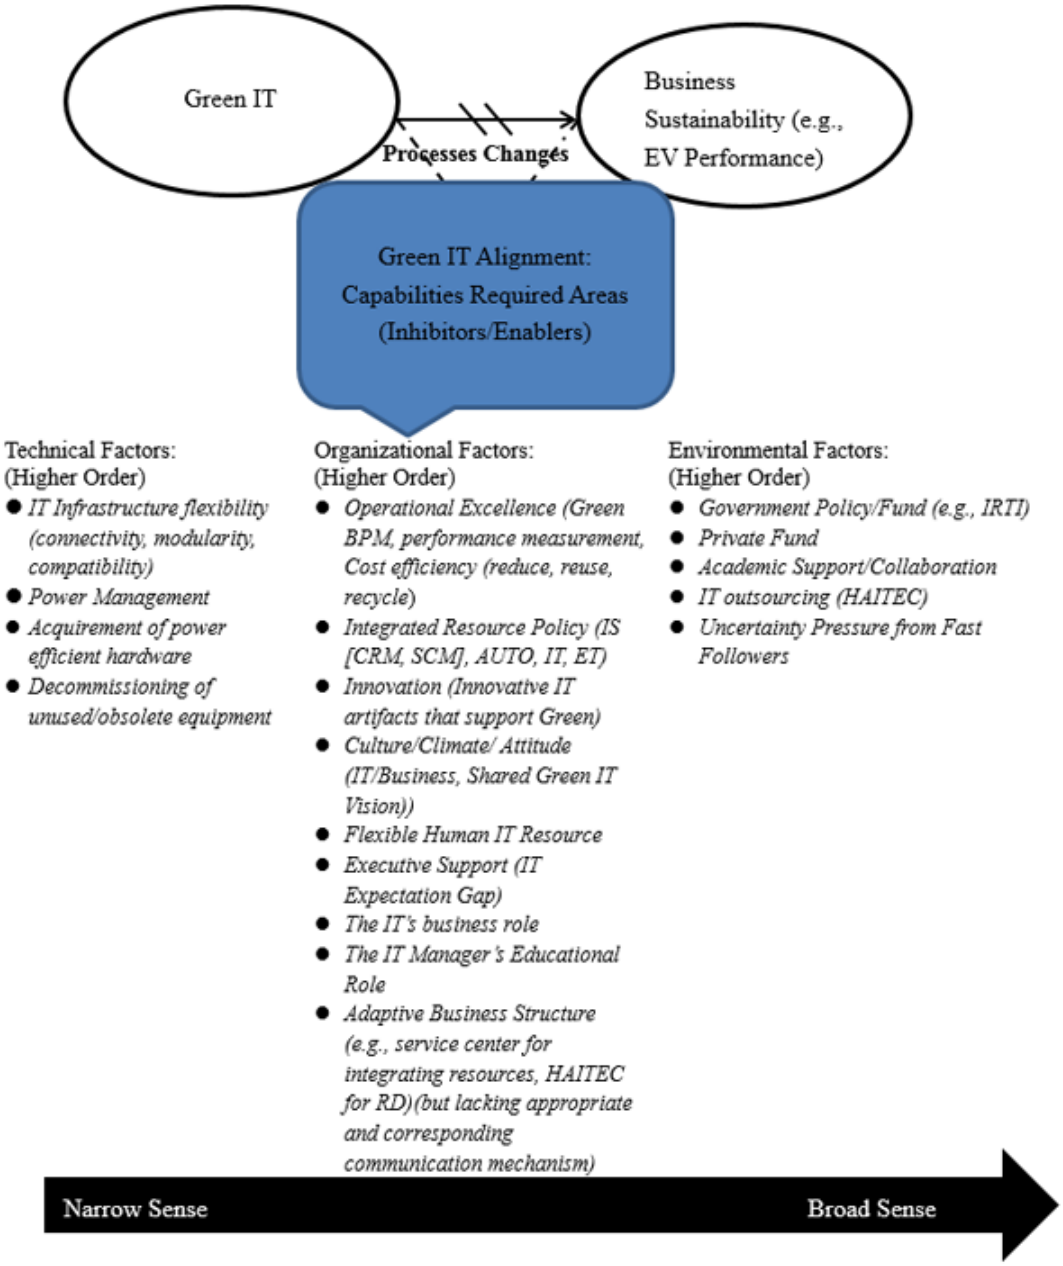
After careful data aggregation and classification, we grouped the responses into several meaningful commonalities across the different types of questions we asked, as indicated in Table 4. These commonalities were compared constantly with new data/responses, and allowed us to realize that they were required to ensure better green IT alignment. These classified commonalities were developed later as the contextual factors that had impact on green IT alignment.

Accordingly, a contingency-based green IT alignment framework of Y Motor was constructed as shown in Figure 1. In the framework, emergent contextual factors were compared with the literature and treated as capability areas that Y Motor needs to reinforce and develop toward effective organizational and environmental performance—i.e., the strategic alignment of IT and business goals while pursuing GREEN. This is similar to the contextual factors that are antecedents to the capabilities that have impact on strategic alignment in the studies of Kearns and Lederer (2003, 2004). In particular, in our case study, CT supported the fact that emergent contextual factors should be appropriately considered and coordinated as an organization's new capabilities when planning and implementing IT to effectively support GREEN (Ryoo & Koo, 2013).

As shown in Figure 1, the capability areas identified in the three dimensions of technical, organizational, and environmental were viewed as higher order factors from the narrow sense to a broader sense of green IT that influences green IT alignment. Because the participants were both from the business and IT sides, we believe that these capability areas truly capture the phenomena of green IT alignment practices. That is, the single source bias was well controlled. In the following paragraphs, capability areas with their key corresponding responses are presented.

4.1. Technical Capability Areas

One of the IT participants commented that '*we need to save IT budget, power consumption, and enhance our entire efficiency of using IT*'. This argument is similar to that in the most recent narrow-sense green IT literature noted previously. This is also echoed by a business senior VP who commented that the cost efficiency of IT resource management is one of Y Motor's strategic concerns in planning IT, as well as



EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 4. Interview guide

Type of Question	Interviewee	Interview Question	RQ to Answer
General Questions	Business Executive (A)	What motivated you company to go GREEN? Has the GREEN proved successful so far? Why or why not?	RQ1, RQ2
Organizational Factors	Business Executive (A) IT Manager (B,C) Functional Manager (D, E, F)	How did you recognize that IT is critical to this GREEN success? How did you endorse IT investments that have not satisfied traditional justification criteria and procedures to support go GREEN? Did you commit to information systems function to pursue GREEN? And why or why not? How did you support the progressive use of IT in your company for GREEN? How did you make choices about IT infrastructure, IT processes and IT people, and even IT outsourcing while the company pursues GREEN? While company pursuing GREEN, how did you decide on centralization, decentralization, or hybrid structures of your IT department? What outcomes were you expecting from green IT practices? How did you set up IT supporting teams for company's GREEN? How did your IT people communicate and interact with non-computer oriented people in terms of their needs for GREEN? And why? How did your IT people recognize organizational key issues and problems of a given GREEN area (e.g., product development)? And why? How did you IT people determine positive and negative impacts of a specific IT system on specified parts of GREEN)? And why? How did your IT people work effectively in cross-functional teams addressing business problems while the company pursues GREEN? And why?	RQ1
Technical Factors	IT manager (B, C)	How did your IT department provide electronic links and connections while the company pursues GREEN? And why? How did your IT department provide access to a large variety of data types, including text, voice, and graphics while the company pursues GREEN? And why? How did your IT department use object-oriented and pre-packaged modular tools to create software applications while the company pursues GREEN? And why? Can computer software modules be easily added to, modified, or removed from existing IT infrastructure with minimal impact? Please explain.	RQ1
Technical Factors	IT manager (B, C)	How did your IT people design and implement databases with a generalized database management system; and develop structured or modular programs while the company pursues GREEN? How did your IT people recognize the appropriate management science model for situations commonly encountered while the company pursues GREEN? How did your IT people formulate and solve complex simulation models while the company pursues GREEN?	RQ1
Environmental Factors	Business Executive (A) IT Manager (B, C)	How did you feel competitive pressure while company pursuing GREEN with the use of IT? How did you feel legitimation pressure to go GREEN with the use of IT? How did you feel social responsibility pressure to go GREEN with the use of IT? What are environmental concerns in planning and implementing IT to support GREEN? And why? Any other concerns? For example, governmental support, attitude, policy, infrastructure, etc., please explain?	RQ1
Green IT Alignment Questions	Business Executive (A) IT Manager (B, C)	What was the role of IT in the GREEN practices? In addition to cost reduction, how do you decide that you have a successful green IT alignment? How IT was previously aligned with business and what changes were necessary to ensure it was re-aligned in the GREEN context? Who made the decisions and why? How did your IT strategy reflect and support mission and goals, and vice versa while the company pursues GREEN? How did your IT strategy recognize external business forces while the company pursues GREEN? How did your IT strategy reflect business resource constraints while the company pursues GREEN? How did your GREEN practices utilize strategic capability of IT? How did your business executives expect IT reasonably while the company pursues GREEN?	RQ2

Figure 1. Emerged green IT alignment framework of Y motor

the baseline of their business goals while pursuing GREEN. Apparently, for Y Motor the fundamentals of performing GREEN with the use of IT is clearly economic-oriented through the development of technical capability areas that can help reduce cost and increase the efficiency of IT use. To do this, the three capability areas are labelled as 'Power Management', 'Acquiring Power Efficient Hardware', and 'Decommissioning Unused/obsolete Equipment', and they allow Y Motor to reduce cost and GHG emissions, as well as retire servers and/or defer the purchase of new servers, thus decreasing electricity

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

consumption and heat waste. Such three capability areas are more associated with the narrow sense of green IT while Y Motor pursues GREEN in its daily business operation.

However, as noted, GREEN towards sustainability is Y Motor's vision. The above narrow-sense three technical capability areas are not sufficient for explaining the new capability required for Y Motor's green product development to be the primary business strategy. As commented by the IT participants,

…our boss seems to expect more from what we can use the systems for, not only to help internal operations, but also to interact updated data and information with those people outside our department or even company…this can help everyone capture timely messages and share the same vision…without deviating from our policy while pursuing GREEN…therefore the IT platform, functions, and communication must flexibly reflect the current and future green business needs… considering the public and government environmental concerns…

To ensure that IT has a comprehensively positive impact on the entire organization while pursuing GREEN, another technical capability area for 'Flexibility in IT infrastructure' is labelled. The term 'flexibility' is borrowed from the literature because our participants' comments are similar to those in Ducan's study (1995). Accordingly, we classify this flexibility into the three types of connectivity, modularity, and compatibility that Y Motor should emphasize in order to gain better green IT alignment.

Based on the previous comments, we argue that, in order to reduce transaction costs and increase efficiency while pursuing GREEN in either the EV production process or general administration routines, Y Motor must improve the connectivity flexibility in electronic links and connections, which ensures that end users are electronically well linked with other end users across departments. This provides smooth communication while exchanging green data and information, and therefore ensures accuracy and updated situations during the process of GREEN implementation (e.g., shared green IT vision among IT and business units).

Y Motor also needs to improve modular flexibility. As commented by business participants,

…our IT systems are just not appropriate to handle current business issues and problems while developing our EV… so our IT decision is often to acquire new IT resources which may not be necessarily needed and often takes too much time and effort to update the systems. This indeed incurred our costs.

In this sense, to reduce costs, Y Motor requires a level of modularity in systems and applications to be improved in order to ensure reusable software modules in new systems development; the use of a great extent of object-oriented and pre-packaged modular tools to create software applications; and software modules that can be easily added to, modified, or removed from existing IT infrastructure with minimal impact while pursuing GREEN.

Because EVs have been one of the core products of Y Motor, various types and sources of data and information have been highly involved in the traditional process of design and even production. This addresses an issue for how Y Motor can integrate these different data and information, and obtain synergy in terms of production efficiency and cross selling. Hence, Y Motor requires an increase of compatible flexibility by providing a great extent of multiple interfaces or web access (EDI) for external suppliers and customers to share all types of information, and also a great extent of access to a large variety of data types, including text, voice, and graphics.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

A total of four technical capability areas were identified. Future research should focus on exploring measurements for these technical capabilities. Moreover, although a variety of technical capability areas were found, given CT, future research should focus on how the moderating (contingent) effect of these technical capability areas may indicate that a certain level of technical capabilities distinguishes the IT plan (i.e., the level of IT management sophistication), which in turn affects green IT alignment, similar to the study of Gupta, Karimi, and Somers (1997).

4.2. Organizational Capability Areas

As commented by a business senior VP, "…recognized that the EV project is critical to our success… embraces a strong broad-based vision for the role of IT and sometimes endorses IT investments, even those that have not satisfied our traditional justification criteria and procedures." This is similar to past findings where the executives' shared IT vision and IT confidence leads to a better strategic alignment (e.g., Preston & Karahanna, 2009; Loeser et al., 2013).

Therefore, the capability area of 'Executive Support' for IT while pursuing GREEN is found, indicating that understanding how importantly business senior VPs perceive IT resources, and thus support IT, is critical and fundamental to achieving a green IT alignment. We also found that effective communication is key to ensuring strong executive support. Although this is a common finding in the literature (e.g., Johnson & Lederer, 2007), we continuously argue that this is true for Y Motor. That is, effective communication facilitates the relationship between business senior VP, IT people, and other units, such as manufacturing, distribution, and car design centre, while pursuing GREEN (e.g., EVs). As a result, they allocate energy to making the relationship more responsive so that IT does not necessarily generate a sustained business value unless top management's perception is much broader sensed while pursuing GREEN.

As commented by a manufacturing participant, "we know that our VP did support EV, and IT people did initiate new IT projects to meet our assembly line [components, body, painting] needs…but we need to streamline our process because current business process and operational procedures seems too complex, out-dated [traditional] to handle …just cannot effectively use IT systems to retrieve data [information] quickly and handle changing and updated EV engineering and design requirements on time…." Participants from the car design/RD centre also complained that they "…always got feedback [very late] from the manufacturing side about whether EV design meets engineering and technical standards…need to correct it if there is something wrong…don't want to slow down the process…need newer and clearer performance criteria…." These comments are similar to past literature (e.g., Chew & Gottschalk, 2009; Herzog, Lefevre, & Pierson, 2012; Rouyet & Spauwen, 2011, Salam, 2011, etc.)

Therefore, the three organizational capability areas of 'Operational Excellence', 'Integrated Resource Policy', and 'Innovative IT Climate' are found as the new organizational capabilities that Y Motor should reinforce or develop in order to alleviate the aforementioned processes issue. The literature argues that an efficient process for developing green products/services is a critical innovative initiative. We believe that this process, including green business process management (BPM), performance measurements (e.g., balance scorecard model), and cost efficiency through reduce, reuse, and recycle of IT resources (as previously commented by IT participants), supports an operational excellence strategy.

This broader-sense operational excellence fulfils Y Motor's vision of GREEN towards sustainability, where it is an environmentally and socially responsible automobile manufacturer. Future research should

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

focus on how BPM and performance measurements can be well integrated and distinguish operational excellence strategies caused by a different perception of the speed-to-market green product development process, and on how this divergence would influence an organization's financial performance (Chew & Gottschalk, 2009).

However, to obtain better operational excellence, we found that an integrated resource policy of using IT-based customer relationship management (CRM), supply chain management (SCM), automation, IT, and even engineering technology, should be formulated to offer greater convenience and flexibility to Y Motor's business units, such as manufacturing, car design centre, distribution, and/or even suppliers and customers, in managing different aspects of their needs for EV products. This is similar to the study of Chew and Gottschalk (2009), which indicated that integrative use of resources can generate intimacy toward sustainable environment pursuing GREEN. Hence, intimacy among internal IT and business units, and external suppliers and customers, is believed to increase the shared vision and thus ensure a green IT alignment that delivers value.

As commented further by the business senior VP, "IT people may not share this enthusiasm [GREEN towards sustainability] when it comes to allocating cash to implement them…but as the IT manager, his job is not only to keep the business running, but also to be innovate; to show the C-suite, the board, and the marketplace ways of running a business, developing IT-based products, and providing insight they didn't know were possible…". This implies that higher executive support depends on how well an IT manager can convince top management. This allows top management to believe that IT people are capable of solving difficult business problems or challenges, and thus increases confidence in endorsing new and unproven IT techniques while pursuing GREEN.

Therefore, we found that building innovative climate, culture, and/or attitude, where innovative IT artefacts effectively support GREEN, is an important organizational capability where IT people can share (the green IT) vision with business and vice versa. This is similar to Olavsrud's study (2015), where setting the IT organization up to an innovative climate of learning, discovery, and iteration is exactly what a company arranges to do. Given CT, future research should focus on how innovative IT climate moderates the organizational impact of green IT alignment.

We also found that the business role of IT is a necessary organizational capability. As noted by the business senior VP, "they [IT people] need to work with key business stakeholders [car design centre, manufacturing] to evangelize for change [EV]…need to ensure on-going communication at regular intervals to all audiences to report progress, provide updates, promote relevant key project milestone wins and recognize project contributors". In Y Motor, changes caused by pursuing GREEN are difficult for most people (business and IT) to accept. To avoid disconnects between the vision and IT implementation, the IT manager needs a clear shared vision (including business financials) and business roadmap to communicate while pursuing GREEN. Given CT, future research should focus on how that shared vision can be developed while pursuing GREEN and what those antecedents are (e.g., Preston & Karahanna, 2009).

Another key organizational capability that we found is that IT human resources should be flexible in order to manage the diverse business contacts of GREEN. Given Y Motor's vision, the new skill from IT people that is different from the traditional should be more business-oriented. As commented by the IT manager, "to ensure IT's contribution not only in energy savings and cost efficiency [cost centre], but also in helping to synthesize all units to realize GREEN goals [EV]…business skills are crucial for both IT managers and staff while coordinating the multi-faceted and sophisticated IT activities…they [IT people] should work as partners to EV engineers to gain knowledge and experiences about procedures". This would increase executives' confidence (and support), and indicates that along with technical skills,

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

IT people are expected to have business skills in order to improve their flexibility in response to a dynamic environment (Huang, 2015). In the literature, Lee's study (2005) shows that IT people need both technical and behavioural skills. Bailey and Mitchell (2006) also identified soft, business (or strategic) concepts, and technical skills that are important for flexible IT people. Given CT, future research should focus on what and how business skills can be complementary and co-evolve with technical skills, which achieves alignment (e.g., Chan, Sabherwal, & Thatcher, 2006; Huang, 2010).

To foster flexible IT human resources, we found that the IT manager plays an educational role. As commented by the IT manager, "being an educator trains how IT people provide flexible solutions for service problems…it is also important to educate executives on green technology issues, knowledge, IT capabilities, and problems". The literature indicates that the organization's education of flexible human resources should include on the job training, experience sharing, relationships, and shared employee insights (Grant, 1996). This education can be conducted by providing organizational elements such as empowerment and autonomous system design teams, enriched and shared jobs, and incentives for collaborative learning and shared work practices in order to build an environment wherein skilled IT people can leverage technical and business skills, and bear the assets of an entire social network. Based on CT, these flexible human IT resources are difficult to fit with internal strategic needs and should be matched with the external environment. With this education, IT people may work flexibly under various business situations and leverage their performance with stronger executive support. This education could also reduce the IT expectation gap and create better strategic alignment (Huang, 2015; Preston & Karahanna, 2009).

We also found that an adaptive business structure is a critical organizational capability area. As commented by the business senior VP, "we need new units to speed up business processes by integrating information and data so as to fulfil our GREEN goals…". This finding supports CT in that an adaptive relationship between the organizational structure and external public environment while pursuing GREEN is the key to strategic alignment. To do this, Y Motor set up HAITEC (i.e., car design/RD centre) as a platform that facilitates and integrates all EV-related business ideas and required information/data. This reduces the possibility of misunderstandings and smoothens the information flow, thus resulting in efficient and precise outcomes for EV development.

However, in spite of HAITEC, as previously noted by the car design/RD centre, obtaining late feedback from manufacturing indicates the lack of an appropriate and corresponding communication mechanism through the use of IT for information and data integration. Future research should focus on how IT-based communication mechanisms differ with the various adaptive business structures (e.g., prospector, defender, and/or analyser [Miles and Snow, 1978]). In other words, future work should investigate whether an appropriate type of IT-based communication mechanism (e.g., an IT steering committee) could effectively help integration in a certain business structure (e.g., conservative defender). We believe that with an appropriate communication mechanism, GREEN project planning and implementation in a specific strategic environment can be effective (i.e., alignment).

A total of nine organizational capability areas were identified. Future research should focus on exploring measurements for such organizational capabilities. With both the technical and organizational capability areas identified, future research could also use analysis of dominance to investigate the relative importance within and between them. This can prioritize the area that is more relatively important to improve green IT alignment. Based on CT, future research will also focus on interaction (i.e., complementary) effect of technical and organizational capabilities on green IT alignment.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

4.3. Environmental Capability Areas

The business senior VP commented that "government's green policy encourages EV development…this utilization of green technology would be a beneficial one against global warming, but also an interest to the market… exactly our GREEN vision". This indicates that government policy that relates to EV is a critical external environment factor. The government must put forth efforts to develop the fundamental infrastructure for EVs (e.g., battery charging), which would increase market acceptance of EVs. With the support of IT, Y Motor should establish a capability that is highly linked with the government or government's research institute (e.g., Industrial Technology Research Institute) to ensure satisfactory communication with regard to EV development and market needs.

Private funding is also important. As commented by the senior business VP, "we have to control our financial debt to avoid financial leverage risk and gain better capital structure… so as to increase our shareholder's value by commercializing EV…we need more cash injection to support RD [new EV ideas]". This implies that Y Motor must acquire sufficient funding support for EVs from private investors. However, the senior business VP claimed that "we must rely on flexible IT systems to keep investors updated on EVs and avoid unexpected disappointments that results in withdrawals"; this echoes the technical capability of flexible IT infrastructure that we found previously. This finding is also similar to Bakker's study (2010). Based on CT, future research should focus on how IT people should work as business partners, and 'talk' the language of investors to ensure private investment is properly managed.

The senior business VP also commented that "IT systems help our team to work…collaboratively with the university on the continuous improvement of engineering technology, battery charging, and infrastructure for EV use". This implies that academic support and collaboration is key to a broader sense green IT (i.e., developing EVs for both public environmental concerns and the economic value of sustainability). We argue that this new capability of collaboration with universities in EV growth and innovation needs more flexible and timely IT systems and infrastructure. This IT-based collaboration could effectively change how Y Motor applies IT to business needs, and how they collaborate both internally and externally. Future research should focus on how this IT-based collaboration might impact green IT alignment. Future research should also focus on the collaborative mechanisms (i.e., what the focus is and what needs to be improved) that capture profits by enhancing intellectual property rights, and avoid slight tacit knowledge involved in the EV product while pursuing GREEN.

Outsourcing is another key external environmental capability. As commented by the senior business VP, by "…leveraging benefits ranging from low cost, improved quality to product, and service innovation…we delegate our EV design and business processes to HAITEC". HAITEC is a third-party company set up by Y Motor. This implies that outsourcing can release internal resources that can be effectively utilized for other purposes while Y Motor pursues GREEN. For example, Y Motor can dedicate more effort to improving (leveraging) engineering technology and IT resources for better alignment with business needs (i.e., EV design) that are effectively provided by a third party while pursuing GREEN. Future research should focus on how certain outsourcing strategies are more effective than others, in particular IT and business strategies (i.e., conservative or aggressive), as well as how effective green IT alignment positively affects outsourcing benefits.

A fast follower is another critical external factor encountered by Y Motor. The senior business VP commented that "uncertain pressure from fast followers indeed gives us a high challenge to speed up our EV innovation…we must differentiate our EV products and integrate our supply chain resources like RD, manufacturing, sales and marketing, and service…". This indicates that EVs are fast becoming a

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

competition between the traditional automotive value chain and a focus on recharging infrastructures. As commented by the senior business VP, "some original equipment manufacturers and newcomers from both western economies and China are our major competitors". This implies that in order to increase competiveness and secure a position, IT must be sufficiently agile and play a critical role in helping the business strategy respond to external pressure by scanning the environment effectively (e.g., global issues of CO2 emissions, fuel economy, fuel price volatility, energy security gaining increased government and consumer attention, etc.), and thus monitor the EV first market signal in time to develop new EV products (e.g., battery pack). Similar to outsourcing, future research should focus on how certain EV product development strategies are more effective than others, in particular IT and business strategies, in improving green IT alignment.

In terms of the environmental dimension, five capability areas were found to impact green IT alignment. Similar to technical and organizational capability areas, future research should focus on exploring measurements for environmental capabilities for the purpose of operationalization. Based on CT, future research will focus on the prediction and interaction effects of the environmental capability area on green IT alignment.

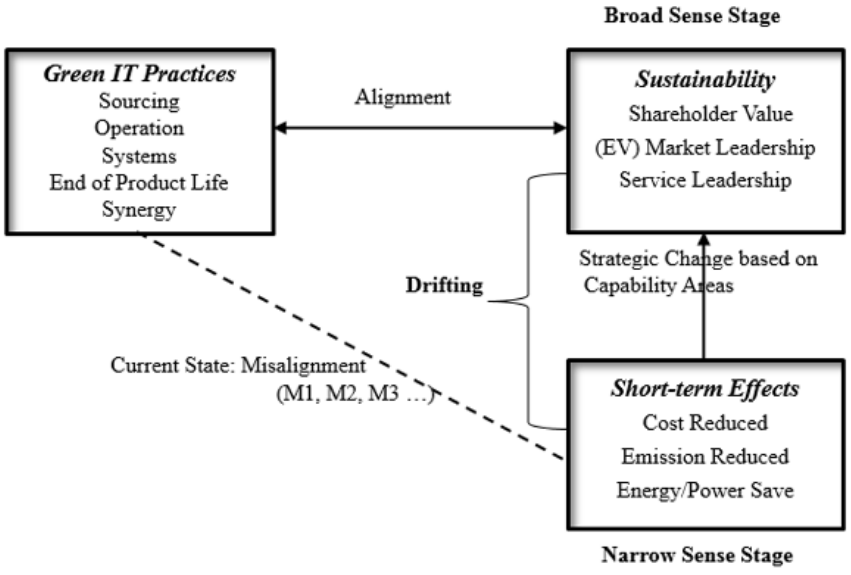
5. CONCLUSION AND POLICY IMPLICATIONS

The results presented in this research are based on qualitative comments from the interviews. We identified 18 capability areas over the three aspects of technical, organizational, and environmental through which the green IT alignment of a car manufacturer can be enabled or inhibited while pursuing GREEN. Our findings demonstrate the CT key concept that they play the influential contextual role of antecedents (or moderators) of green IT alignment.

In comparison with the literature about alignment antecedents such as corporate vision and culture (e.g., Attaran, 2004; Avison, Eardley, & Powell, 1998; Brown & Magill, 1994), shared knowledge (e.g., Reich & Benbasat, 2000), prior experience with IT (e.g., Teo & Ang, 1999), leadership (e.g., Baker, 2004), planning process (Teo & Ang, 19999), and communication styles (e.g., Campbell, 2005; Reich & Benbasat, 2000; Sledgianowski & Luftman, 2005), our results are considered new and different from traditional capabilities of strategic alignment, particularly in the environmental aspect.

For example, car manufacturers should put forth more effort in fostering the capability of building reliable and agile IT systems to scan information relating to governments' GREEN policies/subsidies, and public environmental concerns, other than simply market/product information. To do this, they should have flexibility in electronic links and connections, and provide multiple interfaces or web access (EDI) for external government and the public, as well as suppliers and customers, to share all types of information and vice versa. Doing so should help defend the strategic position, and/or secure the first signal (e.g., timing, content, etc.) of regulation changes, car engineering and technological deployment, green-based new product collaboration with universities (e.g., EV research and development, incubation, etc.), and even the protection mechanism of innovative green ideas, such as patents. This can ensure that car manufacturers obtain updated and correct information, and thus reduce external uncertainty in order to maintain a competitive position while pursuing broad-sensed GREEN toward green IT alignment.

However, this type of environmental capability could develop differently because of different business strategies adopted by car manufacturers, given that executives could perceive environmental uncertainty differently (Miles & Snow, 1978). It also should be noted that all antecedents of strategic alignments in



EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

the literature could be interdependent with the factors found in the green IT alignment framework. For example, a close working relationship between business and IT, corporate culture, and shared knowledge can be an influential background of our organizational capability areas (e.g., Attaran, 2004; Luftman & Brier, 1999). Another example is where building stakeholder commitment and environmental IT scanning can be a foreground (i.e., visible behaviour that influences the alignment) of our environmental capability areas (e.g., Chan & Reich, 2007). Moreover, executive commitment to the strategic use of IT, confidence in the IT department, and knowledge in IT can be a foreground of our technical capability areas (e.g., Teo & Ann, 1999).

The practical implication of our findings is shown in Figure 2, which indicates a Path to Green IT Alignment (P2GA) Paradigm. Understanding the current status of the green IT alignment is very important to proper green IT practices, such as sourcing, operation, systems application, end of product life, synergy with business, etc. Based on the P2GA paradigm, we suggest that the systematic analysis of the present green IT alignment status (e.g., level of misalignment [M1, M2, M3, etc.]) in a company can be the first step in establishing a further direction for alignment in terms of both short-term effects (e.g., cost reduced, emission reduced, energy/power save, etc.) and sustainability (e.g., shareholder value, market leadership, service leadership, etc.). Accordingly, because of the misalignment between short-term effects and sustainability, strategic changes (i.e., action plans) based on capability areas can be identified. However, there must be a drifting time toward the ideal status of green IT alignment. It might take years to complete and/or improve the required capability area, depending on how much executives support the broad sense of green IT while pursuing GREEN, and whether there is a shared IT vision among all stakeholders within the company.

We conclude that the narrow sense of green IT does not guarantee business sustainability, unless comparable efforts are dedicated to the integration of all broad-sensed IT and business resources to generate business value, that is, a green IT alignment that considers both organizational and environmental impacts. However, this is a long-term and difficult task to do.

Figure 2. Path to Green IT Alignment Paradigm

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Our emergent green IT alignment framework provides a guideline for car manufacturers where green IT alignment can only be achieved when those certain identified capability areas are properly fostered and developed together. That is, with CT, we proposed that there is no single solution for alignment problems; rather, it is the capability areas found in the three aspects of technical, organizational, and environmental that allow car manufacturers to leverage engineering technology and IT to gain business value while pursuing GREEN. We further proposed that the measurement models of our identified capability areas are required because the previous literature argues that neglecting to specify exact conceptual or measurement models of fit could lead to inconsistent results in the alignment study (e.g., Chang & Reich, 2007).

The limitations should be noted. Although other industries might refer to our green IT alignment framework, our findings can only be useful to the car industry while pursuing GREEN. This is because the literature argues that alignment can be institutionalized in certain industries, no longer making it a differentiating factor (e.g., Palmer & Markus, 2000). Future research may focus on specific industries to ensure better granularity in findings and deeper understanding in how green IT alignment allows business value creation. Another limitation is that, because the capabilities areas found are higher order factors, we could not explain the specifications for how to improve capability areas (i.e., we lack a first order factor of those capabilities areas that can be operationalized). In other words, with our framework, future research should study how to improve green IT alignment. This echoes our previous proposal that measurement models are needed.

We suggest that stakeholder theory can be used to identify the influences and interests of each stakeholder to construct a well-defined green IT alignment framework, or even a step-by-step mechanism. However, it must be noted that the interests of each stakeholder might change over time while pursuing green IT. Executives must be careful to consider this when examining the status of green IT alignment. We further suggest that the theory of dynamic capabilities can also be used to examine the framework and/or mechanism required to build the company's new capability for developing, deploying, and shaping the IT resources that support green business because the environment is dynamic. In a sense, we may clearly understand how the company can shorten the time required to develop capability areas and streamline the green IT alignment process.

Chapter 13
Understanding Attitude Towards Green IT Among Professionals in IT Service SMEs in Bangladesh

ABSTRACT

Bangladesh is a least developed country which ranks 131 out of 132 in the environment pollution index. Currently, small- and medium-sized enterprises (SMEs) provide 70–80 percent of job opportunities in Bangladesh. Information technology (IT) is one of the industries providing highest employment in the country. The IT professionals' expertise plays an important role in influencing the firms' decisions regarding sustainability. The objective of this chapter is to develop a theoretical model to measure attitude towards green IT usage among IT professionals in Bangladesh. The model will be grounded on self-determination theory.

INTRODUCTION

The study of attitude towards green IT practice has emerged to be a dominant and driving field in current information system research. Many researchers suggest that the green IT perspective can be a partial solution to environmental problems According to Ansari et al. (2010), from the business point of view,

"Green IT is part of a fundamental change in the economy and society. It is a subset of the larger green (sustainable) business trend, which reconciles sustainable business practices with profitable business operations." Molla et al. (2011) defined green IT attitude as sentiment, norms, and values with relation to eco sustainability and role of IT. Esfahani et al. (2015) tested green IT attitude by measuring the impact of argument quality, source credibility and green IT belief. By using value-belief-norm theory, Huijts et al. (2013) measured the predictive power of personal norms on pro-environment behaviour. Akman and Misra (2015) investigated on technology acceptance model to explain the attitude towards using green IT. In this research, we primarily focus on green IT attitude, which will influence end users to adopt green IT practice. On individual level, limited researchers worked on self-determination theory (SDT). The objective of this study is to derive and empirically test a theoretically grounded model of the factors leading to green IT attitude.

BACKGROUND

Burning of fossil fuel, e-waste, deforestation and land clearing for agricultural purposes, and overexploitation of definite resources are some causes behind the increase of greenhouse gases in the atmosphere. According to The *Economist* (2015) special report on climate change, the earth's atmospheric carbon dioxide concentration increased from 361 parts per million in 1995 to 399 parts per million in 2014, with drastic increase between years 2000 and 2015.

Carbon dioxide, methane, CFCs – also commonly known as greenhouse gases – trap heat and warm the earth's surface, thus being the main culprits behind rising temperatures. The earth's temperature now is 0.9 degrees warmer than it was in 1880, that is, before the Industrial Revolution. The rising concern over climate change, pollution and ozone depletion has led to various treaties and agreements among the world leaders. With the Kyoto Protocol, participating countries agreed upon reducing greenhouse gas emissions by year 2020. In addition to the Kyoto Protocol, COP21, held in Paris recently, had participating nations achieve agreement that the global temperature increase should be kept below 2 degrees or 1.5 degrees Celsius above the industrial era (UNFCC, 2015). However, researchers argued reducing carbon emission or mitigating temperature is not achievable over a short period of time (Molla et al, 2009).

On the other hand, innovations in the last century have led to cheaper, better, and faster production. Modern technology has also changed business transactions from traditional business to e-business, and the economy to an e-economy. Information technology has taken an important role, both in business and daily human life. It has made the world closer and smaller, through eliminating global boundaries and creating economic opportunities. Sadly, such opportunities came with their own flaws, like increasing demand of energy, servers, and data centres. Older equipment or e-waste ended in landfills faster than we could imagine – all in order to make way for newer and higher-efficiency equipment (Srivastava & Srivastava, 2012). Although IT is one of the culprits behind environmental issues, Ruth (2009) argued that IT can also provide solutions to address the problem of the remaining 98 per cent of the carbon emission.

The mentioned effects are explained as first-order effects and second-order effects. First-order effects are the negative effects of IT, resulting from all phases of production from cradle to grave. Second-order effects refer to the positive effects of IT on the environment (Esfahani et al, 2014; Faucheux & Nicolaï, 2011). Hence, making greener and environmental friendly IT products is termed green IT, whereas using IT to tackle environmental issues is termed IT for green.

The IT Industry in Bangladesh

Bangladesh is a least developed country (LDC), located in South Asia, with a population of 160 million (Trading Economics, 2015) that has increased 211 per cent in 50 years. The country's vast population led it to becoming a country with large labour markets. Although Bangladesh Bureau of Statistics could not provide accurate data on the number of SMEs, Asian Development Bank reported that SMEs in Bangladesh create 70-80 per cent of all job opportunities in the country. It is estimated that SMEs in Bangladesh account for 90 per cent of employment in the industrial sector (Asian Development Bank, 2013). SMEs also contribute 25 per cent to national gross domestic product (GDP) and 75 per cent to the household income (Rahman et al, 2014).

The IT industry in Bangladesh is now expanding. It has a history of a few decades and is one of the mainstream contributors to the country's income. According to 2012 data from Bangladesh Association of Software and Information Services (BASIS), the information and communications technology (ICT) industry is growing at 20 to 30 per cent annually. The ICT market size is estimated at 350 million US dollars and it has increased 17 per cent compared to that in 2008. Software and IT Enabled Service (ITES) market amount to about 250 million US dollars, which is 70 per cent of the overall IT market in Bangladesh (JICA, 2015). Based on BASIS and other data, there are 800 to 1,000 software and IT service companies, and more than 30,000 IT professionals now working in Bangladesh. Every year, there are almost 6000 IT graduates joining the IT industry. BASIS aims to create 1 million IT professionals by year 2018 (Allmedialink, 2015; BASIS, 2012). According to the report (The New Age, 2015), very few software and IT firms hired a workforce of 300 people. Most IT firms in the country operate with a workforce of 30 people or less, which lead us to conclude that most of the software and IT service providers are SMEs (The New Age, 2015).

IT creates job opportunities alongside changing the business operations. For example, IBM pursues product innovation to improve their hardware energy efficiency, and cradle-to-cradle product life cycle to minimise environmental impact. Fuji Xerox has taken sustainability into their core business. According to their 2013 sustainability report, Fuji Xerox planned to reduce 30 per cent of their carbon emission by 2020, apart from practicing cradle-to-cradle product life cycle. Firms have taken various measures to incorporate sustainability in the business values, whereas IT professionals play an important role in ensuring that the objectives are met. Molla et al (2014) in their study believes that IT professionals play a big role in environmental sustainability. IT professionals stand on the front line in influencing the organisations to practise green initiatives and transformations. They are the ones able to provide technical expertise and solutions.

Green IT in Bangladesh

According to Bangladesh Air Pollution Management Project in 2015, Bangladesh was ranked 131 among 132 countries in the current environmental pollution index. Based on World Health Organization reports, Bangladesh was ranked fourth among 91 countries for the worst urban air quality (*The Daily Star*, 2015). Despite being one of the countries with highest pollution, Bangladesh takes environmental issues seriously. Several policies have been implemented over the years to curb environmental problems. Bangladesh's Ministry of Environment and Forest (MoEF) is formed in 1989 and there are two department fell under the ministry, Bangladesh Forest Department (BFD) and Department of Environment (DoE). MOEF oversees the planning, promotion, co-ordination and the implementation of environment

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

and forestry programmes. BFD is in charge of the reservation of the forestry while DoE is the technical wing and responsible for the implementation of the Environment Conservation Act, 1995 (MOEF, 2016). The breakdown of government policies in Bangladesh are explained in Table 1.

Despite the importance, green IT is rather new, and least focused in Bangladesh. Ansari, et al(2010) reported that the idea of environmental conservation in Bangladesh focused more on preservation of forests and extinct wildlife, though there is increased interest in green IT issues.

Recently, the government agency, banks and industries are taking initiatives for green practice within the organisation. Sobhani et al. (2012) reported only 25 per cent of banks in Bangladesh provided disclosure for environmental sustainability. Sobhani's research identified various green practices like green promotion and marketing, green office, and green finance. But in case of green information technology usage, organisations are still falling behind.

Again, small-scale businesses and local financial intermediaries can play a crucial role by joining hands with the public sector to combat climate change. But accessing financial resources remains a challenge for most SMEs, particularly in least developed countries like Bangladesh. For that purpose, the United Nations proposes that the multi-billion dollar Green Climate Fund (GCF) engage the private sector, particularly SMEs, to combat climate change risks.

THEORETICAL BACKGROUND AND RESEARCH MODEL

The concept of green IT emerged in 2007, in CIO magazines. According to Gartner (2007), green IT manifested when firms wanted to sustain the triple bottom line. Yang et al (2013) argued that being green is regarded as a moral issue in the digital age and were supported by Murugesan. Murugesan (2008) defined green IT as environmentally sound IT. Green IT is the study and practice of designing, manufacturing, using and disposing of computers, servers and related subsystems efficiently and effectively with minimal or no impact to the environment (Murugesan, 2008). Four strategies were identified - green use, green disposal, green design, and green manufacturing. Green use aims to reduce energy usage of IT devices and promote energy efficiency; green disposal aims to minimise e-waste generated by extending the usability of computer equipment; green design aims to provide greener product via product innovation; and lastly, green manufacturing strives to manufacture computer equipment with minimal and or no impact to the environment. Therefore, green IT aims to improve the environmental sustainability via product stewardship, pollution prevention and sustainable development.

Nevertheless, researchers argue about the economic viability of green IT since it is believed that adopting green IT results in longer time to break even (Ambec & Lanoie, 2008). Over the years, the conceptualisation of green IT has been different in different studies – green IT, Green IS, IT for green, green by IT and so on. Bose and Luo (2011) explained that green IT implies three main research areas: namely, energy efficiency, end of life management of IT, and IT as enabler of green governance. The terms green IT and green IS have been used interchangeably in certain studies, while other researchers clearly define and separate green IT and green IS based on the idea that IT is both a cause of environmental problems and a means to solve them. In this study, we will assume both green IT and green IS share the same objective of tackling environmental sustainability.

Many researchers tried to measure green IT by incorporating various theories like belief-action-outcome, organisational motivation theory, process virtualisation theory, theory of planned behaviour,

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Policies in Bangladesh

Year	Policy Name	Task
1970	Water Pollution Control Ordinance	Adopt measures of prevention, control, and abatement of existing or potential pollution of any waters.
1977	Environmental Pollution Control Ordinance	Extends the control on prevention and abatement of pollution to air, water or soil.
1992	National Environmental Policy (NEP)	• Maintain ecological balance and overall development via protection and improvement of the environment. • Identify and regulate environmentally degrading activities. • Environmentally sound development. • Associate with all international environmental initiatives.
1995	National Environmental Management Plan (NEMAP)	• Programmes and intervention aim at implementing NEP. • Manage scarce resources and reduce environmental degradation. • Improve natural and man-made environment. • Conserve habitats and biodiversity. • Promote sustainable development. • Improve quality indicators of human life.
1995 and 1997	Environmental Conservation Act and Rules	• Conservation, improvement of quality standards and control by mitigating pollution. • Coordinate with other agencies relevant to the objectives of the act. • Adopt safety measures and determine abatement measures that may cause environmental degradation. • Advise on environmental use, storage, transportation, import and export of hazardous material or components. • Conduct research and assist other agencies in conservation and improvement of the environment. • Investigate locations, equipment, manufacture to ensure control and mitigation of pollution. • Publish and disseminate information regarding environmental pollution. • Advise government on pollution-causing manufacturing processes and materials. • Ensure potable water quality.
1999	National Water Policy	• Protection of water quality, sanitation and potable water. • Protection of fish and fisheries. • Participation of local communities in all water sector development.
2000	The Environmental Court Act	Support the Environment Conservation Act (1995) and Environmental Conservation Rules (1997).

technological-organisational-environmental framework, technology acceptance model, resource-based view, innovation diffusion theory, stakeholder theory, institutional theory, absorptive capacity theory, stakeholder theory, technology acceptance model, inter-organisational knowledge transfer view, organisational information processing theory, theory of reasoned action, resource dependency theory, and transaction cost theory (Khor et al, 2015; Lei & Ngai, 2013). Lei and Ngai (2013) also clarify that most theories have only been used once. Moreover, the applied theories examine green IT differently, focusing on organisational, individual, environmental and technology perspectives (Esfahani et al, 2014).

However, very few researchers were interested to explore motivational factors of green IT usage attitude. Therefore, we plan to investigate the impact of motivational factors and institutional factors together, to measure the attitude. As a result, this research discovers one specific research question:

Is there any impact of external motivation factors like integrated, identified, introjected and external regulations on attitude towards green IT?

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Based on the above research questions, our research objectives are:

RO1: To examine the effect of integrated regulations on attitude towards green IT.
RO2: To examine the effect of identified regulations on attitude towards green IT.
RO3: To examine the introjected regulations' impact on attitude towards green IT.
RO4: To examine the impact of external regulations on attitude towards green IT.

Self-Determination Theory

Self-Determination Theory (SDT) is an approach to human motivation and personality that uses traditional empirical methods, while employing organismic metatheory that highlights the importance of humans' evolved inner resources for personality development and behavioural regulations (Ryan & Deci, 2000). Three psychological needs of autonomy, competence, and relatedness need to be continuously satisfied through life in order for an individual to experience an ongoing sense of integrity and well-being. These three needs change through a person's life and are influenced by the culture she or he resides in.

SDT categorises motivation into several types – amotivation, intrinsic motivation, and extrinsic motivation. Amotivation refers to the results of not valuing an activity, not being competent to do it, or expecting it to harvest a desired outcome. Intrinsic motivation refers to doing an activity for the inherent satisfaction of the act itself. Extrinsic motivation refers to any activity performed in order to obtain separable types of outcomes. Intrinsic motivations are autonomous motivations, while extrinsic motivations are controlled motivations. According to Gagne and Deci (2005), autonomous motivation happens when people find that the activity they are involved in is interesting, and therefore, they involve in the activity on their own volition. Controlled motivation means performing a certain activity due to pressure, or a sense of feeling compelled to engage in the actions.

Extrinsic motivation is further explained by four sub categories – external regulations, introjected regulations, identified regulations, and integrated regulations. External regulations occur when an individual performs an action in order to avoid being punished or to gain a reward. Introjected regulations imply accepting a certain regulation, but not fully accepting it as one's own. External regulations and introjected regulations are identified as controlled motivations. Identified regulations reflect a conscious valuing of a behavioural goal. Integrated regulations occur when identified regulations are fully assimilated into the self. In the case of green IT, we would like to investigate if extrinsic motivations influence the IT professionals' intention to adoption green IT.

The importance of understanding adoption of green IT by individuals is critical. Practitioners and researchers may gain a better understanding of why people use green IT and predict how motivational factors influence users' attitudes.

Integrated Regulations (IR)

Integrated regulation means identifying so much with the value of doing an activity, that it becomes a habitual part of the self. People who are positively self-motivated have more interest, excitement, and confidence, which in turn enhance their performance, persistence, creativity (Deci and Ryan, 1991). IR has some relation with intrinsic motivation in the form of self-regulation. Intrinsic motivation is characterised by interest in the activity itself, whereas integrated regulation is characterised by the activity being personally important for a valued outcome. In our case, if any IT user believes that by practicing

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

green IT he or she is contributing to conserve nature, then attitude towards green IT will improve. Higher level of IR will lead to higher level of positive attitude towards that activity. As a result, based on the research findings of Koo and Chung (2014), the researcher proposes the following hypothesis.

H1: Integrated regulation (IR) has positive effect on attitude towards using green IT.

Identified Regulations (IDR)

Identified regulation means that a person performs an activity solely because she or he identifies the value or meaning of that behaviour, and accepts the reason why it has to be done. Pelletier et al. (1998) posit that highly self-determined motivational subtypes are expected to lead to positive psychological and behavioural consequences. IDR allows the person to feel a sense of choice or volition about behaving. This is a kind of extrinsic motivation which allows users to act for the goal of improving nature because of its usefulness, rather than finding it interesting. This behaviour is relatively self-determined because the user acts in a certain way willingly for personal reasons, rather than due to external pressure.

In case of green IT, if the IT professionals recognise the values of green IT, that person will have a positive attitude towards green IT use. Koo and Chung (2014) observed identified regulations have positive impact on attitude towards green IT. Thus this researcher hypothesises:

H2: Identified regulation (IDR) has positive effect on attitude towards using green IT.

Introjected Regulations (ITR)

Taking in, but not accepting a regulation as one's own, is the basis of introjected regulations. Introjected regulations refer to behaviour motivated by feelings of self-worth, such as guilt and ego involvement. The IS field by its very nature is reliant on information and communication technologies. IT professionals have no option but to be highly dependent on technology, regardless of the impact on environment. An instance of being regulated by introjects would be a professional who feels like a bad person because she or he does not practise green IT. According to Watson et al (2010), people have a natural tendency to practise green. If IT professionals don't feel guilt while using technologies that effect environment, then attitude towards using green IT would be lower . Based on the findings of Koo and Chung (2014), we propose:

H3: Introjected regulation (ITR) has positive effect on attitude towards using green IT.

External Regulations (ER)

External regulations represent the least self-determined form of extrinsic motivation. External regulations refer to behaving in a certain way, solely to obtain a reward or to avoid a punishment. External regulation is referred to as controlled motivation because the motivation to perform comes from outside the self, or, is less determined by the self than autonomous motivations. If an organisation has no policy, reward or punishment for the employees, there is less possibility that the organisation will receive the desired behaviour from employees. In case of green IT, external regulations often identified the motivation of getting benefit from green IT usage. It implies that if external regulations are high then attitude towards

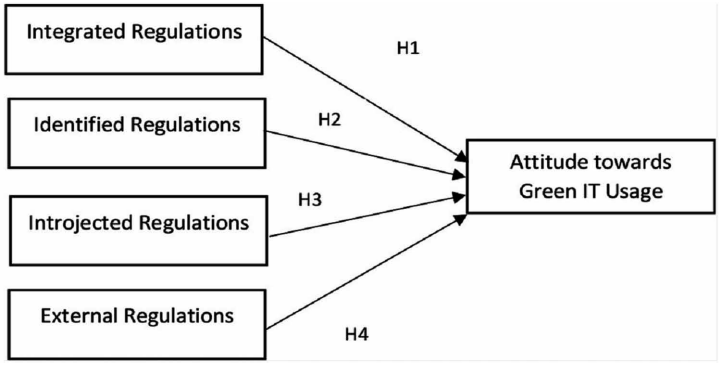
EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

green IT would be positive. Similar evidence was found in green IT research by Koo and Chung (2014). Thus, we propose the following hypothesis:

H4: External regulation (ER) has positive impact on attitude towards using green IT.

Attitude Towards Green IT Adoption (ATT)

Attitude refers to a person's assessment of certain behaviour as favourable or unfavourable. Attitudes are learned dispositions and often result from experience. Molla et al (2011) explained green IT attitude as employees' sentiment, values and norms towards climate change, eco-sustainability, and IT roles. Molla et al. (2011) added that there are two attitudes towards climate change. The first is the belief that human activities are the culprits behind alarming climate change, while the second is skeptical about the change. In addition, Esfahani et al (2015) argued that the former group has positive influence on green IT adoption due to their pro-environment behaviour, while the latter has negative influence on green IT adoption. Hence we conclude that attitude has influence on green IT adoption. In another study by Gholami et al (2013), attitude is affective characteristic of senior managers, as the senior managers play an important role in decision-making in the firms. Attitude measures the extent to which they are aware of, and interested in, green IT.



The research model is shown in Figure 1.

METHODOLOGY

Study Design

In order to empirically test our hypotheses, data were collected via field survey. Purposive sampling method was used in this study. Participants of this study are individuals working in the IT field, across several SMEs, including software development companies, hardware sales and services, internet service providers, and network solution providers. Self-administered survey questionnaires were distributed to the respondents from eight different companies. Out of 250 individuals contacted, data from 108 were collected, generating response rate of 43.2 per cent. Based on the G*power calculation method, sample

Figure 1. Research model

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

collected should have been 124. However, we only managed to collect data from 108 respondents, which is close to the targeted response.

Table 2 provides the demographic information of the respondents. 65.7 per cent of respondents are between 26 and 30 years of age and 76.8 per cent are male. The survey participants represent various IT positions within their industries. 79.6 per cent of our respondents work with information technology from 5 to 8 hours.

Measures

Items of the questionnaire were adapted from valid instruments. The IT managers, who evaluated the questionnaire items, suggested necessary changes to make the questionnaire simpler and easier to understand. The survey questionnaire consists of three parts. The first part focuses on demographic information. The second part explains the basic information of green IT as many respondents might not understand about green IT usage, despite their use of green IT. The third part focuses on measurement items of the research model. All the items are adapted from the research of Koo and Chung (2014). Measurement items are given in Table 3.

Table 2. Demographic information

	Frequency	**Percentage**
Gender		
Male	83	76.8
Female	25	23.2
Age		
21-25	15	13.8
26-30	71	65.7
31-35	18	16.6
More than 35	4	3.7
Use of Technology		
1-5 hrs	7	6.48
5 to 10 hrs	86	79.6
More than 10 hrs	15	13.8
Industry		
Software development company	2	33.3
Network solutions	1	16.6
Hardware sale and service	2	33.3

Table 3. Items of the measurement questionnaire

Measurement Questionnaire
Integrated Regulations
Being green is part of my life
Being green has become a fundamental part of who I am
Being green has been a part of the way I have chosen to live my life
By using green technology, I take care of myself and, at the same time, I take care of my environment
Identified Regulations
Using green IT is a sensible thing to do
Using green IT is a way I have chosen to contribute to protecting the environment
Using green IT is a reasonable thing to do
Using green IT is a good idea to do
Introjected Regulation
I would regret it if I am not doing something for the environment and future generations
I would feel guilty if I did not do something for the environment and future generations
I would feel ashamed of myself if I was doing nothing to help the environment
External Regulations
This green technology device is of benefit to me
The advantages of this green technology device outweigh the disadvantages
Overall, using this green technology device is advantageous
Attitude
Using green technology is a good idea
Using green technology is a wise idea
I have a favour to the idea of using green technology
Using green technology would be pleasant

ANALYSIS AND RESULT

Analysis Technique

We adopted structural equation modelling, using partial least squares (PLS) to analyse the data. PLS has been widely used in theory testing. Of all other structural equation modelling techniques, PLS is best suited for testing a model with small sample size. (Koo and Chung, 2014; Cha, 2012; Haenlein and Kaplan, 2004). We have a small sample size, and therefore, PLS is a suitable analysis tool for the purposes of this study. We decided to use SmartPLS 3.0 to test the research model.

Measurement Model

Convergent validity is the degree to which the items that are used as indicators to a variable must cover high proportion of variance (Hair et al. 2011). According to Hair et al. (2011), factor loadings and average variance extracted (AVE) of more than 0.5 and composite reliability (CR) of 0.7 or above is deemed to be acceptable. Table 4 depicts that all loadings and AVE are above 0.5 and the composite reliability values are more than 0.7. Only IDR1 and IDR3 were removed due to poor loadings. Therefore, we can concluded that convergent validity has been established.

Next, we assessed the discriminant validity which reflects the distinction from one construct to other constructs (Hair et al. 2011). Fornell and Larcker (1981) suggested that to report the discriminant validity, the square root of the AVE should be compared with the correlation of the other constructs. Discriminant validity of the model is reported in Table 5, which shows discriminant validity is fully established in the data.

Table 4. Loadings, AVE, and composite reliability

	Loading	AVE	CR
ATT1	0.897		
ATT2	0.870	0.767	0.929
ATT3	0.872		
ATT4	0.864		
ER1	0.901		
ER2	0.828	0.751	0.900
ER3	0.868		
IDR2	0.913	0.852	0.920
IDR4	0.933		
ITR1	0.843		
ITR2	0.886	0.774	0.911
ITR3	0.910		
IR1	0.892		
IR2	0.890	0.780	0.914
IR3	0.868		

Table 5. Discriminant validity

	ATT	ER	IDR	IR	ITR
ATT	0.876				
ER	0.810	0.866			
IDR	0.847	0.809	0.923		
IR	0.789	0.710	0.764	0.883	
ITR	0.626	0.623	0.571	0.634	0.880

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Multicollinearity is tested by calculating the variance inflation factor (VIF). Our VIF calculation is shown in Table 6.

According to Hair et al. (2011), VIF value of 5 and higher indicate a potential collinearity problem. Our study indicated VIF values of less than 5. Therefore we assume that there is no multicollinearity in our data set.

Structural Model

After analysing the AVE, reliability and validity of the data, we further analysed the structural model by using the evaluation coefficient of determination, and the significance level of each path coefficient. Focusing on the significance level of the path coefficients, our result indicated the following: Integrated regulation (IR) was found to be significantly related to attitude (ATT) towards using green IT ($\beta = 0.247$, $p < 0.01$). Similarly, identified regulation (IDR) was also found to have impact on attitude towards green IT use ($\beta = 0.457$, $p < 0.01$). External regulation (ER) also has significant positive relation with attitude ($\beta = 0.238$, $p < 0.01$). However, introjected regulation (ITR) has positive, but not significant, relation with attitude ($\beta = 0.051$, $p < 0.01$). Thus, hypotheses H1, H2 and H4 are significant; and H3 is not supported. Path coefficients, t-values and results of hypotheses are reported in Table 7.

Blindfolding procedure was performed to measure the predictive relevance (Q^2) of the model fit. Q^2 represents a measure of how well observed values are reconstructed by the model and its parameter estimates. (Chin, 1998). Models with Q^2 greater than zero imply that the model has predictive relevance. In this case, $Q^2 = 0.558$ which indicates the model has predictive relevance. Table 8 represents the strength of effect of each construct to endogenous variable.

Table 6. Variance inflation factor of the constructs

	VIF
ER	3.317
IDR	3.663
IR	2.846
ITR	1.861

Table 7. Hypothesis testing result

Hypothesis	Relationship	Path Coefficient	t value	Result
H1	IR -> ATT	0.247	2.640	Supported
H2	IDR -> ATT	0.457	3.871	Supported
H3	ITR -> ATT	0.051	0.506	Not Supported
H4	ER -> ATT	0.238	3.225	Supported

Importance Performance Map Analysis

The impact-performance analysis provides the variables which need to be improved in the areas of management and marketing. This kind of model measurement technique, based on index value, is for better interpretation of the model (Kirstensen et al. 2000). To improve the performance level of any specific variable, stakeholders should look at the variables with high performance and low performance. According to Slack (1994), the impact of variables on other variables can be derived from the total effects; and the calculation of these values can be derived by reformatting the scores from range 0 to 100 (Anderson and Fornell, 2000).

From Figure 3, identified regulation is highly relevant for increasing total effect on IT professionals' attitude towards green IT use. For example, in ceteris-paribus assessment of output, if the index value of the latent variable (identified regulation) increases one unit, the index value of the endogenous latent variable (attitude) should increase 0.404 points (See Table 9). The same applies as ITR has lower total effect, but IR and ER have comparatively higher performance level than other constructs, except IDR.

Figure 3. Importance-performance map analysis

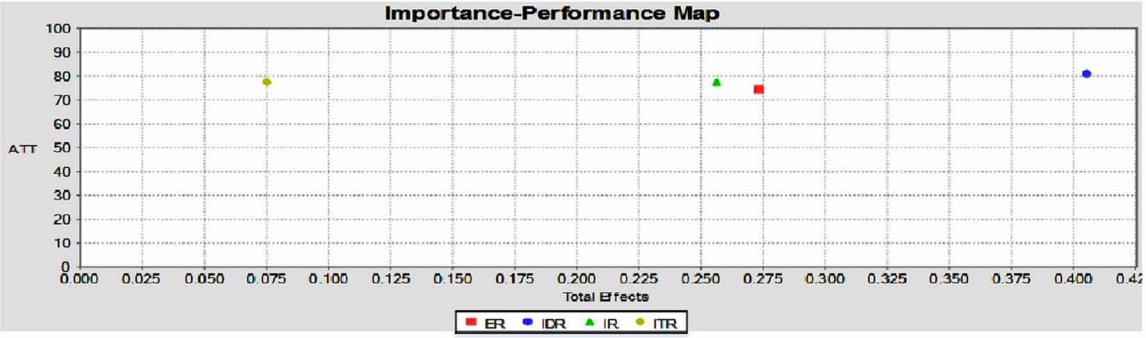

Table 9. Index value and total effects

Constructs	Index Value	Total Effect
IR	77.429	0.247
IDR	80.961	0.404
ITR	77.404	0.076
ER	74.313	0.260

DISCUSSION

The purpose of our study was to test the self-determination theory (SDT) among the IT professionals of SMEs in Bangladesh. The study also examined the relationships of integrated regulations, identified regulations, introjected regulations, and external regulations, with attitude towards green IT use.

The result of our study is similar to the previous green IT research of Koo and Chung (2014), where all the relationships were significant positive relations, except relation with introjected regulations. According to Ryan and Deci (2000), introjected regulations focus on the attitude of people when they perform certain acts to avoid guilt. In the context of Bangladesh, green IT is a new concept and the IT professionals are unaware of its importance. Although there are green IT practices in some cases, IT professionals are still not sure of its environmental impact. As a result, this relationship is not consistent in our study and result was not significant. The importance of using green IT, and its impact on environment, is crucial in the context of Bangladesh (Ansari et al. 2010). Since the variable identified regulations has the highest impact on attitude towards green IT usage, it implies that there is a need for further research to identify the antecedents that have highest variance and effect on identified regulations.

Overall, internal, external, identified, and introjected regulations explain 79 per cent variance on attitude towards using green IT. Results from the study also indicate that identified regulation has highest effect on attitude of IT professionals towards green IT usage.

IMPLICATIONS

This study marks two principal contributions to research and practice. The first contribution is that the paper sets out to revisit psychological behaviour from self-determination point of view. This deserves research attention. Most of the behavioural theories applied to predict behaviour rely on external influences to predict behaviour. For example, theory of planned behaviour (Azjen, 2002) depends on three types of belief to shape one's intention and actual behaviour. SDT, on the other hand, focuses on how one regulates herself or himself to behave through internalised regulations, that is, regulations that have become a part of one's life and shape one's attitude. The application of SDT in research signifies that one's motivational behaviour does not necessarily rely on surrounding influence, but rather on how one is perceived to behave in certain circumstances. Given as such, the application of SDT in this chapter provides new insights on aspects that influence human behaviour.

The second contribution is related to managers. If organisations can conduct several awareness programmes to improve users' attitude towards green IT, they could potentially maximise the likelihood of positive attitude towards green IT. An example would be a green IT photography contest among users on Facebook, or other social media platforms. These events will work as external regulations (ER) to improve attitude. In highlighting the highest impact of identified regulations (IDR) on attitude towards green IT, managers can arrange awareness programmes like green lifestyle. Green lifestyle may include practicing recycling both at work and home. Awareness programmes can motivate employees to take necessary steps willingly to practise green IT.

LIMITATIONS AND FUTURE DIRECTIONS

Despite the useful findings of this study, there are several limitations that need to be acknowledged. Firstly, due to time and resource constraints, the sample size of the study is only limited to 108 respondents. Secondly, the findings cannot be generalised in Bangladesh as the scope of this study only focused on SMEs, and more importantly, only on IT companies. Finally, this research focused only on measuring attitude, which does not represent the measurement of intention to use green IT. The researcher plans to test the theory of planned behaviour in this model in the future, by including two new variables — subjective norms and perceived behaviour control.

CONCLUSION

In this research, it was observed that self-determination theory fits to measure attitude towards green IT. More importantly, identified regulation is a very strong predictor to find out attitude towards using green IT, in the context of IT professionals in Bangladesh. The government, non-governmental organisations, and IT companies can focus to further develop identified regulations to improve attitude of IT professionals. This research, therefore, has meaningful implications for both theory and practice. It contributes to the literature on green IT projects, as well as to self-determination theory in the field of information systems.

KEY TERMS AND DEFINITIONS

External Regulations: Rules or behaviour being practiced in order to avoid punishment or to gain rewards.

Green IT: The practices of using computers and IT resources in environment-friendly manner.

Identified Regulations: Rules or behaviour that a person practices because of the value of such rules and behavior.

Integrated Regulations: Rules or behaviour being accepted as part of a person's life and routine.

Introjected Regulations: Rules or behaviour being practiced, but not being fully accepted.

Self Determination Theory: Theory that studies individual motivation and behaviour.

Chapter 14
Implementation of Green Supply Chain Management in a Globalized Economy

Harish C. Chandan
Argosy University, USA

ABSTRACT

Green supply chain management (GSCM) practices help a firm to become eco-friendly, socially responsible, meet customer expectations, deal with industry peer-pressure and comply with government regulations (Luthra, 2014). GSCM refers to the management of all activities involved in sourcing, purchasing, manufacturing, transportation and distribution of products and services to customers in an eco-friendly way (Sharma, 2013). A conceptual framework of GSCM is presented that consists of eco-friendly organizational culture, collaborative relationships, innovative products and eco-friendly processes (Mutingi, 2013). A SWOT analysis for context specific implementation strategies for global GSCM is presented (Lee and Chen, 2010). The contribution of GSCM practices to a firm's performance is discussed (Laisirihongthong et al., 2013). The critical success factors required to achieve GSCM include top management commitment, government regulations, environment protection literacy and compliance among the supply chain partners, and ISO14001 certification (Jain and Sharma, 2014).

INTRODUCTION

The conventional "Supply Chain Management (SCM)" includes the firm's strategies to efficiently integrate suppliers, manufacturers, warehouses and stores so that merchandise is produced and distributed in the right quantity, to the right location, and at the right time, in order to minimize system wide costs while satisfying service-level requirements (Simchi-Levi et al., 1999). SCM's goal is to achieve downstream integration and upstream collaboration of firm's partners and customers in an effective and efficient manner. SCM includes manufacturing operations, purchasing, transportation, and distribution and is a key component of organizational competitiveness and effectiveness (Womack & Jones, 2005). The practices, concerns, competencies, and performance criteria of conventional supply chain are different from those for green supply chain management (GSCM).

GSCM adds the 'green' component to conventional supply chain management by sourcing, purchasing, designing, manufacturing, operations, transportation, and distribution of products to customers in an eco-friendly way. GSCM uses reverse logistics and waste management for scheduling, applying and monitoring the well-organized, economical drift of raw materials, in-process catalog, finished goods and associated information from the point of ingesting to the point of recollecting value or proper discarding (Srivastava, 2007; Green et al., 2013; Ghobakhloo et al., 2013).

The green supply chain is defined as the chain of touch points for a product or service from the manufacturer to the customer where each link in the chain integrates the concerns for environment along with economic and social concerns into all their processes. The term "green" refers to the environment and is one of the three pillars of the concept of sustainability – environmental, social, and economic. The links in the supply chain include the raw materials suppliers, components, finished product/service, and wholesale and retail distributors. GSCM applies to each of the links in the supply chain acting in an environment-friendly way and involves ensuring that all the partners in the supply chain share the same concern for the environment (Rahimifard & Clegg, 2007). The overall strength of the whole green supply chain is limited by the weakest link.

The stakeholders' demands and government regulations continue to push businesses to be more and more sustainable (Ashby et al., 2012). Motivated by the need for companies to move towards ecologically sustainable business practices including the practices of ISO14000 and ISO 26000, there is a growing need for integrating environmentally sound choices into supply chain management practices. A number of operational guidelines, standards, and legislative frameworks have been put in place to minimize environmental impact of manufacturing, distribution and retailing (Baines et al., 2012). Corporations, consumers and governments are becoming more aware of protecting the environment and adopting strategies for renewable resources (Sharma, 2013). Corporations are upgrading their supply chain management from a purely functional role to a strategic role to comply with current environmental legislations and maintain an enduring competitive advantage, through technological innovation and improved eco-efficiency (Mutingi, 2013).

The strategy of implementing GSCM can be risk-based and/or innovation based (Lee & Chen, 2010). A green supply chain strategy directly impacts the overall environmental, economic and operations performance. The economic benefits are derived from increased efficiency through reduced waste, competitive advantage through innovation, improved product quality, consistent corporate environmental goals and improved public image (Sharma, 2013). In today's globalized economy, corporations are increasingly demonstrating a convergence of supply chains and sustainability (Mollenkopf et al., 2010). The firms' ability to implement green supply chains is becoming a powerful novel source of competitive advantage and good economic performance (Rao & Holt, 2005; Green et al., 2012).

This chapter focuses on the role of the various factors that contribute to a firm's green supply chain management. A conceptual framework of GSCM is presented that consists of eco-friendly organizational culture, collaborative relationships, innovative products and eco-friendly processes. Environmental Performance Index (EPI) and International Environmental and Social standards like ISO 14000 and 26000 are discussed. A SWOT analysis of GSCM is presented to enable a firm to select its context-specific GSCM strategy. The drivers of the implementation strategies for GSCM are described. Finally, the role of GSCM to firm's business performance is presented.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

GREEN SUPPLY CHAIN MANAGEMENT: CONCEPTUAL FRAMEWORK

GSCM practices include green design, green purchasing, reduction in energy consumption, reuse/recycling, packaging, environmental collaboration in the supply chain, cleaner production, internal service quality, just-in-time inventory, environmental auditing, and green innovation. The goals of GSCM are to minimize waste, minimize energy consumption and optimize resource usage. The elements of the green supply chain include green procurement, production, packaging, marketing, logistics and recycling (Emmet & Sood, 2010; Cervera & Flores, 2012). There are two types of GSCM practices – proactive and reactive. Proactive practices include eco-design, green purchasing and reverse logistics while reactive practices include compliance with the legislation and regulation. GSCM performance is influenced by the organizational culture, collaboration with supply chain partners, and the product and process design.

A conceptual framework of GSCM strategy consists of *eco-friendly organizational culture, collaborative relationships with supply chain partners,* innovative and eco-friendly *products and processes* (see Figure 1). GSCM focuses on the green design, green operations, green manufacturing, reverse logistics and waste management (Srivastava, 2007), and must be context specific due to local, national and international environmental regulations. The critical areas of GSCM focus include environmental performance standards, eco-efficiency, green technology innovations, and collaborative supply chain with reduced waste and recycling (Mutingi, 2013).

Organizations are beginning to prioritize the importance of the environmental and social aspects in addition to the economic aspect. The eco-friendly organizational culture and GSCM originates in the boardroom as top management commitment sets the tone and policies for the entire organization. However, when the top management of an organization decides to implement an environmental vision and goals, the employees may resist the change. The same methods that are used for changing the organizational culture can also be used for making the organization more eco-friendly. Communicating the information about the need to become eco-friendly and involving all employees in the process of becoming eco-friendly is essential. Ongoing evaluation of the progress and celebrating successes is crucial since environmental work is an ongoing process.

To implement GSCM effectively, firms must possess both internal environmental management and external collaboration with suppliers and customers in their supply chain to ensure eco-friendly strategy. Firms must collaborate with the first and second tier suppliers to comply with environmental regulations in creating products and services. Green purchasing involves conducting an environmental audit of the

Figure 1. Determinants of green supply chain management strategy

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

supplier and requiring an external international environmental system certification like ISO 14000 (Hsu & Hu, 2008). In global GSCM, the suppliers may not be aware of the environmental regulations in foreign countries so buyers must make their suppliers aware of such regulations (Lee, 2008).

Two main practices of GSCM include green design and green processes. A green product can be an innovative product that may have an unpredictable demand and may have a short life cycle. The innovative product focuses on green efficiency using innovative technology and should be innovative and designed with environment in mind. The manufacturing processes need to be eco-efficient or green-efficient (Paulraj et al., 2008). Green design involves environmentally conscious design (ECD) and life cycle assessment (LCA). Green operations include green manufacturing, reuse, recycle, reverse logistics, and network design.

In a green supply chain of a manufacturer and retailer of a consumer product, one has to determine the effect of the package size and shelf space on profit. Reducing the package size of its product reduces environmentally costly transportation cost, reduces product packaging cost, and cost savings (Swami & Shah, 2011, 2013). Green performance metrics need to be put in place for assessing the impact on business performance. Performance measurement for GSCM includes intra-organizational, inter-organizational and environmental issues that affect all the members in the green supply chain (Hervani et al., 2005). Implementation of GSCM is governed by institutional theory (IT), ecological modernization theory (EMT), and total environmental quality management (TQM) (Muslan, 2013; Li, 2011). Risk theory has been applied to GSCM (Khan & Burnes, 2007).

COLLABORATIVE RELATIONSHIPS BETWEEN GLOBAL GREEN SUPPLY CHAIN MEMBERS

With increased globalization, the supply chain often involves partners across continents. Globalization enables new markets for products and access to suppliers who can provide materials and inputs more efficiently than domestic sources. The globalization of supply chains involves off shoring production, inventories, suppliers and customers. It also represents differences in economies, infrastructures, cultures, and politics in the competitive environment (Manuj & Mentzer, 2008). The green, global and lean supply chain strategies need to be considered in an integrated life cycle management framework (Mollenkopf, Stolze, Tate, & Ueltschy, 2010).

The buyer-supplier quality management facilitates cooperative learning and improves inter-organizational learning processes leading to enhancement of supply chain satisfaction and performance. The interaction of the firm level and supply chain-level quality practices influence buyer-seller performance and lead to buyer-supplier satisfaction. The firm-level quality practices involve top management support, information systems, employee involvement, process improvement, product/service design and customer satisfaction. The supply chain level quality practices involve trust, governance, information integration, process integration, and cooperative learning (Mellat-Parast, 2012).

The relationships between all the links of the supply chain need to be collaborative and based on trust. The collaborative relationship involves enhanced mutual involvement and high degree of information sharing between the stakeholders. A collaborative supply chain is agile, flexible, and responds quickly to dynamic demand using innovation and dynamic technology evolution (Liker & Choi, 2004). Product life-cycle costs and overall supply chain costs are minimized through collaborative relationships (Zhu & Sarkis, 2007).

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Corporations have to take environmental initiatives in inbound logistics, production or the internal supply chain, outbound logistics and, in some cases, reverse logistics which include materials suppliers, service contractors, vendors, distributors and end users working together to reduce or eliminate adverse environmental impact of their business activities (Rao & Holt, 2005).

Trust among the partners in all the links in the green supply chain ensures proper coordination and functioning of the entire supply chain. The geographically distributed supply chain stakeholders represent virtual organizations connected by the trust and information communication technologies (ICT). Trust is a significant factor in achieving supply chain integration. Cooperation of the stakeholders in the supply chain determines their exposure to business and market risk. As the number of links in the supply chain increases, the trust relationships can get more complex. Some partners rely on trust based on direct interactions (e.g., A-B). Other business interactions rely on derivative trust, which affect A through B's interaction with C.

Successful SCM offers all the stakeholder firms a competitive edge. Among medical equipment suppliers, communication, behavioral certainty, asset specificity, partner reputation and perceived benefits contributed to positive trust. The relationship tenure did not have a significant effect on trust (Chao et al., 2013). Trust is a key factor inter-organizational knowledge sharing. Participation and communication which enhance trust, positively influence knowledge –sharing. Opportunistic behaviors, which reduce trust, negatively influence knowledge sharing (Cheng, et al., 2008).

In a study of the supply chain for metallurgical enterprises, stakeholders depended on the direct trust and derivative trust for smooth functioning of the entire supply chain (Gajdzik & Grzybowska, 2012). Trust is a key factor inter-organizational knowledge sharing. Participation and communication which enhance trust, positively influence knowledge –sharing. Opportunistic behaviors, which reduce trust, negatively influence knowledge sharing (Cheng, et al., 2008).

To enhance inter-organizational coordination, manufacturing firms often insist with their partners in supply chain management such as suppliers and subcontractors to establish common processes. This requires sharing process and inter-organization knowledge. It enhances the competitive advantage of the supply chain as a whole (Luthra et al., 2013; Spekman et al., 2002). Knowledge management in supply chain relationships is crucial to firm performance. The three dimensions of strategic orientation (i.e., alliance, leadership and learning and two dimensions of inter-organizational knowledge management (i.e., knowledge creation and acquisition are related and are positively related to firm's performance) (Gupta, 2006). The coercive relationship between supply chain stakeholders has low information sharing, legal contracts -driven and is focused on supply for the predictable demand at the lowest possible cost (Pagell et al., 2007).

A sustainable green supply chain requires proactive relationship management including organizational learning and transfer of knowledge and capabilities from the large players in the supply chain (Mellat-Parast, 2012; Cheung & Rowlinson, 2011). GSCM ensures that each of the links in the supply chain (i.e., all the suppliers, subcontractors and retailers), act in an environment-friendly way (Muslan et al., 2013; Rahimifard & Clegg, 2007).

Supply chain coordination improves performance by aligning the objectives of the links in the chain. The focus is on inventory management and ordering decisions. Some of the channel coordination models include multi-echelon inventory theory, multiple decision makers, asymmetric information, mass customization, outsourcing, short product life cycles and delayed differentiation. To enhance inter-organizational coordination, manufacturing firms often insist with their partners in supply chain management such as suppliers and subcontractors to establish common processes. This requires sharing

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

process and inter-organization knowledge. It enhances the competitive advantage of the supply chain as a whole (Spekman et al., 2002).

GSCM is challenging because different countries involved in the supply chain may not have uniform "green" local regulations and standards and is an improvement over conventional supply chains. It includes green design, green operations, green manufacturing, reverse logistics, and waste management (Srivastava, 2007). Firms should prioritize the relative importance of the four dimensions of GSCM: supplier management, product recycling, organizational involvement and life-cycle management (Hu & Hsu, 2010).

INNOVATIVE ECO-FRIENDLY PRODUCTS AND PROCESSES

There are two main practices towards GSCM: Green design and green operations. Green design is in the direction of systematic environmental consideration in the product design and green operations are related to all aspects of supply chain management operations. Green design involves environmentally conscious design (ECD) and life cycle assessment (LCA). Environmentally conscious design is the process of understanding the ways and means to develop concern over of how design decisions affect a product's environmental compatibility. The life-cycle assessment/analysis (LCA) is to analyze, assess and evaluate the conservational, professional health and resource-related concerns of a product through all the stages of its life cycle. Green operations include manufacturing and remanufacturing, reverse logistics, and network design. Green manufacturing is about using appropriate material and technologies and thereby saving most of the resources which are on the verge of being exhausted.

Remanufacturing is to utilize the waste products in the process of manufacturing to re-use them for manufacturing new valuable products. Recycling is done to regain the material content of used and non-functioning goods. Reverse logistics is the process of scheduling, applying and monitoring the well-organized, economical drift of raw materials, in-process catalogue, finished goods and associated information from the point of ingesting to the point of source for the purpose of recollecting value or proper discarding. The collection is the first stage in the retrieval process is followed by sorting of used products (Ghobakhloo et al., 2013). In a green supply chain of a manufacturer and retailer of a consumer product, one has to determine the effect of the package size and shelf space on profit. Reducing the package size of its product reduces environmentally costly transportation cost, reduces product packaging cost, cost savings. It helps the manufacturer to achieve 'green manufacturer' status (Swami & Shah, 2011).

Innovative eco-friendly processes aim to reduce waste, emissions to the environment, energy usage and increase recycling at the end-of-life for the product. Innovative products and processes go hand-in-hand. The green process is centered on eco-efficiency or green efficiency. Four main areas of focus for environmental performance standards include eco-efficiency, green technology innovations, remanufacturing and recycling. The comprehensive boundaries and flow framework can be valuable for identifying barriers to implementing GSCM (Sarkis, 2012). Fisher's perspective of efficient versus responsive supply chains can be a stepping-stone to the development of two green supply chains-eco efficient and eco-responsive (Youn et al., 2012). The critical success factors required to achieve GSCM include top management commitment, government regulations, environment protection literacy and compliance among the supply chain partners, and ISO 14001 certification (Jain & Sharma, 2014).

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

INTERNATIONAL STANDARDS FOR ENVIRONMENTAL MANAGEMENT AND SOCIAL RESPONSIBILITY

Environmental and social responsibility performance is increasingly being used as additional measures for the overall performance of firms. The ISO 14000 standard addresses various aspects of environmental management and ISO 26000 addresses social responsibility management. The ISO 14000 family provides practical tools for companies and organizations to identify and control their environmental impact and constantly improve their environmental performance. ISO 14001:2004 and ISO 14004:2004 focus on environmental management systems. The other standards in the family focus on specific environmental aspects such as life cycle analysis, communication, and auditing.

ISO 14001:2004 sets out the criteria for an environmental management system and can be certified. It does not state requirements for environmental performance, but maps out a framework that a company or organization can follow to set up an effective environmental management system. It can be used by any organization regardless of its activity or sector. The ISO 14001:2004 can provide assurance to company management and employees as well as external stakeholders that environmental impact is being measured and improved. The benefits of using ISO 14001:2004 can include reduced cost of waste management, savings in consumption of energy and materials, lower distribution costs and improved corporate image among regulators, customers and the public. Small and medium sized enterprises (SMEs) can also benefit from ISO 14001:2004. The publication, ISO 14001 Environmental Management Systems, provide an easy to use checklist for SMEs (ISO, 2014).

Corporate social responsibility is covered by ISO 26000. Social responsibility means acting in an ethical and transparent way that contributes to the health and welfare of society. ISO 26000:2010 provides guidance rather than requirements, so it cannot be certified to unlike some ISO 14001. Instead, ISO 26000:2010 helps clarify the meaning of social responsibility and helps businesses and organizations translate principles into effective actions and shares best practices relating to social responsibility, globally. It is aimed at all types of organizations regardless of their activity, size or location. The standard was launched in 2010 following five years of negotiations between many different stakeholders across the world. Representatives from government, non-government organizations (NGOs), industry, consumer groups and labor organizations around the world were involved in its development, thus meaning it represents an international consensus (ISO, 2014).

Other international occupational health and safety management standards include Occupational Health and Safety Assessment Series (OHSAS 18000), and the Restriction of Hazardous Substances (RoHS). The Waste Electrical and Electronic Equipment (WEEE) enforces compliance with the relevant laws relating to product recycling and prohibit the use of hazardous substances in products for sale in the market (Mutungi, 2013).

ENVIRONMENTAL PERFORMANCE INDEX (EPI), INTERNATIONAL AGREEMENTS, LEGISLATION AND NGOS

The 2014 EPI Framework includes nine issues and 20 indicators. The nine issues cover the areas of environmental health and Ecosystem vitality (EPI, 2014). The three issues in environmental health include health impacts, air quality, water, and sanitation. The ecosystem vitality issues include six issues- water resources, agriculture, forests, fisheries, biodiversity and habitat, and climate and energy. The Environ-

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

mental Performance Index (EPI) is constructed through the calculation and aggregation of 20 indicators reflecting national-level environmental data. These indicators are combined into nine issue categories, each of which fits under one of the two primary objectives. Table 1 lists 2014 EPI values for various economies out of a total of 178 countries.

The international organizations formulate various acts and reach agreements that affect the countries and corporations (Andressen & Boasson, eds., 2012; Yu & Hui, 2008). International environmental agreements such as the United Nations Multilateral Environmental Agreement Negotiator's Handbook (2007), Negotiator's Handbook for Pacific Region (2013), ASEAN agreement on Trans boundary and Haze Pollution, Framework convention on climate change(UNFCCC,1992), the Kyoto Protocol, the Climate Change Treaty and the Montreal Protocol influence the local and national governments to create environmental legislation. This guides and forces the firms to practice GSCM (Chien & Shih, 2007).

CONTEXT SPECIFIC GSCM IMPLEMENTATION STRATEGIES

Implementation of GSCM should be context-specific to the industry sector, country, and firm. Global GSCM presents new challenges since the environmental regulation standards and their enforcement varies significantly from country to country. ISO 14001 certification of all the suppliers helps with managing global suppliers. The Twelve Steps to a Greener Supply Chain include redesign of the product, reconfiguration of manufacturing, shifting to green suppliers, shortening the distances, altering service-level settlements, shrinkage in packaging, plan for inverse supply chain activity, consolidation of shipments, planning for shorter routes, coordination with partners, taking a holistic lifecycle view, starting early and if required starting now (Sharma, 2013). A structural model of natural resource based green supply chain management can provide managers with validated measurement scales to evaluate their strengths and weaknesses in implementing GSCM (Shi et al., 2012).

The SWOT analysis of GSCM helps a firm to see beyond the legislative, social, and peer pressures to create an effective strategy. The strengths, weaknesses, opportunities, and threats for implementing GSCM are listed in Table 2. Using the SWOT analysis, a firm has to create a context-specific strategy by maximizing the strengths, minimizing the weaknesses, taking advantage of the opportunities and guarding against the potential threats. A more critical POWER SWOT may be more helpful as it includes **P**ersonal experience, rank **O**rder, assigning **W**eights, **E**mphasize detail and **R**ank order(Power SWOT, 2014). Using a Balanced Score card and Key Performance Indicators can make additional enhancements.

Table 1. Environmental performance index, EPI and rank of selected countries

Country	Environmental Performance Index, epi, %	Rank Out of 178 Countries
Switzerland	87.67	1
USA	67.52	33
Russia	53.45	73
Brazil	52.97	77
China	43	118
India	31.23	155
Somalia	15.47	178

Table 2. SWOT Analysis for GSCM (adapted from Lee & Chen, 2010)

	Details
Strengths	Green design, materials, process, packaging and recycling, can reduce product-life-cycle costs by reducing waste clean up cost, lower production costs, minimize waste and lower price for consumers
	Enhance efficiency and profit through improvements in workplace settings for employees
	Upgrade corporate image and product reputation, increase market share, Earn the confidence of lenders
	Trust building in each link in the supply chain leading to efficient collaboration and reduced costs
Weaknesses	One or more links in the chain may practice superficial green practices
	Collaboration management challenges with all the links in the chain
	Require R&D expenditure for innovation to find green solutions
	Lack of mutual trust may cause opportunistic behavior for one or more links in the chain and undermine overall goals for the GSCM
Opportunities	Increasing consumer demand for green products/services
	Take advantage of government incentives for manufacturing green products
	Awareness of environmental standards in the host country by each chain link
Threats	In international markets, products may face import barriers and lose competitive edge by not practicing GSCM
	Additional inspection and certification costs to meet international market standards can raise price and lower market share
	Lack of international green certification system may encourage counterfeit green products

A firm in a given industry sector should identify relevant goals for implementing GSCM and specifying long-term plans to achieve these goals (Mudgal, Shankar, Talib, & Raj, 2010). Firms have to select a suitable strategy in accordance with stipulated regulations and customer requirements. For each industry sector in a given geographical context, one has to identify and rank the major strategies that help successful implementation of green supply chain management. Using fuzzy analytic hierarchy processes to prioritize the relative importance of supplier management, product recycling, organizational involvement and life cycle management, it was found that the organizations that place more emphasis on supplier management find it easy to implement GCSM successfully. (Hsu & Hu, 2008). Firms have to prioritize the relative importance of the four dimensions of GSCM – supplier management, product recycling, organizational involvement and life-cycle management (Hu & Hsu, 2010).

The strategy of implementing GSCM can be risk-based and/or innovation based. A risk-based strategy involves the inclusion of basic clauses towards purchasing contracts for suppliers to meet all pertinent environment regulatory requirements. To implement green supply chain, there must be a set instructions and processes that should be well notified to enterprises to follow environment-friendly based methods for all company's operations. Innovation strategy involves more inclusive product life-cycle management deliberations for consumers of their products during the designing stages. Innovation at every step of supply chain structure is necessary in order to differentiate a company's unique selling from its competitors.

The GSCM strategy can be lean-based, innovation centered, compliance-driven or closed loop strategies. Efficiency-based GSCM practice creates an environment of being generous towards the environment by minimal waste generation. This type of strategy involves in meeting operational efficiency objectives like quality standards. Companies should adhere to proper quality control measures in order to meet up to tackle environmental ill effects. Closed-loop strategy is significant in implementing green initiatives.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

This type of a strategy involves product designing through artifact take-back and reverse logistics implemented in the supply chain components for waste reduction (Lee & Chen, 2010). A taxonomic scheme for developing green strategies involves analyzing the green supply chain activities and identifying key dimensions that influence green supply chain management (Mutingi, 2013). The biggest challenge for firms in practicing GSCM is to select suitable strategies in accordance with the stipulated regulations in a given context and customer requirements (Hu & Hsu, 2010).

The organizational factors that influence GSCM are explained by the institutional theory, which includes coercion or external pressure, normative (compliance) and mimetic (imitation). Innovation and technological development to make GSCM effective is explained by the ecological modernization theory. Using Total Environmental Quality Management (TQM) in implementing GSCM helps one to focus on effectiveness and efficiency (Muslan, 2013). Risk theory has been applied to GSCM (Khan & Burnes, 2007).

Another study identified four categories of GSCM implementation strategies in terms of supply chain touch points: non-members, downward stream, organization, and upward stream as shown in Table 3. The first dimension of the non-members of a supply chain includes the international environmental agreements, government legislation and acts formulated by the non-government organizations. The second dimension of the downward stream supply chain management includes involvement of suppliers in green activities, training programs, technology transfer to suppliers and environmental auditing of suppliers.

It is still the firm's responsibility to the public even if an adverse event happens in any one of the links in the supply chain. Some examples are McDonald's recall of 12 million drinking glass gift sets and Mattel's Fisher Price recall of over 10 million lead-painted toys (Lee, Kim, & Choi, 2012).

The third dimension of the organizational perspective includes top management perspective, innovative green practices, employee perspective, economic interests, firm's competitiveness and industrial perspective. The top management perspective includes initiation and commitment, proper company policies,

Table 3. Four dimensions of GSCM Implementation (Adapted from Luthra, Garg, & Haleem, 2013)

	Dimensions	Details
1.	Non-Members of Supply Chain	**International environmental agreements** **Government legislation** **Non-government organizations (NGO's)**
2.	Downward Stream Supply Chain Members	**Involvement of suppliers in green activities, Training programs,** **Technology transfer to suppliers** **Technology transfer to suppliers** **Environmental auditing of suppliers**
3.	Organizational Perspective	**Top Management Perspective**: Initiation and commitment, Proper company policies, Technology advancement, Information technology enablement **Innovative Green Practices:** Environmental management systems, ISO 14000 implementation, Green procurement strategies, green product development and design, eco friendly products and process optimization, eco-friendly packaging and labeling, eco friendly transportation and distribution. **Employee Perspective:** Human resources, Information quality and sharing, Training programs. **Economic Interests** **Firm's Competitiveness** **Industrial Perspective:** Waste management, Reuse and recycle, lean manufacturing, Proper workplace management
4.	Upward Stream Perspective	**Awareness level of customers** **End-of-life management** **Association with local recycling organizations**

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

technology advancement and information technology enablement. The innovative green practices consist of adopting environmental management systems like ISO 14000, green procurement strategies, green product development and design practices, use of environmental friendly packaging and labeling of the products and use of environment friendly transportation and distribution. The environmental footprint is established at the product design stage when one decides the materials and processes to manufacture a product (Zhu & Sarkis, 2007).

The employee perspective includes human resources, information quality and sharing, and training programs. The economic interests include lower cost by reducing waste, recycling and lowering environmental compliance costs. The firm's competitiveness comes from first mover advantage of the green innovations. The industrial perspective includes waste management, reuse and recycle, lean manufacturing and proper workplace management. The fourth dimension of upward supply chain members includes awareness level of customers, end-of-life management, and association with local recycling organizations. These four dimensions play an important role in greening the supply chains and enable the firm to achieve enhanced operational performance (Luthra, Garg, & Haleem, 2013).

GREEN SUPPLY CHAIN MANAGEMENT PRACTICES AND BUSINESS PERFORMANCE

There are two types of GSCM practices: proactive and reactive. The proactive practices include eco-design, green purchasing, and reverse logistics. The reactive practices include legislation and regulation. GSCM practices include green design, green purchasing, reduction in energy consumption, reuse/recycling, packaging, environmental collaboration in the supply chain, cleaner production, internal service quality, just-in-time inventory, environmental auditing, and green innovation

Consumers are demanding eco-friendly products and services and corporations are reporting economic benefits from green practices (Bajdor & Grabara, 2011). Commonwealth Edison reported savings of US$50 million annually from managing material and equipment with a life-cycle management approach. Pepsi saved US$44 million by switching from corrugated to reusable plastic shipping containers. Mitigating environmental impact of production and services is a novel strategy to enhance organizational competitiveness. This includes improvements in their environmental performance to comply with environmental regulations and addressing the environmental concerns of their customers (Bacallan, 2000). GSCM implementation improves business performance when operational efficiency and relational efficiency are improved (Lee et al., 2012; Green et al., 2012). Performance measurement for GSCM includes inter-organizational environmental issues (Hervani et al., 2005).

According to resource dependency theory, firms synergistically combine their own resources with those of other firms to create a resource bundle that is unique and hard to imitate (Harrison et al., 2001). Such interdependent relationship-specific capabilities are superior to what the individual firms possess on their own. This leads to sustainable competitive advantage and improved organizational performance (Paulraj & Chen, 2007; Lee, Kim, & Choi, 2012).

Most of the suppliers around the world are SMEs which often have inadequate proactive environmental strategy and can be a weak link in the green supply chain (Sarkis & Dijkshoorn, 2007). SMEs often lack knowledge workers with expertise on environmental management systems (Lee, 2009). In Europe, a total of 76% of all corporations are SMEs which are responsible for 60% to 70% of all industrial pol-

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

lution, 40% to 45% of CO2 emissions, 40% of water and energy consumption, and 70% of industrial waste production (Heras &Arama, 2010).

There is a direct link between GSCM practice implementation and business performance. Significant indirect relationships were found between GSCM practice implementation and business performance through mediating variables of operational efficiency and relational efficiency. The business performance is improved when GSCM enhances relational efficiency and operational efficiency, Figure 2 (Lee, Kim, & Choi, 2012). Firms need to leverage GSCM practices to facilitate both operational and relational efficiencies to gain greater competitiveness in the dynamic global market place Testa & Iraldo, 2010).

There is a lack of consensus on the impact of GSCM practices on business performance due to a lack of a unified framework for green practices and a variety of performance measures in use (Zhu et al., 2012; Laosirihongthong, Adebanjo, & Tan, 2013)). Implementing different GSCM practices in different settings can result in different performance outcomes (Koh et al., 2012).

Based on empirical studies on GSCM drivers from the manufacturing industries in Germany, Malaysia, India, Taiwan, China, the United Kingdom, and South Korea, three main drivers to implement GSCM emerge that include government regulations (27%), customer pressure/requirements (16%), and competition (14%). Competition includes marketing, product differentiation, competitive advantage, and brand reputation. Other drivers include social responsibility/ethics (6%), business benefits, organizational commitment, awareness, experience (6%), environmental collaboration with suppliers (5%), collaboration with the customers (3%), certification of supplier's environmental management systems (3%), ISO 14001 certification (2%), sustainability of resources (2%), lowered costs (2%) and return on investment (2%) (Jain & Sharma, 2014).

SUMMARY

GSCM has evolved to become a firm's competitive strategy to become eco-friendly, socially responsible and to achieve compliance with customer expectations, peer-pressure and government regulations. Corporate sustainability requires that the concerns for environment ("green") along with economic and social concerns be integrated into all the processes of a corporation including supply chain management (Luthra, 2014). The environmental NGOs, international environmental agreements, and environmental

Figure 2. Improvement in Business Performance through GSCM implementation (Adapted from Lee, Kim, & Choi, 2012)

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

legislation at the local and national level play a significant role in providing motivation to the firms to comply with the regulations.

The implementation of GSCM is specific to the industry sector, firm, and the country, and presents new challenges since the environmental regulation standards and their enforcement varies significantly from country to country. In today's globalized economy, corporations are increasingly demonstrating a convergence of supply chains and sustainability (Mollenkopf et al., 2009). GSCM is challenging because different countries involved in the supply chain may not have uniform "green" local regulations and standards. ISO 14001 certification of suppliers helps with managing global suppliers.

The firms' ability to implement green supply chains is becoming a powerful novel source of competitive advantage and good economic performance (Green et al., 2012; Rao, & Holt, 2005). At the firm-level, greening the boardroom helps gather support for firm's international environmental management systems, establishing trust among members of the supply chain, environmental auditing of the suppliers, green product design and development through innovation, green manufacturing through technology improvements, environmental friendly packaging and labeling, environmental friendly product distribution, environment friendly organizational culture, employee training for green initiatives, and effective use of internet and communication technologies for knowledge management. Context specific strategies for green supply chain management have to be created to enhance the firm's competitive performance.

Chapter 15
The Role of a Strategic and Sustainable Orientation in Green Supply Chain Management

Kuo Ming Chu
Cheng Shiu University, Taiwan

ABSTRACT

The environmental problems we're facing today, with their growing severity and increasingly global nature, are often referred to as humanity's greatest challenge. This paper develops a model that identifies the antecedents and outcomes associated with sustainable supply chain management linkage. The model starts by identifying two antecedents (internal and external orientation) that firms may adopt in order to cope with their sustainability goals. The hypotheses are tested based on the major survey data from 342 Taiwanese and Chinese public corporations. This study not only demonstrates that both the internal supply chain and external environmental orientation exert a positive on green SCM, sustainability orientation, and alliance performance, but also, more importantly, they delineate how green SCM is practiced. This study also sheds light on the role of a sustainable orientation in strategic supply chain alliance's performance, and builds a comprehensive conceptual framework that fills some key gaps in previous research.

1. INTRODUCTION

The environmental issues we're facing today, with their growing severity and increasingly global nature, may be considered the most serious challenge that humanity will face in the coming years. Over the long run, economic development that relies on intensive depletion of natural resources cannot be considered sustainable, from either an environmental or an economic point of view. The turn toward a production model which has less of a negative impact on the environment may actually improve companies' profits by spurring innovations aimed at reducing environmental impact while providing economic benefits (De

Marchi, 2012). However, there can also be dangers; the existing literature has reported the failure rate of alliances to be between 60% and 70% (Zhou & Lu, 2012; Lunnan & Haugland, 2008). Incompatibility of partners is a leading cause of these failures (Das & Teng, 2001; Lambe et al., 2002; Langfield-Smith, 2008). It is imperative that a strategy be utilized to maximize the benefits of cooperation while minimizing the risks. In recent decades, successful inter-firm collaboration has enabled firms to improve their competitive advantage and realize benefits that include such things as reduced costs, assessment of valuable resources, sharing risks and strengthening their market position (Groot & Merchant, 2000; Hagedoorn, 2002; Ding, Dekker, & Groot, 2013). An ideal model should draw upon the virtuous cycle induced by these successful collaborations.

Although the wider perspective of the green supply chain is an important step in determining its relationship to environmental sustainability, consideration of performance outcomes resulting from reducing the environmental impact of a firm's supply chain operations is a concept that has only recently gained momentum (Linton et al., 2007). Many companies have recognized the concept of green SCM, also known as supply chain environmental management. However, while sustainability has become a major challenge for firms, the goal of pursuing sustainability cannot be achieved by a single firm, as its performance will necessarily be affected by other links in the supply chain. Therefore, if overall success is the goal, it is essential to adopt green innovation and to implement Green Supply Chain Management (SCM) practices throughout the organizational value chains (Steger, 1993; Chiou et al., 2011). When properly integrated and planned, green SCM offers the opportunity to boost efficiency, value, and access to markets through improving a firm's environmental, social, and economic performance. In addition, the implementation of green SCM through internal and external environmental management contributes substantial benefits by enhancing corporate competitiveness and improving environmental performance (Chiou et al., 2011; Rao, 2002; Tukker et al., 2001). Of course, it is generally no simple matter to accomplish this, and some researchers have asserted that the attention given to the potential benefits of green SCM practices has actually raised more questions than answers (Linton et al., 2007; Carter & Rogers, 2008). This paper seeks to answer some of these questions by shedding some light on the role of sustainability in green SCM practices through identifying, the antecedents that cause firms to be sustainability oriented and the internal and external orientations which must be adopted in order to cope with the changes of the firms' business goals, and the impact of these practices on their green alliance performance.

2. LITERATURE REVIEW AND HYPOTHESES

2.1. Green SCM of Strategic Orientations

The Resource based view (RBV), in the context of environmental responsibility, suggests that firms recognize and apply strategic resources and capabilities to create unique and difficult to imitate practices that simultaneously reduce the impact of the firm's operations on the natural environment and create value for the firm (Hart & Dowell, 2010; Kirchoff, 2011). The idea of a green supply chain has always been thought of as a costly process in the past because it focuses on reducing unit cost instead of looking at the total landed cost with the onset of global trade. The focus will have to change from looking at the usage cost of an item of equipment (e.g. the cost per page of using a certain copier) to the life cycle cost of this part, equipment, or supply chain process. Therefore, Green SCM has gained popularity with

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

both academics and practitioners alike through its efforts towards reducing waste and preserving the quality of product-life and natural resources, including reducing cost and improving efficiency, mostly through the magic of 'sustainability.' The use of the term sustainability has become synonymous with the triple bottom line and is increasingly popular in the literature and among practitioners over the last several years (Carter & Rogers, 2008). In particular, a supply chain orientation and an environmental orientation must be clearly delineated and defined, and their existence in the firm explained using RBV. Table 1 shows some typical definitions of green supply chain management, and these definitions include some new ideas such as strategic transformation of enterprise and green supply chain design, leading to a great step forward in the theories of green supply chain theory and green supply chain management.

All of these green supply chain models have been created through the expansion of environmental elements into the traditional supply chain system in a manner that alters its fundamental orientation. An orientation is an underlying consciousness or latent philosophy that is considered the way in which a firm view and reacts to the business environment in which it exists (Kotler, 1997). Scholars have acknowledged for decades that a firm's strategic resources are considered to be unproductive in isolation; it is the exploitation of combinations of valuable resources that help firms create competitive advantage and improve performance (Newbert, 2008; Kirchoff, 2011). Thus, green SCM practices, as strategic resources, are in a path dependent relationship with both a firm's environmental orientation and its supply chain orientation. The following sections propose the relationships among an environmental orientation, a supply chain orientation, and green SCM practices.

2.1.1. Environmental Orientation: Green SCM Link

Alongside this, Banerjee (2002) maintained that environmental orientation is one of the two key factors by which firms can pursue corporate environmentalism. From a resource-based view, a firm's strategic orientation (e.g., environmental orientation) can be conceptualized as its valuable intangible resources that guide the development of green strategic practices, and consequently enhances alliance performance (Kirchoff, 2011; Ge & Ding, 2005). Firms that adopt an externally focused environmental orientation

Table 1. Definitions of green supply chain management

Authors	Definitions
Narasimhan & Carter (1998)	Green SCM refers to the efforts of purchasing departments in activities such as reducing pollutants, recycling, and materials substitution
Dan & Liu (2000)	Green SCM is a management mode that considers the environmental effects and the efficiency of resource utilization in the whole supply chain. It is based on green manufacturing theory and supply chain management techniques, involving suppliers, manufacturers, retailers and consumers. It aims to minimize the negative effects on the environment and to maximize the efficiency of resource utilization througout the whole production process.
Zsidisin & Siferd (2001)	Green SCM is a supply chain management technique used to solve the environmental problems within a company's production and service departments.
US-Asia Environmental Partnership (2003)	Activities in which an organization imposes its environmental requirements to its suppliers' production and processes should be called "Green supply chain management".
Zhu (2004)	Green SCM enterprises cooperate with their downstream and upstream partners, optimizing the environmental benefits from product design, material selection and retailing to recycling, improving both economic and environmental performance to achieve a sustainable supply chain.
Zhang, Abu, Thoo, & Kooi (2015)	A Green SC is an innovative supply chain that complies with social development trends. It integrates economic performance, environmental performance and resource efficiency into the entire spectrum of supply chain activities involving raw materials and component purchasing, manufacturing, packaging, distribution, retailing, and the subsequent recycling of the products.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

acknowledge the importance of developing strategic green management practices in the context of the external business environment (Menguc & Ozanne, 2005). Likewise, Chan et al. (2012) and Fraj-Andrés et al. (2009) also show that both internal and external environmental orientations serve as important determinants for firms' practice of environmental strategies, both at the strategic level and within the functional marketing area.

As regards external environmental orientation, its influence can be best explained by institutional theory. According to this theory, firms need to tackle different constraints imposed by various important institutions (North, 1990). From this perspective, it is likely that managers who perceive a strong need to respond to the environmental demands of salient stakeholders will be more inclined to engage in pro-environmental practices (e.g., green SCM) to cope with these demands. As this managerial perception, in turn, falls into the definition of Banerjee's (2002) environmental orientation, it is thus probable that this orientation exerts a positive impact on green SCM. Therefore, an environmental orientation as an antecedent to green supply chain management can be theoretically established, and the following hypothesis presented:

H_1: Environmental Orientation directly and positively contributes to Green SCM of Strategic Orientation.

2.1.2. Supply Chain Orientation: Green SCM Link

Min & Mentzer (2004) and Miocevic & Crnjak-Karanovic (2012) established a critical relationship between supply chain orientation and SCM. Notably, previous studies have identified supply chain orientation as an important antecedent to organizational performance that links the upstream and downstream processes (e.g., Hult et al., 2007; Min, Mentzer, & Ladd, 2007). The intent of green supply chain management is for a firm to work with its upstream and downstream supply chain members to act in a proactive way that focuses on the environmental impact of the entire supply chain system (Sarkis, 2003; Seuring & Müller, 2008). To be successful, these bundled resources need to have dynamic qualities and to be adaptable to the ever-changing business environment (Teece, Pisano, & Shuen, 1997; Sirmon et al., 2007).

Firms that integrate their upstream and downstream supply chain partners into green supply chain management practices will be more successful in these endeavors. Collaborative relationships and partnering with supply chain members facilitate the introduction of green supply chain management practices into firms (Klassen & Johnson, 2004; Vachon & Klassen, 2008). Therefore, supply chain orientation as a philosophy of strategically linking processes and flows throughout the supply chain with the involvement of supply chain members is needed for the implementation of green supply chain management practices as well (Klassen & Johnson, 2004; Hasan & Ali, 2015). Taken together, the above concepts suggest the following hypothesis:

H_2: Supply Chain Orientation directly and positively contributes to Green SCM of Strategic Orientation.

2.2. Sustainability Orientation

While the concept of sustainability has been increasingly discredited as a useful concept by itself, it appears to be serving some purpose when preceded by a delineating modifier like "*ecological*" or "*agricultural*" or "*economic*" (Morelli, 2011). Efforts have been made by members of various professions to give meaning to the term within the context of those respective professions. As defined by Shahidullah &

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Haque (2014), sustainability enterprises are those that attempt to integrate environmental, economic, and social considerations in a holistic manner. Sustainability is an inter-temporal concept, and thus, should be reflected by approaches highlighting development and time as well. After conducting a literature review on sustainable supply chain management, Seuring & Müller (2008) conclude that sustainability should cover three dimensions: social, economic and environment. Roxas & Coetzer (2012) define environmental sustainability orientation as the "*…overall proactive strategic stance of firms towards the integration of environmental concerns and practices into their strategic, tactical and operational activities.*" Economic sustainability should involve analysis to minimize the social costs of meeting standards for protecting environmental assets but not for determining what those standards should be. In order to pursue sustainability in green SCM, there are many practices firms may adopt. Firms have to more cautiously deal with issues like energy consumption, waste disposal, recycling, alternative energies, environmentally preferable products and service, and the like (Brown & Wilson, 2007; Li, Okoroafo, & Gammoh, 2014).

The demand for sustainability in outsourcing is presented in the literature, however, the research that answers to this demand is lacking. Especially, there is an absence of research clearly linking the antecedents, goals, practices, and outcome of sustainability orientation in outsourcing practice (Li, Okoroafo, & Gammoh, 2014). Pagell & Wu (2009) conceptually developed and define a managerial orientation toward sustainability as the extent to which an organization is proactive and committed to economic, environmental, and social concerns in its decision making across its supply chain. Yang (2013) defines sustainability orientation as the extent to which an organization is proactive and committed to economic, environmental, and social priorities in its decision-making. Based on Carter & Rogers (2008); Seuring & Müller (2008) Li et al., (2014)'s definition for sustainable supply chain management, we define sustainable outsourcing as the strategic integration and achievement of a firm's social, environmental, and economic goals in its sourcing to a third-party entity. We investigate the antecedents that push firms to pursue sustainability orientation, the practices of the sustainability orientation, and its outcome using the triple bottom line approach to measure the economic, environmental and social performance of outsourcing.

The importance and necessity of sustainability orientation are well established in the literature and warrants continued research. Porter & Kramer (2006) show that for stigmatized industries, firms may pursue sustainability orientation as a form of insurance to temper public criticism in crisis by its reputation for social consciousness. The positive linkage between corporate environmental management and pertinent sustainabile performance indicators has been well recognized (Pullman et al., 2009; Yang, 2013). Li, Okoroafo, & Gammoh (2014) suggest that internally firms should devote themselves to sustainable product development, and externally firms should conduct sustainable oriented supply management in accordance with their sustainability goals. However, most research focuses on green/environmental issues; research on social aspects and the integration of the three dimensions of sustainability is still lacking. The demand for sustainability orientation in green SCM is presented in the literature, however, the research that answers to this demand is lacking. Especially, there is an absence of research clearly linking the antecedents, practices, and outcome of sustainability orientation in green SCM practice. Thus, this research investigates the role of sustainability orientation in green SCM by examining its antecedents, practices, and corresponding outcomes. As a result, the following hypotheses are presented:

H_3: Green SCM of Strategic Orientation directly and positively contributes to Sustainability Orientation.
H_4: Sustainability Orientation directly and positively contributes to Green Alliance Performance.

2.3. Alliance Performance

Alliance performance is a complex, systems-level concept that becomes relevant only when its component parts are thoroughly understood down to the operational level. Multiple factors determine the performance outcome of international strategic alliances, ranging from the nature of the industry and institutional environment within which the alliance operates to the quality and commitment of the alliance management (Nielsen, 2002). An efficient alliance is one that can effectively manage conflicts and solve problems especially when unforeseeable changes arise. Such inter-firm partnerships allow managers to express their views and get their messages across without being forceful. It also leads to constructive conflict resolutions (Phan et al., 2002), enabling the parties to accomplish their original goals and enhance alliance performance. Integration of Yang (2013); Ince & Çemberci (2011); Hult et al. (2007); and Cheung (2005) defined alliance performance and identified two dimensions: relationship value and perceived supply chain performance. As a result, strategic orientation seems to be an antecedent of green supply chain management, and so the following hypothis is presented:

H_5: The combination of resources through the path dependence of a Strategic Orientation as antecedents to Green SCM and Sustainability Orientation, directly and positively contributes to Green Alliance Performance.

2.3.1. Relationship Value

Following Lapierre (2000) and Cheung (2005), the relationship value construct in this study is defined as the difference between the benefits and the sacrifice (the total costs, both monetary and non-monetary perceived by buyers/or suppliers) in terms of their expectations (Slater & Narver, 1992; Zeithaml, 1988). Sacrifices are the overall monetary and non-monetary costs a firm invests or gives to an exchange partner in order to complete a transaction or to maintain a relationship with an exchange partner. Non-monetary costs can be defined as the time/effort/energy invested or conflicts endured by a firm to obtain products or services or to establish a relationship with an exchange partner (Lapierre, 2000). In an effort to develop guidelines for combining several dimensions proposed in previous studies (see Lapierre 2000; Moller & Torronen, 2003; Corsaro & Snehota, 2010) to form an overall measure of relationship value, they concluded that, to capture the various facets of the construct, research should rely on multidimensional scales of relationship value in business markets rather than overall measures of the construct. In this study, construct relationship value is explored from the perspectives of both the buyers and sellers.

2.3.2. Perceived Supply Chain Performance

Research in supply chain management has received a great deal of attention and has risen to prominence over the last decade (Cooper, Ellram, Gardner, & Hanks, 1997; Antai, 2011). In a supply chain context, as proposed by Mentzer et al. (2001), the outcomes of purposively managing a supply chain are improved customer value and satisfaction as well as profitability. These can all lead to a differential advantage. Supply chain management is about competing in value-collaboration with customers and suppliers in order to create a position of strength in the marketplace based upon the value delivered to the end consumer, as well as to supply chain partners. As firms increase their participation in the global economy, developing supply chain management strategies through which to improve the performance of the entire

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

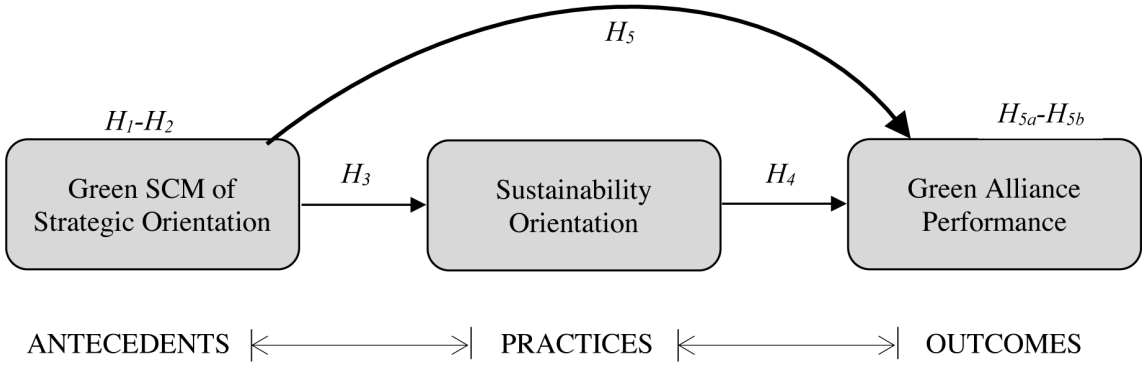
value chain (all functional activities) is becoming increasingly critical. Thus, we can conclude that an understanding of the entire supply chain is critical to identifying and delivering value that improves the competitiveness of the chain as a whole (Slater & Narver, 1994; Woodruff, Locander & Barnaby, 1991).

Linked firms within supply chains share the same responsibility in regard to coordination of value, understanding, creation, and delivery across the whole supply chain (Flint, 2004). Thus, this study proposes that inter-firm knowledge sharing between customers and suppliers is the first step in value understanding, as step that should enhance the effectiveness and efficiency of value creation and delivery. H_1 and H_2 are concerned with the relationship between both an environmental orientation and green supply chain management and a supply chain orientation and green supply chain management. Hypotheses *5a* and *5b* are concerned with the relationship between green supply chain management and the two dimensions of alliance performance. Given the theoretical implications of strategic resource configurations, manifested through the hypothetical relationships already described, three additional hypotheses are needed to show the relationship between the combination of strategic resources and alliance performance.

H_{5a}: The combination of resources through the path dependence of an Environmental Orientation and a Green Supply Chain Orientation as antecedents to Green SCM, directly and positively contributes to Relationship Value.

H_{5b}: The combination of resources through the path dependence of an Environmental Orientation and a Green Supply Chain Orientation as antecedents to Green SCM, directly and positively contributes to Perceived Supply Chain Performance.

3. METHODOLOGY



3.1. Data Collection

All of these internal and external factors (see Figure 1) push firms to pursue sustainability in their green SCM practice. Below we will discuss the different drivers of firms' sustainability orientation. All the hypotheses depicted in Figure 1 were empirically tested through the use of mail survey data collected from a database obtained from the Taiwan Stock (TSE-854 companies) and Over the Counter (OTC-969 firms) Exchanges. The sample was selected from managers of corporate planning departments, R&D, and marketing departments who have participated in the implementation of a particular strategic alliance case. The target firms of this study are all companies listed in the stock exchanges of either Taiwan or China, excluding companies in the services industry. 1,350 companies were involved. For these target companies, this study required the respondents to be engaged in supply chain management with Asian partners (domestic, Big China – Mainland China and Hong Kong, and other Asian countries). Specifically, supply chain, logistics, operations, and purchasing managers at the Managerial, Vice Presidential or Director levels were targeted. The selection criteria are based on job titles, responsibilities, perceived knowledge of supply chain management processes and firm performance.

Overall, three reminder e-mails were sent at equally distributed time intervals. This procedure resulted in 741 unique visitors to the survey website (39.5% of qualified potential respondents actually assessed the survey). 368 respondents submitted their completed responses (49.7% of the 741 who accessed the site or 25.8% of the 1,814 targeted respondents). The remaining 47.6% of potential respondents dropped off quickly or within the first few pages of the survey.

Figure 1. Research framework

3.2. Descriptive Analysis

Information regarding the sampled firms is provided in Table 2. The majority of the survey participants are from the electronics industry (40.35%). The industrial products industry and medical/ pharmaceutical industry contributed 28.07% and 13.74% of the respondents, respectively. Other industries include appliances, automotive, apparel/ textile, and aerospace, among others. Approximately 77% had held their positions for more than 11 years. Overall, the average respondent had approximately 14.5 years of

Table 2. Characteristics of the firms

Description	Frequency	Percentage	Description	Frequency	Percentage
Type of Industry			**Establishment for**		
Electronics	138	40.35	*Less than 5 years*	2	0.58
Industrial Products	96	28.07	*6 - 10 years*	76	22.22
Chemicals/plastics	24	7.02	*11 - 15 years*	115	33.63

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

related experience. Annual sales statistics for the companies represented by the survey participants was also collected. Nearly 65% of the firms had annual sales exceeding NT$ 201 million, and 70% of the firms had more than 500 employees. Only 1.46% of the firms had newly established alliances with current partners, while almost 33% had engaged in alliances more than 6 times. Finally, domestic partners dominated this study (56.44%), and Asia (28.07%).

3.3. Measures

To develop the survey instrument, a pool of items was identified from the literature for measuring the constructs of the research model. Data from a survey sample were used to assess the instrument's validity and reliability, and to test the hypothesized relationships of the research model. All measures of the survey instrument were developed from the literature. All scales reported in this section have single factor structures (PCA, Varimax). Response scales range from 1 (strongly disagree) to 7 (strongly agree), unless stated otherwise. Data was collected online. Prior to estimating the structural models, the measurement model was assessed separately for each model in the full sample. All data analyses were performed using SPSS statistical software, version 19.0. Descriptive statistics were used to describe the characteristics of the variables interest. Standard Pearson correlation and regression procedures were used to examine the interrelationships among the study variables. *P* values less than or equal to 0.05 were considered significant. To assess the validity of our measurement model, we checked for content validity and internal consistency. Content validity between the items and the existing literature was determined by interviews with many MBA students and experts in Taiwan and with a pretest of the model. Information about Cronbach's α values, means, standard deviations, and correlations between scales is to be found in Tables 3 and 4.

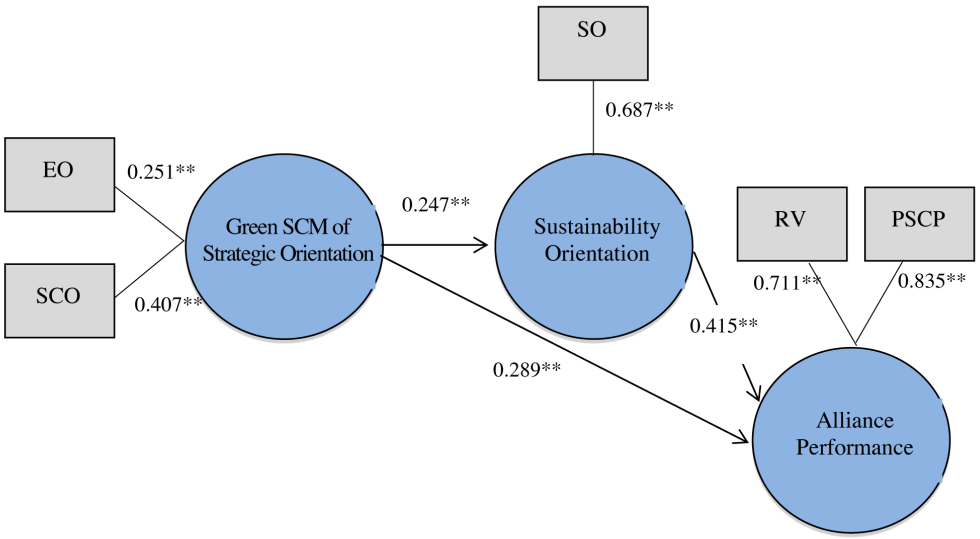
Table 3. The Cronbach's α values for composite variables and the correlation matrix

Variable (Number of Items per Dimension)	α	Mean	SD	EO	SCO	SO	RV	PSCP
Environmental Orientation (EO) (8)	0.87	4.89	1.22	0.57				
Supply Chain Orientation (SCO)(5)	0.89	4.77	1.18	0.36**	0.59			
Sustainability Orientation (SO)(9)	0.84	5.02	1.48	0.21**	0.32**	0.64		
Relationship Value (RV)(8)	0.85	5.30	1.57	0.19**	0.28**	0.17**	0.57	
Perceived Supply Chain Performance (PSCP) (7)	0.91	5.66	1.59	0.23**	0.39**	0.31**	0.29**	0.72

Note: Diagonal elements are the square root of the average variance extracted (AVE). ** represents that the correlations are significant at 0.01 or above, * represents that the correlations are significant at 0.05 or above.

Table 4. Results of factor analysis and reliability tests

Factors	No. of Items	Factor Loading	Item-to-total Correlation
Environmental Orientation (EO)	8	0.685-0.814	0.524-0.846
Supply Chain Orientation (SCO)	5	0.701-0.825	0.496-0.798
Sustainability Orientation (SO)	9	0.754-0.869	0.698-0.793
Relationship Value (RV)	8	0.612-0.837	0.525-0.870
Perceived Supply Chain Performance (PSCP)	7	0.902-0.968	0.786-0.839



EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Tables 3 and 4 present the results of factor analysis as well as those for the reliability tests for measurements of green supply chain management, Sustainability Orientation, and alliance performance. All variables within a factor tend to have a high coefficient of item-to-total correlation. This suggests a high degree of internal consistency for each dimension. In addition, the high coefficient of Cronbach's α on each factor further confirms the reliability of the measurement items.

4. RESULTS

Based on the previous chapter, the results of factor analysis show that each research item has a high factor loading and Cronbach alpha. Therefore, this study uses the second order factor to test the full model by using SEM. The structural model results are presented in Figure 2 and the standardized regression weights and fit statistics for the structural model are summarized in Table 5. It can be seen that the chi-square value of 275.92 with 174 degrees of freedom is acceptable at the 0.05 significance level. In addition, the *GFI* is 0.937, the *AGFI* is 0.946, and the *RMSEA* = 0.041. These fit indices indicate a good fit for this model. As the overall goodness of fit is promising, it seems worthwhile to further identify the magnitudes and significance of the path structural coefficients of the model.

Figure 2. Structural model tested

Notes:

1. χ^2 (df) =275.92 (174); p < .05; GFI (RMR) = .937 (.047); CFI (RMSEA) = .939 (.041)
2. EO = Environmental Orientation, SCO = Supply Chain Orientation, SO = Sustainability Orientation, RV= Relationship value, PSCP = Perceived Supply Chain Performance

4.1. Summary of Hypotheses Tests

The following hypotheses were tested:

4.1.1. Hypotheses Related to Antecedents of Green SCM of Strategic Orientation

H_1: Environmental Orientation directly and positively contributes to Green SCM of Strategic Orientation

The path from environmental orientation (EO) to green SCM of strategic orientation is significant (*$p<0.001$*), is in the direction hypothesized, and is strong (0.251). The data strongly supports the hypothesis that environmental orientation has significant direct effects on green SCM of strategic orientation.

H_2: Supply chain orientation directly and positively contributes to Green SCM of Strategic Orientation.

The path from Supply chain orientation to green SCM of strategic orientation is significant (*$p<0.001$*), is in the direction hypothesized, and is strong (0.407). The data strongly supports the hypothesis. In other words, if the level of environmental and supply chain orientation is high for a focal firm, the probability of obtaining a strategic alliance partner who has a specific level of green SCM of strategic orientation is also high.

According to these findings, it can be stated that the EO and SCO have a significant impact on the green SCM of strategic orientation. While the overall EO has a minor impact on the green SCM of strategic orientation, SCO has a great influence on the green SCM of strategic orientation. H_1 and H_2 support a significant relationship between the bundle of resources in the EO, SCO and green SCM of strategic orientation models in the configuration of EO and SCO as antecedents to green SCM of strategic orientation.

4.1.2. Hypotheses Related to the Practices for Green SCM of Strategic Orientation

H_3: Green SCM of Strategic Orientation directly and positively contributes to Sustainability Orientation.

The path from green SCM of strategic orientation to sustainability orientation is significant ($p<0.001$), is in the hypothesized direction, and is strong (0.247). Therefore, the hypothesis that green SCM of stra-

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

tegic orientation has a positive effect on sustainability orientation is supported. The higher the level of green SCM of strategic orientation, the higher the level of sustainability orientation. The results shown in Table 5 thus indicate the importance of green SCM of strategic orientation in sustainability orientation.

H_4: Sustainability Orientation directly and positively contributes to Green Alliance Performance.

The path from need for sustainability orientation to green alliance performance is also significant ($p<0.005$), is in the direction hypothesized, but is not very strong (0.415). The data supports the hypothesis that sustainability orientation practices lead to an increase in green alliance performance.

4.1.3. Hypotheses Related to Outcomes of Green SCM of Strategic Orientation

H_5: Green supply chain management is positively associated with alliance performance.

The path from green SCM of strategic orientation to green alliance performance is significant ($p<0.001$), is in the direction hypothesized, but is not very strong (0.289). This hypothesis is supported by the data. H_{5a} and H_{5b} are concerned with the relationship between green supply chain management and two dimensions of alliance performance. The combination of resources through the path dependence of an environmental orientation and a green supply chain orientation as antecedents to green SCM, directly and positively contributes to relationship value and perceived supply chain performance. The paths are significant ($p<0.001$), are in the direction hypothesized, and are strong (0.711 and 0.835).

5. DISCUSSION

5.1. Summary of Results

The theoretical model hypothesized a direct, positive relationship between green SCM of strategic orientation and alliance performance. Support for the green SCM-firm performance relationships indicates that managers recognize the ability of green SCM practices to impact similar operational metrics of firm performance and operations, such as inventory turnover, order fulfillment, and stock availability (Kirchoff, 2011). The significance of the relationships found between green SCM and the two constructs of firm performance provides evidence of a more widespread proactive environmental strategy in the firms that participated in the survey. All organizations have an environmental strategy that ranges from resistant to proactive and determines which performance goals the firm will pursue (Aragon-Correa & Sharma, 2003).

Moreover, the high loading provides evidence that successful green SCM practices need to be supported by an underlying environmental corporate and economic culture or orientation (Klassen & Johnson, 2004; Min et al., 2007) in firms defined as EO and SCO, respectively. Orientation refers to the way firm views and reacts to the business environment in which it exists. Therefore, EO and SCO were both hypothesized as important antecedents to green SCM (Klassen & Johnson, 2004; Fraj-Andrés et al., 2009). Environmental management practices also bring positive sustainability performance. This also proves that the practice of releasing corporations' sustainability reports is valuable to firms in terms

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

of profit, protecting the environment, and serving the best interest of society. Strategic orientation to achieve sustainability pushes companies to change the design of products and processes to reduce waste and environmental harm while enhancing corporate image in terms of social responsibility. Therefore, managers who engage in supply chain initiatives to improve sustainability performance should look for alternative ways to integrate all three dimensions of sustainability into their supply chains. It would be worthwhile for corporations that are adopting sustainability initiatives to create sustainability orientation.

In the past, firms selected suppliers based on their economic performance, such as product quality, price, delivery speed and so forth. However, with sustainability orientation, firms can no longer focus only on financial terms when evaluating suppliers; they need to adopt sustainable criteria when looking at supplier's economic, environmental and social performance in order to achieve sustainable orientation (Amindoust, Ahmed, Saghafinia, & Bahreininejad, 2012; Li et al., 2014). As a result, we expect green alliance performance, in terms of environmental and social aspects, to be higher than those that are not sustainability oriented. The literature has shown that green SCM has a positive impact on supplier performance and firm performance (Paulraj, 2011; Li et al., 2014), so we expect sustainability oriented SCM to be positively associated with a firm's economic alliance performance.

5.2. Implications and Future Research

Green SCM has received increasing academic attention in recent years. Green SCM is seen as a major corporate initiative that not only represents more accurately whether a firm is genuinely devoted to ecologically responsible operations or is just engaged in 'green-washing' or 'Green Frenzy' projects. In addition, Green SCM has strong strategic implications for a firm's long-term sustainable growth. Therefore, developing green innovations is a win-win solution for the conflict between economic development and environmental protection. One of the important theoretical contributions of this research is defining and developing the concept of green SCM innovation strategy. This contribution is important for several reasons. First, it is based on multidisciplinary perspectives adding to our understanding of the phenomenon in the green supply chain context. Second, green SCM innovation strategies are conceptualized at the firm level of analysis in a holistic conceptual framework of interrelated antecedents, processes and outcomes. In addition, this study enriches this stream of literature by offering strong additional evidence, from a unique single firm, of the positive effects of green SCM on alliance performance.

Moreover, the inclusion of the EO and SCO construct in this paper contributes to the green SCM literature because both the operationalization and empirical testing of EO has previously only been investigated in the marketing and management literature. The findings here suggest that successful green SCM practices need to be supported by an underlying environmental corporate culture and economic culture or orientation (Klassen & Johnson, 2004; Min et al., 2007) in the firms that are defined in this research as EO and SCO, respectively. This contribution is important for several reasons. First, this study contributes to the recent debate on the performance implications of environmental orientation. It has been widely debated among academics and practitioners whether and how firms' adoption of an environmental and supply chain orientation could enhance their competitiveness. Unfortunately, to date the literature in this area is still rather mixed and far from adequate (Menguc & Ozanne, 2005). This study not only demonstrates that both the internal supply chain and external environmental orientations exert a positive and significant influence on green SCM and alliance performance, but also more importantly, delineates how green SCM practices contribute to this influence (Closs et al., 2011).

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Finally, this paper has shed light on the role of sustainability orientation in green alliance performance by providing a framework that captures the antecedents, practices and outcomes of sustainability orientation, and calls for more research attention on sustainable SCM. Two antecedents that push firms to be sustainability oriented are identified. Two internal and external practices that could help firms to achieve their goal of being sustainable are suggested. Instead of SCM the non-green products to other countries, firms could adopt sustainable product designs that meet sustainability requirements so that not just that firm, but the whole supply chain could become sustainable. At the same time, it is also critical for firms to have green SCM, to select suppliers with sustainable standards, alliance performance using the preset standards, and develop the suppliers to share the common goal of sustainability orientation. In the area of SCM, it would be interesting to investigate the indicators of selecting suppliers with sustainability orientation, and if no current supplier meets the standards for sustainability, how to develop those suppliers to be sustainable-oriented. It would also be meaningful to study how capability emerges and diffuses in sustainable outsourcing.

5.3. Limitations

It is important to highlight the limitations of this study so that future researchers can attempt to overcome some of its shortcomings. To begin, this study deals with Taiwanese focal firms only. Future researchers may wish to attempt to test these hypotheses in similar markets, particularly the transitional economies of Asian neighbors. Secondly, this study contributes to the recent debate on the performance implications of environmental orientation. It has been widely debated among academics and practitioners whether a firm's adoption of an environmental orientation enhances competitiveness, and if so, how. Unfortunately, the literature on this topic, to date, is still rather mixed and far from adequate (Menguc & Ozanne, 2005). Finally, this study relied on self-reports. Although self-reports have been widely used and have been shown to be reliable, it would be enlightening to add external measures such as financial performance indicators through secondary data. Collecting dependent and independent variable data from different respondents would also help eliminate potential problems arising from common method bias. Another limitation is the generalizability of single research study results.

Chapter 16
CSR in Cultural Organizations: A Valorization Model

Lucia Aiello
Sapienza University of Rome, Italy

María del Pilar Muñoz Dueñas
University of Vigo, Spain

ABSTRACT

In this chapter, the authors approach the theme of the definition and classification of CSR for cultural organizations according to the major international literature review dealing with the issue. They argue for more theoretical discussion into the valorisation dynamics of CSR, drawing from the consideration that the CSR could be strategic for cultural organizations as a serious object of investigation despite its managerial and sustainability significance. Starting from the analysis of the main literature on CSR in cultural organizations context, the authors show a valorisation model. As a result, the aim of this chapter is to define the unique dynamics of the valorisation model for cultural organizations in a CSR perspective.

INTRODUCTION

The subject of the proposed work is the link between Cultural Organizations and CSR through the approach based on the value creation integrated into perspective of shared value between society and organization. The value society is the optimal value creation as a result; the idea for this work comes from the consideration of dimensions of CSR for cultural organizations and to links that can activated.

Culture considered a common good, an element of welfare for community, for all people, and as such, each individual has a responsibility to preserve, safeguard and value it. Culture has an exchange value too, and thus it is also a product (commodity, service, idea), and this requires economic, social and cultural models, consistent and shared, however, it mustn't disregard the definition of Cultural heritage by United Nations Educational, Scientific and Cultural Organization (UNESCO), which considers culture a good belonging to all mankind: «Everyone must be enabled to enjoy culture» and «Culture is world heritage». The cultural organizations must allow culture to finance itself through a process involving the quality artistic production, support of public and media, substantial public and private financing and

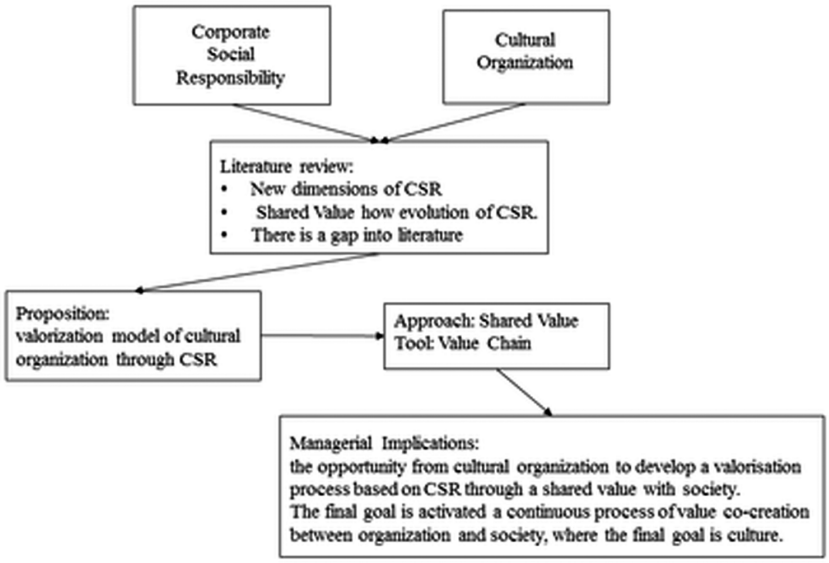
self-financing. The target audience, and then the target to be attained, is becoming more strategically important. An analysis of new and potential opportunities for «new markets space» must be realized to be able to exploit potential benefits. With reference to Management, to date, many studies have proved the strategic importance of CSR, and - in this work - within the processes of value creation of the CSR. As the analysis of cultural organizations shows, the CSR helps the processes of value creation of cultural product; so i.e. cultural enterprise, cultural association. In general, a part of the value added generated by a firm through its activities necessarily goes to the local system where it is situated, as it is transferred to other actors who are part of it, and vice versa. In particular, perspective of competitiveness development, value creation means the strengthening of tangible and/or intangible property in the area and that, as mentioned, determines its terms of competitiveness. There is a literature as well as wide empirical evidence on the ways in which the presence and behavior of firms affect, or may affect, the factors of economic attractiveness in the geographical context they belong to.

Below are the most significant among these modes:

1. Development of quality of human resources.
2. Knowledge transfer to certain local actors.
3. Acquisition of products/services from local businesses.
4. Pulling of local companies in the competitive international contexts.
5. Improving the image/reputation of area.
6. Improvement of quality of local supply with special reference to that of intermediate goods and high value services.
7. Support to share capital, as the cultural sponsorship and strategic partnerships.
8. Contribution in the realization of infrastructural investments.
9. Improvement of the level of sustainability (social, environmental, economic) of local production system.

All aspects can be affecting by CSR. The connection of CSR management and cultural organizations needs an integrated approach involving the analysis of literature (desk) and analysis of practical cases (field).



In literature, there is a gap on CSR analysis in valorization process of cultural organizations. Some studies pay attention on role of CSR into value chain and some authors, as Carroll (2003), put in evidence the process of value creation for organizations and society. There is not any suggestion about the relationship between CSR and value chain that include the valorization of cultural organizations.

According to explored gaps, this chapter propose a new framework to study and consider the active role of CSR into value chain of organizations into shared value approach, from this starts a proposition of a valorization model for cultural organizations.

The characteristic feature of this publication is the theoretical analysis that has made it possible to develop an integrated approach including CSR's management and cultural organizations (Aiello, 2014). This approach is important in order to recognize a common perspective to investigate, create and propose a model for the link between CSR and cultural organizations mainly through shared value. The study of literature, in particular, allowed us to recognize the relationship, which is the proper approach to know the contents, meaning and components of the phenomenon investigated. The perspective adopted is to deepen the theoretical framework of cultural organizations through the «lens» of shared value in order to propose a CSR management for cultural organizations based on both theories of reference and

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Research design

empirical analysis of case studies. This chapter focuses on the CSR and Cultural Organizations through valorizations model that based on value chain. Value chain defines how the organization creates value for its and stakeholders, environment and society.

The analysis of CSR into value chain of cultural organizations and this integration can be considered as a method to reach new model: a valorization model. The object under investigation is the cultural organizations in an integrated and social responsibility's configuration. The question study is: which role and which value has CSR into value chain? The proposition supported is that the CSR to be valorization element for cultural organizations in a multilevel configuration, making shared value approach; thus CSR could be input, philosophy and output of valorization processes in value chain.

The objective of the publication is a proposition of valorization model of cultural organization that based on CSR in a multilevel configuration into value chain. The question below study is mapping the CSR in value chain of cultural organization through the valorization model in shared value approach. The figure one presents the research design.

Thus, in line with research design the research objectives are to design rounded background in CSR for valorization of cultural organizations; to reflect the role of CSR into value chain; to study the link between CSR configurations and value creation and shared value; to suggest a valorization model of cultural organizations through CSR in shared value approach.

BACKGROUND

The main authors defy easy definition of culture (Knight, 1999). The term cultural industries (Power et al, 2004) encompasses a wide variety of commodified activities, including the mass media (print and broadcast media and advertising), film, new media, art, design, music, and architecture. Conversely, although it is an important area of research and of economic activity, there has been a significant gap

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

in systematic studies of these industries (Aiello, 2014; Powder, 2002; Scott 2000; Pratt 1997; Sadler 1997; DiMaggio and Hirsch 1976).

The dissemination of culture, different governments have sought to provide support for their maintenance and growth. The more complicated questions are for the debate around culture in considering if whether culture is good or service and also, whether culture from different countries constitute like or directly competitive or substitutable products. Culture is core business of more and different organizations, which are to be treated but arguments will possible continue as to whether culture is a good or service (Löhr. 2010; Bernier, 2005).

Culture is a value also, so it is a complex (good, service, idea, value) and this value is economic, social, tangible and intangible (Aiello, 2014; Ferri et all., 2009; Voon, 2007; Scott, 2004; Lorente, 2002; Fuchs, 2002; Throsby, 2001; Bryan et al., 2000; Weinstein et al., 2000).

The culture in the society has been subject an increasing economic interest in recent years. Although, it is quite problematic to understand exactly its role, because of perhaps the most difficult step is to define what exactly is. Culture has a value but it is difficult monitoring and define it.

Furthermore, the value and role of culture into society play a crucial role, in fostering the value creation for society, and the valorisation of cultural organizations.

Changing culture organization policy is reshaping the role of value chain in the value creation. The benefits of cultural production are likely much larger than they might appear at first glance, given that they contribute to valued social goods like national identity and social cohesion as well as for business.

In literature, it proposed a theoretical framework of cultural enterprises (Solima, 2006). The framework defines the cultural organizations performing, activity of prevalent artistic and cultural content, in order to achieve an objective of social order, "the community's cultural growth". The organization wishes an adequate tangible and intangible asset, which is an appropriate working capital to achieve its institutional mission. A cultural organization configured in order to management level, cultural activities and cultural heritage; and value chain process, production, creation, and/or supply.

The value chain process could not generalized for all cultural enterprises but it depends on the type of cultural enterprise. The considerations set out above highlight some critical elements of cultural organizations, particularly, the specificity and peculiarity of each cultural organizations and therefore, the value chain configuration.

Several authors argued on different aspects of the complexity of culture and cultural enterprises or industrial (Solima, 2006; Bollo, 2008; Colbert; 2004; Hesmondhalgh, 2002). Precisely for these reasons, Solima, in dealing on cultural enterprise, chooses only some of the possible configurations, pointing out that they are only part of the complex landscape of cultural goods and activities. The configurations of cultural enterprise considered by the author are theatres and opera foundations, libraries, archives, museums and archaeological sites, festivals called actors of the system (Solima, 2004: 55-83). In different overview, cultural features then considered a unique character to embed into an organization both for the enhancement of culture identity in the global market and for the fulfilment of everyone's experiences. The cultural creation, in fact, is a consistent mix of single elements; giving to it size and values. According to Colbert (2003), art and culture are any business at the base of which there is an act of artistic creation (Colbert et al., 2004).

According to a previously study (Aiello, 2014) the cultural organizations are classified in "strict sense" and "broad sense". In first categories, there is performing arts, especially of those in which the core business is a direct contact between the artist, his art and the consumer. In "broad sense" categories,

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

there is the cultural industry and the media – film industry, discography – core business is an art product coming from a production and/or distributive process.

The main difference between tow classifications is the value chain, which based on direct or indirect contact between the public and the arts. Cultural organizations share a social objective, namely the common cultural growth with a view to enhancing the economic value of both a recording or film product and a museum. This involve an economic but social, also, value.

Thus, cultural value is recognized at a powerful factor on brand image and is extensively accepted as one of the central approach in understanding value chain, which determines different choices of consuming and shared value (Park et al, 2009).

Scott (2000) considers the cultural organizations an important and growing element of contemporary economic systems, thus are becoming increasingly prominent in post-industrial societies (Currid 2006; Kloosterman 2004; Throsby 2001; Scott, 2000; Lash et al., 1994; Zukin 1998). Cultural organizations can identify through different levels:

1. Service outputs that focus on entertainment, edification, and information, where the culture is the core product (i.e. recorded music, museums).
2. Manufactured products that focus the culture how essence of product, where the culture is the philosophy of core product (i.e. jewellery or fashion clothing).

The social value is part of culture organizations, which provide share understanding among people in a society that allows them to predict and coordinate social activities and cultural values (Pratt, 2008; McGregor, 2000; Stanwick et al, 1998).

Thus, this different level shifts to description of value chain towards the involvement the CSR (Weber, 2008).

For nature of cultural organization we can show which Gholami) consider a <<reciprocal dependence between an organization and society>> (2011: 148), the author consider the indicators that influence this relationship.

In this view it is important to clarify in detail the elements involved in the process of value chain flexibility (Zhang et al, 2002), the main dimensions of CSR and the link with the context in which this are expresses for shared value. Thus, in the following sections we describe all the components, which contribute to delineate the valorization model, starting from the different value chain typologies in line with CSR into shared value approach.

CSR IN SOCIAL VALUE PERSPECTIVE FOR CULTURAL ORGANIZATIONS

Sustainability meets present needs without compromising the ability of future generations to meet their need. The Green paper defines CSR essentially a concept whereby companies decide voluntarily and beyond the law to achieve social and environmental objectives during the course of their daily business activities, contributing to a better society and cleaner environment. Since companies that behave in a socially desirable way will also gain financial advantages, corporate performance now means both financial and social performance. Within this context, networking means creating and governing the relationships, interactions and exchanges with others in an organized and conscious way. CSR is strategic key for Cultural Enterprise into dynamic and interactive environment (Carroll, 1999).

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

In the following paragraph we deep on these arguments.

CSR value is a significant issue in valorisation process, but it related some role are still challenging. The value changes in the cultural organizations evolution, process and develops a valorisation process through CSR policies. By applying the notions of social value, the cultural organizations introduced to characterize the valorisation on based multilevel. Based on these concepts, CSR and social value measured by a new <<framework value creation cycle>> proposed from Gholami (2011) that is consisted of four dimensions: economic, legal, ethical, and philanthropic dimensions. Thus, the CSR value calculating, in according to author, through a stratification of four dimensions:

- **Economic:** Personal saving rate; business saving rate; inflation rate; manufacturing/supply/distributions lead-time.
- **Legal:** Anti-trust; labour training laws; human right.
- **Ethical:** Codes of conduct; corruption; money laundering.
- **Philanthropic:** Donor attrition; donor acquisition; gift processing time; stewardship calls.

This point of view of CSR value, the construction of dimensions and the build a model of valorisation are insightful for both researchers and practitioners

The economic dimensions focus on create exploiting making per share, stress the position of resilient competitive, and embrace a high level of operational effectiveness. This framework suggests personal saving rate, business saving rate, inflation rate, and manufacturing lead-time indicators to measure the economic dimension. The legal responsibilities dimension, for author, highlight that the process of business should implement the vision and mission of their economic permitting to legal requirements. These tasks are important, because to move in a style uniform of government and law's expectation.

The ethical responsibilities focus on businesses takes that to do what is right, just and fair. Moral rules should define as suitable performances (McGuire et al, 1988) in the organizations and society (Aras et al, 2010).

Gholami (2011: 150) affirms that these responsibilities are important due to the prospects of social mores and ethical norms and recognition ethical or moral norms accepted by society (some variables codes of conduct, corruption, and money laundering). The last dimensions, philanthropic responsibilities named *discretionary responsibilities* highlight be a good corporate citizen, thus resources for community and increase quality of life as a basic indicator for community thus, donor attrition, donor acquisition, gift processing time and stewardship calls as crucial variables estimation philanthropic responsibilities within society (Gholami, 2011: 148-154).

Some authors analyse the concept of Shared Value (SV) (Cacia et al., 2015; Christiansen, 2008; Ashley, 2009; Barton, 2011). Porter and Kramer (2011) expanded the idea that the shared value connected with social responsibility. Actually, companies' responses to the CSR concept verified and sometimes found severely inadequate (Camilleri, 2013). The authors propose that Shared Value guarantees that what is virtuous for business is also virtuous for society; SV emphases on the joining between social and economic development. They define SV as «policies and operating practice that enhance the competitiveness of a company while simultaneously advancing the economic and social conditions in the communities in which it operates» (2011:6).

The connection with cultural organizations is that the shared value could considered applicable to equally profit and non- profit organizations as well as to cultural organizations also. In literature emerges

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

that the social drive of SV represents an higher form of entrepreneurship able to create a positive cycle of prosperity (Cacia et al., 2015).

Porter and Kramer (2006) suggested the SV how strategic dimension of CSR policies, the authors proposed a "new hybrid business models" (Michelini, et al., 2011).

The concept of creating social value clarifies a profounder relationship between business and society and delivers great push to developing social organizations (Yang et al, 2014; Alter, 2007; Kramer, 2005). Wood and Leighton (2010) defined social value as referring to the wider non-financial impacts of programs, organizations and interventions, including the wellbeing of individuals and communities, promotion of social capital and protection of the surrounding environment.

This research considers all the perspective analyzed more interesting; in a perspective of a new model of valorization for cultural organization through CSR, no theory can excluded but integration between them contributes to the proposal of the model of valorization.

Thus, this chapter propose an exploitation of CSR, shared value is a new perspective of CSR dimension, thus economic, legal, ethical, philanthropic dimensions must considered the shared value creation between organization and society.

CSR CONFIGURATIONS IN VALUE CHAIN

The analysis of value chain has underlined three typologies, which depend from CSR's role in shared value:

1. Value chain driven by CSR in creating value. CSR is an input.
2. Value chain based on CSR in value creation. CSR is a philosophy
3. Value chain has among CSR goals to create social value. CSR is an output.

In reference to CSR, the value chain is dynamic and based on three different typologies, in fact even the cultural organization is a mix between the all needs of every levels and the degree of complexity depends on the characteristics of both the organization and value chain. In the figure, both elements have divided into two main variables, respectively: 1. intensity; 2. pervasiveness; 3. shared value capability.

The intensity of CSR increases with the involvement of both secondary and primary value chain activities. The pervasiveness of CSR increases if connection between the organization and the reference society increases. CSR's shared value capability increases if the connection between CSR and shared value of the organization's value chain increases.

The model assumes that the variables of the intensity, pervasiveness and shared value capability influence the degree of complexity of value chain, thus CSR plays a crucial role in the configuration of the value chain.

Corporate Social Responsibility is the responsibility of business firms to ensure the development of the society within which they conduct their operations, even though the efforts in this direction may not bring the firms immediate monetary returns. Corporate social responsibility is getting unbelievably well-liked just lately as a result of mixture of public, ecological, in addition to economic deliberations of which plays a big aspect to make judgments constitutions in addition to operations connected with business. Corporate Social Responsibility is a significant subject for any organization ambitious for long lasting protract (Schwartz et al, 2003). At the same time as it is a more often than not designed concept,

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

there is ever-increasing stress on companies to make a positive participation to people, thus to create shared value with them and with society as a whole.

The scientific value concerns a new approach to Corporate Social Responsibility, focusing on the concept of the value chain (Kaplinsky et al, 2001). The work will represent an important contribution to organizational model (Daft et all, 1993), outlining a new perspective of considering CSR within the relationship between companies and the society as a whole in shared value area. Therefore, CSR requires new model to manage (De Witte et al, 2006).

Corporate Social Responsibility is, by its title, an obligation of a moral, social, and in some country statutory. In the most world, vice versa, it so looked upon as a voluntary decision. It is however, expected that many countries will follow suit in recognizing CSR as an important tool of development. In Cultural Enterprise the social element is part of it, never contribution puts in evidence such as CRS can developed as part of culture. The value of chapter is to highlight what CSR models can developed into a cultural enterprise in which the social element is characteristic.

Cultural Organizations include a wide range of activities; culture is not only art but also the greatest meaning of our pastimes, habits, images, and institutions, perspectives on the world, collective memory and our bilingualism and multiculturalism. From the analysis of the main literature on cultural organizations and the evolution of CSR, the proposal for this contribution emerges mapping three types of value chains where CSR has a specific role in relation to the predominant characteristics of cultural organization in a shared value.

In this perspective, this research is approaching the theme of defining and classifying the valorisation model for cultural organizations through CSR in the value chain according to major international authors dealing with the issue, knowing that CSR is the heart of the chain of value for cultural organizations.

In this perspective, CSR should carefully note, well known, widespread and attractive and diffused in the management of cultural organizations.

According with the main literature, cultural organizations have as core business intangible goods (Lampel et al., 2000). Although the stress on the intangible nature of culture has been largely debatable in the past, in light of the existence of a reciprocal relationship between culture and society. According to more spread definition, cultures are goods and services that include arts, visual arts, heritage conservation (museums, galleries, and libraries), cultural industries (broadcasting, film, and recording) and festivals. This feature differentiates the logic of CSR policies in relation to the type of organization, i.e. size (Udayasankar, 2008: 171).

Therefore, in cultural organizations the CSR exposed to value chain. In this respect, there are mainly three aspects, which are involved around the central component: 1. CSR is an input of value chain; 2. CSR is a philosophy that involves the whole of value chain. These aspects are mainly spinning off organizations, related the role of CSR into value chain. Therefore, corporate social responsibility plays a strategic role into value creation process and shared value between organization and society.

Businesses that have an advantage usually come from a number of activities along the value chain. A sustainable benefit is not a single activity, but many, and reconfiguring the chain often serves to create a new advantage. In this way, the company reflects through its value chain a differentiated way of acting over its competitors.

Although differentiation is an important element, its sources often not well understood: companies consider sources that are capable of influencing differentiation too restrictively. With this contribution, we consider a broader way to identify new sources of benefit, such as CSR.

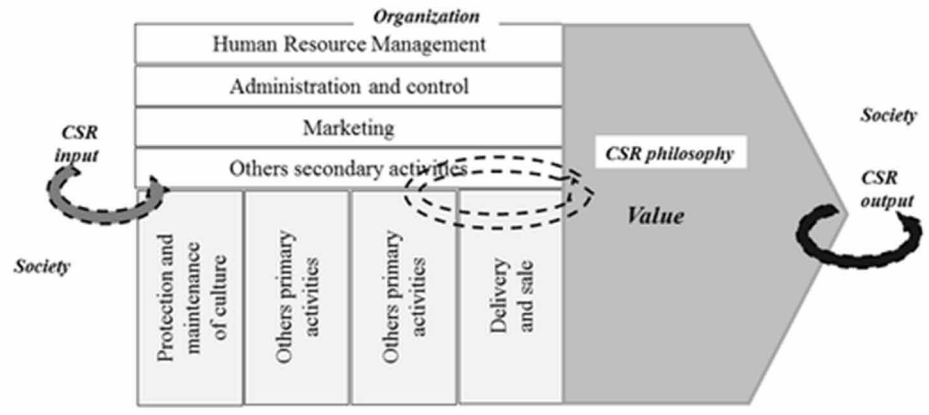
EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Usually, organizations focus on product or marketing differentiation instead of realizing that it can potentially manifest itself in every area of the value chain.

The starting point for generating value is to determine what has value not only for the customer or the reference environment but also for the company.

The CSR in value chain determine, therefore, the degree of three different configurations of value chain, which has been elaborated in the figure 2.

Generally, an enterprise creates value because it justifies a premium price (or preference at the same price) by two mechanisms: decreasing its costs or improving its performance. In fact, through the CSR-based value-added process in the shared value approach, the mechanisms that are activated are much deeper, as there is a shared common goal that reinforces the link between organization, society and the reference environment.



The valorization model presents into figure two aims to consider the role of CSR into valorization process of cultural organization. The model starts from value chain of organization; second step is the configuration of CSR into value chain: input, philosophy and output.

Configuration of CSR as input (dashed gray arrow); CSR policies aim to increase the value chain of other cultural organizations (i.e. donation to other cultural organizations, Della Valle at Colosseo for restructuration). Configuration of CSR as philosophy (dashed transparent arrow); CSR policies involved organization all, the whole chain of value, primary and secondary activities, and relationship with society, supported by CSR policies (i.e. Cucinelli that the share of workers in the division of profits and CSR is mission of organization). Configuration of CSR as output (dashed black arrow); CSR policies aim at defining the culture of social responsibility (i.e. Olivetti that design and construction of new industrial buildings, offices, houses for employees, canteens, kindergartens, giving rise to an articulated system of social services).

If there are all CSR's configuration, we could goal the integration CSR policies, where the complete circle of shared value process is based on CSR.

The perception that the market and all stakeholders have on organization and its products can therefore be as important as the differentiation effort that the enterprise accomplishes through its value chain. If this goes through a shared value, such as that of social and cultural responsibility, the process of valorization is facilitated.

Figure 2. CSR in value chain

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Once you find the sources of value for the buyer, you will have to identify the cost of the existing and potential differentiation sources. This implies choosing a configuration of the value generating activities that it creates for those who purchase a higher value differentiation than the cost of the differentiation supported by the enterprise; check that the chosen differentiation strategy is sustainable against erosions or imitations; reduce the costs of activities that do not affect the form of differentiation that you have chosen.

This will reduce the vulnerability of those who have opted for differentiation based on CSR policies than competitors relying on their value chain on other mechanisms because value sharing strengthens the link between organizations, society, and reporting environment.

Cultural organizations, which have CSR policies in its value chain, can pursue shared value opportunities on three levels: input, philosophy and output of valorization processes in value chain. Thus, CSR could be an input of value chain; for example "Colosseo" that has found from Della Valle (Italian Fashion Firm, shoes production). CSR could be a philosophy that involves the whole of value chain, from human resource management (employees are involved into profit sharing) at branding process (consumer process is the base of the social responsibility of organization); CSR is the way by which organizations improve the quality, quantity, cost and reliability of inputs value-creation processes. There is acting simultaneously in the economic and social development. CSR could be an output into value chain, thus, it is the way to operate in society and to compete and thrive. Redefining productivity in the value chain is the way businesses can improve the quality, quantity, cost and reliability of organization processes.

Based on theoretical conceptualization, combined with some cultural organizations that applied CSR policies, on develop a valorization model framework for approaching CSR in a value chain of cultural organizations. In particular, we aim to highlight the influence of CSR through new configurations on value creation and stress the role of CSR in value chain process.

The valorization model that we propose in section that follows start from this consideration and the configurations of value chain.

VALORIZATION MODEL

The CSR affecting the cultural organizations, joined to the responsibility has transformed the current organizational environment for most organizations, for example cultural organizations. Value chain defines valorizations is now more dependent on continuous value chain development and enhancement, so CSR becomes a central element in valorizations model. Furthermore, the valorizations of cultural organizations closely intertwined. The valorizations needs a successful value chain, both to create force element for the cultural organizations and to provide critical assets and a supportive setting and, also, CSR needs successful valorizations to provide creation opportunities. In literature, the main model on CSR's orientation is 3C-SR model (Meehan et al, 2006). The authors propose that into model must are three component, which are commitments, connections and consistency; weakness in one of these three areas will result in a failure to adequately achieve a real corporate responsibility orientation and building competitive strategies around social resources. Already Waddock and Graves (1997) have demonstrated the link between social welfare benefits and financial performance.

However, this scenario calls for a configuration of value chain, which includes valorization engagement methods and shifts the central goal of companies into creating CSR's value. This aim becomes more influential especially for those organizations that operate in culture through new approach that enable value chain from the perspective of social dimension.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Cultural organizations increasingly have needs of gathering ideas for innovations and providing solutions to existing problems and/or for maintaining the competitive advantage.

While both phenomena are not new, their overlapping requires considerable attention in practice, related to the culture opportunities and benefits that have been enabled by CSR policies. Corporate social responsibility presents a number of potential applications, open to future developments and seem to provide new model and ways to enable this in practice and to create new value chain.

Shared Value effects on preconceiving reputation on society, redefining efficiency in the value chain and allowing culture development. The first one allows organization to meet social needs through CSR. Redefining efficiency in the value chain and enabling culture development in the value chain, in its place, represents the way by which firms can improve the quality, quantity, cost and reliability of inputs value-creation processes. Thus, acting simultaneously in the economic and social development. The last one is the way in which organizations operate in society, to compete and thrive. Organizations need a strong valorization that includes responsibility (World Bank, 2012). The SV opportunities at each level will vary by organizations, company and society, depending on how the company's particular business and strategy intersects with social issues (Porter, 2012).

The evolution of the culture era, which allows you to define the concept of culture's co-creation action, drives organizations to pursue emerging strategies that share the value chain (VC) along the social responsibility's orientation. The use of CSR is necessary because it allows:

1. Reputation, advantage of having greater attention from society.
2. Sharing, opportunity sharing, and interaction whit a network cultural-oriented.
3. Accessibility, this opportunity allows the consumer, suppliers, crowd and every individual outside – which can bring value added to the value chain – to be included, in the valorization model of organizations, dimension conceptual of CSR (Carroll, 1979).

Many authors (Kaplinsky et al., 2001) have analyzed the question of value chain, and the its definition evolved. Flexibility's role (Nair, 2005: 447–463) and the co-creation of value chain (Stevens, 2009) put in action the role of CSR. Thus, we can assert that in the value chain is possible that the traditional parts (workers, managers, suppliers, clients), can was pushed from CSR into shared value process (Peppard, et al., 2006; Mascarenhas et al., 2004; Parasuraman et al., 2000: 170).

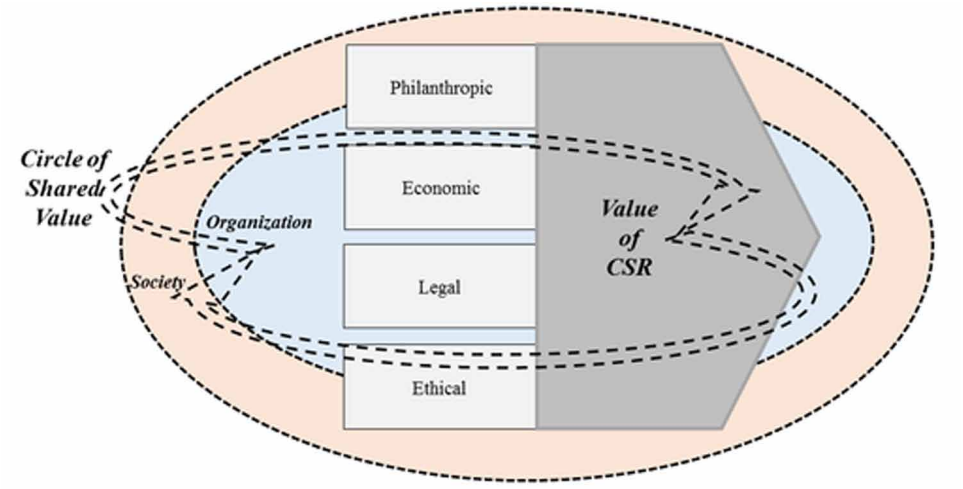
The knowledge economy is undergoing a process of differentiation and spatial segregation leading to a constant rearrangement of the value chain of cultural organizations (Thierstein et al., 2008: 1113–1131).

This work considers the valorization of culture organizations through culture creation and diffusion at the social responsibility is a process happening within the value chain. In a first analysis, we can consider that the hybrid role of CSR (input, output, philosophy) in value chains seems to be a main reason for the concentration of shared value.

The research question is the proposition of the CSR into value chain as facilitator to co-creation of value shared into cultural organization. The co-creation, amplified by CSR, allows you to renew the existing models of the value chain, this allows to have input from society and, therefore, an active role of all actors of the value chain. The internal and external society, which was static subject of the process, is now active subject.

This depends that general views on value creation are evolving toward an integration between internal and external at value chain of organization view, which focuses more intently on collaborations aimed at the sharing of specialized competencies among actors functioning in a network, thus CSR, also. The

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use



contemporary view of value creation based on CSR, into shared value approach as value co-creation, pushes to consider that CSR has a strategic role into vale chain, this is true and more strength in cultural organizations where culture is double value in CSR. The culture is the results of CSR policies and of value chain. Along the value chain, horizontally or vertically, between different subjects there is sharing information and knowledge that impact on value creation. Thus, we can affirm that there is a link between pervasiveness and depth of CSR and value co-creation capacity of organization; the competency, transformation CSR value into shared value that they have considered there is shows a value co-creation between internal competencies and external capabilities, not only but stakeholders but all society.

The study of valorization of cultural organization requires the CSR into shared value approach, because it is cross functional and involves several actors, they have different competencies and different relationships (involving suppliers, customers, institutions, society, others). In accordance with this perspective, co-creation value chain affects the capacity to create adds value for organization and society. Certainly then this convergence towards value creation and shared value creation links CSR processes into value chain. Thus, the CSR must be pervasive and depth. Since, the CSR creates confidence and social identity. The shared value management practices are fundamental because the logic based on the social responsibility, which we proposed through this work, is the input of culture, philosophy of organization and output of social responsibility of value chain, be-directional to shared value between organization and society involved.

The role of the CSR on valorization of cultural organization based on integration main literature review on CSR and value chain, on verifying that the value of co-production requires a shared value approach. CSR policies allow ability to start the valorization of organization and society, in a reciprocity link.

The valorization model of cultural organization start from the framework of value creation cycle proposed from Gholami (2011). Thus, valorization model consider the four dimensions that the author proposed; economic, legal, ethical, and philanthropic; at this dimensions we adjoins the shared value between organization and society, which is able to activate a continuous circle of increasing value (figure n. 3).

Figure 3. Valorization model, CSR in circle of shared value perspective

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

The CSR value calculating through the stratification of dimensions (the four rectangles light gray in the figure); economic (personal saving rate; business saving rate; inflation rate, manufacturing/supply/distributions lead-time), legal (anti-trust; labor training laws; human right), ethical (i.e. codes of conduct; corruption; money laundering), philanthropic (donor attrition; donor acquisition; gift processing time; stewardship calls). These dimensions of CSR, in this study, are goal through shared value circle. The organization activates CSR policies whose dimensions create value. In the shared value approach that we proposed through this work the value of CSR is increased by the virtuous and continuous shared value circle between organization (oval light blue) and society (oval light orange).

CONCLUSION AND FUTURE RESEARCH DIRECTIONS

The advent of a new cultural economy has been increasing. It now accounts for substantial shares of income and employment in a wide range of countries and offers important opportunities to local economic development. This is the first reason why cultural organizations have to be involved from to CSR policies for this ability to create both development for countries and value for enterprise as well as allow different stakeholders to participate in various ways in a new cultural economy. The cultural organizations seem to be moving steadily into a world that is becoming more and more cosmopolitan and eclectic in its modes of it possible think the culture and social responsibility. In this work, we have concentrated on the clarification of the main concepts related to cultural organizations and CSR in shared value approach.

The scientific value concerns the proposition of new model to valorization of cultural organizations through CSR, which is a matter under investigation by different studies as management analysis.

The advanced approach to the study concerns the valorization model; the analysis of CSR is not just about responsibility in some area of organizations; the CSR is not instrument only, but it is an element of value chain. The study intends to be an important contribution to management, in particular to cultural organizations.

The society into cultural organizations has a fundamental role, it not element of environment only but also subject of creation share value capability.

The potential impact of the study is to provide public and/or private organizations a support for realizing a projects of total social responsibility, as a value added offered to meet new needs and creating innovative and potential motivations to CSR policies. The purpose of the study is to advance both scientific literature and practical and operational management of valorization of cultural organizations. The CSR has an active role into value chain, which proves the main assumptions track: 1. Shared value can be activated through the total corporate social responsibility; 2. The CSR has an active role in value chain of cultural organizations.

The work proposes a valorization model for cultural organization through new assumptions that we have taken from the integration between literature review on CSR and cultural organizations.

From the considerations presented so far on the cultural organizations as well as the analysis of the CSR into shared value approach, there have been two main results:

1. There is a relationship between the valorization of cultural organization and its capability of shared value whit society. The point of view is CSR as an active element of the value chain in shared value approach.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

2. The configurations of CSR have a different role on valorization process of cultural organizations in relation to position of CSR in value chain.

The phenomenon analysed is cultural organization; the object of investigation is the construction of a model of valorisation. The main implication management is the opportunity from cultural organization to develop a valorisation process based on shared value of culture and of social responsibility with society. The final goal is activate a continuous cultural process of co-creation between organization and society.

Chapter 17
Green Growth Intervention on Employment Generation in India:
Dynamic CGE Model Approach

Anandajit Goswami
The Energy and Resources Institute (TERI), India

Saswata Chaudhury
The Energy and Resources Institute (TERI), India

ABSTRACT

This article highlights the possible impacts of green growth strategies and interventions on skilled and unskilled employment generation in India. Additionally, it indicates how income generation from selected green growth-related potential interventions can have a ripple effect on selected development indicators, like literacy rates, infant mortality rates, poverty. Job creation might translate to an economic gain for households of different income class across rural and urban India both in the short and long-term. This economic gain can thereafter reduce the level of inter-household and intra-household inter-temporal inequality levels with complementary and effective wealth distribution policies. In the long run, this reduction in the inequality level can create a positive impact on the social sustainability.

INTRODUCTION

The tradeoff between economic growth led development and environment leads to the formulation of the notion of green growth which is a sustainable development path where economic growth takes place without causing environmental, resource degradation, income and wealth distribution inequalities. Thus, green growth policies of developing countries are becoming more important which is intended to resolve both the environmental challenges, economic and income inequalities as well as the enduring unemployment problems inherent in many developing countries (Deschenes, 2013). Green growth

integrated development path of India has been accepted and debated in the recent past within policy circles. Thirteenth Finance Commission of India for the first time recognized the need for such an integrated development path with minimal impact on the use of natural resources. An inclusive green growth pathway for a developing country like India with high inequalities has to comprise of policies and implementation plan of new job creation across different sectors of the economy. Often, green growth pathways create structural macroeconomic tradeoffs if it leads to a reduction in sectoral shares in GDP with subsequent impacts on employment, migration, urbanization (Dercon, 2014). Tradeoffs can be created based on the degree and nature of focus of green growth interventions on areas related to agriculture, trade, technology, infrastructure and urban development. Often a focus in a particular domain in a particular way through government support, policy mechanisms, specific programmes or market-based incentives can lead to a slowdown in the growth process leading to a poverty reduction thereby increasing the social costs of green growth (Dercon, 2014).

It is therefore essential to observe and analyse these tradeoffs from a macroeconomic framework by understanding the interlinking tradeoffs of any green growth-related intervention within the economy of a developing country like India. Such an understanding will help in creating a roadmap for the sectoral interventions as a part of a green growth strategy of a developing country in the short, middle and long-term thereby leading to an inclusive development path. Several macro-level models like Computable General Equilibrium models can provide these indicative directions and can be applied to understand the tradeoffs for a long-term inclusive development pathway. One area in which they can be applied is to understand the basic nature of job creation from sectoral interventions of a green growth strategy of a developing country after assessing the various tradeoffs. Such an understanding will also help in shaping up an inclusive development path by assessing the various sectoral inter-linkages through job creation. This is due to the fact that job creation is an integral component of an inclusive development path. However, job creation has to be necessarily also be complemented by income and wealth distribution policies. Creation of job opportunity, skill enhancement within a green growth path can have the potential to address the challenge of unemployment in India. More than 90% of Indian working population is engaged in the casual and informal workforce due to unavailability of the expected job in organised sector (Hajela, 2012). Owing to the absence of the expected job, often there is a kind of voluntary, frictional unemployment too which is existing within the country. There is also an issue of mismatch between the expectation of the job givers and job seekers regarding the required skill set for a job due to which voluntary and frictional unemployment is rising. This in a way, then also has developmental consequences by impacting the state of happiness, the satisfaction of the job seekers.

The dearth of sufficient skilled workers makes the issue more challenging and contributes to this mismatch of expectation regarding skill sets of job seekers. The conventional vocational training schemes have not been adequately successful to create skill and its spillover effects across different sectors of the Indian economy. Skill shortage, therefore, has aggravated the existing voluntary, involuntary and frictional unemployment challenge within the economy. Further, divide between organized and unorganized sector in terms of skill requirements has also increased in the Indian economy. It has also increased in terms of employment generation within the Indian economy.

On one side, employment in the factory sector increased from 8.5 million in 2004–05 to 13.4 million in 2011–12. However, the total growth of manufacturing employment has fallen down in India after the mid-2000s especially in small firms complemented by an increased informalisation within the organized manufacturing sector. Such a fall has often been related to the increased use of imported components

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

and automated technologies. Parallelly, public and private investment as a proportion of the GDP has gone down in the recent past leading to a slowing down in the manufacturing employment within India.

Currently, only about 5% of the workforce has marketable skills, as compared to 50% to 60% in some developed countries like Japan. The recent initiative of 'Skill India' under Pradhan Mantri Kaushal Vikas Yojana (PMKVY, 2018) by the central government has the potential and aim to address this challenge. The gravity of this challenge is going to increase within the backdrop of inclusion of 12 million persons who are expected to join the workforce every year (IMACS, 2010). This establishes the need for creating both jobs, skill within the Indian economy to address future developmental goals.

Therefore, with this background, it is important to assess the potential of green growth interventions and strategies in addressing skilled, unskilled job creation in the Indian economy to reduce the organized and unorganized sector divide, fall in job creation for ensuring a long-term development pathway with a centralized focus on income inequality reduction within the economy. However, inequality exists in terms of differential access to various resources (like natural, infrastructure, health, public and private), wealth. This paper will however only ponder about the income inequality dimension. Once the income inequality aspects of the different social classes are addressed it can contribute to the development needs of people of the country by impacting a broad section of the population which includes women, youth, farmers, rural population and slum dwellers that can benefit from such job creation (ILO, 2010, p.3,4). Analysis of the quarterly survey on job creation in India shows a gap of 43.15% (Indian Express, 2014). Therefore, this adds to the seriousness of focusing on job creation for the Indian economy as a policy imperative to address income inequality and development path. Policy focus to create jobs in certain sectors of the economy while the country is growing can address this income inequality.

Green building and renewable energy are some of the key sectors of such green growth intervention other than natural resource management and resource, material and autonomous energy efficiency improvement across sectors of the economy. Creation of skilled jobs in green building and renewable energy sector can also address and strengthen implementation of measures recommended by the subgroup (created in August 2009) of the task force on "Climate Change and Green Jobs". Measures of the subgroup to create green jobs under Mahatma Gandhi National Rural Employment Guarantee Act (MGNREGA) (add reference) through the promotion of mitigation measures like enhancement of renewable energy and energy efficiency interventions within the country (ILO, 2010a) can be strengthened by these green growth-promoting measures.

It will also consolidate and accelerate the addressing of the Article 41 of the Indian Constitution. Article 41 deals with providing a non-justiciable right to work under directive principles of state policy. MGNREGA in 2005 mentioned that the state through its economic capacity can actually convert nonjusticiable rights to work into justiciable ones with a focus on skill development (ILO, 2010b, p.3). Green growth and development intervention creates skilled jobs across rural households of India. Therefore, it has scope, potential to feed into this policy, human rights space embedded within the constitution of India.

Literature Review

Tracing back, the literature (Goulder, 1995, p. 290) indicates the direction of impact of carbon taxes on probable GDP loss, labour supply, productivity, environmental health, factor returns. A recent study by Deschenes (2013), portrays a detailed literature review regarding the impact of green growth policies on employment. However, the study failed to make a definitive conclusion about the likely final impact on

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

employment as the impact can vary across time horizons. While in short run, there may be significant employment loss in carbon-intensive sectors, in the long-run, the net employment effects may be null or even positive due to full mobility, substitutability of factors like labour and capital across sectors. Moreover, the study acknowledges that empirical methods can identify only short-run impacts while for measuring long-run economy-wide effects, models like CGE (Computable General Equilibrium) may be preferable. However, there are few studies (Greenstone, 2002, Popp, 2002, and Walker, 2011) which identified long-run effect through empirical methods. In case of China, Wang et al. (2013) found that CDM projects resulted in approximately 99,000 net direct jobs losses while at the same time it created around 3.08 million indirect jobs. On the other hand, Wang et al. (2009) analyse the economic impact of different climate policies using dynamic CGE in case of China. Similarly, Bohringer et al. (2012), measured the labour market impacts of the green growth policy (feed-in tariff) in case of Canada through CGE model. The paper found that the policy has successfully made a positive impact on employment in the 'green' sectors like renewable energy, however, it also indicated that it may increase unemployment in few areas and reduce overall labour force participation. In case of Korea, the economic and environmental impact of green growth policy has been analysed by Hwang et al. (2012). Applying input-output analysis, the impact of green energy investment has been analysed by Markaki et al. (2013) for the Greek economy. Recently, using a dynamic CGE model, Van Heerden et al. (2016) analyses the economic and environmental effect of a carbon tax in case of South Africa. However, studies of similar nature do not exist in the current context of Indian macroeconomic situation.

It is evident from the literature that India needs to transit from traditional fossil fuel based economy to a clean and renewable energy based economy to achieve inclusive energy security in a gradual way (TERI, 2009). Owing to the rising energy demand, and inadequate renewable energy supply to meet the full energy demand, dependence on coal-based electricity will exist for some time. However, gradually the dependence can be reduced through larger renewable energy capacity addition and generation.

Promotion of the renewable energy sector can be a key measure of the green growth strategies for the country in future. So, in a way it will have two-pronged effects: a) On one hand it will enhance India's energy security and at the same time, b) it can create new jobs for an inclusive development pathway.

Dai et al (2016) highlighted and substantiated this fact through a dynamic CGE model mentioning that investment in the renewable energy sector can generate economic impacts and environmental co-benefits by 2050 without imposing substantial macroeconomic costs. The study shows through a dynamic CGE model that significant green growth interventions can positively impact growth of upstream energy sector, reshape the energy industry and can lead to a reduction in emissions of CO_2 (carbon dioxide) and air pollutants such as NOx, SO_2 along with the potential of generating 4.12 million jobs by 2050 from renewable energy-related upstream industries.

However, existing literature on India does not have a mention of the impact of a green growth and development policy or intervention on the degree, level of rural and urban household skilled and unskilled job creation that can have developmental implications for the country and states of India. This paper, therefore, attempts to fill up that gap in the literature through next sections. It starts with a set of research questions, followed by a modelling framework and final findings, policy directions derived from the modelling analysis and results.

RESEARCH QUESTIONS

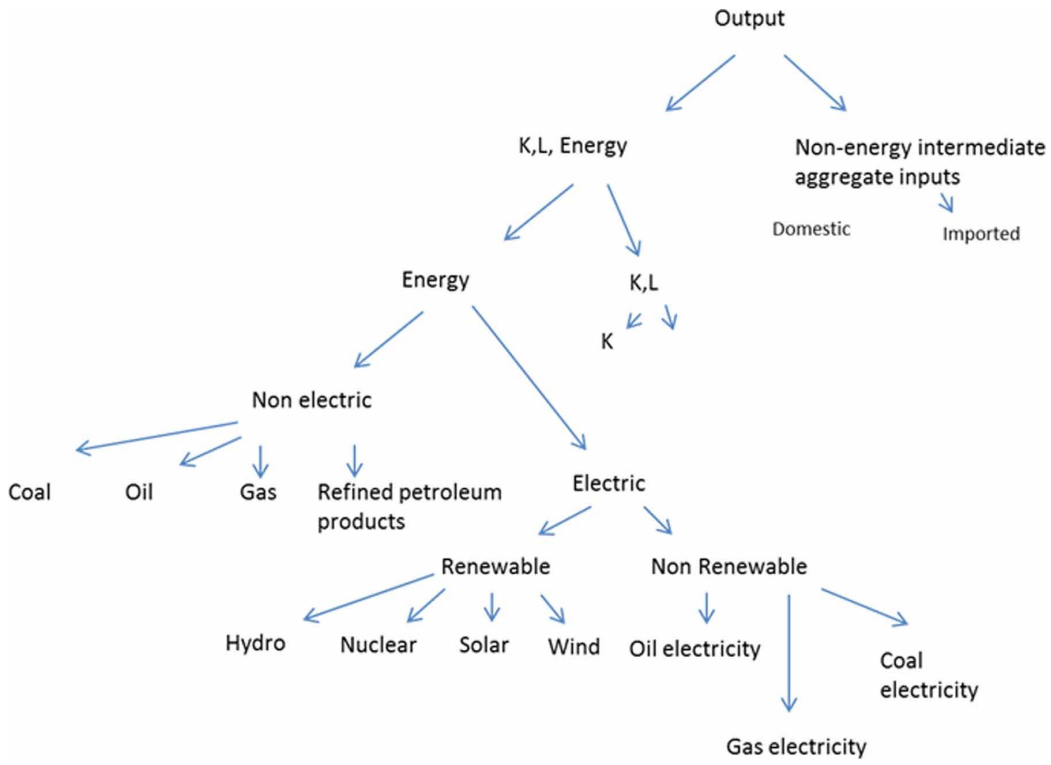
The paper deals with the following research questions:

1. What can or might be the impact of interventions like an increase in investment and economic activity in the renewable energy and green building sector on job creation across rural and urban household income classes?
2. What can be the policy interventions through which potential of this job creation can be realized in the country?

Above research questions are explored through the following methodological processes and model framework. During the course of the study, the 'green sector' has been defined as a sector that uses renewables and produces output in a resource and energy efficient way.

MODEL FRAMEWORK

Model Structure



The model framework comprises of a Social Accounting Matrix (SAM) based national level dynamic recursive Computable General Equilibrium (CGE) model. A social accounting matrix accounts for the flow of goods and services within all the sectors of the economy and also within the rural and urban households. In this case, the flow is accounted by means of the value of money which is flowing from one sector to the other including the rural and urban households.

A recursive dynamic CGE model is constructed in this case. This is because, in the policy parlance, perfect foresight approach of an intertemporal, rational expectation based CGE model might not work. Changes of policy interventions are realized in an economy with a lag and moreover, there is always an interactive adaptation of policy measures by agents (which can be the sector players or household representatives or any other agent of a macroeconomy) within an economy. A perfect foresight based dynamic CGE model will not take into account this behavioural nature of agents in an economy. Therefore, a recursive dynamic CGE model is chosen. Moreover, recursive nature of the model adjusts the response of every agent within the economy in the next time period by taking cognizance of the policy signals coming out in an earlier period. As policy implementation works with lagged effects within an economy, this kind of recursive model is being built. Agents of the economy adjust to create an equilibrium between the supply and demand side by means of changes in factor prices which impact the supply and demand of goods and services within the economy.

The SAM constructed for our dynamic CGE model comprises of sectors like green building, biomass, solar, hydro, wind, nuclear. 43 sectors have been included in the national level social accounting matrix (SAM). It also includes sectors like paddy, wheat, cereals, cash crops, industry, services spanning across primary, secondary and tertiary segments of the Indian economy using national accounts statistics. In order to construct this, input-output table of 2007–08 released by Ministry of Statistics and Programme Implementation (MOSPI) has been used. The core nested structure of the model is explained in Figure 1.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1.

DATA INPUTS IN THE MODEL

Model Data

This section highlights how the data for every sector of the model is integrated into the building up process of the recursive dynamic CGE model. Agriculture sector data of the model has been constructed by applying latest National Account Statistics, Economic Survey data. Data regarding the fossil fuels and petroleum products have been obtained from the input-output table of 2007 - 08. The latest input-output table of 2011 has some issues with base shifting owing to which the earlier input-output table of 2007 – 08 has been considered. Further, this data has been validated with Ministry of Petroleum and Natural Gas reports.

Green building sector data has been built up for the CGE model by applying information from sources like Green Rating for Integrated Habitat Assessment (GRIHA), TERI, Central Public Works Department (CPWD), Agence Française de Développement (AFD) reports and building audit reports of TERI. For household data, the decile MPCE (marginal per capita expenditure) class data from the latest National Sample Survey (NSS) round (68th round) was considered. Further, from decile class, five rural and urban classes were formed using NSS round (68th round). Capital formation data was available from National Accounts Statistics. Labour data for different sectors have been collected from Annual Survey of Industries (ASI), the government of India publication for the year 2007-08. Total labour value figures in terms of emoluments for most sectors were collected from ASI.

Table 1. Interconnection between savings, investment, employment, and sectoral outputs

A 1% increase in employment	A 1.2% increase in savings which highlights that the savings propensity of households in India can be elastic with green growth interventions	Changes in sectoral outputs of Indian economy (will emerge from CGE based endogenous model using the changes in savings as a scenario)
A 1% increase in savings	A .99% increase in investment which indicates that not all of the savings of households get translated to investment owing to different gestation lags	Changes in sectoral outputs of Indian economy (will emerge from CGE based endogenous model using the changes in investment as a scenario)
A 1% increase in employment	A 1.69% increase in investment which indicates the potential of investment and capital formation from green growth and development led employment generation	Changes in sectoral outputs of Indian economy (will emerge from CGE based endogenous model using the changes in investment as a scenario)

Source: Macroeconomic Model Estimates, RBI Statistics.
Note: Savings measured by household financial savings, investment measured by gross domestic capital formation.

Labour value for remaining sectors has been calculated based on sectoral relationship. The value of labour has been created by estimating the proportion of labour employed in a particular sector. Further, the labour wages (indexed by inflationary adjustments) have been considered to get a value of the labour in a particular sector. Moreover, this value is further distributed across different sectors of the economy by considering their composition and contribution in the particular sector.

For instance, labour value of construction sector has been distributed among green, non-green construction sectors based on their composition in total construction. Within labour, a division between skilled, unskilled labour was done. In order to do that, sector-specific skill – unskilled labour ratio was worked out. Further, employment levels of sectors of the economy were available from National Accounts Statistics. Using skilled – unskilled ratio, the presence of skilled and unskilled labour in each sector was obtained.

Interconnection Between Savings, Investment, Employment, and Sectoral Outputs

Every CGE model works on a closure rule. In our recursive dynamic model, the closure rule is defined by a savings and investment equilibrium condition within the macroeconomy of India. Therefore, to maintain equilibrium, whenever, savings will change, investments will change which will thereafter impact the factor prices finally leading to a variation in sectoral employment and outputs. The interconnections between savings, investment, employment and sectoral outputs are highlighted in Table 1.

In order to introduce dynamism (recursive) into scenario-based CGE model, the saving-investment closure rule was brought in the model. Savings and Investments in an economy create a multiplier with a lagged effect and hence bring in a change with a recursive effect within the households and sectors of the economy.

The total public, government and household savings have been proxied for savings. The gross domestic fixed capital formation has been proxied as an indicator of investment variable.

The interconnection between savings, investment, employment and sectoral outputs of the recursive dynamic CGE model is built up through a time series-based error-corrected, co-integration method based econometric analysis. This econometric estimation leads to the formation of elasticity of savings, investment in employees These elasticities are then further plugged into the model as scenarios to understand

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

the economy-wide impacts under a savings and investment closure rule. The interconnected nature of impacts on selected macroeconomic variables is highlighted in Table 1.

This nature of response between the savings and investment was also done outside the model to understand and calibrate the closure rule of the model and to capture the macrostructural changes that can happen within the economy due to causal changes in savings and investments. Investments can change more exogenously: however, it can then lead to endogenous household saving changes. For instance, government programmes and policies related to attainment of 175 GW renewable energy target can lead to several exogenous investments in the economy. This can then bring about endogenous changes in household savings to maintain a savings and investment equilibrium closure rule.

Given this broader macroeconomic context, the next section highlights the impact of green growth and development interventions in the renewable energy and green building sector on skilled, unskilled job creation arising from the CGE model in order to create a relevance to the future national policy discourse on green growth and development.

CGE RESULTS AND DISCUSSION

The dynamic CGE analysis suggests that an increase in an economic activity within the solar sector can have a potential to lead to a *3.2% increase* in the national level GDP. This posits a probable high potential of the solar sector to create economic multipliers across the economy owing to green growth interventions and strategies. Further, a similar increase in economic activity through investments in biomass, wind sector can lead to a 0.4% and 0.1% increase in national level GDP in terms of the economic output and activities. The rise in GDP will happen due to an increase in direct and indirect demands across sectors of the economy owing to a potential rise in the investment which will generate new demand for goods and services in the economy. The latest policy push of the government in the promotion of renewable energy sector viz. solar and wind also bears evidence to that fact.

To illustrate this narrative, as per latest government release (MNRE, 2017), India became fourth and sixth largest country in terms of wind and solar installed capacity respectively. Moreover, within last three and a half years, about 27 GW capacity additions took place in India under grid-connected renewable power. Almost half of it (12.87 GW) was contributed by Solar followed by wind energy (11.7 GW). In addition to that, as reported by the government of India, in the third quarter of 2017, while coal-based power capacity was shrunken (due to retire of some aging thermal plants) by 1. 1 GW, there was a growth of 1.6 GW in solar power capacity (Clean Technica, 2017a). In line with this, recently, the Finance Minister Arun Jaitley has highlighted an allocation of approximately US $790 million (INR 5,020 crore) for the expansion of various renewable energy technologies for the financial year 2018-19 (Sustainability Outlook, 2018). This shows an increase in allocation in comparison to the earlier years.

Moreover, Ministry of New and Renewable Energy (MNRE) is expected to commission 15.62 GW of new renewable energy capacity in 2018-19. The targeted capacity addition is 7.3% larger than the capacity addition target set for 2017-18. There is a target of the addition of 11 GW of solar power capacity, up from nine GW in 2017-18 (Clean Technica, nd). This reflects a clear indication of government initiative of Green India through an increase in investment and economic activity in renewable sector specifically in the solar sector. This investment push in the renewable energy sector viz. solar and wind is also meant for generating demand for new goods and services. Therefore, this is expected to create

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

a social benefit of employment generation and an environmental benefit of a reduction in emissions in the medium and long-term.

At the national level, investments in the green sector (like renewable energy) can also have a potential to increase the factor returns (a 20% increase in investment in the green sector of renewable energy can lead to a 0.2% increase in the factor returns) and can lead to skilled, unskilled job creation within households across different income classes. For that, rural (five for rural) and urban (five for urban) households of India have been divided into five different classes based on monthly per capita expenditure data of households emerging from the 68th round of NSSO (National Sample Survey Organisation) data.

A new activity generation through investments in the green building sector might be able to create seven skilled and 14 unskilled jobs in the highest rural household classes for per 100 households. Skilled and unskilled job creation is four and eight for the highest urban household class for per 100 households measured in terms of monthly per capita expenditure.

Green building is a futuristic/upcoming economic activity, but it is very much a specialized, specific material intensive industry. Thus, in the initial stage, there is a lesser requirement for skilled personnel compared to the unskilled job requirement. However, as the industry matures the chance, the potential for more and more skill (as well as unskilled) personnel might increase. Moreover, an investment in the green building sector has a spillover effect in terms of enhancing its job creation potential and impact within the rural household classes. It not only enables new skilled and unskilled employment in the urban sector but it also generates higher unskilled job creation per 100 households for rural household classes. This also hints towards some possible migration from rural to urban areas. This can happen due to the creation of unskilled jobs through investments in green building sector (assuming that the green building largely comes up in urban areas of the country). Broadly, an investment in all green sectors (as identified in the national level CGE model) leads to 174 unskilled and 87 jobs for highest rural income class (r5) and 128 unskilled and 32 skilled jobs for highest urban income class (u5). Clearly, green growth interventions have a larger spillover effect in terms of job creation for rural households in comparison to urban households. This is happening due to a skill shortage in rural India in terms of the identified green sectors. Therefore, a skill generation in the rural sector has larger implications for the rural households in comparison to the urban sector. Further, the rural-urban migration complemented by a large scale informalisation in the organized sector of the urban economy is not allowing the trickle effect of new skill generation to be percolated to the same extent into the urban households in comparison to the rural sector of the economy. These two factors are going hand in hand to enable a larger spillover effect in rural India. Essentially, skill being more scarce in rural India due to these factors has a higher investment return in the rural sector in comparison to the urban sector. The returns to investment in skill in rural India are higher due to its scarcity enabled by large-scale migration, organized and unorganized sector divide and a large-scale unorganised segment in the urban sector of India. These narratives also need to be integrated into the Skill India Mission of India for its larger success.

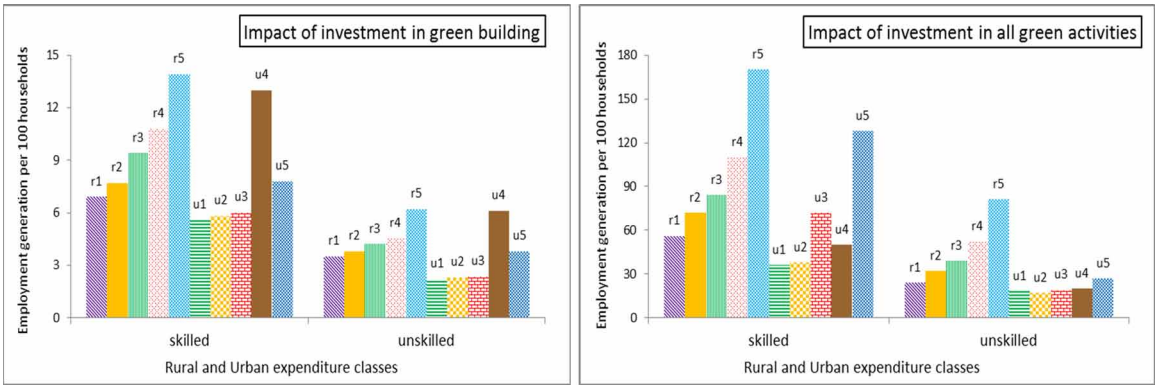
Additionally, the degree of job creation goes up as one moves up in the income class ladder within the rural and urban households. These preliminary results also hint towards the inter and intrahousehold growing inequality debates within the country.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Specific Results

Some of the results showing household level skilled, unskilled job generation owing to green growth and development interventions in the agriculture, renewable energy provision, industry, green building sector for a reference scenario baseline case (in 2015) is indicated in Figure 2.

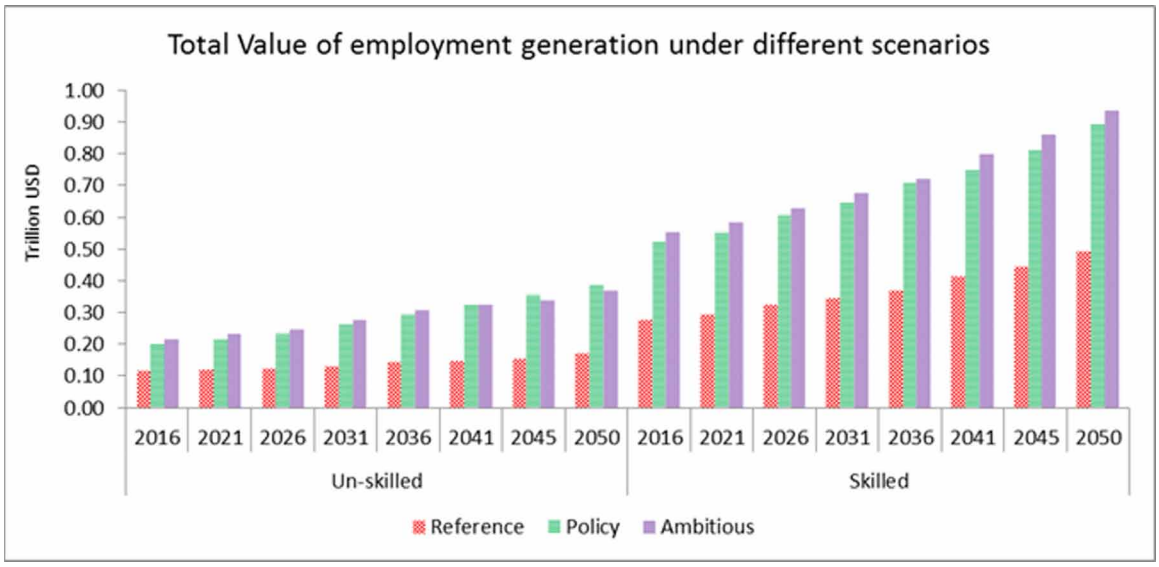
Over the time horizon, the level of skilled and unskilled employment generation is shown by the Figure 3. To project the future level of skilled and unskilled employment generation, three scenarios are constructed.



These scenarios include:

1. Reference (A scenario where business as usual policy measures are continuing which means that the declared renewable energy and green building implementation targets are in mind for implementation in the long term),
2. Policy (Green growth intervention related policies (like Skill India Mission, Renewable Energy Promotion Targets in sectors like solar, hydro, biomass, wind, Energy Efficiency and Natural Resource Management Policies) are implemented along with the associated employment generation schemes), and
3. Ambitious scenario (Government is a little more optimistic and active in terms of implementing the green growth-related interventions and its associated skilled and unskilled employment generation schemes).

This level of employment generation along the above-mentioned path (as shown in Figure 3) through interventions in renewable energy, green building, energy efficiency and natural resource management domains can have a significant contribution to the development of people and can impact the economic and social domains of sustainability.



Having outlined the above potential, the next section will discuss the specific sector of green building and its possible contribution to the employment generation opportunities within the Indian economy. This is because; close to 30% of the total primary energy consumption in India is catering to the building sector. With a rise in future economic growth and policies to promote the service sector driven economic

Figure 3. Scenario-wise skilled and unskilled employment generation in India (Source: Model Estimates)

growth, the energy consumption is expected to increase in the building sector. The next section further elucidates on this sector and its implications on employment while the service sector of the Indian economy grows in future. This is expected to happen by means of reducing energy consumption in green buildings while their demand increases in future due to a rise in overall economic and service sector growth.

Green Building and Employment Opportunities

The building construction industry at present contributes about 10% of Indian GDP and is expanding rapidly at over 9% per year spurred largely by the strong growth in the services sector (Jindal, 2016). This fast pace growth rate is resulting in rapid urbanization, high demand for related infrastructure and thus an increasing demand for energy.

In 2020 almost 500 Million people will be living in Urban India. It is expected that 4127 Million m^2 of real estate space (which includes residential, retail, offices, hotels, health care and education sectors) will be built from 2012 to 2020 (Jindal, 2016).

Electricity consumption by buildings has grown at an average growth rate of 9% in the last 10 years (2001-11). Assuming the same growth, it will lead to more than doubling of electricity consumption in 2019-20 compared to 2010-11. The residential sector constitutes 22% of energy consumption in the building sector and commercial sector constitutes 8% of energy consumption in building sector (Jindal, 2016). As per the same study, 25% of electricity consumption in a commercial building is contributed by lighting while the 55% is contributed by heating, ventilation, and air conditioning (HVAC). While existing (2012 estimate) electricity savings in a commercial building is 8,700 GWH (7.4 million tonnes of CO_2), there is the potential of 90,000 GWH in 2021 from upcoming commercial buildings.

The above study also indicates that while the use of 'efficient glass and roof 'can save approx. 5% of energy, 'energy efficient lighting system' can save about 10% energy. Use of 'energy efficient chillers, pumps and fans' can save up to 15-20% of energy in the commercial building. Combining all potential

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

saving sources, the existing energy saving potential is 67,000 MWH/year assuming that there are 100% energy efficient commercial buildings. This saved energy is sufficient to electrify more than 12,000 rural houses.

Green buildings have various elements like insulation on the wall, roof, double glazed windows, lighting controls and high-performance air conditioning system for ensuring the low energy consumption in green buildings. Although market of energy efficient products is still immature in India, in the last few years there has been a noticeable improvement in the market in terms of availability of products. Energy efficient electrical appliances/equipment of many leading companies/ brands are now available in the market. With the rising demand for insulation materials, high-performance glass, heat reflective paints, energy efficient masonry units, etc., the number of manufacturers and suppliers of these materials is also slowly increasing. As per the information provided by some of the leading manufacturers the sales for Rockwool, polyurethane (insulation materials) has been growing at an average 18% annually and sales of Autoclaved Aerated Concrete Block has been growing at an average 15% annually, in the last five years.

However, there is still a huge market potential for energy efficient products, equipment and technologies, in India. As the green building movement in India will gain momentum, there will be a rise in the construction of green buildings resulting in an increase in the demand for energy efficient products in India. Table 2 highlights a potential pattern of this increase in demand for future.

The green building sector, therefore, has a potential for creating employment opportunities in the sector by means of generating demand for a new set of goods and services. Installation and commissioning of these appliances, devices in the green buildings will require skilled and unskilled labour which in a way is expected to generate further employment in future.

Therefore, a promotion of the green building sector, can not only lead to skilled and unskilled job creation: it can also lead to energy savings. Through this promotion, economic, environmental and social domains of sustainability can, therefore, be addressed in the long run and therefore green building promotion can also be one of the key measures of green growth and development strategies within the country. Further, once the income of the people rises and trickle down across the households, it can lead to a rise in the literacy rates and other developmental indicators (Table 2).

Along with the promotion of green building, green growth and developmental interventions also include measures like the promotion of natural resource management in the agriculture sectors, autonomous energy efficiency improvement. These measures can impact developmental indicators for different time frames (2011, 2020, 2030) by different degrees.

To capture those impacts, three scenarios viz. reference, policy and ambitious are constructed to understand the different degree of impact. A back of the envelope developmental indicator function is

Table 2. Estimated demand for energy efficient building materials

	2011 (Observed – Actual Data)	2020 (Projected Potential)	2030 (Projected Potential)
Annual demand for roof insulation (Million sqm)	3.3	9.4	22.2
Annual demand for wall insulation (Million sqm)	2.8	4.6	7.1
Annual demand for high-performance glass (Million sqm)	8.5	13.8	21.2
Annual demand for T-5 (Million units)	2.16	5.94	19.44
Annual demand for LED (Million units)	1.74	4.81	15.74

Source: Authors' estimates.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

constructed which essentially captures the changes in developmental indicators for different varying levels of income which are created and generated within the economy.

Further, such scenario specific results and directions for future policy making are explained in Table 3. As indicated in Table 3, green growth and development measures through agriculture and natural resource management techniques, structural changes within industry and infrastructure sector bring about a change in the poverty by uplifting people above the poverty line. This happens because the income generated from green growth interventions and new investments get distributed across the rural households through effective policies and institutional mechanisms. Inequality within the rural households can then go down owing to that. Once the inequality levels go down, it is expected, that a rise in income, creates a rise in the aspiration of households to get educated. However, this also has to be backed by the availability of right primary schools, teachers at the local level and a mechanism to ensure that people attend schools, learn and get educated. With a rise in education, the awareness of people regarding health and better quality of life increases. This thereby positively impacts the health indicators like infant mortality rates.

From a modeling perspective, the increase in the income from green growth interventions in agriculture, renewable energy, industry, buildings sector, is fed into an interphase model (which is the back of the envelope model) as an input with development indicators as an outcome variable. In the interphase model, outputs of the CGE model (like household level income, skilled and unskilled job creation over time) feed in as an input. This, therefore, gives rise to a change in the development indicators as an output from the interphase model after considering the CGE model outputs as input variables over time. The theoretical context and hypothesis behind this are that an inclusive, sustainable, green growth is expected to trickle down to the lower classes of the society through strong institutional support structures and mechanisms and can reduce the level of inequality across different layers of the society. So, this hypothesis is assumed to be true and then tested through a scenario specific analysis in our case. However, in a real situation, policy and institutional failures can hinder this trickling down and can impinge upon an inclusive developmental path arising from a sustainable, green growth pathway through reduction of inequality across the social layers.

Given, this background context, Table 3 highlights that a reduction in the inequality level raises aspirations of people belonging to the marginal classes of rural and urban households and they start

Table 3. Scenario-wise impact of green growth and development measures on developmental indicators

Indicator	Units	Reference Scenario	Policy Scenario		Ambitious Scenario		Latest Figure
		2007	2020	2030	2020	2030	2015
Literacy rate (total)	% of people ages 15 and above	62.75	66.40	70.65	71.82	78.16	71.96
Literacy rate (adult male)	% of people ages 15 and above	75.19	76.33	80.29	80.7	86.85	80.94
Literacy rate (adult female)	% of people ages 15 and above	50.82	55.91	61.5	57.43	64.9	62.98

striving for better education which gets reflected in the improved literacy rates within male and female for different scenarios over the time frame - 2020 and 2030.

The latest figures for literacy rates indicate that India has already achieved the projection for the ambitious scenario by 2015, five years before the targeted time. On the other hand, latest figure on IMR indicates that there is huge scope to achieve even the ambitious scenario. Finally, the latest poverty figure may be high in absolute term, but India has performed well in terms of percentage of poverty eradication in the last few decades. All the above figures indicate that 'ambitious' scenario may be achieved with proper execution of suitable policy instruments. On the other hand, job creation (both skilled and unskilled) in 2015 has been 135 thousand (Orfonline, 2018). This needs urgent attention of policymakers.

The dynamic CGE modeling analysis conducted indicates that job creation from green buildings has the potential to generate a savings multiplier for rural and urban households. As the economy grows with a focus on green industries, there would be demand for sector-specific skilled jobs which in turn would enhance wages of related employees and lead to more savings formation in net terms (considering some loss from potential non-green sector). All these, in turn, would have an overall impact on the economy and developmental indicators such as income, employment, improved infrastructure, and clean energy. These will have positive implications for the economic, environmental and social domains of sustainability.

All these findings provide a long-term direction to the country's macro-planning and green growth and development roadmap by addressing the economic, environmental and social domains of sustainability through a progressive transformation from agriculture-based economy towards green, ecologically and socially sustainable, energy efficient industry and service sector.

Green growth and development interventions are expected to create more employment for people from the agriculture sector, raise their skill levels and generate more skilled and unskilled jobs for them in the industry and service sector (which includes the construction sector) of the growing economy. This in a way in the long term will create larger economic and social sustainability which can be feed into the broader policy discourse of green job creation as explained in the next section of this paper.

CONCLUSION AND WAY FORWARD

The results emerging from the modeling analysis feeds into the policy discourse of green job creation that has been formulated by United Nations Environment Programme (UNEP), International Labour Organization (ILO, 2010a, ILO, 2012), International Organization of Employers (IOE), International Trade Union Confederation (ITUC) in 2007.

Results of the model indicate the potential of income, skilled and unskilled employment generation from green growth interventions in the renewable energy and green building sector. The solar sector has the potential of creating economic multipliers. Green buildings can also lead to the creation of skilled and unskilled employment generation. This in a way adds to the policy discourse and context of green jobs. In this regard, one needs to go back a little to the recent past and ponder upon the policy interventions made in the area of – "Climate Change and Green Jobs". The government of India had a task force established on "Climate Change and Green Jobs" in the recent past.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

The Government of India task force on "Climate Change and Green Jobs" created a subgroup in August 2009, which emphasized on the need to create green jobs under MGNREGA through the promotion of mitigation measures like enhancement of renewable energy and energy efficiency interventions within the country (ILO, 2010 a, b). The national skill development corporation focuses, emphasizes the development of resident skill for employment generation in next 10 years in India (NSDC, 2010). In order to generate employment and skills, the council indicates to focus on sectors receiving the support of state and central government. It also indicates that skill and jobs in the area of services related to plumbing, repair mechanics and electrician services will grow more in future with a rise in the renewable energy and green building sector of India. A green growth intervention in sectors like green building and the solar sector has the scope of generating specific skill-based livelihoods. A recent study (Tyagi 2017) has indicated that by 2017, green employment creation by renewable energy (RE) sector has achieved the predicted target (approx. 1.4 Million) set for 2020 by MNRE and CII. Another recent study (by IREDA, Deloitte, and INAE) has indicated that by 2022, more than 1.1 million skilled employees are required to achieve a solar target of 100 GW. However, as per CEEW and NRDC, approximately one million full-time employment (FTE) will be generated by 2022.

This will then contribute to the National Skills Development Mission and its task of achieving a targeted 500 million skilled employment generation by 2022. This humongous target may not be achieved but all the above statistics indicate a positive potential of employment generation by green growth and development strategies in Indian context in the long run. Even a minuscule achievement of this target through green growth interventions like the promotion of green buildings will pave a long way in addressing the sustainability goals of the country in the long run. In order to achieve the long-term sustainability goals of a developing country marked with distinct contrasts and inequality, this targeted implementation and achievement will be imperative for future to create a society with equal opportunities for every section of the social milieu in India. This can only happen when the social, economic and environmental goals and domains of sustainability are balanced and promoted at the same time.

ACKNOWLEDGMENT

The authors will like to thank Ms. Shailly Kedia for her research guidance, research and editorial content and directions, Dr. Prodipto Ghosh, Dr. Sanjib Pohit, for CGE model building-related guidance, mentorship and Mr. Nitya Nanda for a detailed review of the paper. The authors also express their gratitude to Mr. Tarun Garg for the research guidance provided with respect to the building sector. All views expressed in the paper are personal and the authors are solely responsible for any inadvertent errors in the paper. Authors will also like to acknowledge the support of Global Green Growth Institute in conducting this research.

Chapter 18
Contextual Relationship Among 3 C's and Innovative Green Procurement Practices Using ISM and Its Validation Using MICMAC Analysis

Surajit Bag
Tega Industries South Africy Pty. Ltd., South Africa

ABSTRACT

This paper argues for the use of Interpretive Structural Modeling in building a theory of innovative green procurement practices. Earlier researchers have conducted vast studies related to the hard dimensions of green procurement practices. However, there is a dearth of studies focusing particularly on the soft dimensions of green procurement practices. To address the gap in existing literature, this study first systematically reviews the green procurement literature. Secondly, these dimensions were refined through expert interviews from the manufacturing sector. Thirdly, it illustrates the use of ISM method to find the contextual relationship of elements. The ISM model was finally validated using MICMAC analysis. The current study is unique from two perspectives. Firstly, Resource dependence theory was used as a theoretical lens to study the links between elements. Secondly, it integrated innovation and green procurement practices for the purpose of investigation. The findings show strong associations between 3C's (Collaboration, Coordination, and Cooperation) and innovative green procurement practices. The paper concludes with managerial implications and directions for future research.

1. INTRODUCTION

Resource Dependence Theory (RDT) suggests that member firms within the supply chain should coordinate and collaborate to achieve superior performance. Under RDT the most important assumption is that firms cannot be fully independent with regards to strategically critical resources for survival (Sarkis et al., 2011).

Under Green procurement practices, the eco-design of products and materials recovery is outstanding organizational resources requiring partnership with key suppliers to extract performance benefits

DOI: 10.4018/978-1-5225-7915-1.ch018

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

(Zhu et al., 2005). From the RDT viewpoint, customer and supplier relationships are important links for firms to reduce the uncertainty surrounding their operating environment (Carter and Rogers, 2008).

While establishing theoretical foundations for three Cs' and innovative green procurement practices, the following research question is proposed: Do Collaboration, Coordination, and Cooperation create value in improving innovative green procurement practices of the firm?

There are few brilliant studies available in the area of supplier relationship management, supplier integration, and collaboration and has been discussed further to understand the breadth and depth of study available in the area of sustainable procurement.

Bag (2016a) studied the interrelationship between green strategy, supplier relationship management and supply chain performance. Important variables such as supplier integration, ethics, trust, culture and flexibility have been considered in the study to develop supplier relationship model. Green purchasing positively influences flexible systems which in turn reduces operational cost. Bag (2016b) also argued that flexible procurement systems are key to supply chain sustainability. In that study, the important variables considered were supplier integration, supplier responsiveness, and strategic sourcing. The findings suggest that manufacturing organizations having a strong sourcing policy successfully integrate suppliers. This helps in a greater level of flexibility and develops more innovative products successfully. It was also suggested that trust and collaborative efforts between buyers and suppliers improve delivery and product quality, which enhance customer satisfaction and considered as a move towards sustainability.

In another recent study, where Bag and Anand (2016) examined the importance of innovation leadership in cultivating sustainable supply chain practices of an organization. One interesting finding from the study is that empowering junior managers and creating innovation culture among employees facilitate green practices.

The above studies are some of the recent exceptional work in the area of sustainable practices where different links have been examined. However, the missing link in all the past studies is the role of 3 Cs' in influencing innovative green procurement practices.

Firms mostly emphasis on innovation for creating eco-friendly designs, reducing the level of wastage, and value addition. Firms apply different tools and techniques to measure the performance of green practices which generally differ from the conventional practices.

The gaps which emerged from the review of the literature has further motivated to pursue the current study. It will be interesting to understand the underlying mechanics and interrelationships of three Cs' and innovative green procurement practices.

The manuscript has been organized as follows. First theoretical background and research framework are presented. Then research objective and methodology are discussed, and analysis and findings are explained. Finally, the manuscript concludes with a discussion of managerial implications, limitations and suggested future research.

2. LITERATURE REVIEW

A literature review is an important part of any research study. Traditional review approach mostly lacks thoroughness, quality, and information which ultimately make less meaningful to supply chain practitioners. Here the author attempts to use the process of systematic review for exploring the subject and understanding the links. The systematic literature review (SLR) process creates transparency and assists in developing the research question. Earlier SLR was mainly used by researchers in the area of medical sciences, but recently SLR has gained popularity in the area of management sciences. Some of

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

the recently published papers which adopted SLR techniques are (Chakrabarty & Dubey, 2014; Bag & Anand, 2014 a; 2014b; Dubey and Ali, 2014; Dubey & Gunasekaran, 2014a, b; Srivastava & Dubey, 2014). The steps of a systematic review of literature followed in the present study have been adopted based on the guidelines of Tranfield et al. (2003).

Stage 1: Planning the review

In this stage, the researcher conduct studies to assess the breadth and depth of the existing literature and to draw up the boundaries of the topic. The current review focuses on articles published in reputed peer review journals. To set up a time span, a starting position was set at 1990. Library database (EBSCO) was used through a keyword search using keywords "Resource Dependence theory", "Green Procurement", "Collaboration" "Cooperation" and "Coordination". As the literature is interlinked when one thread is picked up, the others were also easy to identify. Finally, only the important selected papers relevant for the present study has been considered for the current study. The list of citations is presented at the end of the study.

Phase 0: Identification the need for a review

The objective of conducting the review is to identify the research gaps from published literature and further develop the problem statement, research questions and research objective for the present research. There are studies available in the area of supplier relationship management, supplier integration, and collaboration, but none of the studies address the importance of 3 Cs' in influencing innovative green procurement practices. Let us understand particularly why the term "innovative green procurement practices" has been used for the study; the underlying reason is that any firm practicing green practices basically performs out of the box thinking; i.e., innovation. Firms are innovating new ways to come out with eco-friendly designs, reduce wastage, reclaim, add value and also save costs. Firms use different tools and techniques to measure performance under green practices which differ from the traditional or standard practices. If we consider any top firm practicing sustainable practices such as Apple, Dell, Ford and Toyota, we can see the approaches of individual firms are different from each other, although the ultimate objective is to save natural resources and reduce carbon footprint. Innovation and green practices are intertwined, and no common, or standard practice can yield the same result to the firm. The central concept is to innovate and come out with better ideas for sustainability. In this study, Resource Dependence Theory is used as a theoretical lens to disseminate further and enhance the existing knowledge base. It is interesting to note that resource scarcity can generate huge risks both internally and externally. Therefore, the author felt the need to identify the interrelationships among innovative green practices and the internal (internal cooperation, internal coordination) and external (supplier collaboration) dimensions. The present study will generate rich insight mainly for the procurement professionals practicing green practices or who are thinking of commencing such practices. The findings will help in developing practical tools for green performance measurement.

Phase 1: Preparation of a proposal for review

Researchers have carried out a detailed review of research articles published in *IJPM, IJPR, IJPE, JOM, AMR, SMR* and other reputed journals to develop building blocks for the present study.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Phase 2: Development of a research protocol

In this step the conceptual discussion of the research problem and a statement of the problems' significance are presented.

The starting point is the innovative green procurement practices. Since natural resources are widely used, there are chances of resources becoming scarce and expensive to acquire. In that scenario, firms need to innovative for sourcing alternate resources. Here firms deviate from the standard practices and adopts the best practices which enhance the brand image in the business world. As per RDT, scarcity can occur internally or externally (Leblebici et al., 1991). When firms have unskilled manpower with poor cooperation and without any coordination may result in resource scarcity. Externally if the firm does not collaborate with customers and suppliers, then the firm might run out of resources and which generally becomes costlier to acquire at the last moment. Also the growth in demand for the eco-designed product increase the demand for the resource. In the case of scarcity of the input resource the firm cannot manufacture the product. Competitive pressures also restrict firms in raising the prices of final products. The internal and external forces compound together and act on the firm. This is a burning problem for the firm and often results in unsuccessful green procurement practices and financial losses.

As per the NSF (2010) study, existing green initiatives have mainly focused on investment in new technology and developing energy saving equipment and facilities. Such initiatives are valuable, but they tend to ignore the green production economics, interaction, and coordination where the flow of products to final customers engages multiple firms in long and complex supply chains. Therefore, the present study is necessary to bring out the richness of 3 C' and its importance in enhancing innovating green procurement practices in today's complex supply chain structure operating under uncertainty.

Stage 2: Conducting a review

In this turbulent business scenario, every supply chain practitioner is struggling to mitigate the risks. The level of uncertainty is more due to long and complex supply chains (Applequist et al., 2000; Juttner et al., 2003 and Kleindorfer and Saad, 2005). In this scenario, every supply chain practitioner spends their time majorly in aligning supply chain strategies with product uncertainties (Lee, 2002). The problem has aggravated with tight competition in the market and strict government regulations. This has raised the question of firm's sustainability and created difficulty to stay in the business (Walker, 2008; Wagner and Bode, 2008). To change the game and remain in business, supply chain practitioners innovated and shifted the focus towards triple bottom line concept and focusing on environmental, social and economic aspects of business sustainability (Carter and Rogers, 2008; Dubey & Bag, 2014; Dubey et al., 2015). Further, they adopted green procurement practices where firms emphasize the reduction of wastage; material substitution through environmental sourcing of raw materials and reduce usage of hazardous materials. Basically, green procurement focuses on life cycle thinking whereas the traditional procurement system used to focus only on costs (Kaiser et al., 2001). In response to the internal and external changes firms have instituted socially responsible buying process (Cater et al., 1998). Currently, green procurement is considered as a noble approach to improving the performance of firms (Hamner & del Rosario 1998; Dubey et al., 2013; Dubey et al., 2014a). Green procurement is controlled by the internal and external forces and the balance between the two forces is necessary for successful green procurement practices. The internal forces are the forces within the firm, and the external forces are basically supplier and customer pressures. From the internal viewpoint the team coordination and cross-functional cooperation

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

among members are necessary for running any projects successfully (Pinto and Pinto, 1990). The tasks and roles embedded in driving innovative green practices as well as rules and procedures to coordinate the project needs the attention of members (Tjosvold, 1988; Hoegl et al., 2004). It is the responsibility of top management to cultivate effective communication, cooperation and trust to achieve rapid milestones in green procurement (Kerzner, 2013).

Also, it is essential to understand the external forces such as supplier pressures and customer pressures. The strict regulations drive firm to form an alliance with suppliers and integrating suppliers into environmental management practices. Green procurement demands environmentally conscious suppliers who have implemented ISO 14000. This necessitates firms in developing environmental policy and environmental supplier evaluation criteria (Green et al., 1996; Green et al., 1998; Chen, 2005; Zhu et al., 2005; Zhu & Sarkis, 2006; Zhu & Sarkis, 2007; ElTayeb et al., 2010; Dubey et al., 2013). Supplier collaboration is an important component of green procurement. Collaborative strategies facilitate closer cooperation between buyer and supplier firms, provides flexibility in handling projects (Bowen et al., 2001). It was found that firms achieved the greatest success in innovative green practices when suppliers are physically involved with buyer's plant and also when the buyer spend maximum time in the supplier's plant (Simpson and Power, 2005). In some of the earlier studies, researchers have used the term innovative practices under green procurement practices such as innovative packaging based on customers' willingness to buy biodegradable packages and they even discussed on green firms being innovative in their environmental practices and innovative approaches in managing waste at source. There is evidence in certain papers where discussions have been done on ways to bring innovative green products in the market (Green et al., 1996; Min and Galle., 1997; Min and Galle., 2001).

The research gaps which evolved from the review of literature have been presented to further develop the research objectives for the present study.

The first gap is that existing studies mainly focused on identifying green procurement drivers and barriers. There is a lack of studies considering the soft dimensions of green procurement such as collaboration, coordination, and cooperation.

Although existing studies discussed innovative approaches and its importance for environmental practices there is hardly any study where scholars have argued that innovation and green procurement are intertwined. This can be considered as the second research gap.

Thirdly, no existing study explains the contextual interrelationships between innovative green practices and the 3 Cs'. There are existing studies showing links between resource dependency theory and green practices (Cooper and Ellram, 1993; Carter and Carter, 1998; Buvik., 2001; Carter and Rogers, 2008; Zhu et al., 2008; Sarkis et al., 2011; Sarkis, 2012; Lee et al., 2012). However, there is a scope for further intensifying the theory and extending the knowledge base.

2.1. Research Objectives

The SLR has revealed the research gaps and provides direction for developing the following research objectives:

- To identify the leading soft dimensions influencing innovative green procurement practices.
- To identify the contextual relationships between innovative green procurement practices and the leading soft dimensions.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

3. RESEARCH METHODS

The research design is the most critical step in any research study. The research design is different for both qualitative and quantitative approaches. Some of the seminal papers available in the area of qualitative research design under management sciences are (e.g., Eisenhardt,1989; Mays & Pope, 1995; Eisenhardt & Graebner, 2007; Verd, 2004; Suering, 2008; Stock & Boyer, 2009). From existing literature, it is seen that case study research is the most popular technique under qualitative approach. Therefore, keeping in mind the qualitative approach for the present study we have several options for addressing the research objectives. However, the author adopted the ISM methodology for identifying the contextual relationships between identified variables. The reason for adopting ISM methodology is basically to generate a robust model from the complex links and for which ISM is the perfect tool. The ISM methodology is interpretive from the fact that as the expert group decides whether one variable enhances another variable, therefore an overall structure is extracted from the relationships of the variables and is further validated using MICMAC analysis. ISM has gained popularity in the branch of supply chain management and the seminal work available are (Mandal & Deshmukh, 1994; Singh et al., 2003; Luthra et al., 2011; Pfohl et al., 2011; Shahabadkar, 2012; Sushil,2012; Attri et al., 2013; Dubey & Ali, 2014; Srivastava & Dubey, 2014; Bag & Anand, 2014a, 2014b; Bag., 2014; Dubey et al., 2014b; Dubey & Singh, 2015).

3.1. Finding Variables From Literature Review

As a result of the review, 30 variables were found to be influencing innovative procurement practices. A problem-solving group was formed comprising seven experts from manufacturing sector. The group was asked to analyze the listed variables, take out the repeated ones and rearrange the list including the ones thought to be valid in relation to the Indian context. The first tour resulted with reducing each of the variables to 22. Through the second tour 18 and the third tour total 15 variables were determined. The final variables were presented in Table 1 and will be further used in developing the ISM model.

4. DATA ANALYSIS

In this step, the contextual relationship between variables with respect to the pairs of variables was examined. To investigate the relations between fifteen variables, a questionnaire was developed. The questionnaire was sent to twelve referees, who are working in the position of senior supply chain manager in the manufacturing sector. The questionnaire was tested for content validity. The instrument developed in this study demonstrates the content validity as the selection of measurement items was based on both, an exhaustive review of the literature and detailed evaluations by senior managers during pre-testing.

4.1. Developing the Structural Self-Interaction Matrix (SSIM)

For developing SSIM in Table 2, the below symbols have been used to denote the direction of relationships between variables (i and j):

V: i lead to j but j does not lead to i

A: i do not lead to j but j lead to i
X: i lead to j and j lead to i
O: i and j are unrelated to each other

4.2. Develop Reachability Matrix

The SSIM has been converted into a binary matrix, i.e., the reachability matrix (Table 3) by substituting V, A X and O by 1 and 0. The substitutions of '1' and '0' is done as below:

1. If the (i, j) entry in the SSIM is V, then the (i,j) entry in the reachability matrix becomes '1' and (j,i) entry becomes '0'
2. If the (i, j) entry in the SSIM is A, then the (i,j) entry in the reachability matrix becomes '0' and (j,i) entry becomes '1'
3. If the (i, j) entry in the SSIM is X, then the (i,j) entry in the reachability matrix becomes '1' and (j,i) entry also becomes '1'
4. If the (i, j) entry in the SSIM is O, then the (i,j) entry in the reachability matrix becomes '0' and (j,i) entry also becomes '0'

4.3. Transitivity Principle

In this step, the concept of transitivity is introduced so that some of the cells of the initial reachability matrix are filled by inference. Transitivity can be explained with the following example if element "i" relates to element "j" and element "j" relates to element "k", then transitivity implies element "i" relates to element "k". It also helps in maintaining the conceptual consistency. The final reachability matrix will then consist of some entries from the pair-wise comparisons and some inferred entries. The transitivity concept is used to fill the gap, if any. Following the above rules, the initial reachability matrix is prepared. After incorporating the transitivity concept as described above, the final reachability matrix is obtained Table 4.

4.4. Level Partitioning

The final reachability matrix obtained above in Table 4 is now partitioned into different levels. After the first iteration, the variable classified to level 1 are discarded, and the partitioning procedure is repeated on the remaining variable to determine the level 2. These iterations are continued until the level of each variable has been determined. The results for iterations 1 to 8 are summarized in Table 5.

4.5. Diagraph

From the final Reachability Matrix and level partitions, the structural model is generated using nodes and lines of edges. This graph is called digraph.

The analysis yields an ISM hierarchy in which Better customer retention (the top level); Create value for customers (second level); Enhanced risk management and Differentiate services (third level); Successful compliance (fourth level); Wastage Reduction (fifth level); Materials recovery (sixth level);

Innovative capability (seventh level) and Internal integration, Information sharing, Governance, Organizational Autonomy, Mutuality, Problem solving and Willingness to adapt to changes(bottom level). The resulting ISM model is illustrated in Figure 1.

4.6. MICMAC Analysis

The objective of MICMAC analysis is to analyze the drive power and dependence power of variables. Based on the drive power and dependence power the variables have been classified into four variables: autonomous variables, linkage variables, dependent and independent variables and presented in Figure 2.

The below Table 6 show the dependence and driving power of key variables which is derived from final reachability matrix (Table 4) of ISM steps.

4.7. Findings From MICMAC Analysis

Cluster 1: *Autonomous Variables*

These variables have a weak drive power and weak dependence power. In this cluster, we do not have any variables.

Cluster 2: *Dependence Variables*

These variables have a weak drive power but strong dependence power. In this cluster, we have seven variables: 2 (Wastage reduction), 3 (Materials recovery), 4 (Create value for customers), 5 (Better customer retention), 6 (Successful compliance), 7 (Enhanced risk management) and 8 (Differentiate services).

15	7	15

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. MICMAC analysis

Cluster 3: *Linkage Variables*

These variables have a strong drive power as well as strong dependence power. In this cluster we have eight variables; i.e., 1 (Innovative capability), 9 (Internal integration), 10 (Information sharing), 11 (Governance), 12 (Organizational autonomy), 13 (Mutuality), 14 (Problem-solving) and 15 (Willingness to adapt to changes). Linkage variables are very sensitive and unstable. Any action on these variables will trigger an effect on other variables and also feedback on themselves.

Cluster 4: *Driving Variables*

These variables have a strong drive power but weak dependence power. In this cluster, we do not have any variables.

5. DISCUSSIONS

The current study argues that Collaboration, Cooperation, and Coordination are the leading soft dimensions influencing innovative green procurement practices. Secondly, the interrelationships have also been studied with respect to Resource dependency theory.

Organizations are generally interested in environmental collaboration with suppliers for successful adoption of green practices. Various case studies from European and Australian organizations have shown that green procurement practices have been used as a tool to gain a competitive advantage as it enhances operational and financial performance.

The success of innovative green procurement practices is dependent on wastage reduction at source, materials recovery program, creating value for customers, better customer retention, successful compliance, enhanced risk management and differentiated services. Firms should not ignore the linkage variables of innovative green procurement practices. Resources are scarce and costly to acquire. Under such

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

circumstances, it is essential for firms to create a collaborative practice based on information sharing and decision synchronization. In this dynamic situation, each partner has resources that other partners need and must be shared because knowledge and cross-functional collaboration are two fundamental resources for successful product innovation and green procurement practices.

6. CONCLUSION

The present study provides a systematic approach in developing a structural model for 3 Cs' and innovative green procurement. The ISM model has identified a hierarchy of factors for implementing innovative green procurement system in the organization.

The ISM modeling yields a hierarchy in which the top level element is better customer retention; Create Value for customers (second level); Enhanced risk management and Differentiate services (third level); Successful compliance (fourth level); Wastage Reduction (fifth level); Materials recovery (sixth level); Innovative capability (seventh level) and Internal integration, Information sharing, Governance, Organizational Autonomy, Mutuality, Problem solving and Willingness to adapt to changes(bottom level).

The ISM model explains the relationships where the most important elements are the bottom level elements. Supply chain practitioners need to focus specifically on these bottom level elements while developing innovative green procurement strategies. Ultimately it will boil down to value creation for customers and better retention of customers. The findings of the current study corroborate with some of existing studies such as (Gunasekaran et al., 2015; Whitelock, 2012; Uttam et al., 2012; Ninlawan et al., 2010; Anvuur & Kumaraswamy, 2008; Heuninckx, 2008).

6.1. Unique Contributions

The study has covered the background and methodology well. It provides a significant contribution in defining the leading soft variables and identifying the contextual relationships which will be important from the practical point of view. This study further extends the boundary of green procurement knowledge base.

6.2. Theoretical and Managerial Implications

The present study provides rich insights for procurement professionals willing to implement innovative green procurement practices. It provides a basic checklist as follows:

Collaboration with strategic suppliers is essential for the uninterrupted supply of alternate/environmental friendly products which is scarce and costlier to acquire. Moreover, spending time with suppliers will facilitate knowledge sharing and ultimately enhance innovation capability. This will help in mitigating risks and also develop trust among the members of supply chain network.

Cooperation among team members will improve problem-solving ability and employees will be flexible to adopt changes in process/system.

Coordination will improve information sharing and enhance innovative green procurement practices.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

6.3. Future Research Directions

The limitations of the current study involve the human intervention in the process which is basically the subjective judgment conducted through a decision maker's opinion. This model can be compared using alternate MCDM techniques such as Fuzzy TISM or Fuzzy DEMATEL method to compare the results obtained in the current study.

Chapter 19
Development of a Research Framework for Green IT Enablers Using Interpretive Structural Modelling

Sania Khan

Abdul Razak Honnutagi
Indian Institute of Technology Bombay, India

Mohammed Shahid Ahamed Khan
CSH Co. LTD., Saudi Arabia

ABSTRACT

The purpose of this paper is to identify the key variables and develop the relationships among the green IT enabling factors which drive consumers towards green purchasing. In this paper Delphi technique and Interpretive structural modelling approach have been employed to model the identified factors. These variables are segregated as 'enablers' that facilitate corporate consumers' to purchase eco-friendly IT products. The major finding of this research is power consumption, e-wastage disposal, product performance and global warming are underlined as significantly important enablers which also drives other factors. The variables are interpreted for sustainable procurement in terms of their driving and dependence powers. For true sustainability the corporate organisations should focus on considering environmental consciousness, Kyoto protocol, corporate social responsibility and eco-label certified products as main interest for green purchasing. Developing the present strategic model and validating it scientifically are further suggested as directions for future research.

INTRODUCTION

The increased power consumption, carbon footprints and early disposal of electronic items containing toxic and non-biodegradable material in the regular IT operations are estimated to be responsible for 2% of global carbon emission from IT industry and also causing serious health problems to mankind (Simon

Mingay, 2007). Consequently, unsustainability through global warming is becoming a major problem on the planet. So the green IT found to be an emerging area in the IT management emphasising on six dimensions namely raw material and resources, energy and climate, excess production, health and safety of mankind, management development and invention through IT. The first generation of green IT which was driven by reduced power consumption, eco-labeled products, recycling and reusing process of e-waste (Murugesan and Gangadharan, 2012) and the second generation was focused on sustainability through IT. Today the green IT studies are progressed far beyond these issues and delivering sustainable benefits in the business by being socially responsible, economically viable and environmental benefits which is considered to be the triple bottom line. Despite reducing 2% of global pollution, green IT initiatives also able to reduced remaining 98% of global emissions to some extent and attracting interest among IT vendors and corporate consumers. Green IT being a potential research area has exciting research opportunities in IT through business sustainability and low carbon economy (Molla, 2008). Hence this research is primarily conducted to provide an evidence of authenticated studies on consumer purchasing behaviour of green IT products which are found to be neglected so far.

This paper identifies and develops the conceptual relationships among the identified enabling factors that are driving the corporate IT consumers towards green IT products using Delphi technique and Interpretive Structural Modelling (ISM) approach. ISM is a popular strategic approach for identifying relationships among various elements in a complex system (Sage, 1977 and Warfield, 1974). The major consensus among experts in this field and a source from literature study are used in developing the relationship matrix using pairwise comparison and thereby developing the ISM model. The suggested variables are gathered as "enablers" from various green IT literature and experts responses as presented in Table 1. Further with the application of integrated approach of Delphi technique and ISM in developing the green IT consumer purchasing behaviour model are discussed in detail followed by conclusions and direction for future research studies.

LITERATURE REVIEW

Green IT being a new area of study since 2007 was primarily looked from the corporate perspective and the consumer perspective has widely been neglected (Mines and Davis, 2007; Velte et al., 2008; Molla, 2008). As green IT includes the attributes related to energy consumption, disposals and recycling will also show influence on the purchasing behaviour of IT products (BITKOM, 2009). Pertaining to the literature review fifteen enabling factors were gathered and are explained below.

The growing impact of IT on environment and awareness among business and consumers has brought significant realisation in their production and consumption pattern (Laroche et al., 2001; Chan T.S., 1996; Kerr, 1990; and Donaton & Fitzgerald, 1992; Noushin et al., 2009). Also most of the consumers understand that the majority of our environmental problems like excess garbage, pollution, waste of energy and material are the outcomes of their consumption behaviours (Christopher et al., 2008) While there is a very clear that the ecological concern is not only applicable to consumers but also appropriate for industrial goods and even services also (Stern, 2006). In reducing the industrial impact on the environment, government is also actively involving in alerting the firms by introducing new regulations from time to time to put down their carbon emissions. Hence towards the sustainable development the federal government and Intergovernmental Panel on Climate Change (IPCC) introduced carbon tax and trade scheme in line with Kyoto protocol established by European Union (Butner et al., 2008). With

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

the recognition of IT industry accountable for 2 percent of global warming approximately equal to 820 million ton emissions per year the ICT product manufacturers were also restricted by regulations in reducing waste and hazardous substances during the manufacturing process (Simon Mingay, 2007, Hugh Wareham, 2009; CGI, 2010). As green IT adoption addresses a broad range of business sustainability most of the firms are adhering to these policies by implementing CSR strategy in their business operations (Chandrasekhar, 2009) while 55% of European organisations provide evidence with these strategies in position (nlyte software, 2011).

IT equipment particularly in the data centers are major power consumers which use 123,000 GWH of electricity across the world on an average equal to the power consumption of a small country such as Poland (Koomey 2007; Schmidt et al. 2009). Power consumption by data centers have doubled from 2000 and 2005, and increased by 40% by 2010 found energy cost will be higher than equipment cost by 2015 (nlyte software, 2011). As electricity is a major cause of climate changes, it is therefore clear that increased energy consumption has positive impact on green IT product purchase. The computing devices like PCs and monitors accounted for nearly 62% of total ICT energy consumption followed by enterprise communications infrastructure with 25% (Gartner, 2008). As stated by U.S Environmental Protection Agency, out of 25 billion computers and other electronic equipment sold since 1980 has generated 2 million tons of e-waste while only 15-20% of them were recycled (Ruth, 2009; Vetter and Creech, 2008; Poniatowski, 2009). It was also found India has generating 3.3 lakh tons of e-waste in 2007 with the expectation of 4.7 lakh tons in 2011 (Anand, 2009; UNEP 2007; Pinto, 2008). All these are found to be due to the lack of awareness on green IT among the people and it can be improved by government's strict regulations (Velte et al., 2008; Noushin et al., 2009; Stephen, 2006, Sania Khan et al., 2011). Computers and office electronics account for 40% of lead and 70% of heavy metals, in landfills leading critical disruption of natural resources (Hobby et al., 2009; Hayes, 1990). The green IT products despite minimising these issues delivers much more financial benefit over the time by lowering operating and maintenance costs, reduced power consumption, space consumption (Clifford, 2009; Dubie, 2009; and Castro, 2009). TCS provides evidence by 12.5% reduction in electricity consumption, 76MWH of solar energy generation, 1.5 cubic meters of water reuse, 28% and 67% of reduction in paper and printer cartridge consumption, leading 2% of carbon footprint reduction in 2007 and 2008 compared to the prior year (Anand, 2009). In relation to this consumers found better choice of eco IT equipment without entering them into the waste stream prematurely (Robert and Nora, 2009; Hobby et al., 2009; Consumer Electronics Association, 2008). In the United States, the EPEAT product registry is a major force in green IT procurement relatively decreasing energy consumption providing superior energy efficiency standards (CGI, 2010; Nordin, 2008). Consumers and corporate buyers recognised eco-labeling or certification programs such as TCO, Energy Star and Blue Angel as one of easiest methods to accurately determine the eco feature of ICT products which can offer additional financial benefits such as operational efficiency and cost reduction (Christopher et al., 2008; Hobby et al, 2009). The driving factors like attitude, desire and intention are much more considered when comes to actual purchasing decision with a better understanding of consumers' behaviour (Tim Flannery, 2010; Roberts, 1996; Yam-Tang & Chan, 1998; Ricky Chan, 2001).

Developed countries being much advanced in green IT issues, and among all South Korea expected to be a world leader in green technology by strictly practicing government policies, strong executive leadership and commitment of CSR (Castro, 2009). The most common green criteria for electronic product purchasing are: environmental performance with greater energy efficiency, durability, and energy rating (William et al., 2010). So the new technologies are coming up with IT operative performance which can

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

reduce power usage up to 75%, carbon emissions by 56%, functional performance by 55%, office space saving by 47% (Hobby et al. 2009; Murugesan, 2008).

Consumers who look for environmental information on labels found to have a better understanding on green products and their green purchasing intention is improving the market visibility with efficient and effective performance products (D'Souza et al., 2006; Schmidt et al, 2010; Hugh Wareham, 2009; CGI, 2010). Especially for green electronic products the present demand found to be 47% and expecting a future growth to 88% where the vendors and manufacturers delivering products in line with customer demands (Grail Research, 2009; Hugh Wareham, 2009). Further these consumer's green purchasing behaviour are driving other market players to encourage green criteria in their products to gain market share (Aysel Boztepe, 2012). The potential market for PC with green IT attributes found to be 26.6% by attracting new customers and gain extra revenues (Schmidt et al, 2010). Hence it can be said there exist a competition among IT product manufacturers towards green initiatives and promote their products with eco-label which can reduce 25% of GHG emissions (CGI, 2010; Grail Research, 2009). Hence a clear driver of green purchasing can develop a sustainability strategy in the organisation with a good impact on their day-to-day operations (Hugh Wareham, 2009; nlyte software, 2011; Nathalie, 2010).

Specially for green electronic products it was found environmental awareness, environmental related factors, attitude and intention towards green purchases has a causal link towards green purchasing behaviour with the influence of regulatory actions majorly (Tim Flannery, 2010; Hugh Wareham, 2009, Ishaswini & Saroj, 2011; Ricky Chan, 2001). So companies implementing green initiatives and financial recession situation have changed two-third of consumers to consider green purchases (Grail research, 2009).

Overall 15 enablers of green IT with respect to socioeconomic and environmental criteria are identified from the literature as shown in Table 1 with the appropriate category they belong to.

INTEGRATED APPROACH OF DELPHI TECHNIQUE AND INTERPRETIVE STRUCTURAL MODEL

Interpretive Structural Modelling was first proposed by J. Warfield in 1974 to analyse the complex socioeconomic systems for identifying the relationships among specific items in a system. The ISM approach starts with an identification of elements which are relevant to the problem or issue. Then a contextually relevant subordinate relation is chosen. Having decided the contextual relation, a structural self-interaction matrix (SSIM) is developed based on pair-wise comparison of elements. After this, SSIM is converted into a reachability matrix (RM) and its transitivity is checked. Once transitivity embedding is completed, a matrix model is obtained. Then the partitioning of the elements and an extraction of the structural model called ISM is derived. Thus it can be seen ISM involves establishing relationship among the elements which are subjected to a series of subsequent processes to categorise the elements suitably and also develop structural relationships among various sets of elements. ISM modelling apart from providing insights into relationships between the various enablers also helps in developing the multi-level hierarchical structure based on the importance of each enabler and provides a visual representation of the scenario in the form of digraph. Therefore this approach is considered prudent and appropriate for this research study in developing a hierarchical structural model by undergoing set of steps in the process. Firstly the major inputs to the methodology are the elements and the relationships among them. The elements were already gathered from literature and to understand their relationship, pairwise comparison of the variables is done by involving a group of green IT experts in a Delphi study from Riyadh, Saudi Arabia.

OVERVIEW OF DELPHI TECHNIQUE

This technique involved twelve industrial experts in the field of green IT from Riyadh, Saudi Arabia in three rounds with an aim to obtain the consensus among expert's opinion towards the development of contextual relationships of the variables. For this a well-developed questionnaire in an excel template was developed with self-explanatory instructions to help them filling questionnaire. A relationship code system for filling the questionnaire was used with V, A, O, X alphabets with the conditions shown in Table 2.

Some conflicts also arised between the expert's opinions which was resoluted by giving them a feedback form after each round on the group opinion along with a new set of questionnaire to be answered in the succeeding round. This procedure provides panelists' an opportunity to review his/her opinions between each rounds. The iteration of this procedure was stopped at the third round as there were reasonable consensus among majority of the experts. The final opinion consensus were summarised and segregated in the form of a structural self-interaction matrix (SSIM) as shown in Table 2 for the further use in the development of ISM model. These final opinions are therefore directly used in developing initial reachability matrix by transforming the codes into binary digits 1's and 0's.

13	Market Players	X	A												
14	Sustainable Strategy	X													
15	Green Purchasing Behaviour														

V = element (i) leads to element (j) but element (j) is not leading to element (i). This is one-way relationship.
A = element (j) leads to element (i) but element (i) is not leading to element (j). This is one-way relationship.
X = both element (i) and element (j) lead to each other. This is two-way relationship.
O = both element (i) and element (j) does not lead to each other. This has no relationship.

INITIAL REACHABILITY MATRIX

The SSIM is converted into the Initial Reachability Matrix as in Table 3, which is a binary matrix with 1's and 0's. The rules for substitution of 1's and 0's are:

- If the (i, j) entry in the SSIM is V, then (i.j) entry in the Reachability matrix becomes 1 and (j, i) entry becomes 0;
- If the (i, j) entry in the SSIM is A, then (i.j) entry in the Reachability matrix becomes 0 and the (j, i) enry becomes 1;
- If the (i.j) entry in the SSIM is X, then (i, j) entry in the Reachability matrix becomes 1 and the (j, i) entry becomes 1;
- If the (i, j) entry in the SSIM is O, then (i, j) entry in the Reachability matrix becomes 0 and the (j, i) entry becomes 0.

FINAL REACHABILITY MATRIX

The initial reachability matrix which is multiplied by itself till it achieve the state of transitivity is called final reachability matrix. The concept of transitivity is introduced so that some of the cells of the initial reachability matrix are filled by inference. The transitivity concept is used to fill the gap if any in the opinions collected during the development of the SSIM. In this case the entries are included to incorporate transitivity. One method of testing for transitivity is by multiplying initial reachability matrix by itself successively i.e., by raising the power of initial reachability matrix successively till two consecutive matrices become identical. After getting the final reachability matrix, the next step is to find the driving power (DRP) and dependence power (DEP) of each element as shown in Table 4. This is done by considering the sum of all 1's in the row to get DRP and in the column to get DEP.

LEVEL PARTITIONING OF THE REACHABILITY MATRIX

From the final Reachability matrix, the reachability and antecedent sets for each enabler are found. The reachability set consists of the element itself and the other elements in its row having digit-1, whereas the antecedent set consists of the element itself and the other elements in its column having digit-1. Thereafter, the intersection of these sets is derived for all the enablers. The enablers for whom the reachability and the intersection sets are the same occupy the top level in the ISM hierarchy. The top-level element in the hierarchy would not help achieve any other element above its own level. Once the top

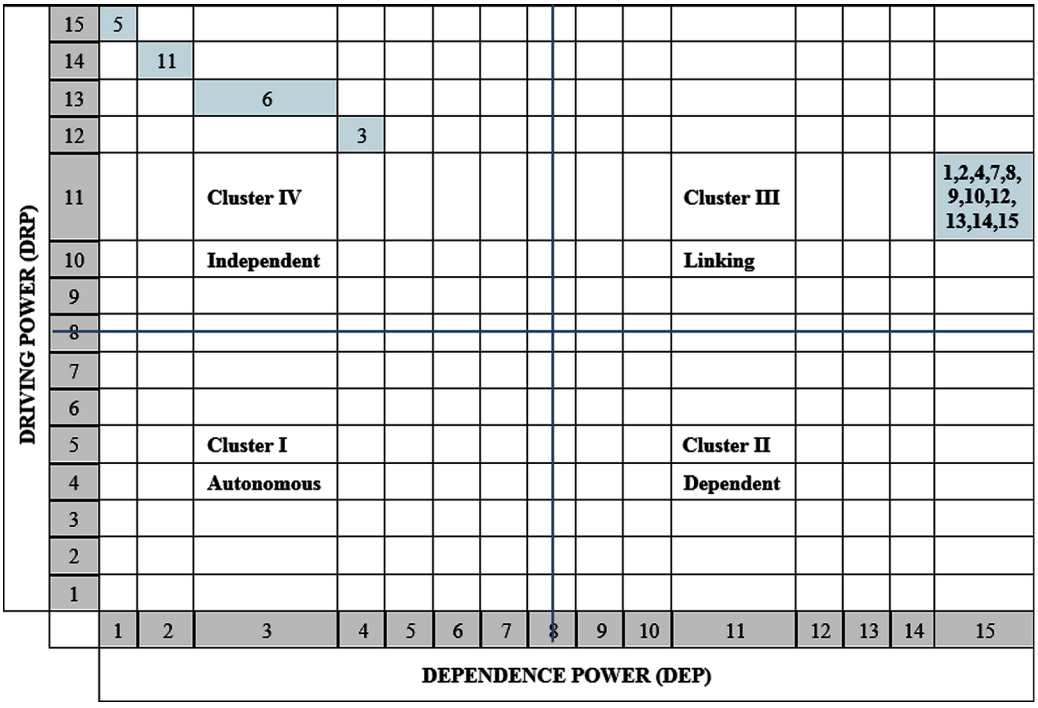
level element is identified as shown in Table 5, it is separated out from the other elements. Then the same process is repeated to find out the elements in the next level. This process is continued until the level of each element is found as shown in Table 5. These levels help in building the digraph (directed graph) and the final model.

CLASSIFICATION OF ENABLERS USING MIC MAC ANALYSIS



The purpose of classifying enablers is to analyse the driving power and dependence power of enablers (Mandal and Deshmukh, 1994). MIC MAC principle is based on multiplication properties of matrices (Sharma et al., 1995). Based on this the enablers are separated into four categories as autonomous enablers, dependent enablers, linkage enablers and independent enablers. The driving power and dependency power for each enablers is shown in Figure 1. In this classification of enablers, the first cluster is of autonomous enablers that have a weak driving power and weak dependency power. The autonomous enablers are relatively disconnected from the system. In this case there are no autonomous enablers. The second cluster consists of dependent enablers that have weak driving power and strong dependency power. In the present case there are no dependent enablers. The third group consists of linkage enablers that have strong driving and dependency power. Any action on these enablers will have an effect on the other enablers and also a feedback effect on themselves. In this case, enablers 1, 2, 4, 7, 8, 9, 10, 12, 13, 14 and15 are in this category of linkage enablers. The fourth cluster includes independent enablers that have strong driving power and weak dependence power. In this case enablers 3, 5, 6 and 11 are in the category of independent enablers.

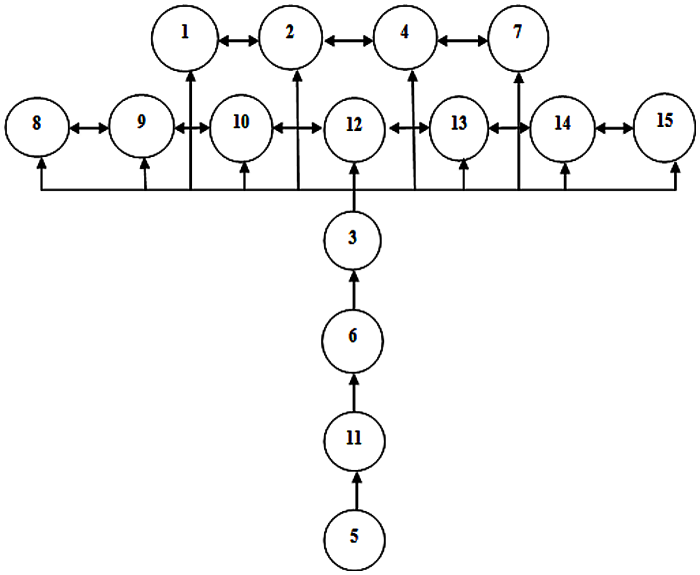
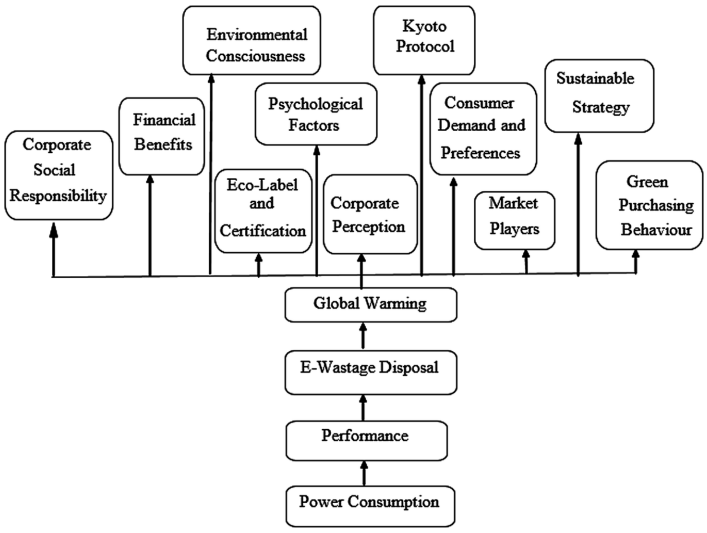
ISM BASED DIGRAPH AND MODEL



The structural model is generated by means of vertices and lines based on the relationship between the variables 'i' and 'j' as in Figure 2. Then the transitivities are removed to develop the digraph or directed graph. This graph is called as an initial directed graph or initial digraph. Directed arrows are used in digraph to depict the relationship. This process is carried out till the last level is reached and transitivity's are removed. The final digraph is converted into an ISM based model by replacing with the respective enablers as shown in Figure 3 illustrating the relation among each element.

It is necessary to understand the levels of green IT enablers for consumers' purchasing as presented in Figure 1. Enabler "power consumption" with high driving power and low dependence among other identified enablers is positioned at lowest level in the hierarchy of ISM based models. This is most important and independent enabler. Next comes the enablers' global warming, e-wastage disposal and performance in second, third and fourth levels in the hierarchy respectively. Eleven enablers as shown in digraph are with high dependence and low driving power hence they are placed on the top level in the hierarchy which is depending on the rest of all the enablers. The enablers in middle layers with high driving power are called "strategic enablers", which need greater consideration from the corporate IT sector. As autonomous variables have low driving power and low dependence power which does not exist in this case. They play less role in driving the green IT product purchasing. Other enablers have a vital role in green IT product purchasing and hence need to concentrate on all the suggested enablers.

CONCLUSION AND FUTURE IMPLICATIONS



Although all the fifteen enablers in the ISM based model have their own importance towards green IT product purchasing after the enabler power consumption, e-wastage disposal, IT product performance and global warming have the highest driving power and less dependency power. So the other eleven factors

Figure 2. Final digraph depicting relationship between green IT enablers

Figure 3. Proposed model of green IT enablers for consumer purchasing

with moderate driving power and high dependency power in the model are highly dependent on these four enablers. In this study, only the key variables as enablers are identified and their interrelationships were developed and as the proposed model lacks scientific validation it is presented as the limitation of the study. Therefore further research studies may identify any other related underlying enablers in developing the present model of green IT enablers for consumer purchasing behaviour using ISM and test the validity of model empirically. Structural Equation Model (SEM) which sometimes referred as linear structural relationship approach can be used as a statistical tool.

Chapter 20
Eco-Innovation Enablers and Typology in Green Furniture Manufacturing

Yudi Fernando
Universiti Sains Malaysia, Malaysia

Muhammad Shabir Shaharudin
Universiti Sains Malaysia, Malaysia

Wah Wen Xin
Universiti Sains Malaysia, Malaysia

ABSTRACT

Fierce competition has forced firms to be more creative and innovative to increase market share. Differentiating between green products or services with conventional products or services is one of the ways for firms to improve their business sustainability. The objective of this chapter is to explore the eco-innovation enablers and design its typology to measure the current green business practices in industry. Although there are many well-documented enablers or practices of eco-innovation that have been researched, this chapter focuses on practices that contribute towards the successful adoption of eco-innovation by one SME in green furniture manufacturing. This chapter uses the case study method as a source of data collection. Eco-innovation typology has been found in this study to define the effort of green company by looking at the target of eco-innovation versus the mechanism of eco-innovation.

The furniture industry will grow and prosper through constant innovation and improvements in the manufacturing process. (H. Mardiyanto, Central Java Governor, 2013)

INTRODUCTION

Firms today face a number of environmental challenges such as pollution, scarcity of natural resources, global warming, and a growing demand for environmentally-friendly goods. It is not a secret that environmental management, also known as eco-innovation (Kemp & Pearson, 2008), plays an important

role due to increasing climate change and uncontrollable business activities. Some many major business disasters include the 2011 earthquake and resulting tsunami in Japan, various earthquakes in Indonesia, flooding in Thailand, and pollution in China. It is no longer one nation's problem but rather a global concern in which such catastrophes mostly affect poor and developing countries. As such, it has an impact on the policymaking and rules in the business industry. However, considering social, economic, and environmental benefits alone is not sufficient as policies and businesses are also subject to political factors. Businesses are very concerned about expansion and profitability, and for any business to achieve this it has to ensure continuity in improvement and innovation (Schumpeter, 1934; Baumol, 2002).

This chapter has two objectives: 1) to explore the eco-innovation enablers in green furniture; 2) to design eco-innovation typology to measure the current green business practices in industry. Some of the drivers of eco-innovation from previous studies are discussed from past studies to guide the authors in identifying enablers. This chapter is organized by first explaining various types of eco-innovation definitions and concepts that would be useful to know when comparing the results of this chapter with previous research, as well as eco-innovation practices that are useful to SMEs. In this study we first reviewed the furniture industry in Indonesia and then selected a sample from a company that managed eco-innovation activities successfully. This company is also as a premier supplier of green furniture to overseas markets. As this is a case study, brief information concerning the firm is presented. Then, the chapter discusses the methodology used and several tools that helped in the analysis of the findings. Last, this chapter provides the discussion, limitations, recommendations for future studies and the conclusion. It is hoped our work concerning the eco-innovation practices in this SME will contribute to the existing eco-innovation concepts and practices, especially in understanding how SMEs in emerging markets can compete by undertaking eco-innovation.

LITERATURE REVIEW

Innovation

In extant management literature, innovation is perceived as a relatively new concept (Türker, 2012). However, innovation is no longer a new concept and phenomenon to popular belief. Türker (2012) argued that innovation is as old as humankind itself. According to Fagerberg, Mowery, and Nelson (2006), innovation seems to be something integrally "human" about the tendency to deliberate about better ways of doing things and practice in reality. This deep-rooted and well-established concept had been worked by scientists during the history of the social sciences.

According to Schumpeter (1934), innovation is defined as "to produce means to combine materials and forces within our reach. To produce other things, or the same things by a different method, means to combine these materials and forces differently". To explain the statement above, Schumpeter (1934) used the concept named "new combinations" for his explanation. It is a strong connection between the definition of innovation that commonly being adopted today and Schumpeter's "new combinations". The "new combinations" can be any new product with which customers are not familiar; a new technique of production that not yet being practised in the branch of manufacture concerned; a new supply source of raw materials and resources; a new target marketplace; or a new organization of any industry (Schumpeter, 1934). Therefore, "new goods" do not fully reflect the meaning of innovation.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Green Technology in Globalization

So-called "Green Technology" is an advance which includes various kinds of methodologies and materials enhancement ranging from techniques for generating energy to non-toxic cleaning products (Kamrudin Bakar et al., 2011). It is increasing the societal push for environmental friendly mechanisms to help reduce the impact resulting from fossil fuel consumption, landfill and industrial sector wastages since there are many studies discussing climate changes and global warming (Cheng & Shiu, 2012; Rennings, 2000).

According to Barlett and Trifilova (2010), the goals underlying the eco-innovation are defined as follows:

- "New or improved use of environmental resources" shows the alternatives which people can reduce waste and pollution by improved use of environmental resources or through the discovery of new uses of such resources;
- "Removing harmful environmental toxins" is concerned with how people can remove environmental pollutants which are potentially harmful to human health and;
- "Recycling" is concerned with how people can re-use the manufacture products and the creation of products from recycled materials.

Eco-Innovation

There seems to be various research conducted on eco-innovation linking business with environmental issues throughout the year. Initially, the eco-innovation definitions from empirical research are similar to the definitions of innovation but with the addition of environmental, economic and social value as its aspiration. The eco-innovation research paper of Kemp and Pearson (2008), which was supported by the European Commission, defined eco-innovation as the production, assimilation, or exploitation of a product, production process, service or management, or business method that is novel to the organization (developing or adopting it) and which results, throughout its life cycle, in a reduction of environmental risk, pollution and other negative impacts of the resources used (including energy use) compared to relevant alternatives (OECD, 2009).

Additionally, Oltra and Saint Jean (2009) also defined eco-innovation similar to the innovation definition of Schumpeter (1934) but with the goal of being to contribute to environmental sustainability. As the line between eco-innovation and innovation becomes thinner, more researchers have attempted to further distinguish the two. Foxon and Pearson (2008) defined sustainable innovation as innovation towards more sustainable technological and institutional systems, and processes broadly understood as systems for which the resources used and waste production remain within appropriate environmental limits through which socially acceptable levels of economic prosperity and social justice are achieved. Although most researchers and policy makers are well-acquainted with the concept of innovation, eco-innovation is a new concept for which a standardized definition does not yet exist (Kesidou & Demirel, 2010).

Kemp and Pearson (2008) provided an eco-innovation typology following diverse objectives. Eco-innovation is categorized in four different categories. Table 1 shows a comparison of four different typologies. The first category is the environmental technologies which are divided into eight subcategories. Environmental technologies are only a part of eco-innovation, and are not limited to it. The second category corresponds to organisational innovation with methods and management systems for dealing with environmental issues in production and products. The third category is product and service

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Typology of eco-innovation

1. Environmental Technologies:
a. Pollution control technologies including waste water treatment technologies.
b. Cleaning technologies that treat pollution released into the environment.
c. Cleaner process technologies: new manufacturing processes that are less polluting and/or more resource efficient than relevant alternatives.
d. Waste management equipment.
e. Environmental monitoring and instrumentation.
f. Green energy technologies.
g. Water supply.
h. Noise and vibration control.
2. Organisational Innovation for the Environment:
a. Pollution prevention schemes: aimed at prevention of pollution through input substitution, more efficient operation of processes and small changes to production plants (avoiding or stopping leakages and the like).
b. Environmental management and auditing systems: formal systems of environmental management involving measurement, reporting and responsibilities for dealing with issues of material use, energy, water and waste such as EMAS and ISO 14001.
c. Chain management: cooperation between companies so as to close material loops and to avoid environmental damage across the value chain (from cradle to grave).
3. Product and Service Innovation Offering Environmental Benefits:
a. New or environmentally improved material products (goods) including eco-houses and buildings.
b. Green financial products such as eco-leases or climate mortgages.
c. Environmental services: solid and hazardous waste management, water and waste water management, environmental consulting, testing and engineering, other testing and analytical services.
d. Services that are less pollution and resource intensive.
4. Green System Innovations: Alternative systems of production and consumption that are more environmentally benign than existing systems: biological agriculture and a renewables-based energy system are examples.

Source: Kemp & Pearson (2008)

innovation which is offering environmental benefits such as new or environmentally improved products and environmentally beneficial services, whereas the last category includes green system innovation.

Drivers of Eco-Innovation

Traditional scholars believed regulation is an additional cost to firms which impacts the ability of firms to gain profit and reduces the competitiveness of the firm (Jaffe et al., 1995). However, this view has been challenged by authors such as Porter and van der Linde (1995), who stated that, in a static world, firms make the decision whether to seek social responsibility (not polluting the environment) or business growth (profit maximization). Furthermore, real world competition is more vigorous and innovation is important because it can offset the cost incurred by the firm. There are five major drivers found to be main determinants of eco-innovation in the extant literature. Table 2 shows the distribution over the time period and it provides the reader with essential information about the literature sample. From the following tables, this study found that the five drivers (regulation, technology, cross-functional coordination, supplier involvement, and market focus) are important for eco-innovation.

- **Regulation:** It is acknowledged that strict regulations and policies enhance the decision of firms to engage in eco-innovation and increase firm performance (Doran & Ryan, 2012). However, there are two views regarding the impact of regulation on firm performance. Since the main concern of businesses is about profit maximization and increasing shareholder's wealth, a traditional view, also known as the cost-based view, argues that if managing the environment is profitability, then firms would long seek to pursue eco-innovation (Jaffe et al., 1995). Porter and van der Linde

(2010)	A framework of diagnosing competitive superiority Construct, proposition and implications of market orientation Eco-innovation and new product development Change of market-led strategic Diversity of eco-innovations with selected case studies
Sub-field 6: Firm specific • Love and Roper (1999)	The determinants of innovation

(1995) believed that firms are able to gain a competitive advantage over non-eco-innovation adoption firms once they have become more expert at reducing or removing pollution, while complying with regulation and improving their products or services that can affect the environment. Eco-innovation regulation drives firms to reduce the cost to firms in the future as well as gain a competitive advantage over other firms.

- **Technology:** The technology driver is essential in the initial development phase of eco-innovation (Horbach, 2008). This statement refers to the capability of firms to gain core competencies or increase their profitability through new products or services that are derived from the adoption of new technology. Technology comes from investment in knowledge, which, ultimately, will introduce more innovation (Baumol, 2002). That is why many Multinational Corporations (MNCs) allocate budgets for the Research and Development (R&D) department to acquire more knowledge.
- **Supplier:** By learning from consumers (forward linkages), suppliers (backward linkages), competitors (horizontal linkages) and universities (private linkages) (Roper et al., 2008), firms can develop the knowledge and skills necessary for innovation. On the supplier side, eco-innovation practice is possible if firms and suppliers together adopt a greener perspective (Doran & Ryan, 2012).

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

- **Market:** Horbach (2008) discovered there is great demand for eco-innovation products, processes and management systems, while Jansson et al. (2011) stated that customer perception is an important indicator for innovation adoption. Such research shows that a firm's innovation is greatly linked to the marketing of its green products or services to customers. Thus, marketing is one of the reasons why firms adopt eco-innovation practices, and is one of the earliest and strongest reasons why firms adopt eco-innovation in the first place.
- **Firm Specific:** Factors such as the size of the firm and industry to which the firm belongs have a different impact on the performance and innovation of the firm (Love & Roper, 1999). Therefore, SMEs with flexible decision making, a lean organizational structure, and less bureaucratic communication are able to respond to changes or develop innovative products or higher quality services. However, industries such as the automobile and pharmaceutical industries where resources such as financial capital play an important role would be disadvantageous for SMEs to operate and become competitive.

Since all eco-innovation practices that are deemed important to the firm have been identified, this chapter will discuss the Indonesia furniture industry, the firm involved for this chapter and the methodology used.

Indonesia Furniture Market Overview

Indonesia is renowned for its traditional culture. Indonesians are very fond of their culture and beliefs, and one of the characteristics of Indonesian furniture or handicraft is that it resembles their culture and heritage. Interestingly, there are different styles or designs for furniture and handicraft across Indonesia due to the many ethnic groups in Indonesia of which the majority is Javanese. According to the Indonesia Furniture Industry and Handicraft Association (Tjahyono, 2007), there are clusters of solid wood and furniture production in the Java and Bali regions. The solid wood industry in Indonesia is not well-developed and the Java region has trouble obtaining a solid wood supply. Accordingly, Tjahyono (2007) also mentioned that wood processing industries are scattered in Sumatera, Kalimantan, Sulawesi, and Papua. This explained why two out of three KWaS (this study's example firm located in Yogyakarta, Indonesia) suppliers for Forest Stewardship Council (FSC)-certified wood are from Kalimantan. Additionally, the majority of furniture manufacturers are SMEs, while ASEAN reported there are approximately 4,000 furniture firms in Indonesia (Global Indonesia Guide, 2013).

The furniture industry in Indonesia is a labour-intensive and segmented with SMEs. In central Java alone, KWaS comprised a total of 26.5% of furniture production while over half of the rattan furniture production is based in Cirebon, a port city north of Java (IFMAC, 2012). As timber is one of the commodities exported to other countries, it is understandable that ASMINDO, the International Furniture & Craft Fair Indonesia (IFFINA), the National Handicraft Council (DEKRANAS), and the ASEAN Furniture Industries Council (AFIC) were created to develop the furniture and handicraft industries.

In Indonesia, furniture manufacturers are segmented in Java Island where wood furniture, rattan furniture, and panes furniture are manufactured. However, the other regions in Indonesia are rich in wood supply. Indonesia is the world's largest rattan producer and has abundant supply of teak wood. Moreover, Indonesia exports reached US$2.2 billion in 2011 and are expected to reach US$2.7 billion in 2012. Previously, the furniture industry has only been an export-driven business until lately when consumer purchasing power increases and rises of middle class people in Indonesia enabled them to increase

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

consumption and home ownership (Global Business Indonesia, 2013). According to Tjahyono (2007), domestic sales of furniture and housewares are worth over US$700 million annually. This explained how SME furniture manufacturers could sustain themselves in the furniture industry.

Since China can produce furniture at low cost, the Indonesian furniture industry faces stiff competition. Nevertheless, Indonesia furniture is still produced at a lower cost because the supply of wood is circulated in Indonesia alone and this advantage has helped Indonesian SMEs furniture manufacturers to produce furniture at a competitive price. Furthermore, Indonesian furniture is also unique in terms of design rather than competing on cost. Nonetheless, in 2014, the large Swedish firm IKEA will open its first franchise in Indonesia due to demand by local consumers (The Jakarta Post, 2012). International market remains the profitable market with a total of 58.1% of Indonesia total export from furniture exports (Global Indonesia Guide, 2013).

Many furniture manufacturing firms seek to open business in Indonesia because some 85% of all rattan is made there and Indonesia is rich with timber such as teak, bamboo, and plywood in addition to natural materials such as water hyacinth. An interesting fact regarding furniture demand is that it is seasonal in the local market, especially during festive seasons such as Eid Fitri (Global Indonesia Guide, 2013).

In order to do improvements and innovates in the production process, there is a need to implement green practices, especially in furniture manufacturing. This is because competition in the furniture industry is very stiff. As more international firms can penetrate into the Indonesia market, local firms such as our example firm (KWaS) needed to go to another level. As green practices in furniture manufacturing are still in the infant stage, local firms need to adopt eco-practices earlier to sustain long-term competitive advantage. Malaysia, Indonesia, Philippines, Thailand, and Vietnam are five strong emerging economies which manufacture furniture not only for export, they also import from other countries.

Green Industry Indonesia

Green industry can be in the shape of various criteria such as clean production, energy conservation, resource efficiency, and adopt eco-design and low carbon technology. The Indonesian government has contrived to introduce more incentives such as tax allowance to develop its green industry in Indonesia (The Jakarta Globe, 2013). Nonetheless, the incentives for "going green" are still feeble (POS Kota, 2013). Furthermore, the Chamber of Commerce and Industry (Kadin) has confirmed that only several SMEs are benefitting from the green incentives provided by the government (Suara Merdeka, 2013). The government is attempting to boast green incentive in Indonesia by giving discounts for equipment and machines to prosper green business (Embassy of Indonesia, 2013).

WWF-Indonesia Conservation Director Nazir Foead said in Indonesia there are only 1.1 million Hectares (Ha) of FSC-certified forest, or 2% of the total Indonesian production forest. However, since 2009 the Borneo Initiative has facilitated 26 companies with a total of 2.6 million Ha for FSC-certification (Lang, 2007). FSC is the only green incentive for furniture industry, even though it is expensive. The Indonesian government has made it mandatory for local firms to implement a Timber Legality Verification System (TLAS) by the end of 2013 as this regulation has a unique capability to meet European Union (EU) Timber regulations. Nonetheless, both certifications are more of a guideline rather than for incentives.

Applying FSC and TLAS can ensure sustainable business in the long-term and regulation is one of the most important factors for green practices. This indicates that environmental awareness is still lacking in Indonesia because most firms still seek to maintain their business financially. Eco-innovation has been addressed to better manage resources for the environment, society, and economy. Realistically, the

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Indonesian government should focus on green incentives in term of green economics more so that firms can achieve its objective. The Global Green Growth Institute (2014) stated that the green economic development strategy should refer to the four pillars of growth; namely: pro-growth, pro- business, pro-poor, and pro-environment. After satisfying these pillars, then more local firms will be more incline towards eco-innovation.

Outlook of Indonesia Furniture Industry

The Indonesian government predicts the nation's economy will grow 7% in year 2012 and ASMINDO Chairman, Mr. Ambar Tjahyono, states the furniture industry in Indonesia will grow due to demand by the USA, Japan, and 27 EU nations have increased their demand for furniture following the recovery of the global economy (IFMAC, 2012). However, a study by Zainuri, Waridin, Santoso, and Susilowati (2012) on the performance and the prospect of SME of furniture industry in Jepara, Central Java found that the furniture industry structure has a monopolistic competition. This is due to many SMEs competing in a segmented market on Java Island while most firms practice product differentiation. Firms engage in differentiation due to many competitors in an industry; thus, every firm must produce a unique or quality product to attract customers.

Nevertheless, the marketplace is changing after the global economic recovery. International consumers are more demanding as a survey also found that consumers now request product specification, meaning the barrier to entry will be much higher in the future. More firms need to invest in technology and meeting customer specification to sustain the business, so green certificates such as FSC and TLAS will make Indonesian furniture manufacturers more competitive.

METHODOLOGY

The Organization for Economic Co-Operation and Development (OECD) is a forum where governments from 30 countries collaborate to address economic, social, and environmental issues. As such, attention has been drawn towards eco-innovation, and the OECD has developed its own definition, framework, practices, and measurement of eco-innovation to expand the study. The typology tool is a framework to study eco-innovation targets and mechanisms by identifying products and processes, organizations and marketing methods, and institutions as eco-innovation targets with modification, re-design alternatives, and creation as standard mechanisms for eco-innovation.

This chapter uses the case study method as a source of data collection. Karya Wahana Sentosa (KWaS) is a pioneer in furniture manufacturing, and is currently active in promoting green practices. KWaS, a firm located in Yogyakarta, Indonesia with over 80 employees, produces four containers of furniture monthly. Data was obtained from company reports and interviews with key informants in the company such as the managing director, production managers, logistics managers, and sales and marketing managers. The data was collected and analyzed by the authors. The literature review was used as a guideline for the interpretation of data. A framework developed by OECD (2009) called Eco-innovation Typology was used to position KWaS based on its understanding and practices at the firm. The typology tool is a framework to paper the eco-innovation target and mechanism. This tool identified 'products and processes', 'organizations and marketing' 'methods and institutions' as eco-innovation targets while 'modification', 're-design alternatives' and 'creation' are standard mechanisms for eco-innovation. By

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

classifying the firm's position according to the target and mechanism, this chapter is able to determine the level of eco-innovation and on what improvements the firm needs to focus.

Results

Based on the interviews with key informants and document reviews, we found that the several steps of eco-innovation adoption related to the eco-innovation enablers in the company. Some of the results include the following:

1. **Regulation:** This is a key factor for eco-innovation practices. We found that regulation is the key factor for eco-innovation enabler in the company. This relates and to meets the demand from the market to be served. To meet the criteria set by the international market, companies must change the business strategy and production processes.
2. **Technology:** The use of environmentally-friendly technology is also the basis for the creation of furniture products which are manufactured without causing negative effects to the environment. The company stopped using any toxic chemicals in the production of its products and reduced usage of synthetic materials. The company is now using equipment approved by local authorities and has passed international certification. Machineries used have met standards for environmentally-responsible equipment and materials.
3. **Supplier Involvement:** The company learned from suppliers to improve knowledge of the eco-innovation. Supplier informs about the latest technologies and international regulation on green products. Suppliers also contribute to the quality of product. The company is working with the University to share knowledge and find new method to improve the quality of products produced and environmentally friendly production.
4. **Firm Specific:** The company has changed the company's vision and mission as a producer of green furniture which produce product quality. The company is also changing production methods which are more efficient and lower cost.
5. **Market Orientation and Focus:** The company also frequently gets consumer feedback on specification of product they want and continuously improve the production process. The concept of built to order and online ordering system are introduced to responses the market demand.
6. **Green Network:** The company actively establishes and develops cooperation with external parties such as government agencies, Non-Governmental Organizations (NGOs), and international trade agencies to expand green furniture markets, especially in developed countries.

KWaS Steps/Stages of Eco-Innovation Adoption

KWaS adopted eco-innovation and began when the firm was in financial difficulty and required something "special" to survive. The KWaS eco-innovation implementation timeline is as below:

2004: On the day of restructuring the business by Robertus Agung, KWaS changed its vision and mission to reflect more of an image of green furniture manufacturer to attract more international consumers.

2004: After KWaS changed its organizational structure, Robertus Agung placed put more effort in creating KWaS network of customers and suppliers. This is the start of "Green Networking" practice at KWaS.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

2005: Collaboration with IFC-PENSA, part of the International Finance Corporation for sustainable wood program, brings KWaS closer to eco-innovation. This program was introduced to increase the supply of sustainable legal wood in the market as well as to use alternative material in furniture manufacturing.

2006: KWaS joined WWF-Indonesia to expand its knowledge and network in using sustainable legal wood. This program however, focuses on supporting producers to use Acacia Mangium wood.

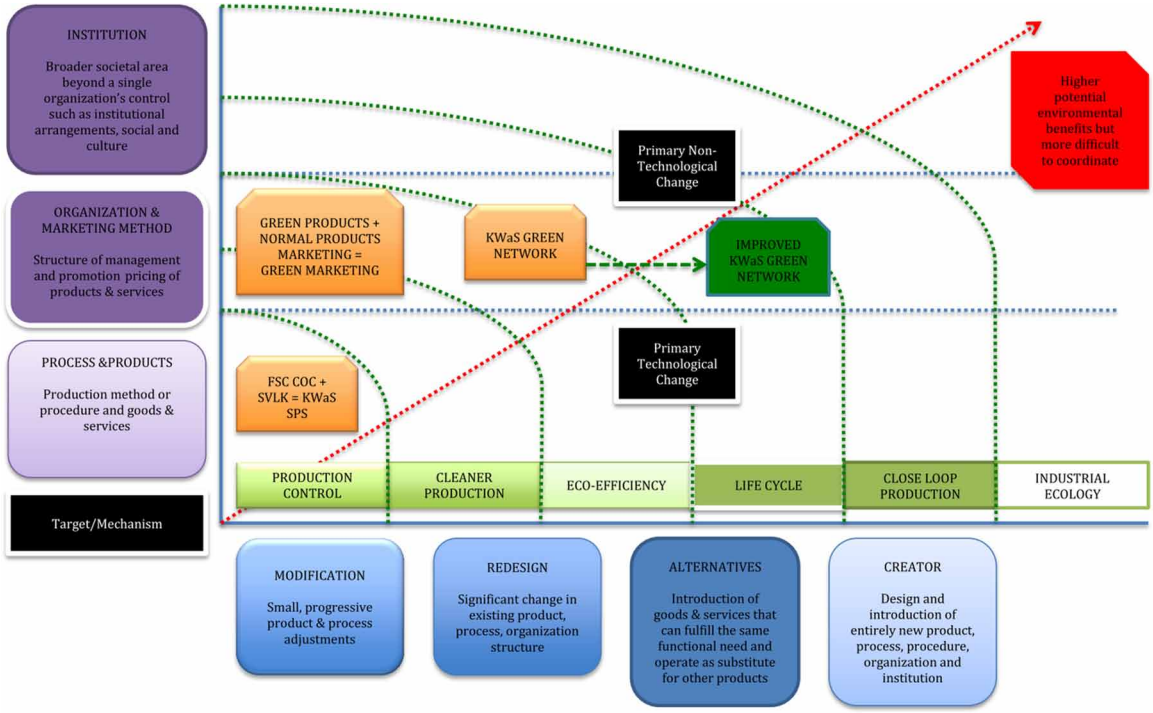
2007: As the firm actively participating in international fairs, KWaS accumulated enough experience to understand customer's preference for sustainable furniture. KWaS won the "Sustainable Home Furnishing Design" competition this year, providing the company with more confidence and motivation to fully implement eco-innovation.

2009: KWaS yet again received aid from international organization, this time from the USA in capital and knowledge transfer to support a creation of sustainable business in developing country through New Venture Indonesia.

2009: KWaS earned the FSC-COC (Chain of Command) certificate, thus requiring the firm to comply with tough and substantial requirements to separate between sustainable and normal wood. This is the year in which KWaS fully adopted eco-friendly practices.

2012: FSC influences in green industry seem to trigger Indonesian government to start its own regulation on sustainable legal wood regulation. This is a starting point for Indonesia to strengthening the infrastructure and promotes green policy.

Based on the findings, it is understood that the understanding of eco-innovation from the perspective of KWaS is quite similar to previous research that has been conducted (Fussler & James, 1996; Little, 2005; Charter & Clark, 2007; Kemp & Pearson, 2008; OECD, 2009). Our research found all of these components to be the same except one new factor that can contribute to the existing knowledge of eco-innovation. During the data collection, the Managing Director of KWaS explained the current activities of eco-innovation which provided us with an understanding of eco-innovation. Our findings define eco-innovation as follows:



Eco-innovation is mostly about producing raw materials from legal natural resources (supply of sustainable legal wood), which are transformed to become a green product (producing green furniture) utilizing certain technology and procedures. Eco-innovation shall consider the concepts of cost management and recycling without any negative effect on the environment (market push-for cost effective and efficiency in production that does not harm the environment). The final product also needs to obtain approval and certificates from the respective agency (regulations for environment, social and economic benefits) and target the local and international markets that need the product (market pull).

Hence, managing this element can help KWaS sustain its business, as it was also part of the KWaS customer network. Furthermore, there is a need to determine the strength of the position of KWaS in green innovation ecology and how the firm can improve its business and position. Using the OECD eco-innovation typology enables us to show the position of KWaS according to the eco-innovation practices at the company with an internationally recognized eco-innovation acceptable tool. This is useful for future comparison and improvements as shown in Figure 1.

Eco-innovation typology can be used to define the effort of KWaS in eco-innovation by viewing the target of eco-innovation versus the mechanism of eco-innovation. As shown in Figure 1, the company's efforts in green marketing are classified as the organization and marketing method and modification mechanism. This means the manner in which KWaS quotes for both green furniture and normal furniture

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Eco-innovation typology

at an agreeable customer price is seen as a part of small and progressive product or process adjustment. The connotation of this marketing method is regarded as a minor eco-innovation practice that contributes towards the sustainability of the firm in the furniture industry.

The ability of KWaS to work well with its network consisting of green suppliers and customers has proven to be substantial according to the typology. If KWaS is able to integrate more suppliers or customers, it will be more challenging and difficult to coordinate but it could put KWaS in a better position, enabling the firm to prolong the production lifecycle of the products and create alternative products or services in innovative ways. Our research also found that the synergy between the suppliers and business partners will lower the production cost and meet the expectations of the customers' green consciousness.

Discussion

SMEs still lack an understanding of the concept of eco-innovation and sometimes do not have a clear standard how best to apply the techniques of eco-innovation. In this chapter, we have outlined some of the enablers that can help SMEs apply the concept of eco-innovation. These include five eco-innovation enablers such as regulation, technology, supplier involvement, firm specific, market orientation and focus, and a green network. In this chapter, we also have discussed eco-innovation typology to measure the attainments of the company in applying eco-innovation.

Previous findings postulated that the network is a mediating factor to foster eco-innovation while our research shows that the green network is one of the main drivers of eco-innovation practices, and, hence, should be put into practice from the beginning of the business or production process. As the firm continues to reap the benefits through its green network, this driver is an inseparable part of the

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

eco-innovation drivers to sustain in the green industry, especially in an emerging market. SMEs will find it difficult to sustain in the green business without fully utilizing the green network to market their products, as this mechanism helps to make the production cost cheaper and reach a wider target market.

The argument is that green products are perceived as a luxury lifestyle product rather than a part of social responsibility to promote environmental sustainability, especially in emerging markets such as Indonesia and Malaysia. In contrast, green-conscious consumers in developed countries such as Canada, France, Germany, Italy, Japan, Spain, the UK, and the USA are willing to pay 5-10 percent more for green products (Manget et al., 2009) because of their high quality perception concerning green products and as part of their responsibility to support environmental care causes. Today, not only are businesses required to take care of the environment, but consumers are also required to support green initiatives.

KWaS furniture is built to order only when the firm's representative (usually the owner) meets potential customers then the customer can customize the furniture according to their needs. Implementing online ordering systems such as that found in the Texas-based Dell Computer Company enables customers to choose the material, components, design, measurement, and additional items for furniture almost everywhere via Internet connection. This system also permits customers to know the price of their custom-made furniture and the desired delivery method. Online ordering systems should be able to capture customer demand or innovation and record of type of materials, components and additional information for KWaS to forecast demand.

While it can be argued that the definition of the green network falls between networking and the green supply chain, it must not be mistaken for a green supply chain as the green network is about sharing knowledge, contacts and fostering a relationship between the supplier and customer with the firm to sustain in the green industry. Although Hermosilla et al. (2010) argued that the diverse contexts of different connotations of eco-innovation may eventually reduce its practical value, as more research regarding green network as a driver of eco-innovation surface in the future, it is expected that the concept will be much clearer, especially in the SME environment.

Future Work and Conclusion

In the future, more research should be done to identify and strengthen knowledge of green networking. In addition, green networking should be associated more with eco-innovation to enhance its relationship. After all, contributes towards business sustainability. Furthermore, more research should occur in emerging markets where technology and huge investments on R&D and innovation are expensive and limited. As a result, firms seek other alternatives to reduce cost. One way to reduce cost while being innovative and considering the environment is to practice lean management (reducing waste) while continuing to improve and innovate by considering customer demands. Such activity is also more practical and affordable for small firms. Additionally, more research should focus on the contribution of SMEs towards eco-innovation and its impact on society as a whole because SMEs with their limited resources are responsible for improving society's quality of life and are regarded as an engine for the economic growth of a country. A country such as Indonesia has the potential to be one of the top producers of green furniture since it is blessed with rich natural resources and a large number of SMEs. Hence, there is a high demand to conduct further studies in this area.

Firms must also continuously add value to their products or services by considering current and future consumer trends. This case study shows that a firm, especially an SME, needs strong support from the government in terms of regulation and policies to encourage them to be innovative. The lack

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

of proper infrastructure and support led to KWaS implementing eco-innovation practices on their own initiative and paying for an expensive FSC certificate which remains limited in its function. The success of the green network that KWaS and its suppliers and customers formed has helped all parties involved to remain in the green business.

By practicing eco-innovation, it is expected that society will benefit from increasing the quality of life and future generations will not suffer from the scarcity of natural resources and pollution. It is understood that in a static world, as explained by Porter and van der Linde (1995), firms will try to balance between profitability and environmental care. However, in the real world it is difficult to find the right balance. As such, both researchers and practitioners have shown that by committing to eco-innovation, firms can create a "win-win" situation as the end results of adopting eco-innovation are profitability and less pollution to the environment.

KEY TERMS AND DEFINITIONS

Built to Order: The furniture produces when customer ordered and paid. This system is able to let customers know the price of their custom made furniture and the delivery method they want.

Eco-Innovation: Innovative in production process which consent to a reduction of environmental risk and benefited to society and stakeholders.

Green Industry: Can be in the shape of various criteria such as clean production, energy conservation, resource efficiency, and adopt eco-design and low carbon technology.

Green Network: Falls between networking and the green supply chain, it must not be mistaken for a green supply chain as the green network is about sharing knowledge, contacts and fostering a relationship between the supplier and customer with the firm to sustain in the green industry.

Online Ordering System: Is system to capture customer demand and record of type of materials, components and additional information for company to forecast the demand.

Typology: Is a framework to study eco-innovation target and mechanism. This tool identified 'products and processes', 'organizations and marketing' 'methods and institutions' as eco-innovation targets while 'modification', 're-design alternatives' and 'creation' are standard mechanisms for eco-innovation.

Chapter 21
Cloud Computing Technologies for Green Enterprises:
Fundamentals of Cloud Computing for Green Enterprises

Parkavi Ravi
Thiagarajar College of Engineering, India

Priyanka Chinnaiah
Thiagarajar College of Engineering, India

Sheik Adullah Abbas
Thiagarajar College of Engineering, India

ABSTRACT

Green computing, also called green equipment, is the environmentally sustainable to use of computers and related resources like - monitors, printer, storage devices, networking and communication systems - effectively with minimal or no impact on the environment. Green cloud is a catchphrase that refers to the potential environmental benefits that information technology (IT) services delivered over the Internet will present society. The word combines the words green meaning environmentally gracious and cloud, the traditional image for online and the shortened name for a type of service delivery model known as cloud processing.

INTRODUCTION

Green Enterprise Computing refers to how business or corporate sectors can deal with the vision of Green computing to manage power utilization and boost energy efficiency. Green Computing or Green IT is the study and practice of using computing resources in an ecological manner to tone down the environmental impacts of computing. All these, in turn, bring up the issue of reducing immoral use of resource and power Green computing whose goals are to reduce the use of perilous materials, maximize

energy efficiency during the product's lifetime, and promote the recoverability or biodegradability of redundant products and factory waste. Computers today not only used in offices but also at homes. This can be called as Green Computing. We use Green Computing because it reduced energy usage from green computing techniques translates into lower carbon dioxide emissions, stemming from a decline in the fossil fuel used in power plants and transportation, Conserving resources means less energy is required to produce, use, and order of products, saving energy and resources saves money. Green computing even includes changing government policy to promote recycling and lowering energy use by individuals and businesses.

Green Cloud computing can be used to manage efficient processing and utilization of computing infrastructure and reduce energy consumption. It is needed for ensuring that the future development of Cloud computing is supportable else, cloud computing with growing front-end client devices interacting with back-end data centers will begin a huge escalation of energy usage. Green Computing is also defined as designing, manufacturing/engineering, using and disposing of computing devices in a way that reduces their environmental impact. IT department is usually always the one department that uses the majority amount of power which in turn is an unnecessary amount of "Green computing" represents environmentally responsible way to reduce power and ecological e-waste. Virtualization, Green Data Centre, Cloud computing, grid computing, Power optimization are the technologies of green computing. Main goals of green computing are to condense the use of poisonous and hazards materials and progress the energy efficiency, recycling of factory waste. Cloud Computing is a model for delivering services in which resources are retrieved from the internet through web-based tools and applications, rather than a shortest connection to a server. Data is stored in servers. Cloud computing structure allows access to information as long as an electronic device has access to the web. This type of system allows human resources to work distantly. It enables hosting of applications from consumer, scientific and business domains. But data centers hosting cloud computing applications consume enormous amounts of energy, causal to high operational costs and carbon footprints to the environment. With energy shortages and global climate modify leading our concerns these days; the power consumption of data center has become a key issue. Therefore, green cloud computing solutions saves energy as well as reduces operational costs. The vision for power resourceful management of cloud computing environments. Such practice expert implementation of server and peripherals as well as decrease the power consumption. It shows how to use resources proficiently and how to reduce the waste Green computing is the requirement to save the energy with the operating cost.

GREEN COMPUTING

Green computing is the ecological use of computers and correlated resources. Such practices include the execution of energy-efficient central processing units, servers, peripherals as well as reduced resource expenditure and proper disposal of electronic waste. Green computing is a study and practice of designing, industrialized, using, and disposing of computers, servers, and associated subsystems such as monitors, printers, storage devices, and networking and interactions systems resourcefully and efficiently with minimal or no impact on the environment." The goals of green computing are similar to green chemistry; reduce the use of hazardous materials, make the most of energy efficiency during the product's lifetime, and promote the recyclability or bidegradability of defunct products and factory waste.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Research continues into key areas such as making the use of computers as energy-efficient as possible, and designing algorithms and systems for efficiency-related computer technologies.

There are several approaches to green computing namely

- Algorithmic efficiency
- Resource allocation
- Virtualization
- Power management

NEED OF GREEN COMPUTING IN CLOUDS

Modern data centers, in service under the Cloud computing model are hosting a multiplicity of applications ranging from those that run for a few seconds to those that run for longer periods of time on collective hardware platforms. The need to manage multiple applications in a data center creates the challenge of on-demand reserve provisioning and allocation in response to time-varying workloads. Normally, data center capitals are statically allocated to applications, based on peak load characteristics, in order to maintain isolation and provide performance guarantees. Recently, high performance has been the individual concern in data center deployments and this require has been fulfilled without paying much deliberation to energy consumption. The average data center exhaust as much energy as 25,000 households. As energy costs are increasing while availability dwindles, there is a need to shift focus from optimizing data center resource management for sterilized performance to optimizing for energy efficiency while maintaining high service level performance.

Data centers are not only luxurious to maintain, but also unsociable to the environment. Data centers now drive more in carbon emissions than both Argentina and the Netherlands. High energy costs and huge carbon footprints are incurred due to huge amounts of electricity needed to power and cool numerous servers hosted in these data centers. Cloud service providers need to adopt measures to ensure that their profit margin is not considerably reduced due to high energy costs. For instance, Google, Microsoft, and Yahoo are building large data centers in unproductive desert land s the Columbia River, USA to exploit cheap and reliable hydroelectric power.

Lowering the energy convention of data centers is a demanding and composite issue because computing applications and data are increasing so quickly that progressively larger servers and disks are desirable to process them fast enough within the essential time period. Green Cloud computing is envisioned to achieve not only well-organized processing and utilization of computing infrastructure, but also minimize energy utilization. This is essential for ensuring that the future growth of Cloud computing is sustainable. Otherwise, Cloud computing with increasingly persistent front-end client devices interacting with back-end data centers will cause an huge acceleration of energy usage.

To address this problem, data center resources need to be managed in an energy well-organized manner to drive Green Cloud computing. In particular, Cloud resources need to be allocated not only to satisfy QoS requirements specific by users via Service Level Agreements (SLA), but also to decrease energy usage.

GREEN CLOUD SERVICES

- **Infrastructure as a Service (IaaS):** "Infrastructure as a Service (IaaS)", delivers computer infrastructure – A platform virtualization environment - as a service. Rather than purchasing servers, software, data-center space or network tackle, clients instead as a fully outsourced service.
- **Desktop as a Service (DaaS):** With DaaS, deployment and management of the desktop environment is beginner's. Data and applications are accessed from beginning to end a virtual environment, allowing businesses and providers to support, patch and maintain one environment rather than managing personage desktops during an organization. And, with one central environment, data is more secure while still allowing users the elasticity to choose between working on desktop or mobile devices.
- **Software as a Service (SaaS):** "Software as a Service (SaaS), sometimes referred to as "software on demand," is software that is deployed over the internet and/or is deployed to run behind a firewall on a local area network or personal computer.
- **Disaster Recovery as a Service (DRaaS):** Serve Restore, our cloud disaster recovery solution for on-premise physical servers, is often called our better than backup solution. With Serve Restore, our engineers prebuilt a fully designed virtual environment for your data. When disaster strikes, we fully manage the recovery of your servers, construct them to run within our cloud environment in just a combine of hours.
- **Backup as a Service (BaaS):** Green Clouds backup solution powered provides a remote, secure, cloud based storage destination for obtainable server infrastructures.

ENERGY SAVINGS IN THE CLOUD

Here are some of the ways that the cloud can help a corporation cut its carbon footprint down to size:

- **Fewer Machines:** With the cloud, server deployment rates are typically 60-70%, while in many small business and industry environments, exploitation rates hover around 5 or 10%. As a result, shared data centers can employ small number machines to get the same capacity.
- **Equipment Efficiency:** Larger data centers frequently have the resources to allow them to improve to energy-saving equipment and building systems. Usually, this is not an option in smaller organizations where this good organization is not the focus.
- **Consolidated Climate Control Costs:** In order for a server to run at its the highest point performance, its temperature and humidity level must be suspiciously controlled, and cloud providers can use high density efficient layouts that are unbreakable for in-house centers to reproduce.
- **Dynamically Allocated Resources:** In-house data centers need extra servers to handle peak data loads, and cloud providers can enthusiastically allocate resources where fundamental in order for fewer machines to sit idle. Cloud computing has massive potential to transform the world of IT: reducing costs, improving efficiency and business agility, and s to a more sustainable world.

There are basically four main entities involved in the Green Cloud Computing Environment:

1. **Consumers:** Cloud consumers suggest service requirements from anywhere in the world to the Cloud. It is main to notice that there can be a difference between Cloud consumers and users of

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

deployed services. For occurrence, a consumer can be a company deploying a Web application, which presents unreliable workload according to the number of users accessing it.

2. **Green Resource Allocator:** Acts as the interface between the Cloud infrastructure and consumers. It requires the communication of the following components to support energy-well-organized resource management:
    a. **Green Negotiator:** Negotiates with the consumers/brokers to complete the SLA with specified prices and penalties (for violations of SLA) between the Cloud provider and consumer depending on the consumer's QoS requirements and energy reduction schemes. In case of Web applications, for illustration, QoS metric can be 95% of requirements being served in less than 3 seconds.
    b. **Service Analyzer:** Interprets and analyses the service requirements of a submitted request before deciding whether to accept or reject it. Hence, it needs the most modern load and energy information from VM Manager and Energy Monitor respectively.
    c. **Consumer Profiler:** Gathers specific characteristics of customers so that important clients can be granted particular privileges and prioritized over other clients.
    d. **Pricing:** Decides how service requests are charged to manage the supply and demand of computing resources and facilitate in prioritizing service allocations effectively.
    e. **Energy Monitor:** Study and resolve which physical machines to power on/off.
    f. **Service Scheduler:** Assigns requests to VMs and determines resource privilege for allocated VMs. It also decides when VMs are to be added or uninvolved to meet demand.
    g. **VM Manager:** Keeps track of the availability of VMs and their resource privilege. It is also in charge of migrating VMs across physical machines.
    h. **6. Accounting:** Maintains the actual usage of resources by requests to compute usage costs. Historical usage information can also be used to improve service allocation decisions.
3. **VMs:** Multiple VMs can be enthusiastically started and stopped on a single physical machine to meet accepted requests, hence providing maximum flexibility to construct various partitions of resources on the same physical machine to different explicit requirements of service requests. Multiple VMs can also parallel run applications based on different operating system environments on a single physical machine. In addition, by dynamically migrating VMs crosswise physical machines, workloads can be consolidated and unexploited resources can be put on a low-power state, turned off or construct to operate at low-performance levels (e.g., using DVFS) in order to save energy.
4. **Physical Machines:** The underlying physical computing servers present hardware infrastructure for creating virtualized resources to meet service demands.

CLOUD COMPUTING MORE GREEN ENTERPRISES

Three approaches have been tried out to build cloud computing environments more environmental friendly. These approaches have been tried out in the data centers under experimental conditions. The methods are:

- **Dynamic Voltage Frequency Scaling Technique (DVFS):** Each electronic circuitry will have an operating clock related with it. The operating frequency of this clock is familiar so that the supply voltage is synchronized. Thus, this method heavily depends on the hardware and is not convenient

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

according to the unreliable needs. The power savings are also low compared to other approaches. The power savings to cost acquire ratio is also low.

- **Resource Allocation or Virtual Machine Migration Techniques:** In a cloud computing environment, each physical machine hosts a number of virtual machines engaging which the applications are run. These virtual machines can be transferred across the hosts according to the varying needs and accessible resources. The VM migration method focuses on transferring VMs in such a way that the power increase is least. The most power well-organized nodes are selected and the VMs are transformed across to them. This method is dealt in detail later.
- **Algorithmic Approaches:** It has been experimentally resolute that an ideal server consumes about 70% of the power utilized by a fully utilized server.

Using a neural network interpreter, the green scheduling algorithms first estimates required dynamic workload on the servers. Then preventable servers are turned off in order to minimize the number of running servers, thus minimizing the energy use at the points of utilization to present benefits to all other levels. Also, several servers are added to help reassure service-level agreement. The bottom line is to protect the environment and to condense the total cost of ownership while ensuring quality of service.

VM Migration

The problem of VM distribution can be divided in two: the first part is admission of new requests for VM provisioning and placing the VMs on hosts, whereas the second part is optimization of current allocation of VMs.

Optimization of present allocation of VMs is carried out in two steps: at the first step, we select VMs that need to be migrated, at the second step chosen VMs are located on hosts using MBFD algorithm. We propose four analytical methods for choosing VMs to migrate. The first methodical, Single Threshold (ST), is based on the idea of setting upper utilization threshold for hosts and placing VMs while maintenance the total utilization of CPU below this threshold. The aim is to preserve free resources to prevent SLA violation due to consolidation in cases when exploitation by VMs increases. At each time frame all VMs are reallocated using MBFD algorithm with further condition of keeping the upper utilization threshold not violated. The new placement is achieved by live migration of VMs.

The other three analytical are based on the idea of setting upper and lower utilization thresholds for hosts and maintenance total utilization of CPU by all VMs between these thresholds. If the utilization of CPU for a host goes less than the lower threshold, all VMs have to be migrated from this host and the host has to be switched off in order to remove the idle power consumption. If the utilization goes over the upper threshold, some VMs have to be migrated from the host to reduce exploitation in order to prevent probable SLA violation. We propose three policies for choosing VMs that have to be migrated from the host.

- **Minimization of Migrations (MM):** Migrating the smallest number of VMs to minimize migration in the clouds.
- **Highest Potential Growth (HPG):** Migrating VMs that have the lowest usage of CPU reasonable to the requested in order to minimize total potential increase of the utilization and SLA violation.
- **Random Choice (RC):** Choosing the essential number of VMs by alternative them according to a uniformly distributed random variable.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

FEATURES OF CLOUDS ENABLING GREEN COMPUTING

Cloud Infrastructure has developed to a key environmental disquiet keeping in view of energy consumption and carbon production. The key technology for power efficient Clouds is "Virtualization", development of presenting a logical grouping or subset of computing resources so that they can be accessed in ways that give benefits over the unusual configuration.

The following are the four key factors that have enabled the Cloud Computing to lower power usage and carbon radiation from ICT. In this way, organizations can reduce carbon radiation at last 30% per user by moving their applications to the cloud.

1. **Dynamic Provisioning:** In long-established settings, IT companies end up deploying far more infrastructure than desired. It is very difficult to forecast the demand at a time and to warranty availability of services and to maintain confident level of service quality to end users. The virtual machines in a Cloud infrastructure can be live migrated to another host in case user application requires more property. Cloud providers observe and expect the demand and thus allocate resources according to demand. Those applications that require less number of resources can be consolidated on the same server. Thus, datacenters always continue the active servers according to current demand, which results in low energy consumption than the traditional approach of over-provisioning.
2. **Multi-Tenancy:** Cloud computing infrastructure reduces on the whole energy usage and associated carbon emissions. The SaaS providers serve multiple companies on same infrastructure and software. This approach is obviously more energy efficient than multiple copies of software installed on different infrastructure, which can minimize the need for extra infrastructure. The smaller variation in demand results in better prediction and results in greater energy savings.
3. **Server Utilization:** Using virtualization technologies, several applications can be hosted and executed on the same server in separation, thus lead to utilization levels up to 70%. Even though high exploitation of servers results in more power consumption, server running at higher operation can process more workload with similar power usage.
4. **Datacenter Efficiency:** The power efficiency of datacenters has main impact on the total energy usage of Cloud computing. By using the most energy well-organized technologies, Cloud providers can considerably improve the Power Usage Effectiveness (PUE) of their datacenters. Cloud computing grant services to be moved involving multiple datacenter which are running with better PUE values. This is achieved by using high speed network, virtualized services and dimension, and monitoring and accounting of datacenter.

APPROACHES TO GREEN COMPUTING

Green Data Center

Practical requirement of data centers are as follows:

- Provide a physical secure position for server.
- Should provide all-time network connectivity in data center.
- Should provide essential power to operate all equipment.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Characteristics:

- Design must be simple.
- Design must be scalable.

The design should be scalable because once it is finalized it must work for any size of computer center:

- Design must be modular.
- Design must be flexible.

Virtualization

Virtualization, a term that used a variety of techniques, methods or approaches to create a virtual environment, such as a virtual hardware platform, virtual operating system (OS), storage device, or network resources.

Challenges

Complexities of licensing are the issue with virtualization. For instance, a Linux based server offers a virtualized windows server must satisfy licensing requirements. Because of this licensing issue flexibility of virtualization and benefits of on demand virtualization is in a weak position. Some venders of proprietary software have attempted to update licensing scheme to address the virtualization but flexibility and cost issues are opposing requirements. Virtualized desktop results in trust on centralized servers (for computing and SAN storage) and the network (and higher-bandwidth requirements). Dependency on centralized server and network leaves the end users vulnerable to server. The user able to operating locally through an outage, but when user logs off or reboots the machine it become dead This is in contrast with thick clients where the user locally operates continually until the connectivity can be restored:

1. **Product Longevity:** Gartner maintains that the PC developed process accounts for 70% of the natural resources used in the life cycle of a PC. Therefore, the biggest involvement to green computing usually is to broaden the equipment's lifetime. Another report from Gartner recommends to "Looking for product longevity, including upgradability and modularity. "For instance, manufacturing a new PC makes a far bigger environmental footprint than manufacturing a new RAM module to improve an existing one.
2. **Data Center Design:** Data center services are heavy consumers of energy. The U.S. Department of Energy estimates that data center services consume up to 100 to 200 times more energy than standard office buildings. According to the U.S. Department of Energy, Information technology (IT) systems, Environmental settings, Air management, Cooling systems and Electrical systems are the primary areas on which to focus energy proficient data center design best practices.
3. **Software and Deployment Optimization:** It includes algorithmic effectiveness, resource allocation, workstation servers and virtualization. The efficiency of algorithms has an impact on the amount of computer resources essential for any known computing function and there are many efficiency trade-offs in writing programs. Allocating resources according to the energy can be saved. With virtualization, a system administrator could merge a number of physical systems into virtual ma-

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

chines on one single, powerful system, by this means unplugging the original hardware and dropping power and cooling disbursement. Virtualization should be able to support distributing work so that servers are either busy or put in a low-power sleep state. Terminal servers have also been used in green computing. When using the system, users at a terminal connect to a central server; all of the authentic computing is done on the server, but the end user experiences the operating system on the terminal. These can be combined with thin clients, who use up to 1/8 the amount of energy of a common workstation, resulting in a decrease of energy costs and consumption.

4. **Power Management:** The Advanced design and Power Interface (ACPI), an open industry standard, allows an operating system to straight control the power-saving aspects of its fundamental hardware. This allows a system to automatically revolve off components such as monitors and hard drives after set periods of inactivity. In addition, a system may hibernate, when most components (including the CPU and the system RAM) are turned off. ACPI is a successor to an previous Intel-Microsoft standard called Advanced Power Management, which allows a computer's BIOS to control power management functions. Some programs allow the user to physically adjust the voltages complete to the CPU, which reduces both the amount of heat produced and electricity consumed. This process is called under volt. Some CPUs can automatically under volt the processor, depending on the workload; this technology is called "SpeedStep" on Intel processors.
5. **Materials Recycling:** Recycling computing tools can keep destructive materials such as lead, mercury, and hexavalent chromium out of landfills, and can also replace equipment that otherwise would need to be pretend, saving further energy and emissions.
6. **Telecommuting:** Teleconferencing and telepresence technologies are often implemented in green computing resources. The advantages are many; improved worker satisfaction, decrease of greenhouse gas emissions related to travel, and increased income margins, resulting from lower overhead costs for office space, heat, lighting, etc.
7. **Telecommunication Network Devices Energy Indices:** The energy expenditure of information and communication technologies (ICTs) is today important even when compared with other industries. Recently some study tried to identify the key energy index that allows a relevant comparison between different devices (network elements). This analysis was focus on how to optimize device and network consumption for carrier telecommunication by itself. The target was to allow an immediate observation of the relationship between the arrangement technology and the environmental impact.

Need of Virtualization for Green Computing

Cloud computing cannot be always appropriate for ecology. The recent studies confirmed that rely on a server is in the main more environmentally friendly, although care must be taken to a entire sequence of parameters to compute the best real efficiency of the cloud. In other words, the data centers force on real environment by producing heat. It is also important to keep in mind that a data center has a more environmental collision than a system. The research was based on setups those include virtualization and without virtualization. It is found that on-site server with no virtualization will emit about 46kg of CO2 per year. If data is stored on the public cloud whose servers are not that well-organized, those servers are not well used and use electricity from higher carbon-emitting sources. Thus, there will be some practices by which servers can be run with greener solutions. Also, studies also proved that cloud systems are more energy capable and carbon efficient than that of an ordinary system. It consists of a

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

concept of use of virtualization. And thus, virtualization is critical to cloud computing. It simplifies the delivery of services by provided that a platform for optimizing complex IT resources in a scalable manner. That makes cloud computing so cost effective. In cloud computing it needs to support many different service environments, to manage the various aspects of virtualization in cloud computing most companies use hypervisors. A hypervisor, also called a virtual machine manager (VMM), is a program that allows multiple operating systems to share a on its own hardware host. Each operating system appears to have the host's processor, memory, and other property all to itself. However, the hypervisor is scheming the host processor and resources, allocating what is needed to each operating system in turn and making sure that the guest operating systems (called virtual machines) cannot disrupt each other. The hypervisors can support different operating system environment hence, the hypervisor becomes a perfect delivery mechanism by allowing you to show the similar application on lots of different systems. Because hypervisors can load multiple operating systems, they are a very practical way of getting things virtualized rapidly and efficiently.

Discussion on How Virtualization Works as in the Green Cloud Computing

Let's discuss about how virtualization makes cloud green or eco-friendly. We know, the data center consumes the power as enormous as that can be used to power thousands of homes. The environmentalists and computer scientists are working on reducing the huge amount of power used and make data centers additional energy-efficient than they currently are. The virtualization can be the solution for it. It can be used to decrease power consumption by data centers. The main purpose of the virtualization is that to make the most efficient use of available system possessions, including energy. A data center, installing virtual infrastructure allows several operating systems and applications to run on a lesser number of servers, it can help to reduce the in the main energy used for the data center and the energy consumed for its cooling. Once the number of servers is reduced, it also means that data center can decrease the building size as well. Some of the advantages of Virtualization which directly brunt efficiency and contributes to the environment include: Workload balancing across servers, Resource allocation and distribution are better monitored and managed and the Server utilization rates can be increased up to 80% as compared to initial 10-15%. The energy saved per server would be near about 7000 KWH per year. It means that there would be large saving of energy.

Green Computing Techniques to Manage Power in Computing System

These techniques can be classified at different levels:

1. Hardware and Firmware Level
2. Operating System Level
3. Virtualization Level
4. Data Center Level

Hardware and Firmware level techniques are applied at the developed time of a machine. These techniques control all the optimization methods that are applied at the time of scheming at the logic, circuit, architectural and organization levels. Operating System level techniques include methods which take care with reference to programs at operator level. Virtualization level techniques used the perception of

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Virtual Machines (VMs) to manage power. In this number of VM are created on a physical server, so that reduce the amount of hardware in use and improve the utilization of resources. Data Center level techniques are practical at data centers and embrace methods which are used to manage workload across physical nodes in data centers.

Adoption of Green Computing Practices

With the digital development, the IT industry has focused on the increase and use of IT products and services to satisfy the raising demands of business consumers. Due to this the following factors are impacting the IT industry and coercing the acceptance of Green Computing practices:

1. Rapid growth in the size and scale of data centers
2. Advancement in CPUs
3. Energy Cost
4. Server utilization
5. Impact on the environment.

Framework for Green Cloud Computing

Green cloud computing frameworks to supply energy capable services to the cloud users. There are mainly four components as described below:

1. **Users/Brokers:** At topmost layer the cloud users/brokers demand for services from anywhere around the world. APIs provides the capacity to store VM images and source files for web server mechanism.
2. **Green Service Request Manager:** It provides a crossing point between the cloud users and cloud infrastructure. It handles all the requests generated by the cloud users and supports the energy efficient resources. It also uses various scheduling schemes for distribution of virtual machines.
3. **Virtual Machines:** Commonly known as Virtual appliances it includes software to create and deploy the applications. VMs are used to handle the service requests at the virtual machine layer.
4. **Physical Machines:** The lowest layer exhibits the physical objects or resource instances to map the services to particular machine so that the calculation of the particular task can be performed.

GREEN CLOUD COMPUTING BENCHMARKS

With the advancement of technology, where the cloud computing resources are being remotely controlled by the service providers It is necessary to provide the energy efficient services while maintaining the cost. To keep such performance tradeoffs various benchmarks were introduced previously to measure the rate of power consumption, energy efficiency, resource utilization etc. at the level of system, data centre and server. These benchmarks are listed with their brief formulation, level of usage and application discipline in Table.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

VM MIGRATION

The problem of VM allocation can be divided in two: the first part is access of new requests for VM provisioning and insertion the VMs on hosts, whereas the second part is optimization of present allocation of VMs.

Optimization of current allocation of VMs is carried out in two steps: at the first step, we select VMs that require to be migrated, at the second step chosen VMs are located on hosts using MBFD algorithm. We propose four heuristics for choosing VMs to migrate. The first heuristic, Single Threshold (ST), is based on the idea of location upper consumption threshold for hosts and placing VMs while maintenance the total exploitation of CPU below this threshold. The aim is to protect free resources to prevent SLA destruction due to consolidation in cases when utilization by VMs increases. At each instance frame all VMs are reallocated using MBFD algorithm with extra condition of keeping the upper exploitation threshold not violated. The new assignment is realized by live migration of VMs.

The other three heuristics are based on the idea of setting upper and lower consumption thresholds for hosts and maintain total utilization of CPU by all VMs connecting these thresholds. If the utilization of CPU for a host goes under the lower threshold, all VMs have to be migrated starting this host and the host has to be switched off in order to remove the idle power consumption. If the utilization goes over the upper threshold, some VMs contain to be migrated from the host to reduce exploitation in order to check potential SLA violation. We propose three policies for choosing VMs that have to be migrated from the host.

- **Minimization of Migrations (MM):** Migrating the smallest amount of number of VMs to minimize migration overhead.
- **Highest Potential Growth (HPG):** Migrating VMs that have the lowest usage of CPU moderately to the requested in order to minimize total potential increase of the exploitation and SLA violation.
- **Random Choice (RC):** Choosing the required number of VMs by selection them according to a uniformly distributed random variable.

RECENT IMPLEMENTATIONS OF GREE COMPUTING

Blackle

Is a search-engine site motorized by Google Search. Blackle came into individual based on the concept that when a computer screen is white home, your computer exhausts 74W. When the screen is black it consumes only 59W.Based on this theory if each person switched from Google to Blackle, mother earth would save750MW each year was a really good implementation of Green Computing. The principle behind Blackle is based on the information that the display of different colors consumes different amounts of energy on computer monitors.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Fit-PC

A tiny PC that draws only 5w: Fit-PC is the size of a book and extremely silent, yet fit sufficient to run Windows XP or Linux.fit-PC is projected to fit where a standard PC is too bulky, noisy and power hungry. you ever wished for a PC to be compact, quiet and green then fit- PC is the perfect fit for you. Fit-PC draws only5 Watts, consuming in a day less power than a conventional PC expend sin 1 hour. You can leave fit-PC to work 24/7 without making a dent in your electric.

Zonbu Computer

The Zonbu is a new, very energy well-organized PC. The Zonbu consumes just one third of the power of a distinctive light bulb. The tool runs the Linux operating system using a 1.2 gigahertz processor and 512 megs of RAM. It also contains no moving parts, and does even surround a fan. You can get one for as little as US$99, but it does involve to sign up for a two-year subscription

Sunray Thin Client

Sun Microsystems is exposure increased customer attention in its Sun Ray, a thin desktop client, as electricity prices scale, according to Subodh Bapat, vice president and chief engineer in the Eco liability office at Sun. Thin clients like the Sun Ray consume far less electricity than predictable desktops, he said. A Sun Ray on a desktop consumes 4 to 8 watts of power, because most of the important computation is performed by a server. Sun says Sunrays are mainly well suited for cost-sensitive environments such as call centers, education, healthcare, service providers, and finance. PCs have more controlling processors as well as hard drives, something thin clients don't have. Thus, expected PCs always consume a significantly larger amount of power. In the United States, desktops need to consume 50 watts or less in idle mode to succeed for new rigorous Energy Star certification

The Asus Eee PC and Other Ultra Portables

The "ultra-portable" class of personal computers is characterized by a small size, practically low power CPU, compact screen, low cost and innovations such as using flash memory for storage rather than hard drives with revolving platters. These factors combine to enable them to run more professionally and use less power than a standard form factor laptop. The Asus Eee PC is one example of an ultraportable. It is the size of a book, weighs less than a kilogram, has built-in Wi-Fi and uses flash memory as a substitute of a hard drive. It runs Linux too.

RESOURCE ALLOCATION STRATEGY

There are various Strategies which are related to Resource Allocation:

1. **Resource Allocation Strategy in Cloud Computing:** In cloud computing, Resource Allocation (RA)is the procedure of allocating accessible resources to the demanded cloud requirements above the internet. Resource allocation starves services if the allocation is not grasped accurately. Resource

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

provisioning solves that impede by permitting the ability providers to grasp the resources for every single individual module. Resource Allocation Strategy (RAS) is all relating to incorporating cloud provider hobbies for employing and allocating manipulated resources inside the check of cloud nature so as to encounter the needs of the cloud application. It needs the kind and number of resources demanded by every single request in order to finish a user job. The order and period of allocation of resources are furthermore an input for an optimal RAS.

2. **Task Scheduling Algorithms in Cloud Environment:** Cloud users join virtualization, computerized multimedia, and internet connectivity to furnish their services. A frank agent of the cloud nature is client, server, and web connectivity. A hybrid computing ideal permits client to impact both area and private computing services to expertise a extra flexible and cost-effective computing utility. The area cloud nature involves Web established request, Data as a ability (DaaS), Groundwork as a Service (IaaS), Multimedia as a ability (SaaS), and Email as a ability (EaaS). A confidential cloud accesses the resources from the area cloud association to furnish services to its clients.
3. **Policy and Job Scheduling Algorithms of Cloud Computing:** Job arranging of cloud computing mentions to the procedure of adjusting resources amid unrelated resource users according to specific laws of resource use below a given cloud environment. Resource organization and job arranging are the key technologies of cloud computing. At present, there is not a uniform standard for job arranging in cloud. Most algorithms focus on job correspondent that is nearly accountable for all the task allocations, replies and retransmissions.
4. **Resource Allocation Policies in Cloud Computing Environment:** Resource allocation is a subject that has been dispatch in many computing areas, such as operating systems, grid computing and datacenter management. A Resource Allocation System (RAS) in Cloud Computing can be seen as any device that aims to guarantee that the applications' requirements are attended to correctly by the provider's infrastructure. Along with this guarantee to the developer, resource allocation mechanisms should also consider the current status of each reserve in the Cloud environment, in order to apply algorithms to better distribute physical and/or virtual assets to developers' applications, thus minimizing the operational cost of the cloud location.
5. **Ant Colony Optimization Algorithm for Resource Allocation:** Cloud computing dispersed cluster uses a Master/Slaves structure. There is a Chief node responsible for manipulating and supervision all the Slave nodes. As the specific condition of resource is strange below cloud circumstance, and the webs do not have a fixed topology, the construction and the resource allocation of the complete cloud nature is unpredictable.
6. **Dynamic Resource Allocation Strategy in Cloud Computing Environment:** Cloud data centers can be a distributed web in construction that is composed of countless compute nodes, storage nodes, and web node. Every single node is industrialized by a sequence of resources such as CPU, recollection, web bandwidth and countless more. These resources are shouted multidimensional resources. The number of contiguous mechanisms (VMs) used in a huge cloud data center every single date can be extremely colossal, and their placement familiarize a momentous burden on the data center web.
7. **Dynamic Resource Allocation using Migration in Cloud:** The cloud computing period guarantees subscribes that it sticks to the ability level concurrence by bestowing resources as ability and by needs. Though, date by date subscribers' needs are rising for computing resources and their needs have animated heterogeneity and period irrelevance. But in cloud computing nature, resources are public and if they are not accurately distributed next it will result into resource wastage.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Reducing Use of Paper

Much of our communication and documentation is still conducted via a paper shadow. Not only does this leave loads of paper to manage, there is the economic cost of all the ink and paper and, more importantly, there is also an environmental cost concerned with printing that we all bear as

"a society. The environmental impact of printing is significant and wide ranging. The printing business is one of the most polluting industries in the world for the following reasons:

- The printing industry uses important amounts of energy from heating and lighting to powering tools and final delivery.
- Large quantities of water are used in most printing processes. In most of the cases, infected water is liable without cleaning.
- Comparatively high levels of waste are generated in the print development. From printing plates and ink tins to pallets and packaging there is plenty of waste formed by the printing industry.
- Many volatile organic compounds (VOCs) are said to branch from the printing industry. As the ink dries, the isopropyl alcohol used as a damping solution, evaporates at room temperature, releasing VOCs. These are colorless, odorless gases that are dangerous to the surroundings; contribute to global warming and the making of ozone, as well as being harmful to pressroom workers.
- To make paper, pulpwood trees are cut down in large numbers and are then transported to document mills where pulpwood fibers are strong and dried into sheets. This process is particularly energy consuming and the polluted waste water produced pose a major environmental hazard. Further, the impact of deforestation on the environment is a greater reason for concern.

The following policies can be adopted to reduce paper wastes in the enterprise:

- Memos and newsletters that workers should see, but need not keep can be posted online.
- Document editing and formatting features of ubiquitous word processing software can be broken instead of making drafts on document.
- Information can be exchanged electronically via e-mails and formal online forums instead of fax or mailed letters when probable.
- An electronic filing system can be put in place for easy and well-organized storage and recovery of all electronic documents.

DESKTOPS VS. LAPTOPS

Laptop computers may require the absolute power of their desktop counterparts, but they are more feasible from a green computing perception.

The following points highlight some of the s of using laptops over desktops:

- **Energy Efficiency:** Laptops consume on average 20-50 watts of electricity (which can be further trimmed in power saving modes) whereas desktops consume about 60-200 watts. The conventional Cathode Ray Tube (CRT) monitors of desktops also use more power than the Liquid Crystal Display (LCD) monitors of current laptops.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

- A laptop is always better to use than a desktop computer as it uses 1/3 of the energy and is portable thus taking up less room. The fundamental issue with present desktops is that they consume significant energy even in idle mode, but by their design, laptops use much less active power.
- **Battery Power:** Laptops benefit from energy efficiency as a necessary importance of their battery-powered design so much so that manufacturers often tout how long laptop computers can run on battery power as a selling position.

The prospect of extending the battery life of laptops can be approached from two perspectives:

- Adding a larger, higher-capacity battery to the laptop
- Designing the laptop hardware to use less energy.
- **Less Potential, Less Consumption:** Laptops contain a lower possible for maximum power consumption because they attribute smaller power supply units (PSUs). A piece desktop computer has the potential to draw 400Wh energy at complete load with a larger PSU, whereas a performance laptop may be limited to 90Wh because of its smaller PSU. Laptops often include considerably slower performing but more energy well-organized processors and other components, compared to correspondingly-named desktop parts, so processes may take longer to complete. However, many firms such as Intel have already inhabited greener desktop computing in a big way with highly energy-efficient processors like Atom Businesses are more and more switching to or substituting on premise solutions with cloud-based models for resource and processing power constraint to tap benefits like faster scale up/scale-down of capacity, pay-per-use pricing, and access to various cloud-based applications. Cloud computing solutions also allow enterprises to ——virtual cloud servers. It eliminates the need to install and preserve bulky, energy consuming physical servers by relocating them on the Internet. In many small business and commercial environments, server utilization rates are around 5 or 10 percent, but with the cloud, consumption rates are typically 60-70 percent due to shared data centers that employ fewer machines to get an equivalent capacity. The cloud-based alternative can be used in areas such as data storage, networking, software applications and operating systems. As a result, business or business sectors can save a lot of money, time and resources on maintenance and support.

The cloud infrastructure addresses two significant elements of a green IT approach: resource efficiency and energy efficiency:

- **Resource Virtualization:** Virtualization is a initial technology for deploying cloud-based infrastructure that allows a particular physical server to run multiple operating system images concurrently. As an enabler of consolidation, server virtualization reduces the whole physical server footprint, which has intrinsic green benefits.
- From a resource-efficiency perception, less equipment is needed to run workloads, which proactively reduces data center space and the ultimate e-waste footprint. From an energy-efficiency perspective, with less physical tackle plugged in, a data center will use less electricity. It is attraction noting that server virtualization is the most extensively adopted green IT project implemented or planned, with 90 percent of all IT organizations worldwide adopting it by
- **Automation Software:** The presence of virtualization unaccompanied does not maximize energy and reserve efficiencies. To rapidly provision, move, and scale workloads, cloud-based infrastruc-

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

ture relies on computerization software. Combined with the right skills and prepared and architectural standards, computerization allows IT professionals to make the most of their cloud-based infrastructure asset by approaching the limits of traditional consolidation and exploitation ratios. The higher these ratios are, the less physical infrastructure is needed, which in turn maximizes the energy and resource efficiencies from server virtualization.

- **Pay-Per-Use Self-Service:** The pay-per-use nature of cloud based communications encourages users to only consume what they need and not more. Shared with self-service, lifecycle management will improve, as users will ——turn off or transfer resources and infrastructure after use. The pay per-use self-service capability of the cloud thus drives resource and energy efficiencies simultaneously.
- **Multi-Tenancy:** Multi-tenancy allows lots of different organizations (public cloud) or many different business units inside the same organization (private cloud) to benefit from an ordinary cloud-based infrastructure.
- **Reduce Costs:** Consolidation means fewer servers, which in turn means lower cooling and space requirements, which means lower energy costs.
- **Fulfill Regulations:** By tapping more efficient and therefore lower-emitting resources, cloud customers can reduce their carbon emission and be better-positioned to meet regulatory standards.
- **Improve Resiliency:** Consolidation and improved exploitation create more space, more command, and more cooling capacity within the same facility. Tapping into the cloud offloads the management of those resources to the cloud provider.

THE SECURITY IMPLICATIONS OF GREEN ENTERPRISES

Virtualization

There is also anxiety that predictable information security controls cannot mark malevolent traffic passing between virtual machines (VMs). “In a virtual environment, if you contaminate one virtual server or one operating system, you peril infecting all the other systems and server management in that environment,” says Doug Cooke, manager, system engineers at anti-virus firm McAfee’s Canadian office. “There’s no documentary confirmation that actual threats have got through all the operating systems in a virtual environment, but ‘white-hat’ groups have proved it’s possible.”

“A few firewall products have been ported to the VMware environment and they organize taps, so they are preliminary to see traffic between the VMs, but they can’t block it”, O’Higgins says. “So these controls are not for the most part effective. After all, you want firewalls to block assured traffic, not just look at it. The approach Third Brigade uses is host security, so that each individual VM is confined, and malicious traffic connecting VMs can be detected and blocked.”

Simple Measures

Consolidation isn’t restricted just too broad operating systems, however. Information security vendors have been squeezing more functions into a single box though driving down power consumption. “As UTM appliances can perform multiple security functions such as firewall, spam / web filtering, IPS/IDS, and gateway anti-virus, firms can reduce the number of dissimilar security systems on their networks”,

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Forti Green allows clients to approximation the potential annual energy savings of a UTM-based network security topology compared to a traditional architecture with multiple info security devices at each site. "You tell Forti Green the number of UTM boxes in the branch offices, and the totals at the head office and the regional offices," James says. "The branch devices can have fewer security functions than the regional office devices, which will in turn have less than the head office boxes."

Routers

Cisco has started putting numerous virtual security functions onto its routers, says Fred Kost, director of advertising, Cisco Virtual Office (CVO). "We offer content program on our ASR edge routers and contented filtering, firewalls and intrusion prevention on our ISR boxes", he says. "Cisco's Adaptive Security Appliances include firewall, IPSec and SSL VPN security, and email screening. The ASR can also run multiple virtual firewalls for divide partitioned networks."

Power Management

The effort made to decrease the power expenditure of servers and information security appliances doesn't eliminate the need to monitor and manage that energy use. Several initiatives are underway to measure and manage IT devices' influence consumption, although information security appliances cannot yet be mechanically powered down while their traffic flow is dormant.

Cloud Computing

Global service line lead for security move toward and hazard management at Accenture, says some cloud providers such a state in their SLA (service level agreement) where they store clients' data, but others don't do so. "I predict cloud providers that are not apparent being locked out of markets likes the European Union, where there are clear laws about how data is stored and transmitted. What's incident in the EU is that firms are looking for intra-European cloud solutions to avoid contravention EU data privacy laws."

Ashdown adds that firms using a cloud provider must insist in their SLA that the provider go through third-party security audits.

"If you store data on a third-party cloud, you could fall victim to a man-in-the-middle attack", says IDC's Senf. "It's vital to encrypt data sent to a cloud, and the provider must have an SLA specifying that they use good authentication."

The answer to man-in-the-middle is to use two-factor authentication in the form of hardware or software tokens, and to prove the IP address of PCs logging on to the cloud, There are clearly benefits for both the information security occupation and the broader IT department when it comes to using green technology. But apply it with care, and guarantee that your power saving efforts doesn't compromise your data.

Advantages of Green Computing:

- Reduced energy method from green computing techniques translates into lower carbon dioxide Emissions, stemming from a reduction in the vestige fuel used in power plants and transportation.
- Conserving resources means less energy is essential to produce, use, and arrange of products.
- Saving energy and possessions saves money.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

- Green computing even includes changing government policy to promote recycling and Lowering energy use by individuals and businesses.
- Reduce the risk existing in the laptops such as chemical known to source cancer, nerve damage and immune reactions in humans.

Benefits of Cloud Computing for Green Enterprises

Reduce Paper Consumptions

The world uses over 300 million tons of documents every year. Businesses account for a very large split of the paper that is inspired. Smart businesses will look for ways to reduce paper expenditure to become promote sustainability. Cloud computing considerably reduces the need for paper, because it enables businesses to use digital technology for projects that may not have been a practicable otherwise. One example is sharing critical documents with organizational counterparts in other regions.

Reduce Server Dependence

While data storage is distant greener than retaining records on paper, it's still not 100% environmentally friendly. Servers involve a decent amount of energy to operate. If you are storing terabytes of data, then you'll likely need a superior server. However, it's much more reasonable to store data on a single large server than frequent hard drives. Since cloud computing allows you to store your data in a central database, you'll significantly decrease the number of servers that you rely on.

Cut Transportation Costs

Transportation and distribution are two other actions that leave a large carbon footprint. Cloud computing is significantly reduced, because your organization will not need to mail nearly as many documents.

Take Your Green Business to the Cloud

There is a diversity of reasons that smart companies are going green. The two most understandable benefits for their bottom line are that they can save on waste and progress their branding with customers that are disturbed about sustainability. They also get to see that they are doing their part to support a better world.

CONCLUSION

Cloud computing is prevailing as a considerable shift as today's organizations which are in front of extreme data overload and skyrocketing energy costs. Green Cloud architecture, which can help combine workload and attain significant energy saving for cloud computing environment, at the same time, guarantees the real-time recital for many performance-sensitive applications.

In the future, there are still a number of research behavior that we plan to carry out, which could improve the performance of Green Cloud and bring solid value to users to attain their business goals and their social dependability in Green IT Applying green technologies is highly fundamental for the

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

sustainable development of cloud computing. Of the various green methodologies enquired, the DVFS technology is a highly hardware oriented approach and hence less supple. Green scheduling algorithms based on neural predictors can lead to a 70% power savings. These policies also enable us to cut down data Centre energy costs, thus leading to a strong, aggressive cloud computing industry. End users will also benefit from the decreased energy bills. As a conclusion, Green Cloud effectively saves energy by dynamically support to workload leveraging live VM migrations, at the same time convention system SLAs.

Chapter 22
Collective Green Creativity and Eco-Innovation as Key Drivers of Sustainable Business Solutions in Organizations

Ziska Fields
University of KwaZulu-Natal, South Africa

Sulaiman Olusegun Atiku
University of KwaZulu-Natal, South Africa

ABSTRACT

The main objective of this chapter was to explore if collective green creativity and eco-innovation can create novel and sustainable business and management practices. A literature review approach was conducted on the link between collective creativity, innovation, and sustainable business practices. It was found that collective green creativity and eco-innovation can create sustainable business practices. The process starts with the creative individual which needs creative thinking skills, creative motivation, green mindfulness and green self-efficacy. A creative collective is then created using their creative intelligence and creative exchange to create a shared green vision. The creative collective requires green transformational leadership with access to green dynamic capabilities and resources to be effective in the business environment. This creative collective follows the six-step creative problem-solving process which enables the collective to create eco-innovation using an additional four steps. The end result is novel and sustainable business practices and solutions.

INTRODUCTION

King (2012) stated that the world has changed and that the planet is in crisis. Holthaus (2015, p.1) wrote that "we have reached the point of no return: climate change nightmares are already here". The climate has visibly changed and more species are dying out at disastrous rates. Dell'Amore (2014) reports that mankind is busy causing the rapid loss of species estimated by experts to be between 1,000 and 10,000

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

times higher than the natural extinction rate. For example, *because scientists do not know how many different species there are on the planet yet*, if there are around 2 million different species on the planet, then between 200 and 2,000 extinctions occur every year. If there are 100 million different species, then between 10,000 and 100,000 species are becoming extinct each year.

Mankind are faced with serious challenges due to human overexploitation of resources and unsustainable living. If this habit and mind-set are not changed very quickly by everyone on the planet, the unsustainable living and destruction of the incredible biodiversity on this planet, which is essential for mankind's survival, can lead to the so-called sixth extinction as identified by Kolberg (2014).

Traditional business and management practices have been blamed for the crises of the planet specifically. Issues like ecological overshoot, population growth, water and food shortages, financial crises, greed and corruption, as well as greater expectations of shareholders are however causing the rethink and transformation of business practices and other unsustainable human activity. An ever-increasing number of businesses are realizing that their long-term profitability is now dependent on social justice and protecting the environment (Global Sustainability Standards Board (GSSB), 2015). These expectations will intensify as businesses, financiers, customers and other stakeholders become more aware of the critical need for a sustainable economy (GSSB, 2015). This book and chapter, aims to play a role in creating more awareness to enable people and business to change and transform to protect the planet and life on it, because mankind have not been and still are not sustainable.

The main objective of this chapter was to explore whether collective creativity and eco-innovation in organizations can create novel and sustainable business and management practices. The secondary objectives were to

1. Explain the concept of collective creativity, green creativity and eco-innovation in business,
2. Identify the barriers to collaborative creativity and eco-innovation,
3. Discuss the determinants for successful organizational, collective creativity and eco-innovation with a view to enhance collaboration, and
4. Show how collaborative green creativity and eco-innovation can be used to solve 'wicked problems' and to create sustainable business practices.

The chapter starts off by providing the background to the chapter. This will be followed by a discussion on collaborative creativity and eco-innovation in organizations and how it can be used to create sustainable solutions, practices and strategies in an effort to minimize damage caused to the planet. Recommendations will also be made to enhance collaborative creativity and eco-innovation at organizational level in contemporary and future organizations.

BACKGROUND

The planet experienced five extinction events. The next extinction, the Holocene extinction, also called the sixth extinction, started at the end of the last Ice Age. Vince (2012) predicts that in the next 300 years, a total of 75% mammal species will disappear due to a human-caused extinction. Mankind's attributes and intelligence are responsible for the biological success and advancement as a specie, however mankind's successes also altered the climate and reduced animal species. Kolbert (2014) chronicles

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

that man's indifference (cruelty) to other life on the planet and unmindful living makes every human a partner in these die-offs.

Unheeded warnings and mankind's reactive mindset are evident throughout history. There will always be people that disagree, those that prefer to ignore warning signs and then action will only be taken after a disastrous event occurred that could have been prevented if proactive action was taken. This is called the Cassandra syndrome or complex.

In Greek mythology, as cited in Greek Myths and Greek Mythology (2016), Cassandra was one of the princesses of Troy, daughter of Priam and Hecuba, who had a gift and a curse of foreseeing the future. There are several different versions explaining the gift and curse of Cassandra. The most popular one is that Apollo fell in love with her and gave her the gift of prophecy as a token of his love. When Cassandra rejected his advances, he placed a curse on her that no one will believe her predictions – even though her premonitions were always accurate. Based on the myth of Cassandra, the French Philosopher Gaston Bachelard, identified the Cassandra syndrome or complex in 1949, which is applied in cases where people would have valid alarms, visions, or dreams about upcoming events, which are disbelieved (Elgueta, 2014), often with disastrous consequences.

In 2000, a small group of leaders from the United Nations (UN) and business created the United Nations Global Impact. The aim of the UN is to build a sustainable, inclusive global community that can thrive within the environmental limits of the planet by creating an inclusive global economy that delivers lasting benefits to all people, communities and markets. The UN tries to inspire, guide and support companies to do business responsibly and take action for a more sustainable future by using the ten principles: Human rights (principles 1-2); Labour (principles 3-6); Environment (principles 7-9) and Anti-corruption (principle 10). However, deep-seated business paradigms and the expectations of societies caused high profile clashes between various organizations and societies (United Nations Global Compact Report, 2015). The Cassandra syndrome became evident from criticism against the UN Global Compact and the future it is trying to prevent, if nothing is done. For example, to name a few, some people view it as a superficial contribution to development; a PR tool; not in line with the traditional position of the UN on issues of economic policy. The UN seems like a less reliable partner for NGOs and other partners particularly in developing countries; and the initiative is seen as "global corporatism" (Bandi, 2007). Despite the criticism and Cassandra syndrome being evident, the goal of the UN is to make sure that mankind does not reap benefits at the expense of the environment and future generations (United Nations Global Compact Report, 2015), which remains a noble and very important one.

A documentary film in 2006, *An Inconvenient Truth*, was an effort by former US vice-president Al Gore to educate citizens about global warming and to reenergize the environmental movement. Gore discussed the present, future effects and consequences of global warming if human-generated greenhouse gases are not significantly reduced. The theme song "I need to wake up" by Melissa Etheridge encouraged viewers and listeners to realize the impact and effect of global warming. In the music video, some alarming facts are highlighted, for example that 70 million tons of CO_2 is released into the atmosphere every single day and that there is more CO_2 in the atmosphere now than in 650 000 years. Al Gore ended the film with the words:

Each one of us is a cause of global warming, but each one of us can make choices to change that with the things we buy, the electricity we use, the cars we drive; we can make choices to bring our individual carbon emissions to zero. The solutions are in our hands, we just have to have the determination to make

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

it happen. We have everything that we need to reduce carbon emissions, everything but political will. But in America, the will to act is a renewable resource.

As with Cassandra, Al Gore's message was criticized by the President of the United States and certain Senators. There was also global criticism. The Prime Minister John Howard for example refused to meet with Al Gore or agree to Kyoto, because he said that he does not take policy advice from films. Even today, the Cassandra syndrome is evident across the world regarding climate change. Current president candidate for the Republican Party in 2016 Donald Trump said that he would "cancel the Paris Climate Agreement and stop all payments of U.S. tax dollars to UN global warming programs" because "the concept of global warming was created by and for the Chinese in order to make U.S. manufacturing non-competitive" (Jacobson, 2016, p. 1). There is a website called the GlobalClimateScam.com and here Beauregard (2015, p.1) reported on the site that climate change is a hoax; 31,000 scientists have signed a petition saying they do not believe in 'Catastrophic Man-Made Global Warming'; and that NASA found that most of the CO2 in the atmosphere was not coming from the industrialized northern hemisphere, but from the rainforests in South America, Africa and China. However, on 'NASA's Global Climate Change – vital signs of the planet' website, it is reported that the "current warming trend is of particular significance because most of it is very likely human-induced and proceeding at a rate that is unprecedented in the past 1,300 years" and that "evidence for rapid climate change is compelling" (NASA Global Climate Change, 2016, p.1). Even with criticism, there were positive responses to the film and the film became a memorable effort to create sustainable solutions for the planet

Vaidyanathan (2016) indicated what happened 10 years after An Inconvenient Truth and stated that scientists that the planet is now in the Anthropocene time, meaning that humans have surpassed nature and that humans are the primary shapers and directors of the planet story. Elizabeth Kolbert wrote a book called, 'The Sixth Extinction: An Unnatural History' which was published in 2014. This is seen as an important book about the future of the world as it predicts the most devastating extinction event since the asteroid impact that wiped out the dinosaurs and confirms Vaidyanathan's statement. Kolbert's book is based on the work of researchers in half a dozen disciplines (for example geologists, botanists, marine biologists) and she accompanied many of them into the field. Kolberg cited in Gore (2014) explains that extinction is a relatively new idea in the scientific community, because most scientists could not imagine a planetary force powerful enough to wipe out forms of life. People in general also find it unthinkable that mankind can destroy the planet's ecology (Gore 2014). Kolberg (2014) however predicts that the sixth extinction is likely to be mankind's most lasting legacy. Kolbert (2014) wrote that:

the qualities that made us human to begin with: our restlessness, our creativity, our ability to cooperate, to solve problems and complete complicated tasks are leading us to change the world so rapidly and profoundly that other species cannot keep up.

Muhammad (2015, p.1) indicates that Kolberg however discusses *"why humanity is wreaking such havoc, with no consideration of the crucial role that capitalism's relentless search for growth and accumulation has played."* This is an important aspect to consider in addition to the issues that are now grouped under the heading of 'sustainability'. These issues are ranging from stopping global warming to saving ecosystems, changing economics and ending global poverty. These issues can be referred to as 'wicked problems'. The concept of a 'wicked problem' was identified by Rittel and Webber (1973) cited in Jackson (2013, p.5) as "a problem that is essentially unique, the search for solutions will never

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

stop, it can be seen as a symptom of another problem and is often intertwined with other problems; it involves many stakeholders, and it generates unexpected consequences over time". It is evident that issues around the sixth extinction, climate change, unsustainable living, to name a few, are complex and not easy to resolve due to the intertwined nature of it and the involvement of a lot of different stakeholders. Another challenge, adding to the wicked problem, is that history has demonstrated that humans often do not listen to warnings about the future, even when warnings were justified. There is still time to listen and to do something about it.

It is important that organizations realize that no business can be prosperous in an environment faced with catastrophic climate change, rampant unemployment and social conflict. The only way to create a prosperous business environment, stable societies and a healthy planet, is for organizations to ensure that the benefits and profits that they reap today, are not at the expense of the environment or future generations. This chapter therefore focuses on organizations specifically as we search for ways to create sustainability.

The question is, what can organizations do to transform themselves to become more responsible and sustainable and can eco-creativity and eco-innovation, as a collaborative effort, help to create novel and sustainable business practices?

COLLECTIVE GREEN CREATIVITY AND ECO-INNOVATION

Organizations can no longer continue on the same path and repeat the old and unsustainable business practices of the past. An overhaul of the traditional and dominant worldviews about resource management and the negative impact of business practices on societies and the environment are necessary and imperative. Creative and innovative thinking and problem-solving can offer sustainable ways to conduct business now and in the future, even if Kolberg (2014) explained that our creativity, our ability to co-operate and to solve problems is changing the world rapidly and profoundly. This ability can be used to improve the world and find ways to assist species to keep up with changes made by mankind.

It is important however to first explain what creativity and innovation mean before it can be explored from an ecological perspective as a possible way to create and enhance sustainable business practices.

Creativity

Cropley (2016) supports the view of Plucker, Beghetto and Dow (2004) when he explains that creativity is like a system with four interacting elements namely the person (which refers to the interaction among aptitude), press (which refers to the process and environment), product (which refers to a novel and useful product) and the social context. Cropley (2016, p. 63) further explains that

Creativity is about solving problems and satisfying needs by developing novel and useful solutions—in other words, creativity is all about the aptitudes, processes, and environmental factors that help us to generate new and useful products.

Vygotsky (2004) states that a creative act is any human act that leads to either a new physical object or some mental or emotional construct that lives within the person who created it. Creativity is also explained as a mental and social process which involves the discovery of novel ideas by combining

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

ideas or seeing new relationships among ideas and discarding preconceived assumptions, in an attempt to come up with a new approach (Afolabi, Dionne & Lewis, 2009, p. 2). Creativity, according to Boden (2004), is the ability to generate ideas that are new, surprising, and valuable. Creativity occurs on the right side of the brain when ideas are sparked. To make creativity useful requires both divergent thinking (generating many unique ideas) (Runco, 2007) and convergent thinking (combining those ideas into the best result). Creativity, according to Groenewald (2013) involves lateral thinking, decision-making and problem-solving.

Cropley and Cropley (2010) explain that creativity is the generation of effective novelty and the National Advisory Committee on Creative and Cultural Education (NACCCE) (1999) agrees and adds that novelty can be identified in three possible ways: individual creativity (also referred to as personal creativity); relative creativity (refers to originality in relation to a person's peer group); and historic creativity (refers to an original previous output). Boden (2004, p. 2) identifies it a bit differently by stating that "psychological" creativity (P-creativity) "involves coming up with a surprising, valuable idea that is new to the person who comes up with it, no matter how many people have had that idea before"; and historical" creativity (H-creativity), "involves an idea that no-one else has had before and seems to appear for the first time in human history".

Parjanen (2012) indicates that there are two different types of creativity namely individual creativity and collaborative creativity. This links to NACCCE's personal and relative creativity as ways to add novelty. According to Parjanen (2012), p. 2)

A collective creativity system becomes a co-creation between the founders of the system and the crowd members, who both design the products and contribute to the design of the system. Out of this comes a kind of system that benefits society through its creative outputs and benefits participants through the mastery they attain.

For this book and chapter, the focus is on collective creativity, because the idea of a lone creative genius will not be useful in the search for the higher potential source of creativity to create novel and sustainable business practices. A collective of creative people working as a team can create better ideas and solutions for unsustainable business practices and living than one individual. In sustainability, the nature of the output of collective creativity can be aggregated which refers to the collection of each participant's work or emergent which refers to something new and novel. Emergent outputs are developed through discovery where the participants find something never seen before or through combination where the participants' work are combined and integrated to produce something novel (Yu et al., 2012).

This is also a valuable view of creativity, which will also be valuable for this chapter, because it shows that creativity can be seen as a concept of growth or development where the human will is the central cause of action, is the view of Rank (cited in De Sousa, Pellissier & Monteiro, 2012), that

Each individual is unique and carries within him or her the potentiality of creating something new, different and unexpected out of past experience (via the human capacity to internalize experiences of the outer environment and making it a part of the self).

From the above explanation, creativity and specifically, collective creativity, seems to be an important phenomenon to consider in the search for sustainable business practices because it creates novel solutions, it can enhance human development and is linked to the human will to make a difference.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Sherwin (2011) wrote in an article that the missing link in sustainable ideas is creativity and agree that creativity needs to play a bigger role in finding better sustainable solutions and business practices. This type of creativity can possibly be linked to eco-creativity and green creativity. Eco-creativity is described as the combination of creativity and art; the marriage of reusing, recycling and creativity (Lapia & Knight, 2011), as well as eco-design where creativity, brainstorming, imagination and trash materials are used. Green creativity was highlighted by Chen and Chang (2013) as part of green product development. They stated that for green creativity and green product development to be successful, green dynamic capabilities and green transformational leadership are required. Chen, Chang, Yeh and Cheng (2015) added that a green shared vision, green mindfulness and green self-efficacy are needed to enhance green creativity. The concept of green creativity therefore can be seen as the most suitable concept that can be used to link creativity to sustainable ideas presently. Green creativity is valuable because it involves a whole-brain activity, linking divergent and convergent thinking, as well as leadership, capabilities, vision, mindfulness and self-efficacy to create novel green solutions to "wicked" unsustainable practices and environmental problems. There are, however, barriers to creativity and bad habits that should be identified and overcome to ensure that any creative endeavor can succeed.

Barriers to Creativity

There are various barriers that can prevent individuals and teams from using creativity and these are, for example, not believing you are creative; acceptance of the status quo; having no creative role-models; narrow-mindedness; feeling silly; red tape, procedure and group-process constraints; conformance pressure; and being too busy.

Hiam (2003) identified nine bad habits that can prevent creativity which are still relevant today and these are:

1. **Failure to Ask Questions:** Creativity requires a lot of why questions to be asked to create creative insight. Not asking questions cannot lead to creative ideas.
2. **Failure to Record Ideas:** If ideas are not recorded, similar ideas can be generated over and over again without having more efficient and productive ideations sessions, where previous ideas can be built upon on linked together to find better ideas.
3. **Failure to Revisit Ideas:** If this is done, old ideas are not given a second chance and old assumptions are not identified.
4. **Failure to Express Ideas:** This is normally done through self-censorship and trying to have an orderly mind which prevents one from figuring out if an idea is worthwhile and novel.
5. **Failure to Think in New Ways:** If a person or team cannot focus on thinking differently and use a variety of structured creative thinking techniques, new and novel ideas cannot be generated.
6. **Failure to Wish for More:** Creativity is about making the impossible seem possible and finding a better way to improve the current status quo. If one does not wish for more and better things, the creative process cannot be successful as only "possible" ideas will be generated.
7. **Failure to Try Being Creative:** Many people still think that creativity is a special and rare gift and that they can never be creative, which prevents them from being willing to be part of the creative process and participate in creative thinking.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

8. **Failure to Keep Trying:** Creativity requires continuous effort, because brilliant novel ideas are not usually created with the first try and it is very easy to abandon a possible idea prematurely and then missing out on a creative discovery.
9. **Failure to Tolerate Creative Behaviour:** When people are being creative, their behaviour might seem weird to others and this should be tolerated to ensure that the creative thinking process leads to useable and novel ideas.

From the discussion in this section it seems that there are a great deal of different barriers and behaviours that can hamper creativity. It is therefore important to be aware of it and to find ways to overcome these barriers and behaviours to be able to solve "wicked" problems and to profit from creative thinking. Some ways to overcome the barriers and bad behaviours for example are to behave in ways that you are creative, behave in ways to generate many fresh ideas, offering ideas to others, applying ideas in the specific context, using divergent and convergent thinking (the whole-brain approach), experimenting with creative thinking processes and techniques as well as breaking boundaries to become an independent thinker/team. It is also helpful to use the five stages of the creative process and creative problem-solving.

The Creative Process and Creative Problem-Solving (CPS)

The creative process consists of five stages and is not a linear process according to Von Oech (cited in Groenewald 2013). The five stage are:

1. Preparation when the problem is defined, information is gathered and creative questions about the problem is formulated;
2. Frustration where the creative questions does not guarantee immediate or effective solutions;
3. Incubation where one steps away from the problem to allow the subconscious to come up with new insights;
4. Illumination where the answer is identified which might need further refinement to create a novel idea and solution; and
5. Elaboration where the idea is refined to develop further through innovation.

Creative problem-solving (CPS) aims to solve specific problems and the process was developed by Alex Osborn and Sydney Parnes (Groenewald, 2013). The process consists of five steps where the problem is defined and the objective is determined, followed by fact finding, idea finding, evaluating and prioritizing ideas and developing and implementing the plan to solve the problem. Various creative techniques can also be used in each of the five steps, for example in step one, the 5Ws/H method can be used when one is uncertain about what the problem really is; in step two, the bug list technique can be used to focus on finding fault with things around us that can lead to corrective action being taken; in step three, brainstorming can be used; in step four, the advantage-disadvantage technique or the reverse brainstorming technique can be used; and in step five, CPS techniques can be used and an action plan developed.

The process of green creativity and green creative problem-solving need to include specific focus areas to make it successful as identified by Chen and Chang (2013) and Chen et al. (2015). The collective (can be an organization/s or team/s for example) gathered to generate novel ideas, need to share a green vision created by green transformational leadership, which are supported by green dynamic capabilities.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

The collective, as individuals, should also possess green mindfulness and green self-efficacy. Collective green creativity will follow the same steps as discussed in this section and the focus will be on achieving new and novel environmentally friendly and sustainable business ideas.

Innovation

Innovation is crucial to the economy and the performance of organizations (Groenewald, 2013). It also involves a variety of approaches like technological innovation, product-market innovation, innovative marketing strategies and management innovation like new organizational systems and techniques according to Groenewald (2013).

The processes of innovation and creativity overlap although these processes are different. Creativity is seen as the cognitive process of development of ideas, which normally takes place first, while innovation occurs when these ideas are applied and turned into something of value, for example, a new product or a new process. Florida (2002) expresses that creativity drives the innovation process which basically means that creativity is the key in generating new business opportunities – the start of any innovative idea. Innovation is the ability to apply creative solutions to enhance or enrich the lives of people according to Scarborough and Cornwall (2015).

Jones and George (2014, p. 23) defines innovation as "the process of creating new or improved goods and services that customers want or developing better ways to produce or provide goods and services". The authors identify two kinds of innovation:

1. Quantum product innovation, and
2. Incremental innovation.

Quantum product innovation is the development of new or radically different kinds of goods and services due to technology and the possibilities of pioneering discoveries. Incremental product innovation takes place when gradual improvements to existing products are made due to existing technologies being perfected. Groenewald (2013) explains that innovation can be divided into radical (similar to quantum production innovation), incremental (similar to incremental product innovation) and modular innovation. Modular innovation which involves the change of some of the components to new or significantly adapted components as per Groenewald (2013).

Hamel and Breen (2007) cited in Groenewald (2013) created a hierarchy of innovation which consists of five different levels. The lowest level, operational innovation, involves innovations to make organizations faster and better by focusing, for example, on the manufacturing processes and the development of online transactions. The second level, product and service innovation, is the most visible one as it involves for example completely new products, line extensions or product repositioning. The third level, business model innovation, focusses on value creation and value capture to enhance the profitability of the organization. The fourth level, architectural innovation, which implies a redesign or reconfigured system and industry. Level five, management innovation, which refers to strategic planning, project management, knowledge management and performance management, for example. Management innovation ensures the long-term success and competitive advantage of organizations (Hamel and Breen, 2007).

Martins (2002) explains that innovation is the implementation of a new and problem-solving idea, practice or artifact through which change is brought about. In addition, Puccio and Cabra (2010, p. 149) stress that *"innovation comes about as the result of the interaction among people, the processes they*

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

engage in, and the environment in which they work". Rothwell and Zegveld in Conway and Steward (2009, p. 9 & 10) define innovation as *"the commercialization of technological change"*. Innovation concerns "novelty" (as with creativity), and is a process that embraces various activities to ensure that the actual discovery is commercialized.

These different views are important for this chapter as it explains that innovation is the result of interaction among people and it creates something new that enhances or enriches lives and leads to change.

Eco-Innovation

Innovation is therefore important for sustainable business practices and can be referred to as eco-innovation, which requires collaboration to make it successful. Eco-innovation is explained as

the production, assimilation or exploitation of a novelty in products, production processes, services or in management and business methods, which aims, throughout its lifecycle, to prevent or substantially reduce environmental risk, pollution and other negative impacts of resource use (including energy) (OECD, 2009, p. 6).

Three aspects are important in eco-innovation as per OECD (2009) namely:

1. The target which refers to products, processes which tend to rely on technology, marketing, organizations and institutions. The target can be technological or non-technological.
2. The mechanism which refers to the method by which the target is changed and can either be possible through modification, redesign, alternatives or creation.
3. The impact which refers to the potential environmental impact due to the target, mechanism and their interaction with the socio-technical surroundings.

Part of eco-innovation is to look at the environmental effects across value chains and product lifecycles. Biomimicry specifically can be very helpful to create eco-innovation. Here innovation comes from nature's best ideas in terms of natural systems and its success in nature. Nature's ideas are then imitated to provide innovative and sustainable solutions (Benyus, 2006). The nine basic laws of biomimicry are also important for eco-innovation because it identifies the key working principles needed for ideas, namely:

1. *Nature runs on sunlight;*
2. *Nature uses only the energy it needs;*
3. *Nature fits form to function;*
4. *Nature recycles everything;*
5. *Nature rewards cooperation;*
6. *Nature banks on diversity;*
7. *Nature demands local expertise;*
8. *Nature curbs excesses from within; and*
9. *Nature taps the power of limits (Benysus, 2006, p. 129).*

The Biomimicry Guild, for example, aims to help businesses to become more sustainable by focusing on the transfer and application of biological knowledge, developing business model innovation as it

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

integrates this biological knowledge into the business focus and strategy, and ensuring that progress are monitored (The Biomimicry Institute, 2015). However, as with creativity, there are barriers to innovation that need to be addressed to make the innovation process successful.

Barriers to Innovation

Innovation is viewed form a number of perspectives which can make the innovation process challenging. As a management process, the focus is on the organization and management; as a social process, the focus is on the importance of social interaction during the innovation process; as political process, the focus is on the use of resources and between alternative solutions; and as emotional process, the focus is on psychological safety in allowing people to challenge the status quo according to Conway and Steward (2009, p. 12). If leadership cannot drive innovation and if the business culture does not support innovation, employees will not be innovative. Barriers are created when leaders, managers and employees do not have the required skills, are not aware of the latest trends and technology, do not have the passion to be innovative, or are afraid of risk taking and the cost involved in failure. The different activities that are necessary for innovation can cause tension and barriers as well. Dougherty (1996, p. 431) cited in Conway and Steward (2009) identifies four tensions due to contradictory practices which are identified in Table 1.

The Innovation Process

The innovation process consists of three phases according to Smith (2010). Phase one is the invention stage where a new idea, product, service, method or process is created. This phase is not yet innovation and can be linked to the creative process discussed earlier in the chapter. The viability of the invention should first be determined by ensuring that it can create a competitive advantage (unique selling proposition), it is aligned with the business strategy and objectives, it creates business value, customer needs are taken into consideration and the invention is successfully executed. This will then lead to phase two, commercialization of the invention, due to value creation and value capture to create demand and profits. Phase three is the final phase and is referred to as diffusion which refers to the adoption rate of consumers

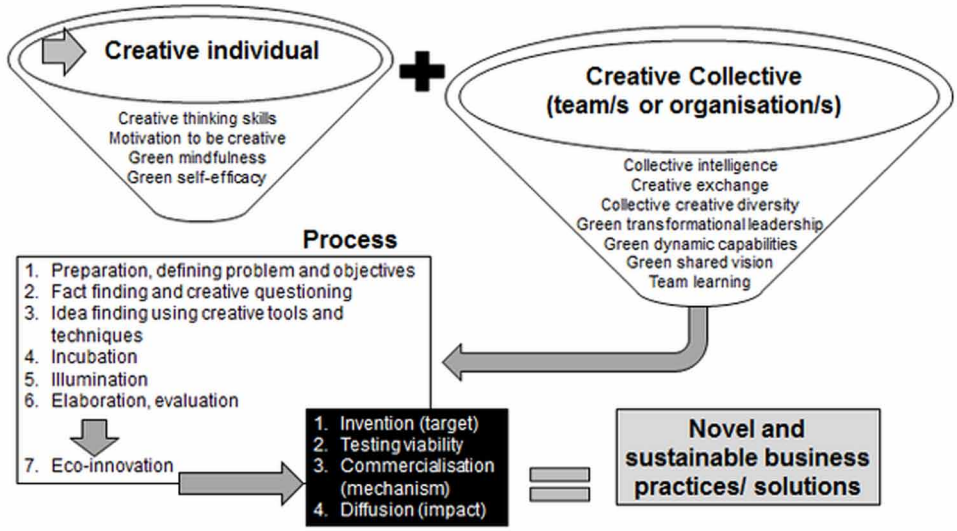
Table 1. The tensions between contradictory practices and capacities to restore the balance

Activity	Tension	Problem of Normal Functioning that Disrupts Tension	Capacities to Restore Balance in the Tension
Market-technology	Outside versus inside	Keeping operations efficient	Generate and maintain an identity based on the value provided to customers
Organizing for creative problem solving	New versus old	Managing complexity	See work of organization in terms of process, focusing on relationships among parts, and changes
Evaluating and monitoring innovation	Determined versus emergent	Controlling multiple activities	Situated judgement, collective ability to be engaged in details of work but also appreciate unstructured problems
Developing commitment to innovation	Freedom versus responsibility	Accounting for work, results	Collective accountability, accept and share responsibility, legitimize innovation and inclusion

Source: Dougherty (1996, p. 431) cited in Conway and Steward (2009)

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

which can be fast or slow. Consumers need to familiarize themselves with the innovation first, so diffusion is normally slow. Figure 1 shows the link between collective green creativity and eco-innovation.



The process starts with the creative individual which needs creative thinking skills, creative motivation, green mindfulness and green self-efficacy. A creative collective (team or organization for example) is then created consisting of a diverse mix of these creative individuals who will use their creative intelligence and creative exchange to create a shared green vision. The creative collective will need green transformational leadership with access to green dynamic capabilities and resources to be effective in the business environment as well as the other determinants to make the process successful. This creative collective will then follow the six step creative problem-solving process which will enable the creative collective to create eco-innovation using an additional four steps. The end result will be novel and sustainable business practices and solutions.

Managing the Creative Collective and Creative Intelligence in Organizations

Collective green creativity and eco-innovation can be seen as creative exchange as identified by Flieschmann and Hutchinson (2012) although the practice of creative exchange was developed for the tertiary education environment. This method however fits into the development of sustainable business practices as well, because it is important to get multi-disciplinary and multi-industry perspectives to generate green creative and eco-innovative ideas. Creative exchange is helpful due to the fact that it fosters debate and dialogue amongst stakeholders, support expertise from various disciplines, acknowledges the differences in culture, communities and industries. In addition, creative exchange supports and develops individual and team development and examines debates and contemporary issues. It seems therefore that creative exchange can play a key role in collective green creativity and eco-innovation.

Parjanen (2012) defines collective creativity as social interactions between individuals due to new interpretations and new discoveries that the individuals involved could not have generated by themselves.

Figure 1. Fields's collective green creativity and eco-innovation process framework
Source: Own compilation

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Collective creativity is not simply the sum of individual creativities (Parjanen, 2012), but is greater than the sum of individual creativities, because it intensifies and multiplies due to the level of the problem and common concerns experienced about the problem. Creativity and innovation is a collaborative process and teams and people from various fields contribute to implementing new ideas. Therefore, managing collective green creativity and eco-innovation is critical for sustainable business practices in business organizations.

According to Parjanen (2012), four key elements are fundamental in managing collective creativity and innovation in business organizations. The first element is strategy. Collective creativity flourishes in an organization where policies are in support of team learning and free flow of productive ideas leading to new products or services (Anderson, Potočnik & Zhou, 2014; Marquardt, 2011; Parjanen, 2012). The second element is the usefulness in enhancing cognitive ideas and innovation is leadership (Parjanen, 2012). The leadership structure that supports collective creativity in developing new products or services will embraces comment from all stakeholders irrespective of their status in the organization (Zhang, Tsui & Wang, 2011). Thirdly, the methods or approaches adopted in collecting and distribution of information within the system will determine the success or failure of creative ideas at the implementation stage (Bissola & Imperatori, 2011; Parjanen, 2012). For example, superior ideas can be generated through informal interactions or interpersonal relationships with the subordinates. This example shows that collective creativity and innovation in organizations are not limited to formal discussions/interactions, or team learning (Parjanen, 2012). The last but not the least element according to Parjanen (2012), is organizational culture. The fourth element relates to a set of core values or management principles that supports continuous learning and knowledge sharing at all levels within the organization (Anderson, Potočnik & Zhou, 2014). Superiors and subordinates are open minded, but thorough in their habits of challenging the status quo. A proper alignment of strategic goals, leadership structures, approaches to interactions and shared values within an organization is necessary for collective green creativity in developing eco-friendly products or services (Chen & Chang, 2013; Parjanen, 2012).

Management support for team learning and knowledge sharing through brainstorming are efforts toward collective creativity. Collective creativity could be enhanced through task experiences, personal and team development. Gino, Argote, Miron-Spektor, and Todorova, (2010) found that teams who acquired direct task experiences are more creative compared to teams who acquired experience through feelings or actions of another person. Empirically, the study found that task experience has a direct positive influence on collective creativity. Therefore, eco-innovation can be enhanced through direct or indirect task experiences either acquired or shared within a group. Statistically, Sung and Choi (2012) found that team experience management and transfer are positively associated with collective creativity and sustainable business outcomes. Through horizontal and vertical communication individual creativity can easily be transformed into collective creativity, provided that policies and programmes are in support of the exchange process (Bissola & Imperatori, 2011; Gong, Kim, Lee & Zhu, 2013). For instance, team activity, storage and retrieval (Decuyper, Dochy & Van den Bossche, 2010) are some of the important elements in building team creativity and innovation. Findings from Bissola and Imperatori, (2011), informed that collective creativity and innovation is a function of individual innovative ideas, group dynamics and managerial resolutions. That is, developing sustainable business practices requires well harnessed individuals, teams and managerial creative capabilities. A learning culture that supports knowledge exchange through interactions within or between work groups is crucial in generating collective ideas and building sustainable business outcomes in the knowledge economy (Martins & Terblanche, 2003; Yoon, Song, Lim & Joo, 2010). Also, corporate entrepreneurial orientations such as creativity, innova-

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

tion, and competitive aggressiveness of individuals and teams could be regarded as collective efforts in building sustainable business outcomes.

The concept eco-innovation for business organizations is an add-on to Corporate Social Responsibility (CSR), which also stands against profit maximization from the classical point of view (Carroll & Shabana, 2010). This chapter submits that collective green creativity and eco-innovation are essential in developing sustainable business models for the interest of all stakeholders in the 21st century. The reason is that, global warming, for instance, is a global issue confronting all stakeholders.

Another interesting emphasis for sustainable business practices in this chapter is the role of technology in collective creativity and team learning. Kirkman, Rosen, Tesluk and Gibson (2004) put it that improvements in information technology (IT) played a significant role in sharing knowledge situated in distance locations across the global with teams. Team members can be linked up using IT, which points to the importance of technology in generating collaborative intelligence. Also, distance is no longer a barrier in the global environment. Collaborative ideas could be easily generated, shared and improved on using online platforms, especially among work groups that are geographically dispersed (Faraj, Jarvenpaa & Majchrzak, 2011). Contemporary work organizations may find the IT based learning platforms valuable in advancing collaborative ideas and developing sustainable business models. Studies conducted by Hill, Brandeau, Truelove and Lineback (2014), reveal that *collaborative problem solving*, *discovery-driven learning* and *integrated decision-making* were instrumental in attaining *collective genius* at selected world leading IT firms. Collaborative problem solving starts with the documentation of interchange content and objectives; by verifying customers' current/future needs, and developing sustainable models in line with the global requirements (Aarikka-Stenroos & Jaakkola, 2012; Kirschner, Buckingham-Shum & Carr, 2012). Collective problem solving sets the pace for teams' discovery-driven learning in the act of creating collective intelligence (Hill, Brandeau, Truelove & Lineback, 2014), which is key to new products or services development. A discovery-driven learning is an action plan to arrive at more efficient, but sustainable business models through continuous update of skills and experiences at team levels (Chesbrough, 2010; McGrath, 2010). A discovery-driven learning in this context, could be enhanced using information and communication technologies in disseminating information among members. An integrated decision-making process in the knowledge economy is more advanced with the use of IT in consultation with all stakeholders or based on green IT balanced scorecard (Bhattacharya et al., 2014; Wati & Koo, 2011). Collaborative intelligence drawn from integrated decision-making process in advancing eco-innovation through green IT balanced scorecard could be regarded as efforts in the right direction toward sustainable business practices of the 21st century. The next section provides explanations regarding the merits of collective creativity and innovation.

Advantages of Collective Creativity and Innovation

Creativity could be referred to as one of the greatest potential sources of competitive advantage in the 21st century (Amabile, 2011). Survival of business organizations in the modern economy is largely dependent on creative capabilities of individuals, teams and management boards. The reason is not far-fetched, state-of-the-art products and services one can count on today emerged from collaborative creativity. According to Articles (n.d.) the following are advantages of collective creativity to business organizations:

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

- **Better Teamwork and Team Bonding:** Collaborative creativity enhances interpersonal relationships within groups. Organizations that generate ideas through the practice of collective culture stand to experience team efficiency.
- **Increased Workplace Engagement and Interaction:** Generally, collaborative brainstorming improves communication and employee involvement in decision making process both at groups and organizational levels.
- **Improved Ability to Attract and Retain Quality Employees:** The sensitive issue of employee retention can be overcome by recognition of creative ideas of competent employees. This gives a sense of belonging and boosts employees' level of engagement and creativity.
- **Increased Staff Morale, Fun and Happiness:** Collective intelligence could be used a motivational tool to improve employees level of productivity, in terms of quality and quantity of units produced or quality of service delivery.
- **Increased Workplace Problem Solving and Productivity:** Involvement of stakeholders in diagnosing and problem solving process puts an organization ahead its competitors. Particularly, when such information are well coordinated, the result; which is collective genius is far rewarding compared to individual intelligence (Hill, Brandeau, Truelove, & Lineback, 2014).

Therefore, this chapter submits that collective creativity and innovation will impact more on organizational productivity and competitive advantage; when the processes are well managed at all level in an organization. In addition, collective green creativity and eco-innovation in organizations and amongst various organizations and industries can create novel sustainable ideas and solutions that mankind has never thought about that can prevent or decrease the 6th extinction to allow mankind to save the planet and all life on it. It is clear that we cannot save the planet with the same kind of thinking used when we are busy destroying it. Mankind still have a long way to go, but we have creative and innovative intelligence that can change the current fate of the planet.

Disadvantages of Organizational Creativity and Innovation

There are however a negative side to creativity and innovation, specifically in the 21st century. It is one of the reasons why our planet is in distress in the first place. Mankind only focused on the ideas and novel innovations without considering the consequences on the planet. In the 21st century, "*an excess of creativity can lead to a breakdown between the phases of the innovation process with detrimental consequences"* (Del-Corte-Lora, Vallet-Bellmunt & Molina-Morales, 2015, p. 4). Accordingly, an overflow of collaborative ideas may cause an adverse effect on organizational productivity, due to issues of absorptive capacity and timing problem. The authors are supporting the positive side of collective creativity and innovation to business organizations, but are aware that excessive creativity may leads to confusion or business failure if not managed properly and sustainably as well. For example, when a creativity idea failed to materialised into desired outcomes after huge investments at the implementation stage. This kind of result may cause a serious setback to an organization, if no provision was made for such circumstance.

Technological innovations around the world created dependency on technology for daily survival (Belcher, n.d.). As such, technological breakdown often disabled humans until the problem is fixed. Another shortcoming of digital automation is that it contributes to the high rate of unemployment, by

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

continuously putting less value in human capital (Belcher, n.d.; Rotman, 2013). Rotman (2013), reports that the service industry contributed 79.7% to the United States (US) Gross Domestic Product (GDP) in 2013, as a result of automation in the US service industry. Automation has taken over jobs meant for employees around the world, for example, the use of electronic banking applications (Automated Teller Machine (ATM), online banking, and mobile banking have displace human resources worldwide in the banking industry. Similarly, Nisen (2013) alerts that advances in artificial intelligence could cause up to 75% unemployment rate in the global environment. This is a projection that requires all hands on deck in developing collective green ideas and eco-innovation to savage employment generation in the knowledge economy. The paradigm shift from collective genius (Hill, Brandeau, Truelove & Lineback, 2014) to artificial intelligence (Gurkaynak, Yilmaz & Haksever, 2016; Rodríguez, Soria & Campo, 2016) is another shortcoming of creativity and innovation, considering its negative influence on humans. The greatest danger is that artificial intelligence might subdue human intelligence in the nearest future (Gurkaynak, Yilmaz & Haksever, 2016). The following are some of the shortcomings of technological innovations in the manufacturing industry, according to Payne (2013):

- **Less Versatility:** Advances and adoption technological innovations in the manufacturing plants displace the human element in an unprecedented proportion.
- **More Pollution:** The use of machines in factories has negative impact on human environment (Melville, 2010). The practice of corporate social responsibility as a compensation is often not commensurate with the amount of damages done to the natural environment (Carroll & Shabana, 2010; Melville, 2010).
- **Large Initial Investment:** It requires huge amounts of money for purchase of automated machines and huge investment are usually made regarding technical know-how and costs of maintenance.
- **Increase in Unemployment:** The high rates of unemployment recorded in the global environment could be traced to utilization of digital automation in workplaces around the world (Nisen, 2013; Rotman, 2013). Therefore, collective efforts are required in building green business models and eco-innovations for the sake of sustainability in the global business environment. The next section unveils the determinants for effective collective green creativity and eco-friendly innovations in modern organizations.

Determinants for Successful Organizational Creativity and Innovation

This chapter submits that collective green creativity and eco-innovations are essential requirements for sustainable business models/practices. One of the basic determinants for sustainable business practices is a corporate culture that supports collaborative ideas and green products development (Chen & Chang, 2013; Im, Montoya & Workman, 2013; Martins & Terblanche, 2003). A cultural pattern that embraces team learning, free flow of information, and shapes attitudes as well as behavioural patterns is effective in stimulating collective creativity and organizational innovation (Martins & Terblanche, 2003; Yoon, Song, Lim & Joo, 2010). Such cultural values are usually aligned with the organizational strategy, structures and objectives. Knowledge management could be regarded as a key determinant for effective collaborative creativity and new products development (Lee, Leong, Hew & Ooi, 2013). Knowledge management at individual, team and organizational levels need to be well planned, delivered and transferred into outstanding discovery and innovation.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Apart from culture and knowledge management that supports collective creativity, superior capability in managing team dynamics is also crucial in building sustainable business models in the 21st century. For instance, Im et al. (2013), found that managing team dynamics and interpersonal relationships are a forerunner to generating collective intelligence, thereby resulting into new products development. The question of newly developed products meeting the global requirements in reducing the issue of global warming is at the centre stage of sustainable business models. Work groups in the 21st century need *green dynamic capabilities*, and *green creativity* in accordance with the global demand for eco-innovation (Chen & Chang, 2013). Accordingly, green dynamic capabilities is the ability of an organization to exploit current resources and collective intelligences to rejuvenate or enhance its business models in responding to business demands in the 21st century. Chen et al. (2015) submit that green creativity is more essential for business organizations operating under the context of eco-innovation and sustainable business practices.

Green transformational leadership is another determinant for sustainable business models and eco-innovation in the global economy (Chen & Chang, 2013; Gumusluoglu & Ilsev, 2009). Green transformational leadership could be referred to as a set of behavioural patterns of business leaders in motivating their organizational members to generate eco-friendly creative ideas and inspire teams to surpass the requirements of eco-innovation (Chen & Chang, 2013). Personality traits of leaders in business organizations can either support or demean collective intelligence in developing new products. For example, transformational leaders could assist in creating new ideas by providing a vision and boosting followers' morals toward development of innovative products or services.

Risk-taking capabilities and willingness to finance creative ideas is a powerful determinant for successful organizational creativity and innovation (Stanley, 2016). Organizations are sometimes sceptical in exploring new products development due the level of risk involved. The fact remains that no creative idea can materialise in new products or services without adequate investments of both financial and non-financial resources (Leachman, 2014). Financial analysis of risk and uncertainty is a key factor to consider in new product development (Mazzucato, 2013). Such analysis would help in making decisions about calculated risk and uncertainty. Rather than treating each determinant for effective organizational creative and innovation in isolation, Parjanen (2012), submits that all determinants should be logically aligned to arrive at expected outcomes. That is, the organizational vision and mission statements should be logically aligned with the corporate/business strategies, organizational culture, structure and leadership, methods of managing team dynamics, knowledge sharing capabilities and approaches of financing innovation.

RECOMMENDATIONS

The threat of the 6th extinction is real and should be treated as such. Organizations can no longer continue on the same path and repeat the old and unsustainable business practices of the past. It is important that organizations understand their impact on the planet and not remain indifferent due to the Cassandra syndrome, and that the various stakeholders of these organizations ensure that organizations behave ethically and sustainably. Various organizational watchdogs should be set up that support the United Nations Global Compact initiative and communities should use their collective power to force organizations to behave responsibly towards the environment and their communities.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Creativity is often seen as a rare gift only given to a selected few. Greater awareness is needed to develop the understanding that creativity is a skill that everyone is born with and this skill can be developed through training and development. Organizations specifically should not only see innovation as an important aspect in business to ensure a competitive advantage, but realise that innovation starts with creativity at an individual level which are then enhanced through collaborative problem solving, discovery-driven learning and integrated decision making to attain collective genius (collective green creativity and eco-innovation for example) in organizations. Organizations need to incorporate creativity and innovation awareness programmes in the training and workshops of all employees at all the various levels in the organization, focusing on individual and collective creativity and innovation.

Organizations should manage creativity and innovation from a strategic perspective by incorporating it in the shared vision, strategic goals and policies. Green creativity and eco-innovation should specifically be focused on to create sustainable business practices and problem-solving. This also calls for organizational intrapreneurship to create strategic renewal, sustained regeneration and pioneering strategies. Leadership should be aligned to the green shared vision and transformational leadership should be developed to encourage team learning, team development and the development of an organizational culture that supports creative and innovative thinking. This may sound easy, however some organizations might struggle to change the current organizational culture that supports unsustainable business practices and where unethical behaviour is rife. It is critical that the top management understands and supports green creativity and eco-innovation before transformation of an organization can start.

Technology will be an important and critical key component to initiate, drive and implement collective green creativity and eco-innovation. Ideas will need to be captured and evaluated using technology. Collective activities should be documented to ensure that a record is kept of all the ideas and innovations to not generate similar ideas and waste time, but rather to encourage building on ideas already identified previously but not implemented. People sharing ideas need to feel that their efforts are not a waste of time and that it is evaluated fairly. A reward system can be an important driver in the process.

There are various recommendations which cannot all be provided in this chapter. It is the hope of the authors that readers will also consider the recommendations provided in other chapters and then to develop a unique and creative strategy for their specific organization.

FUTURE RESEARCH DIRECTIONS

The Fields collective green creativity and eco-innovation framework needs to be empirically tested in various organizations in various countries to specifically focus on the outcome (for example, green and eco-friendly products, services, processes, business practices) and its impact on sustained sustainability for organizations, communities and the planet.

Concepts like green mindfulness, green self-efficacy, collective intelligence and collective exchange in sustainable businesses development should be explored in more detail. Specific processes and techniques should then be developed to enable organizations to implement collective green creativity and eco-innovation in their organizations

CONCLUSION

'Believing Cassandra' is the only way to avoid a predicted disaster of a sixth extinction. Mankind need to take corrective action to ensure that the Cassandra syndrome is recognized and that predictions and warnings are taken seriously. Business organizations also have active and important roles to play in safe--guarding the natural environment. Rather than just considering the customers' needs, technology, investments and profitability, the environmental impacts of new products and services should be taken seriously in the 21st century. The environmental impact, points to the importance of collective green creativity and eco-innovation to develop sustainable business practices in the global economy. Industrial organizations could utilised collective creative intelligences in creating green creativity to solve business and environmental problems, such as; melting glaciers, resource depletion, ocean acidification, and deforestation. This implies that an organization can be conscious of its environment in formulating competitive strategies and design of new products and services. An organization could achieve eco-innovation and sustainable business practices by tapping into the collective creative genius of its members through green mindfulness, green self-efficacy and shared vision, green transformational leadership, and green creativity. Therefore, collective green creativity and eco-innovation can offer novel solutions to the 'wicked problem' we are faced with of unsustainability and the possibility of a global extinction event caused by mankind.

KEY TERMS AND DEFINITIONS

Collective Creativity: Collective of creative people working as a team to create new and novel ideas and solutions.

Creativity: Creativity is about solving problems and satisfying needs by developing novel and useful solutions.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Eco-Innovation: The production, assimilation or exploitation of a novelty in products, production processes, services or in management and business methods, which aims, throughout its lifecycle, to prevent or substantially reduce environmental risk, pollution and other negative impacts of resource use.

Green Creativity: The generation of new and novel environmentally friendly and sustainable business ideas.

Innovation: The implementation and commercialisation of new and problem-solving ideas, practices or products through which change is brought about.

Chapter 23
A Business Model Framework for Crowd-Driven IoT Ecosystems

Xenia Ziouvelou
University of Southampton, UK

Frank McGroarty
University of Southampton, UK

ABSTRACT

This article describes how the era of hyper-connectivity is characterized by distributed, crowd-centric ecosystems that utilise cutting edge technology so as to harness the collective power, co-creation ability and intelligence of the crowd utilising under open participatory value creation models. The Internet of Things (IoT) has fueled the emergence of such ecosystems that leverage not only the power of physical things connected to the Internet but also the wisdom of the crowd to observe, measure, and make sense of phenomena via user-owned mobile and wearable devices. Existing business modelling literature has to date, placed no research attention on business models for such emerging ecosystems. This article aims to fill this gap by examining the dynamics of crowd-driven IoT ecosystems and introducing a business model framework for such environments, encompassing all relevant value-creating actors, activities and processes, facilitating this way a holistic ecosystem business model analysis.

1. INTRODUCTION

A hyperconnected world is emerging; a world where people (Internet of People) and things (Internet of Things) are linked together providing anyone with "anytime, anywhere" access to information (Gomez et al., 2013). This environment intensifies collaboration and facilitates the emergence of new participatory value creation models driven by users and empowered by technological advancements. This era of hyper-connectivity is no longer characterized by centralised firm-centric business structures but rather from distributed, ecosystemic structures that utilise cutting edge technology in order to harness the collective power, co-creation ability and intelligence of the crowd. In these complex technologically advanced and

constantly evolving inter-connected ecosystems, it is the ecosystem's ability to bring together a variety of strategic business elements in order to jointly co-create shared value; defining this way its success.

The Internet of Things (IoT), as a network that links digital and physical entities via information and communication technologies, has moved to a new era that goes beyond the introduction of new types of services and applications, focusing upon the introduction of new ways of leveraging distinct, distributed and embedded value. As such, the role of IoT is catalytic in the emerging crowd-driven value co-creation paradigms as it introduced new user-centric archetypes, like mobile crowd sensing (MCS) (Burkel et al., 2006; Ganti et al., 2011), that go beyond traditional sensing techniques (e.g., sensor networks, etc.). These archetypes leverage the power, the devices (user-owned mobile devices and wearable devices) and the wisdom of the crowd to observe, measure, and make sense of phenomena (crowdsourcing). In this context, co-creation occurs both among and between crowd participants and systems (mobile crowdsourcing and mobile crowdsensing (participatory and opportunistic sensing)). A number of crowd-driven IoT ecosystems (Ziouvelou & McGroarty, 2017) have emerged elevating the role and collective efforts of people for enhancing the shared value creation under a "contextual open innovation 2.0" model that integrates the "environment" as an underlying value component in an IoT setting. Such ecosystems evolve in a "Quintuple Helix" innovation system where cooperation is established between five helices, namely: university, industry, government, civic society and the environment (Carayannis & Campbell, 2010; Carayannis & Campbell, 2014).

However, despite this change in the business logic of emerging IoT ecosystems, there is still a limited understanding of the business dynamics and business models of these emerging, technologically advanced, crowd-driven ecosystems. Based on the analysis of Ziouvelou & McGroarty (2017), the prevalent view of existing research in the area of IoT business models is still primarily firm-centric (Bilgeri & Wortmann 2017; Ju et al., 2016; Weinberger et al., 2016; Dijkman et. al., 2015; Chan 2015; Fleisch, et al., 2015; Hui 2014; Qin & Yu, 2014; Fleisch et al., 2014). Only a few studies adopt an ecosystemic view (Schladofsky et al., 2016; Rong et al. 2015; Turber et al., 2014; Westerlund et al., 2014; Leminen et al., 2012). However, even these studies tend to adopt firm-centric analytical modeling tools such as the business model canvas (Osterwalder & Pigneur, 2010) and only a few propose ecosystem-centric models placing emphasis upon value creation and value capture components (in the context of: (a) Industrial IoT (Iivari et al., 2016) and (b) IoT (Westerlund et al., 2014)) among others[1]. On the contrary, there are no studies defining business models for crowd-driven ecosystems in the context of IoT. However, given the nature of the crowd-driven ecosystems, current approaches to developing business models (firm-centric approaches) fail to capture their dynamics and thus their full potential (Ziouvelou & McGroarty, 2017). This indicates the need for new business model frameworks and components that reflect the dynamic nature of these emerging value ecosystems.

This study aims to fill this gap and shed light into the emergence of crowd-driven IoT ecosystems and their business models utilising an exploratory and explanatory research approach. Initially an exploratory review analysis, of existing research in the area of ecosystems and business models related to the IoT, is provided. This is followed by a classification of existing research under an explanatory framework that facilitates the analysis of crowd-driven IoT ecosystems and their business models and the introduction of an integrated conceptual crowd-driven ecosystem business model framework, which supports the creation of business models for these environments. The proposed Crowd-driven Ecosystem Business Model Framework (CEF) corresponds to the needs of ecosystem-centric IoT environments by integrating all relevant value network participants and value-related activities and processes in an open, ecosystem-centric context.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

The article is structured as follow. Section 2 provides an overview of the approach that has been adopted in this study. Section 3 investigates the emergence of crowd-driven IoT ecosystems and Section 4 explores business models for crowd-driven IoT ecosystems and provides an explanatory framework that classifies existing studies. Section 5 introduces a new business model framework for designing ecosystemic business models for the crowd-driven IoT environment and Section 6, concludes this study and reviews its key implications.

2. THE STUDY APPROACH

The goal of this research is to explore research in the area of crowd-driven IoT ecosystems, their business models and analytical frameworks and to create a business model framework for such technologically advanced environments. For this reason, both an exploratory and explanatory research approach is employed. At first, an exploratory review analysis is presented that integrates two research streams namely, ecosystem research (Moore 1993; Carayannis, 2010) and business model research (Afuah & Tucci, 2000; Afuah, 2003; Osterwalder et al, 2005; Amit & Zott 2015) aiming to reflect upon the notion of crowd-driven IoT ecosystems (Ziouvelou et al. 2017; Ziouvelou & McGroarty, 2017). The methodological process of this analysis involves the exploration of numerous publications, from several sources (journals, academic books, digital research libraries, etc.) in order to identify the most significant publications based on their citations. This is followed by a classification of existing research under an explanatory framework that facilitates the analysis of crowd-driven IoT ecosystems and their business models. Based on this analysis, we were able to introduce an integrated conceptual crowd-driven ecosystem business model framework, which supports the creation of business models for these environments. The proposed Crowd-driven Ecosystem Business Model Framework (CEF) corresponds to the needs of ecosystem-centric IoT environments by integrating all relevant value network participants and value-related activities and processes in an open, ecosystem-centric context.

3. CROWD-DRIVEN ECOSYSTEMS AND CROWD-DRIVEN IOT ECOSYSTEMS

Ecosystem research bridges a number of scientific fields from ecology, to business, and technology. The ecosystemic perspective has to date triggered a lot of research attention focusing on the evolving complex ecosystemic landscapes across disciplines. From biological ecosystems found in the natural world, ecosystems have over the past few years emerged as a business construct that facilitates the description and analysis of the complex networks that populate our hyperconnected society (Lehto et al., 2013; Durst & Poutanen, 2013). This emerging view reflects a much deeper structural shift and change in the way value is created and captured in today's networked society: from standalone companies to integrated corporate constellations and from closed ecosystems to open, crowd-driven ecosystemic structures powered by technology, user participation and open collaborative innovation (Chesbrough & Appleyard, 2007). As such although in firm-centric structures, value creation and value capture are central to the company itself (the buyer captures value by consuming the product), the ecosystemic view provides a broader more inclusive perspective where value mechanisms are embedded within the whole ecosystem, making value creation and capture a collaborative effort (Le & Tafardar, 2009; Lehto et al., 2013; Iivari et al., 2016; Letaifa, 2014). Some important dimensions of value emerge from crowd-driven ecosystems and

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

these relate to the fact that: (1) value emerges from a distributed network rather than a linear corporate function (Kohler, 2015), and (2) value is not only co-created (Allee, 2003; Prahalad & Ramaswamy, 2004) and co-captured but also co-distributed among network participants and contributors acting as an ongoing, circular value creation model (Ziouvelou et al., 2017). This emerging participatory value model mirrors an ongoing process of joint value creation, value capture and value distribution where the later manifests as open "value sharing" across the ecosystem's value-creating participants, accounting for their contribution, as opposed to closed, firm-centric value models where value is captured centrally. In order for this model to function effectively, each value domain should operate in the same way, since a weakness in any domain will undermine the performance of the whole ecosystem.

Despite the business logic shift, from firm-centric to ecosystem-centric and crowd driven ecosystem-centric (Ziouvelou et al., 2017), the prevalent view of existing research in the area of business models is still primarily company centric. As a consequence, the business model analytical frameworks facilitating the development, analysis and implementation of business models that are utilised adopt static, firm-centric tools (Ziouvelou & McGroarty, 2017). However due to the nature of the crowd-driven ecosystems and crowd-driven IoT ecosystems in particular current business model approaches and frameworks, facilitating the development, analysis and implementation of business models, are not directly applicable. As such novel frameworks need to evolve that will be targeting the needs of such ecosystems and adopt a dynamic flexible business model framework (Ziouvelou & McGroarty, 2017).

3.1. Ecosystems: From Biological to Crowd-Driven Ecosystems

The notion of the ecosystems lies in the natural world and in the science of biology. Biological ecosystems are communities of living organisms, combining organic and inorganic matter forming "the productive engines" of the planet (Rosen, 2000, p. 3). Such ecosystems are dynamically evolving, "constantly remaking themselves, reacting to natural disturbances and to the competition among and between species" (Rosen 2000, p. 11). The British botanist Arthur Tansley coined the term in 1935, in order to denote a community of living organisms interacting with each other and their environment as a dynamic system. A few decades later one can identify the first biological analogies in the business (Moore, 1993) and in the economic (Rothschild, 1990) fields. Moore perceives individual corporate structures as members of a broader business ecosystem that crosses a variety of industries. According to this view a business ecosystem as "an economic community supported by a foundation of interacting organizations and individuals – the organisms of the business world" (Moore, 1996), that like biological ecosystems are characterized by high complexity, interdependence, cooperation, competition and coevolution (Moore, 1996; Lehto et al., 2013; Jansson et al., 2014) and are formed both intentionally and as a result of an accident. According to Moore it is "conscious choice" that differentiates between ecological and social systems (Moore, 1996, p. 18). Rothschild, on the other hand, sees the global economy as an ecosystem similar to biological ecosystems, facilitating continuous interactions among participating entities. Existing literature indicates that the natural ecosystem model presents an ideal metaphor for numerous ecosystem types, such as: knowledge, industrial, economic, business, innovation and crowd-driven ecosystems research. However, biological ecosystems also present fundamental differences with other systems such as cultural ones (Norton et al., 1997; Ring, 1997; Ayres, 2004). Some of the drawbacks of this analogy, according to Corallo and Propata, 2007, in the business and economic research are firstly the "intentionality" of human activities toward a specific goal and the satisfaction of human wants, as opposed to biological systems that are governed by no intentionality. The second is that although biological species do not

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

interbreed (exceptions are species with smallest levels of complexity, such as genes and microbes), human beings produce novel outcomes via the combination of heterogeneous facts, skills and ideas on a scale that is unparalleled in the rest of nature (Corallo and Propata, 2007). In the sections that follow we present a brief overview of these six ecosystem analogies, as well as a taxonomy following the analysis of (Ziouvelou et al., 2017, Ziouvelou & McGroarty, 2017) (see Table 1).

- *Knowledge ecosystems* are complex systems integrating organisations, people, technologies, processes and data (knowledge resources, databases, etc.) that via collaborative knowledge interaction they share and reuse existing knowledge and they create and co-create new one. These ecosystems act as evolutionary networks of collaboration (Bray, 2007) that enhance knowledge creation and the speed of innovation diffusion (Baptista, 1998). Such knowledge interactions occur between: (a) geographically clustered organisational entities that enjoy numerous advantages as they can benefit from their co-location, their collective resources and the dynamic knowledge interactions that occur between them (Almeida & Kogut, 1999) and (b) in the online environment, within and between communities that exhibit virtual proximity/co-location (Coughlan, 2014).
- *Business ecosystems* are viewed as economic communities of interacting "organisms of the business world" (Moore, 1996, p. 9), focusing on knowledge commercialisation and delivery value to the end users (Clarysse et al., 2014, Valkokari, 2015). Such business structures have many horizontal "co-opetitive" (collaborative and competitive) interactions (Moore, 1993, Brandenburger & Nalebuff, 2011) that aim towards the joint delivery of products or services to customers (Clarysse et al., 2014). Their actors of these nested networks, according to Moore, are: customers, lead producers, competitors, and other stakeholders[2]. Unlike knowledge ecosystems, which are usually university/academia-centered, business ecosystems are market driven and centered on large companies (Clarysse et al., 2014). "Keystone species" (star structure model, often hierarchical (Mazhelis et al., 2012) versus flat ecosystem model composed by mainly SMEs in addition to large companies (Corrallo et al., 2007) are leading, highly influential business actors (Moore, 1996, p. 25).
- *Digital business ecosystems* are business ecosystems in the online environment that enhance cooperation, knowledge sharing and value creation among their interacting digital species[3] (Nachira, 2002, Nachira et al., 2007, Stanley & Briscoe, 2010). Brought about the diffusion of ICT (information and communication technology) and the convergence of ICT networks, social networks, and knowledge networks (Nachira et al., 2007), digital business ecosystems are seen as a partial digital representation of a physical business ecosystem (Nachira et al., 2007). These ecosystems facilitate the emergence of new forms of dynamic business interactions between human and digital entities, systems as well as global cooperation among companies, public and private organisations, business communities and the academic community (a Triple Helix innovation model of university–industry–government (UIG) (Etzkowitz & Leydesdorff, 2000)) fostering this way economic growth at a local and regional level.
- *Innovation ecosystems* are multilevel, multimodal, multinodal, and multiagent system (Carayannis, 2010) where innovation and co-innovation occur in order to generate shared value (Lee et al., 2012) and provide an economic context (milieu) to catalyse innovation and growth (Russell et al., 2015). Such ecosystems are physical, online or virtual networks that nurture creativity, enable the "cross-pollination" of ideas (Luoma-aho & Halonen, 2010), while at the same time trigger, develop and diffuse innovation in an open or closed innovation context. Thus, they augment the

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

organisational ability to create/co-create value and collaboratively innovate, at a level and pace greater than their competitors. These dynamic collaborative networks exhibit sustainable linkages between four key collaborating entities under a Quadruple helix model (Quadruple helix model: university–industry–government-civic society (UIGC) (Carayannis & Campbell, 2010). Innovation ecosystems, are designed ecosystems that differ from natural ecosystems firstly in the presence of intention and teleology and secondly in the acknowledged importance of governance (Papaioannou et al., 2007).

- *Crowd-driven ecosystems* are powered by technology, open innovation, and participatory value creation/co-creation processes driven by and for users (Ziouvelou et al., 2017). These distributed ecosystems leverage the dispersed network effects and harness the collective power and intelligence of the user community that massively collaborates (Tapscott & Williams, 2008) creating shared value (Porter & Kramer, 2011). As such, crowd-driven ecosystems facilitate the creation of a meta-environment driven by and for users, who are active co-creators, collaborators, co-innovators and co-investors; who communicate their ideas, share data, best practices, create new knowledge (crowdsourcing) and provide their funds (crowdfunding), enhancing the innovation potential of our society. Such dynamic networks, explore the direct and indirect interactions of diverse stakeholder segments with the user community, under a Quadruple helix model (university–industry–government-civic society (UIGC)) (Carayannis & Campbell, 2010). In these setting, the competitive advantage of the network is strongly dependent on the ability of the ecosystem core (single entity or group of entities) to stimulate value co-creation with the crowd and the network participants, co-capture and co-distribute it with the ecosystem members.
- *Crowd-driven IoT ecosystems* (Ziouvelou et al., 2017; Ziouvelou & McGroarty, 2017) utilise advanced Internet of Things (IoT) technological platforms in order to elevate the role and collective efforts of people for enhancing the shared value creation/co-creation under a "Quintuple Helix" model (Carayannis & Campbell, 2010; Carayannis & Campbell, 2014) where cooperation is established between the Quadruple Helix (UIGC) actors and one additional helix "environment" (natural environment as a contextual IoT setting). The Internet of Things (IoT) has acted as a catalyst for harnessing the capacity of the crowd, as it facilitated the introduction of new user-centric paradigms, such as mobile crowd sensing (MCS) (Burkel et al., 2006; Ganti et al., 2011). MCS goes beyond traditional sensing techniques (sensor networks, etc.) leveraging both the power and the wisdom of the crowd (participatory sensing (Burke et al., 2006) and opportunistic sensing (Lane et al., 2010) paradigms) in order to sense, observe, measure and make sense of real-world conditions (environmental, etc.,) and activities (personal activities and interactions, etc.,) using user-owned mobile and wearable devices. Crowd-driven IoT ecosystems can exist in many forms, concentrating on specific crowd-driven functions such as crowdsourcing, crowdsensing and crowdfunding, among others, or, increasingly, they can be hybrid; not tied to a specific mode. One can identify numerous IoT crowdsourcing (e.g., OpenStreetMap - crowdsourced world map, Waze - crowd-driven traffic navigation) and crowdsensing networks (e.g., PhoneLab - open access smartphone testbed, Ushahidi - user geo-location data, APISENSE - crowd-sensing for experimental datasets) that monitor diverse elements ranging from city noise (Rana et al., 2010), to climate (Thepvilojanapong et al., 2010) and emergencies (Ludwig et al., 2014). Furthermore, one can find only a few crowd-driven IoT ecosystems that are "hybrid" assimilating both crowdsourcing and crowdsensing parameters. Examples of such ecosystems are *mCrowd* (crowdsourcing and participatory sensing) (Yan et al. 2009) and *EpiCollect* (crowdsourcing and crowdsensing

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

for survey purposes) (Aanensen et al., 2009). However, the coverage of both crowdsourcing and crowdsensing elements is partial, in these hybrid ecosystems, while at the same time they do not facilitate the integration of physical IoT testbeds and FIRE testbeds with crowd-driven resources such as smartphones. To date, the only crowd-driven IoT ecosystem that manages to successfully integrate crowdsourcing, crowdsensing (opportunistic and participatory sensing) and crowdfunding to a certain degree, while at the same time extends existing IoT testbeds with smartphones is *IoT Lab* (Fernandes, et al., 2015, Ziouvelou et al., 2017).

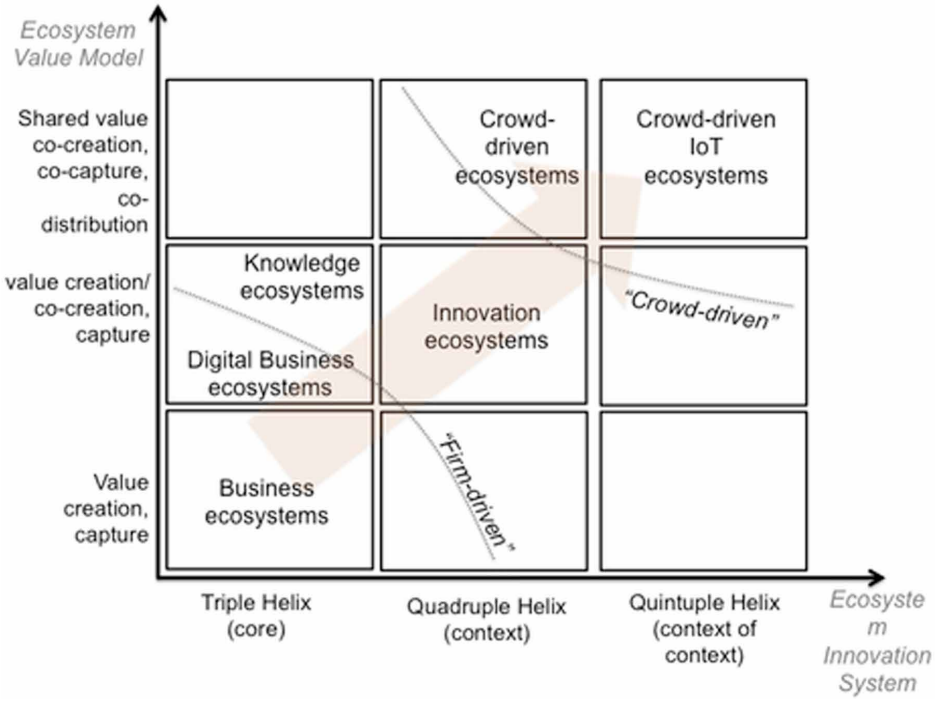
Table 1 summarises and provides a classification of the different types of ecosystems based on their key characteristics. This taxonomy, builds upon existing work in the area (Ziouvelou et al., 2017; Ziouvelou & McGroarty, 2017) presenting some of the key distinctive feature of ecosystems such as:

Table 1. A Classification of the different types of ecosystems

	Knowledge Ecosystem	**Business Ecosystem**	**Digital Business Ecosystem**	**Innovation Ecosystem**	**Crowd-Driven Ecosystem**	**Crowd-Driven IoT Ecosystem**
Function	New knowledge creation/co-creation	Customer value (knowledge commercialisation)	Customer value (knowledge commercialisation)	Innovation creation/ co-innovation	Crowd-driven shared value creation/co-creation	Crowd-driven shared value creation/co-creation
Connectivity	Decentralised and distributed	Geographically clustered	Global and distributed	Geographically clustered or Global and distributed	Global and distributed	Global and distributed
Mode	Physical or online	Physical	Online & virtual	Physical, online & virtual	Online & virtual	Online & virtual
Relationships	Synergetic and co-operative	Competitive and collaborative ("co-opetition")	Competitive and collaborative ("co-opetition")	Co-operative and collaborative	Co-operative, synergetic and collaborative (mass collaboration)	Co-operative, synergetic and collaborative (mass collaboration)
Openness	High degree of openness or closed	Various degrees of openness	Various degrees of openness	High degree of openness or closed	High degree of openness	High degree of openness
Structure	Dynamic inter-organisational, inter-personal	Dynamic or static, and inter-organisational	Dynamic or static, and inter-organisational	Dynamic inter-organisational and inter-personal	Dynamic, complex	Dynamic, complex
Key actors	University, research organisation/ institute	Large company	Large company/ group of companies	Large company/ group of companies, community, University/Research center	NGO/Non-profit initiative – community, company, University/ Research center	NGO/Non-profit initiative – community, company, University/ Research center
Helices Model	Triple Helix	Triple Helix	Triple Helix	Quadruple Helix	Quadruple Helix	Quintuple Helix
Innovation Model	Closed Innovation or Open Innovation	Closed Innovation	Closed Innovation or Open Innovation[4]	Open Innovation or Open Innovation 2.0[5]	Open Innovation 2.0	Contextual Open Innovation 2.0 [*]
Ecosystem Value Model	Value creation/co-creation, capture	Value creation, capture	Value co-creation, capture	Value creation/co-creation, capture	Shared value co-creation, co-capture, co-distribution	Shared value co-creation, co-capture, co-distribution

[*] "Contextual Open Innovation 2.0" integrates the notion of the environment (as a contextual parameter) in an open, ecosystem-centric innovation paradigm based on the principles of Open Innovation 2.0 (Curley & Salmelin, 2013). (extending Ziouvelou & McGroarty, 2017; Ziouvelou et al. 2017; Valkokari, 2015; Clarysse et al., 2014)

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use



function, connectivity, mode, relationships, openness, structure, key actors, helices model, innovation model and the ecosystem value model. It is important to note that each new ecosystemic phase does not make the previous one 'obsolete', but instead extends it (e.g., knowledge ecosystem still exist for new knowledge creation purposes). Also, the last ecosystem type, namely crowd-driven IoT ecosystems, extends crowd-driven ecosystems beyond the Quadruple Helix model of innovation (context) by integrating the "environment" in the innovation model (Quintuple Helix - context of context) so that crowd-driven share value co-creation as well as co-innovation are being contextualized by the natural environment of society (Carayannis & Campbell, 2014).

3.2. Ecosystems: A Taxonomy

The emergence of crowd-driven IoT ecosystems based on value co-creation, co-capture and co-distribution, driven by and for users, demonstrate clearly the two key differentiating aspects of existing ecosystems: (a) *the value model*: specifying the orientation of the ecosystem in relation to value creation, capture and distribution practices and (b) *the innovation system:* denoting the innovation orientation of the ecosystem in relation to the innovation process and architecture (knowledge production and knowledge application (innovation) Carayannis & Campbell 2010). This allows us to identify three generic and distinct phases of ecosystems, adopting an evolutionary perspective, as it can be seen in the taxonomy presented in Figure 1. These phases are:

Phase 1: Closed, firm-centric ecosystems. This phase entails ecosystems that focus on value creation and value capture, under a closed innovation regime (closed company controlled innovation). These

Figure 1. Ecosystems taxonomy

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

ecosystems embed university–industry–government (UIG) relationships (Triple Helix, Etzkowitz & Leydesdorff, 2000). In these settings, users act as consumers and are not directly involved in the value creation process but rather capture value by consuming the product/service.

Phase 2: Hybrid ecosystems. The ecosystems of this phase focus on value creation and co-creation in addition to value capture. These ecosystems embed collaborative creation both under either a Triple or a Quadruple Helix model and a closed or open innovation (Chesbrough, 2003) regime. Under a closed innovation model, value can be collaboratively created under a closed, controlled environment usually led by a single entity (e.g., closed digital business ecosystems, closed knowledge ecosystems), as opposed to an open innovation model where value is co-created in an open and collaborative manner (e.g., open digital business ecosystems, open knowledge ecosystems, open innovation ecosystems). In addition, under an open innovation 2.0 model (Curley & Salmelin, 2013), value is based on the principles of integrated collaboration, co-created shared value and cultivated innovation (e.g., open innovation ecosystem 2.0). Phase 2 ecosystems are manifested either in a Triple or Quadruple Helix architecture. In the latter case, in addition to the three other classes of stakeholders (UIG), the role of the users is active, acting both as producers/creators and consumers of value. As such, these ecosystems leverage the collective intelligence of the society in a collaborative, multi-actor innovation environment.

Phase 3: Inclusive, crowd-driven ecosystems. This phase involves ecosystems that embed a broader more inclusive value perspective, a participatory value model driven by and for users. These ecosystems embrace a circular value creation model, where value is co-created, co-captured and co-distributed among network participants and contributors. The value structures of these ecosystems are expressed in an integrated collaboration, co-created shared value mode of open innovation 2.0 (Curley & Salmelin, 2013) and under a Quadruple or Quintuple Helix innovation architecture. In the latter case (i.e., crowd-driven IoT ecosystems[6]), the "environment" (fifth helix) is the contextual IoT setting of the crowd-driven ecosystems thus "contextually" extending the integrated OI2.0 model of innovation. As such this emerging form of ecosystems can be seen as an amalgam of different networks that consist of economic agents such as civil society, universities, industry, public sector and non-economic ones, such as the environment, technology and their constantly evolving relations.

Although crowd-driven IoT ecosystems constitute a reality, when business modelling for such ecosystems is examined, one can identify a gap in existing research (Ziouvelou & McGroarty, 2017). Existing research in the area place emphasis principally upon the technical aspects of crowd-driven IoT ecosystems mainly related to their development and limited work can be found emphasising upon non-technical elements for such ecosystems such as design (Ziouvelou et al. 2017) and business model considerations (Ziouvelou & McGroarty, 2017). Hence, there is a need for a systematic analysis of business models for such emerging dynamic environments that will address their needs and specifications in order to presented analogous business model analytical frameworks.

4. BUSINESS MODELS FOR CROWD-DRIVEN IOT ECOSYSTEMS

The concept of "business model" has to date received a lot of research attention. Since the late 1990's, the notion of business models has started to gain widespread popularity among scholars and practitioners. The advent of the Internet and the changing firm boundaries enhanced further the interest in the notion

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

of business models and played a critical role for its enhancement (Afuah & Tucci, 2000; Afuah, 2003). However, despite the fact that business models have been considered from multiple perspectives (Zott et al., 2011), no commonly accepted view of the concept specificities and components can be found (Osterwalder et al., 2005; Morris et al., 2005). Instead, a wide array of idiosyncratic views (Zott et al., 2011) exist, which to some extent may be attributed to the different perspectives (organisational, social, economic, strategic, etc.) and research areas (i.e., technology, e-business, m-business, etc.) (Shafer, et al., 2005). In general, one can observe an evolution of the business model conceptualisation over the past decade across a number of perspectives: (a) from firm-centric to ecosystem-centric business models, (b) from static to dynamic, and (c) from closed to open crowd-driven. These perspectives are presented in the sections that follow.

4.1. From Firm-Centric to Ecosystem-Centric Business Models

Over the past few years, there has been a fundamental change in the logic of business models, from firm-centric business models ((BM1.0) Magretta, 2002; Osterwalder et al., 2005; Casadesus-Masanell & Ricart, 2010) to ecosystem-centric ((BM2.0) Westerlund et al. 2014; Rong, et al. 2015; Schladofsky et al., 2016) and crowd-driven ecosystem-centric one ((BM3.0) Ziouvelou et al. 2017; Ziouvelou & McGroarty, 2017). This change, reflects a greater structural shift in the way value is created and captured in today's networked society; that is from open, crowd-driven ecosystemic structures powered by technology, user participation and open collaborative innovation, instead of standalone companies and closed innovation ecosystems. In direct alignment with these transformations, the business model concept has evolved from a construct that explains how a firm creates and captures value in a profitable manner (Baden-Fuller & Morgan, 2010) by interacting with suppliers, customers and partners (Zott & Amit, 2003), to a broader business logic that describes the open, participatory value mechanisms of emerging ecosystems. Unfolding this way, the dynamic, ongoing interactions of the diverse ecosystem actors (economic and non-economic actors) towards joint value creation, value capture and value distribution (circular value creation model). As such the notion of business models has advanced from a corporate blueprint linking strategy and business processes to a constantly evolving network architecture that describes embedded inter-connected value processes. These processes represent a new dimension of innovation that is critical in today's hyper-connected network economy. Product, process and organisational innovation alone are no longer sufficient for companies to stay competitive (Zott et al., 2011; Massa & Tucci, 2014), as such business models constitute a critical new innovation component that complement existing ones (Zott et al., 2011) facilitating success in contemporary complex business ecosystems as they innovate upon the core logic of value creation and value capture.

4.2. From Static to Dynamic Business Models

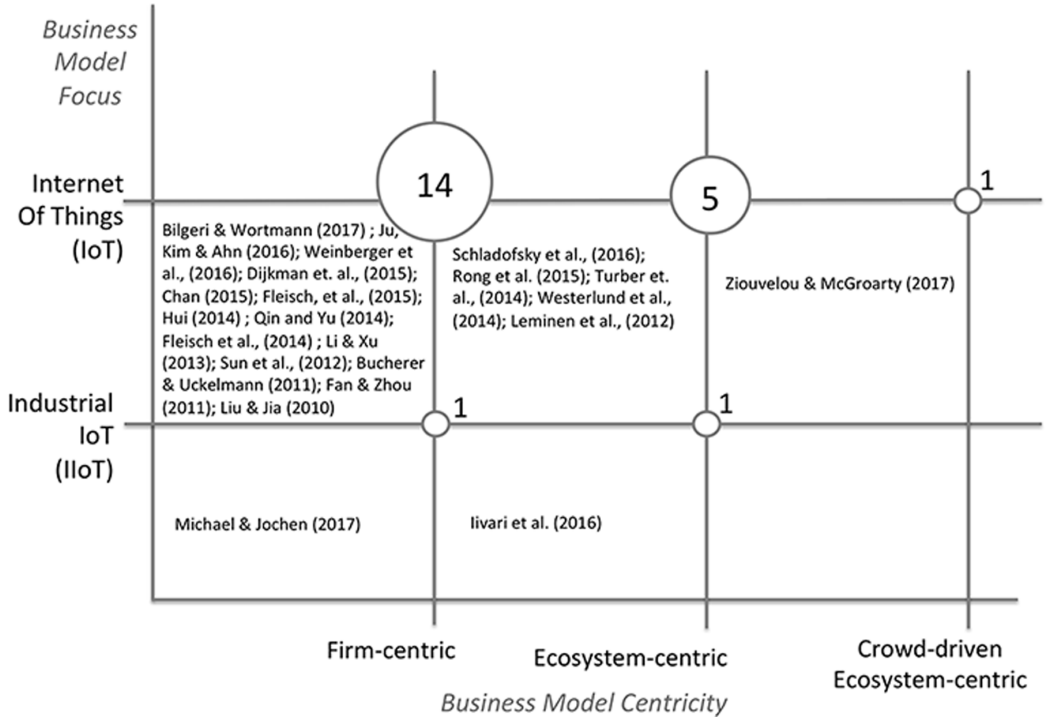
As the networked economy grows and the market environment changes, the value creation and capture processes have undergone a significant shift. Powered by technology, user participation and open collaborative innovation, value emerges from integrated multi-actor constellations and open, crowd-driven ecosystemic structures rather than standalone companies and closed innovation settings. However, these broader more inclusive of value mechanisms, assimilate interdependencies and side effects that need to be considered in order not to ripple through the entire ecosystemic structure. As a consequence, business models need to move beyond the static firm-centric nature of the industrial era into a dynamic, fluid

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

ecosystem-centric nature aligned with the needs of the hyper-networked economy. Therefore, emerging business model frameworks and analytical tools need to adopt taking into account the needs and specifications of today's environment while making the business model reinvention a continual and inclusive process (Red Queen effect, Defus et al., 2008).

4.3. From Closed to Open, Crowd-Driven Business Models

Similarly, in a world of openly communicated knowledge and co-created innovation, closed firm-centric business models can no longer be sustainable, instead open, collaborative and crowd-driven ecosystem-centric business models are needed. This view extends existing work in the area of open business models (Chesbrough, 2006, 2007), that embrace open innovation principles, indicating that companies should look for ways of tapping into and harnessing the ideas that lie beyond their formal boundaries; as well as crowdsourcing business models (Kohler, 2015; Kohler & Nickel, 2017) that is open business models that leverage technology in order transfer value creating activities to the crowd. Open crowd-driven business models are ecosystem-centric rather than firm-centric open business models. As such, they focus on a broader multi-actor value system that is not only integrating crowdsourced value and innovation (outside in) or making unused innovations and value more accessible to external users (inside out) but rather embeds collaborative value mechanisms within the whole ecosystem for co-creation, co-capture and co-distribution of value among the ecosystem stakeholders and contributors in an ongoing circular value creation model. Users, from passive consumers act as empowered collaborators and partners that not only provide but also receive value aligned with their contribution as opposed to closed, firm-centric models where value is captured centrally.



4.4. Business Model Frameworks: A Taxonomy

Aiming to explore existing literature in the area, we performed an exploratory study that builds upon the analysis of Ziouvelou & McGroarty (2017). Utilising a structured approach, we examined numerous interdisciplinary databases and leading journals in the area of IoT business models, which lead us to the identification of the most cited research studies. This exploration, lead us to the identification of research dimensions that facilitate the creation of an explanatory framework. The framework (see Figure 2) classifies existing research along two key research dimensions namely, the (a) analytical focus: denoting the focal area of the business model research either on Internet of Things (IoT) or on Industrial IoT (IIoT) and the (b) analytical context focusing upon the context of each research study (business model centricity) examining an IoT business context (firm-centric), an IoT ecosystem context (ecosystem-centric) or a crowd-driven IoT ecosystem context (crowd-driven ecosystem-centric).

As it can be seen in Figure 2 the prevalent view of existing research (15 out of the 22 studies) is still primarily firm-centric and only a few studies examine ecosystem-centric business models (6 out of the 22 studies). Crowd-driven ecosystem-centric business models are only now starting to emerge, specialising mainly in the IoT context (1 out of the 22 studies). In the context of IoT we see that the vast majority of studies focus on the broader IoT business context (20 out of the 22 studies (Bilgeri & Wortmann (2017); Ju, Kim & Ahn (2016); Weinberger et al., (2016); Dijkman et. al., (2015); Chan (2015); Fleisch, et al., (2015); Hui (2014); Qin and Yu (2014); Fleisch et al., (2014) among others)) and only two studies examine Industrial IoT business models either from a firm or ecosystem-centric perspective (Michael & Jochen, 2017; Iivari et al., 2016).

Figure 2. Crowd-driven IoT business models literature taxonomy

In accordance with the findings of Ziouvelou & McGroarty (2017), one can observe that research focusing on ontological perspectives among ecosystem-centric IoT business models exhibits an emphasis upon the introduction of distinct business models that do not present any direct alignment with existing firm-centric business model frameworks (i.e., the Business Model canvas, Osterwalder & Pigneur, 2010) or either between them. As such, novel frameworks are presented that focus on the notion of value (value creation and value capture) (Iivari et al., 2016; Westerlund et al., 2014) or develop distinct frameworks that adopt the ecosystemic perspective (an integrated 6C framework - Rong et al., 2015; 2 dimensional model - Leminen et al., 2012). However, no study presents a business model framework tailored to the needs of crowd-driven IoT ecosystems. Aiming to fill in this research gap we introduce a specialised business model framework that align with the needs of these ecosystems.

5. A BUSINESS MODEL FRAMEWORK FOR CROWD-DRIVEN IOT ECOSYSTEMS

Building from the literature and aiming to facilitate the analysis of business models of crowd-driven IoT ecosystems we introduce a business model framework for such environments. The proposed model extends existing firm-centric and ecosystem-centric models and aligns with the needs of crowd-driven ecosystems in a broader context as well as in the area of IoT aligned with the findings of existing research in the area (Ziouvelou & McGroarty, 2017).

The Crowd-driven Ecosystem business model Framework (CEF), seen in Figure 3, utilises seven generic building blocks and within each block three key components have been identified (see Table 2). More specifically, the CEF integrates all relevant value network participants and value-related activities and processes in an open, ecosystem-centric context, addressing both the "inner" and the "outer" ecosystem components. In particular, CEF adopts an open, dynamic, participatory approach towards value co-creation, co-capture and co-distribution, providing a holistic view on value mechanism underlying the business model of technologically advanced crowd-driven ecosystems. The generic CEF perspectives and the key elements within each answer four critical business model questions: *What, For/With Whom, How and How Much.*

An overview of the CEF components and sub-components are presented in the sections that follow:

1. **Value Perspective:** This building block constitutes the central pillar of the CEF as it describes the value-creating mode of the business model that links that "inner" with the "outer" ecosystem. The value pillar (what) is an aggregation of the: (a) value dimensions of the ecosystem: an overview of the distinct dimensions of value such as economic, social, environmental value as well as financial and non-financial value; (b) value drivers: the individual and shared value drivers and needs of the diverse ecosystem stakeholders; and (c) value proposition: the integrated public and private benefits for specific actor segments (end-users, ecosystem actors, ecosystem community and society at large).
2. **End-user Perspective:** This building block describes the end-users of the ecosystem; those that will be reached and whose needs will be served. Towards this aim this pillar integrates the following components: (a) end-user segments: the homogeneous groups (same needs, requirements, etc.) of end-users (individual, corporate, public sector users) that will be served via the ecosystem; (b) end-user relation: the segment-specific relationships that the ecosystem will develop with each

Figure 3. Business Model Framework for Crowd-driven Ecosystems (CEF)

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

group; (c) value delivery: the process that the ecosystem will reach (communication, service/product distribution, etc.) its end-user segments in order to communicate and deliver the co-created value.

3. **Stakeholder Perspective:** This perspective describes the broader value network actors (collaborators, partners, etc.). In particular this building block entails the: (a) key ecosystem stakeholders: the internal (partners, internal-collaborators, etc.) and external (complementors, external collaborators, etc.) ecosystem actors; (b) stakeholder drivers: the needs and drivers of each stakeholder segment inside and outside the ecosystem; and (c) stakeholder relation: the actor-specific relations that the ecosystem has and/or will develop.
4. **Community Perspective:** This building block describes the ecosystem community, which constitutes a key value co-creating pillar. The components of this block include the: (a) community/crowd structure: the crowd/community groups and the needs of their members, (b) community/crowd drivers: the individual and shared motives of the different crowd-community segments; and (c) incentive model: the incentivisation schemes for the crowd-community (taking into account the crowd-activities and the crowd-cost) and the rest of the ecosystem stakeholders.
5. **Financial Perspective:** This category represents that financial framework of the business model. In particular, this building block entails the: (a) cost model: the costs incurred by the ecosystem; (b) revenue model: the revenue generation framework of the ecosystem that essentially mirrors the value capture mechanism of the crowd-driven network; and (c) revenue sharing model: this element details the value distribution framework of the ecosystem towards value creating/co-creating segments. This element implicates that value distribution is an important part of the crowd-driven ecosystem business model.
6. **Governance Perspective:** This building block involves the governance model of the orchestration of the broader crowd-driven ecosystem. It denotes the activities and processes underpinning the ecosystem management across multiple levels. The components of this pillar integrate the: (a) ecosystem governance: this element describes the high level ecosystem governance model that entails multiple governance modes (i.e., open vs. closed, for-profit vs. non-profit, hierarchical top-down vs. collaborative bottom-up governance, etc.); (b) technology governance: comprises the technological infrastructure (core system and components as well as the evolving integrated system), the technological mechanisms and rules for the efficient functioning of the broader ecosystem; and (c) community governance: the community principles (control and autonomy within the ecosystem, etc.) and the rules for participation, communication, sharing and co-creation within the ecosystem.
7. **Infrastructure Perspective:** This perspective details the infrastructure underpinning the crowd-driven ecosystem. The components of this pillar include the: (a) ecosystem infrastructure: the multilevel foundation (technical, business, etc.) needed for the ecosystem to make its business model work; (b) key resources: the critical resources (tangible and intangible assets) that are needed in order to support the implementation of a functional ecosystem; and (c) key activities: the activities and processes that should be performed in order for the ecosystem to deliver value to its members, the end-users and the broader community.

These building blocks and their associated components relate to the needs of crowd-driven IoT ecosystems at a particular time period. Given the constantly changing dynamics of these ecosystems, the evolutionary parameter of their business model should be acknowledged and accounted for. This implies both the evolution of the ecosystem itself but also the evolution of the ecosystem community within the network. Future research in the area should address these challenges.

6. CONCLUSION

Distributed, ecosystemic structures prevail in our hyperconnected world. Such structures utilise cutting edge technology and open participatory value creation models to harness the collective power, intelligence and co-creation ability of the crowd. These complex technologically advanced and constantly evolving inter-connected ecosystems have brought about changes across all business functions, redefining business success, which now lies upon the ecosystem's ability to jointly co-create shared value. The Internet of Things has fueled these emerging crowd-driven ecosystems by introducing new user-centric archetypes that leverage not only the power of physical things connected to the Internet but also the wisdom of the crowd to observe, measure, and make sense of particular phenomena by exploiting user-owned mobile and wearable devices.

Although this business logic shift has become the focus of recent studies in the area (Schladofsky et al., 2016; Rong et al. 2015; Turber et al., 2014; Westerlund et al., 2014; Leminen et al., 2012), very little research has been conducted in the business dynamics of these emerging, technologically advanced ecosystems (Ziouvelou et al., 2017; Ziouvelou & McGroarty, 2017) and no study, to our knowledge, has examined business models for these environments. Due to the nature of crowd-driven ecosystems and crowd-driven IoT ecosystems in particular, existing firm-centric business model approaches and frameworks are not directly applicable since they fail to address a number of ecosystemic parameters. As such novel frameworks are needed that will concentrate upon the specificities of these ecosystems and adopt a dynamic flexible business model nature (Ziouvelou & McGroarty, 2017).

Aiming to fill this gap and contribute to this emerging research field, this study examined the dynamics of crowd-driven IoT ecosystems and explored the literature of IoT business models. In particular, it provided an exploratory review analysis of the current scientific knowledge in the context of crowd-driven ecosystems in general as well as in the context of IoT and their business models. This investigation enabled the classification of existing research under two explanatory frameworks that facilitate the analysis of crowd-driven IoT ecosystems and their associated business models.

In addition, this analysis highlighted some key dimensions of crowd-driven ecosystems in general and in the context of IoT. Firstly, the change in the value logic, which adopts a broader more inclusive perspective, as value emerges from a distributed crowd-driven network under a participatory value model. This model depicts an ongoing circular process of joint value co-creation, co-capture and co-distribution. It has been argued, in the course of this paper, that the emerging value component manifests as open "value sharing" across the ecosystem's value-creating participants, accounting for their contribution, as opposed to closed, firm-centric value models where value is captured centrally. Subsequently, it was identified that crowd-driven IoT ecosystems in particular adopt a "Quintuple Helix" innovation system as opposed to crowd-driven ecosystems that utilise a Quadruple Helix one. This implies that cooperation is established between the Quadruple Helix actors (university–industry–government-civic society) and one additional helix the "environment"; natural environment as a contextual IoT setting. This gives rise to a contextual Open Innovation 2.0 paradigm, were innovation emerges in an open, ecosystem-centric, cross-actor innovation process that assimilates the environment. Future research will shed light deeper upon this model and its implications.

This study provided grounds for a new integrated business model framework for crowd-driven ecosystems in general and in the context of IoT, which supports the creation of business models for such environments. The proposed Crowd-driven Ecosystem Business Model Framework (CEF) corresponds to the needs of technologically advanced crowd-driven ecosystems. The seven building blocks of the tool

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Components of the crowd-driven ecosystem business model framework (CEF)

Focus	Perspectives	Key Elements
What	Value Perspective	• Ecosystem value dimensions • Value drivers • Ecosystem value proposition
For/with whom	End-user perspective	• End-user segments • End-user relation • Value Delivery
	Stakeholder perspective	• Key ecosystem stakeholders • Stakeholder drivers • Stakeholder relation
	Community perspective	• Community structure • Community drivers • Incentive model
How	Governance perspective	• Ecosystem governance • Technology governance • Community governance
	Infrastructure perspective	• Ecosystem Infrastructure • Key resources • Key activities
How much	Financial perspective	• Cost model • Revenue model • Revenue sharing model

integrate all relevant value network participants and value-related activities and processes in an open, ecosystem-centric context, addressing both the "inner" and the "outer" ecosystem components. That way, they explain the underlying value mechanism of the ecosystem from a holistic perspective, taking into account the all relevant value sources within the ecosystem and their dependencies. Additional research in this area will examine the diverse life-cycle phases of crowd-driven value-centered ecosystems and identify the implications for the value mechanism of these ecosystems as well as the CEF model in general.

The results of this study should be assessed in the light of their limitations. One general limitation of this study is that it is limited by the number of previously published research studies and their availability. Therefore, on-going research is needed in this emerging research area so as to enhance our understanding further. Another limitation of this research relates to the need to empirically test the CEF model. Empirical validation of this theoretical framework is needed in order to examine its ability to describe the complexity of business models for crowd-driven IoT ecosystems and crowd-driven ecosystems in general (e.g., mobility ecosystems, etc.). As such future research will focus upon the application of the model in an empirical context.

Chapter 24
Green Attitudes and Thinking in The New Green Market:
Using Mathematical Modeling to Satisfy Green Customers' Needs

Nicoleta Valentina Florea
Valahia University of Targoviste, Romania

ABSTRACT

People are concerned by the implications of product consumption on their health, which is why they become followers of a healthy and sustainable lifestyle, using green products and becoming aware of a sustainable environment. To have a viable business and to respond to customers' needs, the organization must have an attractive product that offers utility, value, health, joy, and satisfaction to consumers. This chapter analyses a few approaches regarding the implementation of green marketing policies and the situation of green marketing in the world and in Romania. Green customers' behaviour in choosing a green product (using Markov chains), the impact this could have on the number of specialists and the surfaces used in ecological agriculture on green production (using a regression function) are also anaylsed, and the author developed some measures in order to improve companies' involvement in implementing green activities.

INTRODUCTION

The world is facing enormous challenges like never before. The Earth's systems are under constant pressure due to adverse impacts from human activity: using more energy, creating more waste, and produce more air pollutants (Iannuzzi, 2016, p. xiii). The world is constantly changing and is trying to have a sustainable behaviour and attitude. Global companies have embraced sustainability and are triggering companies to build eco-innovation into their product offerings. Governments have responded by putting pressure on product developers to consider tough new requirements such as removing materials of concern, designing more recyclables, and minimizing packages and facilitating product take-back.

These global regulations started out in Europe and have exploded throughout the world, making it very complicating for business to keep up with the ever-changing requirements and be compliant.

Global companies must eco-innovate products for the market and its customers from the new green economy—who is favoured by politicians, businesses, and policy-makers (Gasparatos &Willis, 2015, p. 19)—and generate economic growth and protect the environment (Vasile & Nicolo, 2017, p. xiv), bringing changes first in the culture (Danaher, Biggs, & Mark, 2016). They must inform their customers about this thing, because a greener product is useless if no one knows it exists. Appropriate marketing of eco-improved products is a critical aspect of a sustainability program (Iannuzzi, 2016, p. xiv). Degradation of environment led to green economy (Ayuk, Oku, Asubonteng, & Nutakor, 2017, p. 1) and its role is to minimize or to eliminate the factors that affect the environment (Nhamo & Mjimba, 2017, p. 3). This analysis is relatively recent and focuses on the need of reaching the consumer with wide spectrum of environmentally friendly products. A window of opportunity has opened up for those firms willing to take the lead in establishing positions of advantage based on greenness (Sahay, Stough, Sohal, & Goyal, 2006, pp. 96-97). It is clear now that the demands will continue to grow, and firms must respond to this challenge to achieve performance.

Every activity supposes a high cost for every stakeholder; this cost consists of consumption of valuable, rare, and unique resources: human, financial, technological, and especially natural. This affects the stakeholder efficiency and also the environment: use of energy for electronics and houses, driving cars, wearing trend-driven fashion, enjoy a wide range of fresh and processes food (Ha, 2008, p. 9). Every product bought is an investment of resources, and its production can contribute to pollution, climate change, and the destruction of habitats. Ecological footprinting has become a popular way of measuring the environmental impact of a given person's way of life. The interest in environmental, organizational, and individual protection and safety is growing every day. Starting in 1960s, the attention grew for environmental issues (Telesiene & Gross, 2016, p. 1; Kahle & Gurel-Atay, 2015), and for green economy, starting with 2000s (Shmelev, 2016, p. 143), and this has created many changes: policies, regulations, rules, and many studies and research made for a greener lifestyle, greener innovations (Peiry, Ziegler, & Baumgartner, 2016, p. xv), and green marketing. Thus, many studies regarding green marketing policies, green consumers' attitudes, green products characteristics, and green thinking and behaviours have been done.

Green business has grown rapidly and it has important expectations from customers, employees, managers, organizations, politicians, and the world in general. Green is not just about protection of the environment; it is about protection and safety of humans and organizations. Before, in order to develop a sustainable strategy, time to convince management to obtain the benefits was needed, but now major companies are making sustainability a platform for growth and funding significant advertising campaigns. Today's climate encourages sustainability improvements and shows how these can help us in the marketplace. People have moved from looking at environmental issues as a risk management function to something that has enormous potential for innovation and growth. Greener products play a bigger role than ever before and should be a growing part of every company's business model (Iannuzzi, 2016, p. 3).

Concern for the environment first appeared in the 1970s, gained momentum for the next two decades, and in recent years, has exploded onto the world business scene (Iannuzzi, 2016, p. 4). Using a green behaviour, the benefits are for everyone: saving resources consumption (natural, human, money), (re) using of waste, and improving personal and professional life.

This chapter brings to the foreground the literature made in the green marketing field, the behaviours of individuals and organizations, the policies made, especially the measures taken by our specialists at

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

the Romanian level compared to European level. The objective of this chapter is to analyse the green market on the Romanian level by simulating customers' behaviours using probabilities calculations and Markov chains. The model used consists of analysing the impact the number of specialists and the surfaces used could have on ecological agriculture and green production by using a simulation model and Excel program. Using these calculations, we proposed some measures in order to improve companies' involvement in developing green activities and improve behaviours with green consumers.

The chapter starts with the definition of the concept of green marketing, and then with a brief discussion about some new ideas: green strategy, objectives, management and employees, green marketing and its four green Ps, and green consumers. These aspects are important for any manager who wants to use the limited resources to obtain maximum performance; this means that by acting efficiently into a new green economy, they could obtain important benefits for their organizations, for their employees, for customers, for the environment, and for stakeholders by implementing a green perspective. This is a step in showing how profitable a green strategy can be for the people, organization, and for the environment.

Green behavior is broader than IT and more global than the Internet and is about developing innovative solutions to advance our society while enhancing our most valuable asset: Earth (Koester, 2016, p. xxv). The best and most successful entrepreneurs recognize an opportunity and create products, services, and businesses that fill that unmet need. As sustainability evolves and takes into account social considerations, a change is occurring in green marketing: to be sustainable the reduction of energy and the resource consumption is needed, and to be green means to change behaviours (Polonsky, 1999, p. 12).

Along the years, some changes have occurred in the managerial perspective, thus appeared the new green marketing perspective. In the opinion of Saxena (2005, p. 657) these changes that affect the green marketing are goals (customer satisfaction, organizational goals, ecosystem compatibility), decision-making (integrated thinking, boundary spinning, long-term orientation), philosophical basis (biocentric, ecosystem a physical limiting factor, eco-costs must be paid), ecological accountability/responsibility (product risk, global/international, full accounting of ecological costs, PSLC members are mutually accountable, joint public-private sectors are mutually accountable), general tools (use life cycle assessment and environmental audits to minimize the impact, the waste, focus on industrial processes, total quality environmental management, use of strategic alliances to accomplish sustainable goals). As the concern for the environment increased in the past three decades, organizations had in mind two goals (Cox, 2010, p. 335): link corporate goals and behavior to the values of environmental quality and avoid if possible any additional environmental regulations that will affect their business.

To define what green means is difficult (The John Marshal Review of Intellectual Property Law, 2010), thus, in this chapter we offer some ideas about what green marketing is:

- Is a term used to refer to a corporation's attempt to associate its products, services, or identity with environmental values and images (Cox, 2010, p. 335).
- Presents managers with the challenge to turn environmentalism into a source of differential advantage and growth (Sahay, Stough, Sohal, & Goyal, 2006, p. 97).
- Is a strategic process involving stakeholders in order to create meaningful long-term relationships with customers while maintaining, supporting, and changing the natural environment (Ferrell, 2008, p. xix).
- Is an ecological issue that concerns all corporates who are called to maintain the ecological balance through developing biodegradable products and reducing the consumption of natural resources (Saxena, 2005, p. 653).

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

- Is an initiative that has been started by the business professionals where the focus is on the conservation of natural resources (Tehrani & Sinha, 2011, p. 328).
- Seeks to inform and persuade consumers about environmentally friendly options (including product labeling and advertising) (Cook & Ryan, 2015, p. 350).
- Is friendly with the environment, developing a success marketing strategy (Johnson, 2011).
- Influences and models the consumers' attitudes and life styles (Grant, 2009).
- Is the marketing of products that are presumed to be environmentally safe (AMA).
- Incorporates a broad range of activities (product modification, changes to the production process, packaging changes, promotion changes) which happen in a manner that is less detrimental to the environment (Chandrasejar, 2010, p. 458).

Marinova, Annandale, and Phillimore (2008, p. 257) say that for any organization to have green marketing activities they must achieve some important tasks such as:

- **Targeting:** Developing a new business unit must design promotion targeting on specific segments of consumers.
- **Green Design:** Production process must be integrated environmental principles to remain competitive.
- **Green Positioning:** The firm must promote the product or the firm's environmental performance as being a core component.
- **Marketing Waste:** The firm seeks to improve efficiency and to reduce waste and to identify viable consumers of waste products.
- **Green Alliances:** Developing joint activities that have some environmental linkage: co-branding activities, more substantive programs, work together to deal with environmental issues.

In the opinion of Florea (2011, p. 283), to obtain success in implementing green marketing the organizations must:

- Increase investment in green branding (without spending money and time) and technology,
- Make green innovation,
- Produce green products,
- Procure green materials,
- Make green manufacturing, advertising, sales, distribution,
- Be implicated in green awareness, education, development, evaluation and monitoring of employees,
- Attract, retain, and maintain green employees and customers.

Many people associated green marketing with organic, biodegradable, carbon neutral, energy efficient, natural, environmentally friendly, low carbon technology, sustainable, and renewable energy used (Kaufmann, 2014, p. 134).

Kotler says that to understand green marketing one also must understand some approaches such as (Rajagopal & Castano, 2015, p. 73-74):

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

- **Product:** Product design should carefully consider the materials and designs used in order to reduce the amount of materials, waste, and the energy required to produce products.
- **Price:** Businesses can offer products that vary in their level of environmental friendliness and price to appeal to consumers with different environmental and price sensitivities.
- **Place:** Production and distribution facilities can be placed closer to the market. More local production and decentralized distribution can be implemented.
- **Promotion:** Businesses should consider shifting promotion from print to online. Labels and advertising should be more specific about ingredients, sourcing, and carbon footprint.

With rising awareness among the mass market consumers about green products and practices, organizations are changing their manufacturing process and marketing strategy. The purchases of the consumers directly affect the manufacture of products and the purchasing decisions of the organization. When the demand of green products increases in the consumer market, the organizations have to produce green products to stay competitive (Tehrani & Sinha, 2011, p. 334).

ISSUES, CONTROVERSIES, CONSEQUENCES

Green is no longer simply a market position, it is a feature (Management Assoc, Info Res, 2014, p. 91) and an important element for the success of every organization, but in this new environment, it must be also important for every leader, manager, supervisor, employee, customer, supplier, producer.

Green business is a complex aspect and analysed by different specialists in the field, and in this chapter, we analysed its importance and its role in the present market by describing some important issues: green strategy, green objectives, green management, green employees, green product, price, place and promotion, green consumers, and green organizations (behavious and attitudes). Understanding these features of the green market all the participants will have a new vision on these relationships, attitudes, behaviours, businesses, and environment – a green one.

Green Strategy

Now is the moment for managers to have a green strategy (Roettgers, 2011, p. 9) and to satisfy the green needs.

From the studies made on this issue are extracted and presented two visions:

- **First Vision:** The firms have developed green strategies based on the 4Rs (reduction, recycling, reusing, and retrieval), which must be reviewed with regard to design and selection of environmentally friendly packaging method (Kirgiz, 2016), and sustainable consumption consists of the 3Rs (reduce, reuse, recycle) view, providing an interesting contrast to traditional environmental views (Kaufmann, 2014, p. 134). Recycling has a positive impact on performance activity of organizations by reducing their costs (OECD, 2015, p. 163).
- **Second Vision:** Based on the benefits the organization could win, it develops a strategy seated on the "4S", going from the green product concept (Kirgiz, 2016):
  - **Satisfaction:** Satisfying the needs of consumers.
  - **Social Acceptability:** Acceptance as a product or a firm being friendly with the environment.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

- **Safety:** Not jeopardizing the health of individuals.
- **Sensitivity:** Companies are realising their products according to the sensitivity of the environment and its pressures: economical, social, political, environmental.

More and more analyses and studies describe the importance of implementation of green strategies; thus, Ottman defines its seven winning strategies for green marketing (Ottman, 2011, p. 47):

- Understand environmental and social beliefs and values of consumers and other stakeholders and develop a long-term plan to align with them.
- Create new products/services that balance consumers' desires for quality, convenience and affordability with minimal impact on environment.
- Develop brands that offer practical benefits with empowering and engaging consumers in meaningful ways about the important issues that affect their lives.
- Establish credibility for your efforts by communicating your corporate commitment and striving for complete transparency.
- Be proactive to solve emerging environmental and social problems. Go beyond what is expected from stakeholders.
- Think holistically. Underscore community with users and with the broad array of corporate environmental and societal stakeholders.
- Don't quit. Promote responsible product use and disposal practices. Continuously strive for "zero" impact.

Sahay, Stough, Sohal, and Goyal (2006, p. 104) say that a strategy for green marketing must have four pillars:

- **Promoting Reconsumption:** The ability to use and reuse goods in whole or in part.
- **Redirecting Customer Needs:** Redirect them towards consumption and the current marketing tools toward such redirection.
- **Reorienting the Entire Marketing:** Everything from product and packaging may be reoriented, but also through assessing the impact of manufacturing, content, package, label, advertising, distribution, use, and disposal of its products on environment.
- **Reorganizing Business:** Restructure and redesign of many processes and systems within a corporation according to the green vision encouragement.

The central idea of achieving green advantage is consisting of the four Ps (Boston Consulting Group, in Tehrani & Sinha, 2011, p. 333):

- **Planning:** Embedding green targets and green resources into corporate strategy (Corporate Social Responsibility).
- **Process:** Reducing wastes in operations, encouraging others especially their suppliers, partners, partners and customers to operate in green way.
- **Promotion:** Communicating the message of company sustainability to its various stakeholders.
- **Products:** Determining offerings, packaging, and pricing, Innovating the consumers to live a green way, knowing which green benefits will really matter to the consumer.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Green Objectives

In the opinion of Cohen (2011, p. 400), the organization will successfully implement green strategies if they align green objectives to the vision of the organization.

Unhelkar (2016, p. 65) thinks that green objectives are the core objectives of a business undertaking green transformation and these may be:

- Ensuring a synergy between the core business objectives and the accompanying green objectives.
- Length of time for potential application: 3-5 years being ideal.
- Key drivers and dimensions that are impacting the organization.
- Identify the growth potential and means for the returns on green investment.
- Finding the niche where the competitive advantage for the organization lies.
- Identifying the areas for formal green IT audits.
- Development of green HR as a part of the strategy.
- Optimization and integration of supply chain systems.
- Attention to collaborative opportunities.
- Incorporation of government rules and regulations.

Green Management

Sustainability of an organization is given by the capabilities and the skills of the leadership to obtain resources used in order to obtain organizational efficiency. Accepting sustainability in a world where the resources are limited involve responsibility towards future generations. Social responsibility belongs to sustainability, due to resource depletion.

Successful leadership requires a more complex mix of skills than in the past. Managers will need to be able to recognise and understand trends and to navigate roadblocks effectively. They must be capable of developing efficient and innovative responses to key challenges and opportunities since the sustainability concept is relatively new (Polonsky, 1999, p. 9). To make decisions and balancing different domains, the managers are facing challenges such as environmental protection, satisfaction of new green demands of consumers, be socially responsible, and offer environmentally friendly products and services. Eco-efficiency is driven by the vision of making the challenge of sustainability a business opportunity.

Green Employees

Employees involved in the sustainable activities and adopting sustainable development principles will become sustainable human resources (Florea & Florea, 2009). Human factor is known as one of the key factors in obtaining international organization success (Holbeche, 2012). The practitioners recognize the importance of the role played by human resources in achieving the objectives of the organizations (Edstrom & Lorange, 1984).

According to the principle "healthy people in healthy organizations", human resources must play an important role in applicating the sustainable development activities. In the last decade, human resources management has played an important role in solving problems like recruitment and selection, performance evaluation, training, processes based on not-discriminating, ethics, equity, diversity, and sustainable development principles. The efficiency of a human resources system is given not only by

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

human resources behavior, knowledge, and capabilities but by the strategic human resource management ethics and sustainable development. Ulrich (1997) says that human resources professionals must create politics and practices that make the employees more competitive (Burke & Cooper, 2005).

Green Product

Products today need to be green and brands need to be socially responsible (Management Assoc, Info Res, 2014, p. 91). To understand better the green product we offer a few definitions from specialists in the field.

Thus, green products:

- Are the products which don't pollute the world or deplete natural resources and are recyclable or preservable and do not threaten the human or animal health. No product has zero impact on the environment, thus any organization must minimize the use of energy, the waste, and the unnecessary use (Kirgiz, 2016).
- Refer to those products that incorporate the strategies in recycling or with recycled content, reduced packaging or using less toxic materials to reduce the impact on the natural environment (Chen & Chai, 2010, p. 29).
- Need special efforts to be noticed by consumers. Since consumers are unwilling to pay more for green products, they need to be persuaded by marketing communication strategies. Advertising is the most popular way to promote awareness of environmental products and create demand for them (Kaufmann, 2014, p. 134). The first environmental advertisements appeared in the late 1960s, and in 1980s green advertising started to become a popular marketing strategy, and 1990s represented the period of making false messages and give confusion among consumers.
- Are generally regarded as more expensive than other alternatives (Kaufmann, 2014, p. 137).

We also offer and present other features linked by product:

- **Green Packaging**: Packaging is costing, thus the producers, the consumers and the activists search for cost-efficiently (Kirgiz, 2016), environmentally friendly and sustainable packaging, focusing on functionality, cost-effectiveness, and support for long-term human and ecological health. Green packaging means that the containers are not affecting future generations (Mansvelt, 2010, pp. 329-330) and must not go to waste and reduce the use of underground resources, respect human needs in terms of pay, working conditions (Mansvelt, 2010, p. 330). Using biodegradable materials in place of plastic which take centuries to decompose, the decomposition takes few weeks.
- **Green Labels**: (Or eco-labels) help consumers differentiate between green and non-green choices by emphasizing various green attributes (rigor and credibility). Some of green labels are carefully regulated by the government entities or nonprofit groups (Cook & Ryan, 2015, p. 350).

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Green Price

Green price takes into consideration the people, planet and profit in a way that takes care of the health of employees and communities and ensures efficient productivity (Patil & Bhakkad, 2014, p. 85). Value can be added by changing ways of thinking, behaviours, and attitudes.

Green price mix aims at delivering superior value and greater benefits to price ratio guided by the objectives of green marketing-oriented companies rather than factors determining sales. For example, high quality standards can be promoted for money can be promoted for low-priced green products (Management Assoc, Info Res, 2014, p. 2001). Green price is an area of concern (Chandrasekar, 2010, p. 462). Most of the products are being sold at a premium which makes it unattractive. Considering that it is not mandatory on the part of the people to buy the green products, the prices in the initial times are definitely higher. Economies of scale can provide a lower price. Green pricing take into consideration the people, planet and profit in a way that takes care of the health of employees and communities and ensures efficient productivity. Value can be added to it by changing its appearance, functionality through customization. Organic vegetables, products are priced at a premium and are now unaffordable to masses. Green products need to be offered through the government's support channel and create more awareness among people. The firm must move beyond simply discussing out of cost price to identify the price of utilizing the good green logistics must be designed to minimize the utilization of resources that will frequently include reverse logistic systems that move packaging and used products back to the firm (Marinova, Annandale, & Phillimore, 2008, p. 257).

Green Place

The distribution of goods generates noise and vibration, causes accidents, and contributes to global warming, being the reason it needs to be analysed in order to decrease its impact on environment (McKinnon, Browne, & Whiteing, 2015, p. 3). Economic theory tells us that higher priced products can and should result in lower levels of customer participation and renewable energy purchases (Wilson & Olson, 2004, p. 25).

Green logistics:

- Is about managing logistics to cut down on transportation emissions (Patil & Bhakkad, 2014, p. 85), thereby in effect aiming at reducing the carbon footprint (Chandrasekar, 2010, p. 462).
- Must be designed to minimize the utilization of resources that will frequently include reverse logistic systems that move packaging and used products back to the firm (Marinova, Annandale, & Phillimore, 2008, p. 257).
- Meaning green transportation and green warehousing consist of pollution prevention, emission control, reduce costs, and fast deliveries (Emmet & Sood, 2010, p. 132).
- Is about saving money and reduces the effects on environment, having economic and social implications (McKinnon, Browne, & Whiteing, 2015, p. 4).

Green logistic is a relatively young but rapidly evolving subject. Without green logistics, a green supply chain will have not ensure success (Emmet & Sood, 2010, p. 132). The supply chains changed, too; now, the green products are found into specialized stores or on the online sites of organizations (Ottman, 2011, p. 8).

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Green Promotion

Green promotion involves configuring the tools of promotion, such as advertising, marketing materials in such a manner that will not affect environment (Patil & Bhakkad, 2014, p. 85). Green promotion mix effectively communicates the value in a company's green product offerings in forms of environmental information about green products, processes and practices, and their environmental significance (Management Assoc, Info Res, 2014, p. 2001). Green marketers link green products and green promotion to enable them making effective purchase decisions. Green promotion involves the tools, such as advertising, marketing materials, signage, white papers, web sites, videos and presentations by keeping people, planet, and profits in mind (Chandrasekar, 2010, p. 462). The firm must include information in its promotional activities that mention environmental benefits of products in addition to other activities green logistics must be designed to minimize the utilization of resources that will frequently include reverse logistic systems that move packaging and used products back to the firm (Marinova, Annandale, & Phillimore, 2008, p. 257).

Green advertising has risen since 1980s and is the inclusion of environment-friendly features and attributes as a persuasive selling point. Criticism on green advertising relies on superficial and unsubstantiated claims at best, misleading and deceptive claims at worst. To protect consumers from false green advertising, the official commissions changed theirs guides and advised marketers on making claims about green product attributes that are truthful and nondeceptive (Cook & Ryan, 2015, p. 351).

The awareness of green products is done through green advertising, blogs, and social networking sites. In green advertising, the green ads are created to influence the homemakers to buy and use environmentally friendly products in their day-to-day activities (Tehrani & Sinha, 2011, p. 328). Green awareness among consumers may occur by using blogs. Green blog is a website that hosts daily updates and posts from people around the world solely devoted to environmental actions and discuss only with green community.

The most successful green marketing campaigns must (Iannuzzi, 2016, p. xv):

- Have a credible greener product story,
- Meet customers' greener product demands,
- Appropriately communicate the products greener attributes.

Green Consumers

Green consumers are sincere in their intentions, with a growing commitment to greener lifestyles (Patil & Bhakkad, 2014, p. 85). They are the individuals who are careful to purchase products that are biodegradable, recyclable or otherwise safe for the environment. They are sometimes called "tree huggers" because of their concern for preserving natural resources. Consumers' attitudes towards green products is increasing (Kaufmann, 2014, p. 128). If producers want to attract the green consumers, then they must have to understand the stages of consumer behavior and try to engage the green consumer more with their green products. To create awareness organizations must develop simple messages according to AIDA principle (attention, create interest, desire and action itself), targeting the wanted consumers, use promotion and focus on positive impacts (Tehrani & Sinha, 2011, p. 323).

A green consumer is someone who make purchases on the basis of firms' roles in society, who is concerned about their everyday habits and the impact on the environment, who translate their environ-

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

mental concern into actively purchasing green products commitment, who is aware of and interested in environmental issues, who usually makes organized petitions, boycotted manufacturers, and actively promotes the preservation of the planet, and who wants a higher quality and is willing to pay a higher price (Universal-Publishers, 2011, p. 46). With the commencement of the new millennium and consumers became center of interest, in 2000s consumers started questioning eating habits, fuel consumption, car usage, energy saving, and recycling methods (Kaufmannn, 2014, p. 129).

The evolution of green marketing made develop a green consumer typology (Kaufmann, 2014, pp. 129-130):

1. Made by Ogilvy and Mather:
    a. **Activists (16%):** Likely to buy green products and services,
    b. **Realists (34%):** Are worried about the environment but skeptical about the green bandwagon,
    c. **Complacents (28%):** See the solution as somebody else's problem,
    d. **Alienated (22%):** Are unware of green issues or see them as transient.
2. Made by US Roper Starch Worldwide:
    a. **True Blue Greens (11%):** Major green purchasers and recyclers,
    b. **Greenback Greens (5%):** Will buy or give green but won't make lifestyle changes,
    c. **Sprouts (33%):** Care but would only spend a little more to buy green,
    d. **Grousers (18%):** Environment is somebody else's problem,
    e. **Basic Browns (31%):** Essentially don't/won't care.

Green Organizations: Behaviours and Attitudes

The environment, the options, the needs, and the consumers' desires, leading implicitly to changing products, vision, mission, behaviours and organization strategies are changing. Thus, a continuous loop of product and organization development according to environment changing and consumers desires is created.

Changes in consumer behaviour (Megicks, Donnelly, & Harrison, 2009, p. 51; Florea, 2014, p. 114):

1. Demographic
    a. Access to sport, due to a rapid aging process of young people and children and exposition to the new technologies and media campaigns,
    b. Changing family relationships (a more reduce size of the houses).
2. Segment Structure
    a. Appearance of monoparental families,
    b. Large number of single persons,
    c. Raising number of working women (70%).
3. Social
    a. Raising the percentage of using the internet (the number of Internet users worldwide increased from 0.36 mil. in 2000 to 19.66 mil. in 2010, to 30.35 mil. in 2014 and to 36.11 mil. in 2016 [www.internetworldstats.com], the growth from 2000 to 2016 being of 900.4%).
    b. Raising the percent for online orders and home deliveries,
    c. Concern for prices raising,
    d. Raising the importance of relationship quality/price/value.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

4. Ethical
    a. Equity in buying,
    b. Buyers with conscious,
    c. Cynicism,
    d. Raising degree of knowing and information,
    e. Implication, human and environment rights defence,
    f. Lifestyle,
    g. Knowing the risks of smoking and alcohol consumption,
    h. Adapting of a healthy lifestyle,
    i. Raising the level of green products consumption.
5. Cultural
    a. Minimizing sugar consumption,
    b. Decreasing the consumption of products with a great level of fat,
    c. Participating to sport activities and fitness.
6. Natural Marketing Institute survey (2009) offered some data in which show, that the green concept became a normal phenomenon for customers and organizations, implying (Ottman, 2011, p. 8):
    a. Recycling materials from plastic, glass and paper (65% of consumers),
    b. Affecting less of the environment,
    c. Consuming less of the resources,
    d. Throwing less of toxic substances in the environment,
    e. Using bicycles (31%), and common transportation (subway and by bus), reducing the consumption of fuel (17%),
    f. Making shopping and using recyclables bags (48%),
    g. Preserving energy by stopping the light sources (95%) and water (85%),
    h. Producing clothing articles using recyclables or natural fibres, eco-detergents, raising healthy animals, making bio dyings, biological pesticides (84% from organizations).

Many organizations made new products, which are at fashion (Ottman, 2011, p. 2):

- Cell-phones which use solar batteries,
- Cars who use eco-fuels,
- Food and juices who are natural in a great proportion,
- Clothes made form recyclable materials,
- Packaging for cosmetics which are made from recyclable paper,
- Phosphate-free detergents (Soundarapandian, 2007, p. 221),
- Cadmium-free batteries,
- Energy-efficient computers,
- Solar water heating (Koester, 2016, p. 48),
- Water purifying systems,
- Cool roofing installation,
- Green building,
- Green cement.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

And many other organizations are implicated in developing new green products in order to satisfy green consumers:

- Toyota Prius had made the first car that has had a green platform from its inception (Iannuzzi, 2016, p. 6).
- Starbucks is well known for their fair and ethical sourcing of coffee and their sustainability program to the visible part of their product (their cup, who ensure that 100% of their cups are reusable or recyclable.
- Kimberly Clarck initiated an advertising campaign about their new, sustainable toilet paper, without the cardboard tube under the brand name "Scott Naturals".
- Toyota presented in 1997 the rechargeable electrical hybrid vehicle and it provides performance and fuel economy today (Kirgiz, 2016).
- Ecologist Dish Washer is one of the best examples of the environmentalist production approach in all products developed by Arcelik A.S.
- AEG Electrolux use a diminished quantity of water, and lowering energy.
- McDonalds is using paper packages in lieu of plastic packages.
- Cell phone producers announce when the battery is fully charged to unplug the charger.
- Olive oil producers like Paksoy are using glass bottles.
- The producers of glass bottles lightening their weight in order to reduce the consumption of natural resources.
- IKEA started charging consumers when they opted for plastic bags and encouraged people to shop using its "Big Blue Bag".
- WalMart unveiled its first recyclable cloth shipping bag (Chandrasekar, 2010, p. 462).

These actions lead to obtaining profit by healthy organizations, growing the level of health of the population, and developing a healthy environment.

Benefits Obtained by Stakeholders by Implementing Green Marketing

Green market is growing, evolving due to new legislation and rules realized for a green consumer, which bring development opportunities for organizations, growing opportunities for sales, increasing opportunities for market shares or in positioning on a new segment and in satisfying new consumers desires. All stakeholders will have to gain, and all will receive benefits.

Using green products conducted to benefits as benefits for organizations and their brand.

Companies all over the world are striving to reduce the impact of products and services on the climate and other environmental parameters. Marketers have taken the cue and are going green (Chandrasekar, 2010, p. 458).

Implementing green marketing, the organizations could obtain the following benefits:

- Increasing the operational costs (Johnson, 2011), including for recruitment and selection (Florea, 2013, p. 56), offering a healthy work environment (Stegaroiu & Florea, 2013, p. 12),
- Reducing the degree of the competition,
- Reducing the consumption of materials.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Companies like Coca Cola (has lightened the silhouette of bottles by reducing the consumption of glass and plastic), Este Lauder (found a new melting method for packaging), Nestle, Procter & Gamble (offers products which are not transported in cardboard boxes), and McDonalds (who is using recycling for packages) are contributing to the reduction of costs and for attracting the attention of customers (Kirgiz, 2016).

Organizations who apply green marketing are:

- Increasing the morale of the employees (Ottman, 2011, p. 2),
- Making a correct functioning of all activities,
- Establishing clear objectives, who may be achieved on long term,
- Encouraging green employees,
- Recruiting of talented green employees,
- Growing the motivation of employees,
- Growing the degree of innovation,
- Growing the level of employees' skills,
- Ensuring price positioning over market value (Kirgiz, 2016),
- Preventing information tangle,
- Protecting against competitive attacks,
- Raising productivity,
- Creating loyalty in the consumer.

Benefits for Consumers

Organizations and retailers came in front of green consumers with new tactics:

- Offer recyclable packaging (for example, McDonalds and Burger King have offered these packaging in order to reduce waste, Coca-Cola pumped syrup directly from tank instead of plastic saving money) (Patil & Bhakkad, 2014, p. 85),
- Offer reduced air pollution for consumers (for example Sheraton Hotels used furniture made of wood harvested from managed forests and all carpets, draperies, paint and wall paper were made free of toxic chemicals; they forbade smoking and use ventilation systems that ensures fresh air in all rooms),
- Retailers use tools to save environment (for example, Wal-Mart runs videos to educate consumers, open ecofriendly stores where rainwater is collected from parking lots, and use solar powered for road signs) (Chandrasekar, 2010, p. 463),
- Safer products (Iannuzzi, 2016, p. 6),
- Saving money through energy efficiency.

Benefits for Society

To be green, organizations must implement (Johnson, 2011) reasonable actions, real advertising campaigns, one research in implementing eco-marketing, green labeling for qualitative products, recyclable measures for energy and paper, maintain sustainable ecological optimism, develop online green marketing opportunities, create eco-niche marketing.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Green market and implication of organizations in green marketing will lead to (Ottman, 2011, p. 3):

- Raising organization reputation,
- Raising the degree of sustainable resources consumption,
- Raising the degree of green consumers satisfaction,
- Raising the life cycle of green markets and green products,
- Raising the quality of environment and the concern for the limited resources.

Benefits for Employees

By implementing green strategies, an organization obtains competitive advantage, satisfies better the needs of all stakeholders and implicitly the employees' needs (Kaufmann, 2014, p. 128). Applying green marketing, the organization may attract better employees. Employees feel betters when they know that they are working for an environmentally responsible company. To not take the wrong actions in green marketing, the firms must find a balance between consumers' expectations, government regulations, science, corporate profit, societal long-term welfare, and motivating employees.

Green isn't just about environment; it also represents a way of seeing the business and its facing challenges through a new lens, which can bring risks but also opportunities. This behaviour has impact on microlevel (save money for all stakeholders, cut wastes, reduce use of resources), and also on macrolevel (impact on jobs, economic development, balance of payments, quality of life, improve infrastructure, reduce financial crises) (Friend, 2009, p. ix).

METHODOLOGY

The main objective of this study is to analyse the actual situation of green marketing in Romania and to:

- Analyse the green customers behaviours using probabilities calculations, MATLAB and Markov chains,
- Analyse the impact could have the number of specialists and the surfaces used in ecological agriculture on green production by using a simulation model and Excel program,
- Propose some measures in order to improve the companies' involvement in developing green activities and improve behaviours with green consumers.

Data Presentation and Analysis

Green Marketing in Romania: Initiatives and Opportunities Through the Prism of Green Agriculture

This chapter will analyse the role of green agriculture, its role being to produce cleaner food in correlation with environment preservation and development. Increase of organic farming areas shows that the first European country has almost 19 percent of total utilised agricultural area (in 2005 having almost 17), while Romania has in 2013 a little over 2 percent (in 2005 having under 1 percent) (ec.europa.eu, EU27, RES 2015, p. 42). The total area under organic farming across Europe increased from 5.9 million ha in

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

2003 to 9.6 million ha in 2011 (63% growth). It is estimated that organic is the fastest growing sector of the food industry, with global revenues increasing from $18 billion in 2000 to $72 billion in 2013, i.e., a fourfold increase in just over a decade (first 2014 estimate being close to $80 billion).

Romania presents some structural characteristics alike with the other agricultural sectors form other EU member countries, but it is unique through the gap between the category of large farms and the small ones, and also through the prevalence of subsistence/semi-agriculture. In 2010, 93% from Romanian exploitations were in these two categories; from these, three quarters were operating on less than 2 hectares and more than a quarter were managed by farmers with age over 65 years (http://www.madr.ro/docs/agricultura/strategia-agroalimentara-2020-2030.pdf). From economical point of view, 73% from the exploitations offered less than 2,000 Euros, which places almost 2.7 mill. exploitations in economic non-viable farms category (being 5% of the surfaces cultivated from EU). Thus, a significant percent of these surfaces from Romania is linked by the agriculture sub-optimal activities, who stay as a barrier in achieving its high potential.

Tough economical conditions after the crisis from 2009 made that 120,000 farms to become farms under 2,000 Euros category (comparing to 2007) and they caused a step back from the condition who limited their percent to two thirds from the total.

A positive aspect is this field is that demographic transition from Romanian agriculture brought positive transformations (http://www.madr.ro/docs/agricultura/strategia-agroalimentara-2020-2030.pdf):

- Between 2005-2010, the number of farms decreased with 400,000 farms,
- The number of young farm managers increased in 2010 (23% of the farmers have less than 45 years comparing with only 17% in 2005).
- Young farm managers contributed more and more to standard agricultural production: 29% in 2010, comparing to just 18% in 2005.
- The average size of the farms grew up modestly (from 3.11 ha in 2002 ha to 3.45 ha in 2010 and to 3.6 ha in 2013), due to the diminishing phenomenon of the used agricultural surfaces.
- The implementation of a life rent schema, favoured a transfer rather through lease (247 thousand ha) then through selling (82 thousand ha), having also a positive role.

The same source (The Romanian Ministry of Agriculture), says that the problems of Romanian agriculture is facing are due to the following factors (www.madr.ro):

- Reluctance to land consolidation,
- Agriculture is still a less attractive field for young entrepreneurs,
- The incomes are too reduced,
- The import of food is growing,
- Agricultural machines are insufficient and under the European standards,
- The agro-food chains are inefficient,
- The access to credits for agricultural investments are deficit areas,
- The conditions for raising animals are poor,
- The promotion of Romanian agricultural and food products is poor,
- A national brand for products is missing,

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

- The capacity for storage is insufficient.

To show a view regarding the current state of some indicators in this study are presented some surveys results:

- The Resource Efficiency Scoreboard (RES) (EU28, 2015) showed that the most reduces levels of resource productivity/indicator are registered in eastern European countries (Romania, Bulgaria). The same report analyses the recycling rates in 2013; more European countries (EU27) are over 40 percent, Romania being the only one under 10 percent (actually being under 5 percent) (ec. europa.eu/RES, 2015, p. 31).
- Eco-innovation index (ec.europa.eu/RES, 2015, p. 33) shows that Romania obtained a little over 300 (being on the 21th place from 28 European countries), the first having an index of over 700.
- Flash Eurobarometer 367 (25568 respondents) made in 2015 showed that a very high proportion of citizens buy environmentally-friendly products so are classified into the two maintenance categories (80%). More than half of respondents are classified as occasional maintenance (54%) and another quarter as regular maintenance (26%). In total, 15% of EU citizens do not buy environmentally-friendly products (ec.europa.eu/public_opinion /flash/fl_367_sum_en.pdf).

The organic products on the Romanian market are quite reduced. The most food, among canned vegetables, fruits, certain breads, are brought form abroad. The total selling of bio Romanian products are representing less than 1% from the retail market, toward the European average of 5-6% (http://www.infomina.ro). In October 2007, Romania had a production from ecologic agriculture of 7457 thousand tones (only for cereals), and the total surface used for this type of agriculture is of 190129 ha, toward 31.4 mil. ha at global level. The consumption for ecologic products is of 1% against other countries as Germany (5%), England and Austria (3%). Romania is one of the East EU members who grew up at bio production, next to the Czech Republic and Poland, but is important to grow to processing and selling too (http://www.ziare.com). Romania has exported in 2014 agri-food products with 6.1% more than previous year, while the imports have grown in a slower pace, surpassing with 2.6% the value obtained in 2013 (http://www.madr.ro/schimburi-comerciale-cu-produse-agroalimentare.html).

The analyses, surveys, and the trends show that in the next years the green market from Romania has a great potential of development in the European organic industry. The most important issues being for Romanian green market that there are no companies for processing the ecological products, thus the raw materials being exported, and they are coming back (processed, labeled, transported) a few times more expensive.

Green Marketing Evolution in Romania Using Simulation Techniques

To understand better the evolution of green marketing in Romania based on the analyses presented above and past data registered officially at European level are implement some models and are used some simulation techniques.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Case 1: Analysing the Actual Situation of Green Marketing in Romania and Implementing Mathematical Calculation to Measure the Impact of Different Factors on Green Marketing Efficiency

This research is made departing from a survey made by Flash Eurobarometer 367 (2013, pp. 8, 10) on 28 countries from Europe:

- In the first case (Table 1) are extracted from Question 5 data just for four countries from South-East of Europe (Romania, Croatia, Bulgaria, and Hungary, noted as RO, HR, BG, and HU) regarding the fact that choosing a labelled green product will cause less damage to the environment.
- In the second case are extracted from Question 2 and calculations regarding the decisions of respondents on what aspects are important when they are buying a product: the quality, the price, the impact on the environment and the brand (name) of the product.

Departing from these data it is seen in tables data extracted from questions Q2 and Q5, developing some calculations using Markov chains.

And then it is build a matrix formed by four lines and four columns, according to the registered data.

$$\begin{pmatrix} 0.15 & 0.31 & 0.45 & 0.09 \\ 0.16 & 0.52 & 0.24 & 0.08 \\ 0.17 & 0.53 & 0.21 & 0.09 \\ 0.22 & 0.44 & 0.27 & 0.07 \end{pmatrix} \tag{1}$$

It is also taken into account the fact that when the respondents are deciding on what aspects are important when are buying a product; they are taking into account the quality, the price, the impact on the environment and the brand (name) of the product.

Making the calculation, according to the registered data at Q2 presented in Table 2, the following scores are obtained:

Below are calculated the scores obtaining:

- For quality:

$$q = (65 \times 5 + 32 \times 4 + 2 \times 3 + 1 \times 2 + 1 \times 1) \div 100 = 4.61 \tag{2}$$

Table 1. Data regarding the confidence that labelled green products cause less damage to the environment

Country/Scale	5	4	3	2 and 1	Total
RO	15	31	45	9	100
HR	16	52	24	8	100
BG	17	53	21	9	100
HU	22	44	27	7	100

Source: data extracted from Flash Eurobarometer 367, 2013, Q5, p. 8.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Factors important when choosing a green product

Analysed Factor/ Scale	5 (Very Important)	4 (Fairly Important)	3 (Not Very Important)	2 (Not at All Important)	1 (Don't Know)
Quality	65	32	2	1	1
Price	40	47	10	2	1
Environment	38	46	12	3	1
Brand	14	32	36	17	1

Source: data extracted from Flash Eurobarometer 367, 2013, Q2, p. 10.

- For price:

$$p = (40 \times 5 + 47 \times 4 + 10 \times 3 + 2 \times 2 + 1 \times 1) \div 100 = 4.23 \tag{3}$$

- For environment:

$$e = (38 \times 5 + 46 \times 4 + 12 \times 3 + 3 \times 2 + 1 \times 1) \div 100 = 4.17 \tag{4}$$

- For brand:

$$b = (14 \times 5 + 32 \times 4 + 36 \times 3 + 17 \times 2 + 1 \times 1) \div 100 = 3.41 \tag{5}$$

To transform into a stochastic matrix, are made the summing up of the scores, which is 16.42, and then is divided each score to this sum, obtaining the following elements of the line vector:

$$T_0 = \begin{pmatrix} 0.28 & 0.26 & 0.25 & 0.21 \end{pmatrix} \tag{6}$$

It is considered that T_0 is the actual moment, thus it will be used the simulation (using Markov chains) of the actual values for the next three years till 2019.

$$\begin{pmatrix} 0.15 & 0.31 & 0.45 & 0.09 \\ 0.16 & 0.52 & 0.24 & 0.08 \\ 0.17 & 0.53 & 0.21 & 0.09 \\ 0.22 & 0.44 & 0.27 & 0.07 \end{pmatrix} \times \begin{pmatrix} 0.28 & 0.26 & 0.25 & 0.21 \end{pmatrix} \tag{7}$$

Using MATLAB, are obtained the following results for quality, price, environment and brand for green products (noted as QPEB). It is observed that these results tend to stabilize and are presented in Table 3.

It is observed that in the next three predicted years, the quality is continuing to decline slightly starting from 0.28 and reaching in 2019 at 0.17 being on the third place in a predicted future; the price is continuing to grow in the next year, and then is stabilizing reaching to 0.48; the value for environment

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 3. The trend of QPEB for the next three years

Analysed Elements/T	T_0	T_1	T_2	T_3
Quality	0,28	0,17	0,17	0,17
Price	0,26	0,45	0,48	0,48
Environment	0,25	0,30	0,27	0,27
Brand	0,21	0,08	0,08	0,08

is rising from 0.25 to 0.30 in the next year, and then is stabilizing at 0.27; the brand diminish its values from 0.21 in T0 to 0.08 in the next three years, stabilizing itself.

The conclusion of this new matrix, where the respondents from the four analysed South-Eastern European, including Romania, is that the analysed countries will change their vision regarding the four analysed elements of a green product: if in T0 the most important element was the quality in choosing a green product, now remain the second (from 0.28 to 0.17), the price which was on the second preferred element in the predicted future is the first (from 0.26 to 0.48), the environment is gaining preference from 0.25 (the third place) to 0.27 (the second place), and the brand is losing in the predicted future reaching from 0.21 in T0 to 0.008 in T3 being on the last place, far from the other values.

Thus, in the present, a buyer prefers a green product after the quality, the price, the environment, and the brand; into a simulated future the buyers will choose a green product after the price (increasing to 0.48 from 0.28), the environment (increasing from 0.25 to 0.27), the quality (decreasing from 0.28 to 0.17), and then the brand (decreasing from 0.21 to 0.08). So, the future buyer is choosing a green product depending on the price and its impact on the environment, choosing to be aware of the consequences on the health of the environment and the consumption of the resources.

Case 2: Analysing the Green Market From Romania and the Impact It Could Have on the Number of Specialists and the Surfaces Used in Ecological Agriculture on Green Production in Romania Using a Simulation Model and Excel Program

This analysis started from data presented in Table 4, in which are presented three variables, one chosen as being dependent and two independent, and the goal is to see if there is a relationship between them. For this it is applicated the regression function and Excel calculation.

Pearson correlation coefficient (Table 5) is equal to 0.9779. The coefficient is positive, so the correlation between variables is direct and very strong (close to 1).

The R value (the value of the correlation coefficient) indicates whether or not there is correlation between the dependent variable (Y) and the independent variable (X1 and X2). The R value is equal to 0.9779, so it can be said that there is a very close, positive, and direct connection between the analysed variables.

R^2 means that 95.63% of the variance in the dependent variable Y is predicted or explained by the independent variables X_1 and X_2.

There are obtained in the Table 6 the values of the regression parameters and the values of a and b (Unstandardized Coefficients) (a is 0.0753 and b is – 0.3134).

Lower 95%, Upper 95% – upper and lower limits of the confidence interval for the parameter. The limits for 0.05 are calculated automatically, regardless of the initialization procedure Regression. It could

Table 4. Data regarding the ecological Romanian production and the two analysed variables

Years	Production in Ecologic Agriculture in Romania: Cereals (Thousand Tones) (Y)	Total Surface Used in Ecologic Agriculture (Ha) (X1)	Nb of Operators Certified in Ecologic Agriculture (X2)
2007	7457	190129	3834
2008	16288	221410	4191
2009	14430	202058	3673
2010	16226	182706	3155
2011	13113	229946	9703
2012	12288	288261	15544
2013	20198	301148	15194
2014	20903	289252	14470

Sursa: www.madr.ro, www.maap.ro.

Table 5. Model summary output

Regression Statistics	Multiple R	R Square	Adjusted R Square	Standard Error	Observations
Values obtained	0.9779	0.9563	0.7824	3776.49	8

Table 6. The parametres of the regression

The Parametres	Unstandardized Coefficients	Standard Errors	T Stat	Sig.	Lower 95%	Upper 95%
Intercept	0	#N/A	#N/A	#N/A	#N/A	#N/A
a (total surface)	0.0753	0.0153	4.9	0.002	0.0377	0.1128
b (nb. of operators)	-0.3134	0.3648	-0.859	0.42	-1.206	0.5793

be said that the linear model parameters are within the following ranges: a between 0.0377 and 0.1128 and b between -1.206 and 0.5793.

The estimated model of regression is:

$$y = 0.0753 \times x_1 - 0.3134 \times x_2 \tag{8}$$

From the formula founded by the computer simulation model results that X1 and X2 (the two analyzed variables) are very important factors in the evolution of Y (production in ecologic agriculture). To increase with a monetary unit the X2 will get an increase of 0.0753 monetary units of X1 and an increase with a monetary unit of X1 will get a decrease of 0.3134 monetary units of X2. It must be noted that the value of free term is zero allowing us to conclude that the factors were not taken into account in the model construction have not any material impact on the evolution of the Y.

Correlation table (Table 7) shows the values of correlation coefficients between the variables “total surface” and “nb. of operators”.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 7. Correlations

	Total Surface	Nb. of Operators
Total surface Pearson correlation Sig. (2-tailed)	1.000	0.9979 0,.42
Nb. of operators Pearson correlation Sig. (2-tailed)	0.9779 0.42	1.000

The T test is applied to check whether there is a significant correlation between the two variables. The Sig Value corresponding of T test is equal with 0,42 so, it can be concluded that it has achieved significant correlation (correlation is significant at the 0.01 level [2-tailed]).

RESULTS, DISCUSSIONS, AND RECOMMENDATIONS

This study aims to highlight the importance of green market in the vision of the green organizations by analysing some important concepts as green strategies, green management and objectives, the four green Ps, green consumers, and green organizations.

The main objectives of this study were to analyse the actual situation of green marketing in Romania by using:

- Probabilities calculations and Markov chains,
- a simulation model (regression function) and Excel program,
- Propose some measures in order to improve the companies' involvement in developing green activities and improve behaviours with green consumers.

Our study reflected that applying a model of linear regression function, one of the most complex procedures of processing and statistical analysis package from Excel, enables statistical and economic analysis, but also builds the necessary fit to the linear model. It was found that by implementing a computer-based simulation model, the two analyzed factors are very important factors in the evolution of the first variable.

After analysing some important green issues in this chapter, some research hypothesis were launched with some recommendations which may help organizations to overcome barriers that stand in front of green consumption and green behaviors/attitudes.

First, this study offers the idea that organizations that are challenged to have a good involvement and a healthy thinking may offer to the new consumers the desired product/service according to the principle of determining the factors which can influence the choosing process.

Thus, we proposed the following recommendations:

- Proposing a plan and some measures to improve the companies' involvement in developing green activities and improve behaviours with green consumers. Starting from the idea that analysing customers' needs and making a segmentation of these customers, the organizations could satisfy them by implementing a plan necessary for improving green implementation. To have a strong

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

and clear green plan the organizations must in have in mind the main objectives of the green marketing:

- Developing New Green Standards:
  - Creating differentiations: products, brand and organization image which is greener than the alternatives,
  - Launching new green products.
- Developing New Green Responsibilities:
  - The way of using the products of consumers to be greener,
  - The campaigns for encouragement of consuming green and healthy products.
- Sustaining the Greenest Innovations:
  - Creating new lifestyles,
  - Creating new business models, normal and acceptable (obtaining green profit).

Thus, we have developed a new marketing style, the niche marketing or the green marketing, which has success with the fulfilment of the following conditions:

- Raising the degree of education of the population in order to understand the impact of the consumption of resources on environment,
- Raising the level of culture,
- Raising the degree of changing the lifestyle,
- Raising the degree of choosing the attractive alternatives: the green alternatives,
- Developing new practices which may substitute the old practices which were based on consumerism and affecting the environment.
  - Making an analysis of the consumers based on segmentation, analysing the internal and the external factors which may influence the green behaviour of consumers.

To improve the consumption of green products and to make aware the consumers about the firm products, the firm must make a segmentation based on some important factors, internal and external. This segmentation consists in determining the internal and the external factors that influence the consumption of green products:

Internal Factors

- **Contextual Factors:** Availability on shelf, location, the moment of consumption, accessibility, consumption opportunity, the way of use, perceived quality, perceived characteristics (flavor, taste, flavor, nutritional value, texture), past experience with the product/brand/manufacturer.
- **Behavioral Factors:** Searched advantages, the importance given to the shopping, attitude and the status of the user, the frequency of the using/shipping, the loyalty, \the increasing level of consumer needs, the size of the shopping.
- **Physiological Factors:** Health state, metabolism, allergies, genetic factors, fashion, comfort, healing sensation/capacity.
- **Socio-Cultural Factors:** Consumer preference, religion, habits, norms, traditions, lifestyle, personality, personal opinion, and values.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

External Factors

- **Technological Factors:** The degree of innovation, R&D, use optimization of resources through human resources quality development.
- **Economic Factors:** Income, price influence, suppliers' attitudes, nature of the competitors, rapid obtaining of profit, continuity of transactions, decision quality in risk conditions, the rapid exchange of goods/services for consumer need satisfaction.
- **Demographic Factors:** Level of education, sex, age, size of the family/house, life cycle of the family, nationality, race, marital status, profession,
- **Political Factors:** Economic politics, legislation, rules, regulations, stability/force of the politic parties.

CONCLUSION AND FUTURE WORK DIRECTIONS

Now, people are living in a new world where they are aware of the impact of their actions on environmental health and also of the consumption of those products that have impact on their health. The goal of this chapter is to implicate all the participants on the market in implementing green issues in business practice to make a difference, so our society will continue to develop in harmony with the nature.

This study presents the role of green issues in our daily lives, such as green strategies, green objectives, green management, green employees, green product, price, place and promotion, green consumers and green organizations. It is known that is difficult for organizations to establish policies and strategies at corporate level who must be in accordance with environmental issues, due to the costs involved (necessary for modifying the marketing process, the way of production, the way of thinking or the attitudes). But trying is not costly, and the results are on long-term, especially for the future generations. It is known from schools that resistance to change is the most important barrier in obtaining performance, so accepting that healthy products, healthy organizations, healthy employees, healthy thinking and attitudes means healthy consumers and environment is the beginning. Changing must start with us, now, and green marketing strategies must be perceived by organizations as a competitive tool that will bring performance on long-term. Everything the organizations and people are doing in present will leave a footprint on the future; thus, they might be responsible of the present actions by implicating in the three Rs actions: reducing, recycling, and reusing.

The strength of this chapter is consisting in using simulation methods (Markov chains, regression function, and IT programs such as Excel and MATLAB) in order to offer for managers and organizations a simple and cost-effective way of analysing the future impact of their actions and decisions on performance and environment, and also on resources consumption. Using such simulation techniques, the managers can see the future trends of green behavior as being a future opportunity for organizations and environment, and the organizations may predict future problems and may solve them in time and with minimum effort.

The limitations of this chapter are the not so very large analyzed period and the analysed data captured in just one moment in time, but this study could offer new opportunities for further research, and a new necessity to investigate the importance of using mathematical simulation in order to determine the future green performance.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

As future work directions, it is proposed to use in any field, not only in green marketing, due to their advantages for future prediction and reduced costs. So, this will lead to a green future that will surely consist of developing clear regulations, offering the necessary equipment to transform, produce, and sell green products, and change step-by-step the thinking and the attitudes regarding the behaviour towards the environment.

KEY TERMS AND DEFINITIONS

Green Economy: An economy responsible and sustainable who comes with healthy regulations and policies for every stakeholder.

Green Employees: Are those employees who act according to those principles based on social responsibility, sustainable development, ethics, equity and not-discrimination.

Green Marketing: Is an activity who must concern every employee and organization in order to offer an opportunity of development and future performance for future generations.

Green Product: An eco-friendly product who does not affect consumers and environment.

Green Strategy: A planning activity and establishing objectives who are made to be safety and to satisfy stakeholders and environment.

This research was previously published in Driving Green Consumerism Through Strategic Sustainability Marketing edited by Farzana Quoquab, Ramayah Thurasamy, and Jihad Mohammad, pages 72-98, copyright year 2018 by Business Science Reference (an imprint of IGI Global).

Chapter 25
Green Marketing as a Tool for Reducing Environmental Footprint of the Construction Industry

Begum Sertyesilisik
Istanbul Technical University, Turkey

ABSTRACT

The world's habitat is being deteriorated in an accelerated way. Construction industry is one of the industries which affect the environment adversely due to its processes' and outputs' environmental footprint. Green marketing can play an important role in changing unsustainable production and consumption patterns in the construction industry and in enhancing its sustainability performance. For this reason, this chapter aims to introduce green marketing as a tool for reducing environmental footprint of the construction industry for establishment of the sustainable built environment. This chapter covers the following topics: need for reducing environmental footprint of the construction industry; need for and ways of as well as advantages of, potential drivers for and barriers against using green marketing as a tool for reducing environmental footprint of the construction industry.

INTRODUCTION

Environmental footprint of the construction industry is affected not only by its production processes (e.g. construction process, project management etc.) but also by its outputs (e.g. built environment). Even if the world's cities occupy 2% of the Earth's land, they cause 60-80% of total energy consumption and 75% of total carbon emissions (UN website, 2014). The construction industry has adverse impacts on: forests and trees, coral reefs, air quality, water, ozone, and the amount of land for agriculture (Dixon, 2010; Hawken, Lovins & Lovins, 1999; Hill & Bowen, 1997; Shen, Tam, Tam & Ji, 2010). Construction industry's activities are CO_2 emissions intensive (Gardezi, Shafiq, Zawawi, Khamidi, & Farhan, 2016, p. 292). Sinha, Lennartsson, & Frostell (2016, p. 162) emphasized the need for reducing construction

DOI: 10.4018/978-1-5225-7915-1.ch025

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

industry's environmental footprint and highlighted that buildings consume "40% of the total energy use, cause more than 1/3 of greenhouse gas emissions, 30% of raw materials use, 25% of water use, 12% of land use, and 25% of solid waste generation (Bribian, Uson, & Scarpellini, 2009; UNEP 2009a, 2009b)". Building material production phase influences construction industry's environmental footprint as well (Sim & Sim, 2017, p. 172). Yeo, Ng, & Song (2016, p. 135) emphasized the importance of materials' environmental footprint and embodied emissions of buildings underlining the fact that approximately 30 billion tons of materials are used in buildings annually (Rincon, 2011). Legislations encourage the construction industry to reduce its environmental footprint and the CO_2 emissions throughout the construction project management phases and outputs (e.g. built environment). Furthermore, the EU policies encourage the reduction in CO_2 emissions. Construction business development towards sustainable products/constructions and production/construction process is needed for creation of value for the nature and for the future generations. Changing unsustainable production and consumption patterns has been identified in the 2002 World Summit on Sustainable Development as one of the objectives of sustainable development (UN, 2002; Barber, 2007, p. 499). Sustainable society needs to rely on sustainable consumption as well as on sustainable production (Lorek & Spangenberg, 2014). Marketing can act as a change agent in the economic system (Polonsky, 2011, p. 1314), and it can play a key role in changing unsustainable production and consumption patterns. Green marketing has a great potential for acting as an effective tool for reducing construction industry's environmental footprint and for enhancing sustainability performance of the demand and supply sides in the construction industry. For this reason, this chapter aims to introduce green marketing as a tool for reducing environmental footprint of the construction industry for establishment of the sustainable built environment. Within the scope of this chapter green marketing's role in enhancing sustainability performance of the construction industry's demand side and supply side [e.g. contractors, subcontractors, and suppliers in the supply chain, as well as their construction project management processes, production and construction processes and outputs (e.g. built environment, materials)] has been investigated. This chapter covers the following topics: green marketing concept; green marketing and the construction industry's supply and demand sides; ways of enhancing effectiveness of the green marketing and integrating its principles into the construction project management phases; potential advantages of using green marketing in the construction industry.

BACKGROUND

Marketing enables the supply to meet the demand. "Marketing is a matching process, one that pairs the capabilities of a company and the wants of the customers. The creation and delivery of unique value to prospective customers and acquire a sustained competitive advantage is of prime importance in marketing" (Londhe, 2014, p. 335).

Green marketing concept is not new and its scope has been evolved throughout the years. It first emerged in the 1970s and it initially only targeted the socially and environmentally conscious customer segment focusing on the customers of the end product (Kicova & Kramarova, 2013; Majerova, 2015, p. 554;_Peattie, 1995; Rex and Baumann, 2007, p. 568; Sharma, Lyer, Mehrotra & Krishnan, 2010; Smirnova, Henneberg, Ashnai, Naude & Mouzas, 2011) and not on the customers in the supply chain (Liu, Kasturiratme & Moizer, 2012, p. 518). Following the 1980's environmental issues have been started to be given importance in the marketing strategy (Menon, 1997; Kumar, Rahman, Kazmi & Goyal, 2012, p. 485). The green marketing literature in the late 1980s and early 1990s (e.g. Margrath, 1992,

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

p. 31; Peattie, 1992; Peattie, 1995; Peattie, 2001; Simintiras, Schlegelmilch & Diamantopoulos, 1994, p. 415) focused mainly on the green market size and on the green consumer's profile revealing 'green market' potential (Rex & Baumann, 2007, p. 568). In the 1990s greening has been emphasised as a tool for enhancing competitiveness of the companies (e.g. Azzone & Bertele 1994; Elkington, 1994; Peattie & Charter 1992; Porter & van der Linde, 1995; Majerova, 2015, p. 554). Integrating sustainability criterion into marketing became an essential requirement in the business as the scope of the marketing concept has been expanded covering intra-personal, inter-personal and future generations' needs (Dam & Apeldoorn, 1996; Kumar et al., 2012, pp. 484-485) as well as various functions including but not limited to: supporting design of the product as well as service, selling, forecasting and communication (Cronin, Smith, Gleim, Ramirez & Martinez,, 2011; Siegel, Shim, & Walker, 2003; Smirnova, Henneberg, Ashnai, Naude, Mouzas, 2011; Liu et al., 2012, pp. 581-582). Furthermore, green marketing scope covers predicting and generating demand for environmentally-friendly products, as well as positioning them in the market to enhance competitive advantages of the companies (Sharma et al., 2010). Green marketing needs to be integrated with other business processes in the supply chain (Liu et al., 2012: 582). "Juwaheer, Pudaruth, and Noyaux (2012) recommended that effective green marketing strategy should be further developed on green branding, packaging, labelling and advertising to create demand for the green products" (Hasan & Ali, 2015, p. 465). For this reason, green marketing should not only target customers of the end product and but also the customers in the supply chain (customers of the production process).

Green marketing aims: to integrate environmental issues into the marketing efforts (Rex & Baumann, 2007, p. 568) and into strategic marketing processes (Chan, He, William & Wang, 2012, p. 558; Brindley & Oxborrow, 2014, p. 46); to contribute to the reduction of the environmental footprint (Chamorro & Bañegil, 2006; Hasan & Ali, 2015, p. 465); to create profit while fulfilling the social responsibility (Mourad & Ahmed, 2012; Hasan & Ali, 2015, p. 465); to create value for individuals and society, as well as for the environment (Polonsky, 2011, p. 1311); to facilitate the purchasing decision of the customer through providing them information about the green/sustainable properties of the products (Rex & Baumann, 2007, p.568). Furthermore, green marketing contributes to corporate image and to integrate environmentally-friendly activities with the business activities (Nadanyiova, Kicova, & Rypakova, 2015, p. 219). Green marketing can encourage the companies (i.e. suppliers, subcontractors etc.) in the construction supply chain to produce value for the nature and for the future generations. It can encourage the companies to develop their construction business enhancing their processes' and outputs' sustainability performance. Furthermore, green marketing can influence the customers' buying decision and it can encourage the customers to purchase environmentally-friendly products.

GREEN MARKETING AND THE SUPPLY SIDE OF THE CONSTRUCTION INDUSTRY

Supply side of the construction industry can be a change agent in the transformation of the construction industry into a more sustainable one and in the increasing of costumer awareness on environmental problems. Green marketing can be an effective tool for fulfilling construction companies' CSR (corporate social responsibility). CSR is "the responsibility of enterprises for their impacts on society (European Commission, 2011)" (Ubreziova et al., 2015, p. 543). "Building Responsible Competitiveness" project, which has been supported by the European Commission (2010), recommends contractors to follow the

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

4 main CSR fields, namely: health and safety, eco-compatibility, supply, and equal opportunities (Jiang & Wong, 2016, p. 850). Accordingly, following activities are among the CSRs: reducing environmental footprint of the construction industry, of the construction project management and of the outputs (e.g. materials, built environment) as well as enhancing environment and sustainability awareness of the customers and enabling them to make environment conscious choices facilitating their purchasing decision with the help of information provided on the sustainability performance of the product. This situation emphasises the importance of the green marketing and its potential role in the CSR and in reducing environmental footprint of the construction industry. Contractors and companies in the supply chain need to fulfil their CSR (Shen et al. 2010; Hill & Bowen, 1997) and reduce their adverse impacts to the environment. Enhancing sustainability performance of the supply chain requires the companies to establish a green supply chain management (GSCM). GSCM is integration of environmental thinking into supply chain management (SCM) (Srivastava, 2007, pp. 54-55). Green marketing and GSCM concepts cannot be considered separately (Cronin et al., 2011; Lamming & Hampson, 1996; Chan et al., 2012, pp. 558-559; Brindley & Oxborrow, 2014, p. 46) and they should be integrated with respect to product, promotion, planning, process, people, and project aspects so that green customers' needs are met and flows of resources (e.g. information, materials, and funds) are enabled (Liu et al. 2012; Liu et al., 2012, p. 581). In other words, green market intelligence, demand management, green product development and green supply chain processes need to be integrated (Sharma et al. 2010; Brindley & Oxborrow, 2014, p. 46). For this reason, companies need to understand the importance of integrating sustainability into their business practices (Kumar et al., 2012, p. 488) so that their green marketing strategies are aligned throughout their supply chain to enhance the supply chain's and companies' performances (Green, Whitten & Inman, 2012, p. 1008). Green marketing can foster green market development. Furthermore, contractors can request their supply chain partners to adhere to the international standards (e.g. ISO 26000: Guidance on Social Responsibility) and guidelines (e.g. Social Accountability 8000, Global Compact Initiative) (Jiang & Wong, 2016, p. 850) so that all partners in the supply chain comply with sustainability requirements to minimize their environmental footprint.

GREEN MARKETING AND THE DEMAND SIDE OF THE CONSTRUCTION INDUSTRY

Customers' purchasing decision influences the supply as companies need to consider characteristics of demand to survive in the competitive market. For this reason, the construction supply side needs to consider the factors influencing customers' purchasing decision when they define their green marketing strategy. Customers' decision on purchasing green products is influenced by: consumers' experiences in environment related problems (Ottman, 2003; Peattie, 2001; Rex & Baumann, 2007: 569; Soler 1995; Straughan, R.D. & Roberts, 1999) and consumers' concern for environmental degradation (Lin & Huang, 2012; Gonçalves, Lourenço & Silva 2016, p. 1485); the price and quality when they buy recycled products (Bei & Simpson, 1995; Gonçalves, et al. 2016, p. 1485); price (Finch, 2005; Gonçalves, et al. 2016, p. 1485); self-image improvement (Sweeney & Soutar, 2001; Finch, 2005; Gonçalves, et al. 2016, p. 1485) and perceived personal relevance (Majerova, 2015, p. 554); consumers' perception that they are preserving the environment when they buy recycled products (Bei & Simpson, 1995; Finch, 2005; Lin & Huang, 2012; Gonçalves, et al. 2016, p. 1485), the individual's belief that his or her efforts will make a difference (Ottman, 2003; Peattie, 2001; Soler, 1995; Rex & Baumann, 2007; Straughan

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

& Roberts, 1999) and the ability of the individual to make an effective contribution (Peattie & Charter, 1992; Majerova, 2015, p. 554). Factors influencing buying behaviour of the consumers for green products include: consumer values, demographic factors (Majerova, 2015, p. 554); preferences, dislikes, beliefs, attitudes and values, their position in the society, education and entourage; as well as their cognitive, affective and conative dimensions but in the same time, the psychographic characteristics (Stoica, Veghe & Orzan, 2015, pp. 923-924). Furthermore, functional, social, emotional, conditional, and epistemic values influence the buying behaviour of a customer (Sheth, Newman, & Gross, 1991) as well as of a green customer (Finch, 2005; Lin & Huang, 2012; Gonçalves, et al. 2016, p.1485).

Eco-information can influence consumers' green behaviour especially for frequently purchased, less-expensive goods (Siriwardena, Hunt, Teisl & Noblet, 2012, pp. 237-241) as customers' difficulty in identifying greener products (Tureac, Turtureanu, Bordean, Grigore, Modiga& Pripoie, 2010; Liu et al., 2012, p. 582) affects consumers' buying decision. Lai & Cheng (2016)'s research on the environmental attitudes and consumer behaviour of the undergraduate students in Hong Kong revealed effectiveness of eco-labelling and importance of emphasizing customers' contribution to the environment when they buy environmentally-friendly products. Customers' knowledge of environmental problems and alternative products can contribute to their purchasing decision (Majerova, 2015, p. 554). Furthermore, government can enhance customers' awareness of green consumption (Liu & Bai, 2014, p. 150) and environmental protection as well as their responsibilities for society (Deng & Huang, 2009; Liu et al., 2012: 582). Companies can influence customers buying decision through their ethical conduct (Mohanty, 2008; Ubreziova et al., 2015, p. 544) and corporate image (David, Kline & Dai, 2005; Kang & Yang, 2010; Keh & Xie, 2009; Lee, Hsu, Han & Kim, 2010; Miles & Covin, 2000; Ko, Hwang, & Kim, 2013, p.1711) as well as their green marketing strategy.

ENHANCING EFFECTIVENESS OF THE GREEN MARKETING

Companies operating in the construction industry need to design their marketing mix carefully to enhance the effectiveness of their green marketing strategy. "*Marketing mix … identifies the principal decision making managers make in configuring their offerings to suit consumers' needs*." (Londhe, 2014, p. 336). Marketing strategy's main aim is to enable the company to get competitive advantage (El-Ansary, 2006; Slater & Olson, 2001) and it is linked with the marketing mix of the company (Kumar et al., 2012, pp. 483-484). There are various marketing mix approaches, namely: 4P, 4C, 4V, 4S, and 5Ps+EE as briefly summarized below:

- **4P Approach:** It has been introduced by McCarty (1960). 4P stands for product, price, place, and promotion. It is known as the traditional marketing mix.
- **4C Approach:** It has been introduced by Peattie & Belz (2010) who have integrated 4P approach to the 4C approach to cover sustainability criterion in the marketing strategy (Kumar et al., 2012, p. 486).4C stands for customer solution, customer price, convenience, communication. 4C approach is known as sustainability marketing mix (Kumar et al., 2012, p. 487).
- **4V Approach:** 4V stands for 'value to customer', 'valued customer', 'value to the market', 'value to society' and it is based on the fact that all stakeholders in the marketing process are value focused (Londhe, 2014, p. 335) as quoted in the following sentences:

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

The customer enters in the marketing process for better 'value' for his money through 'Value to Customer'. The marketers would like to concentrate on the 'valued customer'. The prime objective of any business is to sought value from the business 'value to the marketer'. The marketer and customer would like to keep society's interest intact through 'Value to society'. (Londhe, 2014, p. 335)

- **4S Approach:** 4S stands for scope, site, synergy and system and it is a web-marketing model describing web marketing strategy (Londhe, 2014, p. 336).
- **5Ps+EE Approach:** 5Ps+EE stand for planning, process, product, promotion, people, and eco-efficiency and this approach is called as the Green Strategy Mix and it has been introduced by Violeta & Gheorghe (2009) (Liu et al., 2012, p. 582).

Construction companies and suppliers can enhance their green marketing strategy benchmarking from the conventional marketing strategies. Based on their comparison of the green marketing to the conventional marketing, using Kotler et al. (2001)'s framework of the marketing strategy, Rex and Baumann (2007, pp. 573-574) recommend benchmarking from conventional marketing and rethinking green marketing so that companies' can gain competitive advantage (Rex & Baumann, 2007, pp. 573-574):

- Demand measurement should not focus on the market size only but also on the market needs and wants (Rex & Baumann, 2007, p. 573).
- Customer segmentation and targeting should not only focus on the green consumer but also on all consumers (Rex & Baumann, 2007, p. 574).
- Positioning should not only be carried out on product and eco-label but also on place, price, and promotion (Rex & Baumann, 2007, p. 574).

Companies in the construction industry can support their green marketing strategy with the help of the new technologies. For example, as Lee & Huang (2011, p. 9696) emphasised, recommender systems as an important technology for electronic commerce (Bose, 2009; Kauffman & Walden, 2001) can filter for online shoppers the information so that the customers do not encounter the information overload problem (Chen, Shang, & Kao, 2009). This technology can be useful especially in green marketing of environmentally-friendly construction materials. New technologies can be effective tools for green marketing in case the targeted customer segment is young. Jayaram, Manrai & Manrai, (2015, p. 119)'s research revealed that new technologies can enhance green marketing especially for the young customers' segment in emerging markets.

Organizational culture of the companies can enhance their green marketing strategy's performance. Construction companies and their partners in the supply chain as well as their employees need to share the same vision and culture with respect to their sustainability performance. In this way, all employees and workers can be conscious about their contribution to the sustainability performance of the construction project management and of the construction industry's outputs. They need to be aware of the fact that they do not only create value for the customer but also for the nature and for the future generations. Furthermore, they need to accept the nature and future generations as their stakeholders and consider their potential needs, and demands throughout their activities. They need to influence their customers' perception accordingly.

POTENTIAL DRIVERS FOR AND ADVANTAGES OF USING GREEN MARKETING IN THE CONSTRUCTION INDUSTRY

Using green marketing as a tool for reducing environmental footprint of the construction industry can provide advantages to the companies. These advantages can act as potential drivers for widespread use of the green marketing in the construction industry. Contractors' competitiveness depends not only on achieving the construction projects' targets with respect to time, budget, and quality but also on aligning with societies' expectations and on enhancing their socially responsible image (Jiang & Wong, 2016, p. 851) which can be supported by green marketing. Companies' green marketing strategies and efforts for reducing environmental footprint can provide them various advantages, including: enhanced competitive advantage as well as corporate image and corporate brand image; increased profit margin; fostered green innovation; compliance with environmental legislations and regulations; fulfilled CSR; and enhanced customer awareness on environmental problems and their potential impact on reducing environmental footprint of the construction industry. These potential advantages can be briefly explained as follows:

- **Human Resources:** CSR can help the companies to attract and retain qualified employees (Luo & Bhattacharya, 2006; Pirsch et al., 2007; Piercy & Lane, 2009; Peloza & Shang, 2011; Lii & Lee, 2012). Human resources are key competitive advantage of a company as they cannot be imitated by its competitors. Furthermore, motivated and committed employees' productivity can be high.
- **Value to the Customer and Increased Profit Margin:** Green marketing can support companies' profitability (Lee & Huang, 2011, p. 9696). "Sustainability marketing strategy results in added value to customer…" (Kumar et al., 2012, p. 486). Green business strategy can enhance companies' sustainable growth (Dangelico & Pujari, 2010, Hasan & Ali, 2015, p. 464). Furthermore, as Gadeikiene and Banyte (2015, p. 703) state, CSR can provide long-term financial return due to benefits provided to the society (Sen & Bhattacharya, 2009, Piercy & Lane, 2009) as "…ethical conduct can influence customers' purchasing decisions (Mohanty, 2008)" (Ubreziova et al., 2015, p. 544). Green marketing can contribute to the customer's awareness of environmental problems and of their potential impact on reducing environmental footprint of the construction industry. Parsa, Lord, Putrevu & Kreeger, (2015)'s research provide a case study on the green marketing's effect on price premium. Parsa et al. (2015, p. 250)'s study on investigation into the relationship between consumer awareness of and response toward socially and environmentally responsible practices in the hospitality industry, revealed consumers' willingness to pay a little bit more for CSR (Parsa et al., 2015, p.250). Furthermore, increased profitability (Richey, Musgrove, Gillison & Gabler, 2014, p.1247) and enhanced financial performance (Menon, 1997) can be observed as green marketing strategies contribute to companies' performance (Richey et al., 2014, p. 1247) and as enhanced environmental performance and CSR can contribute to the Return on Assets and Return on Equity (Angelia & Suryaningsih, 2015, p. 348). Fuerst and Shimizu (2016)'s research provide a case study on the green marketing's effect on profitability. Fuerst and Shimizu (2016, p. 108)'s research on price premium impact of eco-labelled buildings in Tokyo revealed that eco-labelled buildings enable higher price premiums compared to non-labelled buildings and that the higher price premiums emerge due to capitalised utility bill savings and intangible benefits of living in a green building.
- **Compliance With Legislations and Regulations:** The public and governments' concerns about environmental problems are increasing (Lee & Huang, 2011, p. 9696). Legislation and EU targets

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

require the companies to enhance sustainability performance of their production processes and outputs. Compliance with the legislation and dealing with possible changes in the environmental laws and regulations as well as directives for reducing the environmental footprint and accounting system (i.e. environmental footprint taxes, calculating the nature's input's cost) can enhance sustainability of the construction companies. The possible changes in the future (i.e. green accounting system, environmental footprint taxes, calculating the nature's input's cost) can act as possible opportunities or threats for construction companies. These possible changes can also encourage the construction companies to transform their outputs and their construction processes into sustainable and regenerative ones for which they can get benefit from effective and efficient green marketing.

- **Getting Benefit From Potential Subsidies and Incentives:** Government can provide institutional incentives to companies (e.g. subsidies, tax, credits, and investments in research and development on green products) (Smirnova et al., 2011, Liu et al., 2012, p.582) to encourage them to enhance their sustainability performance. Furthermore, policy makers can establish regulations and incentives to encourage companies to contribute to the CE (circular economy)'s stricter regulatory market mechanism (Liu & Bai, 2014, p. 150) which supports closing-the-loop production patterns (Ghisellini, Cialani & Ulgiati, 2016, p. 11), and enables not wasting the waste (George, Lin & Chen, 2015, p. 63) as the waste from a factory can be input into other processes (Preston, 2012; Liu & Bai, 2014, p. 145) in other companies. Green marketing can enhance companies' and consumers' awareness of sustainability, CE's success and efficiency as CE requires the adoption of cleaner production patterns at company level, as well as increase in the responsibility and awareness of suppliers and consumers (Ghisellini, et al., 2016, p. 11).
- **Enhanced Corporate Image and Corporate Brand:** Green marketing can enhance corporate image and corporate's brand image as it can influence the way the customers perceive the construction company and its brand. Ko et al. (2013, p. 1710)'s research emphasises that "… socially responsible programs influence consumers' attributions of corporate image, and in turn corporate outcome (Berens, van Riel, & van Bruggen, 2005; Ellen, Webb, & Mohr, 2006)…" and that Environics International CSR Monitor identified CSR as the most important factor influencing consumer awareness of corporate image (Ko et al., 2013, p. 1710). CSR leads to enhanced corporate brand image (Gonzalez-Rodriguez, Diaz-Fernandez & Simonetti, 2015, p. 836) as well as to strong long-term relationships between company and consumer (Gadeikiene & Banyte, 2015, p. 702). Green marketing, as a socially responsible effort and as a CSR, can contribute to corporate image addressing societies' needs (Ko et al., 2013, p. 1710).
- **Fostered Green Innovation:** Sustainability in marketing strategy fosters innovation (Whiting, 2008; Kumar et al., 2012, p. 487). Green innovation can contribute to the companies' performance (Hasan & Ali, 2015, p. 463). Innovation can start based on the feedback from the customers. For this reason, innovation and green marketing are interrelated. Furthermore, green marketing strategy of an environmentally-friendly product (innovation) requires effective introduction of the new product to the market. While companies introduce new products to the market, companies need to decide whether to launch a new brand (considering the potential of the new green brand for becoming a benchmark for the market) or to launch the product under the existing brand (considering the potential limitation of using the existing brand for non-green products as it can remind the non-green version) (Aaker & Keller, 1990; Majid & Russell, 2015, p. 994).

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

All drivers for and advantages of using green marketing as a tool for enhancing sustainability performance of the companies reveal green marketing's impact on the competitiveness of the companies. Green marketing can support companies' competitiveness (Lee & Huang, 2011, p. 9696) and enhance their sustainable competitive advantage (Nadanyiova et al., 2015, p. 226).

SOLUTIONS AND RECOMMENDATIONS

Construction companies and their partners in the supply chain need to integrate green marketing principles and adapt suitable combination of marketing mixes into their construction project management phases (e.g. pre-construction, construction, and post-construction phases) as suggested in the following paragraphs:

- **Pre-Construction Phase:** Pre-construction phase mainly consists of feasibility, design, and contract phases.
- **Feasibility Phase:** In the feasibility phase, the contractor needs to ensure that the project is feasible considering the 'product', 'people', 'place', 'planning', 'process', 'eco-efficiency', 'price' and 'customer price', 'value to customer', 'valued customer', 'value to the market', and 'value to society' constructs. The 'product' which fulfils the 'eco-efficiency' requirements and which can result in creation of 'value to customer', 'value to market' and 'value to society' needs to match with the 'customer price'.
- **Design Phase:** In the design phase, the interdisciplinary design team needs to consider and integrate the 'product', 'people', 'place', 'planning', 'process', 'eco-efficiency', 'value to customer', 'value to the market', 'value to society', 'price', 'customer price' and 'customer solution' constructs into the design. In the design phase, the design team needs to understand what the customer demands and concentrate on how to create 'value to customer', and 'value to society'. As society is stakeholder of the output (e.g. construction), as they will be effected by the construction in their vicinity, it is vital for the design team to consider expectations of the society and to create value for the society. Design team needs to understand what the customer values for and the 'customer solution' so that the design quality meets the customers' expectations. Furthermore, the design team need to concentrate on how to enhance 'eco-efficiency' of the output (e.g. construction) considering the production/construction phase covering 'planning', 'place', 'process', as well as 'value to the market'. They need to consider how to match the 'customer price', the 'value to customer' and the construction 'price' ensuring that the cost does not exceed the 'value created to customer'.
- **Contract Phase:** Construction contract acts like a marketing channel as it is how the contractor (the supply side) meets the customer (the demand side). Construction contract needs to cover the work scope, and contracting parties' rights and obligations. In other words, construction contracts needs to address the 'product', 'people', 'place', 'planning', 'process', 'eco-efficiency', 'value to customer', 'value to the market', 'value to society', 'price' and 'customer price' and 'customer solution' constructs of the marketing. They need to define the 'product' construct with the help of the specifications or Employer's requirements and 'customer solution'. They need to define the financial aspects (e.g. the 'price' construct) and the 'process' construct covering the 'planning' construct as well as contractors' obligations in the construction phase (e.g. site waste management

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

to enhance the 'eco-efficiency' construct). Contractor needs to ensure that all contracting-tiers are coherent and comply with each other so that suppliers and subcontractors in all contracting-tiers in the supply chain comply with the main contract's requirements.

- **Construction Phase:** Throughout the construction phase, companies in the supply chain need to perform in a lean and sustainable way. Adherence to the lean and sustainability principles in the construction phase (including mobilization, site management, and site waste management) can lead to focus on value creation (including 'value to customer', 'value to the market', 'value to society'), on directing the efforts and resources for the accomplishment of the 'product' with the help of efficient and effective 'processes' and to accomplish the construction on time and within the budget achieving profit at the contract 'price'/'customer price'. 'Eco-efficiency' of the construction process can be enhanced with the help of effective control to reduce/minimize the need for rework, and taking remedy actions upon deviation from the quality as determined in the contract. Site management influences the sustainability performance of the construction process. Site needs to be planned considering the construction process (the 'process' construct) enabling reduction or minimization of waste from lean and sustainability management point of views. Site waste management enables the debris to be sorted and sold to skip disposal companies. It contributes to the cleanness of the site and enhances sustainability performance (with the help of enabling the recycling or reuse of waste) as well as health and safety performance. Furthermore, it contributes to smooth flow of the construction process and to reduce the construction costs (through payment received from the debris). Site waste management is a tool for complying with 'eco-efficiency' construct.
- **Post-Construction Phase:** In the demobilization phase, the adverse impacts of the construction site to its vicinity need to be remedied complying with the 'create value to society' construct. In the post-construction phase, construction companies aiming to differentiate themselves from their competitors can provide repair and maintenance services. Efficiently operating constructions necessitate regular repair and maintenance. Efficiency in the operation phase of the constructions can contribute to the 'eco-efficiency' resulting in 'value to customer' and 'value to society' due to reduced environmental footprint. Furthermore, it can result in high customer satisfaction due to reduced operation costs complying with the 'customer price' construct. Customers' feedback need to be received upon completion of the construction. Furthermore, the companies in the supply chain need to analyse the lessons learned and problems emerged in the construction process. Customers' feedback and 'lessons learned' can contribute to the improvement of the 'process' which can lead to enhanced customer satisfaction, and enhanced 'eco-efficiency' due to reduced need for rework.

Construction material suppliers in the supply chain need to integrate green marketing into their manufacturing process and they need to adopt effective combination of marketing mixes into their pre-manufacturing, manufacturing, and post-manufacturing processes and activities to enhance the success of the green marketing. In the pre-manufacturing phase, the suppliers are recommended to carry out the design of the 'product' considering creation of value to customer, the market, and society. The design should be based on the production process requirement and availability of local materials suitable for the product (e.g. decrease in embodied CO_2 and costs). It should enable usage of recycled materials, reused materials or eco-labelled materials. In the manufacturing phase, process should rely on the lean

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

and sustainability principles. It should target zero waste both from lean and sustainability perspectives. Manufacturing process should support the CE. Companies/suppliers can try to collaborate with companies interested in their waste as they can use their wastes as input. Furthermore, companies/suppliers can try to collaborate with companies whose wastes can be input for their manufacturing process. In this way, manufacturing process can support closed loop material cycle creating value to society and enhancing 'eco-efficiency' of the 'process'. Innovation in design as well as in production techniques, and methods should be encouraged to enhance sustainability and lean performance of the product (e.g. dematerialization) and of the production process (e.g. accelerated production process, reduced waste, increased value). Innovation should be value focused and based on customer feedback wherever it is possible. In the post-manufacturing phase, as the product needs to meet the targeted customer segment, effective marketing channel needs to be considered. New technologies and 4S for the web-based marketing can be useful as well. Suppliers can provide post-manufacturing services (e.g. repair and maintenance) in order to differentiate themselves from their competitors. Customer feedback needs to be received as it can provide insights on 'customer solution', 'value', and changes needed in the product etc.

Construction companies, their subcontractors and suppliers in the supply chain need to consider the following items when they establish their green marketing strategy:

- Green marketing in the construction industry can be enhanced with the help of new technologies.
- Value to customer can be achieved with the help of integrating customer into the design process.
- Green marketing usage needs to be widespread to reduce construction industry's environmental footprint as construction industry is among the industries having adverse impact to the nature. For this reason, green marketing requirements need to be considered in establishing marketing strategies.
- Green marketing can be achieved through trainings and providing consultancy.
- Construction companies can establish a common platform where the companies can share their experiences in green marketing and where others can learn from them. The companies experiencing advantages of green marketing can be motivated in green marketing and can encourage other companies who can benchmark from them.
- Green marketing culture should be shaped and shared by all companies in the construction supply chain.
- Green marketing considerations and its requirements need to be integrated throughout the pre-construction, construction, and post-construction phases as well as throughout the pre-manufacturing, manufacturing, and post-manufacturing phases.
- Companies in the green/sustainable supply chain need to recognize the trend that green/sustainable building certificates as well as green/sustainable products increasingly act as a tool for green marketing.
- Communication with the customers and their feedback are valuable inputs into the innovation process. Innovation process needs to create value for customer, society, and future generations. Green marketing needs to support innovation in construction processes (e.g. specific labels/certificates for environmentally-friendly site management), construction materials and in design of construction (e.g. considering potential future needs of the customers throughout the construction's lifecycle (changing climate conditions; adaptable constructions to the customers' current and expected needs due to the changing climatic conditions).

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

- The customers need to be convinced with respect to the value created in a way that they perceive the price lower than the value created. In a free market, price is freely determined in the equilibrium point where the supply and demand curves intersect. Wishes need to be supported by purchasing power so that demand emerges. Reducing the cost through increased efficiency and effectiveness as well as dematerialization can lead to increased profit margin even if the price is kept constant. Elasticity of demand, availability of substitutes and need for complementary goods/products/outputs need to be considered in the pricing strategy. "Green marketing considerations will be low when cost considerations overwhelm green credentials (high competitive advantage, low sustainability advantage)" (Sharma & Iyer, 2012, p. 606). Furthermore, the companies need to consider the investment return rate of the customers' investment. For example, the customers consider the investment return rate of their investment in their decision on whether or not to replace their lighting equipments with sustainable ones. Similarly, they will consider the investment return rate for their investments in insulations or in sustainable buildings. The customers, if they think that they will not live in the building for 20 or 25 years, might tend not to invest in a sustainable building due to its high initial investment cost which can be returned in years. Targeted customer segment's position in the Maslow's hierarchy of needs can influence the price premium and the elasticity of demand for the product as well.
- Green marketing mottos and messages can attract current and potential green customers. Mottos need to be carefully determined considering companies' image, its outputs' green or sustainable properties as well as targeted customer segments, their priorities, characteristics, culture, and their interests. The 'people' construct requires determination of the customer segment accurately. The 'people' construct and the 'communication' construct are interrelated and they need to be covered in the promotion related marketing strategy decisions. 'People' construct will influence company's communication with their customers, the marketing mottos used and the marketing channels preferred. Especially the young customers segment can prefer to be communicated via new technologies such as web marketing strategy where the companies need to consider 4S approach and its requirements. 4S approach can be effective in the construction industry especially for suppliers and in case of purchasing from them. It has great potential to be used by material suppliers in the construction industry.

FUTURE RESEARCH DIRECTIONS

Green marketing is expected to widespread in the construction industry especially with the help of increased customer awareness on the importance of environmentally-friendly built environment. To foster the widespread use of green marketing, future researches are recommended to be carried out on case studies on the changes in the companies' performances (with respect to environmental footprint, financial performances, quality achievement, competitiveness, price premium, profit, corporate image, corporate social responsibility, innovation level, value created) compared to their performances before green marketing adaptation. Furthermore, future research is recommended to be carried out on how to increase the green market size in the construction industry.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

ANALYSIS

The world's living conditions deteriorate faster than the world can regenerate itself. Environmental footprint of the production and consumption need to be reduced. Effective green marketing plays an important role in transforming production and consumption patterns into sustainable ones. Among the industries construction industry has one of the biggest environmental footprints. Construction industry affects the deterioration of the world's habitat due to its production/construction processes and the built environment. For this reason, enhancing sustainability performance of the construction industry is a must for the sustainability of the world and regeneration of the nature. Green marketing's potential role in enhancing sustainability performance of the supply and demand sides of the construction industry can contribute to the recovery of the world's habitat. Effective green marketing can enhance customers' awareness of environmental problems and influence the characteristics of their demand side for more environmentally-friendly production/construction processes and outputs (e.g. sustainable building materials, sustainable built environment etc.). This change in the demand side can influence and motivate the supply side for enhancing the sustainability performance of their production/construction processes and their outputs. In other words, the demand side can influence the supply side. Similarly, the supply side can influence the demand side with the help of green marketing as the demand side can be equipped with the eco-information of the outputs/products and their potential contribution to the solution of the environmental problems with the help of their environmentally-friendly purchasing decisions. Furthermore, green marketing can help the customers to understand CSR actions of the companies in the construction industry and to take their purchasing decision accordingly.

Companies can be motivated for enhancing their sustainability performance and green marketing upon their experience of potential advantages of green marketing. Green marketing is not only a potential way of fulfilling their CSR and enhancing their corporates' images and brands, it can also contribute to the survival of the companies in the highly competitive construction industry. Their competitiveness depends on achieving project targets, and sustainability targets as well as on increasing their profit margin while creating value to the customer. Green marketing should be part of the strategic management as sustainable built environment and sustainable building material markets have the potential for growing further with the help of green marketing. Companies need to keep scanning the sustainable business environment for potential opportunities and threats so that they can adapt themselves to the changes in the business conditions, and in the green market as opportunities do not last forever, and as the threats might have potentials for being converted into opportunities. Potential failure of the companies in adapting green marketing strategy can act as a thread and it can lead to the shrinkage of their market. For this reason, they need to pay attention to the establishment of the effective green marketing strategy through benchmarking from the conventional marketing strategies as well as through adaptation of new technologies (e.g. recommender system) and effective green marketing mix (considering 4P, 4C, 4V, 4S, 5Ps+EE approaches). Integration of green marketing, environmentally-friendly working culture and organizational culture into the construction/production processes and into the entire supply chain can support the effectiveness and success of the green marketing. Green marketing concept and sustainability principles should be adapted to the entire supply chain, as companies in the supply chain are customers in the production/construction process and as they can affect the sustainability performance of the production/construction process and of the output.

Political, economic, and educational supports are important for enhancing effectiveness of the green marketing and reducing environmental footprint of the construction industry. Political and educational

supports can enhance potential customers' awareness of and consciousness of environmental issues. Policies need to support formal and informal education (e.g. festivals, university education, courses, fairs etc.) on environmental problems, and potential role of the customers in transforming consumption and production patterns into sustainable ones. Policies can also encourage companies in the construction industry for transforming their production/construction processes and outputs into sustainable ones and for investing in research and development for green innovation via economic supports such as incentives and subsidies. Furthermore, as there is need for enhancing sustainability performance of the construction industry throughout the world, policies can encourage international collaboration.

CONCLUSION

This chapter aimed to introduce green marketing as a tool for reducing environmental footprint of the construction industry for establishment of the sustainable built environment. Green marketing can encourage customers to act as change agents for sustainability. Green marketing can influence customers' perception and understanding of the climate change as well as of the importance of the sustainable consumption and production. Furthermore, it can influence customers' understanding of their potential contribution to the sustainability of the nature by purchasing environmentally-friendly products. Green marketing can foster sustainable production as increase in the demand for environmentally-friendly products can encourage the companies in the supply chain to reduce their environmental footprint throughout their production/construction process as well as in their output (e.g. construction materials, constructions).

Construction companies and suppliers can get following potential advantages of integrating green marketing into the construction supply chain: enhanced competitiveness, increased profit margin, attracting competent employees; fostered green innovation; compliance with environmental laws and regulations; enhanced corporate image and corporate brand; creation of more value for customers, and nature.

Companies in the construction supply chain can encounter potential barriers while transforming their business into a more environmentally-friendly one and while adopting the green marketing into their marketing strategy and integrating it throughout their production/construction process. These barriers might be related with the need for increasing customers' awareness of the possibility that they can contribute to the sustainability of the environment in case they purchase environmentally-friendly products/constructions. Furthermore, customers might be reluctant in replacing their equipments with environmentally-friendly ones, or in investing in sustainable constructions/construction materials due to their relatively high initial investment cost. Companies can also encounter difficulties in establishing environmentally-friendly working culture in their supply chain.

Companies in the construction industry can enhance their green marketing's effectiveness through:

- Establishment of the green marketing mix effectively.
- Establishment of the green marketing strategy benchmarking from the conventional marketing strategies.
- Adaptation of new technologies which can support the effectiveness of green marketing.
- Integration of green marketing into the construction as well as into the manufacturing processes and outputs.
- Establishment of environmentally-friendly working culture throughout the supply chain.

KEY TERMS AND DEFINITIONS

Circular Economy: Environmentally-friendly economy enabled by closed loop material cycle and zero waste principles based on tangible and intangible resource exchanges among companies.

Construction Supply Chain: Production chain in construction consisting of suppliers and subcontractors taking part in different stages of the production [starting from the raw material extraction to the production of the end product (e.g. buildings etc.)].

Corporate Social Responsibility: Corporate's support and contribution to the societies' needs. Companies do not charge for their CSR activities.

Environmental Footprint: Embodied impact of the product on the environment.

Green Marketing: Marketing processes and activities emphasizing: value for the nature and next generations; importance of sustainability as well as products' and their production processes' characteristics/properties with respect to sustainability. Green marketing can be used as a tool for enhancing customers' awareness of the importance of sustainability and influencing their demand for environmentally-friendly products and production processes.

Marketing: Processes and activities enabling the supply side to meet the demand side. It is an important ingredient/input for design and production as well as for post-production as customers' feedback can provide insights on what the customers value for.

Marketing Mix: Strategic factors to be concentrated on throughout the marketing activities to address the correct customer segment, to promote the product, and to increase the market share.

Value: Value is what the demand side is looking for in the supply side and what the supply side needs to create to meet the needs and expectations of the demand side.

Chapter 26
Green Marketing Initiatives and Sustainable Issues in Hotel Industry

Neeti Kasliwal
Banasthali University, India

Srishti Agarwal
IIS University, India

ABSTRACT

With the fast degradation of the environment and changing lifestyle of the consumers, the companies have started moving towards the concept of green marketing. Although green marketing has been able to address concerns of green consumers but as anticipated has not shown much expected results from companies as well as from mainstream consumers' acceptance level. This chapter is an attempt to draw attention towards sustainable issues in hotel industry, what are the opportunities' and challenges' the hotels are facing with respect to green initiatives and how successful the present companies are in incorporating the green practices. The authors conclude the chapter giving the focus on future research directions in green marketing and green practices to be followed by hotel industry.

INTRODUCTION

Green Marketing concept is emerged in the late 1980s. The term describes an organization's efforts at designing, promoting, pricing and distributing products that will not harm the environment. It has been defined as the management process that is responsible for identifying, anticipating and satisfying the requirements of customers and society in a profitable and sustainable way (Chan E.S.W 2013). Green marketing means the marketing of products and services which are environment friendly. The green marketing has originated under three phases according to Peattie (2001), first phase was termed as "Ecological" green marketing, and during this period all marketing activities were concerned to help environment problems and provide remedies for environmental problems. Second phase was "Environmental" green marketing and the focus shifted on clean technology that involved designing of innovative new products,

which take care of pollution and waste issues. Third phase was "Sustainable" green marketing. It came into prominence in the late 1990s and early 2000. The concept is not restricted to only products but also services. The emergence of green hotels has taken a prominent step and has become major issue in today's scenario because of the increasing concern of environment in the eyes of consumers.

BACKGROUND

Why Green Marketing?

In today's scenario, with the fast degradation of the environment it has become the important part in everyone's life to accept those products and services which can save environment. The fast changing of lifestyle of people also compels them to adapt to those products which will not harm the environment. So marketing of green products and services has become important so that it can be positioned in consumer's mind. Further marketing can also help consumers to make them aware about the green products and services. With the changing time, the concept of green marketing is taking place rapidly. Different rules of green marketing have been identified by Jacquelyn A. Ottman (2010) in his book "The New rules of Green Marketing". The 20 new rules of green marketing are as follows:

1. **Green is Mainstream:** Today, 83% of consumers – representing every generation, from Baby Boomers to Millennials and Gen Ys – are some shade of green. Moreover, there are now finely defined segments of green consumers.
2. **Green is Cool:** In fact, green consumers are early adopters and leaders who influence purchasing behaviour. Celebrities and other cool types generally are espousing green causes.
3. Greener products work equally or better – and are often worth a premium price.
4. Green inspires innovative products and services that can result in better consumer value, enhanced brands, and a stronger company.
5. **Values Guide Consumer Purchasing:** Historically, consumers bought solely on price, performance, and convenience
6. **A Life-Cycle Approach is Necessary:** Single attributes such as recyclable, organic, or energy-efficient matter greatly,
7. **Manufacturer and Retailer Reputation Count Now More than Ever:** In addition to looking for trusted brand names on supermarket shelves, consumers are now flipping over packages, saying, "Who makes this brand? Did they produce this product with high environmental and social standards?"
8. **Save me!:** Today's consumers buy greener brands to help protect their health, save money, or because they simply work better.
9. Businesses are their philosophies: It used to be that companies were what they made. Now, businesses and brands are what they stand for.
10. Sustainability represents an important consumer need, and is now an integral aspect of product quality.
11. The greenest products represent new concepts with business models with significantly less impact.
12. Consumers don't necessarily need to own products; services can meet their needs, perhaps even better.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

13. The brands consumers buy and trust today educate and engage them in meaningful conversation through a variety of media, especially via websites and online social networks.
14. Green consumers are strongly influenced by the recommendations of friends and family, and trusted third parties.
15. Green consumers trust brands that tell all
16. **Green Consumers Don't Expect Perfection:** Keep improving, and report on progress.
17. Environmentalists are no longer the enemy.
18. **Nearly Everyone is a Corporate Stakeholder:** No longer confined to just customers, employees, and investors, publics of all stripes are now corporate stakeholders: environmentalists, educators, and children – even the unborn.
19. **Authenticity:** It's not enough to slap on a recycling logo or make a biodegradability claim. Brands viewed as the most genuine integrate relevant sustainability benefits into their products.
20. **Keep it Simple:** Plato was an environmentalist: "Simplicity is elegance." Today's consumers are cutting out the needless purchases, and getting rid of the gadgets and gizmos that don't add value to their lives.

Green Products and Green Consumers

The term "green" refers to actions that reduce the impact on the environment, such as eco processing or recycling (Han et al., 2011). By Saini (2013), A product may be considered green if it:

- Conserves water and energy;
- Prevents contributions to air, water, and land pollution;
- Protects indoor air quality;
- Uses renewable, responsibly sourced materials;
- Produces little environmental impact;
- Is manufactured in an environmentally conscious way;
- Using one's own bag, rather than a plastic carrier provided by a shop.

In general, Ottman (1999) classifies green products as durable, non-toxic, made from recycled materials and with minimal packaging. It means that green products cannot be visualised only from the viewpoint of the final results of the production process, but also in light of the entire production chain.

According to Ottman (1994) an environmentally friendly or green product, should have the following characteristics: a) be manufactured with a minimum amount of raw materials and with recyclable raw material, b) be manufactured with the utmost energy efficiency and with the least use of water; c) be packed in lighter packaging; d) provide a higher durability and serve multiple purposes; e) be reusable; f) be biodegradable. So here green products refer to those which are eco-friendly and usage of the green products does not harm the environment.

When it comes to know about the green consumers, first thing comes in mind is that consumers who consumes the eco-friendly products and services but consumption of green products does not make them a green person. Green consumers should also be aware and concerned about the environment. There were various concepts of green consumers given by different authors such as, According to Ottman (1999), it is the one that seeks to consume products that cause little impact to the environment – which is called as environment friendly products. It is the individual who makes their buying decisions not only by

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

checking price and quality, but also the fact that products should be environmentally friendly. According to Portilho (2004) study, green consumers are the one who in addition to the variable quality/price, includes in their "power of choice", the environmental variable preferring products that do not harm the environment, whereas Dias (2007) identified, It is the one who is concerned with the environment and adopts a behaviour consistent with these values.

Today, the green consumers are increasing throughout the world and growing concern of consumers towards the environment has shown drastic increase in the usage of green products and services. Bhattacharya et al., (2009) showed that consumers expressed their preference for products from those companies which invest in social issues and environmental responsibility issues. That means consumers wants companies to accept the green products and services which saves environment. In McKinsey research article by Dan & Aline (n.d.), para.2 showed that 66% of the global consumers prefer to buy products and services from companies that give back to society; according to a recent Nielsen survey of 28,000 online respondents in 56 countries, it has been seen that many consumers are aware and they know about the green products and services but consumers hardly make their buying decisions. People generally think as eco-friendly consumers, our actions often fail to match the standards of our intentions. The simple reason can be that people don't really care about the environment. Although social pressures and companies initiatives force people to accept eco-friendly products but they don't actually have genuine environmental beliefs'. According to the McKinsey finding consumers do care about the environment, but there is no alignment in behaviours with intentions. Because consumers tend to focus on the present goals only and future goals treated to be less important. The consequences of consumer's behaviour are uncertain, and their collective effects on the environment would be disastrous. There is one way to overcome it, is to appeal for emotions to the people rather than giving logical reasons for a particular course of action. So this article brought a major issue that consumers are aware and concern towards the environment but problem arises when the consumer behaviour is not aligned with their intentions. Green consumers are increasing and accepting the green products and services to save environment.

Benefits of Green Marketing

In very general terms, the marketing of those products which can save environment is the primary benefit of the green marketing. Many companies want to put their efforts to be Green and they are also coming out of the green products. Some of the advantages of green marketing are:

- It ensures sustained long term growth along with profitability.
- Initially the cost is more but in the long run it saves money.
- With keeping the environment aspects in mind, it helps the companies to market their products and services.
- It helps in accessing the new markets and also companies enjoy the competitive advantage.

Various examples of Green Marketing have being identified from many sources. According to Singh (2013) study various examples are being quoted such as:

- Suzlon Energy manufactures and markets wind turbines, which provide an alternative source of energy based on wind power. This green initiative taken by the company is extremely important for reducing the carbon footprint.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

- Tamil Nadu Newsprint and Papers Limited (TNPL) was awarded the green Business Leadership Award in the pulp and paper sector for the year 2009-10, based on the EVI Green Business Survey conducted by financial Express and Emergent Ventures India. This was given in recognition of two clean development mechanism projects implemented by the company generating biogas from bagasse wash water, and using the same as a substitute for furnace oil.
- Tata Metalikes Ltd (TML) has initiated the use of only sunlight during in its offices.
- ITC has introduced Paperkraft, a premium range of eco- friendly business paper. The company's social and farm forestry initiative has greened over 80000 hectares of arid land.
- Wipro's computers division has launched energy star compliant products in the market.
- HCL Technologies is moving towards phasing out hazardous vinyl plastic and brominated flame retardants from its products.
- Oil and Natural Gas Corporation Ltd (ONGC), India's largest oil company, has introduced energy-efficient Mokshada Green Crematorium, which saves 60 to 70% of wood and fourth of the burning time per cremation.
- IndusInd Bank installed the country's first solar-powered ATM and thus brought about an eco-savvy change in the Indian Banking sector.
- Idea Cellular implemented its national campaign 'Use Mobile Save Paper'. The company organized Green Pledge campaigns to save paper and trees. Idea decorated bus shelters with potted plants and tendil climbers to communicate the green massage.
- Samsung offers a host of eco-friendly products. It was the first to launch eco-friendly mobile handsets (made of renewable materials)- W510 and F268- in India.
- Nokia's policy is to reduce the environment impact of its products. It has taken the initiative to take back, recover useful materials and dispose of waste in a manner that causes least harm to the environment.
- Hero Honda Motor's philosophy of continuous innovation in green products and solutions has enabled it to strike a balance between business, consumers and nature.
- Honda India introduced its civic Hybrid car. However, initially it was unable to sell the same due to the high price. The price was reduced by 8 lakh, and within a day, 98 civic Hybrids were sold, which was more than what Honda had been able to sell during the previous five months since its launch.
- Maruti and Hyundai have come up with LPG and CNG based variants for WagonR and Santro respectively.
- Reva, India's very-own Banglore-based company (now a part of Mahindra Group) was the first in the world to commercially release an electric car. Reva is being sold in countries like UK, Ireland, Belgium, Spain, Cyprus, Greece and Norway.
- Mahindra Group had launched project Mahindra Hariyali in which 1 million trees would be planted nation-wide by Mahindra employees and other stakeholders including customers, vendors and dealers.
- McDonald's restaurants use napkins and bags made of recycled paper.
- Apple has adopted the philosophy that going green streams. It recycles e-waste and also generates revenues.
- IBM is selling green solutions to corporate data centres where energy constraints and costs are limiting their ability to grow, with the promise that the energy costs would be reduced by half.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Green marketing is rising quickly and consumers are willing to pay a lot for green product. There has been little analysis of the impact of this new market on the consumers and the environment so far. Green marketing affects all areas of our economy, it does not just lead to environmental safety but it also generates new market and job opportunities. Hotels are trying to attract green consumers but it is quite difficult to satisfy consumers if they are paying higher prices for hotels. So hoteliers need to convince their green consumers that green services will pay off without sacrificing their comforts. Das et.al.,(2012) has identified various reasons for the companies to adopt green marketing. These are:

- To explore Opportunities or Competitive Advantage
- For Corporate Social Responsibilities (CSR)
- Due to Government Pressure
- Due to Competitive Pressure
- For Cost or Profit Issues
- Due to Increased Customer Consciousness
- Deterioration of Climatic Conditions

The above reasons have compelled many companies to come up with the green products and services to attract and retain their customers for a longer period of time. Also at the same time reduce their costs and increase their profits.

Challenges of Green Marketing

There are various challenges ahead in this sector which companies need to address and so that they are able to adapt cope up for future. One of the main challenge identified with green issues is that firms using green marketing must ensure that their activities are not misleading to consumers or industry, and do not breach any of the regulations or laws dealing with environmental marketing. Other challenges are as follows:

- Green products require recyclable products, which are found to be costly.
- Green products and services needs latest technology, which requires huge investment.
- Most of the people are not very much aware about the green products & services and its uses. Even if they are aware then they do not have much knowledge about its applicability.
- As the green products & services are costly, so most of the consumers are not willing to pay premium price for the green products & services.
- Green Marketing concept is new to the consumers which hinders their decision making process.
- Consumers do not have trust on the companies who are offering them green products. Consumers have perception that they are being cheated by the companies by charging high prices for the green products.

The knowledge gap towards the usage of green products& services will prevent consumers in making buying decisions. Today, consumers want more reliable and credible information about the ecological effect of products rather than only that products are eco-friendly. The above challenges or problems are generally faced by the consumers as well as hoteliers who prevent them in making their purchase decisions regarding green products and services. With the above focus on the challenges, companies need

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

to identify that what exactly the consumer wants from the hotels in terms of the green services? What are their perceptions towards the green services? How will they behave while using the green services? And will they be able to pay higher price for the green services or not? What another steps a hotel can take to convince consumers for using green services? Hoteliers have to find out the answers and have to identify consumers' needs and their preference and accordingly have to apply the strategies to sustain in the market. Those hotels which have revised their policies are coming forward with the innovative services to satisfy their green consumers are true winners.

Despite the fact that green marketing has several challenges but with the changing scenario the opportunities can be seen today for the green marketing such as to achieve competitive advantage, increasing the consumer market segment, meeting with government legislation and corporate social responsibility. Today every industry is heading towards these opportunities to stand out in the market and adopting eco-friendly practices in their organisation. When it comes to India, the implementation of green practices has created problems such as high cost; consumers are price sensitive, lack of awareness among the consumers towards the green products & services, lack of authentication in information and companies making false environment claims (Yadav et.al., 2013). These challenges are majorly faced by the companies to attract consumers in India. Consumers still feel awkward to accept the green products and services in India so it has become important for the companies as well as the hotel sectors to explore more details in green market segment. Also, they need to find out the solution to cope up with these challenges. Consumers face some barriers while making their purchase decisions. Shove and Warde, (2002) and Mont, (2004) in their research discussed that internal barrier is one of the barriers which stop consumers from purchasing eco- friendly products that come from individuals' lack of knowledge and ability to understand the consequences of their acts, and habits. Demeritt (2005), and Yan *et al.*, (2006) also identified that individual purchase decisions are also determined by external barriers that relate to the availability of good products & services, the convenience in accessing them, and to the belief that one person cannot make a difference. External barriers are much stronger than internal knowledge and motivations in obstructing tourist environmental behaviour (Kaiser *et al.*, 1999; Tanner *et al.*2004).

Present Trends in Green Marketing in India

- Green marketing is being considered as an opportunity for the companies in this competitive era.
- Companies believe that green marketing is a social obligation for them which can also save their society from any harmful effects.
- Governmental Bodies are also forcing companies to become more responsible towards the society as well as the environment.
- Companies are shifting towards the green products and services to compete with their competitors so that they can survive in the market.
- Through using green products, one can control their costs and can come out with the new technology for saving water and energy.

Green Marketing Mix

According to Mishra et.al, (2011) every company has its own marketing mix. Some have 4 P's and some have 7 P's of marketing mix. The 4 P's of green marketing are same as compared with the conventional marketing but the challenge before marketers is to use 4 P's in an innovative manner.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

- **Product:** The objective of product is to identify those products which are eco-friendly and can be used to save environment.
- **Price:** Price is a critical factor of green marketing mix. Most of the consumers are still not ready to pay the premium price of the green products, so before fixing price it is important to consider the consumers' mentality and thoughts.
- **Promotion:** There are three types of green advertising: - first, ads that address a relationship between a product/service and the biophysical environment, second, those that promote a green lifestyle and third, ads that present a corporate image of environmental responsibility.
- **Place:** place of a product decides that where the products can be available so that maximum number of consumers can reach there to avail the green products.

Strategies of Green Marketing

The marketing strategies for green marketing includes:

- Develop marketing plan and Marketing Audit while making strategy towards the green marketing.
- The key to successful green marketing communications is credibility. Never overstate environmental claims or establish unrealistic expectations, and communicate simply through sources that people trust.
- Always explore the market before making strategy.
- Identify consumer needs and demands.
- Give value of money to the consumers in terms of green products.
- As the consumers are price sensitive, so it needs to identify their willingness to pay before making strategy.

Future Trends of Green Marketing

There are various lessons that to be learned to avoid certain misconceptions of green marketing. The best and effective marketing of green products requires applying good marketing principles to make green products more attractive and desirable in the eyes of consumers. However there is still a question arise that what is the future of green marketing? Various scholars and researchers has viewed that there are maximum number of consumers who still are not aware and educated about the green products and services. The companies today are not able to match the demand of consumers with the eco-friendly products. Traditionally, marketing of products included only selling products as much as u can but the time has change, companies need to identify consumers' needs to retain their customers. So the future trends of the green marketing are:

- To deliver consumers green products which gives them value of their money
- Target relevant consumer segment
- Educate consumers about the eco-friendly product.
- Make environmental product attributes as "solutions" for consumer needs.
- Make green products trustworthy to the consumers
- Make certified and eco labelled products.

So the above trend has shown that green marketing will help when the above trends could be followed.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

MAIN FOCUS OF THE CHAPTER

The present chapter focuses on the initiatives towards the green marketing and sustainability issues taken by the hotel industry. Knowing the consumer preference for green services, hotel industry is focusing their attention towards green consumers and green practices. This practice not only gives an edge over competitors and but also fulfils their responsibility towards environment.

Sustainability and Tourism

"Going green" has becoming a trend in all over the world. Various ideas of green marketing have emerged not only in the tangible sectors but also in the service sectors in large. Green marketing has emerged to focus on the environmental issues and putting emphasis on reducing the environmental damages. Sustainable marketing has become the most important step to be taken by the service industry. The need for green products and services among the consumers has drastically increased. It is gradually being realised the degradation of environment and it can only be prevented by using environment friendly products and services. Tourism sector is the largest service sectors in the world, where sustainable marketing has become prominent to save the environment and to sustain in the competitive market (World Travel & Tourism Council [WTTC], 2007). In terms of sustainability issues and goals, various businesses (TOI, 2003), governmental and intergovernmental organizations (OECD, 2002, UNEP, 2005, and European Environmental Agency, 2006) make excellent efforts to minimise negative effects and also making and improving benefits from tourism. The result of the various initiatives by the government and individuals has showed the encouraging signs that tourist provision can be improved in terms of resource consumption, waste management and transport management (Upham, 2001, Götz *et al.*, 2002, and VISIT, 2005). The above efforts can be analysed and it can be seen that the corporate and government sectors have adapted various green practices but today tourists are much less interested to adopt sustainable lifestyles. Different Tools and strategies are being adopted by various institutions such as eco-labels, awards and certification schemes, communicating and spreading awareness among others, educational campaigns are designed and implemented to encourage tourists 'behaviour towards the responsible tourism.

Tourism, being a major source of income and employment for many countries depends heavily on environmental resources which causes more degradation of the natural resources. Among the various components of tourism, the hotel industry is one of the major sectors of the tourism that creates a major threat to the environment due to its high consumption of energy, water and less durable goods. The hotel industry is the key of tourism business which may not be the first sector that creates environmental pollution and also consumes significant amount of global resources. But the major aim of hotel is to provide comfortable services such as supplying of hot water, food, drinks, linens, towels, lighting, air conditioning, water, swimming pools etc, which compels hotels to consume large amounts of water, energy, non-recyclable, goods, and natural resources which directly or indirectly harming the environment. A conference which was held in Canada on "Global opportunities for business and the environment" concluded that sustainable development acts as a vehicle or a catalyst for identifying the problems of modern tourism (Tourism Canada, 1990). Sustainable tourism development must meet the need of the present tourists and protecting and improving opportunities for the future regions and future needs.

Sustainability, according to Moore, also involves total integration with the community in which the tourism organisation is located. Total integration here is referred to as involving health and safety is-

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

sues, conservation of natural resources, renewable energy supplies, and other environmental friendly manifestations.

Mowforth and Munt, (1998) go a step further in defining sustainable tourism by stating that the concept is not just about the environmental and social dimensions. In fact, sustainability in tourism incorporates dimensions such as (a) environmental sustainability, i.e., avoiding or minimizing the environmental impact of tourist activities via the utilization of tools such as carrying capacity; (b) social sustainability, i.e., the ability of the community to absorb inputs and to continue function without or with minimum social disharmony; (c) cultural sustainability, i.e., the ability of people to retain or adapt elements in their culture which distinguish them from other people; (d) economic sustainability, i.e., sufficient economic return of tourism activity either to cover the cost of any special measures taken to cater for the tourist and to mitigate the effects of the tourist's presence, or to offer an income appropriate to the inconvenience caused to the local community visited–without violating any of the other conditions–or both; (e) having an educational element, i.e., providing greater understanding of how our natural and human environment works as the goal of the activity; and (f) having local participation, i.e., inclusion of the local population. As a key sector of tourism industry, hotel business, needs to play a role which have several key environmental and social impacts in the society i.e., (1) energy consumption; (2) water consumption; (3)waste production; (4)waste water management; (5) chemical use and atmospheric contamination; (6) purchasing/procurement and (7) local community initiatives (International Hotel Environmental Initiative, 1995; Kirk, 1995).

Green Hotels and Green Practices Adopted by Hotel Industry

According to Green Hotel Association,(2008) Green hotels, also known as environmentally friendly hotels, is defined as an eco-friendly hotel operation that performs various environmentally friendly practices such as saving water and energy, using eco-friendly products and reducing emission and waste disposals to protect the natural environment and reduce operational costs. Consumers appreciate the contribution green hotel practices make to improving the environment, they do not want to compromise on service quality or living comfort.

Hotel industry is one of the major contributors in economic activity of tourism sectors. The potential growth of this sector has an impact on environmental issues like climate change, increasing pollution, wastage of energy and water etc. Much attention towards the negative impact on the environment such as over-consuming of energy and water, using of detergents in laundry that hotels do on a daily basis, using of plastic bags, using of non-recyclable products and other materials while operating business have been caused by hotel industry. This increasing degradation of the environment, hotels are becoming more responsive towards their obligation and over the years, efforts have been made to improve environmental conditions as well as social responsibility in the hotel industry. There are many reasons that have been seen for going green such as government pressures, increasing competition, quality services, social responsibility, self-regulation, brand building and many others which have forced hotel industry to show initiatives for sustainable practices.

With the increasing awareness towards the environment, hotels are taking green initiatives and also coming out with the more green products and services. Various green attributes are being incorporated in the hotels such as participation in environmental partnership or certification program, using recycling programs, having energy saving light bulbs in the rooms, towel reuse program, recycle bins in the guest room, sheets changed on requests etc. According to Watkins, (1994) study, eco-friendly attributes

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

of hotels like recycle bins, energy efficient lights, changing sheets when requested that may influence consumers' decision making these attributes are being widely used in the hotels today which are being adopted by the consumers as well. Today green hotels are using these eco-friendly attributes which helps them to stand out in the market as compared to the conventional hotels. Hotel industry can also reduce their operating costs and expenses by incorporating green techniques in their hotels. Hotel industries can also create a competitive advantage and make profits for themselves by offering green services to their consumers. The awareness level is not limited to the hotel industry. The growing population and changing lifestyle of people, green products and services has taken major place in consumers' day to day life. Consumers has positive attitude and behaviour towards green products and services so it is crucial for the hotel industry to explore more on concept of green hotels in more detail.

More consumers are expressing a preference for environmental products and services (Schubert et al., 2010). Consumers' concern towards the environmental can influence their decision when selecting a hotel. Although consumers have their own preference while selecting a hotel which is focusing on green practices but not all consumers are willing to pay extra amount for the green hotels. Some studies reported that most of the respondents were willing to pay extra for staying in a green hotel. For instance, 67% of the consumers in Kenya have a strong willingness to pay a higher rate for an environmentally friendly hotel (Masau& Prideaux, 2003). (Choi, Parsa, Sigala, & Putrevu, 2009) got similar results in their study of consumers in Greece and the United States. Other studies pointed to the opposite conclusion. One study by Ogbeide,(2012) revealed that the majority of the consumers thought that a green hotel room should cost the same or even less than one in a hotel that does not have green practices. In a study of Indian hotel guests, only 15%of the respondents would like to pay more for the hotel's environmental initiatives. The remaining 85% of the respondents felt that the costs should either be paid for by the hotel or shared (Manaktola & Jauhari, 2007). American hotel guests also had a similar attitude, with only 30% of the respondents expressing willingness to pay more to stay at a green hotel (Kang et al., 2012).

Inquiries over tourists willingness to pay for environmental protection and the well-being of local communities show Dutch tourists to be uninterested (CREM, 2000), over 81% of British tourists being willing to pay up to 3% of the value of their holiday (Martin, 2001), while international tourists in Thailand show there is no desire to pay for environmental quality, but they are willing to do so for raising the quality of service (Baddeley, 2004). Certain research indicates that 70–80% of tourists state their high concerns for eco-social components of holidays, only about 10% convert this concern to purchasing decisions (Chafe, 2005) and, in reality, the majority are reluctant to change their own behaviour in support of sustainability goals (CREM, 2000; Grankvist, 2002; Yan *et al.*, 2006).

Both marketers and consumers are showing their concern towards the need for green products and services. This shift of consumers as well as marketers towards "green" may be expensive in the short term, but will be advantageous in the long run. Consumers have shown their interest in green products and services due to increasing awareness towards the environment and also ready to pay extra amount for the green services. Consumers' demand for green hotels is increasing with changing lifestyle and they are ready to pay even higher prices for the green services but without sacrificing their comforts. Tourist choice of travel depends on flexibility, comfort, convenience, relaxation, a sense of freedom and 'no stress' (Anable & Gatersleben, 2005).

In the tourism sectors, the most important thing for the consumers are comforts and convenience, so keeping this in mind hoteliers have to come out with those green attributes and services which will be attractive for the consumers without making any compromise in their comforts. Awareness and knowledge of the consumers plays an important role in accepting green products and services which helps consum-

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

ers in committing themselves to make purchase decisions. So it has become crucial for the marketers to make consumers aware towards the environment friendly products and services. The consumers are heterogeneous with different tastes and preferences and this has compelled the marketers to come out with those green products and services that can easily suits to consumer's tastes. The hotel industry has developed a standardized and systematized method for measuring the environmental friendliness of hotels. There are international hotel certification programs in place such as Green Globe and Energy Star, and accreditation schemes such as ISO 14001, LEED (Leadership in Energy and Environmental Design), and GSTC (Global Sustainable Tourism Criteria).

Previous studies have identified that younger people and women are found to be more sensitive to environmental issues and more likely to buy green products as compared to men (Mainieri et al., 1997). Consumers' concerns for the environment affect their decision while buying green products and services. A study showed that because of the environmental image of the hotel, consumers were interested in staying at green hotels (Lee et al., 2010). Green practices that hotels are initiating were well accepted by consumers who are environmentally conscious (Millar & Baloglu, 2008). According to Kasliwal and Agarwal,(2014), the result showed that green practices like train employees for better environment performance, use savers to save electricity, recycling programs, having energy saving bulb lights as very important attributes considered by the hotels as well as consumers.

Consumers are showing their interests and expectation for hotels to implement more environmentally friendly practices. The willing to pay (WTP) however is not a universal phenomenon as Indian customers are reluctant to pay a premium for green hotel rooms (Manaktola & Jauhari, 2007) which poses challenges for the industry to meet the expectations of the consumers, because Indian consumers are more price sensitive. According to Kasliwal and Agarwal, (2015) with the analysis of women consumers it was found that the women consumers prefer attribute key cards used to turn power on and off as very important green attribute while choosing a hotel

Hence it is important for hotel industry to understand the attitude and expectations of consumers from a green hotel. Hoteliers also have to identify what green services can attract their consumers and can act as differentiating tool to grab their attention.

By concluding the above, we can say that green products and services have taken major place in consumers mind and hotel industry is also putting efforts to satisfy this latent need of the consumers. There are so many things which excite consumers to buy green products and services but, more awareness needs to be created. Also consumers who are not ready to buy green products and services at premium price needs to be convinced that actual services will be matched with their expectations.

There are various green attributes that hotels have incorporated and various green marketing strategies that a hotel should apply for attaining competitive advantage. Chan, (2013) mentioned various strategies of green marketing for hotels. These are as follows:

- Designing green products and services;
- Contributing to green-conscious customers;
- Saving water and energy resources, reducing wastes, and conserving ecosystem;
- Launching green-certification programs;
- Product-differentiation by green products and services;
- Cooperation with environmentally-friend groups;
- Adoption of environmentally-friendly distribution channels;
- Influencing consumers through green marketing;

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

- Green pricing leads to lower costs of green products and services;
- Adoption of environmental labelling as a marketing tool;
- Trying to create innovative green products and services;
- Using eco-labels on packages and in websites;
- Effect of efficiency of green products and marketing on customers' decision to stay again;
- Launching special program to assure success of green products and services;
- Willingness of customers to pay higher prices for green products and services;
- Contradiction of rivals on environmental claims.

The above mentioned are the major marketing strategies for the hotel industries towards the launching of green products and services. These green marketing strategies will help hotel industry to sustain in the competitive market and also to attract more consumers who are concerned towards the environment.

SOLUTIONS AND RECOMMENDATIONS

The above discussion towards the green marketing and sustainable issues in hotel industry, it can be analysed that various problems has been seen that consumers are still not ready to accept green products and services. This problem can be solved by bringing more awareness of green products and services in the mind of consumers make availability of green products in every hook and corner and also give value for money to the green products and services. These solutions can be useful for both companies and hoteliers to retain their customers for a longer period of time. The lifestyle of consumers is changing and they want to buy innovative products. They are aware of the fact that environment is degrading day by day so companies as well as hoteliers are coming out of the green products and services but consumers are not ready to accept these green products and services. So it has become important to identify the needs and desire of the consumers before proceeding further. It is recommended to the hoteliers to provide green services without making any hindrances in consumer's comforts, hoteliers should know their preferences of the consumers while they choose the hotels and also give best green services which gives them value for money.

FUTURE RESEARCH

Going green is becoming the new trend in the changing lifestyle. Not only in the field of hotel industry but also in the field of tangible things which force have people to change their buying decisioned. Various future studies can be done with respect from consumer's point of view and from management point of view. The managerial implications of the future studies will help to formulate the strategies that should be adopted by the hotel industry to survive in the market. This study has lot of scope when it comes to green services. Generally companies are putting efforts in green marketing to position the green products in the mind of consumers but hospitality sectors has a tough competition and a difficult task to identify green consumers and give them the best green services without compromising their comforts and convenience. Hence it has a future scope to research on analysing employee's behaviour, consumer perceptions, management initiatives, government role towards green products and services and many more.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

CONCLUSION

It is crystal clear and a fact that hotel managers have to develop and implement new strategies to attract and enhance their customers' satisfaction more than their competitors. Development of delightful customers for products and services by upgrading customer satisfaction always help to achieved competitive edge in the market. In the strategic management perspective to achieve greater level of customer satisfaction hotels can use combination of environment product strategy and environment place strategy. Green marketing is a very new term in the hotel industry. It simply means using environmentally-friendly products and services in hotels and accommodations. However, hotel managers are expected to launch quick activities in order to make use of principles of green marketing properly in their hotels. As green marketing is a key factor in the hospitality industries because major portion of the harmful chemicals are found in the hotel industry which harms the environment most. So the green marketing has played a prominent role to market those services which do not harm the environment.

In the current era of globalization and privatisation, we cannot ignore competitions. Competitors are rising and to survive in the market, it is crucial to bring innovative products like green products and services. This chapter has come out with the fact that green marketing is becoming the burning topic for the companies as well as for the service industries. To survive in the market, and further to attract consumers with a motive to save environment, hotel industry needs to come out with the creative strategies.

KEY TERMS AND DEFINITIONS

Green Consumers: Those consumers who are concern towards the environment and buy the green products which are eco-friendly.

Green Hotels: Those hotels which perform environment friendly operations.

Green Marketing: Marketing of those products which are environment friendly.

Green Products: Those products which are environment friendly.

Green Services: Those services which are environment friendly.

Sustainability: The quality of not being harmful to the environment.

Chapter 27
Building Theory of Green Procurement Using Fuzzy TISM and Fuzzy DEMATEL Methods

Surajit Bag
Tega Industries South Africa Pty. Ltd., South Africa

ABSTRACT

Green procurement is the set of procurement policies held, action taken and relationships formed in response to concerns linked with the natural environment. Green procurement has drawn major attention of supply chain practitioners' and has become the theme of most of the seminars and workshops. Green procurement is gaining popularity due to its positive association with the triple bottom line. Firms implement green procurement to achieve sustainability in this dynamic business environment. There are several published papers that have adopted either qualitative or quantitative methodology to build and test theories in the discipline of green procurement. However multiple elements influencing green procurement creates decision making problem among supply chain practitioners. This has motivated to pursue the current study and further extend the theory of green procurement. The main purpose of the current study is to investigate the inter-relationships between elements of green procurement using advanced multi criteria decision making techniques. First systematic review of literature is done to identify the leading drivers. Secondly these drivers were refined through expert interview from manufacturing sector. Thirdly Fuzzy TISM and Fuzzy DEMATEL method were applied to find the intensity of influence of green procurement drivers and make a comparative study of elements. Finally, the conclusions of research are drawn and also present the managerial implications and directions of future research.

1. INTRODUCTION

Globally researchers and industry associations are seeking innovative eco-friendly approaches to conserve the natural resources and curb greenhouse gas emissions. The level of popularity of green procurement can be estimated from the high research output in leading journals such as IJPE, IJPR, IJPM, Resources, Conservation and Recycling Journals. Research output on green procurement has increased over the

years and reached its peak in 2013 and out of which 43 were survey papers, 14 case studies and only 5 were theoretical and conceptual papers (Appolloni et al., 2014). Environmental aspects have been an important consideration in Europe since the treaty of Rome in 1957. However, more importance was given since the United Nations conference on Environment and Development in the year 1992. In the European Union, the Sustainable Development Strategy was launched by the heads of state and government in 2001. Sustainable development strategy did not clearly refer to green procurement. However, at the world summit in 2002 which was organized in Johannesburg called for green public procurement.

In June 2003, the policy paper on integrated product policy has triggered to green public procurement in EU member states by 2006. Therefore, the epicenter of green purchasing, and sustainable development is Europe. The Government procurement agreement developed seeks to protect and preserve environment. Environmental criteria awarding for supplier selection and awarding orders, technology selection, methods and production process are all considered under EU government procurement agreement. It is mandatory for all member states to comply with the directives and allow for the integration of environmental considerations in supply and service contracts. Because of the purchasing power of the public sector the potential for green public procurement is enormous. Outside the European Union green public procurement initiatives has been developed in Japan, Philippines, Canada and USA.

European commission is proud to publish their handbook on Green Public Procurement. This handbook aims to encourage public authorities to buy eco-friendly goods. EU commission helps member states in establishing the plans and targets for green public procurement. Major barrier is the lack of environmental knowledge on the right criteria to include in tender documents, budgetary constraints due to up-front prices that are higher than prices of conventional goods and services. The handbook seeks to help overcome these barriers (Day, 2005). The member countries of EU practice green public procurement and has also influenced private sector to convert into green procurement practices. The EU handbook on Green Public Procurement promotes the idea of defining technical specifications in terms of performance or functional requirements. This allows tender participants to come up with innovative solutions.

Legal frameworks such as international legal framework for government procurement (GPA) are important to be implemented in developing countries like India. There is scope in converting to green electricity, renewable energy, use energy efficient computers and home appliances, water saving toilets and taps, buy organic foods and convert kitchen waste to compost for gardening, recycle waste water for gardening. Government should not only ask citizens to be environmentally conscious but demonstrate the eco-friendly buying process and also the process of recycling, reuse waste.

The main objectives of this paper are:

1. To identify the drivers that influence green procurement programs
2. To determine the interactions among the identified drivers
3. To understand the managerial implications of this study

This paper is structured into seven additional sections. The next section presents the systematic literature review which helps to identify the green procurement drivers. The third section introduces research methods. Forth section presents Fuzzy TISM and fifth section presents Fuzzy DEMATEL. Finally, conclusions, managerial implications, limitations and directions of future research are presented.

2. LITERATURE REVIEW

Literature review is an important part of the any research study. Traditional review approach mostly lacks thoroughness, quality and information which ultimately do not make sense to practitioners. Here author attempts to use the process of systematic review for exploring and understanding the links. The systematic literature review (SLR) process creates transparency and assist in developing the research question which will further enhance the knowledge base. Earlier SLR was mainly used by researchers in the area of medical sciences but recently SLR has gained popularity in the area of management sciences. Some of the recent published papers which adopted SLR techniques are (Chakrabarty& Dubey, 2014; Bag & Anand, 2014a; Dubey and Ali, 2014; Srivastava & Dubey, 2014). The steps of systematic review of literature followed in the present study have been adopted based on the guidelines of Tranfield et al. (2003).

Stage 1: Planning the review

In this stage researcher conduct studies to assess the relevance and size of the literature and to draw up the boundaries of the topic. Our review basically focuses on articles published in reputed peer review journals. To set up a time span, a starting position was set at 2000. Library database (EBSCO) was used through a keyword search using keywords "Green Procurement," "Eco friendly practices" and "Environmental Purchasing." Since the literature is interlinked when we picked up one thread, we could easily identify the rest. Finally, we selected only the important papers relevant for the present study. The list of cited references is presented at the end of the study.

Phase 0: Identification the need for a review

The objective of conducting the review is to identify the research gaps in existing published literature and further develop the problem statement, research questions and research objective for the present research.

Phase 1: Preparation of a proposal for review

Researchers have carried out detailed review of research articles published in *IJPE, IJPR, IJPM,* and other reputed journals to understand the links for the present study and present a review proposal for the present study.

Phase 2: Development of a research protocol

In this step the conceptual discussion of the research problem and a statement of the problems' significance are presented.

New and innovative eco friendly methods of production are required to develop sustainable products which generally attract customers and enhance market share (Bag, 2014). Green procurement promotes sustainable production and consumption (Liu et al., 2012; Tenner and Kast, 2003). Environmental problem

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

not only occur during production but also from consumption of products. Dawson and Rober (2010), argued that sustainable consumption necessitates a sustainable procurement commitment. Therefore, right purchasing is linked to impact of society on the environment. Every purchase decision has ethical, resource, waste and community impact implications (Young et al., 2010). Green procurement reduces negative environment impact related to product production and consumption (Ho et al., 2010; Green et al., 2000). However, the success stories of green procurement implementation in developing countries are few. The underlying reasons are numerous. Firstly, it is due to the environmentally oriented products which are not effective in terms of their market place performance. It is necessary that the products are effective both internally versus competitors (Pujari et al., 2003). Secondly there are numerous barriers to implement green procurement practices and managers lack knowledge of critical success factors (Zhu and Sarkis, 2004). Addressing these critical success factors may provide firms new opportunities for competition (Zhu and Sarkis, 2006).

Firms in developing countries cannot improve on the triple bottom line until they understand the inter-relationships between the antecedents/drivers of green procurement. The present research shows the road map to firms in developing countries to dig out the benefits by implementing green procurement.

Stage 2: Conducting a review

Green Procurement has thrown up unique challenges in areas such as design of eco-friendly products, inventory management, collaboration with suppliers, reverse logistics and life cycle thinking. In this study, we focus at an important area of green procurement which has not received attention so far. The present study is motivated by recent green movement in South Africa and noted developments which can be set as a benchmark for other developing countries such as India.

Hassini et al., (2012) conducted a review considering the published papers during the last decade (2000-2010) which gives us important insights.

Tsai et al., (2012) found that green economy has a positive influence on customer perceived value on green products and motivates manufacturers in new eco innovation for product development.

Liu et al., (2012) found that environmental attitudes, perception of self responsibility greatly influence green procurement behavior.

Arslan et al., (2012) showed that environmental attitudes, environmental behavior and green product awareness have a positive effect on environmentally conscious purchasing behavior. Environmental attitude include action which contribute towards environment preservation and conservation. The environmental problems are present in human behavior, therefore it is essential to change the behavior and culture of organizations. Companies failing to implement environmental responsible operation will encounter a loss of competitiveness. We must note that both producers and customers have important role in environmental conservation.

There are existing studies which have identified green procurement drivers such as the study by El-Tayeb et al., (2010) where they examined the effect of four drivers (i.e., regulations, customer pressures, social responsibility and expected business benefits) on green purchasing.

Another study by Large and Thompson, (2011) also identified five potential drivers of green procurement such as green supply management capabilities, the strategic level of the purchasing department, the level of environmental commitment, the degree of green supplier assessment, and the degree of green collaboration with suppliers. The results suggest that the degree of green supplier assessment and the level of green collaboration exert direct influence on environmental performance.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Lee (2008) finds that buyer environmental requirements and support were positively linked to their suppliers' willingness to participate in green supply chain initiatives. The government can play an important role in motivating these suppliers.

Govindan et al., (2015) used ISM approach to identify inter-relationships among lean, green and resilient practices and supply chain performance. It is found that just in time (lean), flexible transportation (resilient) and green packaging (green) are the key drivers.

Green procurement can be used as a tool in managing environmental risk management (Caniels et al., 2013). They also identified the drivers for participation of suppliers in green initiatives and are supplier readiness and customer requirements.

Other studies on green procurement give us information on supplier development and collaboration. Firms monitoring their suppliers and focusing on supplier development can help to achieve supply materials that are less polluting and generate low wastage (Gimenez et al., 2012).

Gimenez (2012) studied the impact of sustainable operation on triple bottom line and concluded that supply chain collaboration has a statistically significant impact on the triple bottom line.

Vachon& Klassen (2008, 2013) argued that benefits of collaborative green practices were broadest with suppliers rather than collaboration with customers. However environmental information is essential for all collaborative efforts aiming at sustainable competitive advantage (Soler, 2010). The participation of suppliers in the eco-design stage is emphasized in the study by (Fu et al., 2012). Ji et al., (2014) found that top management commitment is the key factor for both green procurement and green supplier development. We have already discussed in the previous section about the importance given to green public procurement in European Union. There is an increasing recognition of the potential of green public procurement as a policy instrument (Burja, 2009). European Unions' "Europe 2020" strategy and 'Sustainable development' strategy portray green public procurement as an essential market based instrument to achieve the EUs' economic, environmental and energy goals (Kunzlik, 2013). In other respected work such as Attri et al., (2010) did a further analysis of environmental criteria in public procurement contracts. Further Azevedo et al., (2011) explored the relationships between green practices and supply chain performance. The findings suggest that there is a positive relationship between green practice implementation and operational performance. There is also a positive relationship between green practices and environmental performance. Researchers such as Kaiser el al., (2001) talked about the importance of life cycle thinking and green procurement practices in context to health care industry. Green Procurement can provide an easy solution to waste generation and disposal issues. In a recent article Kunzlik (2013) talked about sustainable and eco-innovative purchases precisely to stimulate firms to innovate and attain high environmental standards, maintaining its international advantage in environmental technologies.

Green Procurement supports other environmental standards (ISO 14000, Eco labeling). It can also be used as a tool to advance corporate social responsibility (Ho et al., 2010).

The benefits of green procurement are numerous but still many firms in developing countries fear to implement green purchasing thinking of the high costs. But we should bear in mind that the initial costs may be high but they save money during their life cycle. Therefore, it offsets the initial costs incurred in buying. It is essential to take into account the entire life cycle cost of the item.

The research gaps which evolved from the review of literature are presented to further develop the research objectives for the present study.

There are studies which report the drivers of green procurement. However, those studies have either not considered all major drivers or the developed models are not robust. Secondly there is dearth of stud-

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

ies where earlier researchers have demonstrated application of advanced MCDM methods such as Fuzzy TISM or Fuzzy DEMATEL to investigate the inter-relationships between green procurement drivers.

The present research is motivated based on the recommendations of Azevedo et al., (2011) where they have shown potential research area in exploring the enablers and barriers which influence companies in taking green procurement decisions. Although Appolloni et al., (2014) conducted a review on green procurement considering the time frame between 1996 and 2013 but does not highlight the inter-relationships between the antecedents/drivers of green procurement practices and they have also kept it as one of the future research direction. They have also mentioned the need for strong qualitative and quantitative research to support the progress of green procurement.

3. RESEARCH METHODS

Good research is grounded in theory. Theory is necessary for scientific understanding of the underlying phenomenon. Numerous calls have been issued describing the need for greater use of theory in operations management. More theory driven empirical research has occurred as a result of these calls. However, the potential of qualitative research in theory building have been largely underestimated, specifically in the area of project and operations management. The objective of this research is to address this gap in the body of knowledge.

The main objective of this paper is to explore the inter-relationships between the enablers influencing successful green procurement practices. The boundaries of green procurement are still relatively vague. Therefore, at this initial stage of research it is better to select qualitative approach to gain deep insights. The current study intends to develop green procurement theory based on Fuzzy total interpretive structural modeling (Fuzzy TISM) approach and Fuzzy DEMATEL approach.

Fuzzy TISM is an extension of TISM which has its base from ISM. ISM methodology, transforms unclear, poorly articulated models of systems into clear, well-defined models. ISM uses experts to judge the variables, and the relations among the variables are interpreted. ISM depends on the experts' knowledge and familiarity with the firm, its operations, and its industry. Therefore, ISM generates deep knowledge of the subject and is greatly helpful for supply chain practitioners. The evolution of ISM dates back in the year 1974 by Warfield. The use of ISM gradually increased in the last decade where we have seminal works (e.g.: Bag and Anand (2015); Bag (in press); Agarwal & Vrat (2015); Jayalakshmi & Pramod (2015); Khatwani et al., (2015); Dubey& Ali, (2014); Dubey et al., (2015c), Dubey et al., (2014), Attri et al., (2013); Sushil, (2012); Sushil, (2009); Sushil, (2005a); Sushil, (2005b). ISM technique has been explored in depth by (Dubey et al., 2015a) where researchers have demonstrated that ISM is an effective methodology for theory building in Operations and Supply Chain Management. ISM has taken a major leap recently in one of the latest published research by (Dubey et al., 2015 b) where authors argued the use of mixed methods for theory building using ISM, MICMAC analysis and confirmatory factor analysis. Total Interpretive Structural Modeling (TISM) is an extension of ISM methodology and has been used in this study to overcome the limitations of ISM methodology. TISM is an advanced method and designed in a manner to capture both the statements of respondents as well as logic and interpretation. TISM model is a powerful tool and can be employed in complex situations where the number of elements is more since ISM fails in that kind of situation. TISM has greater explanatory power than other established inductive approaches. The merits of TISM have encouraged applying the interpretive logic-knowledge base for the green procurement drivers and developing the green procurement theory.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Fuzzy DEMATEL is an extension of DEMATEL technique. It is basically an extended method for building and analyzing a structural model for analyzing the influence relation among multiple criteria. Some of the seminal work on application of Fuzzy DEMATEL are Lin (2013); Mavi et al., (2013); Hsu et al., (2013); Shen et al., (2013); Kannan et al., (2013); Chang et al., (2013); Wu et al., (2013); Tseng & Chiu, (2013); Chang et al., (2011); Lin (2008).

Based on the above research objectives in mind authors has applied Fuzzy TISM and Fuzzy DEMATEL to develop theory on green procurement.

4. FUZZY TISM

The steps of Fuzzy TISM have been followed as per Khatwani et al., (2015). The Data analysis is segregated into following sub-sections:

4.1. Start the Decision Making Process

In the current study, the responses of five experts from manufacturing sector have been gathered. The input has been utilized to refine the criteria's and further used in modeling.

4.2. Selection of Criteria and Sub Criteria of Green Procurement

This is the second step in Fuzzy TISM modeling approach. For the purpose of this study, twenty-five drivers are identified from literature (Table 1) which influences green procurement practices and finally refined through experts' opinion. The final twenty sub criteria are presented in Table 1.

4.3. Gathering Responses and Calculation of Aggregated SSIM

The responses of five experts has been collected separately and further calculated the aggregated SSIM matrix by applying mode. The aggregated SSIM matrix is shown in Table 2.

4.4. Calculation of Fuzzy Reachability Matrix

The fuzzy reachibility matrix is generated from aggregated fuzzy SSIM matrix in step 4.3 above. The fuzzy reachibility matrix is shown in Table 3.

4.5. Calculation of Final Fuzzy Reachability Matrix

The final fuzzy reachibility matrix is derived from step 4.4 above Table 3. From the final fuzzy reachibility matrix (Table 4) the dependence power (X) and driving power (Y) is calculated based on summing of columns and rows and calculating the crisp value. The crisp value of each element is used as an input to develop fuzzy MICMAC analysis.

4.6. Driving Power and Dependence Power Matrix (MICMAC) Based on Fuzzy Reachibility Matrix of Table 4

Driving Power and Dependence Power Matrix (MICMAC) based on Fuzzy Reachibility Matrix of Table 4 is shown in Figure 1.

Cluster 1. Autonomous Variables: These variables have a weak drive power and weak dependence power. In this cluster we have six variables. Total Quality Environmental management (E2), Management Support (E3), Management Review (E4), Cross functional team building (E6), Organization Culture (E7) and Information System Infrastructure (E9).

Cluster 2. Dependence Variables: These variables have a weak drive power but strong dependence power. In this cluster we have twelve variables. Green process and Technology (E8), Green Design (E10), Re-use, Re-engineering and Recycling of products and materials (E11), Supplier Flexibility (E12), Suppliers' capability to Innovate (E13), Supply risk management (E14), Trust building in suppliers (E15), Low supplier lead time (E16), Customer Satisfaction (E17), Annual Savings from

4.8. Defuzzified Reachability Matrix and Transitivity Check

The paired comparisons are translated in the form of reachability Matrix. The matrix has been also checked for transitivity rule. A final reachability matrix, post transitivity check is presented in Table 6.

4.9. Driving Power and Dependence Power Matrix (MICMAC) Based on Defuzzified Reachibility Matrix of Table 6

Driving Power and Dependence Power Matrix (MICMAC) based on Defuzzified Reachibility Matrix of Table 6 is shown in Figure 2.

Figure 2. MICMAC analysis based on Table 6

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Cluster 1. Autonomous Variables: These variables have a weak drive power and weak dependence power. In this cluster we have no variables.

Cluster 2. Dependent Variables: These variables have a weak drive power but strong dependence power. In this cluster we have nine variables. Information System Infrastructure (E9), Suppliers' capability to Innovate (E13), Supply risk management (E14), Trust building in suppliers (E15), Low supplier lead time (E16), Customer Satisfaction (E17), Annual Savings from green procurement practices (E18), Annual Saving of natural resources (E19), Procurement Excellence (E20).

Cluster 3. Linkage Variables: These variables have a strong drive power as well as strong dependence power. Linkage variables are very sensitive and unstable. Any action on these variables will trigger an effect on other variables and also a feedback on themselves. In this cluster we have three variables. Green Design (E10), Re-use, Re-engineering and Recycling of products and materials (E11) and Supplier Flexibility (E12).

Cluster 4. Driving Variables: These variables have a strong drive power but weak dependence power. In this cluster we have eight variables. Government policy and Regulations (E1), Total Quality Environmental management (E2), Management Support (E3), Management Review (E4), Continuous education of employees (E5), Cross functional team building (E6), Organization Culture (E7), and Green process and Technology (E8).

4.10. Level Partition on Reachability Matrix

The final reachability matrix obtained above in Table 6 is now partitioned into different levels (Table 7). After the first iteration, the driver classified to level 1 is discarded and the partitioning procedure is repeated on the remaining drivers to determine the level 2. These iterations are continued until the level of each driver has been determined.

4.11. TISM Diagraph

The connective and interpretive information contained in the interpretive direct interaction matrix and diagraph is used to derive the TISM. The nodes in the diagraph are replaced by the interpretation of elements placed in boxes. The interpretation of the cells of interpretive direct interaction matrix is depicted by the side of the respective links in the structural model. The final TISM model is presented in Figure 3.

4.12. Discussion on Fuzzy TISM Analysis

In the current study first author proposes a Fuzzy TISM method for identifying the interrelationships among elements influencing green procurement. Due to incorporation of fuzziness in TISM the decision makers have the flexibility in assigning the level of influence of pair wise elements. Apart from wider flexibility Fuzzy TISM also enhance the quality of decision making. The findings from the TISM model show that Customer Satisfaction is in level 1, Annual Savings from green procurement practices, Annual Saving of natural resources and Procurement Excellence are in level 2, Supply risk management is in level 3, Information System Infrastructure and Low supplier lead time is in level 4, Suppliers' capability to Innovate and Trust building in suppliers is in level 5, Supplier Flexibility is in level 6, Re-use, Re-engineering and Recycling of products and materials is in level 7, Green Design is in level 8, Green process and Technology is in level 9, Continuous education of employees, Cross functional

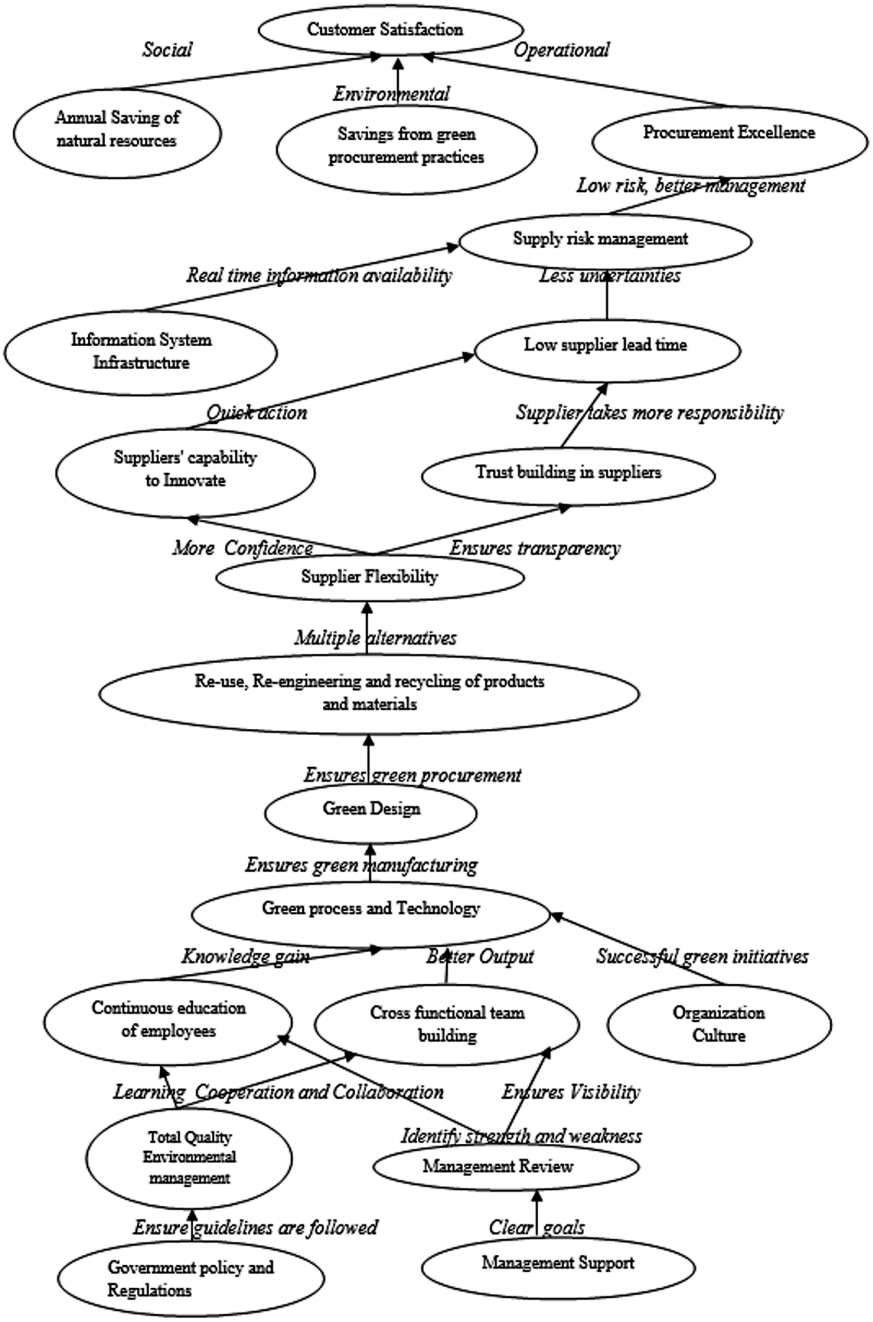
Iteration 12	E3	3	3	3	XII

team building and Organization Culture is in level 10, Total Quality Environmental management and Management Review is in level 11 and Government policy and Regulations and Management Support are in the bottom level.

The fuzzy TISM model gives a clear picture on the inter-relationships between green procurement drivers. The proposed method is a novel attempt in the direction of green procurement theory building. The incorporation of fuzzy allows the decision maker to judge degree of relationship between criteria. Instead of only selecting {0, 1} i.e. binary here respondent can select influence level such as {Very High, High, Low, Very Low, No} of selected criteria. The final fuzzy model consists of fuzzy relationships between one to one criteria. The interpretation of model can assist supply chain practitioners in better decision making.



5. FUZZY DEMATEL

The steps of Fuzzy DEMATEL have been followed as per (Gharakhani, 2012 and Mavi et al., 2013). The Data analysis is segregated into following sub-sections:

Here expert from manufacturing sector has been interviewed to capture the data for further Fuzzy DEMATEL application. The questionnaire has been prepared keeping in mind the pair wise comparison

to evaluate the influence of each score. The evaluation criteria symbols are as follows: Government policy and Regulations (E1), Total Quality Environmental management (E2), Management Support (E3), Management Review (E4), Continuous education of employees (E5), Cross functional team building (E6), Organization Culture (E7), Green process and Technology (E8), Information System Infrastructure (E9), Green Design (E10), Re-use, Re-engineering and Recycling of products and materials (E11), Supplier

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Flexibility (E12), Suppliers' capability to Innovate (E13), Supply risk management (E14), Trust building in suppliers (E15), Low supplier lead time (E16), Customer Satisfaction (E17), Annual Savings from green procurement practices (E18), Annual Saving of natural resources (E19), Procurement Excellence (E20).

5.1. Design the Fuzzy Linguistic Variables

The study addresses response to the human logic variable as Table 8.

5.2. Direct Relation Matrix (T)

The below Table 9 presents a completed direct-relation matrix for first expert within a linguistic scale assessment among the green procurement drivers.

5.3. Transform Triangular Fuzzy Numbers Into Initial Direct Relation Matrix (F)

Here author applied modified CFCS method to develop a crisp value direct-relation matrix for each evaluator. Final results are shown in Table 10.

5.4. Setup the Generalized Direct –Relation Matrix (S)

The generalized direct-relation matrix is presented in Table 11.

5.5. Set Up the Total Relation Matrix (M)

The total relation matrix is obtained from the generalized direct-relation matrix. The total relation matrix is presented in Table 12.

5.6. Sum of Rows and Columns

The sum of rows and sum of columns are separately denoted as D and R within the total relation matrix as below:

Table 8. The Fuzzy linguistic scale

Linguistic Terms	Influence Score	Triangular Fuzzy Numbers
No Influence	0	(0, 0, 0.25)
Very Low Influence	1	(0, 0.25, 0.50)
Low Influence	2	(0.25, 0.50, 0.75)
High Influence	3	(0.50, 0.75, 1.00)
Very High Influence	4	(0.75, 1.00, 1.00)

5.7. Setup Degree of Central Role and Relation

The degree of central role (D+R) in DEMATEL represents the strength of influences both dispatched and received. The degree of influence of green procurement drivers are presented in Table 13.

5.8. Causal Diagram

The relationships of green procurement drivers are constructed in graphical form which will enable to understand the relationships in a transparent manner. The causal diagram is presented in Figure 4.

6. DISCUSSION ON FUZZY DEMATEL ANALYSIS

The total relation matrix (M) includes the direct and indirect effects. $(D+R)_i$ provides an index of strength of influences dispatched and received, i.e., $(D+R)_i$ shows the degree that the element I plays in the problem. The more positive the $(D+R)_i$ the greater is the degree of influence on other elements. If $(D-R)_i$ is positive, then element I is affecting other elements, and if $(D-R)_i$ is negative, then element I is being influenced by other elements. The current study used 20 criteria. The development of diagraphs in Figure 4 shows the interrelationships amongst each of 20 green procurement criteria. We can also distinguish general clusters into cause and effect groups.

The green procurement criteria that are part of the cause cluster include Government policy and Regulations (E1), Management Support (E3), Management Review (E4), Organization Culture (E7) and Green process and Technology (E8).

The effect group cluster consist of Total Quality Environmental management (E2), Continuous education of employees (E5), Cross functional team building (E6), Information System Infrastructure (E9), Green Design (E10), Re-use, Re-engineering and Recycling of products and materials (E11), Supplier Flexibility (E12), Suppliers' capability to Innovate (E13), Supply risk management (E14), Trust building in suppliers (E15), Low supplier lead time (E16), Customer Satisfaction (E17), Annual Savings from green procurement practices (E18), Annual Saving of natural resources (E19) and Procurement Excellence (E20).

If the firm wants to obtain high performance in the "effect criteria", it would control and pay more attention to the "cause criteria" beforehand. The criteria Government policy and Regulations (E1), Management Support (E3), Management Review (E4), Organization Culture (E7) and Green process and Technology (E8) influence dispatching evaluation criteria. These criteria influence Total Quality Environmental management (E2), Continuous education of employees (E5), Cross functional team building (E6), Information System Infrastructure (E9), Green Design (E10), Re-use, Re-engineering and Recycling of products and materials (E11), Supplier Flexibility (E12), Suppliers' capability to Innovate (E13), Supply risk management (E14), Trust building in suppliers (E15), Low supplier lead time (E16), Customer Satisfaction (E17), Annual Savings from green procurement practices (E18), Annual Saving

Figure 4. The causal diagram

of natural resources (E19) and Procurement Excellence (E20). If firm wanted to improve the effectiveness of a specific criteria i.e., Total Quality Environmental management (E2), Continuous education of employees (E5), Cross functional team building (E6), Information System Infrastructure (E9), Green Design (E10), Re-use, Re-engineering and Recycling of products and materials (E11), Supplier Flexibility (E12), Suppliers' capability to Innovate (E13), Supply risk management (E14), Trust building in suppliers (E15), Low supplier lead time (E16), Customer Satisfaction (E17), Annual Savings from green procurement practices (E18), Annual Saving of natural resources (E19) and Procurement Excellence (E20), it would be necessary to pay attention to Government policy and Regulations (E1), Management Support (E3), Management Review (E4), Organization Culture (E7) and Green process and Technology (E8). This is because E1, E3,E4,E7 and E8 are influencing criteria and can be improved, while E2, E5, E6, E9, E10, E11, E12,E13, E14,E15,E16,E17,E18, E19and E20 are influence criteria and can arrive at the effect criteria. Then it is easier for a firm to find the performance of appropriate green procurement drivers by using the above result.

From the cause diagram the results show that (E4) management review is the central criteria for evaluating indirectly the criteria of E1, E2, E3, E5, E6, E7, E8, E9, E10, E11, E12, E13, E14, E15, E16, E17, E18, E19, E20. Management review on periodical basis is important in evaluating the progress of green procurement action plans. Management review provides visibility of the entire green procurement program. It is clear whether team members are taking responsibility, accountability, meeting timelines, and taking appropriate actions for the critical path.

The results also show that (E7) organization culture is the most important and most influencing criterion because its position has the highest intensity of relationships to other criteria. This means that

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

organization culture plays a key role in green procurement practices. The organization silos need to be broken and a healthy organization culture must be created for successful green procurement practices.

7. CONCLUSION

Decision making situations where multiple criteria are involved makes it really difficult to select the right research method for data analysis. Keeping the limitations and benefits in mind here two different MCDM technique has been used to separately analyze the same set of criteria. The results are encouraging and offer practical solutions to problems faced by procurement managers in green procurement decision making.

The driving factors which emerged from Fuzzy TISM and MICMAC analyses are Government policy and Regulations (E1), Total Quality Environmental management (E2), Management Support (E3), Management Review (E4), Continuous education of employees (E5), Cross functional team building (E6), Organization Culture (E7), and Green process and Technology (E8).

Fuzzy DEMATEL analysis resulted into emergence of the cause and effect groups. The green procurement criteria that are part of the cause cluster include Government policy and Regulations (E1), Management Support (E3), Management Review (E4), Organization Culture (E7) and Green process and Technology (E8).

The effect group cluster consist of Total Quality Environmental management (E2), Continuous education of employees (E5), Cross functional team building (E6), Information System Infrastructure (E9), Green Design (E10), Re-use, Re-engineering and Recycling of products and materials (E11), Supplier Flexibility (E12), Suppliers' capability to Innovate (E13), Supply risk management (E14), Trust building in suppliers (E15), Low supplier lead time (E16), Customer Satisfaction (E17), Annual Savings from green procurement practices (E18), Annual Saving of natural resources (E19) and Procurement Excellence (E20).

It is observed that Organization Culture (E7) is the most influence and the strongest connection to other criteria.

The results of Fuzzy TISM and Fuzzy DEMATEL show that some common criteria are falling in the driving/cause group, i.e., Government policy and Regulations (E1), Management Support (E3), Management Review (E4), Organization Culture (E7) and Green process and Technology (E8). These elements are the key players which must be considered while planning green procurement programs.

7.1. Managerial Implications

Firm can gain multiple benefits from green procurement. Firstly, firm can become lean and save lot of money apart from improving quality and wastage reduction. Secondly green procurement promotes sustainability in inventory management, sustainability in production operations, sustainability in distribution chain operations and drives business excellence.

Procurement managers must carefully select the cause criterion and understand its influence on effect criterion while making green procurement decisions otherwise the entire effort may fall back.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

7.2. Limitations and Future Research Directions

The present research has certain limitations. The model is developed purely based on interview with five procurement management experts from the manufacturing sector. Author proposes to statistically validate the model and further extend theory in the field of green procurement.

Chapter 28
Green Information Systems for Sustainability

Mahesh S. Raisinghani
TWU School of Management, USA

Efosa Carroll Idemudia
Arkansas Tech University, USA

ABSTRACT

Green Information Systems (IS) refers to the use of IS to achieve environmental objectives, whereas green Information Technology (IT) refers to the practice and study of using IT and computer resources in a more environmentally responsible and effective manner (Dedrick, 2010). Information Systems, computers and computing in general consume an immense amount of natural resources, the energy used to power them, and the problems that arise in the disposing of obsolete hardware. Mark O'Neill, the author of Green IT for Sustainable Business Practice defines green IT as, "a collection of strategic and tactical initiatives that directly reduces the carbon footprint of an organization's computing operation" (O'Neill, 2010). Issues of sustainability have started to become a significant topic of discussion in the information systems community. IT practitioners are focused more now than ever on reducing the direct impact that IT use has on the environment (Dedrick, 2010).

IMPACT OF GREEN INFORMATION SYSTEMS

Information Systems (IS) and Information Technology (IT) have changed societal behaviors drastically in the last few decades and, as such, have the conceivable backing to shift to a more sustainable society. "The role and contribution of IS to eco-sustainability has become the concern of many IS researchers" (Ijab & Molla, 2011). IS communities around the globe have begun to look seriously at the role IT can play in both creating and reducing environmental impacts. Much of the dialogue is focused on lessening the direct environmental impacts of Information Technology by making IT equipment more energy efficient (Dedrick, 2010). "These efforts can directly reduce IT costs, so there is a strong incentive for organizations to adopt them. Evidence from surveys confirms that IS organizations are responding to these incentives by adopting green practices" (Dedrick, 2010). Many businesses are focused on imple-

menting green business models. They have learned that implementing green IT solutions not only aid in meeting shareholder expectations but help to improve their organizations' corporate image, all while offering cost saving benefits.

By adopting initiatives that have a positive effect on the environment, they save money, and at the same time, use technology more efficiently. Great opportunities lie in the IT department, where reducing the environmental footprint of technology is now top of mind for many IT leaders. ("Green IT: Why")

While cost cutting is the largest impact and factor of implementing green IS practices in an organization, environmental stewardship follows closely behind. Many companies are adopting the mindset of introducing green Information Systems because "it is the right thing to do". The Vice President of Information Technology at a large international investment firm demonstrated this outlook when he said, "Cost cutting is important to every organization, let's be real, but [our] philosophy as an organization is that we live in this world and we want to be good neighbors. With our new investments, we are doing both" ("Green IT: Why,").

USE OF GREEN INFORMATION SYSTEMS

Over the recent decades, there has been a rising concern and various studies in the different ways that information systems have an impact on sustainability through the uses of various energy sources, types of transportation, ways of building and manufacturing for the current society.

- Advanced wind turbines are being transformed with various forms of sensors and controllers that enable the turbines to operate efficiently and safely in various wind speeds and weather conditions.
- A type of smart grid technology is being developed to allocate more energy more efficiently and effectively.
- Smart buildings use various sensors to adjust the surroundings from a distance such as temperature controls.
- Smart meters allow users to make changes to use of energy at various times.
- Having a smart car can improve air emissions as well as reducing the time and energy that is wasted in traffic jams.

EFFECTS OF GREEN INFORMATION SYSTEMS

Taking a longer term, more dynamic view, researchers have framed the impacts of technology on the environment as primary, secondary and tertiary order effects.

- The primary effects are the direct impacts from the hardware during the life of the product, including production, use and disposal of computer equipment.
- The secondary effects are the effects of ICTs (information and communications technologies) and their environmental impact on various developments such as industrial production or transportation.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

- Tertiary effects are longer term and more dynamic. They occur when widespread use of ICTs leads to changes in lifestyles and economic structures. Tertiary effects may be seen in specific cases, such as telecommuting or the growth of home-based businesses built on e-commerce platforms such as eBay or Amazon. So far, these transformative effects are limited, but widespread adoption of the Internet is only a decade or less old in many countries. By comparison, widespread use of automobiles led to suburbanization, motels, fast food chains, and other changes in lifestyle and economic systems, but these changes were not evident until decades after the introduction.

GREEN TECHNOLOGIES THAT ARE IMPROVING ORGANIZATION

Radio-frequency identification (RFID) has transformed transportation and logistics by enhancing the success of companies and growing new sources of profits via information-based means. From a sustainability point of view, IS facilitates the companies to capture, monitor, utilize and standardize data that aid power efficiencies. Companies are decreasing energy and improving supply chain efficiency by decreasing printed items and having them available online.

PRIOR STUDIES ON GREEN IT/PRODUCTS

Worldwide despite the rapid spread of pro-green attitudes; consumers are purchasing non-green alternative because of higher prices, quality, performance, and convenience (Olson 2014). Some scholars and researchers have argued that the environments can be protected and preserved through the development and promotion of green products (Huang and Rust 2011; Hult 2011). It should be noted that it is not easy to be green because environmental friendly products might force customers to make tradeoffs on important attributes relating to price, quality, performance, and effectiveness (Barr 2006; Rokka & Uusitalo 2008). The adoption of green product worldwide is low because most people in the world do not know, understand, and appreciate the advantages and benefits of green product. There has been very few studies that have investigated the adoption of green product (Olson 2014). Worldwide, the US is the leader in per capital energy use; while China is the largest greenhouse gas emitter (Buckley 2010; Lewis 2010). Worldwide most citizens are expressing support for green products and environmental issues (Olson 2014).

All over the world, the average weight and horsepower of cars have been increasing consistently since the mid-1970 (Olson 2014). Also, there have been a consistent increase in the size of most products such as the median TV screen size leading to the rapid increase in electricity consumption (Farhi 2009; Walkeron 2008). It should be noted that the increase in the size of most product is due to consumers preference and choices. Murugesan (2008) argues that Green IT is the process by which individuals and organizations adopt environmental sustainable practices using information technology/systems. Organizations and individuals are legally, ethically, and socially required to use Green IT products; and at the same time implement practices that enhances the adoption of Green IT (Murugesan 2008). Coffey et al. (2013) argue that international approaches and practices toward Green IT are still in their early stages. To date, unlike carbon footprint monitoring, there are very few international guidelines relating to Green IT/Management (Coffey et al. 2013). Organizations and individuals' decision to adopt Green IT is based on financial, legal, moral, and ethical considerations (Chen et al. 2010). Ruth (2009) argues

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

that IT infrastructure is going green based on significant new regulations relating to IT equipment for PCs and hardware. Also, some countries are now having national standards relating to data center power savings (Ruth 2009). Green IT and computing started in the early 1992 (Ruth 2009).

Green information technologies and systems refer to initiatives and programs that directly or indirectly address environmental sustainability in organizations (Jenkin et al., 2011). Green IT/IS is a compound word and refers to the environment and ITIS. It can refer to either "green of ITIS" or "green by ITIS" based on the roles of ITIS in the business operation (Park, Cho et al. 2009). "Green of IT IS" means making the ITIS industry green, while "Green by IT IS" means making activities green by using ITIS. Therefore, green ITIS focuses on either energy-saving IT equipment and information systems or an energy-efficient society by ITIS application.

Jenkin et al., (2011) develop a multilevel research framework to guide future research. To do so, we review the existing green information technology and systems literature, and also draw more broadly from research that addresses environmental sustainability in the management, environmental psychology, and social marketing domains. From this review, we identify important research gaps and present a set of propositions to guide future research. The three aspects of green ITIS adoption motivations are: regulations, competitiveness and ecological responsibility (Zheng, 2014). There is little research involved in business strategy, motivations, and corporate social responsibility (CSR) framework together to explain the phenomenon of green ITIS adoption. Obviously, the motivations of organization and technology are associated with the organization themselves, and the motivations of regulation are not associated with the environment. Thus, business strategy moderates the motivation of organization and technology, and has no relationship with the motivation of regulation. Although there has been research concerning green ITIS in the application of ecological practice, investigation of current IS literature reveals that there is a notable absence of research on green ITIS at the strategic level (Zheng, 2014).

Bhadauria et al. (2014) developed a structural model depicting the impact of green information systems on environmental, economic, and operational performance for which data were collected from 159 manufacturing managers and analyzed using a structural equation modelling methodology. Their findings indicate that green information systems positively and directly impact environmental, economic, operational performance. Green information systems also indirectly impact operational performance through environmental performance and indirectly impact economic performance through environmental performance. Evidence supports the need for manufacturers to develop green information system capabilities to improve environmental and operational performance and their results support the proposition that green information systems are necessary to achieve environmental and economic sustainability.

Fang et al. (2014) report that to better cope with the Internet usage shift from host-centric end-to-end communication to receiver-driven content retrieval, innovative Information-Centric Networking (ICN) architectures have been proposed. However with the explosive increase of global network traffic, the energy efficiency issue in ICN is a growing concern. A number of approaches have been proposed to address the energy efficiency issue in ICN. However, several significant research issues and challenges remain to be addressed before its widespread deployment, including but not limited to shutdown, slow-down, mobility and cloud computing.

Jenkin et al., (2011) develop a multilevel Green Information Technology/Systems (IT/S) research framework to guide future research by placing the fragmented Green IT/IS literature in conversation with the more well-established environmental sustainability literatures in management, environmental psychology, and social marketing domains. From this review, they have identified important research gaps and present a set of propositions to guide future research. This could be a starting point for future

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

research agenda in this domain. For example, within-level and between-level alignment of environmental orientation, as well as its relationship to environmental initiatives (both Green IT/S strategy and Green IT/S implemented) and environmental impacts is a critical area for future research.

MOTIVATIONS FOR GREEN INFORMATION SYSTEMS

Current studies show that various systems of production *and consumption* go hand in hand. Hence, to solve the solutions to the current environmental issues, we should reflect on how consumption and production work together to interact with the environment. Most companies only focus on the production and manufacturing procedures that often simply move the problem somewhere else in the system. An overall perspective is crucial when the companies consider the development of their services department. These departments use various forms of information, sharing and data acquirement to produce 60 percent of U.S. economic production and employment. The various businesses in these departments execute key financial and societal tasks such as education, health care, public utilities, entertainment, banking and finance, transportation, as well as retail and wholesale trade. All of these devour energy and resources which ultimately sway the atmosphere, such as financial institutions and banking. Other than utilities and transportation, these services are not generally linked with environmental impacts. These services thus represent an unexploited resource for improving the environment. Service companies are well positioned to control their suppliers, as well as their consumers, towards a complete change. The more information they have in hand, the more it will aid their decisions.

The communications and information uprising is making various changes to current atmosphere. The changes in the industry are being noticed already, mostly in the materials and energy used, monitoring and managing of emissions from various forms of transportation, inventory and quality, and the improved control of the production processes. The integration of electronic sensors in the energy-saving machinery has been shown to promote cleaner assembly and allows the user to input various information to control the process. For accurate execution and agreement with the regulations, the majority of these processes usually require online computers that use intricate and complex procedures.

Communications and information machinery also increase the inventory control and facilitate to decrease and eradicate defective or substandard products. Due to high demands for companies to decrease expenditure, achieve environmental goals, to increase manufacturability, quality, or performance have been attained by constant development and have resulted in the shared procedures. These developments are supported by the implementation of IT that circulate data and help administer inventory. By combining these benefits and applying IT with new management viewpoints, it could cause more harm to the environment and become more consequential. Companies who have just-in-time can increase the types of transportation, therefore leading to an increase in pollution as well as use of energy.

The majority of the machinery has produced fewer materials per unit of product. Instead of using an old vacuum-tube machine, it is more efficient to use a semiconductor because it has more power without eating up energy and materials. In the same way, on the materials front, metal consumption over the past 20 years has decreased immensely. Most of these reductions can be accredited to the information and communications uprising itself, which inspires many companies to have improved product design systems. These machines also have facilitated advancement of more effective manufacturing processes.

The information and communications uprising is creating a far more incorporated nation. Concentrating on environmental and sustainability issues entails various viewpoints that are entwined with the

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

universal financial system and with nature. The theory of sustainability involves a universal agreement with its sustaining natural environment which will produce a healthier atmosphere, one that is dense with information.

Even though information substitution is a significant contributor, it will not produce the model environment by itself; such substitutions are not without trade-offs. In the transportation industry, there has been an integration of machinery in various forms of transportation and traffic systems, which aid in traffic flow and accidents. Having a significant improvement on public transportation has shown to increase ridership on public transportation which has been shown as a solution for traffic jams. Working from home is another alternative that companies are starting to include but can often lead to low productivity, interfere with privacy of the content, as well as technical issues.

LITERATURE REVIEW

The immense use of information technology in a society to improve economy and provide efficient services has been the motivation to pursue green information systems. Organizations are inspired to 'go green' because it is cost effective for them. There are a number of internal and external processes in an organization. These include email, video conferencing, teleconferencing and file transfer protocols, etc. Adopting environment friendly processes has quantifiably improved businesses and its processes. An example is companies switching their reports from hard copies to soft copies. Prior to 1996, AT&T printed hard copies of their 100,000 page annual environmental report (de Geus, 1997). When they stopped printing the report and started using the internet to publish the reports, their cost for printing was reduced by ten percent. Similarly, Sun Microsystems is also using a system of operation to keep all recorded data in electronic format (Craig, 1997).

Industries have introduced the concept of digital signatures as well to avoid indulging in time consuming activities of sending documents to and fro and waiting for them to be delivered. Electronic marketing and banking is also becoming common among consumers due to ease of use. This, in return, helps the company save additional resources like forms and hard copy notices to the customers. A June, 2013 study by the consulting firm Celent, revealed that 42 percent of Android users in the United States relied on online banking for financial transactions versus 27 percent of people who did not own a smart phone ("Smartphone users prefer," 2013). The advancements in technology have made it easy to adopt environmentally friendly practices especially in supply chain management. Technology, particularly smart phones, are now a part of everyday life for most people. Transportation costs are reduced by providing online facilities for reporting, registering and delivering of goods and other everyday items. The adoption of green information systems requires companies to revamp their processes in order to effectively meet the goal. Some people are resistant to change but once they adopt the processes and understand them, they feel comfortable in doing more in less time.

Apart from cost savings, companies benefit by building healthy public relations and attracting consumers of like mind. A study conducted in 2010 by Accenture revealed that 49 percent of the companies had their brand reputation improved and gained trust of customers by taking sustainability measures (Anne, 2011). A report also shows how Newmarket gained customer satisfaction by delivering software electronically rather than delivering compact discs through courier. The report also shows that the company saved $42,000 in shipping costs ("Choosing sustainability in", n.d.). Providing ease to customers always attract them for future services as well. As people are becoming aware of the benefits of using

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

recyclable material, they prefer companies whose products are environment friendly. Research suggests that companies who go green provide a healthier workplace to employees; thus, their sick leaves are reduced by 20 percent and the company has to pay less for the medical programs they offer. Governments in many countries have also provided compensation in the form of tax incentives for companies that are providing and practicing environmentally friendly services (Joesph, n.d.). This has convinced more and more companies to collaborate with the government in introducing processes for the common public that are environmentally friendly.

By adopting green information systems, staff productivity can be increased. In order to make employees feel as if they are a part of the team and that they are contributing to society by following environmental processes, companies can contribute in the global mission of using resources responsibly. People feel happier to work in a place that is helping society as they realize that investment is required initially in following environmental friendly processes. They feel proud to be a part of a company that invested financial resources for the environment rather than adding it in their profits. They spread awareness in their social circles by explaining their methodologies to handle activities at work. One such example is 10000 friends - a project by individuals and organizations in Pennsylvania dedicated to providing a platform for awareness and practices of eco-friendly activities in organizations and at home. Studies have shown that turnover ratio decreases when people are happy at a workplace and they feel more obliged to contribute to the welfare of the company. By reducing telecommuting costs and allowing work from home, employees are saved from parking issues and are happy to be near their family (Abella & Yap, 2012).

Energy efficient green information systems involve the process of reduction, reusability and recycling of resources for sustainability. One way to do this is to increase the life of a product. To incorporate latest technology with existing ones, modularity concept is embedded in existing systems for easy upgrade. One other way for making efficient systems is to create centric data. A large chunk of data required by users is not sensitive and hence needs not to be decentralized. As far as the software development is concerned, researches are done to investigate the impact of development units in conserving energy and creating an environmental friendly lifecycle of development. These software development units include algorithm execution, efficient allocation and virtualization of resources, usage of terminal servers, power management, availability requirements of data centers, storage medium, support of operating systems, telecommunication and network devices, display and video graphics. Where hardware is concerned, devices are equipped with energy saving materials e.g. light emitting diodes for display, PC power management at module levels and then providing sleep modes at software levels etc. Leading giant industry IBM ("Green IT") has launched a series of computer hardware for efficient energy consumption and sustainability. The Z196 series saves energy up to 75 percent as compared to the other series of hardware that is in use today. The interesting factor about this hardware is that the energy conservation is done by not compromising on performance. This encourages consumers to buy energy efficient computing machines to accomplish their tasks. Gartner estimates presented at Gartner Symposium indicate that IT contributes to 2 percent of the current carbon emission in the world. The Climate Group and Global e Sustainability Initiative estimated in 2008 that by the year 2020, IT can reduce carbon emissions by 15 percent. This is only possible by following methodologies and processes that are environmentally friendly within organizations as mentioned by the Verizon Business ("Go Green"). SAP is business process management software that allows sustainability by providing a number of resources that are efficient as well. The major modules include information lifecycle management and IT infrastructure management that are widely used.

The literature review discussed above shows how significantly operations have improved in organizations by adopting green IT. This includes cost reduction, performance enhancement and customer satisfaction. It also encourages employees, as they feel motivated to be a responsible member of society by following Green IT processes.

IMPLICATIONS FOR RESEARCH: KEY TAKEAWAYS FOR RESEARCH

In the immediate to near future, Green IS will fundamentally impact organizations. The transformative capacity of these technologies can already address service challenges across customer service needs, industry and government planning operations, and new research and innovation. Green IS is the central way of improvement, as its paves the way for future requirements and links to more discoveries and emerging advanced applications.

The overall performance of an organization can already be fused and positively affiliated with coordinated efforts through the use of Green IS. Green supply chain managers are reducing costs and improving their environmental performance through better synergized logistics, tracking, and monitoring environmental information. Their bottom-line effectiveness, as well as competitiveness, benefits from green supply chain management. The Environmental Protection Agency (EPA) finds that enhancing green supply chain management processes will reduce waste, decrease operating costs, lower training needs, increase revenues and lower the use of hazardous waste materials. The green supply chain management process, and its informatics obtained through the use of Green IS, is one example of how companies are accounting for their environmental advantages and expenses. The EPA's guidebook on improving environmental performance suggests that by synthesizing best management practices, some leading U.S. companies "have saved millions of dollars while reducing or eliminating significant impacts" (The Lean and Green, 2000).

Green information systems are transforming environmental issues and revolutionizing global, social, and cross-cultural relations. These technologies provide increasing efficiencies and opportunities that once limited organizations in the physical world. The immediate nature of virtual reality and cloud computing modernizes the way critical problems impacting the environment and communities are researched. Large universities can now offer a multidisciplinary approach to academic research through the use of these technological dimensions. The opportunity to share knowledge and collaborate intellectually gives researchers access to more data, allowing them greater chances of making a global impact.

Business intelligence is the foundation for a green information system network that supports an organization's ability to manage, communicate and develop its intangible assets sustainably. As interactions with other developed countries intensifies, so does the need to share information and knowledge. These intangible assets serve as a new commodity and business intelligence. This ever increasing production of knowledge, as well as information sharing, promotes new solutions and applications for environmental problems. While the possibilities for green information systems are vast, an increasingly global economy and its interconnectedness necessitate more attention. In some way, "knowledge is more important as a product than it has been hitherto – we are seeing the rise of new forms of activity based on the trading of knowledge products" (Smith, 2002). Business information that grants expediency of transactions, access to greater and more diverse customers, and the removal of cultural barriers in the process, provide critical technologies for competing and surviving in today's interconnected market.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Green IS is a dynamic and iterative technology that brings new advancements to the global market. As new environmental strategies provide positive evidence of their impact, the resulting quantifiable and qualitative data fuel more information for business solutions and sustainability purposes. This exchange of knowledge yields to new understandings of environmental change and allows for its transparency. This creates a cycle for new policies, environmental solutions, and supporting technologies.

The use of Green IS stands to directly and indirectly impact human behavior. Business organizations that utilize Green IS and practice sustainability are more likely to foster environmentally charged behaviors in their workforce. Professionals who support and engage in activities that promote sustainable business practices are more apt to understand its importance and adopt new behavior changes. The basis to human involvement in sustainable practices involves consumer awareness. Green IS alone cannot change behavior. Rather, the "emerging and effective tool for encouraging positive change" (McKenzie-Mohr, 2011) is the outcome of Green IS.

CONCLUSION

Information Systems bridge the gap between countries, organizations, and societies, and it enhances their operations through its platform for collaboration. Green Information Systems is a vehicle which is successfully giving rise to the principles of sustainability and fundamentally changing the collaborative, yet complex society dedicated to progressing environmental advancements. The transformative powers of Green IS offer new insights into previously unrealized economic, social, and ecological competitive advantages. There is also a growing awareness that Green IS is not only a contributor, but perhaps will be a key facilitator for sustainable strategies. As the interest for environmental strategies unfolds, so does the understanding for how Green IS will be part of the solution. Its relevance and ever increasing employment only broadens the context of environmental sustainability. Green IS has the strongest capability to impact societal behaviors. Communities around the globe are creating and reducing their environmental impacts by a means of dialogue and interconnectivity that never existed two decades ago. The significant environmental progress at the individual, organizational, and international level through the transformative powers of Green IS is paving the way for future sustainability requirements and discoveries.

KEY TERMS AND DEFINITIONS

Business Intelligence: Business intelligence is the foundation for a green information system network that supports an organization's ability to manage, communicate and develop its intangible assets sustainably. As interactions with other developed countries intensifies, so does the need to share information and knowledge. These intangible assets serve as a new commodity for business intelligence.

Eco-Sustainability: Evidence supports the need for manufacturers to develop green information system capabilities to improve environmental and operational performance and their results support the proposition that green information systems are necessary to achieve environmental and economic sustainability.

Environmental Issues: Concentrating on sustainability and environmental issues entails various viewpoints that are entwined with the universal financial system and with nature. The theory of sustainability involves a universal agreement with its sustaining natural environment which will produce a healthier atmosphere, one that is dense with information.

Environmental Objectives: Green information technologies and systems refer to initiatives, policies, rules, guidelines, and programs that directly or indirectly address environmental sustainability so as to achieve environmental objectives.

Environmental Sustainability: There is also a growing awareness that Green IS is not only a contributor, but perhaps will be a key facilitator for sustainable strategies. As the interest for environmental strategies unfolds, so does the understanding for how Green IS will be part of the solution. Its relevance and ever increasing employment only broadens the context of environmental sustainability.

EPA: The Environmental Protection Agency (EPA) finds that enhancing green supply chain management processes will reduce waste, decrease operating costs, lower training needs, increase revenues and lower the use of hazardous waste materials. The EPA's guidebook on improving environmental performance suggests that by synthesizing best management practices, some leading U.S. companies "have saved millions of dollars while reducing or eliminating significant impacts" (The Lean and Green, 2000).

Green IT: Refers to the practice and study of using IT and computer resources in a more environmentally responsible and effective manner (Dedrick, 2010).

Techniques for Sustainability: Over the recent decades, there has been a rising concern and various studies in the different ways that information systems have an impact on sustainability through various techniques such as the uses of various energy sources, types of transportation, ways of building and manufacturing for the current society. From a sustainability point of view, IS facilitates the companies to use various techniques to capture, monitor, utilize and standardize data that aid power efficiencies. Companies are decreasing energy and improving supply chain efficiency by decreasing printed items and having them available online.

Chapter 29
Value Engineering–Based Method for Implementing the ISO14001 System in the Green Supply Chains

Larry Jung-Hsing Lee
National Central University, Taiwan

André Krischke
Munich University of Applied Sciences, Germany

ABSTRACT

Numerous green regulations currently require companies to be responsible for their effect on the natural environment, in addition to achieving their economic goals. In view of this, many companies have implemented the ISO14001 system in their supply chain to comply with green regulations. However, implementing such a system involves technical and communication efforts; hence, an effective method is needed to support the implementation. In this paper, the authors propose a value engineering (VE)-based model with quality tools to support the implementation of the ISO14001 system in the Green Supply Chains. In it, they applied the framework of VE with the quality engineering tools Fishbone Analysis and Failure Mode Effect Analysis for the qualitative and quantitative analysis of green issues in supply chains to cover quality, risk, and value of the system. The proposed method was applied to a global electronics manufacturing company in Taiwan, and the application results showed positive outputs in terms of CO2 emission, power consumption, water consumption, and waste water recovery. Based on the evidence, academic and industrial implications are discussed.

1. INTRODUCTION

The green supply chain concept is a model in which companies minimize the environmental impact of their industrial activities while maintaining their quality, reliability, cost-efficiency, performance, and energy efficiency. The concept involves a paradigm shift in business operations by transforming the end-of-pipe control operations of an organization to conform to environmental regulations that facilitate the minimization of ecological damage, while maximizing total economic profits (Srivastava 2007). From researching different manufacturing companies, implemented ISO14001 is the way to set up robust environment policy by transforming the entire supply chain to green through greener products and strong regulatory pressure from government and non-government organizations (Dey and Cheffi, 2013). It is critical for organisations to meet the requirements of green guidelines by producing green products and managing their entire supply chain. This also implies an obligation for organisations to treat used materials and products appropriately. Because external pressures have encouraged innovators to identify or develop greener processes and products, companies must incorporate environmental factors into their supply chain system to meet customer expectations (Swanson et al., 2005; Grote et al., 2007).

Walton et al. (1998) asserted that the green supply chain is a value-added concept that assists companies to maintain stable long-term relations with suppliers to benefit both the environment and businesses. However, implementing a green supply chain is complicated. The industrial survey by Al-Darrab et al. (2013) found that most implementation of quality management projects was unproductive and required an integrated approach. We developed a value engineering (VE)-based model combined with quality tools to improve the green performance of a supply chain. To achieve this, we considered the balance between environmental expenses and firm benefits.

In this paper, we first review related literature and then present the methodology of the VE-based model with quality tools in Section 3. We then apply this method to an industrial case in Section 4. On the basis of the application evidence, we discuss the academic and industrial implications in Section 5. Finally, we present our conclusion and suggestions for future research.

2. LITERATURE REVIEW

In this section, we review the literature on green supply chains and research methods. First, we review ISO14001 and green supply chain models. Second, we review green businesses. Third, we review papers on VE and its use in environmental and quality improvements. Lastly, we discuss the findings and gaps in the literature.

2.1. ISO14001 and Green Supply Chain Model

ISO14001 provides the industry with primary guiding principles for developing an environmental management system, and offers self-checking mechanisms on environmental performance. The ISO14001 objectives include both quality and environmental aspects that seek to mitigate emissions and effluents, reduce the environmental effect of industries, and enhance customer satisfaction (Chen, 2005). Nishitani (2009) stated that the relationship between the adoption of ISO14001 and economic performance is positive; implementing ISO14001 satisfies stakeholders because it demonstrates that a firm employs advanced environmental management practices (Prajogo et al., 2014). Asif et al. (2011) discussed envi-

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

ronmental issues from the corporate sustainability perspective and proposed a framework for integrating sustainability in the quality management system.

The green supply chain concept provides companies an opportunity to develop win-win strategies that increase their profits and market share while reducing their environmental risks and impact, thereby improving their ecological efficiency (van Hoek, 1999, Zhu et al., 2012, Mohanty and Prakash, 2014). Zhu et al. (2008) reviewed more than 300 manufacturers implementing a green supply chain model and classified them based on regulatory, market, supplier, and internal pressures. They subdivided these four categories into five measurement items: internal environmental management, green purchasing, customer cooperation, investment recovery, and eco-design. Among these items, two related specifically to ISO14001 certification. Mathiyazhagan et al. (2015) chose ten industries which have already gotten ISO 14001 environmental certification for their studies. Analytical Hierarchy Process was applied to find the ranking of pressures for green supply chain management implementation. The pressures were divided into four groups as environmental regulations, external source, financial factors, and production and operation factors. The result showed that external source is the highest pressure on green supply chain implementation.

Srivastava (2008) developed a framework for analysing a reverse-logistics network and identified raw materials, manufacturing, distribution, and customers as four critical functional aspects. Sheu et al. (2005) formulated the green supply chain to an integrated framework. They identified raw material suppliers, manufacturers, wholesalers, retailers, and end-customers as manufacturing chain members, and defined collection points, recycling plants, disassembly plants, final disposal points, secondary material markets, and remanufacturing factories as reverse-logistics chain members. Lee et al. (2014) selected five dimensions of green supply chain management practices to test the relations with technology innovation. The five dimensions were developed by literature review as internal environmental management, investment recovery, Eco-design, green purchasing, and cooperation with customers. A partial least square-structural equation modelling approach was adopted to get the results as top management commitment and support towards green supply chain management is essential; internal environment management, Eco-design and investment recovery are significantly and positively related to technology innovation but green purchasing and cooperation with customers have an insignificant negative impact over technology innovation.

Ferretti et al. (2007) used a single-buyer single-vendor system to propose a complete numeric model to evaluate the economic and environmental impact of industrial practices. The models showed that green supply chains decreased their pollution output and penalty costs by 10% and 15%, respectively. Sheu (2008) presented a multi-objective optimization programming approach to implement a green supply chain model. The results showed that the model improves performance from 7.4% to 18.4%, depending on the weights associated with the objective functions of the raw materials supplier and waste reverse-logistics chains.

2.2. Green Business

2.2.1. Green Regulations

The European Union (EU) promulgated the EuP directive to promote environmental protection. The directive covers all products that consume any type of energy, although it excludes energy consumed for transportation. Furthermore, any products exceeding a volume of 200,000 units per year must fulfil all

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

specifications stipulated by the EuP directive if the products have a substantial impact on the environment, or if they can be improved (Grote et al., 2007). In 1998, the European Commission proposed the Waste Electronic and Electrical Equipment (WEEE) directive to regulate collecting and recycling electrical and electronic wastes, which specifies targets to increase recycling, reduce hazardous substances, and ensure the proper management of all post-recycling waste. The directive also requires all EU member states to establish collection systems for electrical and electronics waste, and stipulates that manufacturers are accountable for all processing costs from collection points to waste treatment (Webster & Mitra, 2007). The Restriction of Hazardous Substances (RoHS) directive prohibits the use of hazardous substances such as lead, mercury, and cadmium in new electrical equipment. Subsequently, innovative manufacturers have identified or developed substitutes for the lead solder used in assembling integrated circuit boards. The RoHS and WEEE directives are similar, and are a crucial element of a legislative initiative that addresses problems associated with toxic waste (Wang & Gupta, 2011).

2.2.2. Eco-Design

Eco-design is product or process design that systematically integrates environmental considerations. Eco-design addresses the environment throughout all stages of product development, and strives to minimize the environmental impact of products throughout the entire product life cycle (Aoe, 2007). Innovation is essential to realize effective eco-design concepts. Information and communication technologies are enablers of this realization because these two technologies facilitate the dissemination of knowledge and the ability to participate, thereby improving the quality of education, products, and services. Technological innovations offer new and economical tools for improving the efficiency, reuse, recycling, and substitution of natural resources (Azapagic et al., 2004).

2.2.3. Green Purchasing

Green purchasing refers to purchasing products and services that have a minimum impact on human health and the environment. Companies that adopt green purchasing practices into their management systems inspire all suppliers to reconsider the entire process of their production systems, from sourcing raw materials to treating final waste (Chen, 2005; Swanson et al., 2005). To improve the green purchasing behaviour of firms, Li (2007) highlighted three green purchasing strategies in green-suppliers and green-materials that assisted in reducing the source of waste. Zhu et al. (2007) recommended the following five conditions to implement an effective green purchasing strategy: (a) provide suppliers with design specifications for eco-friendly components; (b) cooperate with suppliers to achieve environmental objectives; (c) audit the environmental status of suppliers' upper management; (d) purchase from suppliers that are ISO14001-certified; and (e) evaluate the environmentally friendly practices of second-tier suppliers.

2.3. Value Engineering

VE is a systematic approach employed by a multidisciplinary team to improve the value of a project by analysing its functions. The objective of VE processes is to identify any unnecessary or hidden costs that do not contribute to the function and the desired approval of customers. It involves analysing and modifying the design, process, and specifications of a product or process to maximize value while minimizing costs. By defining value to be function over cost, VE studies are conducted by a multidisciplinary team,

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

which first establishes functional relationships. The VE team then develops a system function matrix against the corresponding costs to achieve the required functions with the lowest system-life cycle cost. This can be achieved using novel materials, creative design, optimized processes, innovative methods, cost- and time-efficiency, improved quality and safety, and minimal environmental impacts. Gupta (2009) examined more than 100 VE projects for four companies and showed that any organization pursuing VE goals can ensure long-term growth despite continuity and change.

Value-based management primarily applies data-driven conceptual approaches. The benefits of designing model-driven decision-making for performance and risk optimisation by implementing value-added performance metrics and applying robust optimisation methods to mitigate risk serve to sequentially optimise the physical and financial dimensions of a business (Hahn and Kuhn, 2012). The traditional VE framework comprises the following six phases: information phase, functional analysis phase, creative phase, evaluation phase, development phase, and presentation phase for value improvement opportunities (SAVE International, 2007).

The traditional value methodology begins by questioning the value of each product feature, and then attempts to apply creative techniques to generate an equal value at a lower cost. It uses a systematic job plan comprising specific steps to analyse a product or service effectively to develop the maximum number of alternatives, thereby achieving the required functions of a product or service (Webb, 1993). The functional analysis phase is the basis of the value study, which elucidates the hierarchical relationships of functions and focuses their creative efforts on identifying ways of accomplishing a specific function that are more efficient (Lewis, 2001).

Romano and Formentini (2010) applied a VE model for a shipbuilding company to improve the recycling systems of a large cruise ship. This project used the VE model as a decision-support tool to improve decision error, which enhanced communication with upstream and downstream suppliers, leading to the adoption of innovative alternatives. Tohidi (2011) demonstrated the VE role in promoting quality and proposed a five-phase project management model using VE techniques throughout the life of IT projects, controlling IT project risk, reducing project costs, and increasing project quality.

2.4. Findings and Gaps from Literature

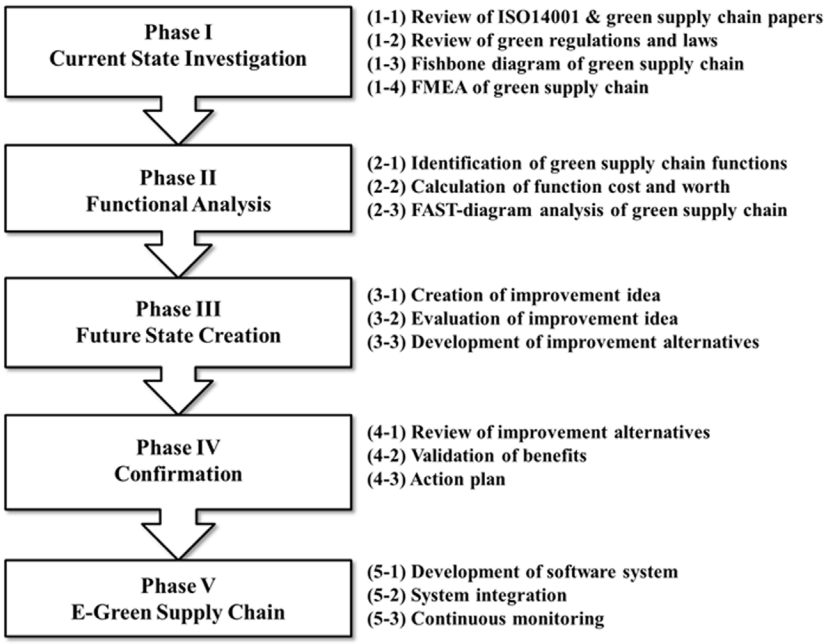
From the aforementioned literature review, we found that customer satisfaction on environmental issues can be achieved by implementing ISO14001 and green supply chains. However, the critical factors for establishing a green business must be identified. Different situations will need different factors. In this study, we focus on green regulations, eco-design, and green purchasing. The regulations in different countries and times are different and change occasionally. A system to update must be established to meet current requirements. From the eco-design literature, we found that an innovative method ensures high performance in the green issue. However, to continuously create ideals, a suitable method and support system must be established. Input definitely affects output. Green purchasing enables the inputs to conform to environmental regulations and meet eco-design requirements. A green supplier evaluation system is required. However, effective communication with suppliers is critical in green purchasing. From a literature review on VE, we found that VE can be adopted in different industries by using quantitative analyses and evaluations to propose useful alternatives for improvement. The last two papers in the review section demonstrate VE improvements in the green issue and IT performance. The results of the case studies show that the methods are feasible. However, each case is different to implement ISO14001 and green supply chain. Therefore, we developed the following method for addressing the green issue.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

3. METHODOLOGY

The realization of an ISO14001-compliant green supply chain involves a systematic engineering approach. Companies must holistically consider all value-added creation processes rather than address specific problems using a traditional problem-finding and problem-solving method (Yang et al. 2011). The traditional costing concept is not suited for all green supply chain situations because of the trade-off between production and contamination. A case study provided an innovative alternative to appraise and apply environmental measures to make economic aspects might not be thought as possible obstacles to sustainability (Savino et al., 2015). Ecosystem encompasses not just companies that make up the supply chain but also consists of their financial and informational partners, governments and regulators of the host countries, infrastructures that enable flow of goods, information, and finance (Viswanadham and Kameshwaran, 2013). Therefore, we examined resource inputs by applying value to compensate for the costs of negative output problems of the green supply chain. To implement the green supply chain, we modified the traditional VE framework and integrated quality engineering tools to produce a VE-based green supply chain model comprising current state investigation, functional analysis, future state creation, confirmation, and an e-green supply chain. Figure 1 presents the framework. Finally, the combined model was verified using a case study.

3.1. Current State Investigation



Optimizing total performance requires identifying the core value of an organization and analysing the mapping between core values and the performance management framework (Abdullah et al., 2012). In the current-state investigation phase, we reviewed the supply chain value-added process and the environmental laws and regulations. We applied the fishbone diagram to assist the team in brainstorming activities to execute cause-effect analysis and to determine critical criteria of the green supply chain (Jayswall et al., 2011).

The quality management field has largely adopted the Failure Mode and Effects Analysis (FMEA) technique to conduct failure analysis, which assists in anticipating critical points throughout the entire supply chain (Ebenezer et al., 2011; Chin et al., 2009). Risks posing from all the components of the ecosystem must be predicted well in advance and corresponding mitigation strategies must be formulated. Otherwise there will be project delays which would eventually affect the economy to a large extent (Viswanadham and Kameshwaran, 2013). The priority of a failure mode for action plans is determined by the risk priority number (RPN), defined as the product of the severity (S), occurrence (O), and detection (D) of a failure. These three factors are rated from one to 10, with lower scores being more favourable. The severity (S) rating with a score of one is regarded as "no effect," whereas a score of 10 is regarding as a hazard warning. The occurrence (O) rating relies on the probability. A nearly non-existent chance of failure is scored as one, whereas imminent failure has a score of 10. A detection (D) rating of one indicates an absolute certainty, whereas a score of 10 indicates an absolute uncertainty. Equation (1) provides the formula.

$$\text{RPN} = \text{Severity} \cdot \text{Occurrence} \cdot \text{Detection} \tag{1}$$

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Framework of VE- green supply chain method

3.2. Functional Analysis

In the functional analysis phase, we analysed the functions of the green supply chain. We calculated function cost, function worth, and thereby value index (VI) to obtain the key functions of the green supply chain. We described the functions using a two-word active verb and measurable noun; for example, the supplier function is defined as "provide materials." We allocated function cost using real cost, whereas function worth is the minimum cost required to perform the function. Costs of item and function are different. Usually an item provides several functions. We need to weight those functions to calculate function cost. Function worth is the least cost of the function. Ordinary, we have many ways to achieve a function, no matter feasible or not. In this way, we could find out some innovative methods. We then calculated the value index of each function using function cost over function worth (Equation 2). A higher value index implies that a product or process is improvable.

$$VI_{ij} = \frac{w_{ij} \cdot C_i}{B_{ij}} \ \forall i, j \tag{2}$$

where $\sum_j w_{ij} = 1 \ \forall i$

i index of main operations or items, $i=1,2,\ldots,I$

j index of operation function, $j=1,2,\ldots,J$

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

C_i function cost of the operation or item

w_{ij} cost weight of each function

B_{ij} function worth (the least cost of the function)

VI_{ij} value index (cost/worth)

The functional analysis evaluates any evidence referring to the green supply chain. Upon completing the functional analysis phase, the key green-supply chain functions can be identified, and the Function Analysis System Technique (FAST) diagram can be adopted for further development.

3.3. Future State Creation

The future state creation facilitates the creation and evaluation of ideas to identify suitable green alternatives according to the key functions identified in the functional analysis phase. The goal of alternative development is to develop workable green alternatives from specific creative ideas to assist designers or managers in making decisions. Analysing each alternative is necessary to ensure that it meets the requirements for adopting appropriate technologies. The idea-creation phase emphasizes group creativity. To improve creativity, daring to be illogical and overcoming resistance to change in an organization are critical; occasionally, an unconventional approach is more suitable for solving problems. Attempting to remove all mental blocks and personal inhibitions encourages imaginative growth. All ideas should be encouraged and not ridiculed, because often great ideas seem absurd when first proposed.

The objective of evaluations is to minimize the number of ideas with the greatest potential for improving the green supply chain. The ideas that are unsupported or those that cannot be accomplished in the near future are disregarded. The remaining ideas are adjusted, combined, and then screened. In this phase, cost is not the only factor to consider; however, other design comments such as weight, volume, and reliability should also be considered. Consulting the marketing department to determine whether customer acceptance could be a problem might also be necessary. The criteria for evaluating value are related to costs, profits, green performance, customer requirements, and safety.

3.4. Confirmation

The confirmation phase includes reviewing alternatives, establishing action plans, validating project benefits, and the commitment of the management board and other stakeholders. The alternative review provides a preliminary report by holding a project strategic meeting to determine the characteristics of each green alternative, establishing action plans for the accepted alternatives, and documenting the rationale for the rejected alternatives. Subsequently, it is necessary to obtain executive commitments, review the time feasibility, and define the execution of the accepted alternatives. An execution plan is next established to track green achievement for the implemented alternatives to validate beneficial changes to ensure that new practices become embedded.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

3.5. E-Green Supply Chain

In this phase, we design or adjust related systems, such as the eco-design and green vendor management systems. These systems must have system-design processes in place to ensure that the new systems fit into the original business information system and connect smoothly with each other. Better planning, selection of contractors, monitoring and execution are the answers to improve the situation. Use of IT, standardization of procurement and other processes, monitoring and execution using call centre based decision support systems, use of supply hubs, automation of financial and other government clearance processes are solutions that can be followed (Viswanadham and Kameshwaran, 2013). IT professionals should develop green supply chain systems. IT system development requires performing operational analyses and mapping business requirements, followed by an analysis of the system gap. Before operating the system, it is necessary to test the environmental setup, train relevant personnel prior to the system pilot run, establish the production application, and support the data conversion. Finally, we commenced the official production run and established vendor and partner portals for green management, including developing green management dashboards for monitoring all green issues.

4. CASE STUDY

The purpose of a case study is to investigate the evidence of real-world phenomena for exploring and explaining the real-world environment (Yin, 1994). Case research is a research method involving the investigation of one or a small number of social entities or situations about which data are collected using multiple sources, and the development of a holistic description (Easton, 2010). A case study concerning the application of a balanced scorecard method for evaluating green suppliers in a large multinational pharmaceutical company was conducted to identify challenges from reality (Genovese et al., 2014). Real case data were adopted from the European automobile supply chain. The data envelopment analysis approach enables management to link performance with external factors such as uncertainties in the supply, process, demand, and control. Hence, it enables managers to address critical questions for making strategic decisions (Gallear et al., 2014). This method is especially appropriate for hypothesis generation and the exploration of problems for which existing knowledge is limited (Cavaye, 1996). To avoid the misuse of case study, researchers should not blindly follow blueprints provided in previously published case studies but carefully revise possible design alternatives (Keutel et al., 2014). We applied the proposed VE-based green supply chain method to a global electronics manufacturing company whose main products include motherboards, digital televisions, notebooks, and all-in-one systems. The main revenue sources for the company are motherboards (33%), desktop personal computers (32%), and notebooks (28%). Approximately 98% of the products are exported. The case company is headquartered in Taiwan and has more than 1,000 business partners and distributors worldwide. Its branch offices and plants operate in the Americas, Europe, China, Japan, South Korea, Brazil, Russia, and the Netherlands. For sustainability in the world market under rigorous green requirements, the case company invested in supply chain management, and more than 1,000 vendors are involved in this study. The project team comprised various units including corporate social responsibility, finance, procurement, production, logistics, marketing, IT, and quality management as well as external experts as consultants. The green supply chain project lasted from 2006 to 2007. The green performance reports of the green supply chain

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

project were acquired from the Industrial Development Bureau, Ministry of Economic Affairs, Taiwan, and the corporate social responsibility annual reports and financial reports of the case company from 2007 to 2010 were obtained.

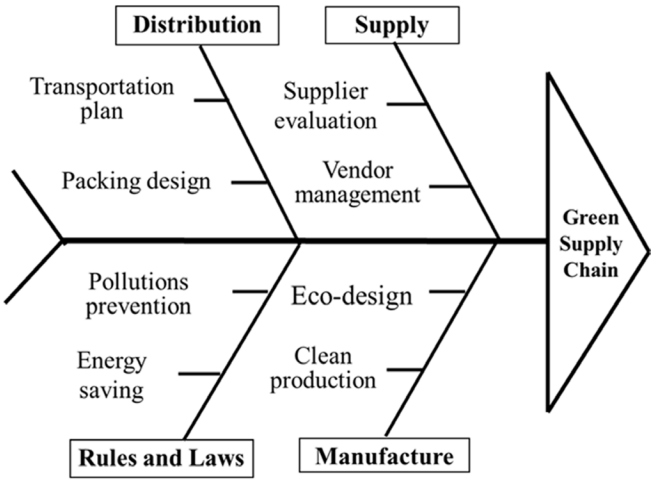
4.1. Current State Investigation

In the first phase, we collected, reviewed, and analysed related information and literature on green supply-chain issues by brainstorming and employing a fishbone diagram. Figure 2 shows the result of the brainstorming led by quality manager of the case company from cause and effect point of view. There are four main items that affect the green supply chain as supply, manufacture, distribution, and rules and laws. The supplier evaluation and vendor management are concerned in supply item. Applying the eco-design and clean production principles in manufacture item is necessary. The transportation and packing design are focused on the distribution item, whereas minimizing pollution and energy consumption belong to the rules and laws item.

We next performed the FMEA by focusing on four essential items adopted from the result of fishbone diagram as supply, manufacture, distribution, and rules and laws from the angle of failure prevention. Through intensive discussion, we identified the most critical potential failure modes (items) as "break rules" (rules and laws), "wrong equipment" (manufacture), "wrong materials" (manufacture), "wrong design" (manufacture), "wrong operation" (supply), and "wrong materials" (supply). The possible actions taken are re-designing, training, and examination. Table 1 presents a summary of the information. The RPNs show how the potential failure affects the system.

Using this investigation phase, we obtained a more concrete picture regarding the green supply chain regarding supplier management, eco-design, and production to improve manufacturing, packing, and transportation, and to reduce pollution and energy use according to the rules and laws item. The result of this phase is that the four critical items are considered for function analysis in the next phase.

Table 2 shows the results of the function analysis based on the results of fishbone diagram and FMEA and focused on functions, using the two-word combination of an active verb and a measurable noun to describe each item and its related initial cost and worth. The item costs were provided by financial department of the case company. Then the VE team discussed and decided the weights of the item functions for calculations according to Equation (2).



After calculating Equation (2), we identified the following key functions: "pack product," "improve product," "provide materials," and "present regulation." To develop more detailed functions, the VE team designed the FAST diagram referring to the results of fishbone analysis, FMEA, and function analysis to present the essential functions supporting the basic functions of the green supply chain. The primary functions for constructing a green supply chain are "manage supply," "streamline manufacture," "optimize distribution," and "conform rules and laws." Figure 3 shows the results. The output of this phase is identifying the primary functions of the green supply chain for further creation activities. We also developed basic system requirements for integrating these functions with the current management system.

4.2. Future State Creation

In this phase, we employed various idea-generation techniques, such as brainstorming and using checklists, to produce as many ideas as possible. The main ideas for "pack product" were reducing packing materials, using different packing materials, reusing packing materials, and redesign. The main ideas for

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Fishbone analysis for the current state investigation

"improve product" were potential improvements including redesign, using different materials, employing different methods, and using different equipment. The main ideas for "provide materials" were managing suppliers to provide acceptable materials including conforming related environmental issues. The main ideas for "present regulation" were studying regulation and analysing regulation, training, and the green database and portal. All ideas can evolve into new related ideas for solving the same problem. During the evaluation process, we screened all of the ideas and excluded certain unsupported ideas.

After evaluating the ideas for green supply-chain management, we selected feasible green alternatives for advancing development. This phase established final executive plans for selected alternatives to persuade management to accept the final alternatives.

4.3. Confirmation

In this phase, we reviewed the preliminary reports following several project meetings to determine the characteristics of each green alternative. We established numerous action plans, including a period to review the accepted green alternatives, such as supplier management, eco-design, reuse, redesign, and establishing a green database and portals. We planned a schedule to track the green achievement results of the implemented alternatives to ensure they were effective, and validated the benefits of the implemented changes to ensure that the management system had successfully incorporated the new practices. This phase confirmed green alternatives in anticipation of developing the green supply-chain management system.

4.4. E- Green Supply Chain

Many companies have adjusted their enterprise's value system in order to maintain good public images to design greener products by adopting new energy saving technology and enhance their supply chain management capability to release environmental concerns (Wang et al., 2011; Dam and Petkova, 2013). In the e-green supply-chain phase, the case company built a green vendor portal and a green partner portal

to the enterprise resource planning (ERP) system. The scope of ERP has expanded beyond classical data and process integration to provide enhanced modelling and analytical capabilities for complex business problems. Strategic business development integrates PLM (product lifecycle management) and SCM to consider value-creating decisions (Hahn and Kuhn, 2012). A shop-floor integration system (SFIS) is an effective cooperation sub-system included in the ERP system, which offers state information of factory activities to the administrator in order to control the factory effectively. For the inter-organizational infor-

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. E-green supply chain of eco-quality information systems

mation, we developed three modules and integrated them with the ERP system: the green PLM system, the green vendor management (VM) system, and the green SFIS. Figure 4 presents the architecture, in which the PLM system enables the collaboration of eco-design and "reduce and reuse" between the case company and suppliers. The PLM system includes the green component data storage, green product Bill-Of-Materials (BOM), and green vendor tracking and review. The system improves efficiency for data verification of restricted substances and regulates collecting and verifying green documents.

The green component data are uploaded to the green BOM system for its approval. Based on green parts and the green BOM database, the case company can guarantee that the green production and green products meet RoHS standards. It also defines the responsibility between the case company and vendors and a production tracing system for sustainable management. The VM system supports the operations of new vendor recruitment, vendor green capability management, and conforming to the rules of green issues. The SFIS outlines the master production schedule and manufacturing execution.

The result of this project was that the case company could effectively produce products by fully employing raw materials using manufacturing technology, operating management, raw material, packing material, and product plans and reforms, in addition to recycling and reuse strategies. The results show the following benefits: (a) approximately US$167,000 in annual savings; (b) approximately 65% of waste was recycled and reused; (c) recovery rate of products reached 85%; (d) the purchasing cost was reduced by 10% from the green vendor management system; and (d) the greenhouse gas production in 2010 was 49,672 metric tons of CO2 emissions, which was approximately 4.1% less than the previous year, fulfilling the environmental responsibility of reducing carbon emissions and mitigating climate change (Table 3). Tables 4 and 5 present the power and water consumption analysis, showing an improvement tendency. Approximately 236,000 m3 of wasted water was recovered annually (Table 6). Figure 5 presents a summary of the green performance of the case company.

5. DISCUSSION AND IMPLICATIONS

Seuring (2013) surveyed the models for sustainable manufacturing, classified their decision goals as economic, environmental, and social, and considered integrating all three dimensions. The models for sustainable manufacturing are classified into the following four categories: (1) life-cycle assessment models; (2) equilibrium models; (3) multi-criteria decision making; and (4) an analytical hierarchy pro-

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 5. The green performance of the case company

cess. These models allow decision-makers to calculate their sustainability strategy to obtain a win-win situation, trade-offs, or minimal performance for environmental and social issues. This survey shows that the cost-oriented decision model dominates the modelling approach for the economic dimension because the social impacts and environmental assessments are difficult to evaluate using quantitative models.

However, the green issue is not only an economic issue; it is also a scientific and social issue. Businesses must adopt both an economic- and organizational-based approach to support sustainability. VE is a systematic methodology that achieves multiple goals by considering the potential worth of a company's deployed resources. During the realization process, VE emphasises teamwork and creative techniques, which are typically positive factors in organisational change. In addition, the ISO 14001 system focuses on continuous environmental quality improvement management, and is an internationally approved management tool. Therefore, we developed a VE-based framework combined quality tools. To verify the feasibility of the model, a case study was conducted, and the application results show that the proposed VE-based green supply chain model is viable.

Srivastava (2007) recommended that operational management teams integrate green issues to yield a more integrative framework that would contribute more to the green supply chain. The proposed VE-green supply chain model follows the five phases to address the problems of green supply-chain implementation. We integrated the developed green systems into the current operational management processes, as recommended by Srivastava (2007) and compared the proposed VE-green supply chain method and the published approaches in the literature. We discussed the differences among them based on the following three dimensions: aim, implementation, and performance.

- **Aim:** The VE-based green supply chain optimises the green supply chain to focus on eliminating unfavourable outputs in the value-added process. However, the published green supply chain ap-

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

proach in the literature reduces environmental risks and impacts, improving ecological efficiency, minimising ecological damage, and maximizing the total economic profit (van Hoek, 2000; Srivastava, 2007; Dey and Cheffi, 2013).

- **Implementation:** The VE-based green supply chain model comprises current state investigation, functional analysis, future state creation, confirmation, and an e-green supply chain on the basis of a five-phase model to perform green product procurement, manage suppliers, reduce waste, minimise energy consumption, and establish a green IT system. This five-phase model integrates both quantitative quality engineering tools and organisational collaboration approaches. However, the published green supply chain approach in the literature uses a multilayer supply chain and either five or seven phases that focus primarily on quantitative approaches to improve functions, optimise reusable equipment, and accomplish IT projects (Sheu et al., 2005, Duhaime et al., 2001, Tohidi, 2011).
- **Performance:** The VE-based green supply chain focuses on reducing waste, improving recycle and reuse rates, and reducing both the procurement cost and the level of greenhouse gas emissions. However, the published green supply chain approach in the literature reduces pollution and incurs less penalty cost, improves the supply of raw materials and waste-reverse logistics chains, and improves processing times, operation costs, and recovery rates (Ferretti et al., 2007; Sheu, 2008; Srivastava, 2008).

The academic implications are that to merge different tools into one framework, each tool must be reviewed thoroughly to identify the components that should be retained or combined with other tools. The adjustments must be continuously optimised. The proposed method is different from DMAIC of sig-sigma approach. The six-sigma DMAIC activities begin by improving the characteristics of a regular process. The DMAIC process involves identifying solutions to eliminate the root causes of performance problems that result in inconsistent processes, while preserving the integrity of the basic process to minimise the occurrence of defects, variations and unnecessary costs resulting from poor quality (Srinivasan, 2014). Applying case study is one of the most effective ways to verify a model. However, choosing a suitable case requires effort. During the case study, communication skills are required. Particularly when dealing with case data, we must distinguish which part should be kept confidential while the study still can be smoothly conducted. Lastly, the management of the case company might demand immediate high performance; substantial evidence must be provided to ensure future favourable results.

The industrial implications are that the legal requirements in different countries might be different; hence, we must be careful when creating the related database. To adopt a new system, training at different personnel levels with different training materials is required. After investigating companies certified with ISO14001, the result shown that environmental training is positively and significantly related to environmental management maturity. Managers must invest in environmental training if they also want to improve environmental management; industry associations may help companies to plan and offer environmental training; universities may also help companies to plan and improve environmental training activities (Jabbour, 2015). Implementing a certified ISO 14001 system is a promise to conduct sustainable business. Adding a complete environmental information system to the current IT system will ensure that the system performs effectively. Substantial experience in environmental protection and IT systems management is essential for implementing a green supply chain. The case company has run a pollution, prevention, and pay committee for years, providing a favourable foundation for green issues.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

A large IT division was assigned in the case company to address all IT affairs including the e-green supply chain. Suitable consultants would be helpful for implementing a project such as the green supply chain. Lastly, the VE study is not a one-time project; multiple studies must be analysed separately to provide value for the enterprise.

6. CONCLUSION

We proposed a VE-based methodology that combines quality engineering tools for implementing ISO14001 with a green supply chain, and designs IT systems to support the requirements of specific green issues. We detailed an empirical case study to implement green supply-chain systems in a global electronics manufacturing company, which executes all methodology phases to verify feasibility. The results indicate improved recycled and reused waste, recovered products, procurement costs, and greenhouse gas production. After receiving the ISO14001 environmental management system certification, factories established a complete environment management system. This study serves as a reference for related researchers and practitioners in implementing green supply chains and contains certain limitations. Although the model combines the advantages of quality engineering tools to produce a workable framework, it does not address all problems associated with green supply chains, but primarily focuses on material supply, manufacturing, distribution, and rules and laws. Future studies should focus on a collaborative eco-design system, material exchange system, and distribution system.

ACKNOWLEDGMENT

This work has been developed within the framework of a research project funded by the Ministry of Science and Technology (MOST) Taiwan, titled “A Distribution Planning Method for the Regional Logistics Center Using Electric Vehicles”, reference MOST-104-2410-H-008-066. Furthermore, the authors would like to thank the Fellowship Programme 2015/2016 of the Munich University of Applied Sciences, Germany, and the reviewers for the constructive and helpful comments.

Chapter 30
Intelligent IoT-Enabled System in Green Supply Chain Using Integrated FCM Method

Rui-Yang Chen
Aletheia University, Taiwan

ABSTRACT

From green supply chain perspective of the internet of things, actualization of the IOT into the complex system for green inventory management will link the real world with the digital world seamlessly. Modeling the complex systems in green supply chain can be hard in a computational utilization and inventory management of relationships exists. Two of the problems of IoT-enabled system are the lack of stable integrated architecture and autonomous mechanism. This paper proposes the intelligent IoT-enabled system in green supply chain using FCM and fuzzy QFD method. It aims to simulate complex system by linked physical and digital objects with relationships while enhancing decision-making performance efficiency for green inventory management. A case study and experiment evaluation of the proposed FCM approach on green supply chain is presented to provide some indication for work improvement. The experiment compares the total effects performance of the green inventory status as estimated by the two methods using the proposed IoT-enabled FCM and traditional FCM.

1. INTRODUCTION

The interrelated networks of green supply chain consist of manufacturers, suppliers, distributors, wholesalers, retailers, recycler and consumer. During the green life cycle of any parts, suppliers of material as well as manufacturers of intermediate/finished goods, distributors, retailer, recyclers and consumers are interconnected due to exchange of product and data. Integration of green supply chain is not easily achieved because different companies may have different or conflicting targets. Thus, supply chain partners must be coordinated and cooperate to achieve a common target. This integration improves the inventory visibility of the green supply chain. A model has been designed based on inventory management aspects of the project from a sustainability perspective. It is important that sustainable behavior

in business has increasing its impact on supply chain management (SCM). So, it might also serve as platform for pervasive presence and ubiquitous computing, enabling smart environment to create industry-driven green supply chain operation. Green supply chain initiatives should provide operation value and environmental benefits. From the perspective of green supply chain operation, inter-organizational exchange of information about physical and virtual objects with unique ID will link the real world with the digital world seamlessly. They are able to active and interact services for green supply chain operations in the associated information platform (CERP-IoT, 2009). With the advent of information system and related emerging technology, such as IoT (Internet of Things) and cloudy computing, a new generation of platform called intelligent industry resource planning (IRP) is available in the market. The internet of things attributed to the Auto-ID Labs (2013) develops novel technology that refers to the possibility of endowing physical objects with the ability to identify and interact with each other to reach cooperation goals (Giusto, 2010). As a consequence of supply chain integration, software system should propose innovative architecture fulfilling the link related to the nature of the IoT. Cheng et al. (2012) presented a knowledge-based customization system for supply chain integration which captures and recognizes the complexity of network analysis.

According to the above mentioned, modeling the green supply chain integration of complex systems can be hard in a computational utilization and inventory management of relationships exists. So, two important problems that need to be solved for IoT-enabled information systems are the lack of stable integrated architecture and autonomous mechanism. To the best of our research, very few presented approaches focus on the integration of IoT-enabled and green supply chain. Furthermore, few papers address the complex relationships of green supply chains and how these relationships can affect both environmental and inventory management outcomes using IoT-enabled system.

The approaches of the two problems are described as following:

1.1. First Problem

The stable architecture to deploy green supply chain application is a heterogeneous collection software system of ubiquitous devices. It has intrinsic status that makes it very cumbersome to development platform for green supply chain application where arbitrary devices and process interact. In the first problem, we propose constructing the IoT-enabled information system architecture for green inventory management in supply chain.

1.2. Second Problem

In the past years, conventional methods were used to modeling complex system is limited in human operation. Human operation mechanism and the complex system involving relationship may be nonlinear underlying IoT environment. Surana et al. (2005) proposed an idea of managing the integrated supply chain transforming information system into an autonomous and dynamic network. The complexity capabilities can autonomously react to a wide range of different situations in order to minimize human intervention (Miorandi et al., 2012). The main task of relationship management of the complex relationship must handle among communication, cooperation and collaboration in the green supply chain. Human way of thinking process is used to describe the autonomous mechanism for the relationship management in IoT-enabled information systems. For such situations, fuzzy cognitive maps (FCM) is considered to deal with complex system (Stylios, 2001). FCM modeling of IoT-enabled system mainly relies on a variety

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

of interconnecting component and supply chain partners to survey and analyze relationship management such as inventory management. In the second problem, we propose the utilization of the fuzzy casual characteristics of FCM and fuzzy QFD as the underlying approach in order to generate a hierarchical and dynamic network of interaction performance impact in green supply chain.

By using the above mentioned two approaches, this paper designs the intelligent IRP platform for green inventory management based on IoT technology in the green supply chain using FCM and fuzzy QFD method. It aimed to simulate green inventory system by linked physical object and digital object with imprecise relationships while enhancing decision-making efficiency for green inventory management. The objective of this article is to explore how IoT-enabled information-sharing can help green supply chains used the proposed green inventory status management stages increase both environmental and inventory management benefits. Our research, through a IoT-enabled inventory management system and FCM analysis, shows two main competitive advantages to the green supply chain:(1) Real-time green inventory traceability, sustainability and visibility (2) Green product inventory management. The former allows continuous inventory replenishment and consumption in order to handle environmental operations for raw material, component, green product, and non-green product in the supply chain. The latter facilitates green inventory coordination and collaboration inside the supply chain.

In a word, this paper proposes an integrated FCM with fuzzy QFD (FQFD) algorithm to model stably the hierarchical IoT-enabled information system in the green supply chain. This paper consists of five sections. Section 2 presents related work of literature overview. Section3 presents IoT-enabled system architecture for green inventory management in the green supply chain and an overview of the FCM with AHP and FQFD. A case study and experiment evaluation of the proposed FCM approach on green supply chain is presented to provide some indication for work improvement in the section4. Section5 concludes and briefly discusses future research.

2. RELATED WORK

2.1. Internet of Things

Miorandi et al. (2012) presented a survey of technologies, applications and research challenges for IoT. The IoT describes a global network infrastructure, internet-based information service architecture around us of a variety of things (objects)-such as Radio frequency identification (RFID) tag, sensors, readers, actuators, mobile phone, near field communication (NFC) etc. Internet of things is as an infrastructure to facilitate the information exchange of products (Atzori, 2010; Amaral, 2011). Atzori et al. (2012) presented to explore social IoT in more effective and efficient way. Carlos et al., (2013) presented novel research that is to establish if an automatic discovery process of relevant and credible news events can be achieved. The followings describe a global network infrastructure and internet-based information service architecture.

2.2. Global Network Infrastructure

The RFID system can improve to cut lead time on inventory management and increase the accuracy of inventory status information. Delen et al. (2007) analyze the inventory data collected from supplier and retailers based on RFID technology. A RFID-based system can provide real-time the traceability

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

of products and visibility to control actual inventory situation throughout the entire supply chain. The RFID technology can be used for the efficient tracing or tracking of parts through supply chain (Niederman et al., 2007; Bi and Lin, 2009). Sarac et al. (2010) conclude the major research on the impact of RFID on supply chain management for inventory inaccuracy problems. In recent years, a new inventory tracking technology has been introduced in the supply chain based on RFID system (Zhu et al., 2012). The application through RFID can be applied in different types and industry of supply chains such as fashion, food and a variety of industries (Banks et al., 2007; Pigni et al., 2008; Ferrer et al., 2010; Lee et al., 2011; Lao et al., 2012).

The technical development of the required infrastructure of components is specified by EPCglobal (2013). Henseler et al. (2008) proposed a network-based approach to adopting RFID system into supply chain using simulation technique and EPCglobal technology. Thakur et al. (2011) proposed a new methodology for modeling traceability information using the EPC information system (EPCIS) framework. Nam et al. (2011) proposed a business-aware framework for developing RFID process in supply chain on the EPCglobal Network. The main purpose of the EPCglobal network provide real-time object visibility, product track and trace (MiraglIoTta et al., 2009). Mo et al. (2009) proposed the advantages of the EPCglobal such as traceability, compatibility and exchangeability. Pilar et al. (2011) proposed distributed EPCglobal network architecture allows level track and trace capabilities of supply chain. From the above mentioned, some previous studies offer several contributions to supply chain through RFID or EPCglobal technology, but they few present network or architecture with RFID such as EPCglobal based on complex information system in the green supply chain.

In the global network infrastructure, it has the following components such as:

- **Various Devices:** These devices consist of reader sensor, PDA, computer, iPad and smart phone which are subject to identify all kinds of physical product.
- **Embedded Product:** The so-called "Embedded product" are meant to use in the IOT which may be defined as physical and virtual objects with unique ID using RFID technology
- **Wireless Sensor Network:** The role of WSN (wireless sensor network) in the IOT is that of a virtual skin by becoming aware of their surroundings to take informed decisions in industrial environments.
- **RFID/NFC Middleware:** The middleware is a filtering and communication interface that aims to capture available data between various devices and software application.
- **EPC Application:** The EPC application is an information repository to capture events/tasks facilitating integration with querying data from RFID/NFC middleware.

2.3. Internet-Based Information Service Architecture

Liu et al. (2013) proposed a model to investigate how IT capabilities affect performance through supply chain agility. Supply chain agility provide collaborative capability to perform integrated activities with supply chain partners (Swafford et al., 2008; Cao et al., 2011). Dominguez-P'ery et al. (2013) proposed an IT-driven service innovation with case study in the jewellery supply chain. Kuremaa et al. (2010) proposed a particular e-business standard (RosettaNat) integrating the telecommunications supply chain. Damien (2005) presented the relationship between the use of business to business (B2B) e-commerce enabling technologies and infrastructure, cooperative partnerships between trading partners, firm performance, and a "systems" view of strategy formulation processes.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

A service-oriented architecture (SOA) information system can deal with seamless integration of supply chain operation by using extensible markup language (XML) and hypertext transfer protocol (HTTP). Applying the service-oriented architectures to information system is an internet-based approach to aggregate the composed services. The service can be transferred into real-time e-service composition for. The internet-enabled information system architecture consists of web-based interface, collaborative environment, modular design and service component. Today, the new technology paradigms are emerging and further affect the future development of internet-enabled information system architecture such as Internet of things.

According to the above mentioned, we know that actualization of the IoT into the information system is possible through the integration of several enabling technology such as EPC (electronic product code). The EPC could support the spread use of RFID in industry-driven global standards based on IoT technology for the EPCGlobal network. Bottani and Rizzi (2008) presented to share EPC information through EPC network using RFID technology. From the EPCGlobal point of view, there is a demand for the development of complex information systems in the IoT-enabled systems that can be archived taking advantage of intelligent IRP platform like autonomous reasoning of systems.

2.4. FCM, Fuzzy QFD and AHP

The Fuzzy theory was proposed by a famous thesis- the "Fuzzy Set" published by professor Zadeh from the University of California at Berkeley in 1965. Basically, the theory was developed to deal with the fuzzy concept and to introduce the concept of Membership Grade. The relationship of the element and the set was defined between the range of 0 and 1, which demonstrated a mathematical description of the real phenomena. Fuzzy Cognitive Maps (Kosko, 1986) is a hierarchy methodology for complex decision systems with graphical illustration by multiple maps, loops, cycles etc.

Quality Function Deployment is a famous quality management theory first proposed by Yoji Akao and Shigeru Mizuno from Japan in 1966. Its main performance is to transfer the customers' expectations and preferences into the design parameters of the product. Zhai et al. (2011) proposed rough-fuzzy QFD system combines fuzzy arithmetic operations to help in improving the discernibility of design objectives and thus facilitate the decision making in product development. Hauser and Clausing (2008) proposed to use the HOQ (House of Quality) matrix in analyzing the relationship of customer requirements, the product characteristics, and the process characteristics. Fuzzy logic-based approach to QFD has found the most invention due to its ability in analyzing the fuzzy represent action. In the respect, rough-fuzzy QFD combines fuzzy arithmetic operations with rough boundary interval (Zhai et al., 2010). The fuzzy QFD methods may be defined the boundary intervals of fuzzy members.

The analytic hierarchy process (AHP) method developed by Saaty (1980). AHP is used to calculate relative weights to the decision-making indices. This method is based on pair-wise comparison between attribute and alternatives (Saaty, 1979). AHP pairwise comparison process is the benefits of decision-making performance with decision maker's judgments. These pair-wise comparisons maybe stated verbally as in "attribute item 1 is equally, mode rarely more or strongly more important than attribute item 2".

3. RESEARCH APPROACH

3.1. IoT-Enabled System Architecture in the Green Supply Chain

As green supply chain is a complex decision problem, we construct this architecture to solve this problem. Green supply chain integrates the intra- and inter-corporate processes as a whole system according to environmental impact performance. The performance of a green supply chain could be influenced by many partners, among which green inventory sharing is the crucial one. Green inventory information sharing can significantly improve the environmental impact performance of green supply chain. IoT is broadly used to refer to the global network interconnecting intelligent products by means of extended web-based technology. IoT-enabled system can be used to create end-to-end green inventory visibility to enabling supplier, manufacturers, logistics provides and retailers to track and trace intelligent product information through the entire green supply chain real-time and at any location. Green inventory status visibility is critical to quick response systems so as to control quickly to market and environmental changes. Besides the capability to track products inventory status as they move through the green supply chain, product traceability is to ensure product on environmental impact consideration. IoT-enabled supply chain integration is the fully automated inter-organizational system-to-system and physical-to-physical exchange of information. This proposed architecture provides a decision support system of green inventory status which can be accessed by tracking or tracing operation based on IoT-enabled system. IoT-enabled system is considered major supply chain partners for inter-organizational collaboration. While in most occasions human decision makers play main roles in green supply chain management, we proposed the IoT-enabled architecture that provides real-time visibility, traceability and sustainability of green inventory status by analyzing automatically and autonomously collected intelligent product data and software agent.

This sub-section presents an overview of the IoT-enabled system architecture for green inventory management in the green supply chain. The IoT-enabled complex system provides green product identification services for green supply chain, and facilitates the inventory implemented in the EPCIS system that is a very advanced, comprehensive and complex system. In such as IoT-enabled system of green supply chain, each enterprise must have its own EPC sub-system interact other supply chain partners for EPC network architecture in Figure 1 in the Appendix. This proposed architecture is described three phases such as fundamental phase, smart objects phase and IRP phase as following:

3.2. Fundamental Phase

First, the fundamental phase consists of physical layer, network layer and protocol layer as follows.

3.2.1. The Physical Layer

The physical layer consists of widely varying objects, including the entities of green supply chain operations, such as green parts, green and non-green product objects. And then these objects will be equipped with smart objects via RFID-related technology. Automatic identified object has recently been investigated in order to realize a ubiquitous computing. At the single product level, the IoT will be based on the notion of “intelligent product”. For what concerns the object of physical product into

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

information system, the relevant activities are mostly carried by the object ID. The object ID should be interoperable with the identification description such as IPv6 address, EPC code. The material of parts, product and shipment that are being tracked, are provided with unique EPC code stored in the chip that is embedded in the RFID tag.

3.2.2. The Network Layer

The network layer defines the environment scattered with wireless network, which the varying objects in the physical layer could communicate with each other using context-aware & semantic web based on wireless sensor network (WSN). A network layer devoted to the sensing of the physical product allows for an interconnection of the existing and widespread short distance communication way, such as: near filed communication and wireless sensor network. Sensor enabled RFID tags provide environmental impact data such as eco-efficiency. From self-organization perspective, sensor networks are able to sensing the environment. Via sensor network, these entities construct three sub-networks which are where-used, channel and EOL activities sub-network. Then, all sub-networks is described as follows. The term" where-used" indicate that raw material or component is used which finish goods. The term "where-used sub-network" indicates how to construct BOM (bill of material) network including design & production for environmental impact consideration with raw material or part/component. The channel sub-network constructs green product operation in sale & distribution channel. The EOL activities sub-network constructs green/non-green product operation for EOL activities such as repair, reuse, remanufacture and recycle.

3.2.3. The Protocol Layer

The protocol layer defines the communication protocols, which the varying equipment how could communicate with each other in the wireless network. In this propose approach, the mechanism of protocol is operated through functions of software agents to interact the entire green supply chain. The software agent can sorted into three categories: BOM agent, sale &distribution agent and eco-efficiency agent. This study attempted to analyze agent-based behaviors of green inventory status to interact among partners in green supply chain. With the IoT-enabled information systems, it has become possible how to create seamless green supply chains in order to control green inventory status of business performance and environmental eco-efficiency.

3.3. Smart Objects Phase

Next, in the smart objects phase, make the object-oriented entities, i.e. each entity object was given the unique ID code which corresponds to the virtual unique object in the virtual world. In accordance with the business model, these virtual objects (green parts, green and non-green product) will be converted to enterprise objects (role objects, behavior objects, organization or group objects, product objects, flow or process objects and structure objects). The enterprise objects are handled in the green supply chain operations. The structure object consists of BOM data of green product based on where-used subnetwork. The flow object consists of green product operation process in sale & distribution channel.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

The behavior object describes green/non-green product how to operate during EOL activities. The role object mainly defines supply chain partner such as supplier, manufacturer and recycle provider. To put the information system into practice based on digitized information, the enterprise objects are required to be digitized and converted to logic objects in the information system.

3.4. IRP Phase

Finally, in the IRP phase, the resources integration platform of the Internet of Things will be designed in accordance with the business model. The above mentioned is linked up with industrial resource planning (IRP) information system of the Internet of Things. It will become a new generation of enterprise application information system linked up with cloud commerce. This phase consists of application layer, EPCIS layer and cloud commerce layer as follows.

3.4.1. The Application Layer

The application layer structure is first categorized into three stages such as Stage1, Stage2 and Stage3. The three stages for green inventory status management system as follows:

Stage 1: Green parts: Design & production for environmental impact consideration with raw material or part /components
Stage 2: Green product: Green product operation in scale & distribution channel
Stage 3: Non-green and green product: Product for EOL activities on reverse logistics operation

Over the last decade, green product has become an important activity of product development (Boons, 2002). Furthermore, the term "green parts" is considered as environmental impact of raw material component during the green product life cycle. Some previous studies had presented to identify and analyze the published definitions of green supply chain management (GSCM) (Abbasi and Nilsson, 2012; Gimenez and Tachizawa, 2012).

Jitendra et al. (2012) proposes a flexible decision model to be engaged in product recovery systems to handle reverse logistics. Reverse logistics has become important to the electronic consumer industry due to unavoidable product recalls and recycle in order to capturing the remaining value in end-of life products. End-of-life activities face some challenging issue such as what end-of-life products to collect, where to collect them, etc. Srivastava (2007) presents GSCM encompassing product design, manufacturing process and end-of-life management. On EOL products, it is important that incorporate EOL product 3R concept into product development to reduce environmental, economic and social impact. In fact, EOL activity is one stage of the product life cycle have gained market value From the supply chain relationship perspective, it is necessary to involve early module design of green product function for new product development process. Thus, green product may be designed to handle the recycling of these green product usages at their EOL activities such as repair, reuse, remanufacture and disposal. Zhu et al. (2004) and Srivastava (2007) have shown that reverse logistics operations handle the end-of-life (EOL) activities with highly uncertain. However, the green supply chain involves heterogeneous entities from both forward and reverse logistics. Many industries apply reverse logistics to operate recycled or disposal products. Nativi and Lee (2012) model the inventory monitoring using two scenarios through simulation-based analysis based on FRID technology on a decentralized supply chain with reverse logistics.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

There are different criteria such as physical product, protocol pattern, network category, digital object and operational activities within each stage. To facilitate the collaborative green inventory process in the IoT-enabled green supply chain, a certain process is classified into the above-mentioned three stages. To assess the three stages level of green supply chain performance, all criteria associated with each attribute have to be incorporated in the green inventory operation

The inventory status of green product life cycle process are called "green inventory" in Table 1 (see Appendix), which consists of four types: Quantity, where-used, location and eco-efficiency during the three stages. The status of green inventory across green supply chain tiers can be precisely obtained with the real-time visibility and traceability of RFID. For achieving efficiency and effective management of green supply chain, the IoT-enabled system is vital for tailoring the composition of eco-efficiency services provided by integrating various digital objects according to intelligent product. The seven major eco-efficiency elements A-G are defined from WBCSD (world business council for sustainable development) for green products which develop eco-design (Karlsson and Luttropp, 2006) in order to reduce environmental impacts (Desimone and Popoff, 1997). Chen and Liu (2003) proposed the relationships between each eco-efficiency element and 39 engineering parameters.

A. Material reduction.
B. Energy reduction.
C. Toxicity reduction.
D. Material recyclables.
E. Resource sustainable.
F. Product durability.
G. Product service.

3.4.2. EPCIS Layer

The EPCIS layer is based on EPCglobal network. The main objective of the EPCglobal network was to link all physical products together for green supply chain operation in term of end-to-end data exchange within a supply chain. The capturing inventory management must be changed by partner to generate EPCIS events from change in the green supply chain. The EPCIS capturing application generates EPCIS events from the obtained tag data through query interface in the repository with some local EPCIS from a global EPCIS. One of the key components of EPCglobal network required to implement track and trace capabilities is the discovery service. The EPCIS is a component for receiving tag data from the filtering operation and allowing the translation of data into business events. It tracked or traced the whole status of a green inventory throughout a green supply chain from the factory to the store where it is sold to the end user.

3.4.3. Cloud Commerce Layer

This architecture has been developed considering the following objectives: facilitate the green inventory operation of the EPCGlobal Network elements through industrial resource planning in the cloud commerce layer. However, EPCIS by distributed intelligent product (smart object) on the internet is achievable through linking and cross-linking with the help of an object naming service (ONS). The role of ONS is to map one or more Universal Resource Locator (URL) corresponding one EPC for details

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

information of physical product. The ONS is based on the well-known Domain Name System (DNS). The intelligent product of EPC code must be converted into a format that the DNS can understand. Queries to the local ONS are therefore performed by means of a DNS query for a URL derived from an EPC. From industrial resource planning perspective, the IoT-enabled system is based on an architectural view focused on reusable service components attributed in three domains aiming at generalizing and facilitating green inventory applications according to its green supply chain operation. The main elements of this architecture consist of three domains such as application system, autonomous operation and intelligent product. ONS is an important component of EPC architecture which partners to find data related to specific EPC based on the DNS. The DNS of the internet leads to the concept of ONS. In the meanwhile, the use of ONS can convert the EPC serial number into the standard DNS query format. Local ONS of the supplier achieves its address mapping related data and reports to the root ONS in order to obtain information query in the EPC network.

3.5. Overview of the FCM With AHP and FQFD

In this article, a novel approach for decision making of casual relationship impact to simulation process using AHP, Fuzzy QFD and FCM is evaluated and contains of three steps in the Figure 2 in the Appendix. This novel approach is separately discussed in the following subsections.

3.5.1. Step 1: IoT-Enabled AHP

However, relationships between IoT-enabled system architecture at the different level with no apparent casual relationships are not always clear. Thus human reasoning of the casual relationships impact of the IoT-enabled system architecture to the efficiency of the decision-making is not always feasible. To resolve this issue, this paper builds a hierarchy of the relative importance of IoT-enabled system architecture using AHP method. The AHP method was used to determine the relative importance of the environmental impact variables enhance and reduction. This determines the weight of each decision element using eigenvalue computations to derive the weights of these variables. These variables were expressed in the form of a pair-wise comparison matrix from each set of judgment are found using expert choice software. The Expert Choice (http://www.expertchoice.com), a computer software package for AHP method, is used to structure the decision into criteria and alternatives. The proposed AHP (namely IoT-enabled AHP) could solve complex system problem involving multiple attributes by constructing problem to the goal, attribute and alternatives for decision making. IoT-enabled AHP constructs three levels in the Figure 3 in the Appendix.

Level 1 is the goal of IoT-enabled system to decide the best casual relationship impact. Level 2 divided into three domains consisting of nine attributes (factors) according to IoT-enabled system architecture. Level 3 contains of three decision alternatives such as visibility, traceability and sustainability that affect the best selection of the goal. The three alternatives were invited to evaluate the relative importance of the casual relationship impact in the IoT-enabled system.

- **Visibility:** Through the green supply chain operation life cycle in industry-driven, many defects and exceptions may occur. However, the complex system must be able to keep its functions working visibility and apply seamless interaction to green inventory operation issue.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

- **Traceability:** These green inventory status among supply chain partners are difficult to be integrated automatically. In order to overcome the drawback, we have focused on a real-time traceability alternative.
- **Sustainability:** However, service of green supply chain operation are ever-increasing, they are complexities link with each other. These complexities cause less sustainability of business in IoT-enabled system.

3.5.2. Step 2: Fuzzy Relationship Using FCM

To identify these factors relevant to the goal of IoT-enabled AHP, fuzzy QFD should be built and then analyzed. Furthermore, a fuzzy casual model based on the factor elicited from the three domains of IoT-enabled system includes nine basic service components using FCM, which describes the relationships between these factors. Based this result of interrelationship matrix by FQFD, we can build the fuzzy relationship to gain initial version adjacency matrix of FCM. The initial version of adjacency matrix can be converted into a following refined values fall between -1 and 1.

3.5.3. Step 3: FCM With AHP and FQFD

In this article, modeling with Fuzzy QFD was used to determine the complex casual relationships of FCM among factors based on three domains of IoT-enabled system. Casual relationships link component to each other and they formulate the adjacency matrix. This step exploited the adjacency matrix representation of fuzzy cognitive maps. The much casual chaining information can be gained from reachable adjacency matrices. Causality admits of degree, and vague degrees at that.

The proposed FCM with AHP and FQFD considers both physical object and digital object related factors and links them with their interrelationships associated with a fuzzy linguistic weight. After representation of the FCM, this step is used to simulate the inference process underlying three alternatives way of the IoT-enabled system for green inventory management in the complex system such as IoT-enabled system using the numerical analysis of FCM.

3.6. Simulate the Inference Process

Based on the nine factors of three domains from IoT-enabled AHP, it describes three input vectors separately from the three alternatives perspectives. Based on the nine service components of three domains from fuzzy QFD, it describes nine factors the adjacency matrix of FCM. In addition, the adjacency matrix can be used usefully for changes of multiple factors. Therefore multiplying effects resulting from this input vector, it can obtain output vector. Once the factor values of the input vector is modified, the output vector may be expressed such that changes way affect these factors each other.

3.7. The Numerical Analysis of FCM

It is necessary to conduct the numerical analysis of FCMs with the factors affecting the performance impact using total effects algorithm. The total effects algorithm for each factor should be evaluated to determine the impact in the IoT-enabled system.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

4. CASE STUDY

A case study was used to illustrate the proposed methodology with a notebook computer supply chain. This section presents experiment execution and application evaluation according three steps from Figure 2. This experiment execution is separately shown as follows. Figure 4 and Figure 5 in the Appendix are the calculated results by performed Expert choice software. The running data were gathered by interviewing the evaluators using a questionnaire. The study distributed a total of 30 copies of the questionnaire according to IoT-enabled AHP, 27 copies were valid. Figure 4 shows the outcome of IoT-enabled AHP and the priority value of the three alternatives. According to the result of the calculation, IoT-enabled AHP objective of the relative weights of the three alternatives are 0.476 (Visibility), 0.226 (Traceability) and 0.298 (Sustainability), respectively. AHP is being employed with the consistency of the subjective evaluations by the consistency ratio (CR). From the result of AHP calculated, the over inconsistency ratio is 0.06 (<=0.1). Then, fuzzy QFD is calculated in the Figure 5 from the nine attributes (factors) of Figure 4. Furthermore, Figure 6 in the Appendix shows fuzzy casual relationships represented FCM graphic according to the Figure 5 and forms initial version of adjacency matrix *W*.

4.1. Simulate the Inference Process

There are nine concept nodes in the Figure 7 (see Appendix) which are interrelated with fuzzy causality values. By referring to Figure 6, the adjacency matrix *W* is derived in Table 2 in the Appendix as follows. In addition, the adjacency matrix can be used for clearly measuring the effects resulting from change of multiple factors. Suppose that some factors are changed base on the questionnaire of three alternatives (Visibility, Traceability and Sustainability), the input vector may be obtained as follows:

Input Vector:
Visibility: [0.32,0,0,0.13,0.33,0,0,0,0.33]
Traceability: [0.18,0,0,0.33,0,0,0,0,0.18]
Sustainability: [0.15,0,0,0.15,0,0,0,0,0.15]

Therefore multiplying this input vector with adjacency matrix, We can obtain an output vector as follows:

Output Vector:
Visibility: [0.3,0,0.16,0.30,0.12,0,0,0.14,0.30]
Traceability: [0.33,0,0.21,0.38,0.5,0,0,0.18,0.33]
Sustainability: [0.12,0,0.05,0.13,0,0,0,0,0.12]

From the above calculated result, the output vector such as visibility alternative may be interpreted such that change in those factors including *Green part*s, *Sale &distribution agent, Eco-efficiency agent* and *Stage3* affect *Green parts* by 0.3,. *Green &non-green* by 0.16, *BOM agent* by 0.3, *Sale &distribution agent* by 0.12, *Stage2* by 0.14, *Stage3* by 0.3. Therefore, we can conclude that changes of four factors may affect the *Green parts, BOM agent* and *stage3* most favorably.

The adjacency matrix shows that the variation of some factors causes an effect on other factors and the effectiveness of green inventory management. The direction and strength of cause and effect linkages

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

are representing the state of relationship management and the performance of green inventory management. If the number of factors that are varied becomes higher, this leads to the great effectiveness of green inventory management. It is possible to find the input vector that leads to the highest effectiveness of green inventory management.

This paper will enhance the quality of performance impact of decision-making efficiency for green inventory management in the IoT-enabled system. According to the above-mentioned inference simulation process, we obtain the result of Table 3 in the Appendix. From Table 3, the results shown in the inference process are analyzed according to the following indicators of the inventory status of green product life cycle process during the three stages: Quantity, Where-used, Location and Eco-efficiency.

- **Quantity:** According to green inventory quantity flow during the supply chain, we can conclude that green inventory quantity control obtain better consistent accuracy performance with casual relationship.
- **Where-Used:** According to green parts is used which product in the design & production consideration, we can conclude that where-used control obtain better used degree performance with relationship.
- **Location:** According to green parts and green product is located which partners during the supply chain, we can conclude that location control obtain better distributive correction performance with casual relationship.
- **Eco-Efficiency:** According to green/non-green product for EOL activities on reverse logistics operation, we can conclude that eco-efficiency control obtain better effective ratio performance with relationship.

In a word, an important advantage of the green inventory status inference process is that they build better controllable capability in the three alternatives such as visibility, traceability and sustainability.

4.2. The Numerical Analysis of FCM

Thus, green inventory status path determines a series of activities that need to deliver a value chain service in green supply chain. The total-effect operation amounts to specifying the strongest of the casual link using min-max strategy. I suppose the casual values are given by{a little ≦ some ≦ much ≦ a lot}. The total effect of a cause variable I on effect variable II, denoted by T(I,II), is the sum of all the indirect effects from all the possible paths connecting I with II. In order to describe the degree of the relationship between causes, it is possible to use fuzzy linguistic terms, such as “a little” [0~0.2], “often” (0.2~0.4], “some”(0.4~0.6], “much”(0.6~0.8], “a lot”(0.8~1], etc. According to the total-effect algorithm, for example, the total-effect T(I, V) of some casual paths from I to V are $E_1(I,V)$: (I, III, IV, V), $E_2(I,V)$: (I, IV, V). So the some indirect effects of I to V are:

$$E_1(I,V) = \min\{\text{a little, a little, a little}\} = \text{a little}$$

$$E_2(I,V) = \min\{\text{some, a little}\} = \text{a little}$$

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

$T(I, V) = \max\{ E_1(I,V) , E_2(I,V) \}$

$= \max\{\text{a little, a little}\}$

$=$ a little

In words, I (Green parts) imparts a little causality to V (Sale &distribution agent).

According to the above-mentioned calculated process, we can obtain total effects of casual path in Table 4 in the Appendix. The highest and lowest casual effects are found in the path from I to IX and I to VIII in the Table 4. From the highest value of total effects, the two most significant factors are "Green parts " and "Stage3 ", respectively. In particular, when taking into consideration the factors "Green parts" and "Stage3", it can be immediately noted that they include the relationship management which are the most significant in improving the decision-making efficiency for green inventory management in the supply chain.

The experiments are conducted by utilizing metrics from green inventory management in the case study. Figure 7 compares the total effects performance of the green inventory status as estimated by the two methods using the proposed IoT-enabled FCM and traditional FCM. It shows the experimental results which exhibited trends similar to those of the experiments using six paths from the Table 4 for the bounded value of total effects. Summarizing, experimental results showed that the proposed IoT-enabled FCM reasoning of the impact of green inventory management can be effective.

5. CONCLUSION

The proposed approach have proved to be able to provide performance evaluation in assessing the most critical factors for controlling green inventory status in the supply chain. The proposed approach using FCM and FQFD can be able to provide a contribution in assessing the most critical factors for green supply chain operation in managing complex system such as IoT-enabled information system. Good complex information system such as inventory management must be provided a solution to the issue of evaluating the factors which are considered to affect the complex system's visibility, traceability and sustainability. This paper will enhance the quality of performance impact of green inventory decision-making efficiency for green inventory management in the IoT-enabled system. It aims to simulate complex system linked physical object and digital object with imprecise relationships while enhancing the impact of decision-making performance efficiency for green inventory management. In this article, a novel approach for decision making of casual relationship impact to human way of thinking simulation process using AHP, Fuzzy QFD and FCM is evaluated.

Chapter 31
Green Information System for a Sustainable Enterprise

Laura-Diana Radu
Alexandru Ioan Cuza University of Iasi, Romania

ABSTRACT

The changes made in the environment as a consequence of massive industrialization led to a change in the vision of mankind on how organizations should interact with the ecosystem. In the same time information system has a key role in their activity. The increasing their use is accompanied by positive effects. This chapter presents the changes necessary for transformation traditional information systems in green information system. The organization's motivations to develop and implement strategies and regulations for environmental protection are varied. They can be the organization's internal drivers, such as reducing delivery costs, increasing efficiency, improving market reputation, and external, such as government legislation or policies, regulations, competition. Changes necessary to implement green information system are presented based on agile model life cycle and in accord with organizations objectives.

INTRODUCTION

The field of environmental sustainability has been studied by marketing researchers, management researchers, operation researchers or business economists (Walker et al., 1998; Bazerman & Hoffman, 1999; Corbett & Kirsch, 2001; King & Lenox, 2001; Midgley & Reynolds, 2004; Collins et al., 2007; Lyon & Maxwell, 2007; White & Lee, 2009). Its benefits have been put to profit from various perspectives, but they have also been criticized mainly due to the way in which they are perceived and implemented. Until 2010, there had been made quite a few studies which presented the way in which environmental sustainability could be engulfed by the information systems (IS) (Melville, 2010). After this year some organizations adopted certain strategies of ecological sustainable development, some important changes came up, in the technical or non-technical fields and currently it is seen as a necessity. In our days *a business that fails to have sustainable development as a top priorities could receive considerable public criticism and subsequently lose market legitimacy* (Du et al., 2013).

For an organization, "going green" means going through an analysis of the current situation as regards the influence on the environment, identifying the drawbacks on organizational level, then developing models to describe the state which the company aims to reach and turn them into business projects in order to improve the equilibrium between the organizational inputs and outputs and the environment (Beal, 2011).

During the last decades, in some countries, by regulation, education and life conditions there have been made attempts to turn sustainable consumption into a lifestyle. The reduction in the electric energy consumption or the use of alternative sources, less non-renewable resources, diminishing waste and encouraging selective waste collection have been assimilated into the natural behavior of some community members.

The studies have shown that technology, including IT, can help with increasing eco-efficiency, which is the ratio between environmental and economic performance, or, more concretely, between (product or service) value added and environmental impact added by that activity (Hack & Berg, 2014).

In these circumstances an important role is held by the IS of the organization which should be green in its turn in order to meet the demands of the international organizations interested in the field of environment protection, but also of a wide range of consumers. This is how the concept of *green IS* appeared and it expands the meaning of phrases such as green IT, ecoinformatics, green computing etc. and it analyses in real terms how the IS within the organization can contribute to the environment protection and how its negative effects can be diminished.

BACKGROUND

Considering the degree of involvement of organizations in promoting sustainable ecological development, Hart (1997) identifies three objectives: (1) preventing pollution by minimizing the waste and CO_2 emissions, (2) manage the product characteristics after consideration the partners/clients' opinions and optimize the whole life-cycle, (3) sustainable ecological development accomplished by diminishing the influence of the organization on the environment and assuming a vision on long-term ecological research. IT and IS can contribute to the accomplishment of these objectives as object and subject of the ecological sustainable development by reducing their influence on the environment, as well as by improving the influence of products and services on the accomplishment they participate in.

The literature in the field identifies six key points which might lay the basis for the ecological sustainability: (1) prevent pollution; (2) more production with less resources; (3) reduce impact on the environment; (4) clean production; (5) environmental performance; (6) output equals input (Tu and Huang, 2015). These key points apply in the IT as well to prove that green design increase efficiency, produce benefits in companies and reduce environmental pollution. The concept of green IS has appeared as a normal extension of green IT. It was introduced in research and practice in 2008 as a consequence of wider ICT use and becoming aware of their impact on the environment, in the production process and later also during the use and after use.

The aim of replacing IS and IT with those considered green is to intensify the way in which these technologies support sustainable development by and in different organizations. The literature in the field as well the practice present different opinions and these, together with the growing interest for this topic make it quite a challenge to clearly define and delineate this concept. For this reason, at the beginning, there will be clarified the notions of green IT and green IS, as well as the differences and resemblances,

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

based on literature. The following table presents a few definitions, considered relevant by the author for the two concepts (Table 1).

The opinions regarding the resemblances and differences between the two concepts are not unitary. Some authors consider that green IT refers exclusively to the technical part of the field, while others include the economic side as well. At the same time, some authors, such as Dedrick, 2010; Molla, 2013; Sarkis et al., 2013; Esfahani et al., 2015 highlight the close relationship between green IS and green IT, but they do not consider that they have different interests and goals. In their opinion, green IT aims to bring the negative effects of IT on the environment to a minimum by producing, using and discharging the equipment and applications only in ecological terms (Murugesan, 2008; Molla et al., 2011; Molla, 2013). On the other side, green IS refers to the use of IS in organizations in order to support the sustainable ecological development by automatisation and changing the products, processes as well as business relationships and practices (Chen et al., 2008; Melville, 2010; Molla, 2013).

In the opinion of other authors as Watson et al. (2010), green IT is a component of green IS, since the first concept's approach focuses on technology, thus its meaning is limited. They consider green IS the design and implementation of IS that contribute to sustainable business process. The table below shows the differences between green IS and green IT in the opinion of the above-mentioned authors (Table 2).

Table 1. ICT and environment: different approaches

Author	Green ICT (Green computing) is…
Murugesan (2008)	… the designing, manufacturing, using and disposing all ICT equipment with minimal impact on the environment or with no negative impact. These equipment include monitors, printers, storage devices, networking and communication devices.
Molla (2009)	… the interest of the company to apply environmental sustainability criteria (pollution, clean technologies and production, e-waste management etc.) in the processes of product design, production, use and disposal of the IT infrastructure (including equipment, human resources and managerial components).
Andreopoulou et al. (2013)	… the design, construction and information diffusion in order to achieve ecologically sustainable development and to improve the company's operational process by adopting and applying technological innovations from ICT industry.
Author	**Green IS refers to…**
Esty and Winston (2006)	… information system modified and used to monitor environmental practices and outcomes.
Jenkin et al. (2011)	… design, development and use of information system in order to support environmental sustainability initiatives and that has direct or indirect favorable impact on the environment.
Löser et al. (2012)	… all information system components (products, service and business operations) in order to minimize the negative impact on the environment manifested by managerial perspective on the investments in information system, his design, his development and use.

Table 2. Green IS vs. Green IT

Green IS	Green IT
• Using a fleet management system and dynamic routing of vehicle to reduce transportation costs through less energy consumption and the avoidance of the traffic congestion; • Collecting and using information on the environmental impact in the production and in the supply of service; • More effective management of operational emission and waste product; • A better information of the consumers about the influence of the products and the services on the environment. They can make green choices more conveniently and effectively; • Using online communication for teamwork and meeting in the case of companies with offices distributed to the world.	• Designing and using green hardware; • Using thin clients instead of personal computers; • Using cloud computing to run applications and operating systems; • Replacing brown sources of energy with green sources in data centers; • Minimizing energy consumption in data centers; • Minimizing e-waste from computing equipment; • Reduce transportation through online communication and remote computer administration.

(Watson el al., 2008)

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Brooks et al. (2012) offers a complete and correct definition of the concept of green IS considering its technical side, as well as the non-technical side. In these authors opinion, they represent the improving of the energy efficiency and the introducing of more environmentally friendly products and services to decrease negative influences on the environment through initiatives concerning the use of IT infrastructures to change organizational practices and processes. Green IS addresses a wider issue and consequently, it is expected to offer more complex solutions. Their impact on the environment is more favorable than green IT. Green IS make entire activity of the organization more sustainable and this includes the use of IS to increase sustainability across the global economy (Watson et al., 2008) and improving, in this way, efficiency in industries that are major sources of GHG emissions, such as the transportation, manufacturing, and energy sectors (Dedrick, 2010). In another definition, given by Watson et al. (2010) green IS is the investments in design, development, management and use of IS in order to decrease or even to eliminate the negative impact of IS, business operations and its specific products and services on the environment. As it can be seen, in this approach, the authors do not mention IT explicitly, as they are considered an implicit component of IS, thus promoting the more complex and wider role of the latter. However, regardless of the adopted approach, it is clear that the aim remains unchanged, namely: introduce and potentiate some advanced methods and techniques to protect the environment, in agreement with the extended use of ICT.

GREEN IS ADOPTION: MOTIVATIONS FOR ENTERPRISES AND FOR SOCIETY

In order to understand how green IS can be introduced in organizations aiming to support a sustainable ecological development, some authors consider that the starting point could be the concept of environmental technologies. It is defined as product design, acquisition and use of production equipment, methods and procedures, delivery and after-sale service through methods and mechanisms that ensure energy conservation and minimize negative influences on the natural balance and protect the environment (Shrivastava, 1995). Without explicitly mentioning green IS, this definition highlights the way in which they can contribute to the protection of the environment by increasing the efficiency in using the resources associated to procedures, equipment and products destined to the end user. A significant role is played by the management team who should propose strategies to encourage the protection of the environment, if they are interested in this aspect.

Based on this interpretation, the researchers identified three stages in the green IT and IS evolution up to the present day (Löser, 2015). The first stage refers to *reducing the negative impact of IT on the environment, mainly that of CO_2 emissions, by promoting green IT*. In the second stage, green IS takes shape in the *innovation of process* which points to the way in which IS contributes to the reducing of the negative effects caused by other fields of activity, such as transport, production or energy. In the end, there was identified a third stage which considers *the innovation of product* and this is accomplished by developing and putting on the market certain products with smaller negative effect on the environment, in the form of diminishing the consumption of resources, the CO_2 emissions and the e-waste and also by creating a smart or intelligent infrastructure. A previous analysis on the green IT and green IS stage underlined the fact that different organizations are going through different stages since the adoption of these concepts (Radu, 2014, 2015a, 2015b). Also, a significant part does not arouse any interest for the purchase, development and use of ICT in agreement with the protection of the ecosystem.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

Fighting the negative impact on the environment by adopting green IS requires a series of actions and decisions among which we consider these are significant: choose the hardware and software suppliers considering their environmental policies, as regards the presence and compliance to the standard (as ISO 14000 series or EMAS), as well as the offer actually present on the market, a rational replacement of the equipment, limited use of IT depending on the organizational needs, policies of eliminating e-waste favorable to the environment and so on. This last aspect is very controversial. The growing countries prove to be the deposit of a great volume of e-waste, even under the conditions of laws in force which actually forbid such practices. The motivations are the following: little awareness on the issue, lack of resources in the hands of the authorities or the presence of corruption. For instance, in China there is exported a great volume of e-waste, although it is legally forbidden since 2000 and 2002 (Li et al., 2006). Approximately 80% of the totals of 40 million tons of e-waste generated yearly is exported to the developing countries (UNEP, 2010). The main importers are China, Pakistan, India, Vietnam, Philippines, Malaysia, Nigeria, Ghana and Peru according to a report of Basel Action Network (Puckett et al., 2005). The presence of contaminants as beryllium or brominated flame retardants as well as dangerous metals such as mercury, arsenic, chromium, cadmium which can be found in e-waste and can affect the population's state of health. Also, an interesting analysis shows that a modern microprocessor requires around 60 elements (more than a half of all existing elements on earth) while in the 1980s, it was produces with 12 chemical elements (Löser, 2015). The responsibility assumed for such practices cannot be found on both parties, whereas finding a solution remains a problem of social consciousness.

Another controversial aspect of this topic is the moment when a piece of equipment is considered e-waste, since sometimes; they are hidden under the form of transactions of functional equipment. In this case, when liability no longer functions as a determining factor in applying the specific green IT practices, the developers end up with the task of finding less invasive solutions for the environment. The positive effects should be spread from the developed countries, which have the proper legal frame and can limit the production of polluting equipment and applications, consuming energy as well, towards the less developed countries which assume mainly the position of consumers, but this status is not given as a rule (China and India for example have important positions on both sides of the market). Another critical aspect is given by the growing purchase of IT equipment in the developing countries which, in a rather short period of time, considering the evolution in the field, will also turn into e-waste and the lack of laws and education in the field of recycling will lead to their improper discharge. According to the estimations, by 2018 the number of computers used in the developing countries will have been greater than in the developed countries (Yu et al., 2010).

Another controversial aspect, specific to IT, is the storage capacity. The increase in the information volume requires more or more efficient storage devices, an increase in the transfer speed, enlarging the access time, hence, more efficient equipment. According to some studies made by IBM, a quantity 2.5 quintillion bytes of data is created daily – this is so huge that 90% of the current volume of data has been created in the last two years (Zikopoulos et al., 2014).

From an organizational perspective, the effects related to the use of IT on the environment suggest the necessity of a holistic approach along the whole life-cycle which actually corresponds to the concept of green IS. The measures currently applied by the organizations interested in the protection of the environment refer to the consolidation and virtualization, intelligent power management functions, dynamically adjustable cooling, separation of hot and cold air flows, and optimized uninterruptable power supplies (USPs), thin clients, mobile instead of desktop computers, power management software, LED displays and multifunction printers, refurbishing, reusing and recycling outdated hardware at the end of life.

EBSCOhost - printed on 2/8/2023 8:31 PM via . All use subject to https://www.ebsco.com/terms-of-use

The role played by the IS is obvious when it comes to implementing the measures mentioned above. They are able to render the information as well as the necessary instruments so as to engulf the characteristics of the sustainable ecological development within the operations and the decision-making process in the organizations. On the other hand, adopting green IS brings significant economic benefits to the organizations due to the following: *increase competition* (Dao et al., 2011; Chou, 2013), *increase efficiency and effectiveness* (Chen et al., 2009; Molla & Abareshi, 2011) and *reduce costs* (Vykoukal et al., 2009; Way, 2009; Mithas et al., 2010; Marett et al., 2013; Talebi & Chou, 2013; Loock, 2013). They are the result of the important role IS play within the organizations. They are considered the core of the business processes and due to this, they might become the main trigger of organizational changes (Ramirez et al., 2010; Popescul & Georgescu, 2015; Löser, 2015).

As it can be seen, the adoption of green IS brings numerous benefits to the companies as well as to the society. There are also many motivations to take measures in this field, reflected mainly by the environment conditions. Even under the current circumstances of technological progress, there are not enough technologies, methods and initiatives to neutralize the negative effects of ICT on the environment. The influences on the environment appear during all cycles of life and take the shape of using non-renewable resources in the production process, consumption of energy, e-waste, and CO_2 emissions. These are the most important and visible. For this reason, the major investments focus in this direction. Nowadays, there would be needed 1.5 planets to meet the demands of all the people and unless essential changes appear, it is estimated that by the middle of the century, 2 planets will be needed (Maclean et al., 2010). Innovation in green IS is essential in order to restore the natural balance.
